2018 Annual Meeting of the
American Society for Bone and Mineral Research

Palais des congrès de Montréal in Montréal, Quebéc, Canada
September 28 – October 1, 2018

GUIDELINES FOR ABSTRACT READERS

The JBMR® Supplement 1 Abstracts serves as a compiled version of the Abstracts. Authors submit their own abstracts and are charged a fee to do so. Each abstract must be sponsored by a current ASBMR member. Authors are responsible for the accuracy of the content that they post. Authors are responsible for ensuring compliance with applicable human subject and animal subject procedures. When an abstract is submitted, one person is identified as the Presenting Author, the person who is expected to present the abstract at the ASBMR Annual Meeting.

The ASBMR depends upon the honesty of the authors and presenters and relies on their assertions that they have had sufficient full access to the data to be and are convinced of its reliability. The ASBMR expects that authors and presenters:

- Will disclose any conflicts of interest, real or perceived.
- Should disclose any relationship that may bias one's presentation or which, if known, could give the perception of bias.
- Will affirm, for any study funded by an organization with a proprietary or financial interest, that they had full access to all the data in the study.
- Are responsible for the content of abstracts, presentations, slides, and reference materials.
- Keep the planning, content and execution of abstracts, speaker presentations, slides, abstracts and reference materials free from corporate influence, bias or control.
- Should give a balanced view of therapeutic options by providing several treatment options, whenever possible, and by always citing the best available evidence.
- Should disclose when any commercial product is not labeled for the use under discussion or that the product is still investigational.

The ASBMR:
- Will note those speakers who have disclosed relationships, including the nature of the relationship and the associated commercial entity.
- Will peer-review the abstracts according to categories, but only to determine which will be selected for oral presentation, for poster presentations or for any awards. Abstracts are not otherwise subject to any quality or content review by ASBMR or JBMR®.
- Expects the audience for the Abstracts to be researchers, physicians and other health and allied health professionals.
- Protects the Abstracts by copyright, and prohibits the reproduction, distribution or transmission of the abstracts without the express written permission of ASBMR.
- Embargoes the Abstracts for public release in written, oral and electronic communications until one hour after the abstract has been presented.

Disclaimer. All authored abstracts, findings, conclusions, recommendations or oral presentations are those of the author(s) and/or speaker(s) and do not reflect the views of the American Society for Bone and Mineral Research or imply any endorsement. No responsibility is assumed, and responsibility is hereby disclaimed, by the American Society for Bone and Mineral Research for any injury and/or damage to persons or property as a matter of products' liability, negligence or otherwise, or from any use or operation of methods, products, instructions or ideas presented in the abstracts or at the ASBMR Annual Meeting. Independent verification of diagnosis and drug dosages should be made. Discussions, views and recommendations regarding medical procedures, choice of drugs and drug dosages are the responsibility of the authors and presenters.

DISCLOSURE POLICY

The ASBMR is committed to ensuring the balance, independence, objectivity and scientific rigor of all its individually sponsored or industry-supported educational activities. Accordingly, the ASBMR adheres to the requirement set by ACCME that audiences at jointly-sponsored educational programs be informed of a presenter's (speaker, faculty, author, or planner) academic and professional affiliations, and the disclosure of the existence of any significant financial interest or other relationship a presenter or their spouse has with any proprietary entity over the past 12 months producing, marketing, re-selling or distributing health care goods or services, consumed by, or used on patients, with the exemption of non-profit or government organizations and non-health care related companies. When an unlabeled use of a commercial product, or an investigational use not yet approved for any purpose, is discussed during the presentation, it is required that presenters disclose that the product is not labeled for the use under discussion or that the product is still investigational. This policy allows the listener/attendee to be fully knowledgeable in evaluating the information being presented. The On-Site Program book will note those speakers who have disclosed relationships, including the nature of the relationship and the associated commercial entity.

Disclosure should include any affiliation that may bias one's presentation or which, if known, could give the perception of bias. This includes relevant financial affiliations of a spouse or partner. If an affiliation exists that could represent or be perceived to represent a conflict of interest, this must be reported in the abstract submission program by listing the name of the commercial entity and selecting the potential conflict(s) by clicking in the box next to the relationship type. Disclosures will be printed in the program materials. These situations may include, but are not limited to:

The skeletal actions of irisin are mediated through alpha V integrin receptors on osteocytes. Bruce Spiegelman*[1], Hyeonwoo Kim[1], Christianne Wrann[2], Roland Baron[3], Mary Bouxsein[4], Lynda Bonewald[5], Clifford Rosen[6]. [1]Dana Farber Cancer Center, United States, [2]mass general hospital, United States, [3]harvard dental school, United States, [4]beth israel deaconess hospital, United States, [5]indiana university, United States, [6]maine medical center, United States

The effects of physical activity on the skeleton are site and force specific. Irisin, an exercise-induced hormone, is a peptide product cleaved from the muscle membrane protein FNDC5. It rises acutely with activity and enters the circulation. Irisin infusions increase cortical bone mass in mice, although the mechanism is not clear. We hypothesized that irisin would act directly on osteocytes. To test that we studied MLO-Y4 cells, employed short-term irisin injections, and performed OVX in a loss of function mouse model,FNDC5 KO (KO). First, we treated MLO-Y4 cells with irisin in the presence of hydrogen peroxide at amounts sufficient to induce apoptosis. Irisin treatment reduced hydrogen peroxide-induced apoptosis at concentrations of 1-500 ng/ml (p<0.01) well within the physiological concentrations of irisin found in human plasma. Next, we examined sost expression after irisin treatments. Irisin raised sost mRNA level in osteocyte cultures in a dose-dependent manner (p<0.01). To examine the regulation by irisin in vivo, we injected recombinant irisin daily into WT mice for 6 days. Irisin injections raised sost mRNA 4 fold in osteocyte-enriched bones, as well as SOST protein by 50% in serum. To test whether the absence of irisin affected bone turnover, we OVX'd 9 month KO mice and their littermate controls (WT, n=4-5 per genotype). As expected, WT B6 mice lost 35% of their lumbar BV/TV post OVX whereas there was no change in BV/TV for the KO mice (p<0.01 by ANOVA). Osteoclast number, osteoclast surface/ bone surface and eroded surfaces/bone surface all were markedly enhanced in controls but unchanged in KO mice (p<0.02 for genotype by ANOVA). Importantly, WT but not KO mice showed a significant increase in lacuna area and density (p<0.01) after OVX, denoting the absence of osteocytic osteolysis in FNDC5 KO. To assess whether irisin also directly affected osteoclasts, we added irisin (1-10 ng/ml) to WT bone marrow cultures treated with mCSF and RANKL and found a significant dose dependent increase in osteoclast number (p<0.001). Ligand binding studies revealed that irisin interacted with aV/b5 integrin, and chemical inhibition of the aV integrins blocked signaling and function by irisin in osteocytes. In sum, irisin acts directly and indirectly on osteocytes by binding to aV integrins. Our results provide new insight into exercise induced changes in the skeleton and potentially offer a new therapeutic approach to treat postmenopausal osteoporosis.

Bone corticalisation requires suppression of glycoprotein 130 signalling in osteocytes, and occurs by region-specific imbalances in bone formation and resorption Emma Walker*, Kim Truong, Narelle Mcgregor, T John Martin, Natalie A Sims. St. Vincent's Institute of Medical Research, Australia

The molecular mechanisms that control bone corticalization (the coalescence of trabeculae to form thick cortical bone during development) are unknown. Recently, it has been shown that this closure of cortical pores requires the intracellular protein SOCS3 in osteocytes. SOCS3 provides negative feedback for STAT3 signaling elicited by a subset of receptors expressed in osteocytes, including leptin receptor (LepR) and glycoprotein 130 (gp130 / Il6st, the receptor for all IL-6 family cytokines). In female mice lacking SOCS3 in osteocytes (Dmp1Cre.Socs3f/f) the phenotype is most extreme, with metaphyseal cortical consolidation being delayed until after 12 weeks of age, when longitudinal bone growth has ceased. This provides a way to identify the specific cytokine receptor that delays corticalization, and a model to study the cellular activities mediating this process.To identify the cellular actions that mediate corticalization, we quantified bone resorbed and formed in female Dmp1Cre. Socs3f/f mice from 12 to 16 weeks of age using co-registered in vivo micro-CT images of the metaphysis. In regions where trabeculae coalesced to form cortical bone, bone formation was significantly and markedely (up to 10-fold) greater than bone resorption. In contrast, in the central region that became trabecular bone, bone resorption dominated (2-fold higher than formation). This indicates that two processes occur during corticalization: (1) bone formation between trabecular struts at the periphery, and (2) resorption of trabeculae in the marrow space.To identify which SOCS3-dependent receptor must be suppressed for cortical bone to form, we sought to rescue the delayed in corticalization by crossing Dmp1Cre. Socs3f/f mice with either Il6st-flox (gp130) mice, or LepR-flox mice. In both females and in males, the cortical defect was fully rescued by gp130 deletion. When quantified at 12 weeks of age, cortical porosity was significantly less in Dmp1Cre.Socs3f/f.Il6stf/f mice compared with Dmp1Cre.Socs3f/f controls (60% less in males, and 77% less in females, p<0.001, n=8-10/group). No such rescue was observed with LepR deletion.In conclusion, the distinct structures of cortical and trabecular bone form by bone formation-mediated closure of cortical pores at the periphery and resorption of trabeculae in the central marrow space. While SOCS3 suppresses signals from multiple receptors expresssed in osteocytes, its suppression of gp130 is critical for metaphyseal corticalization.

Ablation of Osteopontin in Osteomalacic Hyp Mice Partially Rescues the Deficient Mineralization without Correcting Hypophosphatemia Betty Hoac*[1], Tchilalo Boukpessi[2], Daniel J Buss[3], Catherine Chaussain[2], Monzur Murshed[1], Marc D Mckee[1]. [1]Faculty of Dentistry, McGill University, Canada, [2]School of Dentistry University Paris Descartes Sorbonne Paris Cité, France, [3]Department of Anatomy and Cell Biology, McGill University, Canada

Hereditary mutations in the PHEX gene (phosphate-regulating gene with homologies to endopeptidases on the X chromosome) cause the osteomalacic disease X-linked hypophosphatemia (XLH). PHEX is predominately expressed by osteocytes, osteoblasts and odontoblasts, and inactivating mutations in this gene lead to renal phosphate wasting, severe hypomineralization of bones and teeth, hallmark hypomineralized periosteocytic lesions (so-called "halos") that persist despite stable correction of serum phosphate, and the accumulation of mineralization-inhibiting peptides and proteins – including osteopontin (OPN). We have previously identified full-length OPN to be a physiologically relevant substrate for PHEX, and found increased OPN and OPN fragments in protein extracts of human XLH dentin and Hyp (mouse model for XLH) bone, as well as an abundance of OPN localized in the pericellular hypomineralized region around osteocytes. These findings suggest that the accumulation of OPN (and its fragments) may contribute to the mineralization defects observed in XLH/Hyp bone. To investigate the effect of OPN deficiency in Hyp mice, double-null mice for Phex and Opn (Hyp;Opn-/-) were generated, and histomorphometric analysis of resin-embedded, undecalcified bone sections showed significantly reduced osteoid area/bone area of trabecular bone in lumbar vertebrae and decreased average osteocyte lacunar area within the cortical bone of the distal femur, as compared to Hyp bone controls. Furthermore, machine-learning analysis of nano-computed tomography data taken from the mid-diaphysis of the anterior medial tibia confirmed that Hyp;Opn-/- mice had reduced osteocyte lacunar volumes, thus showing partial correction of the characteristic hypomineralized periosteocytic lesions in Hyp mouse bone. Surprisingly, serum biochemistry measurements revealed that the double-null mice had no correction of the hypophosphatemia observed in Hyp mice, indicating that the improved mineralization phenotype observed in Hyp;Opn-/- mice is independent of systemic phosphate-regulating factors. In conclusion, this study shows that OPN accumulation locally in the extracellular matrix of XLH/Hyp bone contributes to its osteomalacia and its hypomineralized periosteocytic lesions, and removal of this mineralization-inhibiting OPN partially rescues the mineralization phenotype without affecting hypophosphatemia.

TGFβ regulation of perilacunar/canalicular remodeling is sexually dimorphic Neha S. Dole *[1], Cristal S. Yee[1], Claire Acevedo[2], Courtney M. Mazur[1], Tamara Alliston[1]. [1]University of California San Francisco, United States, [2]University of Utah, United States

Bone quality, a determinant of fragility, is known to show sex-specific differences. However, the molecular mechanisms responsible for sexually dimorphic bone quality remain unclear, limiting our ability to therapeutically target fragility. Previously, we reported that pharmacologic antagonism of TGFβ, a known regulator of bone mass and quality, increases bone mass more robustly in females than in males. Recently, we found that TGFβ regulates bone quality through osteocyte-intrinsic stimulation of perilacunar/ canalicular remodeling (PLR) in male mice. Since lactation is a potent PLR agonist and female bone mass is more sensitive to TGFβ, we hypothesize that basal and lactation-inducible PLR occurs through a TGFβ-dependent mechanism in female bone.We evaluated virgin female and lactating TβRIIocy-/- mice, where TβRII is ablated from osteocytes using DMP1-Cre, and their wild type littermates (WT). Micro-CT revealed that seven days of lactation induces bone loss in both genotypes, however bone loss was significantly attenuated in lactating TβRIIocy-/- mice. Lactation-inducible expression of several PLR genes (MMP13, MMP14, and Cathepsin K (CTSK), TRAP, and ATP6V0D2) was mitigated in TβRIIocy-/- bones. Further, lactation increased osteocyte lacunar volume in WT but not in TβRIIocy-/- bones. Thus, osteocyte-intrinsic TGFβ is required for maximal induction of PLR during lactation. Analysis of virgin female bone, however, surprisingly revealed sexual dimorphism in the osteocyte-intrinsic role of TGFβ. Unlike male mice, virgin TβRIIocy-/- female mice had no differences in trabecular bone mass compared to WT. Loss of osteocyte intrinsic TGFβ signaling caused coordinated repression of key PLR genes in males, however; PLR gene expression was normal in female TβRIIocy-/- bones. Severe deterioration of osteocyte lacuno-canalicular network (LCN) integrity observed in male TβRIIocy-/- bones was completely absent in females. Moreover, flexural strength tests demonstrate that, despite normal cortical thickness, male TβRIIocy-/- bones have decreased ultimate stress and toughness modulus relative to WT. In contrast, these properties are significantly increased in virgin TβRIIocy-/- females relative to WT controls. Thus, our study shows that, while lactation-inducible PLR is dependent on osteocyte-intrinsic TGFβ; osteocytes possess sexually dimorphic mechanisms to regulate PLR and bone quality during homeostasis.

Do Drug Holidays Reduce Atypical Femur Fracture Risk?: Results from the Southern California Osteoporosis Cohort Study (SOCS) Annette L. Adams*[1], Bonnie H. Li[1], Denison S. Ryan[1], Erik J. Geiger[2], Richard M. Dell[1], Dennis M. Black[2]. [1]Kaiser Permanente Southern California, United States, [2]University of California, San Francisco, United States

Long-term bisphosphonate (BP) use has been associated with increased risk of atypical femur fractures (AFF). BP holidays of 3-5 years have been recommended as a way of balancing the risk of AFF with the intended anti-fracture benefit of the medications, and studies have suggested that women who discontinue BP after 3-5 years of use are not at increased risk for osteoporosis-related fractures. However, whether AFF risk is lowered after discontinuation of BP is uncertain. To address the relationship of time since last BP use and risk of AFF, we conducted a cohort study of women aged ≥50 years who were members of Kaiser Permanente Southern California (KPSC) during the period 1/1/2007-9/30/2015. Women were required to have pharmacy benefits and to have been members of KPSC for ≥1 year prior to cohort entry. We included in the cohort any woman who had used a BP and had at least one available pre-treatment bone mineral density (BMD) total hip scan. AFFs were identified and verified by physician review of x-ray images for fractures occurring during the study period with ICD-9 diagnosis codes for subtrochanteric or femoral shaft fractures. Women were considered to have discontinued BP if there was a gap >3 months between last BP use and cohort entry anniversaries. We also included information on the following potential confounders of the association between time since discontinuation and AFF: age, race/ethnicity, smoking, height, fracture history, duration of BP use, duration of glucocorticoid use, and pre-treatment total hip T-score. Multivariable time-varying Cox proportional hazards methods were used to estimate hazard ratios (HR) and 95% confidence intervals (CI). The cohort included 152,934 women meeting inclusion criteria with 185 AFF (incidence rate 1.70 per 10,000 person-years). After adjustment for all confounders, there was a 44% reduction in the risk of AFF in the first year after discontinuation compared to women who continued to use BP (HR 0.56, CI 0.38-0.82). In years 1 to 4 after discontinuation, AFF risk was decreased by 80% (HR 0.20, CI 0.10-0.37) and after >4 years, AFF risk was reduced by 78% (HR 0.22, CI 0.08-0.59) compared to current users. These results suggest that among women with BP use of varying duration, discontinuation is associated with substantially decreased risk of AFF. Thus, these results suggest that a drug holiday of 3-5 years would likely markedly reduce AFF risk among long-term BP users.

The Impact of Bisphosphonate Drug Holidays on Fracture Rates Jeffrey Curtis*, Rui Chen, Zixu Li, Tarun Arora, Kenneth Saag, Nicole Wright, Shanette Daigle, Meredith Kilgore, Elizabeth Delzell. University of Alabama at Birmingham, United States

IntroductionDiscontinuation of bisphosphonates after at least 3-5 years of continuous therapy is becoming increasingly common in the U.S. However, the benefits and risks of stopping bisphosphonates (BPs), and the timing as to when it might be optimal to restart, are unclear. We conducted a population-based cohort study of women on long term BP therapy to evaluate the rate of hip fracture following a drug holiday (temporary or permanent BP discontinuation).MethodsMedicare data (2006-2015) were used to identify all women with medical and pharmacy coverage who initiated a BP and were at least 80% adherent for at least 3 years ('baseline'), at which time follow-up began. Patients using other bone therapies (e.g. denosumab, estrogen, teriparatide, calcitonin) were excluded (or censored, if they started after follow-up began). Subgroups defined by exclusive use of specific BPs, and prior fragility fracture, were defined.Crude rates of hip and other types of fracture using validated algorithms were evaluated in relation to continuing BP therapy vs. stopping, and time since stopping. Cox proportional hazards ratios (HRs) evaluated the adjusted risk of stopping for more than 2 years compared to continued use, controlling for potentially confounding factors.ResultsA total of 160,369 women were eligible for analysis, and 36% underwent a BP drug holiday of >12 months. Overall, during a median (IQR) follow-up of 2.7 (1.5, 4.1) years, there were 4,823 hip fractures. Compared to continued BP use, hip fracture rates were significantly elevated among women undergoing BP drug holidays. Adjusted HRs for the association between drug holiday >2y and hip fracture are shown overall and for key subgroups (Table). Risk was similarly elevated for humerus fractures but not for other fracture types.ConclusionsIn a large cohort of older U.S. women, a BP drug holiday greater than 2 years was associated with a significantly increased risk for hip fracture but was minimally elevated for other fracture types.

Table: Hip fracture Rate for BP Drug Holiday >2 years

Cohort	Women, n	Number of hip fractures, n	Crude Incidence Rate per 1000 person-years	Adjusted* Hazard Ratio (95% CI)
Any BP	160,369	4,823	14.0	1.22 (1.11 − 1.34)
Alendronate users	81,287	2,245	13.1	1.28 (1.12 − 1.46)
Risedronate users	9,823	269	13.8	1.45 (1.00 - 2.11)
Zoledronate users	13,885	367	18.0	1.31 (0.94 - 1.82)
Prior fragility fracture	6,914	430	37.4	1.38 (1.01 − 1.89)

*Hazard ratio for women with a drug holiday of >2 years compared to persistent users, adjusted for age, region, race, rural or urban, median income, calendar year of study entry, comorbidity (fragility fracture, Charlson comorbidity index), DXA, office visits, office visits with bone specialists, long term care residence, vitamin D deficiency, glucocorticoids, and other factors, assessed...

Bisphosphonate Use and Risk of AFF Varies by Pre-treatment BMD Level: Results from the Southern California Osteoporosis Cohort Study (SOCS) Dennis M. Black*[1], Erik J. Geiger[1], Bonnie H. Li[2], Denison S. Ryan[2], Richard M. Dell[2], Annette L. Adams[2]. [1]University of California, San Francisco, United States, [2]Kaiser Permanente Southern California, United States

While most studies have shown bisphosphonate (BP) use and longer duration is associated with increased atypical femur fracture (AFF) risk, the effect might be attenuated if indications for BP treatment, such as BMD, could be controlled. However, no AFF studies have included pre-BP BMD. To test if pre-treatment BMD attenuates the relationship of BP duration to AFF risk, we analyzed data from Kaiser Permanente Southern California (KPSC), an HMO with ~4.5 million members. We established a cohort of women >50 yrs with cohort entry from 1/1/2007-9/30/15. We assessed all X-rays with ICD9 coded subtrochanteric or femoral shaft fractures using ASBMR 2014 criteria with verified adjudication by 2 experts. Risk factors including age, Asian race, pretreatment BMD (PT BMD), BP use, fracture hx, height, GC use and smoking hx were available for up to 10 years prior to cohort entry and were updated annually thereafter. PT BMD was defined as total hip BMD before or soon after starting BPs. The relationship of BP duration to AFF risk was assessed before and after inclusion of PT BMD in multivariable (MV) Cox models with time-varying covariates. This analysis included women who had both PT BMD and any BP use (N=152,934). There were 185 AFFs overall. In a MV model (without PT BMD), those with longer BP duration had higher AFF risk. Compared to <1 year BP the relative hazard (RH) for 1-4 yrs of BP use was 3(CI 1.4,7.3), for 4-8 yrs was 15(CI 7,33) and >8 yrs was 37(CI 16,83). PT BMD added to the model did not attenuate the relationship of BP duration to AFF risk. Inclusion of PT BMD also showed those with higher BMD had a 40%. AFF risk per SD BMD increase (HR 1.4(CI 1.2 1.7)). To further study PT BMD and AFF, we performed analyses stratified by PT BMD T-score (T>-1;-1 to -2.5;T<-2.5). We consistently observed larger risk increases with BPs for those with higher PT BMD (Figure). For example, in those with normal PT BMD (T>-1) the RH for 4-8 years BP use (vs<1 yr) was 35 compared to 15 in those with osteopenic BMD and compared to 6 in those with osteoporotic BMD (T<-2.5). We conclude that adjustment for PT BMD did not attenuate the relationship of BP use to AFF risk. Surprisingly, our results indicate that women with higher PT BMD have a larger increase in AFF risk with BP use than those with lower BMD. If confirmed in other studies, these results suggest that PT BMD could impact clinical decisions around patient selection for BP initiation and drug holidays.

Increase in AFF Risk with BP Use is Greater For Normal Pre-treatment BMD vs. Osteopenic & Osteoporotic BMD for Each BP Duration (Relative Hazard (RH) and 95% CI)

Clinical features of 35 patients with 172 spontaneous vertebral fractures after denosumab discontinuation: a single center observational study Elena Gonzalez-Rodriguez*, Berengere Aubry-Rozier, Delphine Stoll, Didier Hans, Olivier Lamy. Lausanne University Hospital, Switzerland

IntroductionIn the absence of bisphosphonate treatment, denosumab discontinuation (DD) induces an increase of B-crosslaps above baseline values for two years, and a complete or partial loss of the BMD gain after one year. This rebound effect is associated with spontaneous clinical vertebral fractures (SCVF) in 1 to 10% of patients. We report the clinical characteristics of 35 patients with SCVF after DD evaluated at our center from July 2015 to March 2018.MethodWe report the cases of 35 patients who received denosumab 60mg every 6 months for 2 to 11 doses. All were on calcium and vitamin D during denosumab treatment and after DD. VF have been documented by MRI. A wide biological assessment, performed at the time of fracture, was strictly normal. A secondary cause of osteoporosis was excluded. Patients did not received any osteoporosis treatment between DD and the onset of SCVF.ResultsThirty-four women and one man, 66.3±9.6 years, experienced 172 SCVF (median 5) in the 11.6±2.8 months (median 11; min 7, max 20) following the last denosumab injection. Eight women received a bisphosphonate before denosumab, and nine women received aromatase-inhibitors (AI) with denosumab. Eleven women had prevalent osteoporotic fracture. Twelve women had vertebroplasties with 58 new VF in the following days. The mean B-crosslaps value at the time of SCVF was 1523±588 ng/l. B-crosslaps values increase with the number of denosumab doses (R2=0.28). The number of SCVF was inversely associated with age: 5.4±2.0 vs 2.8±1.3, < vs > 65 years (p<0.001). The delay between DD and the occurrence of SCVF increases with age: 10.4±1.3 vs 12.7±2.6 months, < vs > 65 years (p=0.008). The mean reasons for DD were end of AI or no more osteoporosis (15), omission (7), patient's wish (5), atypical femoral fracture or dental intervention (4).ConclusionAfter denosumab discontinuation, women < 65 years have a higher number of SCVF and in a shorter period than women over 65 years. SCVF are a very severe and frequent clinical complication after DD. A close follow-up for 2 years after DD is necessary. Bisphosphonates may decrease the rebound effect at DD. Studies are urgently needed to better define who and when to treat with denosumab, as well as strategies to avoid SCVF after denosumab discontinuation.

Targeting skeletal endothelium to ameliorate bone loss Ren Xu*[1], Alisha Yallowitz[1], Shawon Debnath[1], Jung-Min Kim[2], Kazuki Inoue[3], Baohong Zhao[3], Jae-Hyuck Shim[2], Laurie Glimcher[4], Matthew Greenblatt[1]. [1]Weill Cornell Medical College, United States, [2]University of Massachusetts Medical School, United States, [3]Hospital for Special Surgery, United States, [4]Dana-Farber Cancer Institute and Harvard University Medical School, United States

Recent studies have identified a specialized subset of vascular endothelium in bone termed type H endothelium (CD31highEndomucinhigh) as an important regulator of bone formation. However, it remains unclear how type H endothelium levels are coupled to anabolic bone formation. Here, we show that the greatly elevated bone formation seen in mice lacking the adaptor protein Schnurri-3 (Shn3-/- mice) is accompanied by an increase in type H endothelium. Osteoblasts control type H endothelium levels, as seen in mice with an osteoblast-lineage specific Shn3 deletion (Shn3osx mice and Shn3ocn-ert mice). Transcriptomic analysis identified the axon-guidance cue SLIT3 as a proangiogenic factor whose expression in bone is restricted to osteoblasts and is negatively regulated by SHN3. Subsequent analysis of germline and osteoblast specific SLIT3-deficient mice (Slit3osx mice and Slit3dmp1 mice) or mice lacking the SLIT3 receptor ROBO1 demonstrated reduced type H endothelium and low bone mass due to impaired bone formation but intact bone resorption, and SLIT3 is necessary for the high bone mass and increased type H endothelium phenotypes of Shn3-/- mice. This osteo-angio crosstalk pathway is essential for bone healing, as shown by the complete blockade in fracture repair in SLIT3-deficient mice and enhanced fracture repair in Shn3-/- mice. Finally, administration of recombinant SLIT3 both enhanced skeletal fracture healing and counteracted bone loss in a mouse model of postmenopausal osteoporosis. Thus, SLIT3 provides proof-of-principle for a class of vascular-targeted osteo-anabolic therapies to treat bone loss.

Intermittent Parathyroid Hormone does not expand type H cell population but impacts transitional vessels by reducing their Coverage by Leptin Receptor Positive Pericytes and Upregulating their Expression of Collagen Type 18/Endostatin. Robin Caire*[1], Bernard Roche[1], Tiphanie Picot[2], Zhiguo He[3], Carmen M Anaei[2], Mireille Thomas[1], Lydia Campos[2], Laurence Vico[1], Marie-Hélène Lafage-Proust[1]. [1]INSERM 1059, Université de Lyon, France, [2]University Hospital Hematology Lab, France, [3]BIIGC, Université de Lyon, France

We showed that intermittent administration of Parathyroid Hormone (iPTH), an osteo-anabolic drug, affects bone vessels. Transitional capillaries close to the bone surfaces express both endomucin (Em+,Fig1A) and CD31 (type H endothelial cells) and bear pericytes which express Leptin receptor (LepR+) and may differentiate into osteoblasts. Increase in Type H cell number is associated with higher bone formation. Thus, our hypothesis was that iPTH impacts transitional vessels by expanding Type H cells. Methods: 3 month-old C57/Bl6J female mice were treated with subcut. injections of either PTH 1-84 (100μg/kg/d) or saline (CT) for 7 or 14d (n=6-8/gp). We quantified LepR+,CD31+,Em+ and type H cells by Flow cytometry (FACS) in bone marrow of long bones. Then, we quantified Em and LepR double immunostaining of 40μm-thick tibia transverse cryosections after confocal microscopy acquisition. Next, we analyzed mRNA expression of 87 angiogenesis-related genes in tibiae (PCR Array, Qiagen) of mice treated with PTH 100μg/kg/d, either intermittently or continuously via ALZET minipumps (cPTH) or saline (CT) for 7,14 and 28d. Results : Unexpectedly, FACS data showed that iPTH dramatically decreased the percentage of type H cells by 78 and 90% at d7 and 14, respectively (p<0.001) and of LepR+ cells at d14 (-46%, p=0.01 vs CT). Immunostained image quantification showed that the transitional Em+ endocortical vessel network was disrupted and intracortical vascular density increased at d14 under iPTH only. In the bone marrow, LepR+ cells were essentially perivascular and connected to each other via a dendrite network (Fig1B) which became less dense after 14d of iPTH (-58%, p<0.01 vs CT). Moreover, LepR+ vascular coverage was decreased by iPTH in transitional vessels only (-51% p<0.01) while the number of free Lepr+ cells not attached to vessels increased in the endocortical area only (+49% p<0.01, Fig1CD). Genomic analyses showed that mRNA expression of PEDF, Collagen 18 α1, MMP-2 and TIMP-1 were consistently upregulated by iPTH at 2 or 3 time points, compared to CT and cPTH. Finally, iPTH increased immunostaining of endostatin, a Collagen 18 domain that can potentially become anti-angiogenic after cleavage, in both endocortical (79%, p=0.02) and peri-trabecular transitional microvessels at d14. Conclusion. Our results show that iPTH specifically remodels transitional vessels and suggest that iPTH promotes mobilization of LepR+ cells from these vessels close to the bone surface.

Hypoxia/HIF Signaling Contributes to Bone Homeostasis by Preventing Premature Senescence and Apoptosis of Multipotent Mesenchymal Progenitor Cells Kassandra Spiller*, Yinshi Ren, Colleen Wu. Duke University, United States

Multipotent mesenchymal progenitors (MMPs) cultured under low oxygen tension exhibit diminished DNA damage, enhanced genomic stability and increased replicative potential. While these findings highlight a role for hypoxia in prolonging MPP lifespan in vitro, the contribution of hypoxic niches in regulating MPP function in has not been fully explored in vivo. Notably, the bone microenvironment (BME) displays vascular heterogeneity leading to regional areas of hypoxia. In response to low oxygen, hypoxia inducible factor (HIF) signaling is activated to facilitate oxygen delivery and cellular adaptation to low oxygen. We sought to define the role of hypoxia and HIF signaling in the regulation of MPP function and bone homeostasis. For our studies, we utilized transgenic mice expressing Cre-recombinase under the control of the Leptin Receptor (LepR) promoter (Lepr-cre) as LepR marks a population of BM cells enriched for MPPs. Confocal imaging of Lepr-cre;tdTomato mice demonstrated that a subset of LepR expressing cells localized to hypoxic perivascular areas and co-stained for HIF transcription factors. Next, to determine the necessity of HIF signaling within LepR cells in regulating bone homeostasis, we crossed mice homozygous for the Hif-2 conditional allele to Lepr-cre mice. μCT and histological analysis of long bones harvested from Lepr-cre;Hif-2fl/fl mutant mice revealed a two-fold decrease in trabecular bone volume when compared to littermate controls. Quantification of multinucleated TRAP positive cells demonstrated no differences in osteoclast numbers suggesting diminished trabecular bone volume was not due to aberrant bone remodeling. Interestingly, Lepr-cre;Hif-2fl/fl mice had fewer colony forming units – fibroblastic (CFU-F) when compared to littermate controls. To elucidate the potential cellular and molecular mechanism driving phenotypic changes associated with loss of HIF signaling in LepR expressing cells, MPPs were cultured under Hx (1% O2) and Nx (21% O2) conditions. Interestingly, hypoxia was associated with decreased β-galactosidase activity, reduced numbers of TUNEL positive cells, and diminished protein expression of p21 and cleaved caspase-3. In addition, hypoxia reduced genotoxic damage as marked by fewer distinct nuclear γH2AX and 53BP1 foci. Taken together, this data suggests that the hypoxic BME may aid in maintaining bone homeostasis by impairing genotoxic damage to prevent premature senescence and apoptosis of MPPs.

1012

Mineralizing Bone Surfaces Drive Blood Vessel Redistribution Through Asymmetric Angiogenesis Robert Tower*[1], Chamith Rajapakse[1], Xi Jiang[1], Wei Tong[2], Nathaniel Dyment[1], Ling Qin[1]. [1]University of Pennsylvania, United States, [2]Xiehe Hospital, China

Angiogenic-osteogenic coupling is important for establishing and maintaining bone hemostasis. Despite extensive research, it is still not clear whether new bone formation plays a dominant role in recruiting the bone marrow vasculature, or whether vessels move to the bone surface first, bringing mesenchymal progenitors to initiate new bone formation. To address this issue, we first established a 3D confocal imaging approach of tissue-cleared femurs from 12-week-old mice that can accurately measure the distance between bone surfaces and the nearest vessel. We observed a close association between vessels and mineralizing, calcein high bone surfaces (21.9 ± 2.6 vs calcein neg, $39.4\pm6.5\mu m$, $p<0.05$). Treatment with PTH for 14 days increased vessel association (14.2 ± 1.9 vs control, 31.7 ± 3.3 μm, $p<0.01$),

through increased mineralization, but showed no significant change in vessel distance at calcein high surfaces. Next, we preformed micro-CT scans on the femur trabecular bone of the same mice at 10 and 12 weeks of age and registered these images to deduct formed and resorbed bone surface within this 2-week period. Furthermore, 12-week micro-CT images were registered with confocal images taken after harvest. Finite element analysis revealed that the top 0.5% strain surfaces at 10 weeks predicts sites of future bone formation with an accuracy of $85.8\pm1.6\%$. At 12 weeks, high strain, calcein negative bone surfaces were selected as non-mineralizing sites of future bone formation. These surfaces failed to show any notable vessel recruitment relative to all calcein neg surfaces, demonstrating that blood vessels are recruited to, but do not precede, actively mineralizing bone surfaces. Bone marrow vessels are coated with a basement membrane (BM) for structural stability. Interestingly, immunofluorescent analysis revealed that the vessel surface neighboring calcein high bone displays significantly less staining for collagen type IV (4-fold, $p<0.001$) and laminin (2-fold, $p<0.05$), two major components of the BM. This also coincided with increased endomucin staining (a marker for dynamic vessels) (2.5-fold, $p<0.01$) and a 194% increased angiogenic filipodia density ($p<0.01$) at the bone-facing surface, compared to the marrow-facing surface. Such differences were not observed in vessels residing in the diaphyseal marrow. Taken together, our results demonstrate that vessel redistributes to mineralizing surfaces via increased asymmetric angiogenesis at the bone-facing vessel surface.
1013

The lysosomal protein arylsulfatase B is a key enzyme involved in skeletal turnover Gretl Hendrickx*[1], Sandra Pohl[2], Alexandra Angermann[1], Anke Jeschke[1], Timur A Yorgan[1], Tim Rolvien[1], Michael Amling[1], Thomas Braulke[2], Thorsten Schinke[1]. [1]Department of Osteology and Biomechanics, University Medical Center Hamburg-Eppendorf, Germany, [2]Department of Biochemistry, Children's Hospital, University Medical Center Hamburg-Eppendorf, Germany

Skeletal pathologies are frequently observed in lysosomal storage disorders, yet the relevance of specific lysosomal enzymes in bone remodeling cell types is poorly defined. Two lysosomal enzymes, i.e. Ctsk (cathepsin K) and Acp5 (also known as tartrate-resistant acid phosphatase), are long known as molecular marker proteins of differentiated osteoclasts. However, whereas the cysteine protease Ctsk is directly involved in the degradation of bone matrix proteins, the molecular function of Acp5 in osteoclasts is still unknown. Here we show that Acp5, in concert with Acp2 (lysosomal acid phosphatase), is required for dephosphorylation of mannose 6-phosphate residues to promote the activity of lysosomal enzymes. Using an unbiased approach, we identified the glycosaminoglycan-degrading enzyme Arsb, mutated in mucopolysaccharidosis type VI (MPS-VI), as an osteoclast marker, whose activity depends on dephosphorylation by Acp2 and Acp5. Similar to Acp2/Acp5-/- mice, Arsb-deficient mice display lysosomal storage accumulation in osteoclasts, impaired osteoclast activity and high trabecular bone mass. Of note, the most severe lysosomal storage was observed in osteocytes from Arsb-deficient mice. Although this pathology did not impair production of Sost and Fgf23, these findings demonstrate that osteocytes participate in bone matrix turnover. Since the influence of enzyme replacement therapy (ERT) on bone remodeling in MPS-VI is still unknown, we additionally treated Arsb-deficient mice by weekly injection of recombinant human ARSB from 12 to 24 weeks of age. We found that the high bone mass phenotype of Arsb-deficient mice and the underlying bone cell deficits were fully corrected by ERT in the trabecular compartment. Taken together, our results do not only demonstrate that the function of Acp5 in osteoclasts is linked to dephosphorylation of lysosomal enzymes, they also provide an important proof-of-principle for the feasibility of ERT to correct bone cell pathologies in lysosomal storage disorders.

1014

Positive effects of intermittent PTH on growing bone and dystrophic muscle in Mdx mouse model of Duchenne Muscular Dystrophy Sung-Hee Seanna Yoon*[1], Marc Grynpas[2], Jane Mitchell[1]. [1]University of Toronto, Canada, [2]Lunenfeld-Tanenbaum Reearch Institute, Canada

Duchenne Muscular Dystrophy (DMD) is a progressive muscle disorder caused by genetic mutations on dystrophin encoding gene. With an absence of functional dystrophin, DMD boys show not only muscle wasting and inflammation, but also compromised bone health with high risk of fracture. The use of high dose glucocorticoids (GC) as the gold standard therapy also contributes to bone fragility in DMD boys. Our previous study showed that the prophylactic use of anti-resorptive bisphosphonates increased bone mineral density (BMD) but did not improve bone mechanical properties in the Mdx mouse model of DMD and dramatically decreased bone turnover. Thus, this study examined the effects of daily administered parathyroid hormone (PTH), the only available bone anabolic therapy, on growing bone and dystrophic muscle in the presence of slow-release pellet of prednisone using the Mdx mice. Five-week GC treated Mdx mice showed decreased cortical bone thickness and area (p<0.001), which was significantly improved by PTH treatment (p<0.001). This bone increase by intermittent PTH was through suppression of osteoclasts on endocortical surfaces (p<0.001). GC-induced decreases in toughness and modulus from three-point bending tests were also improved with PTH therapy (p<0.05). While there was no significant effect of muscular dystrophy on cortical bone, Mdx mice showed significantly less volumetric BMD and bone mass of trabecular compartments in lumbar vertebrae. GC or intermittent PTH by themselves did not have significant effect, but the combination of two treatments resulted in significant increase in volumetric BMD (p<0.001) and percent bone volume (p<0.01). Although only trabecular thickness was improved, PTH significantly improved ultimate load and stress, energy to fail, stiffness and modulus compared to control Mdx in vertebral compression test. In the presence of GC, PTH significantly improved all of structural and material properties. Moreover, GC resulted in significantly improved grip strength and endurance in treadmill running, which were maintained and further improved, respectively, in co-treated Mdx mice. All together, our study demonstrated that intermittent PTH significantly improved GC-induced bone loss and maintained or further enhanced dystrophic muscle function that is already improved by GC treatment. These findings could give an insight into the use of teriparatide in DMD boys, and also other forms of GC-induced osteoporotic patients.

Deletion of PKA Regulatory Subunit 1A to Increase PKA Activity in Osteoblasts Causes Dramatic Expansion of Trabecular Bone at the Expense of Cortical Bone Carole Le Henaff*[1], Florante Ricarte[2], Joshua Johnson[1], Zhiming He[1], Johanna Warshaw[1], Henry Kronenberg[3], Lawrence Kirschner[4], Nicola Partridge[1]. [1]New York University, college of dentistry, United States, [2]Molecular Pharmacology Training Program, Sackler Institute of Graduate Biomedical Sciences, New York University School of Medicine, United States, [3]Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, United States, [4]Department of Cancer Biology and Genetics, Internal Medicine, The Ohio State University, Division of Endocrinology, Diabetes, and Metabolism, Department of Internal Medicine, The Ohio State University Wexner Medical Center, United States

Parathyroid hormone (PTH) plays a central role in regulation of calcium metabolism and is the osteoanabolic hormone for treating osteoporosis. We have previously shown that PTH acts through PTHR1 and protein kinase A (PKA) activation to regulate the life cycle of HDAC4 in osteoblastic cells, thus identifying it as a major regulator of Runx2- and Mef2c-dependent transcription in bone. We hypothesized that similar to PTH (1-34) treatment, an increase in PKA activity in osteoblasts will cause an increase in bone accrual. Our study aims to elucidate the effects of increased PKA activity and better understand the actions of PTH (1-34) in bone. Weekly injections of tamoxifen (1mg/10g) were administered to 1 month-old or 5 month-old C57Bl/6 male and female col1CREERT/Prkar1afl/fl mice or Prkar1afl/fl mice as controls, for 3-4 weeks to delete the PKA regulatory subunit 1A and increase PKA activity. This resulted in a decrease of whole body (-6%), femoral (-24%), and tibial BMD (-22%) in 2 month-old col1CREERT/Prkar1afl/fl mice. They were smaller and bones were very brittle with little bone marrow. μCT showed dramatic excess trabecular bone and absence of cortical bone in vertebrae (Figure 1) and throughout most of the bone marrow cavity in femurs. Surprisingly, no overall BMD changes were observed with 6 month-old mice but they developed tumors in their tails. By μCT, 6 month-old col1CREERT/Prkar1afl/fl mice showed decreases in cortical thickness and cortical BMD and increases in cortical porosity and endocortical perimeter. In trabecular bone, BV/TV, Tb.N and trabecular BMD were increased, while Tb.S decreased. In both age groups, cortical and trabecular bone RNAs showed a substantial increase in bone sialoprotein mRNA levels (3 to 6 fold) with a sharp decrease in osteocalcin (0.2-0.4 fold). Furthermore, genes whose expression is known to be regulated by PTH were significantly changed: SOST expression was decreased to 0.1-0.2 fold, RANKL was upregulated by 2-3 fold and MMP13 was increased by at least 3 fold. These animals mimic mice in which a constitutively-active PTH receptor is expressed under the control of the col1 promoter. Indeed, the overall data show a great increase in trabecular bone mass with breakdown of cortical bone. The bone seems

to be immature and unable to transition to cortical bone. In conclusion, high PKA activity in osteoblasts appears to be involved in increasing immature trabecular bone and resorbing cortical bone.

Low bone mass in mice with conditional Wnt1 deletion and a Wnt1 mutation causing early-onset osteoporosis Nele Vollersen*, Timur Yorgan, Tim Rolvien, Michael Amling, Thorsten Schinke. Department of Osteology and Biomechanics, University Medical Center Hamburg-Eppendorf, Germany

Wnt signaling is long known as a key pathway controlling skeletal remodeling. The more recent identification of WNT1 mutations in individuals with osteogenesis imperfecta type XV or early-onset osteoporosis (EOOP) suggested that Wnt1 is a key ligand stimulating this pathway in osteoblasts. To elucidate the role of Wnt1 in skeletal turnover, we first generated mice with an osteoblast-specific Wnt1 inactivation (Wnt1fl/fl;Runx2-Cre). These mice displayed multiple skeletal fractures, decreased trabecular bone mass and cortical thinning at 24 weeks of age. In contrast, Wnt1 inactivation in osteoclasts did not cause any detectable bone remodeling abnormality in Wnt1fl/fl;Lyz2-Cre mice. We additionally established a mouse model carrying an EOOP-associated recessive Wnt1 mutation (p.Arg-235Trp). Wnt1+/R235W mice displayed decreased trabecular and cortical bone mass at the age of 52 weeks, whereas homozygous Wnt1R235W/R235W showed an exacerbated phenotype already evident at 24 weeks of age. To address the clinically relevant question, if Wnt1 mutations interfere with the osteoanabolic influence of intermittent PTH treatment, we finally treated 52 weeks old Wnt1+/R235W mice by daily PTH injection. Using μCT, dynamic histomorphometry and serum biomarker determination we found no difference between wildtype and Wnt1+/R235W littermates in the response to PTH treatment. Taken together, our results provide further in vivo evidence for a key function of Wnt1 in controlling trabecular and cortical bone remodeling. Moreover, the generation of the Wnt1+/R235W mice will be very informative for understanding the cellular and molecular bases of Wnt1-dependent EOOP. Importantly, the normal response of these mice to intermittent PTH injection strongly suggests that osteoanabolic treatment with teriparatide might be preferable to normalize bone pathologies in individuals with WNT1 mutations.

Loss of Hypoxia Inducible Factor-2 Alpha in Mesenchymal Progenitors Increases Bone Mass Accrual and Osteoblastogenesis Christophe Merceron*[1], Kavitha Raganathan[2], Elizabeth Wang[1], Zachary Tata[1], Laura Mangiavini[1], Mohd Parvez Khan[1], Benjamin Levi[2], Ernestina Schipani[1]. [1]Department of Orthopedic Surgery, School of Medicine, University of Michigan, United States, [2]Division of Plastic and Reconstructive Surgery, Department of Surgery, University of Michigan, United States

Understanding the mechanisms that control bone mass and osteoblastogenesis is crucial to unveil the pathogenesis of skeletal diseases and identify approaches for their treatment. Osteoblastic cells operate in a hypoxic environment. The transcription factors Hypoxia Inducible Factor-1a (HIF1) and HIF2 are key mediators of the cellular response to hypoxia. Both are expressed in osteoblastic cells. HIF1 is known to be a positive regulator of bone formation and osteoblast differentiation. Conversely, the role of HIF2 in the control of bone mass and osteoblast biology is still poorly understood. To fill this gap of knowledge, we generated mutant mice carrying a loss-of-function mutation of HIF2 in mesenchymal progenitors of the limb bud and their descendants using PRX1-Cre. MicroCT and histomorphometric analyses at 12 weeks of age showed a significant increase in bone mass in mutants. The mineral apposition rate, the bone formation rate and the number of osteoblasts were also augmented. Conversely, in vivo overexpression of HIF2 in the same cells resulted in a delay of the osteogenic front in the calvaria, a thinning of the cortical bone, and an impairment of both bone formation rate and osteoblast number in the trabecular compartment of the long bones. In vitro studies of bone marrow stromal cells expressing a gain-of-function mutation of HIF2 demonstrated that HIF2 is a direct inhibitor of osteoblastogenesis, as shown by analyses of Alkaline Phosphatase (ALP) activity, mineralization and mRNAs encoding osteoblastic markers such as Osterix, ALP, and Osteopontin. Interestingly, the level of Runx2 mRNA was not affected by HIF2, which suggests that HIF2 impairs osteoblastogenesis by acting upstream of Osterix through the modulation of Runx2 activity. Consistent with these

data, we gathered evidence that Sox9, which is emerging as a negative regulator of osteo-blastogenesis, is likely to mediate the HIF2-dependent impairment of osteoblast differentiation.Our findings constitute a paradigm shift as activation of the hypoxia signaling pathway has been associated with an increased osteoblast activity through HIF1. They also show that HIF1 and HIF2 have opposing functions in osteoblastic cells.HIF2 can be selectively inhibited by small molecules that are currently in clinical trials in patients with renal carcinoma. Inhibiting HIF2 could thus represent a therapeutical approach for the treatment of the low bone mass observed in chronic diseases, osteoporosis or aging.

Periosteal skeletal stem cells are a functionally and genetically distinct subset of skeletal stem cells necessary for bone healing Laura Ortinau*[1], Hamilton Wang[1], Kevin Lei[1], Yannis Hara[1], Bredan Lee[1], David Scadden[2], Dongsu Park[1]. [1]Baylor College of Medicine, United States, [2]Harvard University, United States

The periosteum is critical for bone healing, suggesting skeletal stem cells (SSCs), which are essential for lifelong bone and cartilage regeneration, reside in the periosteum. Therefore, the manipulation of periosteal SSCs (P-SSCs) is a promising therapy for degenerative bone disease and bone defects. Animal models that selectively label a P-SSC subset by myxovirus resistance-1 (Mx1) with either Rosa-DTR or αSMA-GFP expression were used for lineage tracing and fluorescence-activated cell sorting (FACS) analysis. P-SSC migration and bone injury repair was determined using sequential live intravital imaging of the calvaria. Our previous studies revealed that mature osteoblasts turn over rapidly and are replaced by their stem/progenitor cells genetically labeled by the Mx1 promoter in vivo. Mx1+ cells are abundantly present (> 50%) in the periosteal (PO) cambial layer (outer bone surface) of calvaria and long bones. To determine the necessity of Mx1+ PO cells in bone healing, we treated the calvaria of Mx1/tomato/DTR mice locally with ditheria toxin (DT) reducing the number of Mx1+ PO cells by > 90%, while Mx1+ cells in the BM and in the distal periosteum remained unchanged. Sequential imaging of injury repair for 16 days revealed that local DT-mediated deletion of Mx1+ PO cells completely inhibits the recruitment and proliferation of Mx1+ osteogenic cells at the injury site and delays calvaria bone healing. We then determined that Mx1È PO cells can be further specified by the αSMA mesenchymal marker. Histological and in vivo image analysis of Mx1/Tomato/αSMA-GFP mouse calvaria and tibia revealed that most Mx1+αSMA+ cells reside in the periosteum and calvarial sutures but are nearly undetectable in the bone marrow (BM). FACs analysis of Mx1/Tomato/αSMA-GFP mouse periosteum showed that ~80% of Mx1+αSMA+ PO cells express immunophenotypic SSC markers (CD45-CD31-Ter119-CD140a+CD105+) and highly express known SSC transcripts Grem1, LepR, and Cxcl12. Upon injury to the calvaria, we observed significant migration of Mx1+αSMA+ P-SSCs out of the coronal suture toward the injury sight within 24-48 hours and are present at the injury sight 4-7 days post-injury. Further tracking, histology, and in vivo imaging 14 days post injury revealed Mx1+αSMA+ periosteal cells repopulate the outer layer of the callus and supply most of the callus-forming cells and new osteoblasts during fracture healing. In addition, we found that CCR3 and CCR5, receptors for chemokine CCL5, are specifically expressed in Mx1+αSMA+ P-SSCs. Thus P-SSCs are a functionally and genetically distinct subset of SSCs that are necessary for bone healing

Cfp1 is Essential for the Initiation of Chondrogenesis and Growth Plate Development Diana Carlone*, Emanuele Pignatti, Lijie Jiang, Manasvi Shah, David Breault. Boston Children's Hospital, United States

Mesenchymal progenitor cells (MPCs) are required for proper specification of the developing limb and perturbations in their capacity to expand and differentiate translate into major skeletal defects. Recent data indicate that epigenetic regulation of gene expression plays an essential role in mediating MPC activity. Precisely how this controls MPCs, including their ability to form bone, remains to be determined. CXXC finger protein 1 (Cfp1) is a critical epigenetic regulatory factor that has been implicated in the control of progenitor cell differentiation, through unknown mechanisms. To address this in bone, we deleted Cfp1 specifically in limb bud mesenchyme using Prx1-Cre. Conditional knockout (cKO) mice died shortly after birth and displayed a complete absence of forelimbs, implying a profound defect in MPC function. Embryonic analysis revealed that cKO forelimbs form but are lost by E14.5. In addition, high-density culture of forelimb mesenchymal cells revealed an intrinsic defect of cKO cells to undergo condensation, indicating that Cfp1 is required for the initiation of chondrogenesis in the developing limb. To decipher the mechanism(s) by which Cfp1 regulates MPCs, we performed whole transcriptome analysis of limb buds (E11.5) from cKO and control mice. This analysis revealed a dramatic reduction in chondrogenic gene markers, including the master transcriptional regulator Sox9, further supporting Cfp1's role in the initial steps of chondrogenesis. In addition, our preliminary data indicate that loss of Cfp1 leads to differential expression of signaling pathways important for chondrogenesis, such as FGF, BMP, Wnt and Shh. In contrast to the forelimb, cKO hindlimbs did develop, but were severely stunted. Moreover, high-density culture of hindlimb mesenchymal cells from cKO mice were able to condense and differentiation, similar to controls, suggesting that Cfp1 also functions in chondrocytes during endochondral ossification. Consistent with this, cKO tibia exhibited abnormal growth plate development with reduced proliferation and

accelerated hypertrophy. In addition, decreased ERK/Mapk signaling and Runx2 expression were observed. Finally, deletion of Cfp1 in chondrocytes using, Col2a1-Cre, resulted in smaller mice with shorter limbs, consistent with a physiological role for Cfp1 in chondrocytes during endochondral ossification. Together, our results show that Cfp1 is an essential modulator of skeletal development, through augmentation of regulatory genes and signaling pathways during the initiation of chondrogenesis and growth plate development. These results highlight the intricate nature of the epigenetic regulatory network in the skeleton.

The Role of GATA4 in Mesenchymal Stem Cell Proliferation and Differentiation Aysha Khalid*, Susan Miranda, Alexadria Slayden, Jerusha Kumpati, Gustavo Miranda. University of Tennessee, United States

GATA4 is a zinc finger transcription factor that has been shown to regulate tissue specific gene expression. Previously, we demonstrated that mice with deletion of Gata4 using Cre-recombinase under the control of the Col1a1 2.3 kb promoter, had significantly reduced trabecular bone properties. However, it is not yet known if GATA4 plays a role in mesenchymal stem cell (MSC) biology or MSC commitment to osteoblasts or adipocytes. Gata4fl/fl mice were crossed with mice expressing Cre-recombinase under the control of the Prx1 promoter, which is expressed in limb bud mesenchyme, to create Gata4 PRX conditional knockout (Gata4 PRX-cKO) mice. The Gata4 PRX-cKO mice showed significantly reduced properties of trabecular bone indicating the importance of early expression of GATA4 in maintaining normal bone mass. Bone marrow stromal cells differentiated for 14 days showed reduced fat accumulation and mineralization, as visualized by Oil Red O and Alizarin Red staining, respectively. Less bone and less fat indirectly suggest a cellular defect in MSCs. qPCR analysis of the cDNA of bone marrow MSCs differentiated for 0-14 days in osteogenic and adipogenic media exhibited the highest level of Gata4 expression in undifferentiated cells. FACS analysis of MSCs from PRX-cKO and wildtype (WT) mice display a significant reduction in the MSC population (Sca1+/CD44+/CD34-/CD45-) in PRX-cKOs. PRX-cKOs also had reduced Giemsa staining in CFU-F assays. The immunocytochemistry of Gata4 PRX-cKO bone marrow MSCs showed fewer nestin positive stem cells as compared to WT bones. Cell proliferation rates were also reduced in Gata4 PRX-cKO primary bone marrow MSCs, as determined by IncuCyte proliferation assays and qPCR analysis of cDNA expression levels of proliferation markers. qPCR analysis of the cDNA of Gata4 PRX-cKO bone marrow MSCs also showed a significant reduction in Wnt ligands and signaling. To determine if Wnts are direct targets of GATA4, ChIP qPCR was performed, and we demonstrate that GATA4 is recruited to enhancers near Wnt3 and Wnt10b. Furthermore, qPCR analysis showed a significant reduction of Gata4 in Wnt10b-knockout mice, indicating a co-regulation between GATA4 and WNT10B. Together, these data suggest that Gata4 PRX-cKO have fewer and slower proliferating MSCs due to a reduction in Wnt signaling, which in turn leads to reduced bone mineral density in Gata4 PRX-cKO bones, as compared to wildtype bones.

The TGFß Receptor ALK5 is an Essential Regulator of BMP Signaling in the Growth Plate Weiguang Wang*, Hyelim Chun, Karen Lyons. University of California, Los Angeles, United States

TGFβs and BMPs regulate joint shape, cartilage formation and AC maintenance, but the functions of the TGFβ pathway in cartilage in vivo are unclear. Cartilage-specific loss of the receptor TGFβRII or the intracellular mediator Smad3 in embryos or young mice leads to osteoarthritis (OA)-like pathologies (1-3). However, no structural alterations were observed when TGFβRII was ablated in articular cartilage (4). Furthermore, TGFβ activates Smad2 and Smad3, but the role of Smad2 was unknown. The purpose of this study was to investigate the extent to which TGFβ controls cartilage formation and maintenance in vivo. We therefore generated mice lacking (a) Smads2 and 3, (b) the TGFβ receptor ALK5, and (c) either the BMP receptor ALK1 or both ALK1 and ALK5. Results: Loss of Smad2 in cartilage led to only subtle growth plate abnormalities at birth, but mutants developed OA-like pathologies as they aged. These phenotypes were exacerbated in Smad2/Smad3 cartilage-specific double mutants, demonstrating that both Smad2 and Smad3 transduce TGFβ signaling in cartilage. Cartilage-specific loss of ALK5 led to a far more severe, neonatal lethal phenotype. The greater severity of the phenotype demonstrates that the majority of ALK5 action in cartilage occurs independently of Smad2/3 activity. Characterization of the Alk5 phenotype revealed unexpected evidence that BMP signaling was elevated. Because the BMP receptor ALK1 can associate physically with ALK5, we investigated whether ALK1 interacts genetically with ALK5 in cartilage. We found that loss of ALK1 in cartilage did not lead to a discernable phenotype, but the severe chondrodysplasia found in Alk1 mutants was almost completely reversed in Alk1/Alk5 double mutants. This demonstrated a previously unexpected role for ALK1 in the growth plate. Using reporter assays, CRISPR-modified chondrocytes, chemical crosslinking and proximity ligation studies, we found that ALK1 and ALK5 form complexes in cartilage, and that loss of ALK5 leads to formation of new ALK1/ActRIIB complexes. These complexes drive high levels of BMP signaling. These studies indicate that contrary to expectation, the primary function of the TGFβ receptor ALK5 is not to transduce TGFβ signals, but is rather to restrain exuberant BMP signaling by ALK1.1. Post-Fracture Care gap in Canada from 2000-2001 to 2011-2012: A Nationwide Population-based Analysis Suzanne N Morin*[1], Siobhan O'Donnell[2], Sonia Jean[3], Susan Jaglal[4], Kerry Siminoski[5], Alexandra Papaioannou[6], Jacques Brown[7], Lisa M Lix[8], William D Leslie[8]. [1]McGill University, Canada, [2]Public Health Agency of Canada, Canada, [3]Institut national de santé publique du Québec, Canada, [4]University of Toronto, Canada, [5]University of Alberta, Canada, [6]McMaster University, Canada, [7]Université Laval, Canada, [8]University of Manitoba, Canada

PURPOSE: A high percentage of Canadians who experience fragility fractures do not receive the osteoporosis (OP) screening or treatments that have been demonstrated to be cost-effective for secondary prevention. We aimed to describe the secular trend in the post-fracture care gap in Canada from 2000-2001 to 2011-2012.METHODS: Using linked provincial and territorial health administrative data from the Public Health Agency of Canada's Canadian Chronic Disease Surveillance System (CCDSS), we identified Canadians age 40 years and older who sustained an incident fracture of the hip, humerus, wrist, vertebrae or pelvis during the study period. Outcomes were a new OP diagnosis, bone mineral density (BMD) testing or (in those over 65 years) OP medication prescription (OP med) in the 12 months following the index fracture. RESULTS: We identified a total of 900,000 incident fractures among women and 391,700 among men over the study period. Up to 17.7 % (95% Confidence Intervals [CI] 17.3-18.1%) of women and 8.8 % (8.5-9.2%) of men received a new OP diagnosis, and this improved in men (p for trend <0.001). The percentage of individuals who underwent BMD testing was low, particularly in men (< 10%), but increased slightly during the study period (p<0.001). OP med increased up to a maximum of 16.9% (16.1-17.8%) of men and 26.3% (25.7-27.9%) of women by 2008-2009 (p<0.0001). There was a significant downward trend in OP med for women and men during the last 4 years of the study period (p <0.003). (Figure) Age-specific percentages of women and men who received a new OP diagnosis or OP med increased with age, and was highest, in 2011-12, in women 80-84 y (26.4%; 95% CI 25.1-27.9%) and in men ≥ 85 y (19.6%; 95% CI 18.0-21.4%). BMD testing in the year following a fracture was highest in women 55-69 y (12.7%; 95% CI 11.7-13.8% to 13.0%; 95% CI 12.0-14.1%) and men 65-74 y (6.6%; 95% CI 5.6-7.7% to 7.1%; 95% CI 6.0-8.4%), and lowest in the oldest age-groups.CONCLUSIONS: As documented in many countries, secondary fracture prevention strategies are infrequently implemented in Canada. Few were given a new diagnosis of OP or underwent BMD testing. Only one in four women and one in six men received a new OP prescription in the year following a major osteoporotic fracture and this proportion decreased significantly in the last 4 years. Ongoing efforts to improve post fracture care through fracture liaison services should be vigorously supported.

1023

Hip fractures rates and time trends in use of anti-osteoporosis medications in Denmark for the period 2005 to 2015 Bo Abrahamsen*[1,2], Michael K Skjødt[1], Peter Vesteragaard[3]. [1]Holbæk Hospital, Dept of Medicine, Denmark, [2]Univ of Southern Denmark, OPEN, Denmark, [3]Aalborg University and University Hospital, Steno Diabetes Center North Jutland, Denmark

Background: Declining use of bisphosphonates (BP) in the United States and Europe may lead to a widening of the treatment gap for osteoporosis and an increase in osteoporotic fracture rates. However, a shift to non-bisphosphonates and to hospital administered i.v. BPs could lead to overestimation of the treatment gap if analyses are based exclusively on BPs and on non-hospital use. We analysed a best-case scenario where all use of BPs, denosumab, raloxifene and PTH analogues - including the oncology area - was contrasted with the trend in hip fracture rates over the same period.Methods: Aggregate statistics were obtained from the National Board of Health and the National Medicines Agency on surgically treated hip fracture events and total use in DDD (defined daily doses) of the above medications with number of persons covered assuming a medication possession ratio of 100. The Danish 50+ population was 1.8 mio in 2005 and rose to 2.1 mio in 2015. The number of fractures prevented was estimated by assuming a primary prevention scenario (taken from alendronate FIT, no prior vertebral fracture) with an absolute risk reduction of 0.3 hip fractures per 100 person years.Results: A plateau in prevalence of use of osteoporosis medications (bars, fig1) occurred in 2014. Between 2005 and 2015, hip fracture rates (solid line, fig 1) declined by 30%. Statistically, 363 hip fractures were avoided in 2015 due to osteoporosis medications compared with 133 in 2005 (dotted line, fig 1). However, only 10% of the observed reduction in hip fracture rates is statistically attributable to treatment even in a best-case scenario. Discussion: The use of anti-osteoporosis treatment in Denmark reached a plateau in 2014 even in a best-case scenario where all pharmacy and hospital dispensations of osteoporosis drugs is assumed to be for the osteoporosis indication. A limitation to the study is lack of individual adherence data. About 90% of the decline in hip fracture rates appears to be due to factors other than osteoporosis medication; prior studies using APC models have suggested major cohort effects with a transient decrease in rates. The plateau in use of osteoporosis treatment is problematic given the predicted increased age-specific hip fracture rates.

A Comparison of U.S. and Canadian Osteoporosis Screening and Treatment Strategies: What proportions of postmenopausal women are identified for screening and treatment? Carolyn Crandall*[1], Joseph Larson[2], Joann Manson[3], Jane Cauley[4], Kristine Ensrud[5], Andrea Lacroix[6], Jean Wactawski-Wende[7], Mrirul Datta[8], Maryam Sattari[9], John Schousboe[10], William Leslie[11]. [1]University of California, Los Angeles, United States, [2]Fred Hutchinson Cancer Research Center, United States, [3]Harvard Medical School, United States, [4]University of Pittsburgh, United States, [5]University of Minnesota, United States, [6]University of California, San Diego, United States, [7]the State University of New York, United States, [8]Purdue University, United States, [9]University of Florida, United States, [10]Park Nicollet Institute, United States, [11]University of Manitoba, Canada

Objective. To compare 1) the proportion of postmenopausal women identified for screening under the United States Preventive Services Task Force (USPSTF) and Osteoporosis Canada (CAROC) strategies; and 2) the proportion of women identified for drug treatment under the National Osteoporosis Foundation (NOF) and Canadian Association of Radiologists and Osteoporosis Canada (CAROC) treatment strategies. Methods. We used 10-year follow-up data from 111,707 women aged 50-79 years in the WHI Observational Study and Clinical Trials. Fractures were self-reported annually. Bone density information was available for a subset of 8,134 participants. Results. For women ≥65 years, 100% were identified for bone mineral density (BMD) screening by the USPSTF and Canadian strategies, 35-74% were identified for treatment under NOF, and 16-37% were identified for treatment under CAROC (range among 5-year age strata) (Table). Among women aged >65 years who experienced major osteoporotic fracture (MOF) during 10-year follow-up, sensitivity for identifying treatment candidates was 50-83% for NOF and 27-52% for CAROC (range among 5-year age strata). Among women 50-64 years-old, 16% of women were identified for BMD screening under the USPSTF strategy; 52% were identified for screening under the Canadian strategy. Among women 50-64 years-old who experienced MOF during follow-up, USPSTF and Canadian strategies identified a small fraction of this group for BMD screening. Specifically, the USPSTF strategy identified 4% of women 50-54 years-old and 36% of women 60-64 years-old for BMD screening at baseline; the Canadian strategy identified 54% of women 50-54 years-old and 61% of women 60-64 years-old for BMD screening at baseline. Among women 50-64 years-old, the NOF strategy identified a larger proportion for drug treatment to prevent fractures (16%) than did the CAROC strategy (3%). Among women aged 50-64 who experienced MOF during follow-up, the NOF strategy had a higher sensitivity for identifying them as treatment candidates at baseline, but sensitivity was low for both strategies (NOF 10-38%; CAROC 1-15%). Conclusion. Among women aged 50-64 years, the screening and treatment strategies examined identified only a small proportion of women who subsequently experienced MOF. Among women aged ≥65 years who subsequently experienced MOF, the NOF strategy identified more women for treatment than the CAROC strategy. Osteoporosis screening and treatment strategies warrant reconsideration.

Screening of high fracture risk in primary care not effective Thomas Merlijn*[1], Karin Swart[1], Coen Netelenbos[2], Petra Elders[1]. [1]Department of General Practice and Elderly Care Medicine, VU University Medical Center, Netherlands, [2]Department of Internal Medicine, Endocrine Section, VU University Medical Center, Netherlands

Objective: To study whether screening of fracture risk and subsequent treatment of older women in primary care can reduce osteoporotic fractures, in comparison to usual care. Method: In the SALT Osteoporosis Study (SOS), a pragmatic randomized trial in women 65-90 years we compared a fracture risk screening program and subsequent treatment with usual care. All women in 224 GP practices in the Netherlands received a questionnaire to assess clinical risk factors for fractures. We randomized 11,331 women with at least one clinical risk factor for fractures (previous fracture, parental hip fracture, low body weight, secondary causes for osteoporosis). Participants in the intervention group underwent bone densitometry and vertebral fracture assessment. Anti-osteoporotic medication was recommended if the 10-year major osteoporotic fracture probability (FRAX) was above an age dependent threshold. The outcomes were time to first osteoporotic fracture and time to first hip fracture, analyzed with Cox proportional Hazard analysis. Self-reported fractures at 18 and 36 months were verified with the GP or hospital. Results: The mean follow up was 3,7 years and was complete in 94% of the participants. We identified 573 osteoporotic fractures and 140 hip fractures in the intervention group (n=5734) and 605 osteoporotic fractures and 146 hip fractures in the control group (n=5597). Screening and subsequent treatment had no effect on time to first fracture (HR=0.91, 95%CI=0.81 to 1.02) nor first hip fracture (HR=0.92, 95%CI=0.73 to 1.17). Conclusion: Screening and subsequent treatment of older women with increased fracture risk in primary care has no effect or at most limited effect in reduction of osteoporotic fractures. This finding is in line with the main results of two simultaneous trials (SCOOP and ROSE) however a reduction in hip fractures was not reproduced in our trial. Active screening of increased fracture risk in primary care should not be recommended in guidelines.

Identification of Prevalent Vertebral Fracture Increases Utilization of Pharmacologic Fracture Prevention Therapy John Schousboe*[1], Lisa Lix[2], Suzanne Morin[3], Sheldon Derkatch[2], Mark Bryanton[2], Mashael Alhrbi[2], William Leslie[2]. [1]Park Nicollet Clinic & HealthPartners Institute, United States, [2]University of Manitoba, Canada, [3]McGill University, Canada

Purpose: Many guidelines recommend targeted lateral spine imaging for prevalent vertebral fracture assessment (VFA) to aid in fracture risk assessment and identification of those who may benefit from pharmacotherapy. However, whether the findings of VFA impact use of fracture prevention pharmacotherapy is unknown. Our aim was to estimate the association of vertebral fractures documented on VFA with subsequent prescription of pharmacologic fracture prevention therapy (Rx). Methods: Since 2010, in Manitoba (Canada) densitometric VFA imaging has been performed at the time of bone densitometry (BMD), in men and women with a central T-score ≤ -1.5 and one of the following; a) age ≥ 70 years; or b) age ≥ 50 years plus historical height loss > 5 cm, measured height loss > 2.5 cm, or chronic systemic glucocorticoid therapy. Among 6652 treatment naive individuals with at least 90 days follow up and VFA imaging (mean [SD] age 76 [7] years, 92% women), 923 (13.9%) had ≥1 definite vertebral fractures (positive VFA) using a modified algorithm-based quali-

tative method. Subsequent osteoporosis Rx initiated within the subsequent 12 months was identified using population-based pharmacy data. Logistic regression models were used to estimate the association of positive VFA with Rx prescription, compared to negative VFA. Results: Osteoporosis Rx was initiated by 1527 (23.6%) individuals (39.1% with positive vs 20.7% with negative VFA, p-value<0.001). Positive VFA was associated with subsequent Rx prescription adjusted for FRAX with BMD (OR 2.37 [95% CI 2.04-2.75]), or adjusted for BMD T-score category at any site (OR 2.38 [95% CI 2.03-2.79]). The association of positive VFA with subsequent Rx was highest in those without osteoporosis by BMD criteria, and in those designated (before VFA results are known) to have low to moderate FRAX fracture risk probability (Table). Conclusion: Identification of prevalent vertebral fracture on VFA increases subsequent prescription of fracture prevention medication, particularly for those not already designated to be at high fracture risk or who do not have osteoporotic BMD T-scores. Even amongst those with high fracture risk or osteoporotic BMD T-score, documentation of prevalent vertebral fracture modestly increases prescription of osteoporosis medication. Targeted VFA imaging at the time of BMD can improve identification of those at high risk of fracture for whom fracture prevention therapy is indicated.

Table: Association of Positive vs Negative VFA with Subsequent Rx Prescription, OR (95% CI)

FRAX 10-Year Major Osteoporotic Fracture Risk Category*			WHO BMD T-Score Category^	
<10%	10% to 20%	>20%	Osteopenia	Osteoporosis
4.18 (2.84, 6.16)	2.99 (2.43, 3.66)	1.44 (1.14, 1.83)	4.51 (3.48, 5.85)	1.72 (1.43, 2.08)

*p-value<0.001 for interaction between positive VFA and MOF 10-year risk
^p-value<0.001 for interaction between positive VFA and BMD T-Score Category (based on worst T-score among lumbar spine, total hip, and femoral neck)

The role of apolipoprotein E in fracture healing and osteoblast differentiation
Xiaohua Zong*[1], Puviindran Nadesan[2], James White[3], Phillip White[3], Gurpreet Baht[4]. [1]Department of Orthopaedic Surgery, Duke Molecular Physiology Institute, Duke University, United States, [2]Department of Orthopaedic Surgery, Duke University, United States, [3]Department of Medicine, Duke Molecular Physiology Institute, Duke University, United States, [4]Department of Orthopaedic Surgery, Department of Pathology, Duke Molecular Physiology Institute, Duke University, United States

Apolipoprotein E (ApoE) is an extracellular matrix protein involved in the transport of fatty acids. Recent studies link ApoE polymorphisms, found in 20% of the population, to an increased incidence of hip and vertebral fractures and ApoE knockout mice (ApoE-/-) display increased bone mineral density. However, little is known about the function or the mechanism of action of ApoE in bone. Wildtype (WT) and ApoE-/- mice underwent tibial fracture surgery; fracture calluses were assessed for healing at 7-, 14-, and 21-days post injury. μCT and histological analysis revealed that in ApoE-/- mice fracture calluses contained 50% more bone and deposited tissue was 35% denser than in WT controls. Osteoblast (Ob) differentiation was assessed by measuring colony-forming-units from bone marrow aspirates of unfractured mice. Cultures from ApoE-/- mice contained 40% less progenitor cells; however, Ob differentiation and Ob activity were both doubled in response to loss of ApoE expression. Transcripts for osteogenic markers (Col1, Bsp, Alp) were elevated in Ob cultures from ApoE-/- mice. Conversely, treatment of cultures with exogenous rApoE decreased osteoblast differentiation, mineral formation, and the level of osteogenic transcripts. Due to ApoE's association with lipid metabolism, we investigated the transcript levels of genes involved in fatty acid oxidation and glycolysis. During Ob differentiation in ApoE-/-mice, fatty acid oxidation transcripts were unaltered; however, genes involved in glycolysis were significantly upregulated. Metabolic flux analysis revealed increased glycolytic rate and increased uptake of radio-labeled glucose in ApoE-/- Ob's. Furthermore, transcript and protein levels of glucose transporter 1 (Glut1) were higher in cultured Ob's from ApoE-/- mice. This finding was recapitulated in vivo: immunohistochemistry of fracture calluses from WT and ApoE-/- mice revealed elevated levels of Glut1 expression in ApoE-/- Ob's. Finally, differentiation of ApoE-/- Ob's was more sensitive to glycolytic inhibition than differentiation of WT Ob's and the enhanced fracture healing observed in ApoE-/- mice was ameliorated by high fat diet. These data confirm a negative role for ApoE in bone fracture healing and Ob differentiation. Specifically, loss of ApoE serves to elevate glycolysis within Ob's and subsequently differentiation. This identifies ApoE as a novel target for therapeutic intervention to improve fracture healing or osseous integration of implants.

Osteoblasts Mediate the Adverse Effects of High-fat Diets on Bone and Fat Metabolism Through Glucocorticoid Signalling Sarah Kim*, Holger Henneicke, Sylvia J. Gasparini, Lee Thai, Markus J. Seibel, Hong Zhou. Bone Research Program, ANZAC Research Institute, The University of Sydney, Australia

Overconsumption of energy-dense diets is a major public health challenge due its causal association with obesity, diabetes and poor skeletal health. Most animal studies examining diet-induced obesity and diabetes have focused solely on combined high-energy, high-fat diets. We therefore aimed to define whether the adverse health outcomes are due to the high energy density or high fat content of these diets. Since osteoblasts co-regulate overall energy balance under the control of glucocorticoids, we also examined whether abrogating glucocorticoid signalling in osteoblasts and osteocytes protects mice from diet-induced metabolic and skeletal disturbances.We utilised transgenic (tg) mice in which glucocorticoid signalling has been disrupted in osteoblasts and osteocytes via targeted overexpression of the glucocorticoid-inactivating enzyme, 11β-hydroxysteroid dehydrogenase type 2 ('HSD2OB-tg' mice). Seven-week-old male tg mice and their wild-type (WT) littermates were fed ad libitum for 18-weeks one of the following diets: High-energy, standard-fat (fat=14% total-energy, 16.3kJ/g); high-energy, high-fat (fat=43% total-energy, 16.3kJ/g); standard-energy, high-fat (fat=43% total-energy, 13.8kJ/g) or standard-chow (fat=14% total-energy, 13.8kJ/g). At endpoint, body composition, serum lipids, glucose handling and bone mass were measured. High-energy feeding, regardless of dietary fat content resulted in significantly increased fat mass in WT mice compared to WT chow-fed mice along with hyperlipidaemia, fasting hyperglycaemia and reduced insulin sensitivity. Both high-energy diets induced significant tibial trabecular and cortical volume loss to a similar extent. WT mice on the standard-energy, high-fat diet remained lean and insulin sensitive but displayed pronounced trabecular and cortical bone loss (Fig.1A). Notably, HSD2OB-tg mice were protected from high-energy diet-induced excessive fat accrual, hyperlipidaemia, insulin resistance, glucose intolerance and bone loss (Fig.1B), despite consuming the same amount as their WT littermates on either high-energy or standard-energy, high-fat diet.We conclude that high energy density rather than high fat content induces metabolic dysfunction in male mice, whereas high dietary fat results in bone loss. Both effects are mediated by glucocorticoid signalling in osteoblasts and osteocytes.

Bone marrow adipose tissue: white, brown or beige? Hero Robles*[1], Madelyn Lorenz[1], Eric Hilker[1], Kristann Magee[1], Jesse D Procknow[1], Zhaohua Wang[1], Charles A Harris[2], Clarissa S Craft[1], Erica L Scheller[1]. [1]Department of Internal Medicine, Division of Bone and Mineral Diseases, Washington University, United States, [2]Department of Internal Medicine, Division of Endocrinology, Metabolism and Lipid Research, Washington University, United States

Adipocytes within the skeleton, collectively known as bone marrow adipose tissue (BMAT), make up approximately 60-70% of bone marrow and 8% of total fat mass in the average adult human. Recent studies have shown that BMAT has the ability to contribute significantly to both peripheral and local metabolism. However, its characterization as a white, brown, or beige adipocyte remains controversial. To clarify this point, we first examined the ultrastructural nature of BMAT using three dimensional electron microscopy (3D-EM). Reconstruction of the bone marrow niche via 3D-EM demonstrated that BMAT has an extensive mitochondrial network interspersed around and between multiple lipid droplets (Fig.1A). We also found that CL316,243 was capable of inducing lipid droplet remodeling in a subset of mouse bone marrow adipocytes in vivo; suggesting that BMAT has a distinctive phenotype which, like beige and brown adipocytes, may undergo adrenergic-induced remodeling and potentially thermogenesis. To address this, we developed two genetic mouse models. In the first, we used UCP1-Cre to drive diphtheria toxin (DTA) expression and cell death after β3-agonist stimulation (UCP1Cre+/DTA+). This facilitates a quantitative, region-specific analysis of induced UCP1 expression in BMAT and WAT. In the second,

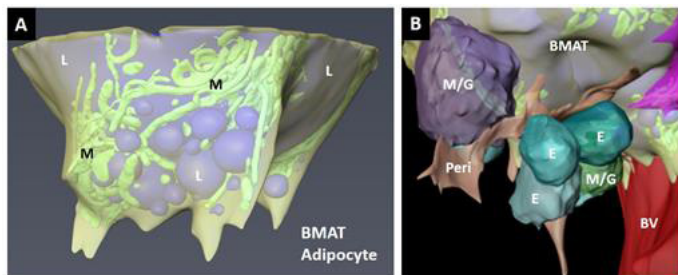
UCP1-Cre mice were crossed with mTmG reporter mice (UCP1Cre+/mTmG+) to allow visualization of UCP1 expressing cells in intact tissues by monitoring GFP expression. As expected, CL316,243 treatment was associated with depletion of inguinal beige adipocytes in adult UCP1Cre+/DTA+ mice and regions of GFP expression in UCP1Cre+/mTmG+ mice. However, despite the extensive mitochondrial network observed with 3D-EM and lipid droplet remodeling after CL316,243, we did not observe loss of BMAT beyond that of control animals in the UCP1Cre+/DTA+ model of induced cell death. Similarly, UCP1-induced conversion of the mTmG transgene did not occur in the BMAT. Our data suggests that BMAT adipocytes are capable of induced lipid droplet remodeling, however, they are not true UCP1-expressing beige or brown adipocytes. This supports a paradigm by which BMAT adipocytes are a unique subpopulation which, based on our EM analyses, is likely specialized to support cells within the skeletal and hematopoietic niche (Fig.1B).


Figure 1. Ultrastructural morphology of the bone marrow adipose tissue (BMAT) niche. (A) BMAT adipocyte from the mouse proximal tibia with small lipid droplets around a large lipid globule (L, blue) which are enmeshed by an extensive mitochondrial network (M, green). Cytoplasm in yellow. (B) The BMAT adipocyte adheres to a sinusoidal blood vessel (BV, red) and interfaces directly with cells of the niche including pericytes (peri, tan and pink), myeloid/granulocyte lineage cells (M/G, purple and green) and erythroblasts (E).

Lrp4 expression by adipocytes and osteoblasts modulates endocrine actions of sclerostin Soohyun Kim[*1], Hao Da[1], Priyanka Kushwaha[1], Zhu Li[1], Thomas Clemens[2], Ryan Riddle[2]. [1]Johns Hopkins University School of Medicine, United States, [2]Johns Hopkins University School of Medicine, Baltimore VA Medical Center, United States

Sclerostin exerts profound local control over bone acquisition and also mediates endocrine communication between fat and bone by regulating Wnt signaling in adipocytes. Consequently, Sost-/-mice exhibit a marked decrease in body fat mass as well as the expected increase in bone volume. In the osteoblast, sclerostin's anti-anabolic activity is enhanced by Lrp4, which facilitates its interaction with Lrp5/6. To determine if Lrp4 similarly affects sclerostin's endocrine functions, we specifically disrupted Lrp4 expression in adipocytes and osteoblasts by crossing Lrp4loxP/loxP mice with adipoQ-Cre (AdΔLrp4) or Ocn-Cre (ObΔLrp4) mice. In vitro, Lrp4 expression parallels triglyceride deposition in adipocytes and coincides with the ability of sclerostin to enhance fatty acid synthesis. Loss of Lrp4 function in the adipocyte mirrored the effect of sclerostin-deficiency on whole-body metabolism, as AdΔLrp4 mice exhibited a reduction in adipocyte hypertrophy and improvements in glucose and lipid homeostasis, including increased glucose and insulin tolerance and reduced serum fatty acids when compared to littermate controls. Intriguingly, loss of Lrp4 function in the osteoblast, which increases Sost expression and the circulating levels of sclerostin, produced the opposite effect. When compared to controls, ObΔLrp4 mice exhibited significant increases in whole body fat mass and impaired glucose tolerance and insulin sensitivity, despite the development of a high bone mass phenotype. Taken together these data indicate the expression of Lrp4 by both the adipocyte and osteoblast is required for normal sclerostin endocrine function. Additionally, they suggest that the impact of sclerostin on adipocyte physiology is distinct from its anti-anabolic effect on osteoblast function.

Maternal Obesity-Mediated Epigenetic Regulation of Osteoblast Differentiation through SATB2 Jin-Ran Chen*, Haijun Zhao, Oxana P. Lazarenko, Kartik Shankar. Arkansas Children's Nutrition Center and the Department of Pediatrics, University of Arkansas for Medical Sciences, United States

Nutritional status during intrauterine and/or early postnatal life has substantial influences on adult offspring health, mostly linked with permanent metabolic changes. However, evidence on the impact of high fat diet (HFD)-induced maternal obesity on regulation of fetal bone development is sparse. Thus, we investigated the effects of maternal obesity in rodents on both fetal skeletal development and epigenetic regulation of osteoblast differentiation in offspring. First, female Sprague-Dawley rats were fed either a low-fat AIN-93G control diet or a high fat diet (HFD) (45% fat calories) for 10 wks starting at 6 wks of age.

After 10 wks of these diets, lean (from control diet) and obese (from HFD) female rats were time-impregnated (n=6 per group) by control diet male rats. At gestational day 18.5 (E18.5), all fetuses were taken and embryonic osteogenic calvarial cells (EOCCs) were isolated. We found epigenetic regulation of polycomb-regulated gene Ezh2 (Enhancer of zeste homolog 2) in embryonic rat from HFD obese dams. Increased enrichment of repressive histone mark H3K27me3 on the gene body of SATB2 (ChIP Seq analysis) was associated with aberrant differentiation of EOCCs to mature osteoblasts. Knocking down Ezh2 in EOCCs and ST2 cells increased SATB2 expression, on the other hand, Ezh2 overexpression in EOCCs and ST2 cells decreased SATB2 expression. These data were consistent with ChIP experimental results showed strong association between H3K27me3, Ezh2 and SATB2. Second, we generated pre-osteoblastic cell specific Ezh2 conditional knockout mouse model by breeding Ezh2 flox/flox and Osterix-Cre+ mice. In 6-week-old mice, we found significantly increased SATB2 mRNA and protein expression in bone from Ezh2flox/flox Osterix-Cre+ conditional knockout mice compared with those from Ezh2flox/+Cre+, Cre+, Ezh2flox/flox Cre-, Ezh2flox/+Cre- and wild type mice. These findings indicate maternal HFD-induced obesity-associated decreasing of fetal pre-osteoblastic cell differentiation is under epigenetic control through SATB2 expression. Supported by USDA-ARS Project #6026-51000-010-05S.

Cellular Senescence in Tendon Aging and Pathology Anne Gingery*[1], Tamara Tchkonia, James C Kirkland, Peter C Amadio. Mayo Clinic, United States

Tendons and ligaments are responsible for the integrity and mobility of the musculoskeletal system. Tendon injuries are slow to repair as compared to other musculoskeletal tissues, and the failure to repair tendon damage that occurs with age, overuse, and injury is a significant clinical musculoskeletal challenge. Senescent cells, which are defined as cells growth arrested in response to stress (e.g., telomere shortening, reactive oxygen species, mechanical stress), play an important role in wound healing; however, it has recently been noted that these cells accumulate with age in many tissues and failure to clear these cells contributes to the pathology of age-related diseases. Senescent cells can exhibit a senescence-associated secretory phenotype (SASP) that is thought to mediate disease pathology. Recent work in our tendinopathy model revealed a senescence signature. Further, the incidence of tendinopathy increases with age. Therefore, we tested the hypothesis that senescent cell accumulation contributes to age and injury related tendon pathologies. To test our hypothesis we utilized both mouse models of tendon aging and a rat chronic tendinopathy model (collagenase-induced). Several markers of cellular senescence, including histological marker - senescence associated beta-galactosidase (SABG), gene expression markers p16, p53, as well as SASP factors such as TGF-ß, PAI-1, and IGF-1 increased with age. Ablation of p16ink4a positive senescent cells using mice expressing the INK-ATTAC "suicide" transgene or by targeting with senolytics such as dasatinib +quercetin (DQ) reduced markers of senescence, as well as fibrotic markers, in aged (23-24 months) mouse tendons as compared to young tendons (4 months). Furthermore in a chronic Achilles tendinopathy model we found increased expression of SABG, p16, TGF-ß, Col3, as well as dysregulation of check point genes indicating that cellular senescence may play a causal role in chronic tendon pathologies. Collectively these data demonstrate that cellular senescence plays a role in tendon aging and in chronic tendinopathy. Furthermore, this work establishes that targeting cellular senescence may provide a novel and much needed therapeutic target for tendon pathologies.

p18 is required and regulated by BMP4 in Muscle-Derived Stem Cell-mediated Osteogenesis and Bone Regeneration during aging Haizi Cheng*[1,2], Xueqin Gao[1], Aiping Lu[1], Johnny Huard[1]. [1]The University of Texas Health Science Center at Houston, Houston, TX; Steadman Philippon Research Institute, Vail, CO, United States, [2]University of Pittsburgh, Pittsburgh, PA, United States

INTRODUCTION: Bone morphogenetic protein 4 (BMP4) induces bone formation by muscle-derived stem cells (MDSCs), and promotes stem cell self-renewal. The cyclin-dependent kinase inhibitors p16INK4A (p16) and p18INK4C (p18) cause early G1-phase cell cycle blockade by targeting cyclin-dependent kinase (CDK) 4/6. It is unclear if p18 correlates directly or inversely with p16 in natural aging. We found that aged MDSC exhibit weakened proliferation and attenuated multi-lineage differentiation potential, but can regenerate bone in a critical-sized skull defect in 6-week-old CD-1 nude mice after transduction with BMP4/green fluorescent protein retrovirus (retro-BMP4/GFP). METHODS: Young (3-week-old) and aged (2-year-old) MDSCs, isolated by a modified preplate technique, were transduced with retro-BMP4/GFP. FACS was performed for GFP; BMP4 was quantified by ELISA. MDSCs were then transplanted in a critical-sized calvarial bone defect model using fibrin sealant in CD-1 nude mice. In vivo bone regeneration was measured by microCT bi-weekly for 6 weeks. Gene expression was quantitated by qRT-PCR. Statistical analysis was by unpaired or multiple t-test.RESULTS: BMP4-transduced aged MDSCs, when transplanted into the skull defect in CD-1 nude mice, showed significantly improved osteogenesis (Fig. 1); Increased p18 transcription, even with low BMP4 expression, caused aged MDSCs to regenerate more bone in the first 2 weeks; thereafter, more BMP4 induced more bone (Fig. 2). H&E staining demonstrated functional bone formation in the defect area (Fig. 3a). GFP staining confirmed that the newly generated bone was derived from the transplanted BMP4/GFP MDSCs (Fig. 3b). Herovici's staining showed major bone matrix collagen type

I formation in aged MDSCs (Fig. 3c). p18 was temporarily upregulated after BMP4 transduction and before osteogenesis.DISCUSSION: BMP4 transduction improved osteogenesis by old MDSCs in vivo. BMP4 transduction in aged MDSCs caused p18 upregulation and p21 and p16 downregulation, conferring characteristics of young MDSCs. p18 and p16 may have compensatory effects, as either can cause cell cycle G1 arrest. BMP4 transduction may result in a transition between p16 and p18. Therefore, regulating the p18:16 ratio using growth factors such as BMP4 could reverse aged stem cells from senescence to quiescence, conditionally increasing the stemness of aging stem cells.

Male-Female Spatio-Temporal Differences of Age-Related Bone Loss

Julio Carballido-Gamio*[1], Elisa A Marques[2], Sigurdur Sigurdsson[3], Kristín Siggeirsdottir[3], Alexandria Jensen[1,4], Gunnar Sigurdsson[3,5,6], Thor Aspelund[3,7], Gudny Eiriksdottir[3], Vilmundur Gudnason[3,5], Thomas F Lang[8], Tamara B Harris[2]. [1]Department of Radiology, School of Medicine, University of Colorado Denver, Denver, CO, United States, [2]National Institute on Aging, Intramural Research Program, Laboratory of Epidemiology and Population Sciences, Bethesda, MD, United States, [3]Icelandic Heart Association Research Institute, Kópavogur, Iceland, [4]Department of Biostatistics & Informatics, Colorado School of Public Health, Aurora, CO, United States, [5]University of Iceland, Reykjavik, Iceland, [6]Landspitalinn University Hospital, Reykjavik, Iceland, [7]Centre of Public Health Sciences, University of Iceland, Reykjavik, Iceland, [8]Department of Radiology and Biomedical Imaging, University of California, San Francisco, CA, United States

Normal aging leads to bone loss, and older women lose bone at a faster rate than men. The spatial distribution of bone loss in the proximal femur is mostly unknown. The objective of this work was to assess the spatio-temporal distribution of the deterioration of bone in older men and women with aging. A better understanding of how age-related loss might affect the fracture-prone regions of the hip could lead to more informed fracture-prevention strategies.A subset of 305 men (74.9±4.8 yr) and 371 age-matched women (74.8±4.7 yr) with no history of fracture were randomly selected from the Age, Gene/Environment Susceptibility-Reykjavik StudySigurdsson-2006,Harris-2007. QCT scans of the left proximal femur obtained at baseline and at 5.2 ±0.4 years follow-up were automatically processedCarballido-Gamio-2015to assess local changes in volumetric bone mineral density (vBMD), cortical bone thickness, cortical vBMD, vBMD in a layer adjacent to the endosteal surface, and structure in men and women, as well as sex differences using voxel-based morphometry (VBM)Ashburner-2000,Carballido-Gamio-2013a, surface-based statistical parametric mapping (SPM)Friston-1994,Carballido-Gamio-2015, and tensor-based morphometry (TBM) Davatzikos-1996,Carballido-Gamio-2013b. The statistical assessments of local parametric changes were performed using linear mixed effects models allowing for baseline and time-varying covariates, yielding Student's t-test statistical maps (t-Maps) that were corrected for multiple comparisonsGenovese-2002.The t-Maps in Fig. 1 summarize the results of this study. Except for minor spatial differences, men and women showed similar spatial bone deterioration (Fig. 1A-E). However, compared to older men, older women showed significant larger: 1) losses of trabecular vBMD in the femoral neck and trochanteric region (Fig. 1F); 2) losses of cortical vBMD laterally and at the inferior-anterior cortex (Fig. 1H); 3) losses of endosteal vBMD in the greater trochanter and inferiorly in the femoral neck (Fig. 1J); 4) contractions of the principal compressive group and cortex (Fig. 1G); and 5) expansions of the trabecular compartment in the greater trochanter (Fig. 1G).Using Computational Anatomy and longitudinal QCT scans, we have shown that older women lose more bone than older men with aging, and that they do it in fracture-prone regions according to previous prospective studiesCarballido-Gamio-2013a-b, providing new information on the pathophysiology of osteoporosis.

Fig. 1. (A-E) t-Maps of VBM, TBM and SPM stratified by sex. Positive t-values indicate significant negative associations of time with vBMD (A, C, E) and cortical bone thickness (D), and significant positive associations with expansions (B); while negative t-values indicate significant positive associations of time with contractions (B). (F-J) t-Maps (left) and color maps to support the interpretation (right) of VBM, TBM and SPM addressing sex differences. The yellow regions on the right side maps indicate significant larger vBMD loss (F, H, J), cortical bone thinning (I) and structural changes (G) in women.

1035

RANKL produced by osteocytes is required for cortical, but not cancellous, bone loss with age Jinhu Xiong*, Keisha Cawley, Ryan Macleod, Maria Almeida, Charles Obrien. University of Arkansas for Medical Sciences, United States

Like humans, mice lose cortical and cancellous bone with advanced age. Previous studies in mice have shown that loss of cortical bone with age is associated with increased osteoclast number at the endocortical surface compared to young adult animals. However, osteoclast number in cancellous bone is reduced in aged mice. These findings suggest that different mechanisms underlie age-associated bone loss in these two skeletal compartments. Osteocytes are an essential source of RANKL for osteoclast formation and recent studies have found that RANKL mRNA is increased in cortical bone of aged mice, suggesting a possible mechanism responsible for the increased endosteal bone resorption. To determine if osteocyte-derived RANKL plays a role in age-associated bone loss, we deleted the RANKL gene using a Dmp1-Cre transgene and compared bones of conditional knockout (CKO) and control (f/f) female littermates at 6 and 24 months of age. Serial analysis of bone mineral density (BMD) beginning at 5 months of age showed that control mice maintained stable femoral BMD until 20 months of age, after which it declined. In the spine of control mice, BMD began to decline at 20 months of age. In contrast, BMD in the femur and spine of CKO mice increased until the end of the experiment. MicroCT analysis revealed that femoral cortical thickness in control mice was significantly lower at 24 months compared to 6 months. In contrast, cortical thickness in CKO mice was higher at 24 months than at 6 months. The loss of cortical bone in control mice was due to expansion of the endosteal perimeter with age, which did not occur in CKO mice. Analysis of L4 vertebrae revealed that both genotypes lost cancellous bone volume with age, even though cancellous bone volume was higher in CKO mice compared to controls at both ages. These results demonstrate that RANKL produced by osteocytes is required for the increase in resorption and bone loss that occurs at the endosteal surface in murine long bones. Together with the finding that RANKL mRNA is elevated in cortical bone of aged mice, these results also suggest that the age-associated increase in osteocyte RANKL is a key factor driving cortical bone loss with age. In striking contrast, the loss of cancellous bone with age occurs even in the absence of osteocyte-derived RANKL, demonstrating that different molecular mechanisms underlie the age-associated cellular and structural changes in these two compartments.

RANKL+ plasmacytic B and TGFβ+ myeloid cells are attracted to bone marrow during aging by a TRAF3-dependent mechanism to increase bone resorption, decrease bone formation and promote osteoporosis Jinbo Li*, Akram Ayoub, Zhenqiang Yao, Brendan Boyce. University of Rochester Medical Center, United States

Levels of TGFβ1 and RANKL increase in bone marrow (BM) with age and induce lysosomal degradation of TNF receptor-associated factor 3 (TRAF3), a negative regulator of NF-kB signaling, in osteoblast (OB) and osteoclast (OC) precursors, respectively. Mice we generated with TRAF3 conditionally deleted in mesenchymal lineage cells (using Prx-1 Cre) or myeloid cells (using Lys-M Cre) develop accelerated osteoporosis with aging. Low-grade chronic inflammation (LLCI) also induces bone loss during aging; we hypothesize that TGFβ1 and RANKL mediate this loss. We found that BM cells (BMCs) comprise 62±5% of TGFβ1 and 75±7% of RANKL expression in leg bones from 22-m-old mice with significantly higher levels of TGFβ1 (16±3 vs 10±1 ng/ml) and RANKL (644±50 vs 475±19 pg/ml) than in BM from 4-m-old mice. 78% of TGFβ1+ BMCs were CD11b+Ly6GhiLy6C+C-CR5+ myeloid cells and 70% of RANKL+ BMCs were B220hiIgM+IgD+CD138+CXCR4+ plasmacytic B cells. The % and absolute # of these cell populations were 2-fold higher in BM from old than young mice. In addition, protein levels of CCL5, a CCR5 ligand, and CXCL12, a CXCR4 ligand, were increased 12- and 16-fold, resp., in BMCs from old than young mice. CCL5 and CXCL12 mRNA levels were 4- and 7-fold higher, resp., in CD45-mesenchymal cells from BM from old mice, but not in CD45+ hematopoietic cells. Of note, mice with TRAF3 conditionally deleted in mesenchymal lineage cells, but not in myeloid cells, had elevated CCL5 and CXCL12 expression, increased BM RANKL+ plasmacytic B and TGFβ1+ myeloid cells, enhanced OC formation and reduced OB differentiation, similar to changes detected in old WT mice. Consistent with these findings, old WT mice treated with the FDA-approved drugs, Plerixafor (P), a CXCR4 antagonist, or Maraviroc (M), a CCR5 antagonist, had significantly reduced absolute #s of plasmacytic B cells (by 59% for P) and myeloid cells (by 49% for P; 57% for M) in BM, and increased vertebral trabecular bone mass (BV/TV: 17±4% for P, 15±4% for M vs 12±2% in Ctrl).Our findings suggest that RANKL+ plasmacytic B cells and TGFβ1+ myeloid cells are attracted to BM in response to increased CXCL12 and CCL5 expressed by mesenchymal cells deficient in TRAF3 either genetically or during aging to promote LLCI-mediated bone loss. Plerixafor and Maraviroc are potential new therapies for osteoporosis that could inhibit bone resorption and enhance bone formation by keeping these RANKL- and TGFβ-expressing cells in blood and away from BM.

Investigating the influence of adult hip shape genetic variants across the life course: findings from a population-based study in adolescents Monika Frysz*[1,2], Denis Baird[2], Jenny Gregory[3], Richard Aspden[3], Jonathan Tobias[4], Lavinia Paternoster (Cox)[1,2]. [1]Population Health Sciences, Bristol Medical School, University of Bristol, United Kingdom, [2]MRC Integrative Epidemiology Unit at the University of Bristol, United Kingdom, [3]Institute of Medical Science, School of Medicine, Medical Sciences & Nutrition, Aberdeen, United Kingdom, [4]Musculoskeletal Research Unit, Bristol Medical School, University of Bristol, United Kingdom

Hip shape is a well-recognized risk factor for both hip osteoarthritis (OA) and hip fracture. Recent genome-wide association meta-analysis identified nine loci associated with hip shape in adults (mean age 62, range 48 -74 years), however it is unclear whether the same genetic variants affect hip shape across the life course. In the present study, we investigated the relationship between adult loci and hip shape in adolescents.Hip DXA scans were obtained in offspring from the Avon Longitudinal Study of Parents and Children, at mean ages of 13.8 and 17.8 years. To quantify hip morphology, each image was analysed in Shape software based on a 53-point Statistical Shape Model (SSM). Principal component analysis was used to generate 10 linearly independent modes of variation (hip shape modes (HSMs) using the same model as a previous adult study). Genetic variants which had previously shown genome-wide significant association with specific HSM(s) in adults were tested for association with the same HSM at the two adolescent time points using SNPTEST (18 tests in total). Complete genotypic and phenotypic data were available from 3550 and 3175 individuals at mean ages of 13.8 and 17.8 years respectively. There was evidence to suggest all genetic variants tested were associated with the relevant HSMs measured in adolescence (Table 1). The directions of effects were consistent with those of adults, although adolescent effect sizes were generally smaller. The strongest evidence was for two variants located near SOX9 (rs2158915 and rs2160442) with consistent effects across both adolescent time points for HSM1 and HSM5, which both capture femoral neck width (FNW). There was also strong evidence of association between rs10743612 (near PTHLH) and HSM1 and between rs6537291 (near HHIP) and HSM2 across both time points. HSM1 scores capture femoral head curvature, whereas both HSM1 and HSM2 capture FNW along with variation in greater and lesser trochanters. The genes implicated by the strongest associations with hip shape in adolescents, namely SOX9, PTHLH and HHIP are known to be involved in endochondral bone formation.In conclusion, variants implicated in endochondral bone formation appear to consistently influence hip shape across the life course, including aspects of hip shape related to risk of hip OA and/or fracture in later life.

Changes in the Risk of Subsequent Major Osteoporotic Fractures over Time in Men and Women: A Population-Based Observational Study with 25-year Follow Up Suzanne N Morin*[1], Lin Yan[2], Lisa M Lix[2], William D Leslie[2]. [1]McGill University, Canada, [2]University of Manitoba, Canada

PURPOSE: The risk of subsequent major osteoporotic fractures (MOF: hip, spine, forearm and humerus) following an index fracture is elevated but declines over time. Our aim was to study changes in the risk of subsequent fracture over time, in men and women, to inform the timing of implementation of intensive anti-fracture strategies.METHODS: Using the Province of Manitoba (Canada) linked administrative healthcare databases, we performed a matched historical cohort study in 17,721 men and 57,783 women ≥ 50 y who sustained an index MOF during 1989-2006. Rates of subsequent MOF until 2016 were compared with those of age- and sex-matched controls (n=165,965), allowing for at least 10 y and up to 25 y of follow up. Annual crude rates and cumulative incidence for subsequent fractures were estimated, accounting for competing mortality, stratified by sex and age. Hazard ratios (HR) with 95% Confidence Intervals (CI) for subsequent MOF (cases vs. controls) were estimated from Cox proportional hazard models for each of the first 15 y of follow up with a final category for ≥ 15 y, stratified by sex.RESULTS: We identified 29,694 index MOF cases (11,028

wrist; 9313 hip; 5799 humerus; 3554 spine). The annual crude rate of subsequent MOF per 1000 person-years among cases was 18.5 (95% CI:17.3-19.8) in men and 29.6 (95% CI: 28.28.8-30.4) in women. Rate ratios across all follow up years were 2.5 (95% CI 2.3-2.7) in men and 1.6 (95% CI 1.6-1.7) in women compared to controls. The cumulative incidence of subsequent MOF to 25 y was higher in cases vs controls for both sexes and across all age categories except >80 y where this relationship reversed due to competing mortality. HRs for subsequent MOF were higher in men than women, particularly in the first year following the index fracture (HR 3.3, 95% CI 2.6-4.1 in men; HR 1.8, 95% CI 1.7-2.0 in women), and remained very high for men during the first 3 y of follow up. Risk declined over time but remained elevated even $\geq$ 15 y after the index fracture (HR 1.8, 95% CI 1.4-2.4 in men; 1.5, 95% CI 1.3-1.6 in women). (Figure)CONCLUSIONS: The risk of subsequent MOF was elevated in both sexes over 25 y of follow up with time-dependent attenuation that was most evident in men. The risk of subsequent MOF was higher in men than women, particularly in the first 3 y. These results underscore the importance of timely recognition of fracture events, especially in men, a population in whom secondary prevention is vastly under-implemented.

Advanced glycation endproduct content is increased in cortical bone of the femoral neck in men with type 2 diabetes mellitus Pablo Palomino*[1], Heather Hunt[1], Eric Marty[2], Rehan Saiyed[2], Matthew Cohn[2], Joseph Lane[2], Robert Ritchie[3], Bernd Gludovatz[4], Eve Donnelly[1]. [1]Cornell University, United States, [2]Hospital for Special Surgery, United States, [3]University of California, Berkeley, United States, [4]UNSW, Australia

Patients with type 2 diabetes mellitus (T2DM) have a greater fracture risk than non-diabetic patients despite having normal to high bone mineral densities. Bone quality in T2DM may be impaired by accelerated accumulation of advanced glycation endproducts (AGEs) due to hyperglycemia. However, the influence of AGEs on bone fragility in vivo is poorly understood. Our objective was to relate bone tissue AGE content, microscale fracture properties, and microscale morphology in cortical bone from patients with and without T2DM. Under IRB approval, femoral neck specimens were retrieved from men undergoing total hip arthroplasty for osteoarthritis. Glycated hemoglobin (HbA1c) was measured pre-operatively. Notched beams (1x1x10mm) were excised from the medial cortex and allocated to two groups based on T2DM diagnosis at time of surgery: type 2 diabetic (T2DM, n=33, age=64.5±8.5y, HbA1c=6.9±0.8%), and non-diabetic (Non-DM, n=32, age=60.3±9.6y, HbA1c=5.5±0.3%). Three-point bending in a variable-pressure SEM was performed on a randomly selected subset of samples (Table 1) to assess initiation toughness and propagation toughness (R-curve slope). After testing, micro-computed tomography (voxel ~3.38µm3) was used to assess crack deflection (tortuosity) and cortical morphometric parameters. Adjacent bone tissue of the full set of samples was homogenized for fluorescence spectrometry to assess total fluorescent AGE content (fAGEs). Statistical analyses were adjusted for patient age.Fluorescent AGE content was 19% higher in T2DM vs. Non-DM bone (p = 0.05) but was not correlated with pre-operative HbA1c. Initiation and propagation toughness, crack tortuosity, and cortical morphometric parameters were similar across groups. Initiation toughness was negatively correlated with fAGEs (R2 = 0.13, p = 0.03).When cortical bone fAGEs were compared across patient groups, AGE content was higher in the T2DM group, reflecting increased glycation of the collagen matrix with dysregulated glucose metabolism. In addition, our work demonstrates a common inverse relationship between fAGEs and crack initiation toughness in men with and without T2DM, consistent with prior work that establishes a role for AGEs in bone embrittlement in non-diabetic bone. Because T2DM is associated with an increase in fAGEs, further analyses are required to discern whether these biochemical changes contribute to the greater hip fracture risk with T2DM observed clinically.

Figure 1: (A) Patient characteristics; (B) Pre-operative glycemic control was worse in type-2 diabetes mellitus (T2DM) vs. non-diabetic (Non-DM) group; (C) Total fluorescent AGEs were 19% higher in T2DM group for full cohort. (D) Initiation toughness trended toward a negative correlation with total fluorescent AGEs across patient groups in the mechanically tested subset (regression fit: R2 = 0.13, p = 0.03). (E) Representative plots of stress intensity vs. crack extension (R curves) in the non-DM and T2DM groups. Crack initiation and propagation toughness calculated from R-curves were not different between patient groups.

Definitions of sarcopenia as predictors of fracture risk independent of FRAX, falls and BMD: A meta-analysis of the Osteoporotic Fractures in Men (MrOS) Study Nicholas Harvey*[1], Anders Oden[2], Eric Orwoll[3], Timothy Kwok[4], Magnus Karlsson[5], Bjorn Rosengren[5], Eva Ribom[6], Peggy Cawthon[7], Kristine Ensrud[8], Cyrus Cooper[1], John Kanis[9], Claes Ohlsson[2], Dan Mellstrom[2], Helena Johansson[2], Eugene Mccloskey[9]. [1]MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton SO16 6YD, United Kingdom, [2]Centre for Bone and Arthritis Research (CBAR), Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, [3]Oregon Health & Science University, Portland, OR, United States, [4]Department of Medicine & Therapeutics and School of Public Health, The Chinese University of Hong Kong, HK, Hong Kong, [5]Clinical and Molecular Osteoporosis Research Unit, Department of Clinical Sciences Malmo, Lund University and Department of Orthopedics, Skane University Hospital, Malmo, Sweden, [6]Department of Surgical Sciences, University of Uppsala, Uppsala, Sweden, [7]Research Institute, California Pacific Medical Center, San Francisco, CA, United States, [8]Medicine and Epidemiology & Community Health, University of Minnesota, MN, United States, [9]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, United Kingdom

We have demonstrated that the predictive value for fracture of appendicular lean mass/height2 (ALM/ht2) is markedly attenuated by femoral neck BMD(fnBMD). Since the majority of sarcopenia definitions use ALM/ht2, and to inform approaches to clinical assessment, our aim was to investigate the predictive value of sarcopenia definitions for incident

fracture, independent of fnBMD, FRAX probability and prior falls.In US, Sweden and Hong Kong MrOS cohorts, we used an extension of Poisson regression to investigate relationships between sarcopenia(y/n) and incident major osteoporotic fracture(MOF: clinical vertebral, hip, wrist, proximal humerus). Sarcopenia definitions tested were those published by Baumgartner, Fielding, Cruz-Jentoft, Morley, Chen, Delmonico, Studenski(1 & 2, using ALM adjusted for BMI). Associations were adjusted for age and time since baseline, and reported as hazard ratio (HR) for first incident MOF. Further analyses adjusted additionally for FRAX MOF probability(available in 7531 men and calculated+/-fnBMD), prior falls(y/n) or fnBMD T-score. Results were synthesized by meta-analysis.Complete data were available for: 5660 men in USA, 2764 in Sweden and 1987 in Hong Kong; (mean ages 73.5, 75.4 and 72.4 years respectively). Mean follow-up time: 8.7 to 10.9 years. Prevalence of sarcopenia ranged from 0.9%(Studenski 2) to 21%(Baumgartner) in US; corresponding figures were 0.4% to 22% in Sweden and 4% to 35% in Hong Kong. Sarcopenia status, by all definitions except those of Studenski, was associated with incident MOF(HR: 1.39 to 1.76), e.g. Cruz Jentoft(HR:1.76; 95%CI:1.38, 2.26); Fielding(HR:1.60; 95%CI:1.27, 2.01); Morley(HR:1.74; 95%CI:1.29, 2.36). Associations were robust to adjustment for prior falls or FRAX probability (without fnBMD), but were slightly attenuated by adjustment for FRAX(with fnBMD), although remaining statistically significant. Adjustment for fnBMD T-score alone led to marked attenuation to below or borderline statistical significance, e.g. Cruz Jentoft (HR:1.34; 95%CI:1.04, 1.73); Fielding (HR:1.24; 95%CI:0.98, 1.56); Morley (HR:1.24; 95%CI:0.91, 1.69). Chen(Asian) and Cruz Jentoft definition behaved similarly. In conclusion, the predictive value for fracture of sarcopenia definitions based on ALM is reduced by inclusion of fnBMD T-score. Given that both ALM and BMD are derived from DXA, these findings suggest that other muscle measures, e.g. from pQCT, might usefully be investigated in characterising sarcopenia status.

Muscle mass assessed by D3Cr dilution and incident fractures in older men

Peggy Cawthon*[1], Katherine Peters[1], Steven Cummings[1], Eric Orwoll[2], Andrew Hoffman[3], Kristine Ensrud[4], Jane Cauley[5], William Evans[6]. [1]California Pacific Medical Center, United States, [2]OHSU, United States, [3]Stanford, United States, [4]University of Minnesota, United States, [5]University of Pittsburgh, United States, [6]University of California, Berkeley, United States

Muscle mass likely influences fracture risk in several ways: muscle exerts strong forces on bone, and bone must remodel to accommodate these forces; muscle tissue produces myokines which are pro-anabolic on bone; and muscle influences fall risk and thus fracture risk. However, previous studies have been unable to assess the relation between muscle mass and fracture risk given limitations in the widely used approximations of muscle mass. Whole body dual energy x-ray absorptiometry (DXA) measures lean mass (which includes water, muscle, and all other non-bone non-fat tissue), not muscle mass per se. We have previously shown that men with low muscle mass assessed by D3Cr (deuterated creatine) dilution are more likely to have incident injurious falls and worse physical performance. Therefore, in 1388 men (mean age 84.2 yrs) at the Year 14 Visit of the MrOS study, we tested the hypothesis that men with lower D3Cr muscle mass (standardized to body mass) were more likely to fracture than those with higher muscle mass, and that similar associations would not be seen with DXA-based appendicular lean mass/height2 (ALM/ht2). Cox proportional hazards models were used to determine the HR for any clinical fracture (N=103), non-vertebral fracture (N=93) or hip fracture (N=21) over 2.4 years of follow-up. Models were adjusted for age and femoral neck BMD, and then further adjusted for 10-year probability of hip fracture from FRAX (with BMD). Fractures were centrally adjudicated.Each SD decrement in D3Cr muscle mass/wgt was associated with a 23-25% increased risk of any clinical or non-vertebral fracture, and a 72% increased risk of hip fracture, after accounting for age, BMD and FRAX (with BMD) (p<0.05). Men in the lowest quartile of D3Cr muscle mass/wgt had an approximate 2-fold increased risk of any clinical or non-spine fracture and an 8-fold increased risk of hip fracture compared to men in the highest quartile, after accounting for age, BMD and FRAX (with BMD). Confidence intervals were wide, especially for hip fracture. Low DXA ALM/ht2 was not significantly associated with fracture risk.In conclusion, these results suggest that the D3Cr measure of muscle mass may be a novel risk factor for fracture in older men while DXA ALM/ht2 is not useful for fracture prediction. Future studies should investigate the relation between D3Cr muscle mass and fracture in women and younger men.

Table. Multivariate adjusted risk of fracture ([HR(95%CI)] by D₃Cr muscle mass/wgt or ALM/ht² in 1388 older men

Osteoblast-derived NOTUM Reduces Cortical Bone Mass in Mice and the NOTUM Locus is Associated with Bone Mineral Density in Humans

Karin Nilsson*[1], Sofia Movérare-Skrtic[1], Petra Henning[1], Thomas Funck-Brentano[1], Maria Nethander[1], Fernando Rivadeneira[2], Antti Koskela[3], Juha Tuukkanen[3], Jan Tuckermann[4], Christine Perret[5], Ulf Lerner[1], Claes Ohlsson[1]. [1]Centre for Bone and Arthritis Research at the Sahlgrenska Academy, 41345 Gothenburg, Sweden, [2]Department of Internal Medicine, Erasmus University Rotterdam, Rotterdam, The Netherlands, Netherlands, [3]Institute of Cancer Research and Translational Medicine, Department of Anatomy and Cell Biology, Faculty of Medicine, University of Oulo, Finland, [4]Institute of General Zoology and Endocrinology, Universitu of Ulm, Germany, [5]Inserm, Institut Cochin, Paris, France

Osteoporosis is a common skeletal disease, affecting millions of individuals worldwide. There is a medical need to improve the therapy for non-vertebral fractures, mainly caused by reduced cortical bone mass. WNT proteins are crucial regulators of both trabecular and cortical bone mass. It was recently demonstrated that NOTUM is a secreted WNT lipase inactivating WNTs by removing their attached lipid group essential for activation of Frizzled receptors. To determine if NOTUM regulates bone mass, we developed a global Notum-/- mouse model. Although Notum-/- mice were embryonic lethal, adult female Notum+/- displayed specifically increased cortical bone thickness. Notum expression was high in cortical bone and conditional Notum inactivation in mice revealed that osteoblast-lineage cells are the principal source of NOTUM in cortical bone. Importantly, osteoblast-lineage specific Notum inactivation resulted in substantially increased cortical bone thickness and bone strength associated with increased canonical WNT signaling in cortical bone. In contrast, trabecular bone mass was unaffected. Large scale human genetic analyses using the powerful UK Biobank dataset (n = 445921 European subjects) identified two independent genetic variants mapping to the NOTUM locus (17q25.3) that are associated with BMD (P value <1*10-10) as estimated with quantitative ultrasound in the heel. Thus, osteoblast derived NOTUM is an essential regulator of cortical bone thickness and bone strength in mice and genetic variants in the NOTUM locus are associated with BMD variation in humans. Therapies targeting osteoblast-derived NOTUM may prevent non-vertebral fractures.

Role of Osterix (SP7) in Regulating Osteocyte Biology and Dendrite Formation Fatemeh Mirzamohammadi *[1], Hironori Hojo[2], Tetsuya Enishi[1], Nicolas Govea[1], Henry M. Kronenberg[1], Marc N. Wein[1]. [1]Center for Skeletal Research, Endocrine Unit, Department of Medicine, Massachusetts General Hospital, Harvard Medical School, 50 Blossom Street, Boston, Massachusetts 02114, United States, [2]Center for Disease Biology and Integrative Medicine, The University of Tokyo Graduate School of Medicine, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113-8656, Japan

Osteocytes participate in inter-cellular communication through an elaborate network of dendritic projections coursing throughout mineralized bone matrix. Osteocyte projections allow these cells to communicate with each other in order to sense mechanical and hormonal cues that regulate bone homeostasis. SP7, a key transcription factor required for skeletal development, is also required for osteocyte-specific sclerostin (SOST) expression. To study the role of SP7 in osteocytes in more detail, we generated mice lacking SP7 in osteocytes

using DMP1-Cre. Surprisingly, these mice display a dramatic bone phenotype that cannot be explained solely by reduced SOST expression. Specifically, SP7 conditional KO mice display cortical bone porosity due to intracortical bone remodeling. Detailed analysis of osteocyte morphology in these mice revealed a near-complete absence of osteocyte dendrites (Fig.1a,b). We next established an in vitro system to study the role of SP7 in osteocyte dendrite formation. When osteoblasts are cultured in 3D collagen gel conditions, they undergo a dramatic cuboidal-to-dendritic morphology change which relies on the presence of SP7 (Fig.1c). Notably, in SP7 knockdown cells, we observe a reduction in the number of large dendrites from each cell, and reduced "spine-like" projections emanating from each dendrite. Therefore, SP7 is required for osteocytes to form dendrites, both in vivo and in vitro. To determine the molecular mechanisms through which SP7 regulates osteocyte dendrite formation, we performed RNA-seq in OCY454 cells (an osteocyte-specific cell line) after SP7 knockdown or over-expression. To understand the molecular mechanisms through which SP7 controls osteocyte biology, we performed SP7 ChIP-seq to determine its global pattern of chromatin binding in OCY454 cells, and compared its binding pattern in osteocytes versus osteoblasts. These studies revealed a core group of 78 genes whose expression is regulated by SP7 and show nearby SP7 binding sites. Furthermore, amongst SP7-regulated genes, OSTN and PANX3 showed functional effects on osteocyte dendrite formation in our in vitro assays using CRISPR/Cas9-mediated knockout and over-expression approaches. Taken together, these data indicate that SP7 orchestrates the osteoblast-to-osteocyte transition by regulating a group of genes that controls dendrite formation.
Figure 1. Cortical bone from tibia of 8 week old control and osterix (SP7) conditional knockout mice (a) was stained with phalloidin (green) to mark actin filaments. Control mice show typical dendritic projections, which are absent in osterix mutants. b, quantification of results. c, Control (Ctrl) and osterix (SP7) knockdown (Sh-SP7) MC3T3-E1 osteoblasts were cultured in standard 2D conditions (left), or in 3D collagen gels, then stained with phalloidin (green) and DAPI (blue). Osterix is required for optimal dendrite formation, and for the formation of spine-like projections emanating from each dendrite.

Hypermineralization of bones by Col2a1-expressing osteoblasts Yukiko Kuroda*, Koichi Matsuo. Laboratory of Cell and Tissue Biology, Keio University School of Medicine, Japan

Auditory ossicles and specific parts of skeletal bones are highly mineralized; however, cellular mechanisms that enable formation of highly mineralized bone matrix during development are unknown. In this study, we examined developmental ossification processes of highly mineralized bones, such as auditory ossicles and the humerus. Ordinary osteoblasts highly express type I collagen, encoded by Col1a1, and Col1a1-GFP transgenic (Tg) mice also express green fluorescent protein (GFP) at high levels. Unexpectedly, in these Tg mice, osteoblasts in auditory ossicles and in specific regions of the distal humerus express very low GFP levels. Histological analysis of those tissues revealed that a new type of Col1a1low osteoblast, marked by Col1a1 expression lower than that of ordinary osteoblasts, produces highly mineralized bone. These novel cells are genuine osteoblasts, based on their expression of alkaline phosphatase and osteocalcin, their localization along alizarin-labeled new bone, and their terminal differentiation into osteocytes. Curiously, Col1a1low cells were undetectable in auditory ossicles of severely osteopetrotic mice, suggesting that generation of mature Col1a1low osteoblasts marked by robust osteocalcin expression depends on chondroclasts. To define collagen subtypes produced by Col1a1low cells in highly mineralized bones, we compared collagens from auditory ossicles with those from the femoral diaphysis, a skeletal bone exhibiting average bone mineral density. The diaphysis exhibited type I collagen only, while auditory ossicles contained both type I and II collagens as major components of the collagen matrix. Surprisingly, Col1a1low osteoblasts produced type II collagen at high levels, an activity previously thought unique to chondrocytes. Finally, expression of type I (Col1a1) and type II collagen (Col2a1) transcripts in a mesenchymal stem cell line was induced by exogenous type II collagen, suggesting that the extracellular environment, including the collagen matrix, can stimulate generation of Col2a1-expressing cells. We conclude that Col1a1lowCol2a1high osteoblasts are distinct from previously characterized osteoblasts and form type II collagen-rich, highly mineralized bone matrix. We propose that these Col2a1-expressing cells be called 'hypermineralizing osteoblasts'.

In vivo cell fates of CXCL12+ perisinusoidal bone marrow mesenchymal stromal stem cells Yuki Matsushita*, Noriaki Ono. University of Michigan School of Dentistry, United States

Mesenchymal stem cells (MSCs) are widely believed to stand at the pinnacle of the skeletal cell lineage, playing critical roles in bone formation and regeneration. Although MSCs are retrospectively identified as cells that can self-renew and differentiate into the trilineage, i.e. osteoblasts/cytes, chondrocytes and adipocytes in vitro and upon transplantation, their in vivo behavior has not been fully elucidated. MSCs are proposed to reside in a perisinusoidal space of bone marrow; reticular stromal cells expressing C-X-C motif chemokine ligand 12 (CXCL12) occupy this position, which are termed as CXCL12-abundant reticular (CAR) cells. Here, we set out to investigate whether CAR cells can behave as MSCs and contribute to bone homeostasis and regeneration. For this purpose, we generated a tamoxifen inducible Cxcl12-creER transgenic line, and analyzed this line with a Rosa26-tdTomato reporter allele, a Cxcl12-GFP allele and a Col1a1(2.3kb)-GFP transgene. Cxcl12-creER specifically marked a subset of CAR cells without marking osteoblasts or chondrocytes upon tamoxifen injection. Virtually all Cxcl12-creER+ cells (96.9%) juxtaposed with endomucin+ sinusoidal endothelial cells. Analysis of colony forming unit-fibroblasts (CFU-Fs) revealed that a small fraction of CFU-Fs (3.7%) were marked by Cxcl12-creER, and that a majority of individual Cxcl12-creER+ colonies could self-renew and differentiate into the trilineage in vitro, indicating that Cxcl12-creER can effectively mark perisinusoidal MSCs. Subsequently, we traced the cell fate of Cxcl12-creER+ MSCs in vivo. These cells remained mostly dormant in physiological conditions, contributing to trabecular bone osteoblasts, but rarely to cortical bone osteoblasts without producing new reticular cells in growing marrow space. However, these cells were highly reactive, readily proliferating and differentiating into trabecular and cortical osteoblasts after bone marrow ablation and drill-hole injury, respectively. Moreover, these cells also differentiated into chondrocytes beneath the growth plate and converted into marrow adipocytes upon feeding with high-fat diet containing PPARg agonist rosiglitazone. Taken together, our study demonstrated for the first time that a subset of CAR cells can behave as MSCs, revealing unique in vivo characteristics of perisinusoidal MSCs that are dormant during steady-state conditions but can become a potent source of differentiated cells during regenerative conditions.

Osteocyte-Specific CXCL12 Expression Is Critical for Load-Induced Bone Formation in Adult Mice Pamela Cabahug-Zuckerman*, Chao Liu, Emily Fang, Alesha Castillo. New York University, United States

Load-bearing exercise is an inexpensive means to counteract osteopenia; however, in older patients, mechanical loading alone may be insufficient to enhance bone mass (1). Identifying key signaling events in load-induced bone accrual could reveal promising therapeutic targets to prevent increased fracture risk in aging (2). Our previous work showed that CXC Motif Chemokine Ligand 12 (CXCL12) expression is enhanced in osteocytes (OCYs) in response to in vivo mechanical loading, and that antagonizing its receptor, CXCR4, significantly reduced load-induced bone formation in mice ulnae (3). We hypothesize that osteocyte-specific CXCL12 expression is critical in mechanically-driven bone formation. All procedures were approved by the NYU Institutional Animal Care and Use Committee. We generated male and female mice in which CXCL12 was deleted from OCYs (CXCL12ΔOCY) by crossing CXCL12 floxed mice and 10kb DMP1-Cre transgenic mice (gifts from Drs. Geoffrey Gurtner and Lynda Bonewald, respectively). The 10kb DMP1-Cre has been shown to be robustly expressed in odontoblasts and OCYs, with little to no activity in cells from non-mineralized tissues (4). Growing mice (n=3-8/group) were given fluorochrome labels every two weeks between 4-16 weeks of age. A second group of 16-week-old mice (n=3/group), were subjected to tibial axial cyclic loading (1200με, 2Hz, 120cycles, 3days/wk for 2 wks) (5). Basal and load-induced periosteal (Ps) and endosteal (Es) mineralizing surface (MS/BS, %), mineral apposition (MAR, μm/day) and bone formation rates (BFR/BS, μm3/μm2/year) were calculated (6) at mid-length. No significant differences were detected in basal bone formation during development. However, relative load-induced Ps rMAR was reduced by 50% in female (p=0.02) and 75% in male (p=0.002) CXCL12ΔOCY mice; and similarly, Ps rBFR/BS was reduced by 50% in female (p=0.01) and 70% in male (p=0.001) CXCL12ΔOCY mice (Figure 1). Es bone formation was not affected by CXCL12 deletion. In summary, OCY-specific CXCL12 expression plays a critical role in load-driven Ps MAR, suggesting that CXCL12 signaling may positively regulate osteogenic differentiation and/or mature osteoblast function. Underlying mechanisms are being explored. Thus, OCY-specific CXCL12 signaling may be a promising target to enhance load-induced bone formation in

the elderly. (1) Gianoudis+ JBMR 2014 (2) Holguin+ JBMR 2016 (3) Leucht+ JOR 2013 (4) Lu+ J Dent Res 2007 (5) Liu+ Bone 2018 (6) Dempster+ JBMR.2013.

Cyclic and Alternating Parathyroid Hormone (PTH) and Alendronate Treatment Regimens Further Improve Bone Microarchitecture and Strength Beyond Daily and Cyclic PTH Regimens Hongbo Zhao*[1], Wei-Ju Tseng[1], Tien-Jung Lee[2], Wonsae Lee[1], Yihan Li[1], Chantal De Bakker[1], X. Sherry Liu[1]. [1]University of Pennsylvania, United States, [2]National Central University, Taiwan

Bone mineral density rapidly decreases upon withdrawal from intermittent PTH treatment despite its potent effect of promoting bone formation. Our previous study showed a continuous anabolic window during the first week of PTH discontinuation in ovariectomized (OVX) rats, which offers a new mechanism in support of a cyclic administration regime with repeated cycles of on and off PTH treatment to maximize the treatment duration. However, osteoclast number increases significantly following the anabolic window. Therefore, we hypothesized that incorporating an anti-resorptive treatment during the off-PTH period of cyclic treatment regimen may further improve the treatment efficacy.29 4mo-old SD rats underwent OVX surgery and developed osteopenia for 4 wks (51% and 11% reduction in BV/TV and Tb.Th, respectively) before they were assigned to 5 treatment regimens: VEH (n=6, 18-wk saline), PTH-VEH (n=6, 9-wk PTH 40 μg/kg/day followed by 9-wk saline), Cyclic PTH-VEH (n=7, 3-wk PTH followed by 3-wk saline, 3 cycles), Cyclic PTH-ALN (n=5, 3-wk PTH followed by 3-wk ALN, 3 cycles) and Cyclic ALN-PTH (n=5, 3-wk ALN followed by 3-wk PTH, 3 cycles). In vivo μCT (Fig A) indicated that bone loss continued in VEH for 18 wks. Meanwhile, 9-wk PTH treatment in the PTH-VEH group led to greater BV/TV and Tb.Th than all the other groups. However, these improvements disappeared after the 9-wk discontinuation from PTH (Fig A-C). On the other hand, Cyclic PTH treatment efficiently maintained the benefit of 3-wk PTH treatment in BV/TV from the 1st cycle of treatment, and increased Tb.Th over the next 2 cycles of treatment. Furthermore, both alternating PTH-ALN and ALN-PTH further improved the benefit of PTH treatment in BV/TV when compared to cyclic PTH-VEH (Fig A-C). Vertebral BV/TV in both cyclic PTH-ALN and ALN-PTH were greater than all other groups (Fig D). Additionally, compression tests of L2 suggested that peak load, energy to failure, and apparent-level toughness were 29%, 45%, and 43% greater in the cyclic PTH-ALN than the cyclic PTH-VEH, and 29%, 48%, and 46% greater in the cyclic ALN-PTH than the cyclic PTH-VEH, respectively (Fig E-G). No difference was found in any of the L2 mechanical properties among VEH, PTH-VEH, and cyclic PTH-VEH (Fig E-G).In summary, cyclic and sequential treatment of PTH and anti-resorptive agent further improve the treatment efficacy of daily and cyclic PTH treatment on bone microarchitecture and bone strength and extend PTH treatment duration.

[1]Section on Heritable Disorders of Bone and Extracellular Matrix, NICHD, NIH, United States, [2]Clinical and Investigative Orthopedics Surgery Unit, NIAMS, NIH, United States, [3]Biodata Mining and Discovery Section, Office of Science and Technology, NIAMS, NIH, United States, [4]Ludwig Boltzmann Institute of Osteology, Austria, [5]Molecular Genetics Section, NHGRI, NIH, United States, [6]Immunoregulation Section, NIAMS, NIH, United States, [7]Autoimmunity Branch, NIAMS, NIH, United States, [8]Clinical Research, NIAMS, NIH, United States, [9]Rheumatology Branch, NIAMS, NIH, United States, [10]Dermatology Branch, NIAMS, NIH, United States, [11]Office of Clinical Director, NIAMS, NIH, United States, [12]Clinical Trials & Outcomes Branch, NIAMS, NIH, United States

Melorheostosis is a rare dysostosis of unknown etiology, with characteristic radiographs of "dripping candle wax". Because of its sporadic occurrence, somatic mutations have been hypothesized as causative, but bone tissue was not previously investigated. We recruited 15 unrelated melorheostosis patients, who underwent paired biopsies of affected and contralateral unaffected bone. Using exome sequencing, we identified somatic mosaic mutations in MAP2K1, encoding the Mitogen-Activated Protein Kinase Kinase 1 (MEK1), in gDNA from affected, but not unaffected bone, of 8 of 15 patients, and confirmed these mutations by ddPCR. Mosaicism for MAP2K1 mutations was also detected in skin overlying bone lesions in some patients, but not in blood samples. Located within the negative regulatory domain of MEK1, these activating mutations (p.Q56P, p.K57E, p.K57N) were previously identified in various malignancies. Immunohistochemical analysis in affected bone displayed a mosaic pattern of activation of ERK1/2, the substrates of MEK1. In addition, flow cytometry of osteoblasts cultured from affected bone demonstrated two cell populations with distinct ph-ERK1/2 levels. Histology of melorheostotic bone was distinctive, with exuberant initial deposition of distinctive parallel layers of primary lamellar bone, followed by intense bone remodeling with increased cellularity. The elevated RANKL/OPG ratio in affected osteoblasts correlates with increased osteoclast number and bone remodelling. In cultured osteoblasts, the MAP2K1 mutations enhanced cell proliferation with increased cyclin D expression. Interestingly, MAP2K1 mutations inhibited BMP2-mediated osteoblast differentiation and mineralization in vitro, underlying the significant elevation of unmineralized osteoid in melorheostotic bone. Melorheostosis, a benign bone overgrowth condition, is caused by somatic mosaicism for MAP2K1 activating mutations previously identified as cancer-associated. Increased MEK1-ERK1/2 signaling enhanced osteoblast growth and bone remodeling, while inhibiting osteoblast differentiation and bone. This is the first demonstration that the MAP2K1 oncogene is important to human bone formation. MEK1 inhibition, already in trials for cancer, may be a treatment for melorheostosis.

Osteocalcin Function On Energy Metabolism Is Conserved In Humans: Results of a 5 Year Prospective Cohort of Diabetes Onset Cyrille Confavreux*[1], Pawel Szulc[2], Matthieu Wargny[3], Marie Christine Carlier[2], Elisabeth Sornay-Rendu[2], Matthieu Pichelin[3], Bertrand Cariou[3]. [1]INSERM UMR1033 - University of Lyon - Department of Rheumatology, Hospices Civils de Lyon, France, [2]INSERM UMR1033 - University of Lyon, France, [3]INSERM UMR 1087/CNRS UMR 6291- Department of Endocrinology, University Hospital of Nantes, France

Background. Experimental studies show that bone is an endocrine organ active on energy metabolism through at least one hormone: osteocalcin. In vivo, osteocalcin regulates insulin secretion by pancreatic β-cells and adiponectin secretion by adipocytes. In humans, data are limited to cross-sectional and retrospective studies. The aim of this study is to assess the association between baseline osteocalcin concentration and the prospectively assessed risk of type 2 diabetes mellitus. Methods. The NANTOS project is a 5-year single center prospective cohort study of men and women followed annually for diabetes onset. To be included, these patients had to be prediabetic with an elevated FINRISK, a score risk to predicting diabetes and a fasting blood glucose between 1.1 and 1.26 g/L. At baseline, patients underwent a clinical examination and a morning fast blood withdrawal. Primary endpoint was the onset of diabetes based on abnormal fasting blood glucose >1.26 g/L. Total serum osteocalcin was assessed at baseline using ELECSYS-Roche diagnosis methods. We performed a multivariate survival analysis (Cox model), a Youden analysis and a quartile analysis to analyze the link between osteocalcin and diabetes onset. Results. Among 323 prediabetic individuals with all available data, 40 subjects became diabetic during the follow-up. Median time to diabetes onset was 14.7 months [interquartile range 12.7-26.5 months]. Cox multivariate model has been adjusted for the following parameters: age, BMI, current smoking, achooool consumption, familial history of diabetes, renal function (creatinin), glycated hemoglobin A1c, HDL-cholesterol and diuretics. Lower total serum osteocalcin was significantly associated with an increased risk of diabetes onset (HR= 1.81 per 1SD decrease [95%IC: 1.14–2.89 ; p<0.05]). Moreover, the lowest quartile (≤14.7 ng/mL for men and 16.1ng/mL for females) was also associated with an increased risk of diabetes onset in multivariate analysis (HR= 2.98 vs. three upper quartiles combined, 95%CI: 1.48–6.00; p<0.005). Youden's index found that the osteocalcin concentration of 14.8ng/mL was the most discriminating cut-off in the entire cohort. Individuals who had osteocalcin levels below 14.8 ng/mL had higher risk of incident diabetes mellitus compared with those who had higher osteocalcin levels (HR=3.28, 95%CI: 1.63–6.58, p<0.001). Conclusion. We show for the first time that low osteocalcin concentrations are associated with markedly higher risk of incident type 2 diabetes mellitus in the prospectively assessed prediabetic individuals. These data strenghten the hypothesis that the effect of osteocalcin on energy metabolism, discovered in rodents, may be conserved in humans.

Association between serum total osteocalcin and diabetes risk

RANK Ligand inhibitors improve muscle function and glucose homeostasis Nicolas Bonnet*, Lucie Bourgoin, Emmanuel Biver, Thierry Chevalley, Melany Hars, Andrea Trombetti, Serge Ferrari. Service of Bone Diseases, Faculty of Medicine (UNIGE), Switzerland

RANKL is a factor of osteoclastogenesis, but is also expressed in muscle, with implications in Duchenne's dystrophy. Data from the FREEDOM trial suggests that RANKL inhibition influence both the risk of falls and the development of diabetes. We investigated if RANKL inhibitors (OPG or denosumab, Dmab) modify muscle function, and glucose homeostasis in mice overexpressing human RANKL (huRANKL) and in a model of type 2 diabetes (Pparβ-/-). HuRANKL were treated with Dmab (10mg/kg/week) or vehicle (Veh) and Pparβ-/- with Opg-Fc (4mg/kg/week) both for 4 weeks. Muscle function was investigated by running and handgrip test and glucose homeostasis by GTT, ITT and EH clamp. In addition, 18 post-menopausal women treated for osteoporosis with Dmab were evaluated by DXA, HOMA and handgrip (65.0±1.4years) at baseline and after 3 years. They were matched to 49 controls for age, BMI, BMD and fracture. HuRANKL mice have severe osteoporosis and lower maximal speed and limb force, respectively -41% and -11% vs WT (p<0.05). Although they exhibit a normal body weight, gastrocnemius and soleus mass were lower (-29% and -57% vs WT, p<0.05). ITT AUC was higher, +31% vs WT (p<0.05) and GIR, an index of insulin sensitivity was lower (-24.6%, p<0.05). 2D[14C]-glucose incorporation indicated a lower glucose uptake in soleus (-51.9% vs WT, p<0.05). Dmab increased limb force, gastrocnemius mass (+34.7% and +9.8% vs Veh, p<0.05) and normalized ITT (AUC 464±25.1 vs 353.9±8.1 in Dmab, p<0.05). In Pparβ-/-, Opg-Fc increased BV/TV (+107% vs KO Veh, p<0.05) as well as force and muscle volume of the limb (+6.7%, +12%, p<0.05). Moreover, Opg-Fc decreased GTT and ITT AUC (-36.7% and -22.3% vs KO Veh, p<0.05) arguing for a restoration of insulin sensitivity, confirmed by western in muscle. In women, Dmab improved LSBMD, appendicular lean mass and handgrip as compared to controls (0.012±0.12g/cm2, 0.098±0.27kg, 0.36±2.3kg, vs -0.046±0.0712g/cm2, -0.22±0.34kg, and -2.81±1.64kg, all p<0.05) over 3 years. HOMA was not different between groups. In conclusion, overexpression of huRANKL causes bone loss and impairs muscle function and insulin sensitivity.RankL inhibitors restored muscle strength and improved insulin sensitivity in both osteoporosis and diabetes mice, while denosumab improved muscle mass and strength in osteoporotic women. Altogether these data point towards a potentially new mechanism linking RANKL to fracture risk, i.e. not only by decreasing bone density, but also muscle strength.

Sympathetic Outflow Regulates Bone Metabolism in Humans: Evidence from Cellular, Epidemiological, and Direct Interventional Studies Sundeep Khosla*[1], Matthew Drake[1], Tammie Volkman[1], Brianne Thicke[1], Sara Achenbach[1], Elizabeth Atkinson[1], Michael Joyner[1], Clifford Rosen[2], David Monroe[1], Joshua Farr[1]. [1]Mayo Clinic, United States, [2]Maine Medical Center Research Institute, United States

There is considerable evidence from rodent studies that the sympathetic nervous system (SNS) regulates bone metabolism principally via β2-adrenergic receptors (β2-ARs). As results from human studies have been conflicting, we used multiple approaches to evaluate a possible role for SNS regulation of human bone metabolism. RNA sequencing of human bone biopsies and cultured osteoblasts demonstrated absence of β3-AR, whereas β1- and β2-ARs were expressed in both human bone and cultured cells. In a population study, we identified 67 subjects aged > 50 yrs who had used β-blockers for at least 1 yr over the past 5 yrs; 63 were on β1-selective blockers (atenolol/metoprolol). Relative to non-users (n=185), those on β1-selective blockers had better HRpQCT-derived bone microarchitecture at both the distal radius and tibia (e.g., 7-9% higher BV/TV and TbN; all p<0.05). We next performed a direct interventional study that also sought to define β-AR selectivity for SNS effects on human bone. 155 postmenopausal women were randomized to one of five treatment groups for 20 wks: (1) Placebo (PL); (2) propranolol, 20 mg BID; (3) propranolol, 40 mg BID; (4) atenolol, 50 mg/d; (5) nebivolol, 5 mg/d. As no clinically available β2-AR selective antagonists exist, we took advantage of the β1-AR selectivity gradient of these drugs (propranolol [non-selective] << atenolol [relatively β1-selective/some β2-AR antagonism] < nebivolol [highly β1-AR selective]) to define the β-AR selectivity for SNS effects on bone. Relative to PL, at 20 weeks both atenolol and nebivolol, but neither dose of propranolol, significantly (P < 0.05 by Dunnett's test) reduced serum CTx (by ~20%) and PINP (by ~15%) (Fig. A). Despite the short duration of the intervention, both atenolol and nebivolol significantly increased ultra-distal radius BMD (relative to PL by 3.6% and 2.9%, respectively; Fig. B). Collectively, these studies demonstrate that: (1) β1- and β2-ARs, but not β3-ARs, are expressed in human bone; (2) patients on β1-selective blockers have better bone microarchitecture; and (3) β1-selective blockers (atenolol, nebivolol), but not a non-selective β-AR blocker (propranolol), have favorable effects on bone turnover and BMD in postmenopausal women. These 3 independent lines of evidence strongly support a role for the SNS in regulating bone metabolism in humans principally via β1-ARs and warrant future clinical trials with atenolol or nebivolol for the prevention of bone loss in postmenopausal women.

Effects of β-AR non-selective and β₁-AR selective blockers on bone turnover and BMD over 20 weeks

DMP1 overexpression prevents bone alterations, FGF23 elevations and cardiac hypertrophy in mice with chronic kidney disease Corey Dussold*[1], Claire Gerber[1], Samantha White[1], Xueyan Wang[1], Connor Francis[1], Lixin Qi[1], Ying Liu[2], Chaoyuan Li[2], Jian Q Feng[2], Myles Wolf[3], Valentin David[1], Aline Martin[1]. [1]Division of Nephrology and Hypertension, and Center for Translational Metabolism and Health, Northwestern University Feinberg School of Medicine, Chicago, IL, United States, [2]Department of Biomedical Sciences, Baylor College of Dentistry, Texas A&M University, Dallas, TX, United States, [3]Division of Nephrology, Duke University, Durham, NC, United States

Disordered bone and mineral metabolism is a common complication of chronic kidney disease (CKD), including an exponential increase in production and secretion of the osteocyte-derived hormone fibroblast growth factor 23 (FGF23) during CKD progression. Excess FGF23 is independently associated with increased risk of cardiovascular disease and mortality, perhaps by contributing to development of left ventricular hypertrophy (LVH). Dentin matrix protein 1 (DMP1), an extracellular matrix protein produced by osteocytes, is an established inhibitor of FGF23 production and a promoter of bone mineralization. We hypothesized that overexpression of DMP1 in CKD would improve bone health and prevent FGF23 elevations and consequent adverse cardiovascular outcomes in CKD.We studied the Col4a3KO mouse, an established model of progressive CKD, which typically shows a shortened lifespan (21.4±0.6 weeks). We overexpressed DMP1 (DMP1Tg-3.6Kb ColIa1 promoter) in the bone of WT (DMP1Tg) and Col4a3KO (Col4a3KO/DMP1Tg) animals and we assessed renal function, serum FGF23 and phosphate (Pi) levels, bone and cardiac phenotype in 20 week-old mice, and overall survival.Compared to WT, Col4a3KO mice showed impaired renal function (blood urea nitrogen: 94±18 vs 25±2 mg/dL), reduced cortical bone mineral density (BMD: 1154±14 vs 1194±5 mg/cm3), altered osteocyte morphology and connectivity, an 8-fold increase in serum FGF23 levels, hyperphosphatemia (serum Pi: 9.2±0.6 vs 6.2±0.2 mg/dL), and LVH (LV Mass: 124±7 vs 101±4 mg) (p<0.05 vs WT for each). Overexpression of DMP1 in Col4a3KO/DMP1Tg did not improve renal function but corrected CKD-induced BMD decrease by 40% and fully prevented alterations in osteocyte morphology and connectivity. Col4a3KO/DMP1Tg also showed lower FGF23 levels (631±124 vs 1161±196 pg/mL) resulting in higher serum phosphate levels (11.4±1.0 mg/dL) (p<0.05 vs Col4a3KO for each). As opposed to Col4a3KO, Col4a3KO/DMP1Tg mice did not have LVH (LV Mass: 93±5 mg; NS vs WT). Finally, Col4a3KO/DMP1Tg had improved survival compared to Col4a3KO (24.2±0.9 vs 21.4±0.6 weeks; p<0.05).Overexpression of DMP1 in bone prevented CKD-associated osteocyte alterations and FGF23 elevations, development of LVH and improved survival, despite persistently impaired renal function and worsened hyperphosphatemia. These results support the contribution of FGF23 excess to cardiac injury in CKD and suggest that DMP1 represents a novel therapeutic approach to improve bone and cardiac outcomes in CKD.

Overexpression of PTHrP in Transgenic Mammary Tumors Causes Hypercalcemia and Rapid Fat Wasting but does not Increase Energy Expenditure. Pamela Dann*[1], Farzin Takyar[1], Kellen Bean[2], Rachel Perry[1], Gerald Shulman[1], John Wysolmerski[1]. [1]Yale University, United States, [2]Yale College, United States

PTHrP has been reported to cause beiging of white adipocyte tissue (WAT) in cancer cachexia by interacting with the PTH1 receptor (PTHR1) to induce a hypermetabolic state associated with fat and muscle wasting. We utilized a tetracycline-regulated bitransgenic, MMTV-rtTA;pTet-PTHrP, system to overexpress PTHrP in the MMTV-PyMT model of murine breast cancer (Tet-PTHrP;PyMT mice) in order to ask whether PTHrP might contribute to cachexia in breast cancer. Tet-PTHrP;PyMT mice (10-12 weeks old) with mammary tumors were treated with doxycycline (Dox) to induce PTHrP expression. Within 2-4 days of Dox treatment, the mice developed severe hypercalcemia with elevated levels of circulating

PTHrP in the absence of bone metastases, reproducing the cardinal features of humoral hypercalcemia of malignancy (HHM). HHM in these mice was associated with rapid weight loss; within 4 days of Dox treatment, Tet-PTHrP;PyMT lost 15% of their body mass. There was a dramatic decrease in the weight of all fat pads, and histology and perilipin immuno-fluorescence demonstrated a decrease in the size of adipocytes characterized by loss of the central lipid droplet but the absence of multi-locular droplets. Immunofluorescence staining demonstrated increased expression of UCP-1 in lipid-depleted adipocytes. None of these changes occurred in control Tet-PTHrP;PyMT mice off Dox. Despite the upregulation of UCP-1 expression, metabolic cage studies were not consistent with a hypermetabolic state. Tet-PTHrP;PyMT mice were studied for two consecutive periods, first off Dox and then on Dox, allowing each mouse to serve as its own control. As expected, when treated with Dox, Tet-PTHrP;PyMT mice lost weight and fat mass as assessed using proton NMR. There were no differences in activity counts but, when placed on Dox, the mice had a decreased VO2, VCO2, food and water intake, and energy expenditure. RER was decreased, suggesting an overall increase in fat oxidation. Rates of systemic WAT lipolysis appeared to be elevated as indicated by increased circulating glycerol and non-esterified fatty acids. In order to determine whether these effects of PTHrP were mediated by PTHrP acting on the PTHR1, we also treated mice with an anti-PTHR1 blocking antibody. This resulted in normalization of calcium but not PTHrP levels, as well as prevention of weight loss and fat and muscle wasting. Anti-PTH1R treatment also normalized circulating levels of glycerol and fatty acids, consistent with an inhibition of PTHrP-induced WAT lipolysis. Finally, we also treated Tet-PTHrP;PyMT mice with rhOPF-Fc to normalize circulating calcium levels. Interestingly, this also prevented weight loss. In summary, overexpression of PTHrP in transgenic breast tumors causes HHM and rapid weight loss. The weight loss is associated with increased WAT lipolysis but decreased overall energy expenditure. Calcium as well as PTHrP levels may contribute to fat wasting.

1054

A novel regulatory network mediated by the miR182-PKR-IFN-β axis plays a key role in osteoclastogenesis and osteoprotection Kazuki Inoue*[1], Zhonghao Deng[2], Yufan Chen[3], Gregory Vitone[2], Eugenia Giannopoulou[4], Ren Xu[5], Shiaoching Gong[6], David G. Kirsch[7], Matthew Greenblatt[5], Anil K. Sood[8], Liang Zhao[3], Baohong Zhao[1]. [1]Hospital for Special Surgery, Weill Cornell Medical College, United States, [2]Hospital for Special Surgery, United States, [3]Nanfang Hospital, Southern Medical University, China, [4]New York City College of Technology, City University of New York, United States, [5]Weill Cornell Medical College, United States, [6]Department of Molecular Biology, The Rockefeller University, United States, [7]Duke University Medical Center, United States, [8]The University of Texas MD Anderson Cancer Center, United States

Bone loss is a severe consequence of diseases such as rheumatoid arthritis (RA) and osteoporosis, in which osteoclasts are a culprit directly responsible for bone destruction. MicroRNAs (miRNAs) are important regulators in various biological and disease settings. MiRNA-based therapeutics recently shows significant promise in disease treatment. Such progress however remains underexplored in bone diseases. Here we identify miR-182 as a key positive regulator of osteoclastogenesis, bone homeostasis and pathologic bone resorption using complementary gain and loss-of-function approaches. Myeloid-specific knockout of miR-182 protects mice against excessive osteoclast formation and bone resorption in disease models of ovariectomy-induced osteoporosis and rheumatoid arthritis. An osteoclast precursor (OCP) specific transgenic mouse model of miR-182 showed a complementary phenotype with markedly decreased bone mass and enhanced osteoclastogenesis. Treatment of these disease models with nanoparticles containing miR-182 inhibitors completely suppresses pathologic bone erosion driven by enhanced osteoclastogenesis, highlighting the therapeutic implication of miR-182 inhibition. Mechanistically, we performed genome wide analysis based on two parallel RNA-seq experiments, one with miR-182 deficient OCPs and the other with miR-182 overexpressed OCPs. We found that miR-182 promoted the expression of key osteoclastogenic genes by selectively and significantly suppressing endogenous IFN-β-mediated autocrine inhibitory loop of osteoclastogenesis. We further identified protein kinase double-stranded RNA-dependent (PKR) as a new and essential miR-182 target. Genetic deletion of PKR in OCPs showed increased osteoclast formation and impaired IFN-β-mediated feedback inhibition. The regulatory role of miR-182 is well conserved in human osteoclastogenesis. In RA, the expression levels of miR-182, PKR and IFN-β are significantly altered in monocytes isolated from RA patients, correlated with the osteoclastogenic capacity of the RA OCPs and regulated by TNFi treatment. Collectively, these findings reveal a novel regulatory network in osteoclastogenesis mediated by miR182-PKR-IFN-β axis that plays a key role in bone biology and diseases. The genetic and pharmacological evidence from mouse disease models as well as the correlation between miR-182 and RA disease present miR-182 inhibition as a novel therapeutic strategy to prevent pathologic bone destruction.

Transcriptional Co-factor Jab1 is Vital for Mouse Chondrocyte Differentiation
Murali Mamidi*, William Samsa, Ricky Chan, Guang Zhou. Case Western Reserve University, United States

The evolutionarily conserved transcriptional cofactor Jab1 regulates cell proliferation, differentiation, and apoptosis by modulating the activity of various transcription factors. We previously reported that the chondrocyte-specific deletion of Jab1 mutant mice, Col2a1-Cre+; Jab1flox/flox , displayed a lethal chondrodysplasia phenotype at birth. Jab1-deficient chondrocytes displayed increased apoptosis, accelerated chondrocyte hypertrophy, and G2 phase cell cycle arrest. Jab1-deficient chondrocytes also showed enhanced expression of Smad1/5 phosphorylation and increased BMP response, indicating that Jab1 inhibits BMP signalling in chondrocytes to inhibit chondrocyte hypertrophy. To further identify Jab1 downstream targets in chondrocytes, we performed in-depth analysis of Col2a1-Cre+; Jab1flox/flox mouse chondrocytes by various methods in this study. Our immunoprecipitation (IP) results showed that the endogenous Jab1 interacts with endogenous Smad1/5, but not with endogenous Smad2/3 and Smad7. Interestingly, the small molecule inhibitor of type I BMP receptor LDN-193189 can partially block the increased BMP signalling in Jab1 cKO chondrocytes. Indeed, although Jab1 did not directly interact with a key type I BMP receptor Acvr1, the interaction between Smad1/5 and Acvr1 was significantly increased in Jab1-deficient chondrocytes. Thus, Jab1 might negatively regulate BMP signalling during chondrocyte differentiation in part by sequestering Smad1/5 from Acvr1. RNA-Sequencing analysis of Jab1 cKO chondrocytes showed a total of 1993 differentially expressed genes (1060 increased and 933 decreased). Moreover, gene set enrichment analysis (GSEA) showed that Jab1 regulates essential developmental pathways, such as p53, BMP/TGF-β, and apoptosis. Moreover, the reporter assay in Jab1 cKO chondrocytes also demonstrated that Jab1 regulates multiple pathways, including Hedgehog signalling, which is involved in hypertrophic chondrocyte differentiation. Finally, ChIP-qPCR showed that Jab1 might directly regulate key cartilage-specific enhancer elements in Col2a1 and Aggrecan genes. In conclusion, our data showed that Jab1 acts as a transcriptional co-factor to interact with key developmental pathways to control chondrocyte differentiation.

Targeting the Hedgehog Signaling Pathway to Ameliorate Metachondromatosis Jiahui Huang*, Douglas Moore, Michael Ehrlich, Wentian Yang. Department of Orthopaedics, Brown University Alpert Medical School and Rhode Island Hospital, United States

Metachondromatosis (MC) is a rare autosomal dominant tumor syndrome featuring the growth of osteochondromas and enchondromas in the long bones and digits. Recently, disease-associated whole-genome sequencing and linkage analysis using high-density SNP arrays uncovered heterozygous early frameshift or nonsense mutations in PTPN11 in >50% of MC cases. PTPN11 encodes the protein-tyrosine phosphatase SHP2, which is required for RAS/ERK pathway activation in most receptor tyrosine kinase, cytokine receptor, and integrin signaling pathways. Germline PTPN11 activating mutations cause Noonan syndrome, whereas PTPN11 mutations that substantially impair SHP2 catalytic activity cause LEOPARD syndrome, both of which include incompletely penetrant skeletal abnormalities. Somatic PTPN11 activating mutations are the most common cause of the childhood myeloproliferative diseases and several solid tumors. It remains unclear how heterozygous loss-of-function PTPN11 mutations cause MC.Using genetically modified animals and biological and biochemical approaches, we report here that Ptpn11 functions as a tumor suppressor in cartilage. Somatic Ptpn11 deletion, likely due to Ptpn11 loss of heterozygosity (LOH) mutations in the Prrx1+ mesenchymal cells, in the CtsK+ chondroprogenitors, and in the Col2a1+ but not Col10a1+ chondrocytes cause MC (Fig.1). To gain insight into the molecular pathogenesis of MC, differential gene expression array and RNA-seq analysis were carried out using SHP2-sufficient and SHP2-deficient chondrocytes and progenitors, respectively. These assays revealed that multiple genes and pathways that had previously been reported to be critical for chondrocyte proliferation and maturation were affected by Ptpn11 deletion. Ptpn11 deficient chondroid cells had decreased ERK activation and enhanced IHH and PTHrP expression. Treatment of chondroid cells with FGFR or MEK inhibitor also increased Ihh and Pthrp expression. Most importantly, Smoothened inhibition ameliorated the metachondromatosis phenotype in Tg(Ctsk-Cre;Ptpn11fl/fl) mice. Thus, in contrast to its pro-oncogenic role in hematopoietic and epithelial cells, Ptpn11 is a tumor suppressor in cartilage, acting in part via a FGFR/MEK/ERK-dependent pathway in chondroid progenitors to prevent excessive Ihh production and MC formation.

Fig. 1 Mice lacking SHP2 in the Prrx1+, Ctsk+ and Col2a1+ chondroprogenitors develop osteo-chondromas and enchondromas, which recapitulate the features of human metachondromatosis. X-ray (i, iii) and μCT images (iii) show the growth of osteochondromas and enchondromas on the proximal and distal femur (I, iii) and metatarsal bones (ii). Fluorescent images of vertebrate (iv) showing the growth of osteochondromas comprised of cells derived from SHP2 deficient OCPs.

Teasing Apart Endocrine and Inflammatory Control of Cyp27b1 Expression Reveals Vital Relationships of Vitamin D3 Metabolites and Enzyme Levels to Skeletal Health Mark Meyer*[1], Nancy Benkusky[1], Seong Min Lee[1], Melda Onal[1], Martin Kaufmann[2], Glenville Jones[2], J. Wesley Pike[1]. [1]University of Wisconsin - Madison, United States, [2]Queen's University, Canada

The vitamin D endocrine system regulates mineral homeostasis. Terminal activation of vitamin D3 to its hormonal form, 1,25(OH)2D3, occurs in the kidney via the cytochrome P450 enzyme CYP27B1. Despite its importance in vitamin D metabolism, the molecular mechanisms underlying the regulation of the gene for this enzyme, Cyp27b1, were unknown. Clinically, fundamental questions of 25(OH)D3 sufficiency and conversion to 1,25(OH)2D3 in health and disease are still hotly debated. To tackle these questions, we identified a set of enhancers defining a kidney-specific control module governed by a renal cell–specific chromatin structure located distal to Cyp27b1 that mediates unique basal and parathyroid hormone (PTH)-, fibroblast growth factor 23 (FGF23)-, and 1,25(OH)2D3-mediated regulation of Cyp27b1 expression. Genomic deletion using CRISPR-Cas9 in C57BL/6 mice resulted in a debilitating skeletal phenotype after loss of Cyp27b1 PTH sensitivity (M1-IKO deletion), or a quasi-normal bone mineral phenotype after loss of FGF23 sensitivity (M21-IKO deletion). Furthermore, subsequent new deletions within the M1-IKO enhancer reveal a bimodal expression whereby Cyp27b1 expression is increased by selective removal of a basal suppressor. Refinement of the M21-IKO enhancer deletion narrows the unknown transcription factor mediating FGF23 genomic activity to a few hundred base pairs. A combination of deletions (M1/M21-DKO) resulted in a complete loss of basal as well as endocrine-insensitive renal Cyp27b1 expression. On the other hand, inflammation-induced non-renal cell Cyp27b1 expression, a complication of sarcoidosis and autoimmune diseases, was unaffected by these deletions, thus separating endocrine and inflammatory regulation

of Cyp27b1. We then identified the inflammatory region and subsequently deleted it in vivo leading to the unique loss of inflammation-induced Cyp27b1 activation. Importantly, each of these mouse models represent a unique tissue-specific deletion of 1,25(OH)2D3 production that will allow a detailed exploration of long-standing questions regarding non-renal production, contribution, and action of locally produced 1,25(OH)2D3 as well as assessment of the vital relationships that exist between 25(OH)D3 levels, Cyp27b1/Cyp24a1 expression, and enzymatic conversion of 1,25(OH)2D3 and skeletal health and vitality. We conclude that these models open new avenues for the study of vitamin D metabolism and therapeutic strategies for human health and disease.

Change in Bone Turnover as a Surrogate for Fracture Outcomes: A Novel Individual-level Analysis of Pooled Anti-resorptive Trials from the FNIH Bone Quality Study Douglas Bauer*[1], Eric Vittinghoff[1], Dennis Black[1], Mary Bouxsein[2], Li-Yung Lui[3], Jane Cauley[4], Anne De Papp[5], Andreas Grauer[6], Sundeep Khosla[7], Bruce Mitlak[8], Charles Mcculloch[1], Richard Eastell[9]. [1]University of California, San Francisco, United States, [2]Harvard Medical School, United States, [3]California Pacific Medical Center, United States, [4]University of Pittsburgh, United States, [5]Merck & Co., Inc., United States, [6]Amgen Inc., United States, [7]Mayo Clinic College of Medicine, United States, [8]Radius Health, United States, [9]University of Sheffield, United Kingdom

To determine if treatment-related change in bone turnover markers (BTMs) can be used as a surrogate for fracture risk reduction for drug development, the FNIH Bone Quality Project is compiling individual patient data from as many osteoporosis randomized trials as possible. Thus far, we have compiled individual BTM data on >100,000 individuals from 14 anti-resorptive (AR) osteoporosis treatments trials (5 bisphosphonates and 3 SERMS). One component of the criteria for FDA qualification of a proposed surrogate marker is the Percent of Treatment Explained (PTE). Previous change in BTM analyses from individual trials reported non-vertebral fracture PTEs ranging from 28 to 77%, but analysis methods differed and single studies were too small to give precise estimates. We used our pooled data to estimate PTEs for BTM change, using a novel three-stage procedure. In the first stage, we used a linear mixed model (LMM) to estimate participant-specific total alkaline phosphatase trajectories. In the second, we used additional LMMs to estimate BTM trajectories, using the predicted total alkaline phosphatase values to help impute the BTM for participants with no observed BTM values. In the third, we fit nested models for the effect of treatment on time to vertebral, non-vertebral and hip fracture. PTE was calculated as the percentage change in the coefficient for treatment after adding estimated BTM change, based on the second-stage LMM, to the base model. Confidence intervals were obtained using seemingly unrelated regressions. This pooled analysis includes data from trials that measured at least one of 3 serum BTMs (Bone ALP, PINP and sCTX). Twelve trials (N=48,833) reported 3,532 incident vertebral fractures and 14 trials (N=56,758) reported 5,272 non-vertebral and 702 hip fractures. Pooled PTE estimates ranged from 69-123% for vertebral fracture and from 85-138% for non-vertebral fracture (Table); all were statistically significant. Hip fracture PTEs ranged from 43-139%, but CIs were wide and only the PTE for PINP was statistically significant. In this large pooled analysis of individual data from AR trials, we found that change in BTMs explain a substantial proportion of the vertebral and non-vertebral fracture benefit observed with AR treatments. Despite the challenges of imputing missing BTM values and estimating PTE with precision, our findings are proof of concept for the potential utility of BTMs as surrogate markers in trials of AR treatments.

Table. Percent of Treatment Effect (95% CI) Explained by Change in BTMs in Anti-resorptive Trials with Fracture Outcomes

	Bone ALP	PINP	sCTX
Vertebral (12 trials)	123% (81, 165%) p<0.0005	69% (24, 113%) p=0.003	89% (43, 135%) p<0.0005
Non-vertebral (14 trials)	119% (24, 214%) p=0.014	138% (33, 244%) p=0.01	85% (1, 169%) p=0.048
Hip (14 trials)	55% (-48, 157%) p=0.30	139% (4, 274%) p=0.043	43% (-61, 146%) p=0.42

Effect of Denosumab and High-Dose Teriparatide on Peripheral Bone Mineral Density and Microarchitecture Joy Tsai*[1], Amy Yuan[1], Natalie David[1], Hang Lee[1], Mary Bouxsein[2], Benjamin Leder[1]. [1]Massachusetts General Hospital, United States, [2]Beth Israel Deaconess Medical Center, United States

Background: In postmenopausal women with osteoporosis, 15 months of combined denosumab (DMAB) and high-dose (HD) teriparatide (TPTD) increases bone mineral den-

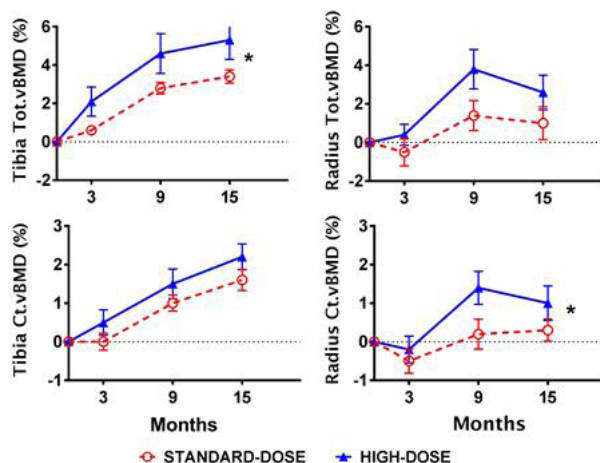
sity (BMD) at the spine and hip more and faster than combined DMAB and standard-dose (SD) TPTD. The effects of combined DMAB and HD TPTD on peripheral volumetric BMD and microarchitecture are unknown. Methods: We randomized 69 postmenopausal women ages 52-83yo at high fracture risk to 1 of 2 groups: TPTD 20-mcg (SD) or TPTD 40-mcg QD (HD) given months 0-9 overlapped with DMAB 60-mg SC Q6M given months 3-15. Women were excluded if they ever received IV bisphosphonates (BP) or oral BPs within 6 months. Total, trabecular, & cortical density (Tt.vBMD, Tb.vBMD, Ct.vBMD); trabecular thickness, spacing, & number; and cortical thickness & porosity (Ct.Th, Ct.Po) were measured by high-resolution peripheral QCT of the distal tibia and radius. Results: Tt.vBMD at the tibia increased more in the HD (5.3±5.4%) than the SD group (3.4±1.9%) (p=0.01). Tt.vBMD also increased more in the HD group (2.6±4.4%) than the SD group (1.0±4.5%) at the radius, but this did not meet statistical significance (p=0.06). Ct.vBMD at the tibia increased by 2.2±1.8% in the HD group compared to 1.6 ± 1.5% in the SD group (p=0.13) whereas at the radius Ct.vBMD in the HD group increased by 1.0±2.2% which was significantly greater than the increase in the SD group (0.3±1.5%) (p=0.047). Changes in Tb.vBMD at both the tibia and the radius showed a similar pattern but between group comparisons were not significant. Tb.vBMD at the tibia increased by 1.7±2.0% in the HD group and by 1.2±2.2% in the SD group (p=0.17) whereas at the radius Tb.vBMD increased by 2.2±4.0% in the HD group and by 1.2±4.2% in the SD group (p=0.14). Ct.Po did not increase in either group at the tibia or the radius and there were no between group differences. Conclusions: The TPTD 40-mcg/DMAB combination increases Tt.vBMD at the radius and tibia and Ct.vBMD at the radius more than TPTD 20-mcg/DMAB combination. Moreover, in contrast to the well-described decrease in Ct.vBMD and increase in Ct.Po that is observed with TPTD alone, co-administration of DMAB prevents these deleterious changes even when TPTD is given in double the standard dose. These results show that the HD combination results in more favorable changes in both trabecular and cortical peripheral bone than does the SD combination and may be a useful therapy in patients at high risk of fragility fracture.


Figure. Mean percent change (SEM) from baseline in Tt.vBMD and Ct.vBMD at 15 months. *p-value <0.05 between groups.

Effect of Dual-Task Functional Power and Mobility Training on Falls and Physical Function in Older People Living in Retirement Villages: A Cluster Randomised Controlled Trial Robin Daly*[1], Rachel Duckham[1], Jamie Tait[1], Timo Rantalainen[2], Caryl Nowson[1], Dennis Taaffe[3], Keith Hill[4], Lucy Busija[5], Kerrie Sanders[6]. [1]Institute for Physical Activity and Nutrition, Deakin University, Australia, [2]Gerontology Research Centre, University of Jyväskylä, Australia, [3]School of Medical and Health Sciences, Edith Cowan University, Australia, [4]School of Physiotherapy and Exercise Science, Curtin University, Australia, [5]Mary MacKillop Institute for Health Research, Australian Catholic University, Australia, [6]Department of Medicine, University of Melbourne, Australia

Many falls in older people result from an inability to produce a rapid explosive movement when balance is lost often whilst concurrently performing other attention-demanding cognitive or motor tasks. This 12-month cluster RCT examined whether dual task functional high velocity (power) training (DT-FPT) could reduce falls and improve physical function in older adults. Residents (n=300) at risk of falling (mean age 77 y, 73% women) from 22 independent living retirement villages were randomised to DT-FPT involving high velocity strength and mobility training performed simultaneously with cognitive or motor tasks, or a usual care control (CON) group. The intervention consisted of 6 months supervised training (45-60 min, 2/week) at each village followed by a 6 month maintenance program. Falls were monitored monthly by diaries. Secondary outcomes included lower limb muscle strength, power and balance/mobility under single and dual-task (DT) conditions. Data on falls were obtained from 278 (93%) and 250 (83%) participants at 6 and 12 months. Mean exercise adherence for each training phase was 50% and 40%, respectively. Overall 89 falls were

recorded by 65 fallers in the first 6 months. The rate of falls was 30% lower in DT-FPT vs CON [IRR: 0.70 (95% CI 0.42, 1.17)], but this difference was not significant. In contrast, the relative risk (RR) for multiple falls (≥2) was significantly lower in DT-FPT [RR 0.30 (95% CI, 0.09, 0.97)]. There were no differences in the risk of falling [RR 0.89 (0.50, 1.60)], injurious falls [RR 1.03 (0.50, 2.13)] or falls requiring medical attention [RR 1.15 (0.33, 3.92)]. During the step-down phase, 76 falls were recorded by 53 fallers (37 had first fall). There were no significant group differences in any falls outcome, with the exception that there were fewer falls requiring medical attention in DT-FPT [RR 0.10 (0.02, 0.54)]. In terms of physical function, DT-FPT significantly improved muscle power (five sit-to-stand, P<0.001), mobility (four square step test, P<0.05) and choice stepping reaction time (CSRT, P<0.05) compared to CON after 6 and 12 months. There were also greater improvements in dual task motor (P<0.05) and cognitive (P=0.05) gait speed and CSRT (P<0.05) in DT-FPT vs CON after 12 months. In conclusion, dual task functional power training reduced the risk of multiple falls and improved muscle power, mobility and dual task performance in the elderly at increased risk of falling residing in retirement villages.

Skeletal Benefit/risk of Long-term Denosumab Therapy: A Virtual Twin Analysis of Fractures Prevented To Skeletal Safety Events Observed Serge Ferrari*[1], E Michael Lewiecki[2], Peter W Butler[3], David L Kendler[4], Nicola Napoli[5], Shuang Huang[3], D Barry Crittenden[3], Nicola Pannacciulli[3], Ethel Siris[6], Neil Binkley[7]. [1]Geneva University Hospital, Switzerland, [2]New Mexico Clinical Research & Osteoporosis Center, United States, [3]Amgen Inc., United States, [4]University of British Columbia, Canada, [5]Università Campus Bio-Medico di Roma, Italy, [6]Columbia University Medical Center, United States, [7]University of Wisconsin-Madison, United States

Purpose: Osteoporosis (OP) is a chronic disease, yet skeletal safety events—atypical femoral fracture (AFF) and osteonecrosis of the jaw (ONJ)—remain a concern with long-term treatment. Ten years of denosumab (DMAb) therapy in postmenopausal women with OP has demonstrated sustained and low vertebral and nonvertebral fracture rates, with low adverse event rates (Bone Lancet Diabetes Endocrinol 2017). Here, we generated a DMAb skeletal benefit/risk ratio derived from observed data and model-based estimates from the FREEDOM trial and its Extension.Methods: Exposure-adjusted subject incidence per 100,000 subject-years of clinical, major osteoporotic, vertebral, nonvertebral, and hip fractures was calculated for long-term (LT) subjects randomized to DMAb in the 3-year FREEDOM trial and enrolled in the 7-year Extension (follow-up time on DMAb 3 to 10 years). Due to the lack of a long-term placebo group, fracture rates in a hypothetical cohort of 10-year placebo controls (virtual twins [VT]) were estimated: A regression model was generated using data from subjects randomized to PBO during FREEDOM and then enrolled in the Extension; a VT with identical baseline characteristics to each LT subject was derived; and fracture rates were then predicted for the untreated VT group using the regression model. The number of fractures prevented per 100,000 subject-years was calculated as (VT rate – LT rate). AFF and ONJ incidences on DMAb were based on observed cases in the LT group during the Extension; the VT group was assumed to have no AFF or ONJ in the absence of treatment. A skeletal benefit/risk ratio was calculated from fractures prevented per AFF or ONJ observed.Results: This analysis included 2343 subjects. The estimated number of clinical fractures prevented was 1403 per 100,000 subject-years (Table). There was 1 case of AFF and 7 ONJ (mild and moderate), corresponding to rates of 5 (AFF) and 35 (ONJ) per 100,000 subject-years. Hence, there were 281 and 40 clinical fractures prevented per AFF and ONJ observed, respectively. The skeletal benefit/risk ratio for other fracture endpoints is shown below (Table).Conclusions: As long-term placebo-controlled fracture outcome studies in postmenopausal OP are not ethical, the virtual twin model provides a reasonable estimate of untreated fracture rates. Using this model, long-term DMAb therapy has a highly favorable benefit/risk profile when comparing fractures prevented per skeletal adverse event observed.

Table. Ratio of Fractures Prevented per Skeletal Safety Event Observed in Long-term FREEDOM Extension Subjects Using the Virtual Twin Method

		Exposure-adjusted subject incidence per 100,000 subject-years				
		Clinical fractures N = 2343 Exp = 18295	Major osteoporotic fractures[a] N = 2343 Exp = 18772	Vertebral fractures N = 2116[b] Exp = 18385	Non-vertebral fractures N = 2343 Exp = 18451	Hip fractures N = 2343 Exp = 19742
Long-term		1777	1525	901	1528	149
Twin		3180	2699	1879	2924	297
Ratio[c]		0.56	0.57	0.48	0.53	0.54
Fractures prevented		1403	1174	978	1396	148
Ratio of fractures prevented per AE observed[d]	AFF (5)[e]	280.6	234.8	195.6	279.2	29.6
	ONJ (35)[e,f]	40.1	33.5	27.9	39.9	4.2

Based on LT denosumab subjects. All results are based on 5000 bootstrap samples.
N = number of LT subjects who had fracture outcome data; Exp = exposure time in subject years indicating the time from FREEDOM baseline to the onset of first event (for subjects who had a fracture event) or end of study or last assessment date, whichever was greater (for subjects who did not have a fracture event)
[a] Major osteoporotic fractures were defined as clinical spine, forearm, hip, or shoulder fracture
[b] 227 LT subjects had missing vertebral fracture outcome data during FREEDOM and/or its Extension
[c] Calculated as (LT rate) / (VT rate)
[d] Calculated as (VT rate – LT rate) / AE rate
[e] The number in parentheses indicates the AE subject incidence rate per 100,000 subject-years in LT subjects
[f] There were 2 mild, 5 moderate, and no severe cases of ONJ in the LT group
AE: Adverse event; AFF: atypical femoral fracture; ONJ: osteonecrosis of the jaw

The Calgary Vitamin D Study: Bone Microarchitecture Effects of Three-Year Supplementation With 400, 4000 or 10000 IU Daily Lauren A Burt*[1], Marianne S Rose[2], Emma O Billington[1], Duncan A Raymond[1], David A Hanley[1], Steven K Boyd[1]. [1]McCaig Institute for Bone and Joint Health, Cumming School of Medicine, University of Calgary, Canada, [2]Research Facilitation, Alberta Health Services, Canada

Most studies exploring the effect of daily vitamin D supplementation on bone mineral density (BMD) have used dual X-ray absorptiometry (DXA) to evaluate changes, and apart from treatment of vitamin D deficiency, the effect of vitamin D on bone health is unclear. Furthermore, few studies have investigated supplementation of doses at or above the IOM's recommended tolerable upper limit (TUL) of 4000 IU daily. In a 3-year, double-blind RCT, we investigated the effect of daily doses of 400, 4000 and 10000 IU vitamin D on measures of areal BMD (aBMD) using DXA at the hip, and volumetric BMD and estimated strength by high resolution peripheral quantitative computed tomography (HR-pQCT) at the radius and tibia.Participants were healthy men and women 55 to 70 years with DXA T-score above -2.5 and serum 25(OH)D between 30 - 125 nmol/L. Participants consuming <1200 mg/day of calcium received calcium supplementation. At baseline and annual visits participants had standard DXA measurements at the hip. Additionally, the radius and tibia were scanned on a second-generation HR-pQCT (XtremeCT II, SCANCO Medical AG, Switzerland) to measure total volumetric BMD (TtBMD) at baseline, 6, 12, 24 and 36 months. Finite element analysis from HR-pQCT was calculated to estimate failure load. Following an intent-to-treat analysis, we used constrained linear mixed effects models to determine treatment group by time interactions.311 participants were randomized; 299-303 were included in the primary analysis. Mean (SD) serum 25(OH)D concentrations increased to 76 (18), 115 (23) and 188 (39) nmol/L after 3 months, in 400, 4000 and 10000 IU groups, respectively. Total hip aBMD decreased over study duration, but no difference among treatment groups was detected (p = 0.868). In contrast, there were significant group-by-time interactions for TtBMD. Over a period of 3-years, TtBMD decreased at the radius (400 IU: -1.4%, 4000 IU: -2.6% and 10000 IU: -3.6%, p<0.001) and tibia (400 IU: -0.9%, 4000 IU: -1.2% and 10000 IU: -2.1%, p<0.001). We did not observe significant group-by-time interactions for failure load at the radius (p = 0.259) or tibia (p = 0.062).In this 3-year study of non-osteoporotic individuals with adequate baseline 25(OH)D serum, vitamin D supplementation was associated with no detectable difference in DXA aBMD, but a dose-related decrease in HR-pQCT bone density at the radius and tibia, with the largest decrease occurring in the 10000 IU/day group.

Physiotherapy Rehabilitation for Osteoporotic Vertebral Fracture - A randomised controlled trial and economic evaluation (PROVE trial): ISRCTN 49117867 Karen Barker*[1], Meredith Newman[2], Nigel Stallard[3], Jose Leal[1], Catherine Minns Lowe[2], Muhammad Javaid[1], Angela Noufaily[3], Anish Adhikari[1], David Smith[1], Varsha Gandhi[1], Cyrus Cooper[1], Sarah Lamb[1]. [1]University of Oxford, United Kingdom, [2]Oxford University Hospitals Foundation Trust, United Kingdom, [3]University of Warwick, United Kingdom

Purpose: Vertebral fragility fractures are associated with significant pain an reduction in quality of life. Physical therapy is often recommended for patients and typically includes manual vs. exercise therapy. There is little evidence to support either approach. We investigated the clinical and cost-effectiveness of two different physiotherapy programmes for people with symptomatic osteoporotic vertebral fractures compared with a single session of physiotherapy.Methods: We performed a multicentre, assessor blinded, three-arm randomised trial of 7 sessions of manual therapy vs. exercise therapy delivered over 12 weeks compared to a single one hour session with a specialist physiotherapist in patients with symptomatic vertebral fractures. The co-primary outcomes were quality of life (QUALLEFO 41) and muscle endurance (Timed Loaded Standing (TLS) test) at 12 months. Secondary outcomes were: thoracic kyphosis measured with a Flexicurve ruler, balance evaluated via the Functional Reach (FR) test and physical function by the Short Performance Physical Battery (SPPB), 6 minute walk test and Physical Activity Scale for the Elderly (PACE), a health resource use diary and the EQ-5D-5L at 4 and 12 months.Results: 615 patients were enrolled with 216 patients randomised to the exercise therapy arm, 203 patients to manual therapy arm and 197 to usual care arm. The mean age was 72 .1 yrs and 87% were female. At 12 months, there were no significant benefits of either a course of exercise or manual therapy over a single hour session of physiotherapy. For the secondary outcomes, relative to a single session, there is significant improvement from exercise therapy at 4 months in the SPPB, the FR test and the six minute walk test and from manual therapy at four months in TLS and FR. The treatment differences for TLS were significant in those patients under 70 years old, but not older. Neither the manual or exercise physiotherapy interventions were cost-effective relative to a single physiotherapy session using the £20,000 per QALY threshold.Conclusions: In the largest trial assessing physiotherapy in patients with osteoporotic fragility fractures, benefits were seen at 4 months but neither intervention was superior to a single one-hour advice session with a specialist physiotherapist at 12 months. Future research should focus on improving adherence to therapy recommendations.

Impaired Dendritic Cell Function and Bacterial Load Increase in the Oral Microenvironment as Contributing Factors to the Induction of MRONJ
Ranya Elsayed*[1], Esteban Celis[2], Hussein Sultan [2], Christopher Cutler[1], Mahmoud Elashiry[1], Mohamed Meghil [1], Zoya Kurago [1], Mohamed Awad [1], Mohey Eldin El- Shikh[3], Mohammed Elsalanty[1], Riham El Sayed[3]. [1]Department of Oral Biology, Dental College of Georgia, Augusta University, United States, [2]Biochemistry and Molecular Biology, Georgia Cancer Center, Medical College of Georgia , Augusta University, United States, [3]Queen Mary, University of London, United Kingdom

Previous studies have shown the important role of immune cells during the early stages of bone healing. We propose that anti-resorptive medication-related osteonecrosis of the jaw (MRONJ) may be a consequence of disruption in the local immune response in the bone microenvironment. While bisphosphonates are known to target osteoclasts mainly, immune cells from the same lineage, such as macrophages and dendritic cells (DCs), could also be affected. Our aims were to: 1) test the hypothesis that Zol treatment increases oral bacterial load in vivo and reduces DC uptake of oral bacteria in-vitro. 2) test the hypothesis that Zoledronate (Zol) modulates local immune response by impairing DC differentiation and function. Using immunofluorescence, we confirmed that bisphosphonates are internalized by DCs and macrophages. Phagocytic function and bacterial clearance by murine bone marrow-derived DCs (BMDCs) were impaired by Zol treatment, leading to a significant decrease in the uptake of FITC dextran and inability to phagocytose common periodontal pathogens, such as P. gingivalis and F. nucleatum, evidenced by flow cytometry. Increased bacterial load was confirmed in oral samples from Zol-treated animals compared to controls. Zol-treated BMDCs demonstrated a significant decrease in the expression of maturation markers MHCII, costimulatory molecules CD86, CD80 and CD83, and inflammatory cytokines IL-6, IL-12, IL-23 interferon gamma (IFN-g), and increase in the anti-inflammatory cytokine IL-10, as demonstrated by qPCR and flow cytometry. Furthermore, Zol-treated DCs were defective in CCL19-induced migration, consistent with a significant decrease in CCR7 receptor expression. There was also a decrease in the expression of the tetraspanin CD9. Electron microscopy imaging was performed to confirm Zol-induced changes in morphology and cytoskeleton of DCs. Moreover, Zol treatment reduced the capacity of DCs to present OVA peptide to OT-II transgenic mice-derived (OVA specific) T-cells shown by CFSE proliferation assay, with a significant decrease in the production of Th-1 activation cytokines IL-2 and IFN-g shown by ELISA. In conclusion, Zol treatment causes disruption of DC function, combined with an increase in bacterial load in alveolar bone, both of which could contribute to the pathogenesis of osteonecrosis.

Gnas inactivation alters adipose tissue properties during progression to heterotopic ossification
Niambi Brewer*[1], John T Fong[2], Deyu Zhang[2], Frederick S Kaplan[2], Robert J Pignolo[3], Eileen M Shore[1]. [1]Departments of Orthopaedic Surgery and Genetics, Perelman School of Medicine, University of Pennsylvania, United States, [2]Department of Orthopaedic Surgery, Perelman School of Medicine, University of Pennsylvania, United States, [3]Division of Geriatric Medicine and Gerontology, Mayo Clinic College of Medicine, United States

Heterotopic ossification (HO) is a common physiological response to severe tissue trauma such as combat blast injuries, high impact trauma, and hip replacements. The investigation of rare genetic disorders provides insight into the aberrant mechanisms that cause HO formation and leads to identification of targets for pharmacological intervention in both genetic and non-genetic forms of HO. HO in the rare genetic disorder, Progressive Osseous Heteroplasia (POH), initiates in subcutaneous soft tissues then progresses into deeper connective tissues. POH is caused by inactivation of GNAS, a gene that encodes the alpha stimulatory subunit of G proteins (Gsα). Our previous work demonstrated that adipose derived stromal cells (ASCs) from Gnasp-KO mice exhibit enhanced osteogenic and impaired adipogenic potential in vitro, supporting that osteogenesis and heterotopic bone in POH occurs at the expense of adipogenesis, however, the pathophysiology of POH remains poorly

understood. To examine the mechanisms and signals that lead to initiation of heterotopic bone caused by GNAS inactivation in osteogenic progenitor cells, we developed an in vivo HO model using Gnas-null mice (Gnasfl/fl;Cre-ERT2 or Gnasfl/fl;Ai9fl/fl;Cre-ERT2) that consistently and reliably induces spontaneous HO. Through microCT, histologic, and immunohistochemistry analyses in cross-sectional and longitudinal studies, this model initiates HO within subcutaneous adipose tissues with progressive expansion over time. Using the same model and methods, we investigated the tissue changes that precede HO formation and identified increased extracellular matrix content, as well as a shift from white to beige adipose tissue, including UCP1 expression and decreased adipocyte size and lipid content. Cell implant studies showed that fluorescent-labeled Gnas-null ASCs form HO when implanted within Gnas-null adipose tissue, as expected. However, wildtype (WT) ASCs also induce HO in a Gnas-null background, although less robustly than mutant ASCs, suggesting that the tissue microenvironment strongly influences cell fate. Further, neither WT nor Gnas-null ASCs implanted into a control background formed HO, supporting that the mutant osteogenic progenitor cells are insufficient to induce HO. These data highlight the importance of the microenvironment within the adipose tissue in supporting ectopic bone formation by Gnas inactivation and provide insights into the pathophysiology of POH and other GNAS-related disorders.

Prevention of Zoledronate-Induced MRONJ with Indocyanine Green (ICG) Labeled Bisphosphonates
Shuting Sun*[1], Akishige Hokugo[2], Frank H. (Hal) Ebetino[1], Keivan Sadrerafi[1], Philip Cherian[1], Charles E. Mckenna[3], Ichiro Nishimura[2]. [1]Biovinc, United States, [2]UCLA School of Dentistry, United States, [3]Chemistry Department, University of Southern California, United States

Medication-related osteonecrosis of the jaw (MRONJ) is a rare but serious concern, particularly for oral surgery patients who have received a nitrogen-containing bisphosphonate (BP) drug to avoid skeletal complications and bone pain due to multiple myeloma or metastatic bone cancer. We recently introduced the concept of legacy bisphosphonate displacement via local administration with a suitable inactive BP as an approach to prevent or treat BP-associated MRONJ. We have developed an efficient synthesis to provide several novel BP compounds to facilitate efficacy studies. Our synthetic procedures allow for analogs including novel ICG-conjugated BPs which offer a fluorescent imaging moiety that is approved as a human diagnostic. For our therapeutic purpose, we hypothesized that these analogs need to maintain their bone affinity, but not possess pharmacological activity. Potentially useful bone affinity was demonstrated with these new fluorescent BP analogs on incubation with hydroxyapatite although that of BV700601was higher. Anti-prenylation activity (a marker for inhibition of bone resorption activity) was evaluated in J744.2 macrophages to show that BV501001 (AF647-ZOL) and BV700601 (ICG-C-pRIS) had undetectable activity up 100 μM. Efficacy to prevent the development of Zol-induced ONJ was determined in female 8-10 wk old C57B16J mice pretreated with 500 μg/Kg ZOL. Subsequently, mice were subjected to intra-oral injection of vehicle saline, BV501001 (350μM) or BV700601 (350μM) to the palatal mucosa adjacent to the left maxillary first molar. Ten days later, the maxillar left first molar was extracted. Two weeks after tooth extraction, the maxilla was harvested, subjected to ex vivo fluorescent imaging (IVIS), and the developmen of osteonecrosis adjacent to the extaction wound was measured in histological cross-sections. The area of necrotic bone over the left palatal bone area in the saline, BV501001, and BV700601 groups was 19.8±6.0%,15.4±3.6%, and 2.5±0.9% respectively. BV700601 intra-oral injection resulted in the prevention of osteonecrosis development, potentially due to its higher bone affinity than BV501001. Our results provide support for the proposal that local BP displacement prophylaxis, prior to dental surgery, can prevent or mitigate the induction of MRONJ associated with legacy nitrogen containing BP accumulated in the jawbone after routine therapy, while preserving the therapeutic effect of NBPs at other diseased skeletal sites.

The Effect of Androgens on Renal Calcium and Phosphate Handling, Independent of Bone and in Circumstances of Low Dietary Calcium Rougin Khalil*[1], Na Ri Kim[1], Ferran Jardi[1], Frank Claessens[2], Dirk Vanderschueren[1], Brigitte Decallonne[1]. [1]KU Leuven, Department of Chronic Diseases, Metabolism & Ageing (CHROMETA), Clinical and Experimental Endocrinology, Leuven, Belgium, [2]KU Leuven, Department of Cellular and Molecular Medicine, Molecular Endocrinology, Leuven, Belgium

We have previously shown that orchidectomy (ORX) in adult mice induces hypercalciuria and upregulation of renal Ca2+ and PO43- transporters, but also bone loss already after 2 weeks. Pretreatment with a risedronate inhibited bone resorption and hypercalciuria but confirmed the upregulation of renal Ca2+ and PO43- transporters, suggesting bone-independent renal effects of androgens.We hypothesize that androgens regulate renal Ca2+ and PO43- homeostasis, independent of the dietary Ca2+ content as well.ORX was performed on 18-week-old male mice (vs SHAM) and pretreated all animals with risedronate. Mice were fed either a normal Ca2+ diet (NCD, 1%) or a low Ca2+ diet (LCD, 0.02%), while PO43- was unchanged (0.6%). At 1 and 2 weeks post-ORX 24 hr urine (metabolic cages) and serum was collected. After sacrifice (2 w post-ORX) kidneys were taken for qPCR of Ca2+ and PO43- transporters, trabecular bone was analyzed by microCT (L5 vertebra), and femoral bone was analyzed for Ca2+ content by ashing.Serum Ca2+ and PO43-, and urinary Ca2+ excretion were similar under both diets, but PO43- excretion was significantly increased in both the SHAM and ORX groups (239% and 268%, P< 0.0001) under LCD diet. Under LCD, increased serum levels of 1,25-dihydroxyvitamin D and PTH were observed. While risedronate efficiently blocked ORX-induced bone loss under the NCD, microCT analysis revealed that bone resorption was not fully blocked under the LCD, with a decrease in bone volume density of 14% compared to the NCD fed SHAM mice (P < 0.05). Also the femur Ca2+ content was significantly reduced in the LCD group (7.2 versus 8.8 mg in the NCD fed SHAM mice, p < 0.0001). Under the NCD an increase of renal Ca2+ and PO43- transporter expression after ORX was confirmed. In the LCD group a small but significant additional increase of renal Ca2+ transporter expression was observed, with a 1.7-fold increase for TRPV5, a 2.1-fold increase for CaBP9K and a 1.5-fold increase for PMCA (vs respectively a 1.6-, 1.5- and 1.3-fold increase for the NCD). Expression of PO43- transporters (NaPi-2c, PiT1, PiT2) was similar in both diet groups.In conclusion, low dietary Ca2+ results in secondary hyperparathyroidism with ORX-induced bone loss despite treatment with bisphosphonates, and an additional increase in renal Ca2+ transporters. These findings underline the importance of adequate dietary Ca2+ intake along with anti-resorptive drugs in circumstances of bone loss post-androgen deprivation.

PPARγ in cells of the mesenchymal lineage is dispensable for the age-dependent decline of bone mass and hematopoietic changes in the appendicular skeleton Maria Almeida*, Michela Palmieri, Ha-Neui Kim, Li Han, Xin Zhang, Wen Li, Yonghan He, Robert Weinstein, Daohong Zhou, Stavros Manolagas, Robert Jilka. UAMS, United States

Age-dependent bone loss is associated with an increase in marrow adipocytes. Because both osteoblasts and adipocytes originate from a common mesenchymal progenitor, it has been postulated that this bone loss is due in part to diversion of mesenchymal progenitors to adipocytes at the expense of osteoblasts. Mesenchymal progenitors also give rise to stromal cells, which along with adipocytes, are critical sources of factors that support the hematopoietic stem cell (HSC) niche. With age, HSCs increase but their progeny is skewed toward the myeloid lineage at the expense of lymphoid cells. PPARγ is a master transcriptional regulator of adipocytes. To investigate the contribution of marrow adipocytes to age-related changes in bone and bone marrow, we generated mice lacking PPARγ in the mesenchymal lineage of the appendicular skeleton using Prx1-Cre (PPARgΔPrx1 mice) in the C57BL/6J background. PPARγ-flox littermates were used as controls. Deletion of PPARγ was confirmed by qPCR of DNA from cortical bone and RNA from bone marrow-derived stromal cell cultures. Consistently, and in contrast to cells from control mice, rosiglitazone failed to stimulate adipocyte differentiation or to inhibit osteoblast differentiation in ex-vivo bone marrow cultures of 22 month old PPARgΔPrx1mice. Cancellous bone volume at the femoral distal metaphysis and cortical thickness at the diaphysis were indistinguishable in PPARgΔPrx1 and control females and males at 3 and 6 months of age, as determined by micro-CT. Control mice exhibited the expected loss of cortical bone thickness at the diaphysis and the proximal end of the femur, at 22 months of age. The volume of the cancellous bone compartment of the femoral head declined from 60% to 45% between 6 and 22 months of age. However, cortical and cancellous bone mass was indistinguishable between PPARgΔPrx1 and aged matched controls. Cancellous bone at the distal femur was undetectable in both control and PPARgΔPrx1 mice. Moreover, the effect of aging on hematopoietic stem cell number was unaltered by PPARγ deletion, as measured by HSC number and circulating B, T, and myeloid cells, using FACS. We conclude that PPARγ expressed in mesenchymal progenitors and their progeny plays no role in the age-dependent decline of bone mass or the hematopoietic system changes in the appendicular skeleton of mice.

An Antibody against Oxidized Phospholipids Promotes Bone Anabolism by Preventing their Binding to the Scavenger Receptor ScrB1 and thereby their Pro-Apoptotic Effect on Osteoblasts Elena Ambrogini*[1], Michela Palmieri[1], Li Han[1], Xuchu Que[2], Sotirios Tsimikas[2], Joseph L Witztum[2], Stavros C Manolagas[3], Robert L Jilka[3]. [1]Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and the Central Arkansas Veterans Healthcare System, United States, [2]Department of Medicine, University of California San Diego, United States, [3]Center for Osteoporosis and Metabolic Bone Diseases, Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and the Central Arkansas Veterans Healthcare System, United States

Oxidized phospholipids (OxPL) are pro-inflammatory products of lipid peroxidation. Scavenger receptors (SRs) and toll-like receptors (TLRs) recognize OxPL and dispose of oxidatively-modified molecules. Natural antibodies (nAbs) of the innate immune system also recognize OxPL and block their deleterious effects. However, persistence and/or excessive amounts of OSEs overwhelm these defense mechanisms and result in several diseases, such as atherosclerosis and osteoporosis. Oxidized phospholipids containing phosphocholine (PC-OxPL) are components of oxidized low density lipoproteins (OxLDLs), and are also present on the surface of apoptotic cells. The nAb IgM E06 recognizes PC-OxPL. It was previously reported that male transgenic mice expressing a single chain (scFv) form of the antigen-binding domain of E06 IgM (E06-scFv) are protected against high fat diet-induced atherosclerosis and have increased cancellous bone in the distal femur and vertebrae when fed a normal diet. These anabolic effects are associated with increased bone formation. We report here that the same bone phenotype is present also in female E06-scFv mice fed normal diet, and both sexes exhibit an increase in cortical thickness of the diaphyseal femur due to a reduction in medullary area. Together, these findings indicate that lipid peroxidation negatively affects bone under physiologic conditions, in part by restraining bone formation. To elucidate potential mechanisms responsible for this effect, we used qPCR to measure the levels of the SRs and TLRs known to bind PC-OxPL, and found that calvaria osteoblastic cells primarily expressed ScrB1, while CD36, TLR2, 4 and 6 were expressed at 3-30-fold lower levels. Ox-LDL decreased the replication, differentiation and survival of osteoblast cells in vitro; and these effects were reversed by purified E06 IgM. Reduction of ScrB1 in calvaria osteoblastic cells using shRNA protected them from OxLDL-induced apoptosis. Furthermore, bone marrow- or calvaria-derived osteoblasts from

ScrB1 knock-out mice were protected from the pro-apoptotic effect of OxLDL, whereas osteoblastic cells from wild type mice were not. Together with published evidence that ScrB1 knock out mice have high bone mass, our results indicate that ScrB1 mediates the deleterious effects of PC-OxPL on osteoblasts and that anti-PC-OxPL antibodies, like E06, may exert their bone anabolic effects in part by preventing OxPL from binding to SR-B1.

Change in BMD as a Surrogate for Fracture Risk Reduction in Osteoporosis Trials: Results from Pooled, Individual-level Patient Data from the FNIH Bone Quality Project Dennis Black*[1], Eric Vittinghoff[1], Richard Eastell[2], Douglas Bauer[1], Li-Yung Lui[3], Lisa Palermo[1], Charles Mcculloch[1], Jane Cauley[4], Sundeep Khosla[5], Fernando Marin[6], Anne De Papp[7], Andreas Grauer[8], Mary Bouxsein[9]. [1]University of California, San Francisco, United States, [2]University of Sheffield, United Kingdom, [3]California Pacific Medical Center, United States, [4]University of Pittsburgh, United States, [5]Mayo Clinic, United States, [6]Eli Lilly and Company, Switzerland, [7]Merck & Co., Inc., United States, [8]Amgen, Inc., United States, [9]Harvard Medical School, United States

To facilitate future drug development in osteoporosis, the FNIH Bone Quality Project aims to identify a surrogate that can be used in place of fracture in future clinical trials. To do so, we compiled and pooled individual patient data from 25 randomized, placebo-controlled osteoporosis trials that enrolled >125,000 subjects. Changes in BMD are an obvious candidate surrogate. One step in the validation of a surrogate biomarker is to estimate the percent of treatment explained (PTE) by the surrogate. Previous analyses of individual trials reported PTEs for BMD change ranging from 4% to ~80%, but analysis methods differed, and single studies were too small to give precise estimates. We used our pooled data to estimate PTE for BMD change, using a two-stage procedure. In the first stage, we used linear mixed models (LMM) to estimate participant-specific BMD trajectories. In the second, we fit nested pooled logistic regression (PLR) models for the effect of treatment on time to vertebral, non-vertebral and hip fractures. PTE was calculated as the percentage change in the coefficient for treatment after adding time-dependent BMD change, based on the first-stage LMM, to the base PLR model. Confidence intervals for PTE were obtained using the method of seemingly unrelated regressions. We analyzed PTE for femoral neck, total hip and lumbar spine BMD for vertebral, hip and non-vertebral fractures including people with at least one BMD measurement. We examined the change in BMD at 24 months, and included all fractures to the end of the trials. The current analyses included 21 trials (including bisphosphonates, SERMs, estrogen, odanacatib, denosumab, PTH1-34, and PTH1-84) with 83,395 subjects with DXA who suffered 4515 vertebral, 6608 non-vertebral and 873 hip fractures. We found that PTE for 24 month change in femoral neck BMD was 65% (95% CI: 53-77%) for vertebral, 74% (95% CI: 43-105%) for non-vertebral and 65% (24-106%) for hip fractures (see Table). The results were similar for total hip, but PTE was lower for lumbar spine BMD. Our results indicate that changes in total hip and femoral neck BMD explain a large proportion of the treatment-related reduction in fracture risk for all 3 fracture types. Importantly, this analysis included therapies with differing mechanisms of action. These data, along with others generated from this project, support the potential value of DXA BMD change as a surrogate for fractures in future trials.

Table. Percent of treatment effect (%, 95% CI) explained by changes in total hip (TH), femoral neck (FN) and lumbar spine (LS) at 24 months for vertebral, hip and non-vertebral fractures.

	ΔTH BMD	ΔFN BMD	ΔLS BMD
Vertebral Fx	66% (55, 77%) p<0.0005	65% (53, 77%) p<0.0005	27% (14, 40%) p<0.0005
Hip Fx	60% (27, 93%) p<0.0005	65% (24, 106%) p=0.002	42% (7, 76%) p=0.019
Non-vertebral Fx	69% (41, 96%) p<0.0005	74% (43, 105%) p<0.0005	56% (25, 87%) p<0.0005

Probiotic Treatment Using a Mix of Three Lactobacillus Strains Protects Against Lumbar Spine Bone Loss in Healthy Early Postmenopausal Women Claes Ohlsson*[1], Dan Curiac[2], Klara Sjögren[1], Per-Anders Jansson[3]. [1]Centre for Bone and Arthritis Research, Institute of Medicine, the Sahlgrenska Academy at University of Gothenburg, Sweden, [2]CTC, Gothia Forum, Sahlgrenska University Hospital, Sweden, [3]Department of Molecular and Clinical Medicine, the Sahlgrenska Academy, University of Gothenburg, Sweden

The gut microbiota composition has been associated with several different diseases. Experimental studies using rodents indicate that manipulation of the gut microbiota compo-

sition may alter bone homeostasis and we recently introduced a new term "osteomicrobiology" for the rapidly emerging research field of the role of the gut microbiota in bone health (Trends Endocrinol Metab. 2015 26:69-74). Several recent studies have demonstrated that certain probiotic treatments protect rodents from ovariectomy-induced bone loss but there is no adequately powered clinical study of the effect of probiotic treatment on postmenopausal bone loss in women. The aim of the present study was to determine if a combination of three bacterial strains protects against the rapid lumbar spine bone loss occurring in early postmenopausal women. We performed a multicenter, randomized, placebo-controlled, parallel group, clinical study to evaluate the efficacy on lumbar spine bone mineral density (LS-BMD) and safety of a probiotic treatment consisting of three lactobacillus strains (L. paracasei DSM 13434, L. plantarum DSM 15312 and DSM 15313; 1x1010 CFU/capsule once daily for 12 months) in 234 healthy early postmenopausal women (LS-BMD T-score >-2.5; 2-12 years after menopause; mean age 58.6±4.0 (SD) years, mean BMI 24.0±2.7 kg/m2) that were analysed by LS-DXA both at baseline and after 12 months. The primary endpoint was the percentage change from baseline in LS-BMD at 12 months. The LS BMD loss was significant in the placebo group -0.77% (p=0.0006) but not in the probiotic treated group -0.17% (p=0.40). The percentage change in LS-BMD from baseline was small but significantly different in the probiotic group compared with the placebo group (p=0.04; Wilcoxon rank-sum test). The most pronounced protective effect of probiotic treatment was observed for women below the median of 6 years from menopause. For these women, the LS-BMD loss was clearly less pronounced in the probiotic treated group -0.18% (p=0.56) compared with the placebo group -1.21 % (P=0.0001). The adverse events were similar between the two groups. In conclusion, probiotic treatment using a mix of three lactobacillus strains protects against lumbar spine bone loss in healthy early postmenopausal women. These findings indicate that the pronounced lumbar spine bone loss occurring during the first years after menopause is reduced by specific probiotic treatment.

VK5211, a Novel Selective Androgen Receptor Modulator (SARM), Significantly Improves Lean Body Mass in Hip Fracture Patients: Results of a 12 Week Phase 2 Trial Branko Ristic*[1], Vladimir Harhaji[2], Paul Dan Sirbu[3], Moises Irizarry-Roman[4], Gabor Bucs[5], Istvan Sztanyi[5], Neil Binkley[6], Denise Orwig[7], Joel Neutel[8], Ken Homer[8], Marianne Mancini[9], Hiroko Masamune[9], Geoff Barker[9], Brian Lian[9]. [1]Clinical Center Kragujevac, Clinic for Orthopedics and Traumatology, Serbia, [2]Clinical Center of Vojvodina, Clinic for Orthopedic Surgery and Traumatology, Serbia, [3]County Hospital for Emergency Sfintul Spiridon Iasi, Clinical Section of Orthopedics and Traumatology, Romania, [4]Infinite Clinical Research, United States, [5]PTE ÁK Traumatology and Clinical Surgery, Hungary, [6]University of Wisconsin School of Medicine and Public Health, United States, [7]Department of Epidemiology and Public Health, University of Maryland School of Medicine, United States, [8]Integrium Clinical Research, United States, [9]Viking Therapeutics, Inc., United States

IntroductionHip fractures are a leading cause of disability and morbidity in older people. Post-facture, an increased catabolic state often leads to loss of muscle, which can impair balance and endurance, potentially increasing the risk of further injury. Anabolic steroids have been shown to improve muscle mass in certain settings. Selective androgen receptor modulators (SARMs) could be similarly effective in older patients who have suffered muscle loss following hip fracture, while potentially avoiding undesired side effects associated with broad-acting anabolic agents. VK5211 is a novel, non-steroidal, orally available SARM that has been shown to improve muscle mass and bone mineral density in animal models. In humans, a prior Phase 1 study demonstrated increases in lean body mass after 21 days of dosing. PurposeA 12 week study was conducted to assess the safety and efficacy of VK5211 in patients who had suffered a hip fracture. MethodsA randomized, double-blind, placebo-controlled, multicenter, international Phase 2 trial was conducted to evaluate VK5211 in patients recovering from hip fracture. Patients were randomized to receive daily oral VK5211 doses of 0.5 mg, 1.0 mg, 2.0 mg, or placebo, for 12 weeks. The primary endpoint evaluated change from baseline in lean body mass, less head, in patients receiving VK5211 compared with placebo. Secondary and exploratory endpoints included changes in appendicular lean mass, bone density, and functional performance. ResultsA total of 108 patients were randomized (83 F, 25 M; mean age 77). Patients receiving VK5211 demonstrated significant increases in lean body mass, less head, after 12 weeks. Placebo-adjusted increases were 4.8% at 0.5 mg, 7.2% at 1.0 mg, and 9.1% at 2.0 mg (p < 0.005 for each). The proportions of patients experiencing at least a 2.0 kg increase were 14% with placebo, 57% at 0.5 mg, 65% at 1.0 mg, and 81% at 2.0 mg (p < 0.01 for each). Patients receiving VK5211 demonstrated improvement in certain measures of functional performance, including the 6-minute walk test and short physical performance battery (these endpoints were not powered for significance). The rates of adverse events were similar in cohorts receiving VK5211 as compared with placebo, and no drug-related SAEs were observed in VK5211-treated patients. ConclusionVK5211 was well-tolerated and produced improvements in lean body mass in hip fracture patients following 12 weeks of dosing. Further evaluation in this setting is warranted.

Rapid and Large BMD Increases in Postmenopausal Women Treated With Combined High-Dose Teriparatide and Denosumab: The DATA-HD Randomized Controlled Trial Benjamin Leder*[1], Hang Lee[2], Natalie David[2], Richard Eastell[3], Tsai Joy[2]. [1]Harvard Medical School. Massachusetts General Hospital, United States, [2]Massachusetts General Hospital, United States, [3]Mellanby Centre for Bone Research, United Kingdom

In the DATA study, we demonstrated that when given concomitantly, denosumab (DMAB) fully inhibits teriparatide (TPTD)-induced bone resorption while allowing for continued TPTD-induced modeling-based bone formation. These effects on bone turnover, in turn, result in greater gains in hip and spine BMD than can be achieved with either drug alone. We thus hypothesized that combining DMAB with a larger anabolic stimulus, in the form of high-dose TPTD, would further expand the separation between rates of bone formation and resorption and result in even larger and faster increases in bone mass. Methods: 69 postmenopausal osteoporotic women (age 52-83) were randomized to one of two treatments: TPTD 40-mcg (high dose-HD) or TPTD 20-mcg (standard dose-SD) given months 0-9 overlapped with DMAB 60-mg SC given months 3-15 for a total study duration of 15 months. Subjects were excluded for oral BP exposure within 6 months or any exposure to TPTD, DMAB, or IV BPs. Results: At month 15, mean total hip (TH) BMD increased more in the HD (6.1 ± 3.4%) than the SD group (3.9 ± 2.9%, P<0.001). Femoral neck (FN) BMD also increased more in the HD than SD group (6.8 ± 4.1% vs 4.3 ± 3.7%, P=0.04) as did spine BMD (17.5 ± 6.0% vs 9.5 ± 3.2%, P<0.001). Of note, both TH and FN BMD had increased by >5% and spine BMD by >14% by month 9 (after only 3 months of TPTD followed by 6 months of combined therapy). Additionally, the relative greater BMD gains in the HD vs the SD group continued to expand during the final 6-months of treatment despite the fact that both groups were receiving identical DMAB monotherapy during this phase.In the initial 3-months of TPTD monotherapy, serum bone formation markers increased significantly more in the HD than SD group (P1NP, 402% vs 153%, OC 254% vs 140%.), as did bone resorption (CTX, 159% vs 84%). At month 9, OC remained above baseline in the HD but not SD group (+10% vs -27%) and P1NP was significantly less suppressed in HD than SD (-32% vs -43%). CTX was also less suppressed in the HD than SD group (-46% vs -69%). Month-15 bone turnover markers (after 6 months of DMAB monotherapy) were similarly suppressed in both groups. Summary: The combination of TPTD 40-mcg and DMAB increases hip and spine BMD faster and more than standard combination therapy or any available single drug. These robust and rapid increases in BMD suggest that by expanding the separation between bone formation and bone resorption, the HD regimen may provide the fastest means of restoring skeletal integrity in osteoporotic patients at the highest risk of fragility fracture. Larger trials are urgently needed to fully evaluate the efficacy and safety of this treatment approach.

T-score as an Indicator of Fracture Risk on Therapy: Evidence From Romosozumab vs Alendronate Treatment in the ARCH Trial Felicia Cosman*[1], E. Michael Lewiecki[2], Peter R. Ebeling[3], Eric Hesse[4], Nicola Napoli[5], Daria B. Crittenden[6], Maria Rojeski[6], Wenjing Yang[6], Cesar Libanati[7], Serge Ferrari[8]. [1]Columbia University, United States, [2]New Mexico Clinical Research & Osteoporosis Center, United States, [3]Monash University, Australia, [4]University Medical Center Hamburg-Eppendorf, Germany, [5]Campus Bio-Medico University of Rome, Italy, [6]Amgen Inc., United States, [7]UCB Pharma, Belgium, [8]Geneva University Hospital, Switzerland

BMD is a strong predictor of fracture (fx) risk in untreated patients. Recent evidence suggests that BMD achieved during treatment also reflects fx risk; thus, T-scores are being considered as a target to guide osteoporosis treatment. In ARCH (NCT01631214), romosozumab (Romo), an investigational bone-forming agent with a dual effect of increasing bone formation and decreasing bone resorption, followed by alendronate (ALN) had greater efficacy in fx risk reduction and BMD gains vs ALN alone (Saag NEJM 2017). Of note, a cardiovascular imbalance was observed with Romo in ARCH and a comprehensive assess-ment of these data is ongoing. Here we explored the relationship between T-scores achieved on-study after 1 year with Romo or ALN and subsequent fx risk.Postmenopausal women with osteoporosis and prior fragility fx were randomized 1:1 to receive Romo 210mg SC QM or ALN 70mg PO QW for 12 months, followed by open-label (OL) ALN 70mg PO QW for ≥12 months, with an event-driven primary analysis. We examined change from baseline in BMD and T-scores at 12 months and the relationship between total hip (TH) T-scores at month 12 and subsequent nonvertebral (NVT) fx rates. We also compared fxs in the OL period, including new vertebral (VT) fxs in year 2 (based on month 24 spine radiographs) and clinical, NVT, and hip fxs between arms in the full OL period.ARCH enrolled 4093 patients (2046 Romo, 2047 ALN); mean baseline T-scores were at the lumbar spine and –2.80 at the TH. 3465 patients (1739 Romo, 1726 ALN) received ≥1 OL ALN dose in the OL period (median 1.9 years follow-up). Mean TH BMD increased by 6.2% for Romo and 2.8% for ALN in the first year, with increases in T-score of 0.31 and 0.15, respectively. At month 12, the achieved TH T-score was associated with the 1-year NVT fx rate observed in the OL period (Figure) and the relationship was independent of the drug received in the first year. During the OL period, when all patients were on ALN, patients who received Romo first had a 75% lower relative risk of new VT fx (P<0.001), and had reductions in clinical (32%, P=0.001), NVT (19%, P=0.120), and hip (40%, P=0.041) fxs vs patients who received ALN first.Higher absolute TH T-scores achieved on therapy at month 12 resulted in subsequent lower fx risk regardless of the treatment recieved, with ongoing benefits from building a BMD foundation. These data support the concept of a T-score target to improve outcomes in osteoporosis treatment.

Breast Cancer Bone Metastases are Attenuated in a Tgif1-deficient Bone Microenvironment Marie-Therese Haider*, Hiroaki Saito, Eric Hesse, Hanna Taipaleenmäki. Molecular Skeletal Biology Laboratory, Department of Trauma, Hand and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Osteoclast activation is a hallmark of breast cancer-induced osteolytic bone disease. However, much less is known about the role of osteoblasts during this process. Our experiments revealed that osteoblast-conditioned medium stimulates breast cancer cell (BCC) migration in vitro (p<0.001), suggesting that osteoblasts may also play a role during early stages of bone metastasis. Furthermore, we identified the homeodomain protein TG-interacting factor-1 (Tgif1) as a strongly up-regulated molecule in osteoblasts upon stimulation by BCCs, indicating a potential role of Tgif1 in the osteoblast-BCC interaction. Indeed, conditioned medium from osteoblasts of mice bearing a germline deletion of Tgif1 (Tgif1-/-) failed to induce BCC migration compared to conditioned medium obtained from wild-type osteoblasts (p<0.05), suggesting that Tgif1 in osteoblasts supports the activation of BCC movement. To better understand this finding, we performed unbiased SILAC and RNA-seq analyses and identified Semaphorin 3E (Sema3E) to be abundantly expressed and secreted by Tgif1-/- osteoblasts. Recombinant Sema3E dose-dependently impaired BCC migration, suggesting that Tgif1 supports BCC migration by suppressing Sema3E expression in osteoblasts. To test the hypothesis that Tgif1 contributes to the initiation of metastatic bone disease in vivo, we employed a syngeneic metastasis model. In support of our hypothesis, bioluminescence imaging revealed a decreased number of bone metastases in Tgif1-/- mice compared to control littermates (36% vs. 56%, respectively) 7 days after intracardiac injection of 4T1-GFP-Luc BCCs. Consistently, the presence of single BCCs or micro-metastases in the tibiae was reduced by 25% in Tgif1-/- mice determined by confocal microscopy. Further histological analyses revealed that BCCs localize in close proximity to Endomucin-positive vascular cells and to osteoblasts. Although Tgif1-deficiency did not affect the number or size of the vessels in the bone marrow, the number and activity of osteoblasts

were reduced compared to control littermates (p<0.05). This suggests that the protective effect on bone metastases might be mediated by the osteoblasts and not by the bone marrow vasculature. In summary, we propose that lack of Tgif1 in osteoblasts attenuates cancer cell migration and metastases formation, possibly through suppression of Sema3E. Thus, our findings establish osteoblasts as important regulators during early stages of bone metastasis.

TGF-beta inhibition restores the responsiveness to osteoanabolic PTH treatment in the Crtap-/- model of recessive Osteogenesis Imperfecta Ingo Grafe*, Jennifer Zieba, Elda Munivez, Yuqing Chen, Ming-Ming Jiang, Brian Dawson, Carrie Jiang, Alexis Castellon, Joseph Sliepka, Sandesh Nagamani, Brendan Lee. Department of Molecular and Human Genetics, Baylor College of Medicine, United States

Osteogenesis Imperfecta (OI) is characterized by low bone mass and fractures, and better treatment options are needed. Most cases are caused by dominant type I collagen mutations. Mutations in CRTAP, involved in post-translational collagen modifications, cause severe recessive OI. Previously, we have shown that increased TGFb signaling is a key contributor to the phenotype in OI mouse models, including Crtap-/- mice.Intermittent PTH treatment increases BMD in patients with osteoporosis; however, in a randomized clinical trial, we have shown that PTH treatment does not improve aBMD in patients with severe forms of OI. Others have shown TGFb and PTH signaling interactions, e.g. that TGFb-in-hibition increases PTH signaling and bone mass. Our preliminary in vitro studies suggest that BMSCs of Crtap-/- mice, cultured in osteogenic conditions, exhibit an increased pS-mad2/Smad2 ratio (increased TGFb signaling), and reduced pCREB/CREB ratio, suggest-ing impaired PTH signaling.Hence, we hypothesized that inhibition of the increased TGFb signaling in Crtap-/- mice restores the osteoanabolic effects of PTH treatment. To test this hypothesis, we treated 8-week-old Crtap-/- and wild-type (WT) mice with PTH (40 µg/kg, 5x/week, s.c.), low-dose of the pan-TGFb neutralizing antibody 1D11 (Genzyme/Sanofi; 1mg/kg, 3x/week IP), or control treatment (vehicle/control antibody) for 4 weeks.MicroCT of femurs of control treated Crtap-/- mice showed reduced BV/TV (36% of WT control) and Cort.Th (88% of WT). In WT mice, PTH treatment increased BV/TV by 29% and Cort. Th by 7%. In contrast, in Crtap-/- mice PTH was less effective, only slightly increased BV/TV (by 4% to 40% of WT) and did not improve Cort.Th. Low dose 1D11 treatment in WT mice increased BV/TV (+49%) but Cort.Th was unchanged. In Crtap-/- mice 1D11 mod-erately increased BV/TV (to 57% of WT) and did not increase Cort.Th. Combined 1D11 and PTH treatment increased BV/TV (+66%) and Cort.Th (+5%) in femurs of WT mice. In Crtap-/- mice, combined 1D11 and PTH treatment synergistically restored BV/TV and Cort. Th to 96% and 93% of control WT mice, respectively.In summary, we show that inhibition of increased TGFb signaling restores responsiveness to intermittent PTH treatment in the Crtap-/- model of severe recessive OI. Because increased TGFb signaling also contributes to the skeletal phenotypes in dominant OI, combinatorial anti-TGFb and PTH treatment might be an attractive new treatment option for patients with OI.

Osteocyte Senescence Underlies the Increase in RANKL in Aged Mice via a GATA4 Mediated Mechanism Ha-Neui Kim,*[1], Srividhya Iyer[2], Jianhui Chang[2], Li Han[1], Aaron Warren[1], Stavros Manolagas[1], Charles O'Brien[1], Daohong Zhou[2], Maria Almeida[1]. [1]University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, United States, [2]University of Arkansas for Medical Sciences, United States

The accumulation of senescent cells causes age-related diseases and curtails longev-ity. Old mice exhibit increased number of senescent osteoprogenitors and osteocytes and markers of DNA damage. In addition, the expression of the senescence associated secretory phenotype (SASP) is elevated, as is the expression of RANKL in osteocyte enriched bone shafts. These changes are associated with accumulation of GATA4, a transcription factor that induces the SASP. Elimination of p16 expressing senescent cells in bone decreases osteo-clasts and increases bone mass in old mice. However, the cellular and molecular mechanisms mediating these effects remain unknown. Here, we examined whether cellular senescence caused by DNA damage and GATA4 activation could be responsible for the increase in RANKL with old age. We subjected cultured bone marrow-derived stromal cells to 10 Gy of γ-radiation (IR), an established inducer of DNA damage and senescence. After a few passages, the irradiated cells exhibited elevated senescence associated β-galactosidase ac-tivity, increased expression of GATA4 and RANKL. Similarly, exposure of ex-vivo cultures of osteocyte enriched cortical shafts, from young C57BL/6 mice, to IR caused an increase in γH2AX, a common marker of DNA damage. IR also increased the levels of GATA4 and RANKL. Overexpression of GATA4, using a retroviral vector, in primary osteoblastic cells or the MLO-Y4 osteocytic cell line increased RANKL and other elements of the SASP including IL-1α and MMP13. To test whether elimination of senescent cells in old mice altered RANKL levels, we administered the senolytics ABT263 (40 mg/kg body weight), or Bcl-PROTAC (40 mg/kg body weight) for 30 days to 24-month-old female mice. Bone marrow stromal cells from the femurs were cultured in the presence of osteogenic medium for 10 days to collect mRNA. Both the stromal cell cultures and osteocyte-enriched shafts

from mice treated with ABT263 or Bcl-PROTAC had decreased markers of senescence and lower transcript levels of RANKL compared to mice treated with vehicle. Our findings indi-cate that RANKL is part of the SASP in cells of the osteoblast lineage and that the increase in RANKL with age is caused by DNA damage and GATA4 activation. Together with evidence, presented elsewhere in this meeting, showing that RANKL deletion in osteocytes prevents the loss of cortical bone with aging, this work demonstrates that senescence in osteocytes is a critical mechanism of skeletal aging.

BLU-782; a highly selective ALK2 inhibitor, designed specifically to target the cause of fibrodysplasia ossificans progressiva Alison Davis*[1], Brian Hodous[2], Timothy Labranche[1], Michael Sheets[1], Natasja Brooijmans[1], Joseph Kim[1], Brett Williams[1], Sean Kim[1], Lan Xu[3], John Vassiliadis[1], Julia Zhu[1], Ruduan Wang[1], Rachel Stewart[4], Paul Fleming[5], Chris Graul[4], Elliot Greenblatt[4], Keith Bouchard[6], Vivek Kadambi[1], Timothy Guzi[1], Jeffrey Hunter[6], Christoph Lengauer[1], Marion Dorsch[1], Andrew Garner[1]. [1]Blueprint Medicines, United States, [2]Accent Therapeutics, United States, [3]Foghorn Therapeutics, United States, [4]Inviro, United States, [5]Akebia Therapeutics, United States, [6]Alexion Pharmaceuticals, United States

Therapies that precisely target the causative disease driver can lead to profound clinical benefit, while minimizing the potential for off-target toxicities. Fibrodysplasia ossificans progressiva (FOP) is a rare, severely disabling and ultimately life-shortening disease. FOP is characterized by episodic soft tissue edema (flares), and the progressive replacement of skeletal muscle and connective tissue by heterotopic bone. FOP is caused by a gain-of-func-tion mutation in ACVR1, which encodes activin-like kinase 2 (ALK2). The most common ALK2 mutation identified in FOP is R206H, which imparts hypersensitivity to BMPs and a neomorphic response to activins.Here we describe the generation and characterization of a highly selective ALK2 inhibitor, designed specifically to target the underlying genetic driver of FOP. To achieve this, we analyzed the Blueprint Medicines proprietary small molecule library, which is annotated against 392 human kinases, for selective ALK2-binding com-pounds. This analysis identified a novel series of compounds, that exhibited a unique ALK2 selectivity profile. Using structure-guided drug design, we optimized the potency, selectiv-ity and pharmaceutical properties of the initial leads to generate BLU-782. Biochemical kinome profiling demonstrated BLU-782 preferentially bound ALK2 with high affinity. In cells, BLU-782 potently inhibited ALK2R206H, while it did not significantly inhibit ALK1, ALK3 or ALK6 activity.The in vivo activity of BLU-782 was evaluated using a condition-al knock-in ALK2R206H transgenic mouse model, which develops soft tissue edema, in-flammation and heterotopic ossification (HO) upon mechanical muscle injury. When dosed prophylactically, BLU-782 inhibited edema and prevented cartilage and bone formation without impacting body weight. Moreover, histological analysis of untreated ALK2R206H mice identified muscle breakdown, endochondral cartilage and heterotopic bone at the injury site. Conversely, in BLU-782-treated ALK2R206H FOP mice, heterotopic bone was absent, while organized muscle repair and regrowth were frequently observed. This establishes that selective ALK2 inhibition in ALK2R206H FOP mice prevents the formation of heterotopic bone and enables skeletal myofiber regeneration to proceed to restore muscle architecture. Collectively, these data demonstrate the selectivity and in vivo activity of the investigational agent BLU-782 and support its progression into clinical development.

Estrogen Deficiency and Cellular Senescence Represent Independent Mechanisms in the Pathogenesis of Osteoporosis: Evidence from Studies in Mice and Humans Joshua Farr*, David Monroe, Daniel Fraser, Brittany Negley, Brianne Thicke, Jennifer Onken, Robert Pignolo, Tamar Tchkonia, James Kirkland, Sundeep Khosla. Mayo Clinic, United States

Estrogen (E) deficiency is a seminal mechanism in the pathogenesis of osteoporo-sis. Mounting evidence, however, indicates that cellular senescence, a fundamental aging mechanism that drives multiple age-related diseases, also causes osteoporosis. Recently, we systematically identified an accumulation of senescent cells, characterized by increased p16Ink4a and p21Cip1 levels, in mouse bone with aging. We also found similar results in bone biopsies from older vs younger women, indicating parallel findings in humans. We then demonstrated that senescent cells mediate age-related bone loss using multiple approaches, e.g., treating wild-type (WT) mice with "senolytics" (i.e., drugs that eliminate senescent cells) and reducing senescent cell burden using mice expressing the INK-ATTAC "suicide" transgene via drug (AP20187)-inducible caspase-8 driven by the senescence-associated p16Ink4a promoter. These approaches improved bone mass and strength by suppressing bone resorption and stimulating bone formation. Here, we investigate a possible role for E in the regulation of senescence in bone. In adult (4-month) WT mice, 8 wks post ovariectomy (OVX, n=15) or orchidectomy (ORCH, n=15), we found no changes in p16Ink4a or p21Cip1 mRNA levels in bone vs sex-matched WT mice that underwent sham surgery (SHAM, n=15/sex). We next obtained human bone biopsies from 40 healthy postmenopausal women ran-domized to either placebo (PL, n=20, 73±6 yrs) or short-term E (STE, n=20, 71±5 yrs) thera-py for 3 wks. As compared to PL, STE therapy had no effect on p16Ink4a or p21Cip1 mRNA

levels in human bone. Finally, we randomized 4-month-old female INK-ATTAC mice to SHAM+vehicle (SHAM+VEH, n=11), OVX+VEH (n=10), or OVX+AP20187 (n=17) for 8 wks. As anticipated, OVX+VEH caused bone loss as compared to SHAM+VEH. However, treatment with AP20187, which eliminates senescent cells in INK-ATTAC mice, did not rescue the OVX-induced bone loss (Figure). In addition, there was no evidence of changes in senescence biomarkers, including p16Ink4a, p21Cip1, and EGFP (encoded by the INK-AT-TAC transgene), in response to AP20187. Collectively, our data establish that E deficiency and cellular senescence represent independent mechanisms in the pathogenesis of osteoporosis. Moreover, these findings have important implications for testing novel senolytics for skeletal efficacy, as these drugs will need to be evaluated in models of aging, as opposed to the current FDA model of prevention of OVX-induced bone loss.

Lower CYP27B1 expression impairs osteoblasts activity in adolescent idiopathic scoliosis – a new insight to improve bone quality by vitamin D supplementation

Jia Jun Zhang*[1,2], Yujia Wang[1,2], Carol Cheng[1,2], Tsz Ping Lam[1,2], Bobby Kin-Wah Ng[1,2], Jack Chun-Yiu Cheng[1,2], Wayne Yuk-Wai Lee[1,2]. [1]Department of Orthopaedics and Traumatology, SH Ho Scoliosis Research Laboratory, The Chinese University of Hong Kong, Hong Kong, [2]Joint Scoliosis Research Center of the Chinese University of Hong Kong and Nanjing University, The Chinese University of Hong Kong, Hong Kong

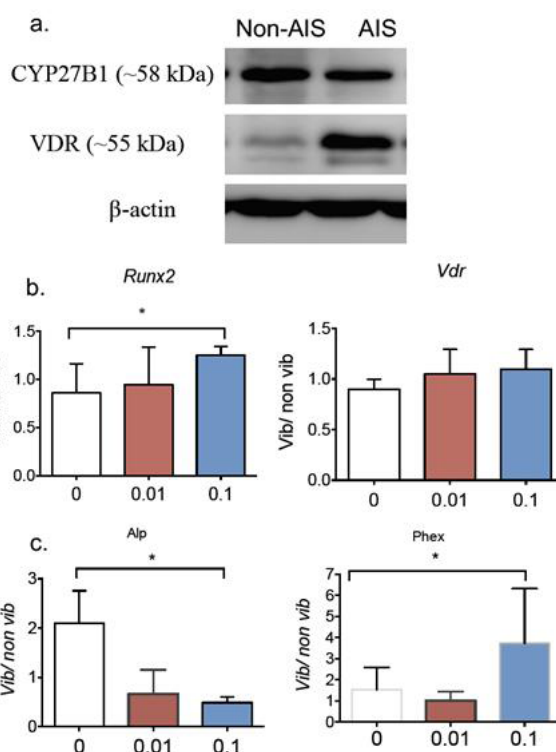
Purpose: Altered bone mass and microstructure are associated with curve progression of AIS. Previous studies reported lower serum VitD level and association between polymorphism in VitD receptor (VDR) and low bone mass in AIS. The preliminary finding of our randomized controlled clinical trial (RCT) demonstrated that bone quality improvement by vitamin D (VitD) and calcium supplementation could result in lower chance of curve progression to surgical threshold. Another RCT study showed that AIS subjects with higher serum VitD (>40 nmol/L) showed enhanced response to whole body vibration. These findings suggest that VitD and related metabolic pathway could be candidates underlying low bone mass in AIS. Method: This study aimed to study the effect of VitD on the cellular activities of primary osteoblasts and osteocytes derived from AIS patients and control subjects. Primary osteoblasts were isolated from iliac crest trabecular bone biopsies from 10 AIS patients undergoing spinal fusion and 4 age-matched control subjects undergoing respective orthopaedic surgery. Primary osteocytes culture was derived by culturing the osteoblasts in 3D collagen gel. Protein level of CYP27B1 and VDR of osteoblasts were determined by Western blot. The osteoblasts and osteocytes were treated with 1, 25-dihydroxyvitamin D3(1,25-VitD) at different concentrations (0, 10, 100 nM) for 7 days with or without vibration (0.3g, 35 Hz, 20 minutes daily). mRNA level of representative osteoblast and osteocyte markers were determined with qPCR. Mann-Whitney test was used for statistical analysis. Result: AIS osteoblasts had lower protein level of CYP27B1 but higher VDR when compared with the control. Therefore, AIS osteoblasts were more sensitive to 1,25-VitD treatment. Vibration enhanced the response of AIS osteoblasts and osteocytes to 1,25-VitD treatment as indicated by up-regulation of Runx2, Alp, Spp1, Bglapand VdrmRNA in primary osteoblasts, and Spp1, Phex, Cx43and E11mRNA in primary osteocytes. Conclusion: This is the first in vitroevidence showing intrinsically lower ability of CYP27B1 mediated Vit-D activation in AIS osteoblasts, which is speculated to limiting the response of AIS to Vit-D despite higher VDR expression. The additive effect of vibration on 1,25-VitD treatment in AIS is in line with our clinical observation. Taking together, our findings partly support the notion to improve bone quality in AIS subjects with Vit-D supplementation which could be enhanced by WBV.


Figure a. Representative image of western blot result of CYP27B1 and VDR
b. mRNA level of representative osteoblast markers in primary osteoblast from AIS and control
c. mRNA level of representative osteocyte markers in primary osteocyte from AIS and control

Age at Peak Fracture Rate Depends on Fracture Type and Trabecular/Cortical Dominance of Fracture Site – Expanding Explanations of Peak Fracture Rate beyond Lag in Mineralization

Bjorn Rosengren*, Daniel Jerrhag, Magnus Karlsson. Clinical and Molecular Osteoporosis Research Unit, Departments of Orthopedics and Clinical Sciences, Skane University Hospital and Lund University, Sweden

BACKGROUNDEarly research on childhood fractures has shown differences in peak fracture rate in boys and girls and between fracture types. Studies have pointed to a major explanatory role of the mineralization lag found during rapid growth, as the two coincide, at least for wrist fractures. This explanation is often used also for other fracture types, however with questionable support in literature.We therefore sought to examine recent age rate patterns of fractures in general, specific fracture types and of fractures located mainly in cortical or mainly in trabecular bone .METHODSBy use of official in- and out-patient record data for children (≤ 20 years) in Sweden (Skåne region), we ascertained fractures during 3.5 million person-years (py) 1999-2010. To compare age rate patterns between fracture types we normalized the age specific rates within each fracture type to the highest incidence of that specific fracture type.RESULTSWe found 71,525 fractures during 3.5 million py corresponding to an overall fracture incidence rate of 205 per 10,000 py (boys 254, girls 155).Wrist fractures and hand fractures together accounted for 50% of all fractures. Age rate patterns and age at peak incidence were different between boys and girls, between the 20 examined fracture types and between cortical fractures (examples in top panel of Fig) and trabecular fractures (examples in bottom panel of Fig). Peak fracture age occurred at 13 years for any fracture (boys 14, girls 11) but ranged from 2 to 19 depending on the specific fracture type.The incidence rate ratio (IRR) between boys and girls for any fracture was 1.6 (95% CI 1.6, 1.6). The highest boy to girl IRR was found for fractures of the skull (2.8 [2.6, 3.0]), femur diaphysis (2.6 [2.2, 3.1]) and scapula (2.5 [1.8, 3.7]). The only fracture type more common in girls was of the proximal humerus (0.8 [0.7, 0.9]).CONCLUSIONAge at peak incidence and age rate patterns are different between boys and girls, between fracture types and between fractures in cortical and trabecular bone. The results challenge the widespread notion that age at peak fracture incidence is determined by the lag in mineralization

during rapid growth and indicate that other factors, such as physical activity patterns and risk taking behavior are important.

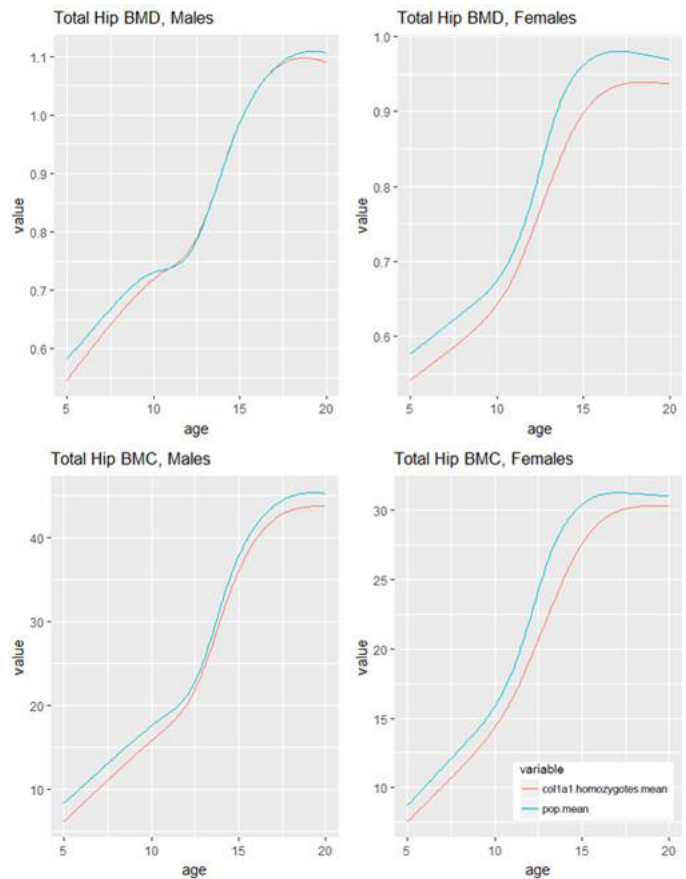
The COLIA1 Sp1 Variant and Bone Accrual in Childhood Diana Cousminer*[1], Shana Mccormack[1], Jonathan Mitchell[1], Alessandra Chesi[1], Joan Lappe[2], Heidi Kalkwarf[3], Sharon Oberfield[4], Vicente Gilsanz[5], John Shepperd[6], Andrea Kelly[1], Benjamin Voight[7], Babette Zemel[1], Struan Grant[1]. [1]Children's Hospital of Philadelphia, United States, [2]Creighton University, United States, [3]Cincinnati Children's Hospital, United States, [4]Columbia University, United States, [5]Children's Hospital of Los Angeles, United States, [6]University of Hawaii, United States, [7]University of Pennsylvania, United States

Over two decades ago, a low frequency variant (rs1800012) in an Sp1 binding site within the first intron of the type I collagen alpha 1 (COLIA1) gene was reported to be associated with osteoporotic fracture. The influence of this variant is known to vary with age: it only moderately influences adult peak bone mineral density (BMD) but has a relatively pronounced effect in the high bone turnover state of postmenopausal bone loss (Uitterlinden et al, NEJM 1998). Another high bone turnover period is during childhood and adolescence; however, the role of rs1800012 is unclear in this setting. We assessed association between rs1800012 and areal-BMD (aBMD) and bone mineral content (BMC) Z-scores at multiple skeletal sites in the Bone Mineral Density in Childhood study, a mixed-longitudinal, densely phenotyped cohort of healthy children and adolescents (n=1,419). We tested a recessive model using a mixed random effects method accounting for multiple measurements (1-7 annual per subject), adjusting for relevant covariates, in both sex-specific and combined settings. We then tested for pubertal stage interactions in pre-pubertal (Tanner stage (TS) 1), pubertal (TS 2-4), and post-pubertal (TS 5) groups. Finally, SITAR modeling was used in girls and boys separately for each skeletal site; this method reduces complex growth curves into three parameters representing the a-size, b-timing, and c-velocity of bone accrual, and we tested the difference between genotype groups using t tests for each parameter. We found that AA-genotype carriers had significantly lower aBMD and BMC at all skeletal sites prior to puberty, with an effect that was attenuated by TS 5, reflecting significant puberty interactions (e.g. hip neck aBMD P=2x10-6). AA carriers began bone accrual later than their peers (later b-timing; e.g. total hip BMC P=0.005), and had slower accrual during puberty (slower c-velocity; e.g. total hip BMC P=0.04), particularly in girls, and most markedly at the total hip (Fig.1) and femoral neck. Our data suggest that rs1800012 principally affects bone density in a context-specific manner, i.e. during periods of high turnover, both in early and late life, when estrogen levels are low or absent. Investigating the interaction between genetics, maturational phase, and the hormonal milieu can therefore yield important insights into bone gain and loss that may be masked during the relatively quiescent state in adulthood.


1083

Reliability of annual changes and monitoring time intervals for bone strength, size, density and micro-architectural development at the distal radius and tibia in children: A 1-year HR-pQCT follow-up Amy Bunyamin*[1], Kelsey Björkman[2], Chantal Kawalilak[1], Seyedmahdi Hosseinitabatabaei[3], Adrian Teare[1], James Johnston[1], Saija Kontulainen[2]. [1]Department of Mechanical Engineering, College of Engineering, University of Saskatchewan, Canada, [2]College of Kinesiology, University of Saskatchewan, Canada, [3]Division of Biomedical Engineering, College of Engineering, University of Saskatchewan, Canada

High-resolution peripheral quantitative computed tomography (HR-pQCT) imaging, together with computational finite element (FE) analysis, offers an attractive method of non-invasively quantifying bone strength development in children. However, evidence of annual change and error in repeated HR-pQCT measures in children are limited, and time intervals required to reliably capture change in pediatric bone strength and micro-architecture have not been defined. Study purposes were to: 1) Quantify annual changes in bone properties at the distal radius and tibia in children; 2) characterize observed mean change in contrast to reported pediatric precision errors (Kawalilak et al. 2017); and 3) estimate monitoring time intervals (MTIs) required to reliably characterize growth and development in bone properties at the distal radius and tibia of children. We analyzed distal radius (7% of ulnar length) and tibia (8% site) bone properties from 38 typically developing children (22 girls; mean baseline age: 10.6 years) obtained from HR-pQCT scanning and FE analysis at baseline and after 1-year. We characterized mean annual changes (via paired t-tests) and contrasted changes in relation to pediatric precision errors. We estimated MTIs based on median annual changes and precision errors. Annual increases (and MTIs) in bone strength (failure load, stiffness, apparent modulus, ultimate stress), total area, cortical thickness and density ranged between 3.2-27.3% (MTIs: 0.5-4.9 years) at the distal radius and 2.5-16.3% (0.5-3.1 years) at the distal tibia. Trabecular area and cortical porosity decreased 2.4% and 22.0% at the distal radius, respectively, and 1.3% and 7.9% at the distal tibia. Observed bone changes exceeded their respective precision errors. MTIs ranged between 0.5-∞ years at the distal radius and 0.4-8.1 years at the distal tibia. Increased bone strength coincided with cortical bone growth, bone consolidation and trabecular coalescence at distal bone ends in children. Estimated MTIs indicated that changes in bone strength and micro-architecture

(cortical and trabecular thickness, density, cortical porosity) can be reliably monitored in 1 to 2 year intervals in children.

Glycemic Control Influences Trabecular Microarchitecture in Youth with Type 1 Diabetes Deborah Mitchell*[1], Signe Caksa[2], Amy Yuan[2], Mary Bouxsein[2], Madhusmita Misra[1]. [1]Pediatric Endocrine Unit, Massachusetts General Hospital, United States, [2]Endocrine Unit, Massachusetts General Hospital, United States

Fracture risk is elevated in patients with type 1 diabetes (T1D) throughout the lifespan, but the etiology of this risk remains poorly understood. As DXA-based aBMD alone does not explain the increased fracture risk, we hypothesized that bone microarchitecture and trabecular morphology are negatively altered in youth with T1D and that these alterations are influenced by glycemic control as assessed by hemoglobin A1c (HbA1c). We conducted a cross-sectional study of girls ages 10-16 years (62 with T1D and 60 controls). We measured microarchitecture by high-resolution peripheral quantitative computed tomography (HR-pQCT) and trabecular morphology by individual trabecular segmentation (ITS) at the distal radius (7% site) and distal tibia (8% site). We estimated bone strength with micro-finite element analysis. The mean age at diagnosis of T1D was 8.8 ± 3.0 years and the mean duration of disease was 4.8 ± 3.2 years; no subject had microvascular complications. Median HbA1c in the T1D group was 8.5%. The groups were well-matched for age, bone age, pubertal stage, and height. Weight was higher in T1D (Z-score 0.7 ± 0.8 vs. 0.4 ± 0.9, p=0.050), and serum 25OHD was lower (26 ± 8 vs. 33 ± 10 ng/mL, p<0.001). We observed no differences in aBMD at the whole body, spine, hip, or radius. At the distal tibia, subjects with T1D had lower bone volume fraction (BV/TV) (p=0.012) and trabecular thickness (p=0.025), with lower plate BV/TV (p=0.009) and axial BV/TV (p=0.010) (adjusted for bone age, height, and weight). As shown in Figure 1, after dividing the T1D subjects into those at or below vs. those above the median HbA1c, only those with a high HbA1c (>8.5%) had significantly different microarchitecture and morphology compared to controls, including a 9.5% lower BV/TV and a 19.5% lower plate BV/TV (p=0.007 for both comparisons). Micro-finite element analysis revealed a significantly lower failure load in T1D, again limited to those with a high HbA1c (7.1% lower, p=0.012). After further adjustment for 25OHD, the association of high HbA1c with trabecular parameters and failure load was attenuated but remained significant. We observed no significant differences in trabecular indices or failure load at the distal radius though numerically these were all lower in the T1D group. In summary, in girls with T1D, hyperglycemia is associated with unfavorable trabecular microarchitecture and morphology early in the course of disease and may contribute to diabetic skeletal fragility.

A common SNP in the CYP2R1 promoter decreases transcriptional activity and is associated with low serum 25(OH)D levels and reduced responsiveness to vitamin D supplementation. Jeffrey Roizen*[1], Alex Casella[2], Caela Long[1], Zahra Tara[1], Meizan Lai[1], Hakon Hakonarson[1], Michael Levine[1]. [1]The Children's Hospital of Philadelphia, United States, [2]University of Maryland, United States

Optimal bone and mineral metabolism, as well as immune and cardiovascular function, depend on normal vitamin D metabolism. Ineffective sunlight exposure and inadequate dietary vitamin D each have well understood roles in the pathophysiology of vitamin D deficiency; however, the extent to which common polymorphisms in genes encoding vitamin D metabolizing enzymes contribute to vitamin D homeostasis remains undefined.

Several genome wide association studies (GWAS) have identified significant associations between serum [25(OH)D] and single nucleotide polymorphisms (SNPs) in or near the locus for CYP2R1, the gene encoding the principal vitamin D 25-hydroxylase enzyme. By targeting DNAse hypersensitivity sites we identified rs7949459 as a SNP that is likely in a transcription factor binding site. This SNP is in high linkage disequilibrium with the commonly nearby SNPs identified in GWAS for 25(OH)D (for each of rs10500804, rs10741657, and rs10766192, D > 0.98). Using a promoter reporter we found that the minor allele of this SNP causes a greater than 80% decrease in reporter activity. We used CRISPR/Cas9 to generate iPSCs that were homozygote major, homozygote minor and heterozygote at this allele and differentiated these iPSCs into hepatocytes. In iPSCs differentiated to hepatocytes presence of the minor allele significantly decreased CYP2R1 mRNA and 25-hydroxylase activity. Consistent with the idea that this effect was due to changes at rs7949459 rather than off-target effect, the genotype at this allele caused no differences in promoter reporter activity. In a pediatric cohort, presence of a single rs7949459_T allele (the minor allele) was associated as a continuous variable with 25(OH)D (beta= 0.35, SE=0.15, p=0.02). Similarly, the rs7949459_T allele was more common in decreased responders to supplementation (chi-squared analysis p < 0.03). Thus, our genetic and cell-based studies provide evidence that this common genetic variation in CYP2R1 has significant effects on CYP2R1 transcription, and rovide a functional context for interpreting GWAS that show relationships between circulating 25(OH)D and CYP2R1.

YAP and TAZ deletion in mature osteoblasts reduce bone formation and increase marrow adipocyte accumulation Mengrui Wu*[1], Joshua Chou[2], Dorothy Hu[1], Kenichi Nagano[1], Daniel Brooks[3], Mary Bouxsein[3], Francesca Gori[1], Roland Baron[1]. [1]Harvard School of Dental medicine, United States, [2]University of Technology Sydney, Austria, [3]Beth Israel Deaconess Medical Center, United States

YAP and TAZ are transcriptional effectors of Hippo signaling, regulating cell fate, tissue development and homeostasis. YAP and TAZ have redundant functions and are often referred as YAP/TAZ, although some distinct functions of YAP or TAZ have been reported. Furthermore, no specific ligands or receptors have been identified that regulate the Hippo cascade. Importantly however the activity of the two key effectors of Hippo signaling, YAP and TAZ, can also be regulated by Wnt signaling. Given that Wnt signaling is one of the most dominant anabolic pathways in bone, interactions between WNT signaling and YAP and/or TAZ may contribute to skeletal homeostasis. To test this hypothesis, we generated mice lacking YAP and/or TAZ in mature osteoblasts. YAPf/fTAZf/fBglap-Cre (DKO), YAPf/fBglap-Cre (YAP CKO) and TAZf/fBglap-Cre (TAZ CKO) mice develop normally and have similar body weight compared to their YAPf/fTAZf/f, YAPf/f or TAZf/f littermates. Double deletion of YAP and TAZ leads to a marked decrease in trabecular number, cortical bone area and cortical thickness as indicated by mCT analysis in 12-week-old mice. Intriguingly, YAP CKO affects only trabecular bone, while TAZ CKO affects mostly cortical bone, revealing for the first time unique functions of these two Hippo effectors in bone. Consistently, histomorphometric analysis shows that DKO female mice display a significant decrease in bone formation rate (BFR/BS = 0.78 ± 0.11 vs 1.19 ± 0.03 μm3/μm2/year, p=0.02), while osteoblast and osteoclast numbers remain similar. Active β-catenin levels are largely reduced in DKO long bones and primary osteoblasts, indicating that YAP and TAZ are required for proper canonical Wnt signaling activation. Interestingly, DKO mice also display an increased accumulation of marrow adipocytes and mesenchymal stem cells (MSC) isolated from DKO mice marrow have decreased osteoblast differentiation potency and increased adipocyte differentiation potency, as indicated by alkaline phosphatase and Oil red O staining, respectively. These findings suggest that YAP and TAZ activity is involved in MSCs cell fate decision between osteoblasts and adiocytes.Given that modulation of the WNT signaling cascade is a target for anabolic treatment in diseases associated with bone loss and fragility, identifying novel signaling cascades interacting with WNT signaling may help understand how WNT affects bone homeostasis and open novel therapeutic avenues for the treatment of skeletal diseases.

The Wnt Agonist R-spondin 3: An Unexpected Negative Regulator of Bone Formation Kenichi Nagano*[2], Kei Yamana[2], Hiroaki Saito[2], Virginia Parkman[2], Jun Guo[1], Henry Kronenberg[1], Francesca Gori[2], Roland Baron[2]. [1]Endocrtine Unit, Massachusetts General Hospital, United States, [2]Division of Bone and mineral Research, Harvard Medical School and Harvard School of Dental Medicine., United States

Wnt signaling regulates cell proliferation, differentiation and function and its activation exerts a positive action on bone homeostasis. R-spondins (RSpos), cysteine-rich secreted glycoproteins, have been shown to promote canonical Wnt signaling in vitro. Accordingly, RSpos are expected to exert a positive influence on bone formation and mass. Despite the biological and therapeutic importance of Wnt signaling in bone, RSpo molecular mechanisms of action in bone remains elusive.Among the 4 RSpos, RSpo3 is highly expressed in bone and has been found associated with bone density in several GWA studies. We therefore

explored its role and mechanism of action in skeletal homeostasis. While global deletion of RSpo3 resulted in embryonic lethality at E10.5, before skeletal development, RSpo3+/- mice develop normally and are healthy. Contrary to our expectations, Rspo3 haploinsufficiency led to a significant increase in trabecular (but not cortical) bone mass in both genders and at several time points. Dynamic histomorphometry showed that this gain of bone mass was due to a 4X increase in BFR/BS (23.4 ± 12.7 vs 108 ± 14.3, $p < 0.01$) and osteoblast (OB) number (2.22 ± 0.15 vs 8.52 ± 1.33, $p < 0.01$) whereas osteoclast (OC) number was not altered (0.36 ± 0.05 vs 0.44 ± 0.09, NS). FACS analysis demonstrated a marked increase in the Lin-CD45-CD31-CD51+Sca1+ mesenchymal stem cell (MSC) population in the bone marrow of Rspo3+/- mice (0.36 ± 0.07 vs 0.66 ± 0.09, $p < 0.05$). These MSCs have a higher OB potential, as indicated by CFU-F and CFU-OB assays. Remarkably, absence of RSpo3 in E9.5 MEFs, resulted in a significant activation of ERK signaling and an unexpected increase in canonical Wnt signaling that, in turn, leads to accelerated OB differentiation. Inhibition of canonical Wnt signaling by Dkk1, while preventing canonical Wnt signaling activation in wt cells showed significantly less inhibitory potential in RSpo3-deleted cells. This finding was confirmed in vivo with RSpo3 haploinsufficiency partially preventing the decrease in BFR and BV induced by Dkk1 targeted overexpression in OBs.Thus, our findings reveal a novel and unexpected function of RSpo3 as a negative regulator of bone formation and indicate that, despite its co-activating function for canonical Wnt signaling, RSpo3 exerts a negative influence on bone homeostasis. This negative effect is, at least in part, exerted via the ERK pathway and the enhancement of Dkk1 inhibitory activity.

EZH2 is Regulated by the MiR-23a Cluster to Maintain Bone Mass In Vivo
Benjamin Wildman*, Tanner Godfrey, Mohammad Rehan, Yuechuan Chen, Quamarul Hassan. University of Alabama at Birmingham, Institute of Oral Health Research, United States

Differentiation of pre-osteoblasts is critical to controlling in-vivo development and growth of bone. Recent studies highlight the importance of epigenetic regulation in directing osteoblast commitment and function. Here we show that the microRNA-23a cluster (miR-23a, 27a, and 24-2) controls bone mass in-vivo through a previously unknown EZH2 mediated epigenetic mechanism.First, we knocked down the miR-23a cluster in mouse pre-osteoblasts (MC3T3-E1) cells with an anti-microRNA cassette (miRZIP). Next, we created a mouse model that inducibly expresses the miRZIP cassette to knock-down the microRNA cluster (miR-23aClZIP) in-vivo. Luciferase and Chromatin Immunoprecipitation (ChIP) assays along with RNA sequencing were performed to elucidate the mechanism of miR-23a cluster action in maturing osteoblasts.MiR-23a cluster knockdown increased the intensity of Alkaline Phosphatase staining in MC3T3-E1 cells. Additionally, it upregulated mRNA expression of osteogenic marker genes such as Runx2 and Osteocalcin. Micro-CT analysis of 2 month old femurs showed that trabecular bone volume and trabecular number significantly increased in miR-23aClZIP mice as compared to controls. Additionally, connective density and trabecular thickness were significantly greater while trabecular space was significantly decreased. Supporting this increased bone mass, Runx2 expression levels were significantly upregulated while the levels of a potent epigenetic repressor Ezh2 were significantly reduced in whole bone RNA sequenced from miR-23aClZIP mice. Mechanistically, we found that the miR-23a cluster inhibits RUNX2 translation by binding to the 3' UTR of Runx2 mRNA transcripts. Furthermore, ChIP assays revealed RUNX2 binds to the Ezh2 promoter inhibiting transcription in MC3T3-E1 cells. Additional ChIP experiments in miR-23aClZIP mouse primary calverial pre-osteoblasts showed that miR-23a cluster knockdown results in decreased binding of the epigenetic repressor EZH2 to osteogenic gene promoters such as Osteocalcin and Runx2, resulting in a more osteogenic transcription program. We developed a novel microRNA cluster knockdown mouse model allowing us to decipher how the miR-23a cluster orchestrates bone mass maintenance in-vivo.

Versatile Transcriptional Co-Factor Jab1 is Required for Osteoblast Differentiation and Postnatal Bone Growth
William Samsa*, Murali Mamidi, Lindsay Bashur, David Danielpour, Guang Zhou. Case Western Reserve University, United States

Jab1 (Jun activation domain-binding protein 1), also known as Cops5/Csn5, is the fifth subunit of the highly conserved macromolecular complex the COP9 Signalosome. Jab1 plays crucial roles in regulating proliferation, apoptosis, and differentiation. We previously reported that the loss of Jab1 specifically in mouse osteochondral progenitor cells of the limb buds, using a Prx1-cre driver, results in drastically shorter limbs, with highly disorganized epiphyseal growth plates and a severely reduced number hypertrophic chondrocytes. We found increased apoptosis as measured by TUNEL staining and cleaved Caspase 3 IHC in the growth plates of mutant mice. Real-time qPCR analysis of osteoblasts from these mutant mice showed reduced expression of osteoblast differentiation markers. Micromass cultures of E12.5 Jab1-null limb bud cells displayed significantly reduced BMP reporter activity, and decreased expression of Sox9 and its downstream targets. Thus, Jab1 is a master regulator of limb development in mice. To determine the specific role of Jab1 in osteoblast differentiation and postnatal bone growth, we generated a novel mouse model in which Jab1 is deleted specifically in osteoblast precursor cells under the control of the Osterix-cre (Osx-cre) promotor.

These mutant mice appeared normal at birth, but developed progressively worsening dwarfism. Importantly, all of these mutant mice die prior to weaning age. Histological analysis of long bones revealed a disorganized epiphyseal growth plate with a reduced hypertrophic zone in the mutant mice. H&E staining revealed a reduced amount of primary trabeculae, delayed and impaired secondary ossification center formation, and altered bone marrow cellularity that is reminiscent of pancytopenia. Moreover, we show that in ex vivo cultures of primary calvarial osteoblasts, Jab1 is expressed at both the early and late stages of osteoblast differentiation, and that the loss of Jab1 resulted in impaired osteoblast differentiation and reduced mineralization. Furthermore, the loss of Jab1 in primary calvarial osteoblasts resulted in lower phospho-SMAD1/5 expression, indicating reduced BMP signaling activity. Additionally, shRNA knockdown of Jab1 in the preosteoblastic cell line MC3T3 led to a decreased level of Osterix. Thus, Jab1 is necessary for osteoblast differentiation and postnatal bone growth, likely through positively regulating BMP signaling and other master transcriptional factors, such as Osterix.

Transcription Factor 7 like 2 (TCF7L2) is a Novel Regulator of Osteoblast Functions and Peak Bone Mass in Mice
Chandrasekhar Kesavan*[1], Nagraj Puppali[2], Nikita Bajwa[2], Subburaman Mohan[1]. [1]VA Loma Linda Healthcare System, Loma Linda University, United States, [2]VA Loma Linda Healthcare System, United States

It is now well recognized that peak bone mass attained early in life is an important factor affecting the risk of osteoporosis in later years. While the importance of transcription factors such as Runx2 and Osterix in the regulation of osteoblast (OB) development and attainment of peak bone mass is well known, our understanding of transcriptional regulation of OB commitment and differentiation is incomplete. In our effort to identify transcription factors (TFs) that are critical for OB differentiation, we found that expression of TCF7L2, an early acting TF whose mutations have been associated with various clinical diseases, increases several-fold during OB differentiation, in vitro. To elucidate the role of TCF7L2 in OBs, we generated mice with conditional disruption of TCF7L2 in OBs by two generation breeding of TCF7L2 floxed mice and Col1α2-Cre mice. All of the pups that were homozygous for the TCF7L2 floxed allele and were Cre positive died either during pregnancy or immediately after birth. Alizarin red staining of skeletons of homozygous TCF7L2 conditional knockout (cKO) pups prior to birth revealed smaller size bones with compromised mineralization. We, therefore, evaluated the skeletal phenotype of heterozygous 4-5 week old cKO mice by micro-CT. Trabecular (Tb) bone volume of the femur was reduced by 30% ($P < 0.01$) in both male and female TCF7L2 heterozygous cKO mice compared to control littermates, mediated by reduced Tb number and thickness and increased Tb separation. In addition, the bone size at the mid-diaphysis of the femur was reduced by 25% ($P < 0.01$). To determine the mechanism for reduced trabecular bone, we evaluated the consequence of knockdown of TCF7L2 expression by treating floxed OBs with adenoviral iCre and found reduced proliferation (25%, $P < 0.05$) as well as differentiation (40%, $P < 0.05$). To identify TCF7L2 target genes, we searched for the presence of putative TCF7L2 regulatory motifs in the promoter region of genes involved in OB differentiation and identified members of the Wnt signaling pathway as direct targets of TCF7L2. We found that expression levels of Wnt1, Wnt16, β-catenin and Axin were reduced by 30-60% ($p < 0.05$) in OBs-derived from heterozygous cKO mice vs. control mice. In conclusion, our findings provide the first evidence that TCF7L2 is a key regulator of OB functions, in vitro and in vivo that acts in part via regulating the expression of Wnt family members.

Osteoblast-intrinsic IRE1a/XBP1s Signaling Regulates Bone Development and Bone Marrow Homeostasis
Hongjiao Ouyang*[1], Shankar Revu[2], Kai Liu[2], Yuqiao Zhou[2], Qi Han[1], Faisal Alshalawy[1], Yuji Mishina[3], Alejandro Almarza[2], Donna Stolz[2], Konstantinos Verdelis[2], Randal Kaufman[4]. [1]Texas A&M University, United States, [2]University of Pittsburgh, United States, [3]University of Michigan, United States, [4]Sanford-Burnham-Prebys Medical Discovery Institute, United States

The inositol-requiring enzyme 1α (IRE1α)/X-box binding protein 1 spliced (XBP1s) pathway is an endoplasmic reticulum (ER) stress signaling branch required for the development of secretory organs. IRE1α is an endoribonuclease that generates Xbp1s from Xbp1 upon ER stress. However, it remains elusive as to how this pathway regulates bone development and homeostasis. Our laboratory generated and characterized mice lacking osteoblast-specific IRE1α (CKO), and their wild type littermates (WT), by breeding Ire1αFlox/Flox mice with Osterix-Cre mice. It was found that 2-month-old female IRE1α CKO mice displayed osteoporosis with decreased osteoblastogenesis, increased bone marrow fat and reduced osteoclastogenesis, On one hand, it was observed that IRE1α-deficient osteoblasts exhibited exacerbated ER stress and consequently experienced activation of the PRKR-like endoplasmic reticulum kinase (PERK)/eukaryotic translation-initiation factor 2α subunit (EIF2α) signal transduction pathway, both in vivo and in vitro, compared with WT counterparts. Consequently, IRE1α-deficient osteoblasts had a reduced steady-state protein level of β-Catenin, a transcription factor central for canonical Wnt signaling, both in vivo and in

vitro, compared with WT counterparts. Similarly, the bone marrow stromal cells (BMSCs) that were deficient in XBP1, the downstream effector of IRE1α, also had a reduced β-Catenin protein level in vitro, compared with WT counterparts. LiCl treatment of IRE1α CKO mice partially but significantly rescued osteoporosis in these mice. These results revealed a novel role of IRE1α/XBP1s signaling in regulating osteogenesis and bone marrow adipogenesis via modulating Wnt/ β-Catenin signaling. On the other hand, 2-month-old female IRE1α CKO mice had significant reduction in both the osteoclast number and serum level of RANKL in vivo, compared with WT littermates. Consistently, XBP1-deficient murine BMSCs also had decreased RANKL expression in vitro, compared with WT counterparts. Conversely, XBP1s overexpression in human BMSCs led to an increased RANKL expression and an enhanced capacity of these cells to support osteoclast formation from osteoclast progenitors. Taken together, these data suggest osteoblast-intrinsic ER stress IRE1α/XBP1s signaling plays essential roles in regulating bone development and bone marrow homeostasis via modulating osteoblast-mediated osteoclastogenesis, osteoblastogenesis as well as bone marrow adipogenesis.

Osteocyte Notch3 is Responsible for the Osteopenia of Lateral Meningocele Syndrome (LMS) Ernesto Canalis*, Jungeun Yu, Lauren Schilling, Stefano Zanotti. UConn Health, United States

Notch (1 to 4) receptors determine cell fate and function and their expression is cell lineage-dependent. In the osteoblast lineage, Notch3 mRNA is preferentially expressed by osteocytes, and in the myeloid lineage Notch3 is not detected. This suggests that the osteocyte is responsible for the phenotype of skeletal diseases associated with alterations in Notch3 activity. LMS (OMIM 130720), a rare genetic disorder characterized by developmental abnormalities and bone loss, is associated with mutations in exon33 of NOTCH3. The mutations lead to the translation of a truncated protein lacking the PEST domain, and NOTCH3 gain-of-function. We reported a mouse model (Notch3tm1.1Ecan) harboring a Notch3 mutant allele reproducing LMS, where a termination codon was introduced at base pairs 6691-6696 of the Notch3 coding sequence leading to the translation of a truncated 2230 amino acid protein devoid of the PEST domain. Heterozygous Notch3tm1.1Ecan mice develop pronounced osteopenia, but the mechanisms and whether organs outside the skeleton are responsible for the phenotype are unknown. We report that young and mature Notch3tm1.1Ecan mutant mice appear healthy, and histopathology of multiple organs including the brain revealed no abnormalities. This was associated with low levels of Notch3 expression in most organs outside the skeleton. Notch3 target genes were induced in bone extracts from Notch3tm1.1Ecan mice, confirming Notch signal activation. Notch3tm1.1Ecan mice had pronounced cancellous and cortical bone osteopenia. Osteoblast cell replication was enhanced in vitro. This was reflected by an increase in osteoblast and osteocyte number and a modest increase in bone formation in vivo, which was not sufficient to prevent the osteopenic phenotype. Notch3tm1.1Ecan mice had increased osteoclast surface associated with an increase in RANKL expression by the osteocyte. Notch3tm1.1Ecan mutants exhibited enhanced osteoclastogenesis in vitro, possibly related to events operating in vivo. Co-cultures of bone marrow macrophages (BMMs) and osteoblasts from wild type and Notch3tm1.1Ecan mice revealed enhanced osteoclastogenesis in Notch3tm1.1Ecan cells, which was due to osteoblast- and BMM-dependent effects. In conclusion, Notch3 is preferentially expressed by the osteocyte where it increases RANKL to cause the osteopenia of LMS. The function of Notch receptors is cell lineage specific and dependent on their level of expression.

Tgif1-mediated Repression of PAK3 Supports Osteocyte Spreading Simona Bolamperti*[1], Hiroaki Saito[1], Antonio Virgilio Failla[2], Hanna Taipaleenmäki[1], Eric Hesse[1]. [1]Molecular Skeletal Biology Laboratory, Department of Trauma, Hand and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Germany, [2]Microscopy Imaging Facility, University Medical Center Hamburg-Eppendorf, Germany

Adherence and spreading of osteoblasts on bone surfaces and the formation of an organized lacuno-canalicular network by osteocytes are important for the integrity of the bone tissue. We observed an increased expression of the homeodomain protein TG-interacting factor 1 (Tgif1) during the spreading of osteoblasts on collagen I-coated surfaces in vitro, suggesting a role for Tgif1 during this process. In support of this hypothesis, calvarial osteoblasts obtained from mice bearing a germline deletion of Tgif1 (Tgif1-/-) and osteocyte-like cells of the OCY454 cell line with a transient knockdown of Tgif1 were impaired in their capacity to adhere and spread (p<0.05). Furthermore, immunocytochemistry demonstrated that Tgif1-deficient osteoblasts and osteocytes have a reduced capacity to form focal adhesions and cell protrusions, retaining a more spherical cell shape (p<0.01). Investigation of a panel of factors known to regulate cell spreading revealed an increased expression of the p21-activated kinase 3 (PAK3) in Tgif1-deficient osteocytes at the mRNA and protein level (p<0.01), suggesting an inhibition of PAK3 expression by Tgif1. This hypothesis was supported by chromatin immunoprecipitation, which revealed the binding of Tgif1 to a conserved binding site within the PAK3 promoter. Furthermore, gene reporter assays demonstrated an increased activity of the PAK3 promoter in the absence of Tgif1 (p<0.01). Mechanistically, inhibition of PAK3 expression in Tgif1-deficient osteocytes using siRNA restored the capacity of the

cells to spread and to form focal adhesions as well as cell protrusions (p<0.001). To confirm these observations in vivo, we analyzed the bones of Tgif1-/- mice. Tgif1-deficient osteoblasts appeared to have a less cuboidal appearance compared to cells of control littermates. Furthermore, osteocytes in the trabecular compartment of Tgif1-/- bones were irregularly shaped and formed a disorganized lacuno-canalicular network (p<0.05). A reminiscent phenotype was found in bones of mice with a targeted deletion of Tgif1 in mature osteoblasts and osteocytes using the cre-recombinase controlled by the Dmp1-promoter (Dmp1-Cre+;Tgif1 loxP/loxP). This confirms that the altered osteocyte shape is cell-autonomously driven. In summary, our findings demonstrate that Tgif1-mediated repression of PAK3 is important for osteoblasts and osteocytes to adhere and spread. This mechanism might contribute to the formation of an organized osteocyte network in bone.

Osteocytic Kindlin-2 regulates bone mass accrual and maintenance and mediates skeletal response to mechanical loading and PTH anabolism Huiling Cao*[1], Qinnan Yan[1], Dong Wang[2], Yumei Lai[2], Simin Lin[1], Yimin Lei[1], Liting Ma[1], Yuxi Guo[1], Yishu Wang[1], Yilin Wang[1], Huanqing Gao[1], Xiaochun Bai[3], Chuanju Liu[4], Jian Q. Feng[5], Chuanyue Wu[1], Di Chen[2], Guozhi Xiao[1]. [1]Department of Biology and Guangdong Provincial Key Laboratory of Cell Microenvironment and Disease Research, Southern University of Science and Technology, China, [2]Department of Orthopedic Surgery, Rush University Medical Center, United States, [3]Department of Cell Biology, School of Basic Medical Sciences, Southern Medical University, China, [4]Department of Orthopedic Surgery, New York University School of Medicine, United States, [5]Department of Biomedical Sciences, Texas A&M University College of Dentistry, United States

Osteocytes embedded in a mineralized bone matrix regulate bone homeostasis in response to mechanical and other signals by currently unknown mechanisms. This study shows that osteocytes express abundant Kindlin-2, an integrin co-activator, and that deleting Kindlin-2 in osteocytes causes lifelong severe osteopenia in mice. Kindlin-2 loss in osteocytes not only drastically decreases osteoblast number and function, leading to reductions in osteoid production mineralization and bone formation, but also the promotion of osteoclast formation. Mechanistically, Kindlin-2 loss increases sclerostin expression in osteocytes and inhibits β-catenin signaling in osteoblasts and bone formation. Additionally, Kindlin-2 loss in osteocytes promotes the differentiation of mesenchymal stem cells to adipogenic lineage, further reducing osteoblast formation. Furthermore, Kindlin-2 loss increases the activator of nuclear factor-kappaB ligand (Rankl) expression in osteocytes and promotes osteoclast formation and differentiation from bone marrow monocytes. Kindlin-2 loss impairs osteocyte spreading and reduces osteocyte density by increasing cell apoptosis. Importantly, mice lacking Kindlin-2 in osteocytes fail to increase bone mass and mineral density in response to mechanical loading using a tail suspension model. Finally, of clinical significance, Kindlin-2 loss in osteocytes impairs the anabolic actions of intermittent parathyroid hormone in bone in adult ovariectomized mice. These studies uncover a previously unknown function for Kindlin-2 and define novel mechanisms through Kindlin-2 for osteocyte regulation of bone homeostasis.

Specific Gut Bacterium Alters Commensal Microbiota Immunomodulatory Actions Regulating Skeletal Development Jessica Hathaway-Schrader*, Nicole Poulides, Sakamuri Reddy, Caroline Westwater, Chad Novince. Medical University of South Carolina, United States

The commensal gut microbiota critically regulates post-natal skeletal development. We have previously shown the commensal gut microbiota enhances osteoclastogenesis and suppresses osteoblastogenesis, which appears to be mediated by TH17/IL-17 immune response effects in bone marrow and liver. Of interest, segmented filamentous bacteria (SFB) is a genomically distinct commensal gut bacterium that potently directs TH17/IL-17 mediated immunity. Study purpose was to delineate the influence of SFB on commensal gut microbiota immunomodulatory actions regulating post-natal skeletal development. Nine-week-old, female, C57BL/6T *murine-pathogen-free (MPF) mice (*specific-pathogen-free mice colonized by SFB) and #excluded-flora (EF) mice (#specific-pathogen-free mice devoid of SFB) were euthanized, and tissues were collected. Proximal tibia trabecular bone was analyzed by uCT and histomorphometric analyses. Mesenteric lymph node (MLN), liver lymph node (LLN), spleen, and bone marrow cells were isolated for flow cytometric analyses. Ileum, liver, spleen, and bone marrow were assessed for target genes by qRT-PCR and nCounter. Il17 was substantially increased in the ileum of MPF mice, which is in line with SFB induction of TH17/IL-17 immunity. EF vs. MPF mice had decreased body weight and tibia length. Increased proliferative and hypertrophic chondrocyte zone heights in the growth plate of EF mice imply that reduced tibia length is due to altered endochondral bone formation. MPF mice had decreased trabecular bone volume fraction, which was attributed to reduced trabecular number. TRAP+ osteoclast numbers lining trabecular bone were enhanced in MPF vs. EF mice. MPF mice had increased MLN and LLN weight per body weight, upregulated % cytotoxic T-cells in MLNs, and enhanced % helper T-cells in LLNs. Paralleling the increased

osteoclast numbers, the critical osteoclastic transcription factor Nfatc1 was increased in marrow of MPF mice. Decreased Col1a1, but no difference in Ocn and Opn in the marrow of MPF vs. EF mice, indicate that suppressed early osteoblast activity contributes to the osteopenic trabecular bone phenotype found in MPF mice. C3, C4b, C5a and Lcn2 were upregulated in liver and marrow of MPF mice, which provides novel mechanistic insight about commensal gut microbiota osteoimmune response effects. This research notably reveals that specific microbes critically impact commensal gut microbiota immunomodulatory actions regulating post-natal skeletal development.

Haploid Embryonic Stem Cell-Mediated Targeted Genetic Screening In Vivo Identifies Novel Factors for Bone Development Yujiao Han*, Weiguo Zou. Shanghai Institute of Biochemistry and Cell Biology, China

Functional mutagenic screening has been used to identify key factors required for a wide range of developmental processes. However, such screens can only be successfully applied in lower organisms. Here, we develop a knockout (KO)-based screen in mouse using androgenetic haploid embryonic stem cells (haESCs). We screened factors involved in bone development by introducing a sgRNA library containing 216 sgRNAs targeting 72 preselected candidate genes into haESCs, which carried constitutively expressed Cas9 and were injected into oocytes to produce semi-cloned (SC) mice. We produced 426 SC pups and among them, 404 pups carried one sgRNA and covered all 72 genes. The skeletal phenotypes of each SC pups at birth were analyzed by alcian blue and alizarin red staining. Through the screen we identified transcriptional factor Irx5 as a positive regulator of bone development and the phenotype were validated by the generation of KO mouse lines through zygotic injection. Two lines of Irx5 KO mouse exhibited obvious decreased bone mass and increased adipogenesis in the bone marrow. Moreover, the deletion of Irx5 from bone marrow cells prohibited osteoblast differentiation and enhanced adipocyte differentiation ability in vitro. Mechanistically, IRX5 promotes osteoblastogenesis and inhibits adipogenesis by inhibiting PPARγ expression. We conclude that haESC-mediated SC technology, in combination with a targeted sgRNA library, can be used as a powerful reverse genetic screening strategy in vivo in mouse.

A Novel In Vitro Fluidic Approach to Measuring the Apoptotic Bystander Effect in Osteocyte Networks Sean Mccutcheon*[1], Robert Majeska[2], David Spray[1], Maribel Vazquez[2], Mitchell Schaffler[2]. [1]Albert Einstein College of Medicine, United States, [2]The City College of New York, United States

Osteocytes are widely regarded as the primary sensors and transducers in bone. In response to apoptosis in nearby cells, osteocytes upregulate RANKL which in turn triggers recruitment and differentiation of osteoclast precursors. How osteocytes sense apoptosis and respond to tissue level stimuli is still under intensive study. The spatial constraints of the lacunar canalicular system (LCS) and the network structure of osteocytes within it are key determinants of sensory and response communication pathways, yet a high throughput in vitro device to study osteocyte behavior in such a confined system has yet to be developed. In this study we utilized a novel multi-scale fluidic device that mimics the architecture and diffusion parameters of the LCS to examine paracrine signaling between dying and surviving osteocytes (the "bystander effect"). The device, (the Macro-micro-nano, or Mμn) consists of two cell seeding regions separated by a 100μm-wide channel array. The channel array, which provides conduits similar to canaliculi for osteocyte processes in vivo, is composed of ~900nm-wide channels separated by 10μm. When cultured on both sides of the array, MLO-Y4 osteocytes extend processes that form functional gap junction connections within the array channels. To test the bystander effect, apoptosis was induced in osteocytes on one side of the Mμn by heat stress, and RANKL expression was quantified on the non-apoptotic side via a fluorescent RANKL gene reporter system. Apoptosis induction resulted in ~2-fold increase in RANKL-expressing bystander osteocytes after 12h, which diminished with distance from the apoptotic source (Fig); similar to the pattern for osteocyte RANKL expression seen around microdamage sites in vivo. Inhibiting caspase 3 (10μM QVD) eliminated this elevation. Activation and spread of RANKL signaling in bystander osteocytes was also prevented by blocking the membrane channel Pannexin 1 (500μM Probenecid). However, RANKL signaling in bystander osteocytes was unaffected by inhibiting Connexin 43 (30μM 18α-GA). These data indicate that diffusible paracrine signals and not direct gap junction signaling, are the primary mechanism by which bystander osteocytes respond to nearby apoptosis. Furthermore, the dependency of RANKL activation in bystander osteocytes on the Pannexin 1 channel points to ATP release as a dominant chemical signal in this process.

Fracture targeted PTHR1 agonists for accelerated bone repair Stewart Low*[1], Jeffery Nielsen[2], Philip Low[2]. [1]Purdue, United States, [2]Purdue University, United States

Background: Over 6 million bone fractures occur in the United States each year, resulting in significant morbidity, mortality, and lost productivity. In general, conventional therapy has focused on mechanically stabilizing fractures with little consideration of a pharmaceutical approach to accelerate fracture repair. Development of locally-applied bone anabolic agents (such as BMP-2) have resulted in accelerated bone growth but have limited approved uses due to the invasiveness of their application (via surgery) and their potential for ectopic bone growth. Likewise, efforts to accelerate fracture repair by systemically-administered anabolic agents have yet to achieve sufficient therapeutic concentrations at the fracture site;We have developed a systemically-administered fracture-targeted therapeutic that demonstrates remarkable specificity to the site of a fracture and significantly accelerates bone repair. With systemic administration, multiple doses of the drug can be administered in a non-invasive manner while targeting allows for therapeutic concentrations of anabolic to accumulate at the fracture site, an objective only previously achieved by local application. Furthermore, by limiting drug accumulation to the fracture site, systemic toxicities are avoided along with any ectopic bone growth associated with local anabolic administration.Methods: Our fracture-targeted bone anabolic agent was prepared by synthesizing a parathyroid hormone-related protein (PTHrP) fragment conjugated to a hydroxyapatite-homing acidic oligopeptide. In vivo experiments were conducted on Swiss Webster mice (10 per group). Femoral fractures were induced with a 3-point bending device and stabilized. Mice were dosed with 30 nmol/kg/d of targeted-PTHrP, non-conjugated (free) PTHrP, or saline. Following a 4-week study, fracture callus densities were measured using microCT. A marked increase in bone density (30%) was observed in the free-PTHrP group over the saline group, whereas a far greater (70%) increase in bone density was observed in the targeted-PTHrP group over the saline group. Further studies confirmed that the greatest difference in ossification occurred early in the fracture healing process (2 weeks), with the fracture callus resolving to cortical bone by 8-weeks.Conclusions By targeting bone anabolic agents to bone fractures, we can deliver sufficient concentrations of anabolic agent to the fracture site to accelerate healing.

Mechanical stimulation prevents the decline in anabolic response to prolonged Sclerostin-neutralizing antibodies exposure Maude Gerbaix*, Serge Ferrari. Division of Bone Diseases, Geneva University Hospitals and Faculty of Medicine, Switzerland

Inhibition of sclerostin leads to a massive increase, followed by a drastic down-regulation of bone formation. Whether or not osteoblastic cells remain responsive to anabolic stimuli after the exhaustion of Sclerostin-neutralizing Ab (Scl-Ab) effects on bone formation however remains unclear. We investigated the effects of mechanical stimulation on bone microarchitecture and gene expression in mice continuously exposed to Scl-Ab.Four month-old mice received Scl-Ab (50 mg/kg/w) or Veh for 5 weeks. At week 3, axial compression was applied on the left tibia 3 days per week for 2 weeks. Subgroups of treated and Veh mice were euthanized at 2, 4 and 5 weeks of treatment for analyses of bone microstructure, serum markers and bone gene expression by RT-QPCR.In Scl-Ab animals, P1NP peaked at 2 weeks and decreased at 5 weeks. Scl-Ab increased BV/TV at distal femur and vertebrae (+141%, +157% respectively vs Veh; $p<0.01$) and femur cortical thickness (Ct.Th) (+22% vs Veh; $p<0.01$) by 2 weeks; by 4 weeks, Scl-Ab had maximaly increased BV/TV at distal femur and vertebrae (+232%, +462% respectively vs Veh; $p<0.01$) and femur Ct.Th (+30% Veh; $p<0.01$), with no further gain at 5 weeks. Under continuous Scl-Ab treatment, loading further increased tibia trabecular BV/TV (+14% vs nonloaded tibia; $p<0.05$) and femur Ct.Th femur (+19% vs nonloaded tibia; $p<0.05$), as also observed in Veh treated animals. Scl-Ab upregulated Coll1, BGlap, Sost and DKK1 genes expression (+74.78%, +135%, +21%, +56% respectively vs Veh; $p<0.05$) and down-regulated Posnt and NRG1 gene expression (-32%; -24%; respectively vs Veh $p<0.05$) at week 2, whereas at week 5, gene expression levels did not differ from Veh. Loading further increased Coll1, ALP, Wisp1 and Posnt genes expression in Scl-Ab as compared to Veh (+17%; +992%; +284%; +31% vs Veh; $p<0.05$). NRG1 and SerpinF1 genes expression were also upregulated by loading under veh and AbScl treatment. In summary, stimulation of osteoblastic gene expression related to bone formation is not sustained with Scl-Ab, as counterregulatory mechanisms such as Sost and Dkk1 are induced, and co-stimulatory pathways, such as periostin, are repressed. Mechanical loading however is able to maintain these bone forming mechanisms despite the continuous inhibition of Sost. These observations suggest that lining cells and osteoblasts precursors are still responsive and could be further stimulated by mechanisms that are at least partially independent of Sost inhibition.

An Anti-Angiogenic Agent Induced Osteonecrosis of the Jaw-Like Lesions in Rice Rats (Oryzomys palustris) Jonathan Messer*, Jessica Jiron, Abel Abraham, Evelyn Castillo, Josh Yarrow, Don Kimmel, J Ignacio Aguirre. University of Florida, United States

Medication-related osteonecrosis of the jaw (MRONJ) is a potentially serious adverse event seen in patients taking powerful anti-resorptive (pAR), and more recently, antiangiogenic (AA) agents. Multiple recent pre-clinical experiments indicate that combined local factors (e.g., dental infection) and systemic factors (e.g., pARs, etc.) are required to induce MRONJ. However, no pre-clinical experiments have investigated a role for AAs (e.g., anti-VEGF antibody, aVEGF) in MRONJ.We hypothesize that despite lacking anti-resorptive activity, AAs cause MRONJ-like lesions in rice rats with localized periodontitis (PD), which results in progression of oral infection and necrosis of oral soft and hard tissues.Rice rats were randomized at age 4 wks into 3 groups (N=15) that received 1) intravenous (IV) zoledronic acid (ZOL; 80 µg/kg BW 1X/mo); 2) subcutaneous aVEGF (Genentech rodent cross-species anti-VEGF MAb [B20-4.1.1]; 5mg/kg BW 2X/wk), or 3) IV vehicle (VEH; saline 1X/mo). Bi-weekly oral exams were conducted with binocular loupes (4X) to inspect the oral cavity of rats between ages 4-22 weeks. At each exam, oral lesions were identified and scored using an integral 0-4 severity scoring system, in which 0 was normal and 4 was marked gingival recession with exposed bone (MRONJ-like lesion). At the end of the study, rats were euthanized, and high resolution photographs of jaw quadrants were analyzed. Jaw quadrants were processed for MicroCT analysis and histopathologic assessment. 40% of VEH rats developed spontaneous, localized PD lesions at the interdental region of maxillary molars 2-3 (M2M3) with low-grade severity (1-1.5), as previously described. 55% of ZOL- and 73% of aVEGF-treated rats developed lesions at M2M3 with severity of 1-4. Gross MRONJ-like lesions were detected in 0, 25, and 47% of VEH, ZOL, and aVEGF rats, respectively. MicroCT, histopathologic, and immunohistochemical analyses are ongoing to confirm MRONJ lesions, and determine the extent of morphologic or histologic variation in the affected tissues among the different groups.Our data suggest that AA inhibits healing of focal PD lesions, promoting the development of MRONJ lesions in similar circumstances to those induced by ZOL. This is the first pre-clinical, prospective experiment to establish a potential causal relationship between an AA agent and MRONJ.

Spinal loading regulates bone remodeling and angiogenesis in a mouse model of postmenopausal osteoporosis Xinle Li*[1], Jie Li[1], Daquan Liu[1], Hiroki Yokota[2], Ping Zhang[1]. [1]Department of Anatomy and Histology, School of Basic Medical Sciences, Tianjin Medical University, Tianjin 300070, China, [2]Department of Biomedical Engineering, Indiana University-Purdue University Indianapolis, IN 46202, United States

Osteoporosis is characterized by reduced bone mass and deterioration of bone micro-architecture, and an increased risk of fractures. While angiogenesis is essential for repairing of bone disorders such as fracture and osteonecrosis, mechanical loading is reported not only to stimulate bone formation, but also to promote vessel remodeling in osteonecrosis of the femoral head. Spinal loading is one form of loading modalities, in which compressive loads are applied to the lumbar spine. Using ovariectomized (OVX) mice, we examined whether spinal loading prevents bone loss through regulating a Wnt pathway in postmenopausal osteoporosis.Sixty C57BL/6 female mice (~14 weeks) were divided into three groups (n=20): the sham control, OVX, and spinal loading-treated OVX group. Spinal loading (4 N at 10 Hz for 5min/day) was applied for 2 weeks. Bone mineral density (BMD) and bone mineral content (BMC) were measured, and ink perfusion was performed to evaluate angiogenesis.Femora were harvested for bone histomorphometry and Western Blotting, and bone marrow-derived cells were isolated to examine osteoclast development, osteoblast mineralization, and differentiation of endothelial progenitor cells(EPCs). RNA interference for Wnt3a was employed to test whether Wnt3a is involved in bone remodeling and angiogenesis.The results showed that OVX mice presented bone loss with reduction in a vessel volume, and daily application of spinal loading for two weeks significantly increased BMD, BMC, trabecular bone volume, and the number of osteoblasts on bone surface. It also enhanced differentiation and mineralization of osteoblasts. Regarding osteoclasts, the loaded group presented significant reduction in osteoclast activity and suppression of their formation, migration and adhesion. While the levels of RUNX2, alkaline phosphatase, and osteocalcin were increased, those of NFATc1, RANKL, and cathepsin K were decreased by spinal loading. Spinal loading also enhanced a microvascular volume, migration and tube formation of EPCs, and VEGF expression. Transient knockdown of Wnt3a blocked the observed loading effects on osteoclast development, osteoblast mineralization, and differentiation of EPCs.Collectively, this study shows using OVX mice that spinal loading stimulates bone formation and angiogenesis and it suppresses bone resorption via the Wnt pathway. Further understanding of spinal loading can contribute to developing potential therapies for postmenopausal osteoporosis.

Low Affinity Bisphosphonate Exerts a Strong Anabolic Effect on Trabecular Bone Abigail Coffman*[1], Robert J. Majeska[1], Jelena Basta-Pljakic[1], Mark W. Lundy[2], Frank H. Ebetino[3], Mitchell B. Schaffler[1]. [1]City College of New York, United States, [2]Indiana University School of Medicine, United States, [3]University of Rochester, United States

PURPOSE: Bisphosphonates (BPs) in clinical use to prevent bone loss are characterized by high binding affinity for hydroxyapatite (HA), reflecting bone matrix targeting and high potency of FPPS inhibition. Many BPs with low HA affinity (thus rapid biological clearance) and strong FPPS inhibition have not been developed clinically. Their effects in vivo are not well understood, but BPs with short half-lives and rapid clearance from the body potentially offer certain advantages over long half-lives of current clinical BPs. Here we explored whether one such compound, NE-580251, might have beneficial effects on bone. METHODS: Young adult female C57Bl/6 mice (15 w.o, JAX, n=5/group, IACUC approved) underwent OVX; they were treated with NE-58025 (NE-025, 200μg/kg daily,sc), Risedronate (RIS, 2.4 μg/kg2 3x/wk,sc) or PBS, and sacrificed at 3 mo. NE-025 has much lower HA binding and similar FPPS inhibition than RIS.1 Sham, baseline and age matched cage controls were also studied. Femurs were assessed by μCT (6.7 μm resolution) and trabecular microarchitecture analyzed. Comparisons: ANOVA and post-hoc Tukey test; data shown as mean±SD. RESULTS: Tb.V/TV in OVX mice decreased ~70% from baseline. This loss was prevented by RIS, as expected. Surprisingly, Tb.V/TV in NE-025 mice increased >140% vs baseline (p<0.0001), driven by increased Tb.N but with no change in Tb.Th (Fig 1). DISCUSSION: The anabolic effect of NE-025 on bone was surprising– particularly its magnitude; its underlying mechanisms are as yet unknown. Most BPs with varying HA binding and FPPS inhibition are anti-apoptotic3,4 at very low doses, and prolonged osteoblast life span might contribute to bone formation. Intriguingly, low concentrations of clinical BPs were also shown to promote osteoblast proliferation in vitro5,6- an effect not seen in vivo. We speculate that the high HA affinity of clinical BPs limit their access to osteoblastic cells in vivo, while osteoclasts may "see" the BPs released from matrix as they initiate resorption. As NE-025 is not retained on bone surfaces nearly as strongly, its presentation to osteoblastic cells is more direct and similar to that seen in vitro. Regardless of mechanism, this remarkable anabolic action of NE-025 on cancellous bone needs to be explored further. Siglec-15-Targeting Therapy Increases Bone Mass in Rats and Is a Potential Therapeutic Strategy for Juvenile Osteoporosis Dai Sato*[1], Masahiko Takahata[1], Masahiro Ota[1], Chie Fukuda[2], Eisuke Tsuda[2], Tomohiro Shimizu[1], Hiroki Hamano[1], Sigeto Hiratsuka[1], Akiko Okada[2], Ryo Fujita[1], Norio Amizuka[3], Tomoka Hasegawa[3], Nrimasa Iwasaki[1]. [1]Department of Orthopaedic Surgery, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Japan, [2]Rare Disease Laboratories, Daiichi Sankyo Co., Ltd., Japan, [3]Hokkaido University, Department of Developmental Biology of Hard Tissue, Graduate School of Dental Medicine, Japan

Although osteoporosis is rare in children and adolescents, the number of juvenile patients with secondary osteoporosis increases based on the long-term survival of patients with intractable diseases owing to advances in medical treatments. Therefore, the management of juvenile osteoporosis is gaining importance. However, the treatment of juvenile osteoporosis has not been established due to a lack of data regarding the efficacy and adverse effects of therapeutic agents. The possible adverse effects of the long-term use of antiresorptive therapies on skeletal growth in children is of particular concern. Sialic acid-binding immunoglobulin-like lectin 15 (Siglec-15) is a cell surface receptor that regulates osteoclast development and bone resorption, and its deficiency suppresses bone remodeling in the secondary spongiosa, but not in the primary spongiosa, due to a compensatory mechanism of osteoclastogenesis. This prompted us to develop an anti-Siglec-15 therapy for juvenile osteoporosis. Using growing rats, we investigated the effects of an anti-Siglec-15 neutralizing antibody (Ab) on systemic bone metabolism and skeletal growth, comparing to those of bisphosphonate. Male 6-week-old F344/Jcl rats were randomized into six groups: control (PBS twice per week), anti-Siglec-15 Ab (0.25, 1, or 4 mg/kg every 3 weeks), and alendronate (ALN) (0.028 or 0.14 mg/kg twice per week). Treatment commenced at 6 weeks of age and continued for the next 6 weeks. Changes in bone mass, bone metabolism, bone strength, and skeletal growth during treatment were analyzed. Both anti-Siglec-15 therapy and ALN increased bone mass, bone mineral density and the mechanical strength of both the femora and lumbar spines. Anti-Siglec-15 therapy did not have a significant effect on skeletal growth as evidenced by micro-CT-based measurements of femoral length, high-dose ALN resulted in growth retardation with morphological abnormalities in the metaphysis of femur. ALN therapy decreased the perimeter of osteoclasts relative to the bone perimeter in the primary spongiosa with growth plate dysplasia in histological sections, whereas anti-Siglec-15 Ab therapy did not result in these outcomes. This unique property of the anti-Siglec-15 Ab can probably be attributed to compensatory signaling for Siglec-15 inhibition in the primary spongiosa, but not in the secondary spongiosa. Thus, anti-Siglec-15 therapy could be a safe and effective for juvenile osteoporosis.

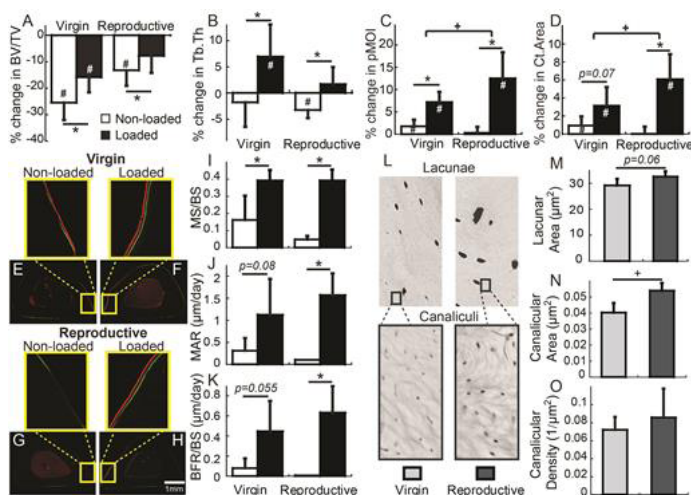
Peri-Lacunar/Canalicular (PLC) Remodeling Enhances Mechano-Sensitivity in Rat Maternal Bone when Subjected to Estrogen Deficiency Yihan Li*[1], Chantal De Bakker[1], Wei-Ju Tseng[1], Hongbo Zhao[1], Ashutosh Parajuli[2], Liyun Wang[2], X. Sherry Liu[1]. [1]University of Pennsylvania, United States, [2]University of Delaware, United States

Pregnancy and lactation lead to substantial changes in the skeleton but exert no adverse, or even protective effects on postmenopausal risk of fracture. Our previous study found that rats with multiple reproductive cycles had attenuated ovariectomy (OVX)-induced bone loss compared to virgins. It has been suggested that the osteocyte can actively remodel its peri-lacunar/canalicular (PLC) matrix during lactation. Therefore, we hypothesized that PLC remodeling may enhance bone's mechano-sensitivity by priming the microenvironment of osteocytes, exerting protective effects post-menopause.At age 10mo, Virgin (n=7) and Reproductive (n=6, 2 cycles of pregnancy, lactation, and weaning) rats underwent OVX surgery and, starting at 6wks post-OVX, were subjected to a 2-wk in vivo dynamic loading of the tibia (~1500µε at midshaft). In vivo µCT indicated that virgin and reproductive rats underwent 25% and 13% trabecular bone (Tb) loss in the non-loaded tibia, respectively (Fig A). Loading attenuated OVX Tb loss in virgins and abolished Tb loss in reproductive rats (Fig A). Loading also led to a 7% increase in Tb thickness (Tb.Th) in virgins and abolished OVX-induced reduction in Tb.Th in reproductive rats (Fig B). At the tibial midshaft, loading led to 7% and 13% increased polar moment of inertia (pMOI) in virgin and reproductive rats, respectively (Fig C). Similar results were found in cortical area (Ct.Area, Fig D). Moreover, ANOVA test indicated greater loading responses in pMOI and Ct.Area in reproductive rats than in virgins. Dynamic histomorphometry showed significant increases in periosteal double-labeled bone formation by loading in reproductive rats, while only trends of elevation (p<0.1) were observed in virgins (Fig E-K).Backscattered SEM imaging of tibial cortex indicated a trend toward greater lacunar area (by 11%, p=0.07) and 33% greater canalicular area in reproductive rats than in virgins (Fig L-N), while no difference was found in canalicular density (Fig O). According to a lacuna-canaliculi system (LCS) fluid flow model [1], the enlarged LCS area in reproductive rats would lead to increased PLC fluid space, resulting in increased fluid shear stress on osteocytes and cell processes.In summary, reproduction and lactation exert long-term functional adaption in modulating osteocyte LCS environment to enhance bone's mechano-sensitivity to protect the maternal skeleton from future estrogen deficiency.[1] Weinbaum S et al., J Biomech., 1994.


(A-B) Comparisons of % changes in trabecular bone and (C-D) midshaft cortex over the 2-wk loading period between non-loaded and loaded tibia in virgin and reproductive rats. (E-H) Comparisons of representative histology images and (I-K) periosteal bone formation parameters between non-loaded and loaded tibia in virgin and reproductive rats. (L) Comparisons of bSEM images and (M-O) LCS structure between virgin and reproductive rats. p<0.05: # pre- ≠ post-loading; * non-loaded ≠ loaded; + virgin ≠ reproductive.

Deletion of Prostaglandin E2 (PGE2) Receptor EP4 in Myeloid Lineage Cells Restores the Anabolic Effects of Continuous PTH in Mice Shilpa Choudhary*, Joseph Lorenzo, Carol Pilbeam. Musculoskeletal Institute & Department of Medicine, UConn Health, United States

We previously found that the anabolic response to continuously infused PTH in mice is suppressed by the induction of serum amyloid A3 (SAA3). In vitro experiments indicate that SAA3 is produced in myeloid cells in response to RANKL through a mechanism that requires PGE2. We hypothesized that the required PGE2 acts via the EP4 receptor. To test this, we generated Ep4rfl/fl (Control, CON) and Ep4rfl/flLyz2Cre+/- (targeted deletion in myeloid cells, TD) littermates in a CD-1 background. In bone marrow macrophages (BMMs) from TD mice, cultured with M-CSF +/- RANKL, Ep4r mRNA was reduced >96% compared to CON BMMs. RANKL induced Saa3 mRNA 1600-fold in CON BMMs, which was reduced

by 99% in TD BMMs. RANKL-induced SAA3 protein was undetectable in the culture medium of TD BMMs but easily measured in CON medium. Male (3-mo-old) CON and TD mice (n=6/group) were continuously infused with vehicle or hPTH 1-34 (40 µg/kg/d) for 12 days. Measurements included mRNA from unflushed tibiae after ends removed; serum analyses; and femoral µCT. Data were analyzed by 2-way ANOVA. Vehicle-infused CON and TD mice did not differ in any of the measurements. PTH induced mRNA for cyclooxygenase 2, the major enzyme producing PGE2, equally in CON and TD tibiae (7-fold). In contrast, the induction of Saa3 mRNA (37-fold) by PTH was reduced 91% in TD tibiae. Although PTH infusion caused bone loss in CON mice, decreasing distal femoral trabecular BV/TV 50%, PTH infusion was anabolic in TD mice, increasing BV/TV 64%. PTH increased cortical area and thickness 20-24% and tibial expression of osteogenic genes, Bglap, Igf1 and Wnt10b, only in TD mice. mRNA for Sost, an inhibitor of bone formation, was decreased by PTH only in TD tibiae. PTH elevated serum P1NP, a marker of bone formation, >400% in TD mice, compared to 35% in CON mice. In contrast to the striking differences between CON and TD mice in measurements associated with PTH-stimulated bone formation, PTH stimulated factors associated with bone resorption similarly in CON and TD mice. Serum CTX, a marker of bone resorption, was elevated by PTH 5-fold in both CON and TD mice. In addition, PTH increased the Rankl/Opg mRNA ratio similarly in CON and TD tibiae. We conclude that the EP4 receptor in myeloid cells mediates the PGE2 effects required for SAA3 suppression of the bone formation response to continuous PTH. Hence, antagonists of the EP4 receptor may enhance the therapeutic potential of PTH for treating bone diseases.

The Gut Microbiota Is Required For The Anabolic And Catabolic Effects Of PTH In Bone Jau-Yi Li*, Mingcan Yu, Abdul Malik Tyagi, Chiara Vaccaro, Jonathan Adams, Rheinallt M. Jones, Roberto Pacifici. School of Medicine, Emory University, United States

There is increasing evidence that the gut microbiome plays a pivotal role in bone health and disease, but the relationship between microbiota and PTH remains unexplored. This study was designed to investigate the role of the gut microbiota in the skeletal effects of PTH. Continuous PTH treatment (cPTH), a model of hyperparathyroidism induces bone catabolism. Conversely, teriparatide treatment, which is modeled by intermittent PTH (iPTH) administration, induces bone anabolism. We investigated if the gut microbiota affects the bone anabolic activity of iPTH by injecting iPTH (80 µg/Kg/day, SC) daily for 4 weeks into 8-week-old germ-free (GF) mice, conventionally raised (Conv.R) mice, and Conv.R mice treated with wide-spectrum antibiotics (Abx). Abx treatment decreased gut bacterial DNA by > 99 %. iPTH treatment increased trabecular bone volume (BV/TV), µCT indices of trabecular structure, and bone formation in Conv. R mice, but not in GF mice and Conv. R. mice treated with Abx. Moreover, Abx treatment blocked the capacity of iPTH to induce osteoblast differentiation, to activate Wnt signaling in osteoblastic cells, to increase the number of regulatory T cells (Tregs), and to upregulate the production of Wnt10b by bone marrow CD8+ T cells. Tregs and Wnt10b have been previously reported to mediate the effects of iPTH on Wnt signaling and bone formation. To investigate the role of the gut microbiome in models of hyperparathyroidism, 16-week-old Conv. R. mice and Abx treated Conv. R. mice were infused with cPTH (80µg/kg/day delivered by osmotic pumps) for 2 weeks or fed a low Ca diet (0.01% calcium) for 4 weeks. cPTH and low Ca diet induced trabecular and cortical bone loss and stimulated bone resorption in control mice but not in those treated with Abx. cPTH is known to induce bone loss by upregulating TNF and IL-17 production by T cells and RANKL production by osteocytes. We found that cPTH and low Ca diet stimulated IL-17 and TNF production in Payer's patches and the bone marrow; however, Abx treatment prevented the increase in TNF and IL-17 levels induced by cPTH and low Ca diet. In summary, these findings provide compelling evidence that the microbiota and the gut/bone axis play a critical role in the anabolic and catabolic effects of PTH in bone. The gut microbiota is required for activating both the Tregs/Wnt10b/Wnt signaling pathway that leads to iPTH induced bone anabolism, and the TNF/IL-17/RANKL pathway that causes bone loss in hyperparathyroidism.

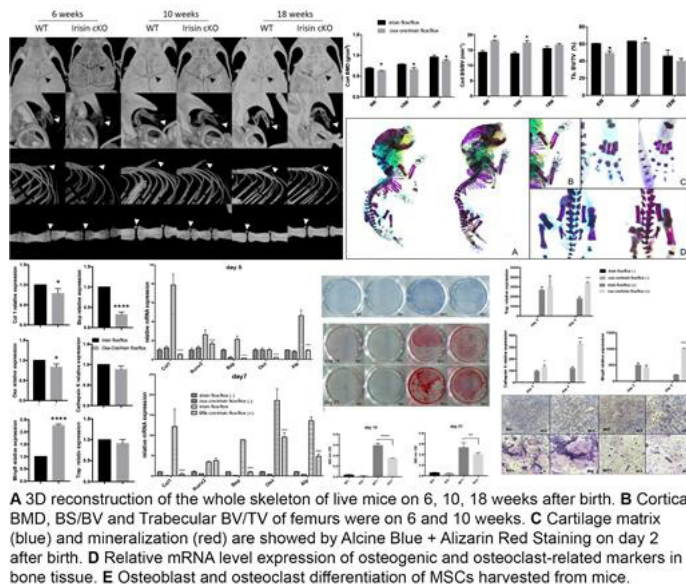
Impaired 1,25 dihydroxyvitamin D action underlies the development of enthesopathy in the Hyp mouse model of XLH Eva Liu*[1], Janaina Martins[2], Marie Demay[2]. [1]Brigham and Women's Hospital , MGH, and Harvard Medical School, United States, [2]Massachusetts General Hospital and Harvard Medical School, United States


The enthesis is a specialized fibrocartilaginous tissue that forms at the site of attachment of tendon to bone, optimizing the transfer of mechanical stress from muscle to bone. X-linked hypophosphatemia (XLH) is characterized by elevated serum FGF23 levels, leading to decreased production of 1,25 dihydroxyvitamin D (1,25D) and hypophosphatemia. A complication of XLH is enthesopathy, an abnormal mineralization of bone-tendon attachment sites, which leads to pain and impaired mobility. Compared to WT, Achilles tendon entheses in mice with XLH (Hyp) have an expansion of aberrant Safranin O positive (SafO+) hypertrophic enthesopathy cells (HECs). Hyp entheses exhibit increased expression of BMP and IHH target genes, implicating these signaling pathways in the pathogenesis of enthesopathy. Treatment of Hyp mice with either 1,25D or an FGF23 blocking antibody attenuates the enthesopathy phenotype, suggesting that impaired 1,25D action in XLH plays a pathogenic role in the development of enthesopathy.Studies were undertaken to identify a pathogenic role for impaired 1,25D action in the development of enthesopathy. Global ablation of the vitamin D 1-alpha-hydroxylase (Cyp27b1KO) resulted in an enthesopathy phenotype similar to that seen in Hyp mice. The Achilles tendon entheses of Cyp27b1KO and Hyp;Cyp27b1KO mice exhibit an expansion of SafO+ HECs, immunoreactive to BMP induced p-Smad1/5 and the BMP and IHH target genes Sox9, Patched and Runx2. In contrast, entheses from FGF23KO and or Hyp;FGF23KO mice which have elevated serum 1,25D levels did not exhibit enthesopathy. Deletion of Cyp27b1 in FGF23KO and Hyp;FGF23KO mice led to an expansion of HECs expressing BMP and IHH targets.Prior studies have demonstrated that BMPs regulate IHH signaling in chrondrocytes. Since impaired 1,25D action in mice leads to expression of BMP and IHH target genes in the fibrocartilaginous HECs, studies were performed to address the hypothesis that 1,25D suppresses BMP/IHH signaling, in chondrogenic cells. Primary murine chondrocytes were treated with rhBMP2 with or without 1,25D. 1,25D pretreatment suppressed the induction of BMP and IHH target genes by rhBMP2.These results demonstrate that impaired 1,25D action, rather than direct effects of increased FGF23, underlies the pathogenesis of XLH enthesopathy. They also suggest that optimizing 1,25D treatment will prevent the development of enthesopathy in XLH by suppressing BMP and IHH signaling in entheses.

Irisin Deficiency Disturbs Bone Metabolism Zoe (Xiaofang) Zhu*[1,2], Jake (Jinkun) Chen[3,4], Guofang Shen[5], Qisheng Tu[1]. [1]Tufts University School of Dental Medicine, United States, [2]Shanghai Jiaotong Univ., China, [3]Division of Oral Biology Tufts University School of Dental Medicine, United States, [4]Department of Developmental, Molecular and Chemical Biology Sackler School of Graduate Biomedical Sciences Tufts University School of Medicine, United States, [5]Shanghai Jiaotong Univ., China

Metabolic bone diseases caused by abnormalities of mineralization, such as rickets, osteoporosis, osteopetrosis are among the most common public health issues. Irisin, a recently identified novel hormone-like myokine, is the cleaved and secreted portion of the fibronectin-type III domain-containing 5 (FNDC5). Recent studies reported the involvement of the irisin in many physiological and pathological conditions with bone mineral density changes, such as osteoporotic fractures. In addition, injection of recombination irisin is shown to have increased bone mass in mice. Those led us to hypothesize thatirisinregulates bone metabolism.We first designed and constructed the irisinflox/flox mice. Osx-Cre/irisinflox/flox mice, in which irisin was specifically deleted in bone, were created by crossing our irisinflox/flox mice with osterix-cre mice. The mice were grouped according to the southern blot and standard PCR genotyping results, and phenotypes were analyzed. Gene and protein expression of the irisin were remarkably decreased in bone but no significant difference in other tissue in knockout mice. We found both young and adult irisin knockout mice were smaller and lighter than normal. In vivo analyses using Micro CT showed lower Co. BMD, Co. Thickness and Tb. BV/TV of femurs, and significantly delayed bone development and mineralization of skull, hyoid, ribs, xiphoid and coccyx on 6, 10, 18 weeks after birth in knockout mice. Whole skeleton staining also showed the mineralization delay on P2 in knockout group (as shown on figure). Our assessment indicates increased osteoblast-related genes expression and decreased osteoclast-related genes expression in bone tissues in knockout mice. By harvesting and culturing the MSCs, we identified that the osteoblastogenesis was inhibited and the osteoclastogenesis was increased in MSCs from konckout mice cultured in vitro. For the first time, we established the irisin gene flanked mice: irisin flox/flox mice, and irisin bone-specific knockout mice model: Osx-Cre/irisin flox/flox mice. The irisin deficiency mice showed delayed bone formation and mineralization, and increased osteoclastogenesis. Irisin, as a new hormone-like polypeptide, plays an important role in bone metabolism and in the crosstalk between bone and other organs, representing a potential molecule for the prevention and treatment of bone diseases.

A 3D reconstruction of the whole skeleton of live mice on 6, 10, 18 weeks after birth. **B** Cortical BMD, BS/BV and Trabecular BV/TV of femurs were on 6 and 10 weeks. **C** Cartilage matrix (blue) and mineralization (red) are showed by Alcine Blue + Alizarin Red Staining on day 2 after birth. **D** Relative mRNA level expression of osteogenic and osteoclast-related markers in bone tissue. **E** Osteoblast and osteoclast differentiation of MSCs harvested from mice.

There is a growing need to identify individuals at "imminent" risk of fracture. In particular, since many fractures occur in persons with osteopenia, better approaches for stratifying fracture risk are needed. Thus, we combined data from 7 cohorts to conduct a prospective study of bone microarchitecture, evaluated by HR-pQCT, and 2-year incidence of fracture. Participants included 6,763 individuals (4,768 women, 1,995 men) from the Framingham Osteoporosis Study, Geneva Retirees, Mayo Clinic, CaMos, Qualyor, OFELY, and STRAMBO cohorts. Participants underwent HR-pQCT scanning (XtremeCT, Scanco Medical AG) at the distal radius and tibia. We estimated hazard ratios (HR) for the association between each bone measure and 2-year fracture incidence, adjusted for age, sex, cohort, height and weight, and then additionally adjusted for femoral neck (FN) areal BMD (aBMD) or FRAX (calculated with FN aBMD) for major osteoporosis fracture. Mean age was 68¬±9 years (range, 40-96), and 71% were women. Only 8% had FN T-score ≤ -2.5, whereas 55% had

FN T-score between -1.0 and -2.5 and 37% had FN T-score ≥-1.0. Two-year cumulative incidence of fracture was 4% (271/6,763). Fractures included 67 (25%) wrist, 34 (13%) spine, 32 (12%) ankle, 28 (10%) rib, 20 (7%) upper arm, 8 (3%) hip and 82 (30%) at the pelvis, lower thigh, and other sites. For each SD decrease in radius cortical indices, fracture risk increased 38% to 73% and remained increased by 29% to 61% after additional adjustment for FN aBMD (Table). Trabecular indices were also significantly associated with 2-year fracture risk, independently of FN aBMD, with adjusted HRs ranging from 1.15 (SD trabecular number) to 1.54 (trabecular volumetric BMD, vBMD). Decreased failure load was associated with nearly a 2-fold (HR=1.97) increased fracture risk, and after adjustment for FN aBMD, HR=1.77. Results for the tibia (not shown) were similar to those for the radius, and findings were similar when models adjusted for FRAX (Table). In this large, community-based population of older adults, cortical and trabecular bone microarchitecture and density predicted short-term risk of fracture, independent of FN aBMD and FRAX. These results indicate that HR-pQCT may be a useful adjunct to traditional assessment of imminent fracture risk in older adults, including those with T-scores above the osteoporosis range.

Hazard ratios (HR) and 95% confidence intervals (CI) for the association between DXA aBMD at the femoral neck (FN) and HR-pQCT indices at the radius and two-year incidence of fracture: Bone Microarchitecture International Consortium (BoMIC)

Prediction of Incident Hip Fracture: Can we do Better than Femoral Neck aBMD? A Comprehensive Image-Based Assessment in Men and Women Julio Carballido-Gamio*[1], Sigurdur Sigurdsson[2], Kristín Siggeirsdottir[2], Alexandria Jensen[1,3], Gunnar Sigurdsson[2,4,5], Thor Aspelund[2,6], Gudny Eiriksdottir[2], Vilmundur Gudnason[2,4], Thomas F Lang[7], Tamara B Harris[8]. [1]Department of Radiology, School of Medicine, University of Colorado Denver, Denver, CO, United States, [2]Icelandic Heart Association Research Institute, Kópavogur, Iceland, [3]Department of Biostatistics & Informatics, Colorado School of Public Health, Aurora, CO, United States, [4]University of Iceland, Reykjavik, Iceland, [5]Landspitalinn University Hospital, Reykjavik, Iceland, [6]Centre of Public Health Sciences, University of Iceland, Reykjavik, Iceland, [7]Department of Radiology and Biomedical Imaging, University of California, San Francisco, CA, United States, [8]National Institute on Aging, Intramural Research Program, Laboratory of Epidemiology and Population Sciences, Bethesda, MD, United States

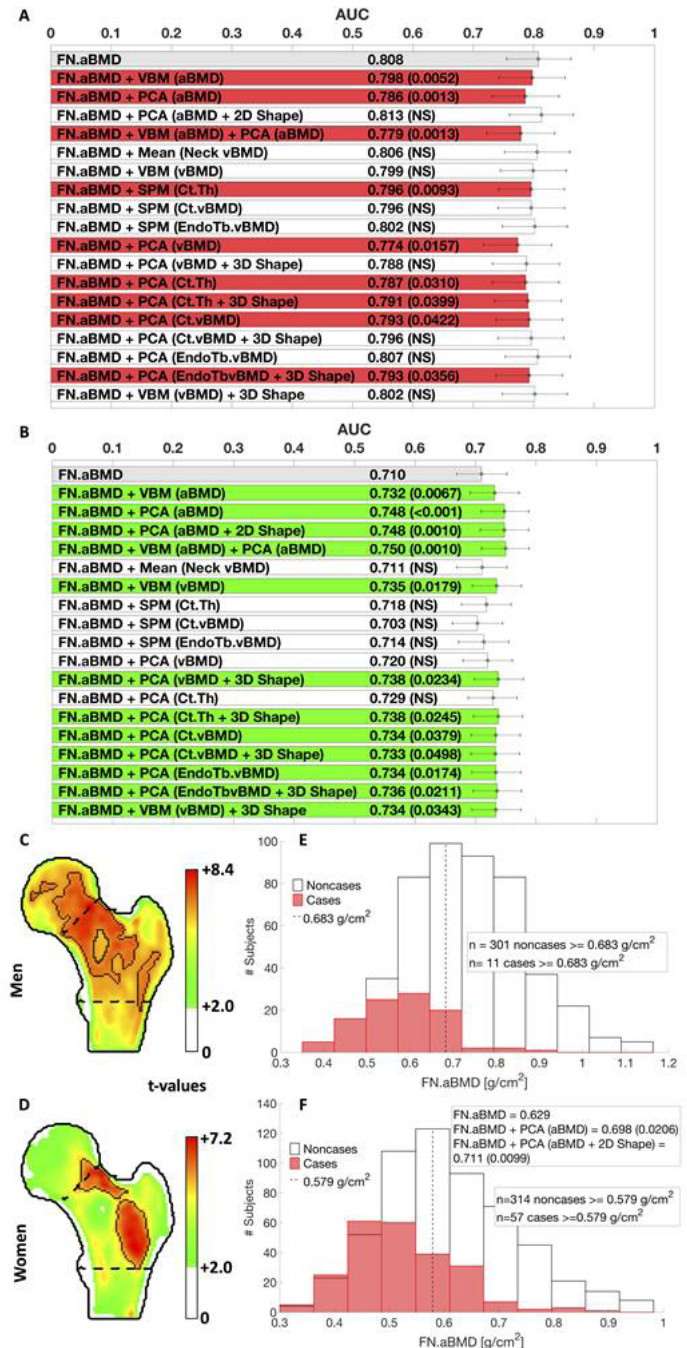
Fragility hip fractures lead to devastating personal and financial effects. DXA aBMD is the clinical standard to assess osteoporosis and hip fracture risk. However, subjects with normal aBMD do fracture, underscoring the necessity of better hip fracture prediction techniques. The objective of this work was to perform a comprehensive image-based assessment of hip fracture prediction using advanced image analyses and machine learning. A subset of 585 men (76.9±5.6 yr) and 796 women (77.0±5.5 yr) from the AGES Reykjavik Study was included in this work, including 100 men and 234 women having incident hip fracture. Using baseline hip QCT scans, 3D parametric maps of vBMD, cortical bone thickness, cortical vBMD and endosteal vBMD, and 2D QCT-derived aBMD maps were generated. Local parametric comparisons were then performed between cases and noncases —stratified by sex— using voxel-based morphometry (VBM) and statistical parametric mapping (SPM) with general linear models allowing for covariates. Statistical multi-parametric modeling (SMPM) —based on principal component analysis (PCA)— was also performed for all the parameters with and without shape. VBM and SPM yielded Student's t-test statistical maps (t-Maps) indicating regions where the parameters were significantly associated with fracture. These regions were subdivided to identify the most significant clusters using fuzzy c-means (FCM). SMPM generated scores for each subject, parameter and PC representing different spatial parametric patterns. Mean parametric values within the FCM clusters and SMPM scores were then used with machine learning elastic net regularization to generate hip fracture prediction models, whose performance was assessed with ROC analyses measuring AUC improvements with respect to mean femoral neck aBMD (FN.aBMD). The full pipeline was performed with stratified 10-fold cross-validation. Fig. 1 summarizes the results of this study with 3 important findings: 1) in men, FN.aBMD was the best predictor; 2) in women, several QCT parameters performed better than FN.aBMD, however, PCA of aBMD maps was the best predictor; and 3) in women with high FN.aBMD, PCA of aBMD maps remained as the best predictor. Our results indicate that FN.aBMD might be a good predictor in men, and that advanced image analyses and machine learning improve aBMD-based prediction in women. Ultimately, QCT enables 3D assessments of both BMD and bone quality that capture diagnostic information that cannot be measured by DXA.


Fig 1. AUCs (p-values) for the prediction models in men (A) and women (B). VBM t-Maps of aBMD comparisons between cases and noncases in men (C) and women (D) with dotted lines enclosing the FCM clusters. Distribution of FN.aBMD values in men (E) and women (F). PCA of aBMD remained as the best predictor in women with high FN.aBMD (F).

Notes: The femoral head was excluded from the SPM analyses due to the thin cortical bone, and from the 2D VBM and PCA analyses for a more realistic DXA scenario. White pixels in (C) and (D) were not significant after false discovery rate correction for multiple comparisons. Abbreviations: Ct.Th = cortical bone thickness; Ct.vBMD = cortical vBMD; EndoTb.vBMD = vBMD in a layer adjacent to the endosteal surface; NS = nonsignificant.

Deterioration of Bone Microstructure Identifies Women at Imminent Risk of Fragility Fractures Roland Chapurlat*[1], Elisabeth Sornay-Rendu[1], Roger Zebaze[2], Minh Bui[2], Eric Lespessailles[3], Ego Seeman[2]. [1]INSERM UMR 1033, France, [2]University of Melbourne, Australia, [3]IPROS, France

The burden of fragility fractures in the population arises from women with osteopenia or normal bone mineral density (BMD), not osteoporosis. Microstructural deterioration increases bone fragility out of proportion to the bone loss producing it. Our goal was to determine whether women at imminent risk for fracture, particularly those with osteopenia or normal BMD, are detectable by measuring microstructural deterioration. We measured distal radial microstructure, BMD and the Fracture Risk Assessment (FRAX) score in two prospective studies of postmenopausal women, the OFELY (n = 589) and QUALYOR (n = 1540) studies, in France. Microstructural deterioration of cortical porosity and trabecular density relative to the mean in premenopausal women was measured with high resolution peripheral quantitative tomography and expressed as a Structural Fragility Score (SFS). The thresholds used were a T score of < - 2.5 SD for BMD, a FRAX score > 20 and the SFS > 70. Fracture risk associated with BMD, FRAX and the SFS was estimated by odds ratios (OR) using the exact logistic regression method before and after removing the contribution of the other two tools. Among 1996 women (mean age 67 [range 42-96]), during 2 years, 98 had a fracture at a median of 1.06 years; 20.4% had osteoporosis, 79.6% had osteopenia or normal BMD. Neither BMD nor FRAX predicted fracture independent of the Structural Fragility Score. By contrast, the Structural Fragility Score, independent of BMD or FRAX, identified 14 of 20 women with osteoporosis having a fracture (sensitivity 70%, specificity 63.1%, odds ratio, OR 3.95, p=0.01), 29 of 78 women with osteopenia or normal BMD having a fracture (sensitivity 37.2%, specificity 83.6%, OR 3.01, p<0.001) and 19 of 24 women over 70 years of age having major fragility fractures (sensitivity 79.2%, specificity 69.3%, OR 8.52, p<0.001).We conclude that most postmenopausal women at imminent risk for fracture within 2 years remain undetected using BMD or FRAX but are identifiable by measuring microstructural deterioration non-invasively. These women are likely to need prompt treatment that is not triggered using FRAX or BMD.

Prevalent Vertebral Fracture Identified on Densitometric Images Predict Incident Fractures in Routine Clinical Practice John Schousboe*[1], Lisa Lix[2], Suzanne Morin[3], Sheldon Derkatch[2], Mark Bryanton[2], Mashael Alhrbi[2], William Leslie[2]. [1]Park Nicollet Clinic and HealthPartners Institute, United States, [2]University of Manitoba, Canada, [3]McGill University, Canada

Purpose:Using vertebral fracture assessment (VFA) on densitometric lateral spine images to identify those with prevalent vertebral fracture is not widely accepted, in part because the predictive validity of VFA in clinical practice has not been established. Our objective was to estimate the associations of prevalent vertebral fractures identified on VFA images obtained during routine practice with incident hip, non-vertebral, major osteoporotic, and clinical vertebral fractures.Methods: Using the Manitoba (Canada) Bone Density database from 2010 onward, VFA images were obtained for 9972 men and women (mean age [SD] 76 [6.9] years) referred for bone densitometry (DXA). Definite prevalent vertebral fractures (positive VFA) were identified in 1575 (15.8%) using a modified algorithm-based qualitative method. Incident fractures were identified using administrative claims data during a mean follow-up of 2.8 [1.7] years. Cox proportional hazards models estimated the associations between positive VFA and incident fractures adjusted for: (1) FRAX (with femoral neck bone mineral density [BMD]) probabilities of major osteoporotic fracture (MOF); (2) FRAX risk factors (age, body mass index, femoral neck BMD, prior fracture, parental hip fracture, glucocorticoid use, alcohol use, smoking, rheumatoid arthritis) as separate covariates; or (3) FRAX risk factors with lumbar spine BMD and osteoporosis drug therapy (Rx).Results: Hazard Ratios (95% CI) for incident fracture in those with positive VFA vs VFA negative for vertebral fracture are shown in the Table. Positive VFA was significantly associated with the incidence of all fracture outcomes. Interaction terms between positive VFA and MOF FRAX with BMD score or BMD T-score category for prediction of fracture at any skeletal site were nonsignificant.Conclusions: Prevalent vertebral fracture identified on densitometric VFA images in routine clinical practice are strongly associated with incident hip, vertebral, and other clinical fractures, adjusted for BMD and other clinical risk factors. These associations do not vary by FRAX with BMD score or BMD T-score level. These associations are similar in strength to those shown in prospective studies using standard radiographs to identify prevalent vertebral fracture, and establish the predictive validity of using VFA at the time of bone densitometry to aid fracture risk assessment in routine clinical practice.

Table: Hazard Ratios (95% CI) for Incident Fracture in Those with Definite vs No Prevalent Vertebral Fracture

Fracture Outcome	Covariates		
	FRAX with BMD MOF Score	FRAX risk factors	FRAX risk factors + LS-BMD + Osteoporosis Rx
Hip Fracture (n=226)	2.20 (1.65, 2.94)	1.95 (1.45, 2.62)	2.13 (1.51, 3.02)
All Non-Vertebral (n=715)	2.10 (1.77, 2.47)	1.99 (1.68, 2.35)	2.08 (1.71, 2.54)
Major Osteoporotic* (n=552)	2.07 (1.71, 2.50)	1.95 (1.61, 2.37)	2.07 (1.65, 2.09)
Clinical Vertebral* (n=93)	2.78 (1.77, 4.35)	2.68 (1.69, 4.23)	3.09 (1.85, 5.16)

*Excludes vertebral fractures during first 12 months of follow-up

Screening for Incomplete Atypical Femur Fractures in Bone Density Laboratories Sameh Melk*, Robert Bleakney, Lianne Tile, Rowena Ridout, Heather Mcdonald-Blumer, Angela Cheung, Moira Kapral,, Judite Scher,, Alice Demaras. UHN, Canada

Background: Complete atypical femur fractures (AFFs) are a rare complication of antiresorptive medications used to treat osteoporosis, with reported frequencies of approximately 1 in 1000 patient-years after long-term (6-10 yrs) use. Recent studies suggest that incomplete AFFs (iAFFs) may be more common because approximately 75% of patients with complete AFF have prodromal symptoms prior to their fracture. Imaging with either plain radiographs or densitometer-based techniques may detect an iAFF prior to a complete break. This study examined the frequency of iAFFs at 3 academic bone density laboratories in Toronto.Methods: We screened women either postmenopausal or over age 50 who had been on at least 5 years of oral bisphosphonate therapy or 3 years of intravenous bisphosphonates or denosumab from bone density laboratories at three academic centres in Toronto (Toronto General Hospital, Toronto Western Hospital and Princess Margaret Hospital). All women had to have pain, discomfort or weakness in their upper leg. Subjects underwent a Single Energy (SE)-femur scan using Hologic Discovery or Horizon A densitometers, scanning from above the lesser trochanter to the medial condylar flare, and a plain radiograph of the femur for comparison. Scans were read by an expert with extensive experience in identifying femur characteristics along the AFF spectrum.Results: 1361 women met age and/ or postmenopausal criteria and of these, 315 (26%) had leg symptoms, and 255 consented to participate in the study. Of the 545 femurs scans completed, SE-femur identified 2 iAFFs in 2 (0.8%) women, one of whom had a prior AFF on the contralateral side which was not previously recognized as AFF. 13 (5%) women (19 femurs) had an equivocal focal cortical reaction (2 were endosteal). 81 (32%) women (121 femurs) had generalized cortical thickening. Follow-up imaging (SE-femur +/- plain radiograph) 6 months to 2 years later did not yield further iAFFs. SE-femurs detected other abnormalities including vascular calcifications, an intraosseous lipoma, avascular necrosis, enchondromas, tug lesions and gold threads from acupuncture.Conclusions: Incomplete AFFs are rare even in this higher risk group of women on long-term potent antiresorptive therapy and who have upper leg symptoms. However, they may be more frequent than complete AFFs. Further studies are needed to better define the cost-effectiveness of screening strategies to identify iAFFs in those at risk.

Genomic Prediction of Osteoporosis Using 426,000 Individuals from UK Biobank Vincenzo Forgetta*[1], Julyan Keller-Baruch[2], Marie Forest[1], Audrey Durand[3], Sahir Bhatnagar[4], John Kemp[5], John Morris[1], John Kanis[6,7], Douglas Kiel[8], Eugene Mccloskey[9], Helena Johansson[6,7], Nicholas Harvey[10], Dave Evans[5], Joelle Pineau[3], William Leslie[11], Celia M T Greenwood[2], J Brent Richards[2]. [1]Centre for Clinical Epidemiology, Lady Davis Institute, Jewish General Hospital, McGill University, Canada, [2]Department of Human Genetics, McGill University, Canada, [3]School of Computer Science, McGill University, Canada, [4]Centre for Clinical Epidemiology, Lady Davis Institute, Jewish General Hospital, Canada, [5]University of Queensland Diamantina Institute, Translational Research Institute, MRC Integrative Epidemiology Unit, University of Bristol, Australia, [6]Centre for Metabolic Bone Diseases, University of Sheffield, United Kingdom, [7]Australian Catholic University, United Kingdom, [8]Institute for Aging Research, Hebrew SeniorLife, Harvard Medical School, Broad Institute of MIT & Harvard, United States, [9]Mellanby Centre for Bone Research, Centre for Integrated Research in Musculoskeletal Ageing, University of Sheffield, United Kingdom, [10]Medical Research Council Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, [11]Department of Medicine (Endocrinology), Department of Radiology (Nuclear Medicine), University of Manitoba, Canada

Background The prediction of clinically relevant traits using genetics has not yet been generally successful, even those which are highly heritable, such as bone density, the measure most often used to diagnose osteoporosis. We tested whether machine learning methods could improve prediction of estimated bone mineral density (eBMD) from genotypes. Methods We used the UK Biobank to identify 426,812 individuals with eBMD measures at calcaneal ultrasound and genome-wide genotypes, who were of British descent. Dividing the cohort into separate training (N = 341,450), validation (N = 42,681) and test (N = 42,681) datasets, we first evaluated a prediction model containing only age and sex, two commonly used metrics to identify people for BMD testing. Next, we undertook a genome-wide association study for eBMD in the training set. Using top-ranked SNPs from the GWAS by P-value we trained a machine learning algorithm, least absolute shrinkage and selection operator (LASSO), using six different SNP sets to predict eBMD in the training set. We optimized tuning parameters for these SNP sets in the validation dataset and selected the best performing SNP set for evaluation of prediction in the test dataset. Last, we tested whether genomic pre-screening could identify individuals unlikely to have a diagnosis of osteoporosis by eBMD measurement. Results In the test dataset, the variance explained in eBMD by age and sex was 5.8%. The area under the receiver operator curve using age and sex was 71.3% [95% CI: 68.7%-74%] for the diagnosis of osteoporosis. Using the machine learning algorithm and adding genotypic information, the variance explained increased approximately five-fold to 29.7%. The area under the receiver operator curve for the diagnosis of osteoporosis increased to 81.3% (P = 2x10-17, compared to age and sex alone). The maximal combined sensitivity and specificity for the diagnosis of osteoporosis were 75% and 75%, respectively. Including only individuals aged 55-, or 65- and over generated similar prediction performance. Interpretation The use of genotypes in a machine learning algorithm resulted in a clinically-relevant improvement in the identification of individuals at risk for eBMD-defined osteoporosis and provides the opportunity to use a genomic pre-screening to focus clinical screening programs.

Excess intra-abdominal adipose tissue accumulation increases the risk of fragility fracture: A Mendelian randomization study with Genome-wide association meta-analysis on fracture Yi-Hsiang Hsu*[1], Chia-Yen Chen[2], Ching-Ti Li[3], Douglas Kiel[4]. [1]Harvard Medical School and Broad Institute of MIT and Harvard, United States, [2]Analytic and Translational Genetics Unit, Massachusetts General Hospital, United States, [3]Dept. Biostatistics, School of Public Health, Boston Univ., United States, [4]Hebrew SeniorLife and Harvard Medical School, United States

Although high BMI and obesity have been traditionally considered to reduce fracture risk, the association between obesity and the risk of fragility fracture from observational studies is controversial, possibly due to confounding factors and reverse causality. To overcome such challenges, Mendelian randomization (MR) has been proposed to estimate causal relations between an exposure and outcome. MR utilizes genetic risk factors as instrumental variables that are naturally randomized at birth. In addition, the BMI phenotype does not reflect the actual amount of fat tissue that may affect the skeleton. Visceral adipose tissue (VAT) measured by qCT better quantifies metabolically active fat. To determine the causal relation of VAT with the risk of fracture, we selected SNPs associated with VAT from a genome wide association study (GWAS) meta-analysis (10,557 adult Caucasians) as instrumental variables. These SNPs are located in ADAD2, CLSTN2, DCLK2, DNAH10, GJB5, KCNG4, KSR2, LOC642502, LOC92017, MPZ, PCP4L1, PDCD6IP, RREB1, SDHC, TAF1C, TRAM1L1 and WFDC1 GWAS loci. The fracture GWAS meta-analysis was done in 264,973 adult samples from 23 cohort studies (37,857 fracture cases, 227,116 controls). To estimate the per SNP causal relation between VAT and fracture risk, we used the 2-sample MR analytical approach. To increase statistical power, we combined each SNP result into a multi-instrument summary-level MR variable. To avoid bias from pleiotropic genetic effects, we applied a newly developed method, the Mendelian Randomization Pleiotropy RESidual Sum and Outlier (MR-PRESSO) test. We found a causal effect of VAT on fracture risk with a 10% increased risk for all fractures per each SD increase in genetically-estimated VAT (OR=1.10, 95%CI=1.04-1.16). We did not detect any pleiotropic biases in our MR analysis. Among tested SNPs, the maximum OR was 1.19 (19% increase risk). We performed MR-analyses on other obesity relevant measurements (Body fat%, waist circumference, hip circumference, waist-hip ratio & overweight). None of them were causally associated with fracture risk. In summary, with robust GWAS studies and genetically-driven MR analyses, we found that VAT, but not other classical obesity indies, causally increase fracture risk. These findings suggest that specific efforts to reduce VAT might lower the risk for fracture. Gender-specific MR-analyses are underway to identify whether the increased fracture risk from VAT is gender-specific.

Serum 25-Hydroxyvitamin D Values and Risk of Incident Cardiovascular Disease: A Population-Based Retrospective Cohort Study Daniel Dudenkov*, Kristin Mara, Tanya Petterson, Julie Maxson, Tom Thacher. Mayo Clinic, United States

Background: Concentrations of serum 25-hydroxyvitamin D [25(OH)D] below 20 ng/mL and above 50 ng/mL have been associated with chronic adverse events including cardiovascular disease. Our objective was to conduct a comprehensive population-based study in the United States of the relationship of low and high serum 25(OH)D levels with cardiovascular disease.Methods: We identified all serum 25(OH)D measurements in adults age 18 years and older residing in Olmsted County, MN between January 1, 2005 and December 31, 2011, using the resources of the Rochester Epidemiology Project. Any new diagnosis of cardiovascular disease (arrhythmia, cardiac arrest, cardiomyopathy, cerebrovascular disease, coronary artery disease, heart failure, myocardial infarction, peripheral vascular disease) was the primary outcome, and time zero was 30 days after first 25(OH)D measurement. Patients were followed until their last clinical visit as an Olmsted County resident, December 31, 2014, or death. Categories of 25(OH)D values were examined using predetermined ranges of interest: <12, 12-19, 20-50 (reference range), and >50 ng/mL. Multivariable Cox proportional hazards models were adjusted for age, BMI, sex, race, smoking history, season of 25(OH)D measurement, hypertension, hyperlipidemia, and Charlson comorbidity index at time of 25(OH)D measurement. Results: A total of 11,022 unique persons had a 25(OH)D measurement during the seven year interval, with a mean (±SD) value of 30.0±12.9 ng/mL. Mean age was 54.3±17.2 years, and the majority were female (77.1%) and white (87.6%). There were 4,355 incident diagnoses of cardiovascular disease in this cohort after a median overall follow-up of 4.8 years (IQR 3.4-6.2). Unadjusted cardiovascular disease hazard ratios (HRs) (95% confidence interval) for 25(OH)D values <12, 12-19, and >50 ng/mL, compared to the reference range 20-50 ng/mL, were 1.36 (1.21-1.53), 1.12 (1.03-1.22), and 1.17 (1.02-1.33), respectively. Adjusted hazard ratios for the same 25(OH)D categories were 1.33 (1.17-1.51), 1.22 (1.12-1.33), and 1.15 (1.00-1.31). Figure shows the HRs for cardiovascular outcomes with 25(OH)D values as a continuous variable.Conclusion: Values of 25(OH)D <20 ng/mL were associated with the development of a new diagnosis of cardiovascular disease after adjusting for comorbidities. There may also be an association between 25(OH)D >50 ng/mL and cardiovascular disease, although the results are not statistically significant.

Estradiol and Follicle Stimulating Hormone as Predictors of Onset of Menopause Transition- related Bone Loss in Pre- and Perimenopausal Women Albert Shieh*[1], Gail Greendale[1], Jane Cauley[2], Carrie Karvonen-Guttierez[3], Carolyn Crandall[1], Arun Karlamangla[1]. [1]University of California, Los Angeles, United States, [2]University of Pittsburgh, United States, [3]University of Michigan, United States

Purpose. The menopause transition (MT) could be an optimal but time-limited window for early interventions to prevent future fractures. In order to intervene before substantial bone loss has occurred, we must be able to determine when a woman is about to begin losing bone. The objective of this study was to examine the ability of single and serial measures of serum estradiol (E2) or follicle stimulating hormone (FSH) to predict the onset of MT-related bone loss.Methods. We used data from 1,113 participants in the Study of Women's Health Across the Nation (SWAN) who had at least 2 measurements of E2 and/or FSH from pre- (regular menstrual bleeding), early peri- (less predictable menstrual bleeding at least once every 90 days), and/or late perimenopause (menstrual bleeding less than once every 90 days), as well as corresponding measurements of bone loss. Onset of MT-related bone loss was defined as a decline in BMD from SWAN baseline to the first follow-up visit after the E2 or FSH measurement that exceeded the site-specific least significant change (3.9% for lumbar spine [LS]; 6.2% for femoral neck [FN]). In our first set of analyses, E2 and FSH (log-transformed, base 2) were each modeled as predictor of MT-related bone loss onset in separate models, using mixed-effects, repeated-measures, modified Poisson regression, adjusted for age, BMI, race/ethnicity, MT stage, and study site. In our second set of analyses, within-woman changes in E2 and FSH from SWAN baseline to a follow-up visit before postmenopause were each modeled as primary predictor in separate models, adjusted for level of E2 or FSH, respectively, plus the above covariates. Results. Single Measures: Each doubling of E2 was associated with 9% and 11% lower risk of bone loss onset at the LS (p<0.0001) and FN (p=0.01). Similarly, each doubling in FSH was associated with a 39% and 27% greater risk of bone loss onset at the LS (p<0.0001) and FN (p<0.0001). Serial Measures: Within-woman change in E2 or FSH did not predict onset of bone loss at either the LS (p=0.2 for E2, 0.8 for FSH) or FN (p=0.9 for E2, 0.5 for FSH) independent of E2 or FSH level.Conclusions. We conclude that that single measures of E2 or FSH early in the MT may aid in prompt identification of women who are about to begin losing bone, and that tracking within-woman change in E2 or FSH does not add independent prediction ability.

The Association between Objectively Measured Physical Activity and Bone Strength and Microarchitecture Among Older Men Lisa Langsetmo*[1], Andrew Burghardt[2], John Schousboe[1], Peggy Cawthon[2], Jane Cauley[3], Nancy Lane[4], Kristine Ensrud[5], Eric Orwoll[6]. [1]University of Minnesota, United States, [2]University of California, San Francisco, United States, [3]University of Pittsburgh, United States, [4]University of California, Davis, United States, [5]University of Minnesota, Minneapolis VA Health Care System, United States, [6]Oregon Health and Science University, United States

To examine the association between objectively measured physical activity (PA) with bone strength of the distal limbs, we studied 994 older men (mean age 83.9 years, SD 3.9) with 5-day activity assessments and at least 90% wear time (SenseWear Pro3 Armband) at Y7 and Y14 Visit who also had Y14 bone microarchitecture assessments of the distal radius and tibia (Scanco high resolution peripheral quantitative tomography [HR-pQCT]). PA parameters were averaged over the 2 time-points. Armband data along with height, weight, handedness, and smoking status were used to estimate total energy expenditure [TEE], total steps per day, and level of activity: sedentary (<1.5 METs), light (1.5-3 METs), or at least moderate (≥3 METs). Peak 30 minute cadence [P30MC] was obtained from data by ordering cadence (counts/minute) by 1 min episodes and then taking mean of the top 30 episodes. Estimated failure load (force required to break) was determined from HR-pQCT data using finite element analysis. Total, cortical, and trabecular volumetric BMD were also computed from HR-pQCT data. We used multiple linear regression models with standardized PA and HR-pQCT variables (yielding effect size) and adjusted for age, race, weight, limb length, education, alcohol use, and smoking history. For partitioned activity time, 1 unit=30 minutes. In the study cohort, the means (SDs) for daily activity were: 2338 (356) kcal [TEE]; 5739 (2696) [step count], 60 (20) counts/minute [P30MC], 67 (28) min [light activity], and 85 (52) min [at least moderate activity]. Higher TEE, step count, and P30MC were each associated with higher failure load of the distal radius (effect size from 0.08 to 0.13) but not with higher volumetric BMD or compartment specific BMD. Higher TEE, step count, and P30MC were each associated with higher failure load of the distal tibia (effect size from 0.19 to 0.21) and also with higher volumetric BMD (effect size from 0.08 to 0.15), higher trabecular BMD (effect size from 0.07 to 0.11), and higher cortical BMD (effect size from 0.09 to 0.13). Time spent in at least moderate activity vs time spent in sedentary behavior was related to bone strength at both sites after adjustment, whereas time spent in light activity was not. These results suggest that at least moderate physical activity averaged over a period of time may have a modest effect on bone strength among older men with slightly stronger effect sizes at a weight-bearing vs. a non-weight-bearing skeletal site.

Table 1: Associations* of Objective Measures of Physical Activity with Failure Load, Total BMD, and Compartmental BMD

Distal Radius	Failure Load	Total BMD	Trabecular BMD	Cortical BMD
Total energy expenditure	0.13 (0.06, 0.20)	0.01 (−0.06, 0.09)	0.05 (−0.03, 0.12)	−0.03 (−0.10, 0.05)

Lower Insulin Sensitivity in Patients With High Bone Mass due to a LRP5T253I mutation Jens-Jacob Lindegaard Lauterlein*, Anne Pernille Hermann, Moustapha Kassem, Kurt Højlund, Morten Frost. Department of Endocrinology and Metabolism, Odense University Hospital, Odense, Denmark

The aim of this investigation was to assess the clinical effects of increased Wnt signaling on glucose homeostasis and body composition in individuals with high bone mass (HBM) due to a LRP5T253I mutation.The LDL receptor-related protein 5 (LRP5) is an important co-receptor in the canonical Wnt signaling pathway, and LRP5 is involved in the differentiation of mesenchymal stem cells favoring osteoblastogenesis over adipogenesis as well as substrate utilization, e.g. by favoring β-oxidation of fatty acids in the osteoblast. In vivo, Lrp5 deficient mice display glucose intolerance, impaired pancreatic β-cell function and low bone mass. In humans, loss of function mutations in LRP5 cause severe osteoporosis and impaired glucose metabolism due to reduced β-cell function, whereas LRP5 gain of function mutations causes HBM and has been reported to be associated with reduced insulin resistance (HOMA-IR) and a beneficial fat distribution.We recruited 14 patients with LRP5T253I HBM and 14 healthy age-, sex- and BMI-matched controls. Insulin secretion was assessed using a 1-hour intravenous glucose tolerance test (IVGTT), and insulin sensitivity was measured as insulin-stimulated glucose disposal rates (Rd) using a 3-hour euglycaemic hyperinsulinaemic clamp. Substrate metabolism was evaluated by indirect calorimetry, and body composition was investigated using whole body DXA.One LRP5T253I HBM patient with undiagnosed diabetes (HbA1c: 7.6%, ref. <6.5%) was excluded from further analyses. There was no difference in age (48(5) vs. 47(4) years), BMI (29.4 vs. 29.7 kg/m2) or HbA1c (5.4% in both) between LRP5T253I HBM and controls. Furthermore, we observed no difference in β-cell function between the two groups (IVGTT: normal first and second phase insulin response). Insulin sensitivity was reduced by 25% in LRP5T253I HBM compared to controls (Rd 258(19) vs. 347(26) mg/m2/min, p<0.01), whereas insulin-mediated suppression of hepatic glucose production was intact. Respiratory exchange rate in the insulin-stimulated state was lower in LRP5T253I HBM (0.89 vs. 0.95, p<0.05), consistent with a higher rate of lipid oxidation (p<0.05). There was no difference in the distribution of peripheral and central fat mass between groups.These data indicate that the LRP5T253I mutation impairs glucose metabolism in humans by reducing insulin sensitivity in skeletal muscle. The mutation does not affect hepatic insulin sensitivity, pancreatic β-cell function or fat distribution.

Genetic and epigenetic defects at the GNAS locus lead to distinct patterns of skeletal growth but similar early-onset obesity Patrick Hanna*[1], Harald Jüppner[2], Guiomar Perez De Nanclares[3], Giovanna Mantovani[4], Alessia Usardi[5], Susanne Thiele[6], Agnès Linglart[7]. [1]INSERM U1169 and Paris Sud Paris-Saclay university, Bicêtre Paris Sud hospital, France, [2]Endocrine Unit and Pediatric Nephrology Unit, Massachusetts General Hospital and Harvard Medical School, United States, [3]Molecular (Epi)Genetics LaboratoryBioAraba National Health Institute, OSI Araba University Hospital, Spain, [4]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico Endocrinology and Diabetology Unit, Department of Clinical Sciences and Community Health, University of Milan, Italy, [5]APHP, Reference Center for rare disorders of the calcium and phosphate metabolism, filière OSCAR and Plateforme d'Expertise Maladies Rares Paris-Sud, Bicêtre Paris Sud hospital, France, [6]Division of Experimental Pediatric Endocrinology and Diabetes Department of Pediatrics, Center of brain, behavior and metabolism, University of Lübeck, Germany, [7]APHP, Endocrinology and diabetes for children, Bicêtre Paris Sud hospital, France

Introduction: Pseudohypoparathyroidism type 1A (PHP1A), pseudoPHP (PPHP), and PHP1B are caused by maternal and paternal GNAS mutations, and abnormal methylation at maternal GNAS promoter(s), respectively. Adult PHP1A patients are reportedly obese and short, whereas most PPHP patients are born small. In addition to PTH resistance, PHP1A and PHP1B patients may display early-onset obesity. Objectives: characterize the growth and weight gain patterns in patients with GNAS molecular defects. Methods: Through an

international collaboration, we collected growth and weight data from birth until adulthood for 306 PHP1A/PPHP and 220 PHP1B patients. Results: PHP1A/PPHP patients were smaller at birth than healthy controls, especially PPHP (length z-score PHP1A: -1.1±1.8; PPHP: -3.0±1.5). Short stature is observed in 64% and 59% of adult PHP1A and PPHP patients. PHP1B patients displayed early post-natal overgrowth (height z-score at 1 year: 2.2±1.3 and 1.3±1.5 in autosomal dominant and sporadic PHP1B). After birth, both PHP1A and PPHP patients displayed a moderate catch-up growth, but showed a progressive decline in growth velocity and lack of pubertal spurt leading to a final short stature (height z-score: PHP1A: -0.6±1.7 at 3 years, -0.9±1.3 at 10 years, -2.5±1.1 at 18 years; PPHP: -1.5±1.5 at 3 years, -0.2±1.1 at 10 years, -1.9±1.2 at 18 years). PHP1B patients showed a gradual decrease in growth velocity resulting in normal adult height (height z-score: AD-PHP1B: 1.2±0.9 at 3 years, -0.2±1.3 at 10 years, and -0.4±1.1 at 18 years; spor-PHP1B: 1.1±0.9 at 3 years, 0.8±1.3 at 10 years, and -0.4±1.1 at 18 years). Early-onset obesity characterizes GNAS alterations (BMI z-score at 1 year: PHP1A: 3.5±2.3, AD-PHP1B: 2.5±1.6 and spor-PHP1B: 2.9±1.4) and is associated to significant overweight and obesity in adults (BMI z-score: 1.4±2.6, 2.1±2.0, and 1.4±1.9 in PPHP, PHP1A, and PHP1B, respectively). Conclusion: The growth impairment in PHP1A/PPHP may be due to Gsα haploinsufficiency in the growth plates; the paternal XLαs transcript likely contributes to prenatal growth; for all disease variants, a reduced pubertal growth spurt may be due to accelerated growth plate closure. Consequently, early diagnosis and close follow-up is needed in patients with GNAS defects to screen and intervene in case of early-onset obesity and decreased growth velocity.

Sclerostin Resistance Protects Bone Mass and Improves Insulin Sensitivity in a Mouse Model of Type 1 Diabetes Giulia Leanza*[1,2], Francesca Fontana[2], Rocky Strollo[1], Paolo Pozzilli[1], Nicola Napoli[1,2], Roberto Civitelli[2]. [1]Campus Bio-Medico University, Italy, [2]Washington University in St Louis, United States

Patients with type 1 diabetes (T1D) are at increased risk of fracture, but the mechanisms of such increased bone fragility remain largely unknown. In a preliminary study, we found high circulating levels of the Wnt inhibitor sclerostin (Scl) in T1D patients, suggesting a potential role of Wnt signaling in diabetic bone disease. To test this hypothesis, we introduced the Scl-resistant Lrp5A214V mutation, associated with high bone mass (HBM), in mice carrying the Ins2Akita mutation (Akita), which become spontaneously diabetic at age 4-5 week. Bone mass by DXA was significantly higher in Akita/HBM relative to Akita littermates at 12 weeks (88.2±5.2 vs 67.9±4 mg/cm2; p<0.001; n=7-11), persisting higher for up to 26 weeks (90.2±3.0 vs 70.4±1.7mg/cm2; p<0.001 n=5) despite overt diabetes. Further analysis by μCT at age 20 weeks revealed lower trabecular bone volume/total volume (BV/TV) in Akita compared to wild type (WT) mice (0.2±0.02 vs 0.35±0.05; p<0.05; n=3-5). Conversely, both trabecular (Tb) and cortical (Ct) parameters were significantly higher in Akita/HBM mutants compared to Akita littermates, including total Ct area (1.6±0.06 vs 1.2 ±0.07mm2), Ct bone area (0.9±0.1 vs 0.6±0.05mm2), and Ct thickness (0.2±0.02 vs 0.1±0.01 mm, p<0.001, n=5-7). Tb BV/TV and Tb thickness were also higher in Akita/HBM mutants relative to Akita littermates (0.4±0.05 vs 0.2±0.02; and 0.1±0.02 vs 0.09±0.03mm, respectively, p<0.001, n=3-5). We found no significant differences in total Ct area between Akita and WT mice, consistent with observations in humans with T1D. As expected, both Akita and Akita/HBM mutants developed diabetes (non-fasting blood glucose >300 mg/dl), albeit with different onset timing. At 8 weeks, only 40 % of Akita/HBM mice had developed hyperglycemia, compared to 90% of Akita mice (n=10). Only at 12 weeks were most Akita/HBM mice hyperglycemic. Intriguingly at age 6 and 8 weeks, glucose tolerance was significantly better in Akita/HBM relative to Akita mice (p<0.05 for difference in areas under the curve, AUC; n=3-6). Likewise, insulin sensitivity (by intraperitoneal insulin tolerance test) was higher in the Akita/HBM compared to the Akita group (p<0.01 for difference in AUC; n=4-8) at age 7 weeks. In summary, Wnt activation protects bone mass and may retard the onset of metabolic abnormalities in T1D, thus disclosing a potential additional therapeutic advantage to Scl inhibition.

AdipoRon, an Adiponectin Receptor Agonist, Ameliorates Diabetic Bone Disorders by Inhibiting Osteoclastogenesis and Promoting Bone Formation Xingwen Wu*[1,2], Maxwell Tu[1], Wei Qiu[1], Junxiang Lian[1], Youcheng Yu[2], Jake Chen[1,3]. [1]Division of Oral Biology, Tufts University School of Dental Medicine, United States, [2]Department of dentistry, Zhongshan hospital, Fudan University, China, [3]Department of Developmental, Molecular and Chemical Biology Sackler School of Graduate Biomedical Sciences Tufts University School of Medicine, United States

Objectives: Adiponectin (APN), a primary adipokine, has insulin-sensitizing and anti-diabetic properties. Recent literature indicates a strong correlation between low levels of adiponectin and bone disorders. AdipoRon (APR), a recently found orally active small molecules, binds and activates both adiponectin receptors (AdipoR1, R2), with potent effects similar to adiponectin. In this study, we investigated whether APR can ameliorate diabetic bone disorders through inhibiting osteoclastogenesis and promoting bone formation in both in vitro and in vivo models.Materials and Methods: We used experimental periodontitis

calvarial bone defect mouse models to test our hypothesis. Three types of animals were used including diet-induced obesity (DIO) mice, APN knockout (KO) mice and normal-chow (NC) diet wild type mice as controls. Moreover, RAW 264.7 cells and bone marrow macrophages (BMM) were used to explore if APR can inhibit osteoclastogenesis. Primary calvarial bone osteoblasts were used to test if APR can promote osteogenesis.Results: APR increased the expression level of ALP, RUNX2 and OCN during osteogenic induction of primary calvarial bone osteoblasts (Figs. A-C), while the RANKL-enhanced expressions of Cathepsin K, TRAP and MMP9 were decreased by APR treatment in osteoclastic differentiation of RAW264.7 cells and BMMs (Figs. D, E). APR reduced alveolar bone destruction in experimental periodontitis in NC and DIO mice (Figs. F-O). The expression of CCL2, IL-6 in palatal gingiva and the number of TRAP-stained osteoclasts exhibited significantly increased in DIO-Vehicle group than in NC-vehicle group and the APR treatment decreased the CCL2 and IL-6 production and osteoclast number. APR treatment inhibited osteoclastogenesis of BMMs in both NC and DIO mice (Figs. V-X). APR promoted the healing of calvarial bone defect in DIO and KO mice (Figs. P-U). BV/TV, Tb.N and the percentage of newly formed bone were significantly increased in APR treated group than in vehicle controls. In KO mice, APR treatment increased the chemotactic gradient of SDF-1 between bone marrow and calvarial bone defect site showing a decreased level in bone marrow and an increased level in defect area (Fig. Y).Conclusions: APR could inhibit the inflammatory alveolar bone destruction and promote bone defect healing by inhibiting the osteoclastogenesis, enhancing the mineralization of osteoblasts, and promoting a favorable SDF-1-mediated chemotactic gradient for stem cell migration.

Selective Deletion of Marrow Adipocytes Leads to Increased Mesenchymal Precursors, a Shift in Lineage Allocation, and Increased Bone Mass with Improved Bone Biomechanics Steven Tommasini*[1], Tracy Nelson[1], Chad Faulkner-Filosa[1], Matthew Rodeheffer[1], Clifford Rosen[2], Dieter Lindskog[1], Mark Horowitz[1]. [1]Yale University School of Medicine, United States, [2]Maine Medical Center Research Institute, United States

Although marrow adipocytes (MA) were identified more than a century ago, it is only recently that significant progress has been made in understanding the origin, development, and function of these cells that become so prominent in the bone marrow (BM) with age and following injury. We have performed lineage tracing of MA following induction of BM adipogenesis with either rosiglitazone-enriched (rosi) diet or irradiation of double fluorescent mT/mG reporter mice to determine the ontogeny and identity of MA progenitor cells. Following either irradiation or rosi diet in Prx1-Cre:mT/mG mice, all MA were eGFP+ and therefore derived from the Prx1 lineage. Thus, we reasoned that crossing Prx1-Cre mice with mice expressing a Pparγfl/fl allele would ablate MAs. Histologically, the marrow in distal tibia of Cre-negative (control) mice was filled with MA. In contrast, Prx1-Cre:Pparγfl/fl (Cre+) mice had no marrow adipocytes in this space. To determine if MA could be induced in the proximal tibia or femur, mice were sub-lethally irradiated and MAs measured by osmium tetroxide staining. As expected, irradiated control mice had extensive MA appearing below the growth plate, extending through the metaphysis, and into the diaphysis. As in the distal tibia, Cre+ mice had no detectable MA in these bones. To determine how the lack of MA affected bone, long bones were first analyzed by micro-CT. Bones from Cre+ mice had a significant increase in trabecular BV/TV and Tb.Th, and Ct.Th and pMOI. The increased bone mass could be accounted for by the striking increase (>50%) in CFU-Fs from female and male BM. Biomechanical properties of the femurs were assessed via 4-point bending. Stiffness, maximum load, post-yield deflection, and total work were significantly increased in the Cre+ femurs compared to controls. The uniform tracing of MA by the mesenchymal

progenitor transgene Prx1-Cre bred with mice expressing Pparγfl/fl allowed us to selectively delete MA. Marrow in the distal tibia of these mice was devoid of MA and MA could not be induced in the tibia or femur by x-irradiation, indicating that Prx1 is an early marker of MA ontogeny. The loss of MA resulted in a lineage shift from MA to osteoblasts. Taken together, these data indicate that ablation of MA results in increased bone, which functionally is stronger, suggesting that MA have at least an indirect regulatory effect on bone mass.

A novel crosstalk between TGF-β/BMP and Wnt families through Smad4 in endochondral ossification Sho Tsukamto*[1], Mai Kuratani[1], Noriko Sekine[1], Misato Okubo[1], Yutaka Nakachi[1], Shinya Tanaka[2], Eijiro Jimi[3], Hiromi Oda[2], Takenobu Katagiri[1]. [1]Division of Pathophysiology, Research Center for Genomic Medicine, Saitama Medical University, Japan, [2]Department of Orthopedic Surgery, Saitama Medical University, Japan, [3]Faculty of Dental Science, Oral health●Brain health●Total health Research Center, Kyushu University, Japan

Members of the transforming growth factor-β (TGF-β) family, including BMPs, GDFs and Activins, regulate skeletal development in embryos by activating Smad transcription factors. Smad4 is a critical co-activator essential for the Smad-dependent intracellular signaling in target cells. However, the role of the TGF-β family on skeletal growth after birth is still unclear, because Smad4 knockout mice are lethal at early stages in embryos. In the present study, we established Smad4 conditional knockout (Smad4 cKO) mice under the control of tamoxifen by crossing Smad4 floxed mice with CAG-CreERt mice. The established mice were injected tamoxifen at 10-w-old to delete the Smad4 gene in adulthood. On day 23 after the injection, the Smad4 cKO mice showed an increase in bone mass in trabecular bone but not in cortical bone in micro-CT analysis.They also showed an increase in numbers of hypertrophic chondrocytes and osteocalcin-positive bone-forming osteoblastsin growth plates and primary spongiosa, respectively. Bone histomorphometry suggested that the increased bone mass was due to an increase in bone formation rather than a decrease in bone resorption. We found that the osteoblastic cells increased in the Smad4 cKO mice were positive for β-catenin. Quantitative RT-PCR analysis of the Wnt signaling related genesrevealed that expression of Wnt7b mRNA was increased in the growth plates of Smad4 cKO mice. The expression of Wnt7b mRNA was decreased in response to BMP-4 stimulation in vitro. Wnt7b was detected in hypertrophic chondrocytes in growth plates in immunohistochemical analysis. Moreover, Wnt7b stimulated mineralization of primary osteoblasts in vitro was greatly enhanced by treatment with Wnt7b. We establisheddouble conditional knockout mice of Smad4 and Wnt7b (Smad4;Wnt7b dcKO) crossed with the CAG-CreERt mice. In contrast to the Smad4 single cKO mice, the Smad4;Wnt7b dcKO mice did not show the increase in bone mass after the tamoxifen injection even they had many hypertrophic chondrocytes. Taken together, our findings suggest that the inhibition of Smad4-dependent signaling pathwayin chondrocytes enhances endochondral ossification in vivo by stimulating differentiation to hypertrophic chondrocytes and expression of Wnt7b. This is a novel crosstalk between the TGF-β/BMP and Wnt families through Smad4 in endochondral ossification.

GDF11 Locally Controls Axial Skeletal Patterning and Systemically Improves Bone Formation As Opposed to Myostatin Joonho Suh*[1], Je-Hyun Eom[1], Na-Kyung Kim[1], Joo-Cheol Park[2], Kyung-Mi Woo[1], Jeong-Hwa Baek[1], Hyun-Mo Ryoo[1], Se-Jin Lee[3], Yun-Sil Lee[1]. [1]Department of Molecular Genetics & Dental Pharmacology, School of Dentistry and Dental Research Institute, Seoul National University, Republic of Korea, [2]Department of Oral Histology-Developmental Biology, School of Dentistry and Dental Research Institute, Seoul National University, Republic of Korea, [3]Department of Genetics and Genome Sciences, University of Connecticut School of Medicine, United States

Growth and differentiation factor 11 (GDF11) and myostatin (MSTN) are closely related TGF-beta family members that have been reported to have distinct functions. While MSTN is a negative-regulator of muscle mass, the reported functions of GDF11 are more diverse and controversial. Since Gdf11-/- mice display anterior homeotic transformations of vertebrae, it has been suggested that GDF11 expressed from the tail bud forms concentration gradients like a morphogen, and regulates anterior-posterior (A-P) axial skeletal patterning. However, we show here that locally expressed GDF11 determines positional fate of axial skeleton. In detail, we used a Cdx2-Cre transgene to eliminate Gdf11 expression in posterior regions. Cdx2-Cre; Gdf11flox/flox mice exhibited equal vertebral characteristics to Gdf11-/- mice in posterior regions, developing 9 lumbar vertebrae (vs. 6 lumbar vertebrae in wt mice), while displaying normal skeletal phenotype in anterior regions. Interestingly, we also found decreased bone formation in both Gdf11-/- and Cdx2-Cre; Gdf11flox/flox mice. Micro-CT analysis of P0 mice revealed that both bone volume (BV) and bone mineral density (BMD) were significantly diminished in Gdf11-/- mice, and mildy reduced in Cdx2-Cre; Gdf11flox/flox mice compared to wt mice, indicating that GDF11 systemically regulates bone formation. Surprisingly, Mstn-/- P0 mice exhibited enhanced BV and BMD in contrast to Gdf11-/- mice. In addition, micro-CT and DXA analysis showed that temporal deletion of Gdf11 in all tissues of CAG-Cre-ER; Gdf11flox/flox mice, induced by 4-hydroxytamoxifen or tamoxifen injection, reduces bone formation in both E18.5 embryos and young adult mice

aged from 6 to 10 weeks. We also analyzed 10-week old F66 transgenic mice overexpressing Follistatin, a GDF11/MSTN inhibitor, and found that while their muscle mass increased as much as Mstn-/- mice, their BMD significantly decreased compared to that of wt and Mstn-/- mice. Finally, in vitro analysis revealed that osteoblast differentiation was impaired and osteoclastogenesis was enhanced in Gdf11-/- mice, while the opposite was observed in Mstn-/- mice. All of our data strongly suggest that GDF11 locally regulates A-P patterning of axial skeleton, and systemically enhances bone formation as opposed to MSTN. Because GDF11 and MSTN share equal binding molecules, the opposing role of GDF11 in bone formation must be carefully monitored when developing MSTN-targeting drugs to improve bone and muscle mass.

Conditional Disruption of the Osterix (Osx) Gene in Chondrocytes During Early Postnatal Growth Impairs Secondary Ossification in the Mouse Tibial Epiphysis. Weirong Xing*[1], Catrina Godwin[2], Sheila Pourteymoor[2], Subburaman Mohan[1]. [1]VA Linda Healthcare System, Loma Linda University, United States, [2]VA Loma Linda Healthcare System, United States

The canonical pathway of endochondral ossification, the process of replacing cartilage with bone, involves apoptosis of hypertrophic chondrocytes followed by vascular invasion to bring in osteoclast and osteoblast precursors to resorb cartilage and produce bone matrix, respectively. However, our recent findings support a new paradigm in which the prepubertal increase in thyroid hormone levels induces IHH and OSX signaling in hypertrophic chondrocytes to transdifferentiate them into osteoblasts and promote secondary ossification at the epiphyses. To test if Osx expressed in chondrocytes contributes to transdifferentiation and secondary ossification, we generated Osxflox/flox;Col2-Cre-ERT2 mice and treated them with a single injection of tamoxifen (200 μg) at postnatal day (P) 3 prior to evaluation of the epiphyseal bone phenotype by microCT, histology, and immunohistochemistry at P21. Vehicle (oil)-treated Osxflox/flox;Col2-Cre-ERT2 and tamoxifen-treated Cre-negative Osxflox/flox mice were used as controls. MicroCT analysis of tibial epiphyses revealed that trabecular bone mass was reduced by 23% (P < 0.01) in the Osx conditional knockout (cKO) compared to control mice. Trabecular number and thickness were reduced by 28% and 8%, respectively, while trabecular separation was increased by 24% in the cKO mice (all P < 0.05). Trichrome staining of longitudinal sections of tibial epiphyses showed that bone area and bone area adjusted for total area were decreased by 22% and 18% (both P < 0.01), respectively, in the Osx cKO mice compared to oil-treated vehicle controls. Immunohistochemistry studies revealed that there was abundant expression of OSX in prehypertrophic chondrocytes of control mice which was considerably reduced in the cKO mice. Furthermore, expression of MMP13, COL10, and BSP was reduced in the epiphyses of cKO mice. To determine if Mmp13 and Col10 are direct targets of Osx, we evaluated their expression levels in response to Osx overexpression using lentiviral vectors in ATDC5 chondrocytes. We found that Osx overexpression increased Col10 (2.5-fold P<0.01), Mmp13 (1.5-fold, P<0.05), Alp (9.7-fold, P<0.001) and Bsp (127-fold, P<0.001) expression in ATDC5 chondrocytes. Based on these data, we conclude that Osx expressed in chondrocytes plays an important role in secondary ossification by regulating expression of genes involved in chondrocyte hypertrophy and transdifferentiation.

Mechanical Signals Preserve Bone and Muscle While Suppressing Adiposity in a Murine Model of Complete Estrogen Deprivation Gabriel M. Pagnotti*[1], Ryan Pattyn[2], Laura E. Wright[2], Sutha K. John[2], Sreemala Murthy[2], Trupti Trivedi[2], Yun She[2], Clinton T. Rubin[3], William R. Thompson[2], Khalid S. Mohammad[2], Theresa A. Guise[2]. [1]IUPUI, United States, [2]Indiana University, United States, [3]Stony Brook University, United States

Adverse musculoskeletal effects, such as bone loss and muscle weakness, are experienced by post-menopausal, breast cancer patients treated with aromatase inhibitors to deplete estrogen production. Bisphosphonates, inhibitors of osteoclastic resorption, reduce bone metastases and cancer-induced fractures, but do not cause disease regression. Mechanical signals generated during exercise are anabolic to bone and muscle; however, many patients are unable to participate in regimented exercise programs due to musculoskeletal symptoms. Low intensity vibrations (LIV), mechanical signals similar to stimuli generated from exercise, previously prevented bone loss in two cancer models without elevating longevity and mitigated fat accrual in ovariectomy models. We hypothesized that LIV could improve musculoskeletal morbidity in mice undergoing complete estrogen deprivation, such as that in postmenopausal breast cancer patients. To generate this model, C57Bl/6 mice ovariectomized at 8w of age and treated with the aromatase inhibitor letrozole daily for 24w were administered either LIV (n=10; 90Hz at 0.4g) or control-LIV treatment (CTL; n=10) for 4w prior and 24w post-surgery. Whole body DXA scanning performed consecutively every 3w measured lean and fat tissue. LIV significantly increased lean mass (p<0.02) over the 28w-treatment period relative to baseline, while LIV restricted total fat mass by 41% (p<0.001). Forelimb grip strength was 32% greater (p<0.05) in LIV-mice compared to CTL mice at 28w. High-resolution (12μm) ex vivo micro-computed tomography was performed on lumbar vertebrae, a mechanosensitive load-bearing site of bone metabolism. BV/TV and

connectivity density of L5 vertebrae were 22% (p<0.05) and 53% (p<0.05) greater, respectively, after 24 of LIV. Dynamic histomorphometry indicated a 70% (p<0.05) greater BFR/BS and 60% greater trend in MS/BS in response to LIV. Mineral apposition rate increased, trending 18% greater in LIV-treated L5 versus those of CTL-mice. Osteoblast numbers were 38% (p<0.01) greater in Von Kossa-stained LIV-treated L5 vertebrae than in CTL sections. TRAP-stained sections indicated a 41% reduction in osteoclast surface (p<0.01) and 37% (p<0.05) fewer numbers of osteoclasts in LIV vertebrae. Together, these data highlight the profound impact of estrogen deprivation on musculoskeletal tissue and support the role of physical activity and mechanical signals in maintaining bone and lean tissue mass while limiting the accrual of fat.

Alpha-Ketoglutarate Ameliorated the Age-related Osteoporosis via Regulating Histone Methylations of Mesenchymal Stem Cells Yuan Wang*, Liang Xie, Jing Xie, Yuchen Guo, Yuting Liu, Yunshu Wu, Rixin Zheng, Hongke Luo, Xiaofei Zheng, Quan Yuan. State Key Laboratory of Oral Diseases, West China Hospital of Stomatology, Sichuan University, China

Osteoporosis is an age-related progressive bone disorder that seriously threatens the health of aging population. Alpha ketoglutarate (αKG) is an essential intermediate in the tricarboxylic acid (TCA) cycle. Recently, αKG has been reported to possess an anti-aging effect, as the treatment of αKG extended the lifespan and delayed age-related phenotypes in worms. Here we aimed to investigate the effect of αKG on the age-related osteoporosis and senescence-associated (SA) phenotypes of mesenchymal stem cells (MSCs).First, we treated the aged mice with αKG via oral administration (0.25% and 0.75%), and observed a dose dependent increase in bone mass in treated group compared with control group. Moreover, MSCs isolated from αKG-treated mice also exhibited a promoted osteogenic potential. Besides, in vitro supplementation of αKG reduced the expression of SA genes (p16, p21, p53, IL6) in aged MSCs. Similarly, the positive cells of SA-β-gal staining and immunofluorescence (IF) of nuclear senescence-associated markers (laminA/C, γ-H2A.X) were declined by αKG administration. Furthermore, αKG treatment promoted self-renewal, migration, and more importantly, osteogenesis of aged MSCs in vitro.Next, we fed 2m-old adult mice with αKG (0.25%) or distilled water and harvested the bone tissues at 4m/6m-old. MicroCT and histological analyses showed that αKG precluded the progressive bone loss of adult mice upon aging, as evidenced by increased bone mineral density (BMD), trabecular bone volume (BV/TV) and osteoblast number (N.Ob/B.Pm), etc. Additionally, αKG improved the healing of femoral bone defect in an aged rodent model.Since αKG is an indispensable cofactor of the Jumonji C domain-containing (JMJD) family histone demethylases, we hypothesized that the positive effect of αKG on age-related osteoporosis might relate to histone methylations of MSCs. Interestingly, in vitro and in vivo study showed that αKG treatment relieved the overall accumulations of H3K9me3 and H3K27me3 along with aging, but not other histone marks that were reported to be regulators of bone metabolism. In addition, CHIP assay revealed that αKG reduced their enrichment on the promoters of BMP2, BMP4,Nanog and Oct4 .In summary, αKG ameliorated the age-related osteoporosis via regulating histone methylations of MSCs, suggesting that αKG might be a potential therapeutic agent for the treatment of osteoporosis.

Improving Mitochondrial Function via CypD Deletion is Effective in Stimulating Bone Formation Brianna Shares*, Roman Eliseev. University of Rochester, United States

Bone marrow mesenchymal stem cells (BMSCs) are multipotent progenitors that can differentiate into osteoblasts, adipocytes, and chondrocytes. As BMSCs undergo osteogenic differentiation they upregulate use of their mitochondria and oxidative phosphorylation (Ox-Phos). Our data and the literature indicate that active mitochondria are required for osteoblast differentiation. Our lab is investigating if strategies aimed at improving mitochondrial Ox-Phos are effective in stimulating bone formation. One such strategy is inhibition of opening of a non-selective mitochondrial pore called the mitochondrial permeability transition pore (MPTP). MPTP opening is the most common mechanism of mitochondrial dysfunction and is positively regulated by cyclophilin D (CypD). Recently, our lab showed that protecting the mitochondria by genetic removal of CypD protected against age-related bone loss in mice. However, the role of CypD during osteogenic differentiation in physiological and pathological settings has not been fully elucidated. To uncover the role of CypD during osteogenic differentiation, we isolated BMSCs from CypD KO mice and control littermates to perform osteoinduction. Throughout osteogenesis the MPTP closes, which is further desensitized by CypD KO. CypD KO BMSCs show improved mitochondrial function and mineralization during osteogenesis as indicated by metabolic profiling and staining, respectively. In addition, CypD KO BMSCs produced larger ossicles following an ectopic bone formation assay, indicating their increased osteogenic potential. To uncover the role of CypD in a pathological setting, tibial fractures were done on both CypD KO mice and control littermates. At 0, 7, 14, 21, 28, and 35 days post-fracture, blood and bones were collected. Fractured and unfractured tibiae were analyzed via biomechanical testing, histology, IHC and mCT. We observed that CypD KO mice show enhanced fracture healing in regards to bone biomechanical parameters and bone formation when compared to control littermates, which may result from

a truncated cartilage phase and faster ossification phase. This work shows that improving mitochondrial function via CypD genetic deletion is effective in stimulating bone formation, further highlighting the importance of mitochondria for bone formation.

TRAP as a Novel Regulator of Bone Formation in Osteoblasts at Sites of Bone Remodeling Diana Metz-Estrella*, Tzong-Jen Sheu, J Edward Puzas. University of Rochester, United States

Purpose: Emerging evidence is defining a new role for tartrate-resistant acid phosphatase (TRAP). Literature findings indicate that although TRAP is predominantly produced by osteoclasts, it can be found inside of osteoblasts at sites of bone remodeling. Uptake of residual TRAP through endocytotic mechanisms accounts for this. Moreover, over expression or copious uptake of TRAP in osteoblasts leads to a strong stimulation of bone formation. Can these observations explain the spatial coupling observed during remodeling? That is, is TRAP one of the signals that directs new bone formation to sites of prior resorption and is, in part, responsible for the spatial orientation of osteoblast activity that maintains skeletal microarchitecture? Our recent findings posit a mechanism for how endocytosed TRAP stimulates osteoblastic activity.Methods: In prior work we used a phage-display method to identify osteoblast proteins that demonstrated a high affinity for TRAP. We were able to identify a key intermediate involved in the regulation of cell function. New data indicate that this intermediate plays a dual role in the osteoblast. Using a phosphorylation detection method, sub-cellular fractionation techniques and confocal microscopy we have defined two pathways by which TRAP can stimulate formation.Results: Inside osteoblasts TRAP will enter the cytosol through a process known as endosome escape. In the cytosol TRAP binds to a phosphorylatable protein known as TRIP or TGFbeta-receptor-interacting-protein (with high affininity, $Kd = 10\text{-}10M$). TRIP is also known as a component of the protein synthetic initiation factor complex, i.e. eIF3-alpha. When TRIP is phosphorylated (by the type II TG-Fbeta receptor kinase) it acts to initiate translation of proteins used in bone. However, when TRIP is dephosphorylated it can enter the nucleus and act as a co-regulator for the expression of osteoblast-specific genes. Our data indicate that intracellular TRAP is the phosphatase that dephosphorylates TRIP, thereby stimulating the final differentiation of osteoblasts on TRAP-coated resorption surfaces.Conclusion: Site-specific bone formation is required to maintain skeletal microarchitecture. There have been only a few theories presented to explain this phenomenon (i.e. canopy formation and sphingosine kinase). Now, we offer another possibility that can account for how osteoblasts can recognize a resorption lacuna and target formation to precise sites in bone.

Osteoclast-derived autotaxin is a characteristic factor controlling bone degradation upon inflammation. Olivier P*[1], Sacha Flammier[1], Fanny Bouguillaut[1], François Duboeuf[1], Gabor Tigyi[2], Fabienne Coury[1], Irma Machuca-Gayet[1]. [1]INSERM U1033, France, [2]University of Memphis, United States

Rheumatoid arthritis (RA) patients in sustained clinical remission or low disease activity often continue to accrue bone erosions despite control of inflammation. Osteoclasts are responsible for focal bone erosions and systemic bone loss in RA. Current therapies using anti-resorbtive drugs are suboptimal in RA because they could lead to issues by shutting down physiologic remodeling in long term treatment supporting the need for alternative therapies. Autotaxin (ATX) is a secreted lysophospholipase D converting lysophosphatidylcholine into lysophosphatidic acid. ATX is upregulated in the synovial liquid of patients with RA and contributes to synovial inflammation. However, ATX role in bone resorption is totally unknown.We found that ATX was up regulated during the course of osteoclastogenesis and LPS or TNFa applied to mature osteoclasts further enhanced ATX expression. In vitro osteoclast-derived ATX was necessary for bone resorption activity that was blocked by pharmacological ATX inhibitors (PF-8380, BMP22). We generated mice with conditional genetic ablation of ATX in osteoclasts (ΔATXCtsk mice) that were challenged using LPS injections that induced a 43 % decrease in the trabecular BV/TV (BV/TV) in control mice but had no impact on bone in ΔATXCtsk mice. The challenge with K/BxN serum transfer that induces severe arthritis revealed that ΔATXCtsk mice were protected from systemic bone loss, and displayed almost no local bone erosion. Intriguingly, in a non-inflammatory bone loss condition as observed in mice after ovariectomy (OVX), ΔATXCtsk and control mice revealed similar impact on bone 4 weeks post-OVX with a 30% decrease in BV/TV. As supported by an absence of bone phenotype at steady state on ΔATXCtsk mice, these results indicate that osteoclast-derived ATX might be dispensable for osteoclast function under non-inflammatory conditions. By using a pharmacological approach on a second inflammatory mouse model exploiting transgenic hTNF mice that develop aggressive arthritis with joint swelling and bone erosions, we found that albeit inefficient on synovitis, BMP22 treatment induced a 28% increase in BV/TV and a 50% decrease in the extent of bone erosion (BS/BV).These results establish that ATX is a new factor produced by osteoclasts that controls inflammation-induced bone loss without interfering with osteoclast function in non-inflammatory conditions. ATX might be a promising therapeutic target for the prevention of bone erosion occurrence in RA.

Protease-activated receptor 1 (PAR1) deletion causes enhanced osteoclastogenesis in response to inflammatory signals through a Notch 2-dependent mechanism Judy Kalinowski*[1], Sandra Jastrzebski[1], Hicham Drissi[2], Archana Sanjay[1], Sun-Kyeong Lee[1], Ernesto Canalis[1], Joseph Lorenzo[1]. [1]UConn Health, United States, [2]Emory University School of Medicine, United States

We found that protease-activated receptor 1 (PAR1), a G-protein coupled receptor, is transiently expressed in osteoclast (OC) precursor cells during RANKL-induced osteoclastogenesis. Studies of PAR1-deficient (PAR1 KO) and wild-type (WT) mice in homeostasis at 8-weeks-old showed minimal differences in either bone mass or bone cells. However, bone marrow macrophages (BMM) and FACS-purified murine bone marrow OC precursor cells cultured with M-CSF+RANKL produced more OC in PAR1 KO cultures than in WT (22 to 48% more OC in PAR1 KO, p<0.01). To determine if this enhanced osteoclastogenesis with RANKL occurred with other TNF superfamily members, we tested osteoclastogenic responses to the proinflammatory cytokine TNF-α (TNF). Treatment of BMMs with submaximal doses of TNF + RANKL produced an enhanced osteoclastogenic response. In vivo we treated WT and PAR1 KO mice with daily injections of TNF over their calvariae for 4 days and examined TRAP+ OC 1 day later. TNF induced a 2.9-fold increase (p<0.01) in OC area in WT mice vs. vehicle controls. Strikingly, TNF increased OC area by 9.5-fold in calvariae of PAR1 KO mice, which was a greater response than in either TNF-treated WT mice or vehicle-treated PAR1 KO mice (p<0.01 for both). Because TNF can activate Notch signaling, we examined if inhibiting Notch2 in PAR1 KO mice abrogated their enhanced OC response to TNF. WT and PAR1 KO mice were treated with TNF over the calvaria and either a control antibody (Ab) or an Ab to the Notch 2 negative regulatory region (N2-NRR Ab), which specifically blocks only Notch 2 signaling. Treatment of PAR1 KO mice with N2-NRR Ab reduced TNF-induced osteoclastogenesis to WT levels (p<0.01) without affecting TNF responses in WT mice. In BMM cultures N2-NRR Ab reduced RANKL-induced OC in PAR1 KO BMMs to levels seen in WT cultures (p<0.01) but did not alter RANKL-induced OC in WT BMMs. PAR1 KO BMMs treated with M-CSF had higher Hes1 mRNA levels (a Notch target gene) by 3.4-fold over WT (p<0.01). RANKL+M-CSF or RANKL+TNF+M-CSF treatment of WT BMMs increased Hes1 mRNA to levels seen in M-CSF-treated PAR KO cells but had little additional effect on Hes1 mRNA in PAR KO cells. These results demonstrate that both in vivo and in vitro PAR1 deletion causes enhanced osteoclastogenesis in response to inflammatory signals in bone through a Notch 2-dependent mechanism. We speculate that PAR1 activation could be a drug target for the development of treatments for inflammatory bone diseases.

Examining the influence of senescent cells on PTH/PTHrP signaling in bone Joseph Gardinier*, Chunbin Zhang. Henry Ford Hospital, United States

Age-related bone loss predisposes both men and women to osteoporosis. The chronic low-grade inflammation produced by the senescent-associated secretory phenotype (SASP) of senescent cells contributes to age-related bone loss. However, the influence of SASP on osteoblast function is poorly understood. Given that parathyroid hormone (PTH)/PTH-related protein signaling plays a key role in regulating osteoblast growth and differentiation, we hypothesize that SASP suppress osteoblast expression of the PTH/PTHrP receptor (PPR). To test this hypothesis, MC3T3 derived osteoblasts were treated with conditioned media (CM) from two models of senescent cells. To model senescence, MC3T3 pre-osteoblast cells were exposed to oxidative stress (350 uM H2O2) or irradiation (10 Gy). The onset of senescence was then verified by the presence of beta galactosidase and expression of several inflammatory cytokines and chemokines such as interleukin-6, interleukin-1a (IL-1a), tumor necrosis factor alpha (TNF-a), and chemokine ligand 1. Mature osteoblasts were then treated with CM from each model of senescence for 2 days. Control cells were treated with CM from non-senescent cells. As a result, CM from senescent cells caused a significant reduction in osteoblast PPR expression compared to controls. Antagonists against chemokine receptors 1 and 2 failed to prevent PPR suppression in response to CM. Independently, IL-1a and TNF-a treatment were able to suppress PPR expression directly, but not IL-6. The impact of SASP on PPR expression was then evaluated in-vivo using C57/Bl6 male mice. Between 2 and 18 months of age, we found an increase in cellular senescence within bone, based on P16ink4a expression, and a decrease in PPR expression that corresponded with a loss in sensitivity to exogenous PTH(1-34) treatment based on c-fos expression. To verify that senescent cells are responsible for the loss in PPR expression, 78-week old mice were treated with a combination of dasatinib and quercentin (DQ). After 1 week of DQ treatment, the presence of senescent markers was significantly reduced, while the expression of PPR was significantly increased. Overall, these data demonstrate that senescent cells suppresses the expression of PPR through their release of cytokines IL-1a and TNF-a. Targeting the underlying mechanisms that influence PPR expression has the potential to enhance the sensitivity to PTH signaling in bone in an aging population.

Argininosuccinate lyase deficiency as a model to study nitric oxide function in Bone Zixue Jin*[1], Jordan Kho[1], Brian Dawson[1], Monica Grover[2], Ming-Ming Jiang[1], Yuqing Chen[1], Brendan Lee[1]. [1]Baylor College of Medicine, United States, [2]Stanford University, United States

Nitric oxide (NO) is an important signaling molecule that influences a wide range of biological processes, including bone metabolism. Previous studies have shown that NO donors may potentially increase bone mineral density in women with postmenopausal osteoporosis. However, the function of NO in bone metabolism remains controversial in both pharmacological and genetic studies. NO is enzymatically produced by three nitric oxide synthases (nNOS, iNOS and eNOS) from L-arginine. NOS knock out (KO) mice have been used to study NO function; however, analyses have been limited by the potential redundancy of the three NOS isoforms. Argininosuccinate lyase (ASL) is the only mammalian enzyme capable of generating arginine, the sole precursor for NOS-dependent NO synthesis. Moreover, we recently showed that it is also required for channeling extracellular arginine to NOS for NO production. Hence, deletion of ASL leads to a cell- autonomous deficiency of NOS-dependent NO production due to combined loss of endogenous arginine production and extracellular arginine channeling. ASL deficiency is thus a Mendelian model for cell-autonomous, NOS-dependent NO deficiency.To study NO function in bone formation, we generated Asl osteoblastic conditional knockout (cKO) mice by crossing Aslflox/flox mice with osteoblastic-specific Cre transgenic mice. Interestingly, we found that early deletion of Asl from osteoblast precursors using Osterix-Cre transgenic lines (Osx-Asl cKO mice) led to increased bone mass. In contrast, deletion from mature osteoblast using Osteocalcin-Cre transgenic lines (Ocn-Asl cKO mice) led to decreased bone mass. Mechanistically, impaired osteoblast function was observed in both Osx-Asl cKO mice and Ocn-Asl cKO mice, whereas decreased osteoclast number and activity was observed only in Osx-Asl cKO mice. In addition, deletion of Asl in Osx-Asl cKO mice resulted in decreased RANKL/OPG mRNA ratio, thereby reducing bone resorption. Furthermore, we provide evidence that NO generated in early osteoblast lineage inhibits OPG expression, while enhances RANKL expression, at least in part via the cAMP responsive element binding protein (CREB) pathway. Taken together, we established new mouse models to study NO function in bone by conditional deletion of ASL in osteoblastic cells. Our findings reveal that cell-autonomous NO production is important for osteoblast function and stage-dependent osteoblast coupling with osteoclast.

Activin type 1 receptor ALK4 regulates postnatal bone mass Shek Man Chim*, David Maridas, Laura Gamer, Vicki Rosen. Harvard School of Dental Medicine, United States

As effectors of both osteoblast and osteoclast formation and activity, activins have a complex role in the skeleton. Activins signal via complexes containing both type 1 and type 2 receptors; ALK4 is a unique type 1 receptor for activins on skeletal progenitors, while the type 2 receptors utilized by activins, ACVR2A and ACVR2B, also participate in BMP and GDF signaling. As such, modulating ALK4 availability on skeletal target cells is the most direct way to determine the specific effects of activin signaling in the skeleton. Here, we generated mice lacking ALK4 in skeletal progenitor cells (Alk4 f/f; Prx1-Cre = Alk4 cKO), and by targeting the type 1 receptor, removed activin signaling from early limb mesoderm without affecting BMP and GDF signaling. We found that newborn Alk4 cKO mice have normal skeletons that could not be distinguished from control littermates in whole mount skeletal preps stained with Alizarin Red and Alcian Blue. Western blot analyses demonstrated that pSmad2 and pSmad1/5/8 levels were unchanged in bone lysates of newborn Alk4 cKO mice. These results suggested that Alk4 is dispensable for formation of limb skeleton. We then performed Micro-CT analyses of Alk4 cKO mice at 2 and 6 months of age and found that removal of ALK4 from skeletal progenitors resulted in significant increases in trabecular bone mass at 2 months (32% compared to littermate controls) and 6 months (67% compared to littermate controls) of age. At each time point, cortical thickness remained unchanged. Bone histomorphometric analysis showed that osteoclast number and bone-eroded area were not changed in Alk4 cKO mice, consistent with a specific effect of activin on bone forming cells. Western blot analyses demonstrated that pSmad2 levels were reduced in bone lysates of Alk4 cKO mice, while pSmad1/5/8 levels were unchanged, providing direct evidence that removal of Alk4 specifically impaired activin signaling without altering BMP signaling. As circulating activin levels increase with age and in patients with inflammatory diseases, physiological states where reduced bone mass is observed, we believe that targeting activin signaling in osteoblasts through ALK4 provides a novel way to control bone mass.

A Novel Osteolineage-Derived Cancer Associated Fibroblast Population In Primary Tumors Expresses Dkk1 And Enhances Tumor Growth Biancamaria Ricci*, Francesca Fontana, Sahil Mahajan, Roberto Civitelli, Roberta Faccio. Washington University in St Louis, United States

We recently described that mice bearing extra-skeletal tumors have increased levels of the Wnt/β-catenin inhibitor Dkk1 in circulation and bone marrow fluid. Although Dkk1 is

known to modulate bone remodeling, during tumor progression Dkk1 induces the expansion of myeloid derived suppressor populations to inhibit anti-tumor T cell responses. The goal of this study was to determine the source of Dkk1 and whether Dkk1 acts locally or systemically to exert immune suppressive functions. Dkk1 was highly expressed by osteoblasts (OBs) and osteocytes in mice with extra-skeletal tumors. Although we did not detect expression of Dkk1 in our tumor lines, we found expression in the tumor mass by the cancer-associated fibroblasts (CAFs). Unexpectedly CAFs also expressed two OB-specific markers Osterix (Osx) and Osteocalcin (Ocn), leading to the hypothesis that Dkk1 at tumor site is produced by a novel osteolineage-derived fibroblast population. To test this possibility, we turned to a mouse model carrying the R26R-tdTomato reporter protein (TdTomato) under the control of a TET-off doxycycline Osx-Cre (TdTOsx) driven promoter. Doxycycline was administered to moms and pups until weaning to prevent Osx-Cre activation in perinatal mesenchymal stem cells and, at 8 weeks of age, mice were orthotopically inoculated with B16 or PyMT cell lines. We found that 3-9% cells in the tumor mass were TdTOsx+. This population expressed several fibroblast markers and Dkk1. Importantly, TdTOsx cells isolated from B16 tumors and co-injected together with B16 cells into WT recipient mice significantly increased tumor growth compared to the tumor line alone. Next, to determine whether Osx+ cells support tumor progression via production of Dkk1, we generated Osx-Cre;Dkk1fl/fl mice and observed a significant reduction in tumor size compared to control mice. Since Osx-Cre targets also the OBs, to specifically evaluate the contribution of CAF-derived Dkk1, we generated Fsp1-Cre;Dkk1fl/fl mice. Strikingly, tumor growth was also significantly reduced in the Fsp-Cre;Dkk1fl/fl mice indicating that fibroblast-derived Dkk1 plays an important role during tumor progression. In summary, we have identified a novel population of CAFs that expresses the osteolineage marker Osx, contributes to Dkk1 production and strongly supports tumor growth.

Notch2 is a new marker of breast cancer stem cell and is involved in bone marrow cellular dormancy Mattia Capulli*[1], Dayana Hristova[2], Zoe Valbret[1], Kashmala Carys[1], Ronak Arjan[1], Antonio Maurizi[1], Francesco Masedu[1], Nadia Rucci[1], Anna Teti[1]. [1]University of L'Aquila, Italy, [2]University of Cambridge, United Kingdom

Tumor dormancy is responsible for breast cancer (BC) relapse after a prolonged disease-free period. Clinical and experimental data indicate bone marrow as a candidate tissue to host BC dormancy. Since dormancy also requires tumor initiation properties to start a secondary disease, we hypothesized that dormancy and initiation represent two sides of the same coin and are regulated by orchestrated signals. We identified a subpopulation of BC cells expressing high levels of Notch2 (Notch2+) that displays the dual properties of dormancy and tumor-initiation, in which Notch2 was the molecular switch mediating these opposing behaviors. In MDA-MB-231 human BC cell line (MDA), Notch2+ cells represented 1-5% of the total population. They did not belong to the classical CD44+/CD24- MDA stem population but were enriched in the HSC stem markers, CD34, c-kit, Tie2 and Cxcr4 (+103,103,102,10fold; p< 0.01, respectively), suggesting a unique HSC-mimicry. Notch2+MDA stemness and tumor-initiating ability were confirmed in culture by the generation of more (+2fold; p=0.00323) and larger primary mammospheres (p=0.0001) and more secondary mammospheres (+15fold; p=0.0033) vs Notch2-MDA, despite their lower proliferation in standard 2D-cultures (-54%; p=0.03). Similar results were obtained when the HSC stem cell marker Tie2 was used for sorting MDA. When injected intratibially in immunocompromised mice, Notch2+MDA in-bone growth (-70%; p=0.02) and dissemination to distant organs (-67%; p=0.0001) were lower vs Notch2-MDA, suggesting that the bone microenvironment favors dormancy vs tumor-initiation. In immunocompromised mouse tibias injected with luciferase+MDA that after one month showed no bioluminescence or osteolysis (presumed dormancy), we identified single Notch2+, non-proliferating (Ki67-) MDA located close to the endosteum. In the same mouse model, single treatment with a γ-secretase inhibitor dislodged Notch2+MDA from the endosteum (p< 0.0001) and increased distant organ colonization (+3fold of liver metastases; p=0.0496) vs vehicle. Conversely, both chronic and acute inflammation proved ineffective in reactivating tumor cells. Key results were confirmed in mouse 4T1 BC cells in vitro and in vivo. Moreover, intratibially injected MDA cells that survived a prolonged chemotherapy treatment (42 days) with doxorubicin (0.1mg/kg) were dormant and Notch2+. In conclusion, our data indicate a key role for Notch2 and HSC-mimicry in BC cell dormancy and tumor-initiating ability.

Circulating osteoprogenitor cells provide a novel diagnostic biomarker for bone metastasis Hyun Jin Sun*[1], Kyung-Hun Lee[1], Kyoung Jin Lee[2], Serk In Park[2], Young Joo Park[1], Seock-Ah Lim[1], Sun Wook Cho[1]. [1]Seoul National University Hospital, Republic of Korea, [2]Korea University College of Medicine, Republic of Korea

The accurate estimation of viable tumors of bone metastases is critical for optimal treatment. However, the current image-based diagnostic modalities have limitations. This study aimed to investigate the potentials of circulating osteoprogenitor cells (cOPs) for diagnosing disease progression and treatment monitoring of bone metastasis. We performed flow cytometric analyses of cOPs in the blood samples from a mouse model of bone metastasis as well as from breast cancer patients with or without bone metastasis. First, in an in vivo bone metastasis models of human breast cancer cells growing in the tibiae of nude mice, flow cytometric analyses of peripheral blood mononuclear cells showed that cOPs (CD15-CD45-Osteocalcin+) were significantly increased as early as 1 week after tumor injection, compared to the non-tumor bearing age-matched control mice, even before the development of detectable bone metastases by BLI as early as 2 weeks. In contrast, histological analyses detected tumor cell colonization in the endosteal niche were observed only at 1 to 2 weeks after tumor injection, and overt metastatic lesions with bone destruction were observed at 4-week. Subsequently, to evaluate the changes of cOPs in response to cancer therapy, zoledronic acid (ZA) was administrated immediately after intratibial cancer cell injection. At 1-week after treatment, cOPs were significantly reduced in the ZA-treated group compared with controls in the tumor-bearing bone, while no significant changes in the non-tumor bearing controls were observed. Next, cOPs (CD15-CD34-Osteocalcin+) were analyzed in 98 metastatic breast cancer patients. 61 patients had bone metastasis and 37 had metastasis in other sites than bone. cOPs were significantly higher in bone metastasis than other metastasis group, while serum bone-specific alkaline phosphatase or CTx showed no difference. Due to the heterogeneity of the disease status of bone metastasis, we then divided the patients into two groups, stable (n=30) and persistent (n=31) groups based on their diagnostic imaging studies performed on 0 and 3 months after blood sampling. cOPs were significantly higher in persistent than stable group with minimal overlaps in the levels of cOPs between groups. Furthermore, 11 patients who had paired sampling before and 3-months after first ZA administration showed that cOPs were significantly decreased after ZA treatment than before. In conclusion, cOPs increased in the micro-metastatic stage of bone metastasis, and changed significantly earlier than detectable lesions in imaging studies. In addition, cOPs increased in actively progressing bone metastasis in our cross-sectional cohort, and decreased in response to a bone-targeting agent, suggesting the potentials of cOPs as diagnostic tools for disease progression and treatment monitoring of bone metastasis.

An IAP Antagonist Inhibits Breast Cancer Metastasis to Bone by Killing Cancer Cells, Inhibiting Osteoclast and Enhancing Osteoblast Differentiation Wei Lei*, Rong Duan, Brendan Boyce, Zhenqiang Yao. University of Rochester Medical Center, United States

Development of breast cancer (BC) bone metastasis (B.Met) depends on cancer-bone cell interactions, in which enhanced osteoclast (OC) formation causes osteolysis, osteoblasts (OB) fail to repair lytic lesions, and factors released from bone or produced locally promote cancer cell growth. We found that SM164, a small molecule compound, which degrades inhibitor of apoptosis proteins (IAPs) to kill cancer cells, also inhibited OC formation and stimulated OB differentiation in vitro. We tested its effects on BC B.Met in 5 week-old female athymic nude mice inoculated with MDA-MB-231luci cells into their left cardiac ventricles, starting 2d after inoculation. SM164 significantly reduced bioluminescent imaging (BLI) signals in the hind-limbs vs. vehicle (p<0.01) and combined standard chemotherapy (STC): adriamycin, cytoxan and zoledronic acid (p<0.01) after 2, 3 and 4 weeks of treatment. Mice were euthanized on day 29 to evaluate B.Met by histologic analysis. SM164 significantly reduced the number of mice with B.Met (25%; 2/8, p<0.05) compared with vehicle group (100%; 7/7), but STC did not (71%; 5/7). Similarly, mice treated with SM164 had fewer osteolytic lesions in tibiae and femora (9%; 3/32) than those given STC (39%; 11/28; p<0.05) or vehicle (61%; 17/28, p<0.05 vs. vehicle and STC). Both SM164 and STC significantly reduced a bone destruction score evaluated by the presence of tumor in bone marrow, cortical bone, growth plate, secondary ossification center and outside the bone. Importantly, SM164 and STC reduced OC numbers inside metastatic sites, 19+/-8 and 6+/-1.7, respectively, versus 52+/-15/mm2 in the vehicle group. SM164 also increased the bone formation rate in vertebrae that had no B.Met (0.84+/-0.19 vs. 0.58+/-0.12 cm2/cm3/d in vehicle, p<0.05). When SM164 was given 2 weeks after cancer inoculation when B.Met was eastablished, it also inhibited cancer cell BLI in the bones 2 weeks later, but this effect did not reach significance histologically. Interestingly, SM164-induced apoptosis of MDA231 cells was dependent on macrophage production of membrane-bound TNF. Finally, SM164 prevented RANKL- and TGFbeta1-induced TRAF3 degradation in macrophages and OB lineage cells, respectively, to inhibit OC and enhance OB differentiation. Our findings suggest that SM164 could act as a novel agent to prevent BC B. Met by simultaneously killing cancer cells, inhibiting OC and enhancing OB differentiation.

Bone-targeting Bortezomib significantly increases its efficacy in the treatment of human multiple myeloma in vitro and in vivo in mice Jianguo Tao*, Venkatesan Srinivasan, Xichao Zhou, Frank Ebetino, Robert Boeckman, Brendan Boyce, Lianping Xing. University of Rochester, United States

Multiple myeloma (MM) is plasma cell malignancy that arises in bone marrow and causes osteolytic lesions throughout the skeleton. It is treated with first-line drugs, such as Bortezomib (Btz), which inhibit proteasomal degradation and kill MM cells. MM is currently incurable in part because adverse effects on non-skeletal tissues, including thrombocytopenia and peripheral neuropathy, limit the amount of drug that can be given, and tumor cells become Btz-resistant. To attempt to circumvent these issues, we have linked Btz to a

bisphosphonate (BP) that binds avidly to bone, but is not anti-resorptive, using novel linkers to generate (BP-Btz) conjugates. We hypothesize that BP-Btz will 1) reduce MM burden and bone destruction and kill Btz-resistant MM cells more effectively than Btz; and 2) have improved efficacy with a slow release rate. We tested the effects of our lead BP-Btz conjugate (BP-Btz1; 3nM) and found that it killed the human MM cell lines, U266, RPMI8226, and JJN3, in vitro with an IC50 similar to Btz. Bone slices that were pre-incubated with BP-Btz1 killed MM cells in vitro, but those pre-incubated with Btz did not. In NSG mice inoculated with JJN3 human MM cells, BP-Btz1 (1x/4d for 3wk) reduced tumor burden and bone destruction as effectively as Btz (1x/2d for 3wk) compared to Veh: CD138+ MM cells (25±14 vs 32±11 vs 48±13%, respectively); lytic lesions: (35±18 vs 40±14 vs 100±10%); and bone volume (42±8 vs 26±21 vs 9±7%). Btz, but not BP-Btz, decreased platelet counts compared to Veh (1038±217 vs 816±192 vs 1132±223). Importantly, a 3-fold higher dose of BP-Btz1 had no systemic side effects in vivo but was able to kill Btz-resistant human MM cells in vitro than needed to kill Btz-sensitive MM cells (9 vs 3nM). To test if varying the release rate of Btz from BP-Btz by altering the linker chemistry affects its efficacy, we synthesized two new BP-Btz conjugates with faster and slower release kinetics vs BP-Btz1. These killed MM cells at a similar IC50 as BP-Btz1 in vitro, but had significantly reduced ability to reduce MM tumor burden in vivo compared to BP-Btz1 and Veh (tumor area: 65±18 (faster) vs 42±25 (slower) vs 23±28 and 79±8%) and bone destruction (spinal paralysis: 20 vs 20 vs 0 and 60%). In summary, BP-Btz1 reduces myeloma cell tumor burden in mice bearing human MM cells and associated bone loss more effectively than Btz with less systemic adverse effects. BP-Btz may represent a novel therapeutic agent to treat patients with MM.

FGFR and mTOR Signaling Cooperate in Osteosarcoma Pathogenesis and Metastasis Arshiya Banu*[1], Sorrel Bunting[1], Carolina Zandueta[2], Susana Martinez-Canarias[2], Haritz Moreno[2], Beatriz Moreno[2], Fernando Lecanda[2], Agamemnon Grigoriadis[1]. [1]King's College London, United Kingdom, [2]CIMA Pamplona, Spain

Osteosarcoma (OS) is the most common primary malignancy of the skeleton, occurring primarily in children and adolescents. Metastatic disease is the single most important prognostic factor with a high frequency of patients developing lung metastases. We have recently demonstrated that high FGFR1 signalling in a transgenic model of OS as well as in human OS samples contributes to the pathogenesis and metastasis of OS. Significantly, xenograft OS studies showed that genetic or pharmacological inhibition of FGFR1 decreased lung metastasis.A recent shRNA kinase library screen identified mTOR signaling as a cooperating pathway with FGFR signaling. To validate this finding, we stimulated murine and human OS cell lines with FGF2 and found an increase in pAkt/mTOR signaling and mTOR target genes that was inhibited by the FGFR inhibitor, PD173074. Functional analysis by colony assay showed that FGF2 stimulated colony growth of OS cells, and the mTOR inhibitor, Rapamycin, completely blocked this response. Moreover, shRNA silencing of mTOR prevented FGF2-stimulated cell migration in wound/scratch assays, suggesting functional crosstalk between these pathways.To confirm pathway cooperativity in vivo, we performed xenograft studies. Silencing of mTOR in FGFR1-expressing OS cells reduced tumor formation on a chick chorioallantoic membrane, with reduced mitotic (pHistone-H3) index. Interestingly, using a murine intratibial OS xenograft model, inhibition of FGFR1 and mTOR signaling (AZD4547 and AZD8055, respectively), either alone or in combination, showed a decrease in bioluminescence imaging in the lungs of mice treated with the mTOR inhibitor alone as well as with the combined FGFR/mTOR inhibitors, compared to controls with a marked reduction in both the size and diameter (p<0.01) of spontaneous pulmonary metastatic nodules. No differences were observed in the number of lung nodules and in treated primary tumors. Immunostaining analysis showed a marked decrease in the number of Ki67+ cells in lung metastases of FGFR/mTOR inhibitor-treated mice (p<0.01), whereas no changes in activated caspase-3 were detected. Thus, combinatorial treatment significantly decreased lung metastasis of OS cells. Ongoing analysis of activated FGFR and mTOR pathways in patient-derived tissue microarrays will enable patient stratification that will be useful in the clinical setting to exploit this as a potential anti-metastatic therapy in OS.

Off-treatment Bone Mineral Density Changes in Postmenopausal Women after 5 Years of Anastrozole Ivana Sestak*[1], Jack Cuzick[1], Glen Blake[2], Rajesh Patel[3], Robert Coleman[5], Richard Eastell[4]. [1]Centre for Cancer Prevention, Queen Mary University London, United Kingdom, [2]Division of Imaging Sciences, King's College London, United Kingdom, [3]Imperial College London, United Kingdom, [4]Academic Unit of Bone Metabolism, Metabolic Bone Centre, Northern General Hospital, United Kingdom, [5]Academic Unit of Clinical Oncology, Weston Park Hospital, United Kingdom

Background: Anastrozole (A) has been shown to prevent breast cancer in postmenopausal women at increased risk of developing the disease, but has been associated with substantial accelerated bone mineral density (BMD) loss during active treatment. Here, we investigate changes in BMD assessed by dual energy X-ray absorptiometry (DXA) 2 years after treatment cessation in women included in the IBIS-II breast cancer prevention trial.

Methods: IBIS II randomly assigned 3864 postmenopausal women to A 1mg/day or placebo (P) for 5 years. 1410 were included in a BMD sub-study and stratified into three strata according to their baseline T-score at spine or femoral neck (stratum I (N=760): T-score>-1.0 and observed; stratum II (N=500): -1.0<T-score>-2.5 and randomised to weekly risedronate or placebo; stratum III (N=150): -2.5<T-score>-4.0 or/and two fragility fractures and all on risedronate). The primary objective of this analysis was to investigate whether DXA BMD at the spine and hip changed 2 years after stopping A or P. All results are presented as mean % BMD changes (95% CI) between 5 and 7 years of follow-up.Results: 5 and 7-year BMD data were available for a total of 529 women who did not receive risedronate. In stratum I, cessation of A (N=205) led to an increase in BMD at the spine that was larger than in those on P (N=206) (A=1.29% (95% CI 0.78 to 1.79) vs. P=0.2% (-0.23 to 0.62), p=0.001). At the hip, BMD remained unchanged between 5 and 7 years after cessation of A but continued to a decrease in those who had been on P (A=-0.07% (-0.51 to 0.37) vs. P=-1.31% (-1.67 to 0.94), p<0.0001). Similar results were observed for women with osteopenia (stratum II). Those previously on A (N=53) had a significantly larger BMD increase at the spine after treatment cessation compared to those stopping P (N=64) (A=2.81% (1.40 to 4.23) vs. P=0.57% (-0.36 to 1.50); p=0.007). Loss of BMD at the hip continued in women who had been on P but increased slightly following cessation of A (A=0.47% (-0.42 to 1.36) vs. P=-1.33% -2.12 to -0.54); p=0.003).Conclusions: These are the first results reporting BMD changes after stopping A in a breast cancer prevention setting. BMD at the lumbar spine improved significantly more in women who were originally randomised to A compared to those who received P. Our results show that the negative effects of A on BMD in the preventive setting are partially reversible.

Patients with prostate cancer and androgen deprivation therapy have increased risk of fractures – a study from the Fractures and fall injuries in the elderly cohort (FRAILCO) Marit Wallander*[1], Kristian F Axelsson[2], Dan Lundh[3], Mattias Lorentzon[4]. [1]Department of Medicine Huddinge, Karolinska Institute, Sweden, [2]Department of Orthopaedic Surgery, Skaraborg Hospital, Sweden, [3]School of Health and Education, University of Skovde, Sweden, [4]Geriatric Medicine, Department of Internal Medicine and Clinical Nutrition, Center for Bone Research at the Sahlgrenska Academy, Sweden

Purpose Androgen-deprivation therapy (ADT) in patients with prostate cancer (PC) is associated to increased risk of fractures compared to PC patients without ADT. Most previous studies are however small or are lacking sufficient data on traditional fracture-related risk factors. In this study, we investigated the relationship between ADT in patients with PC and the risk of incident fractures and non-skeletal fall injuries both compared to those without ADT and compared to patients without PC. Methods We included 179,744 men (79.1 ± 7.9 years (mean ± SD)) from the Swedish registry "Senior alert" (a cohort of elderly individuals) to which national directories were linked in order to study associations regarding fractures, fall injuries, morbidity, mortality and medications. Among these men, we identified 159,662 patients without PC, 6954 with PC and current ADT (prescription of GnRH-agonist within the previous year) and 13,128 patients with PC without ADT. During a total follow-up of approximately 270,300 patient-years we identified 10,916 fractures of which 6525 were major osteoporotic fractures (MOF) including 4860 hip fractures. We performed multivariable Cox regression analyses adjusted for age, weight, height, previous fracture, per oral glucocorticoids, calcium- and vitamin D, alendronate use, rheumatoid arthritis, secondary osteoporosis and estimated alcohol over-consumption, previous falls and Charlson comorbidity index. Results After multivariate adjustment and compared to men without PC, those with PC and ADT had increased risk of any fracture (HR 95% CI: 1.40 (1.28-1.53)), hip fracture (1.38 (1.20-1.58)) and MOF (1.44 (1.28-1.61)) but not of non-skeletal fall injury (1.01 (0.90 – 1.13). Hazard ratios were similar when comparison was made to patients with PC but without ADT. Patients with PC without ADT did not have increased risk of any fracture (0.97 (0.90-1.05), hip fracture (0.95 (0.84-1.07), MOF (1.01 (0.92-1.12)) and had decreased risk of non-skeletal fall injury (0.84 (0.77 – 0.92)). Conclusions Patients with PC and ADT is a fragile patient group with increased risk of fractures compared to patients without PC and compared to those with PC without ADT. We believe that medical treatment in order to prevent fractures should be considered in the routine evaluation of all patients with PC and ADT.

Low Parathyroid Hormone Levels are Associated with Increased Hazards of Fracture and Death in Stage 3 and 4 Chronic Kidney Disease Karen Hansen*[1], Sinong Geng[2], Zhaobin Kuang[2], Peggy Peissig[3]. [1]University of Wisconsin School of Medicine & Public Health, United States, [2]University of Wisconsin, United States, [3]Marshfield Clinic, United States

Chronic kidney disease (CKD) affects ~20% of older adults. Secondary hyperparathyroidism (sHPT) afflicts over half of stage 3-4 CKD patients. Cross-sectional studies have linked secondary hyperparathyroidism (HPT) to greater risk of fractures, vascular events and death. Thus, the National Kidney Foundation recommends treatment of sHPT in CKD patients. In a recent systematic review, we found no placebo-controlled clinical trials proving that treatment of sHPT reduced fractures, vascular events or death. Three retrospective studies reported that calcitriol and alfacalcidol therapy reduced death. We hypothesized that lower PTH levels at baseline would be associated with lower risk of fractures, vascular events and death in stage 3 and 4 CKD patients. We used Marshfield Clinic electronic health records spanning 1985 to 2013 to assess relationships between baseline PTH levels and subsequent 10-year probabilities of clinical fractures, vascular events and mortality in stage 3 and 4 CKD patients. We studied adults with ≥2 PTH measurements at baseline. We used ICD-9 codes to identify subjects' medical conditions, fractures, vascular events and death. In multivariate models, we assessed relationships between serum PTH and the three clinical outcomes, controlling for age, gender and co-morbidities.The 7594 subjects were 68±13 years old and 55% were women. Fractures, vascular events and death occurred in 19%, 60% and 29% of the cohort, respectively. In multivariate models controlling for age, gender, tobacco use, bisphosphonate and hormone therapy, PTH predicted fracture. The PTH value at which the probability of fracture was minimized equaled 23 pg/mL. Below this level, the 10-year probability of fracture dramatically increased (Figure). After controlling for age, gender, tobacco use, vascular disease, diabetes, hypertension, lipids and obesity, PTH was a significant variable in models predicting death. The 10-year probability of death was lowest at a PTH of 50 pg/mL and below this level, the probability of death increased sharply. Vascular event rates were high regardless of PTH values, but rates were lowest at a PTH value of 50 pg/mL.To our knowledge, ours is the first study to suggest that low parathyroid hormone levels are associated with an increased probability of fractures and death in stage 3-4 CKD patients. Findings suggest that over-suppressing PTH with vitamin D analogs might cause harm. Further studies are needed to confirm these findings.

Prevalence and risk of vertebral fractures in primary hyperparathyroidism: A nested case-control study Henriette Ejlsmark-Svensson*[1,2], Lise Sofie Bislev[1,2], Siv Lajlev[2], Torben Harsløf[2], Lars Rolighed[3], Tanja Sikjær[2], Lars Rejnmark[1,2]. [1]Department of Clinical Medicine, Aarhus University, Denmark, [2]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Denmark, [3]Department of Otorhinolaryngology, Head and Neck Surgery, Aarhus University Hospital, Denmark

IntroductionPrevalence of vertebral fractures (VFx) in patients with primary hyperparathyroidism (PHPT) remains uncertain. The presence of VFx is of importance to choice of treatment. International guidelines recommends parathyroidectomy in patients with PHPT and osteoporosis including the presence of VFx. We aimed to estimate the prevalence of VFx, investigate potential risk factors associated with VFx and whether bone mineral density (BMD) differs between PHPT- and osteoporotic-patients with VFx. MethodsThrough the Danish National Patient Register, we identified patients diagnosed with PHPT between 2005-2015. The diagnosis was verified by retrieving biochemistry data. Patients with ionized-calcium levels above and PTH levels in upper third or above upper limit of the reference range were included (averages of two measurements). X-ray reports of the thoracolumbar spine were reviewed by two investigators. Osteoporotic patients with VFx were identified from our outpatient clinic and matched on age and sex with PHPT patients with VFx. ResultsWe identified 792 PHPT patients among whom spine X-ray was available from 588 patients. VFx were present in 122 (21%) patients and were equally frequent among sex (77% females). Fractured patients were older (70 [IQR: 62-77] yrs. vs 63 [55-71] yrs.) and had lower heights (163 [158-169] cm vs 166 [160-172] cm) compared to non-fractured patients (pall <0.02). After stratification by age-groups, the prevalence of VFx differed significantly between sexes (p<0.01). Ionized-calcium and PTH did not differ between groups. BMD at total hip and forearm were lower in fractured compared to non-fractured patients (pall <0.03) after adjusting for age, sex and BMI. Compared with osteoporotic patients with VFx (N=108), BMD at the lumbar spine was higher in PHPT patients with VFx (N=108) (p<0.01). This did not change by excluding patients with lumbar VFx (p<0.01). ConclusionThe severity of PHPT assessed by biochemistry does not seems to be associated with risk of VFx and the relatively high prevalence of VFx supports a proactive screening in all patients diagnosed with PHPT. Compared with osteoporosis; VFx seems to occur at a higher BMD in PHPT.

Fracture Risk Assessment in Women with Breast Cancer Initiating Aromatase Inhibitor Therapy: A Registry-Based Cohort Study William Leslie*[1], Suzanne Morin[2], Lisa Lix[1], Eugene Mccloskey[3], Helena Johansson[3], Nicholas Harvey[4], John Kanis[3]. [1]University of Manitoba, Canada, [2]McGill University, Canada, [3]Centre for Metabolic Bone Diseases, United Kingdom, [4]MRC Lifecourse Epidemiology Unit, United Kingdom

PURPOSE: Aromatase inhibitors (AI) for breast cancer induce bone mineral density (BMD) loss and have been reported to increase fracture risk. FRAXR was developed to predict 10-year risk for major osteoporotic fracture (MOF) and hip fracture in the general population. We evaluated the performance of FRAX for fracture prediction in women treated with AI. METHODS: We conducted a BMD registry-based cohort study linked to population-based data for the Province of Manitoba, Canada. We identified women age 40 years or

older initiating AI for breast cancer with at least 12 months AI prescribed (N=1775), with breast cancer but not receiving AI (N=1016), and from the general population (N=34,205) during 2005-2016. FRAX scores were computed with and without BMD. Survival methods (with competing mortality) and Cox proportional hazards models were used to study time to first incident fracture, adjusted for baseline risk, in breast cancer subgroups compared to general population.RESULTS: Mean age at baseline was 65 years for all groups (P=0.607). Cumulative fracture incidence to 10 years showed no significant between-group differences for incident MOF (P=0.198) or any fracture (P=0.157); there was a lower incidence of hip fracture in AI users (P=0.039). FRAX stratified risk for MOF, hip and any fracture equally well in all subgroups (all P-interaction >0.1). At baseline AI users had higher BMI, higher BMD, lower osteoporosis prevalence and fewer prior fractures (P<0.001). When adjusted for FRAX score without BMD and with AI use entered as a secondary cause of osteoporosis (Table, Model 1), AI users were at significantly lower risk for MOF (HR 0.78, 95% CI 0.63–0.97), hip fracture (HR 0.44, 95% CI 0.26–0.73) and any fracture (HR 0.77, 95% CI 0.64–0.92). AI use was no longer significantly associated with fractures when AI use was not entered as secondary osteoporosis (Model 2) or when BMD was included in the FRAX calculation (Model 3). Similar results were seen when analysis was limited to 918 women with at least 5 years of AI use.CONCLUSIONS: Our findings challenge the view that all women with breast cancer initiating AI therapy are at high fracture risk. Fracture probability scores from FRAX stratify fracture risk equally well in women receiving AI therapy as in non-users, but including secondary osteoporosis as a risk factor for AI users overestimates fracture risk.

Table. Hazard ratios (HR) with 95% confidence intervals (CI) for incident fracture according to breast cancer status and aromatase inhibitor (AI) use, adjusted for baseline risk.

|	Model 1: Adjusted for FRAX without BMD (+ AI secondary)	Model 2: Adjusted for FRAX without BMD (- AI secondary)	Model 3: Adjusted for FRAX with BMD

Towards a physiologically-based definition of hypogonadism: Dose-response relationships between testosterone and bone density in older men Elaine Yu*, Benjamin Leder, Hang Lee, Laura Krivicich, Emily Gentile, Sarah Hirsch, Karin Darakananda, David Lin, Joel Finkelstein. Massachusetts General Hospital, United States

Introduction: Testosterone (T) replacement in older men is controversial, partly due to a lack of a physiologically-based definition of late-onset hypogonadism. We previously found that T levels above 200 ng/dL prevented increases in bone resorption and decreases in bone mineral density (BMD) in young men. However, it is not clear whether the same physiologic thresholds apply to older men. Thus, we performed a randomized controlled physiologic study in older men to determine the T thresholds that lead to bone loss.Methods: Healthy men aged 50-75 (n=177) were randomized to 1 of 6 groups. Groups 1-5 received goserelin acetate (Zoladex®, AstraZeneca LP, 3.6 mg q4wk) to induce severe hypogonadism, together with 0 (placebo), 1.25, 2.5, 5, or 7.5 g/day of a T gel (AndroGel®, Abbvie) for 16 weeks. Group 6 (Controls) received placebo Zoladex® and placebo Androgel®. BMD of lumbar spine was assessed by DXA (L1-L4) and by QCT (L4). Serum C-telopeptide (CTX) was measured at weeks 0 and 16 to assess bone resorption. The mean percent change from baseline of CTX and spine BMD for the Controls was compared with the mean change for each of the other 5 groups using Dunnett's test for multiple comparisons.Results: Mean age at baseline was 65 ± 4 years. Mean baseline T levels were 490 ± 151 ng/dL in the full cohort, and were similar in each of the 6 groups. Mean (± SD) serum T and E levels measured every 4 weeks were 35 ± 34, 206 ± 116, 324 ± 162, 549 ± 290, and 807 ± 381 ng/dL and 3 ± 2, 11 ± 7, 15 ± 7, 28 ± 13, and 36 ± 18 pg/mL in the 0, 1.25, 2.5, 5, and 7.5 g/day T dose groups, respectively, and 533 ± 142 ng/dL and 28 ± 5 pg/mL in the Controls. Serum CTX increased 103 ± 57% in the 0 g/day T group and 41 ± 30% in the 1.25 g/day T group (P<0.01 vs Controls for both), but did not differ significantly from Controls in groups that received 2.5, 5, or 7.5 g/day of T. When assessed by QCT, spine BMD decreased by -6 ± 8%, -5 ± 7%, and -5 ± 8% in groups that received 0, 1.25, or 2.5 g/day of T (P<0.05 vs Controls for each of the 3 groups). There were no differences in DXA spine BMD in any group compared with Controls.Conclusions: The strong dose-response relationships between T dose and CTX and BMD in older men suggest that increased bone resorption and bone loss begin when serum T levels fall below 200-300 ng/dL and serum E2 levels fall below 10-15 pg/mL. These data suggest that the relationship between gonadal steroid levels and bone health is similar in older and younger men.

Mettl3-mediated m6A regulates the fate of bone marrow mesenchymal stem cells and osteoporosis Yunshu Wu*[1], Liang Xie[1], Mengyuan Wang[1], Yuchen Guo[1], Rui Sheng[1], Jing Li[1], Peng Deng[1], Rixin Zheng[1], Qiuchan Xiong[1], Yizhou Jiang[2], Ling Ye[1], Xuedong Zhou[1], Shuibin Lin[3], Quan Yuan[1]. [1]State Key Laboratory of Oral Diseases & National Clinical Research Center for Oral Diseases, West China Hospital of Stomatology, Sichuan University, China, [2]Institute for Advanced Study, Shenzhen University, China, [3]Center for Translational Medicine, The First Affiliated Hospital, Sun Yat-sen University, China

Aged-related osteoporosis is featured with low bone mass and excessive accumulation of adipocytes. However, explicit mechanisms under which the lineage allocation of bone marrow mesenchymal stem cells (MSCs) favors adipogenic to osteogenic lineage remain unclear. Being the most abundant internal mRNA epigenetic modification, N6-methyladenosine (m6A) exerts great influence in modulating multiple RNA processing events. Recent studies uncovered that m6A modification maintains the proper lineage commitment of functional stem cells and participates in mammalian development and disease control. To study the potential role of m6A methylation and its methyltransferase Mettl3 in MSCs lineage allocation and bone diseases, we first performed immunostaining which showed that Mettl3 is prevalently expressed in murine bone cells and bone marrow. Next, we generated Prx1-Cre driven Mettl3 conditional knockout mice and discovered that decreased m6A level upon loss of Mettl3 in MSCs led to low bone mass and high marrow adiposity in mice, much resembling the pathological features of osteoporosis. In consistent with in vivo phenotypes, cell culturing of primary Mettl3fl/fl and Prx1-Cre;Mettl3fl/fl MSCs revealed that m6A reduction impaired the osteogenic while promoting the adipogenic differentiation potential of mutant MSCs. More interestingly, mice with conditional Mettl3 over-expression in MSCs exhibited less bone loss after ovariectomy, which highlights the therapeutic potential of Mettl3 in preventing estrogen deficiency-induced osteoporosis. Mechanistically, our MeRIP-seq and RNA-seq demonstrated that Mettl3-mediated m6A regulates PTH (parathyroid hormone)/Pth1r (parathyroid hormone receptor-1) signaling axis, one of the most essential pathway in bone homeostasis. Knockout of Mettl3 reduced the translation efficiency of MSCs lineage allocator Pth1r, thus further blocking the downstream pathways, such as cyclic AMP-dependent protein kinase A (PKA) and extracellular signal-regulated kinases (ERK), responsible for the anabolic effect of PTH. In addition, Mettl3 conditional knockout mice displayed an obviously inert response to intermittent PTH injection. They failed to undergo an effective increase in bone remodeling and their excessive accumulation of marrow fat was also hardly alleviated after PTH treatment. Our results demonstrate the pathological outcomes of m6A mis-regulation in MSCs and unveil novel epitranscriptomic mechanism in skeletal health and diseases.

Fat Regulates Inflammatory Arthritis Yongjia Li*[1], Wei Zou[1], Jonathan Brestoff[1], Nidhi Rohatgi[1], Xiaobo Wu[2], John Atkinson[2], Charles Harris[3], Steven Teitelbaum[1,4]. [1]Department of Pathology and Immunology, Washington University School of Medicine, St. Louis, United States, [2]Division of Rheumatology, Department of Medicine, Washington University School of Medicine, St. Louis, United States, [3]Division of Endocrinology, Metabolism and Lipid Research, Department of Medicine, Washington University School of Medicine, St. Louis, United States, [4]Division of Bone and Mineral Diseases, Department of Medicine, Washington University School of Medicine, St. Louis, United States

Obesity and inflammatory arthritis (IA) are common disorders in western society, yet their relationship is poorly understood. To explore the possible association of fat to IA, we cross-mated diphtheria toxin (DTA)flox/flox mice with those expressing Adiponectin Cre. The resultant mice are fat-free (FF) as they completely lack visible visceral, subcutaneous and brown adipose tissue, confirmed by virtually undetectable circulating adipocyte-specific adipokines. To test whether fat is involved in the pathogenesis of IA, we injected K/BxN

serum into WT and FF mice. K/BxN serum induces severe IA characterized by dramatically enhanced paw and ankle thickness, increased osteoclast number, inflammation and severe bone destruction in WT mice. Surprisingly, FF mice are completely resistant to K/BxN serum-induced inflammatory arthritis. Importantly, transplantation of WT, mature fat into FF mice totally reverses their arthritis resistance suggesting that adipocyte products promote IA. To determine which adipokines are involved in regulating IA, we administered K/BxN serum to adipokine-knock out (KO) mice, including those deleted of adiponectin, leptin, combined adiponectin/leptin (double-KO) or adipsin. While all other adipokine KO mice develop inflammatory joint disease comparable to WT, adipsin deficiency totally prevents K/BxN serum induced IA. This observation suggests fat-mediated development of IA requires adipocyte-expressed adipsin. Consistent with this posture, unlike WT fat, transplantation of adipose tissue derived from adipisin-deficient mice into FF mice fails to enable K/BxN induced IA. Neutrophils play a key role in inflammatory joint destruction. Using flow cytometry, we established that neutrophils comprise more than 90% of immune cells in synovial fluid of WT mice injected with K/BxN serum, but less than 5% in similarly treated FF and adipsin-KO mice. These results suggest absence of adipsin is responsible for the arrested inflammation in the joints of FF and adipsin-KO mice. Recently it has been reported that alternative pathway of complement activation is critical for IA development as complement component, factor B-deficient mice are resistant to K/BxN induced joint destruction. Since adipsin (complement factor D) is involved in alternate complement activation, our results suggest that fat is important for IA development by modulating fat-free (FF) alternate complement activation via adipsin. Our study provides the first direct evidence that fat regulates IA development.

Deletion of Ror2 Promotes Bone Formation by Attenuating IL-6 Signaling

Hiroaki Saito*[1], Jonathan Gordon[2], Josech R. Boyd[2], Michiru Nishita[3], Yasuhiro Minami[3], Jane Lian[2], Gary Stein[2], Hanna Taipaleenmäki[1], Eric Hesse[1]. [1]Molecular Skeletal Biology Laboratory, Department of Trauma, Hand and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Germany, [2]Department of Biochemistry, College of Medicine, University of Vermont, United States, [3]Department of Physiology and Cell Biology Kobe University Graduate School of Medicine, Japan

Canonical Wnt signaling is among the strongest inducers of bone formation while much less is known about non-canonical Wnt signaling in bone mass accrual. Receptor tyrosine kinase-like orphan receptors 1 and 2 (Ror1, Ror2) play an important role in activating non-canonical Wnt signaling. To determine the physiological role of Ror1 and Ror2 in bone formation, we deleted each receptor individually and in combination within the osteoblast lineage using the cre-recombinase under the control of the 2.3 kb fragment of the collagen type 1 promoter (Col1-Cre+). Deletion of Ror1 in 8-week old Col1-Cre+;Ror1fl/fl mice did not show any alteration of the bone phenotype compared to Col1-Cre+;Ror1wt/wt control littermates. However, mice bearing a targeted deletion of Ror2 in osteoblasts (Col1-Cre+;Ror2fl/fl) demonstrated an increase in the number of osteoblasts and in the bone formation rate without changes in bone resorption, thereby augmenting trabecular and cortical bone mass (p<0.05). This phenotype was recapitulated in Ror1/2 double conditional knockout mice (Col1-Cre+;Ror1,2fl/fl), demonstrating that in osteoblasts Ror1 is dispensable while Ror2 inhibits bone formation. In support of these findings, Ror2-deficient mouse embryonic fibroblasts showed an improved osteoblast differentiation. Furthermore, reducing the abundance of Ror2 in Kusa-A1 and Ocy454 osteoblast-like cells using the CRISPR/Cas9 system and in calvarial osteoblasts using the GapmeR technology, increased osteoblast differentiation

and mineralization as well as the expression of the osteoblast-related genes Runx2, alkaline phosphatase and osteocalcin. To elucidate the mechanisms by which Ror2 suppresses bone formation, we performed a genome-wide RNA-seq analysis in Ror2-deficient calvarial osteoblasts. Comprehensive bioinformatics analysis of 699 upregulated and 665 downregulated genes revealed that target genes of the IL-6 and TNF-α pathways (Ccl5, Cxcl1, Cxcl10, Bcl3, Icam1 and Pik3r3) were significantly decreased in Ror2-deficient osteoblasts. Since these cascades are known to impair osteoblast function and bone formation, we hypothesized that lack of Ror2 might attenuate IL-6 signaling. Indeed, phosphorylation of Stat3 and the expression of Socs3 in response to IL-6 treatment were impaired in Ror2-deficient osteoblasts compared to controls. These findings suggest that deletion of Ror2 promotes bone formation and gain in bone mass by attenuating IL-6 signaling in osteoblasts.

BMP2-CXCL12 Axis Regulates Prx1 Expression During Fracture Repair

Alessandra Esposito*, Lai Wang, Tieshi Li, Jie Jiang, Xin Jin, Anna Spagnoli. Rush University Medical Center, United States

Despite the clinical significance of fractures, mechanisms governing the cellular and humoral responses during repair are still not completely known. Studies, including from our laboratory, have reported that Paired Related Homeobox 1 (Prx1) regulates mesenchymal stromal cells differentiation and is postnatally expressed within the periosteum and endosteum. We previously reported that a bone morphogenic protein 2 (BMP2+)-chemokine C-X-C motif-ligand-12 (CXCL12+) endosteal/perivascular cell population is recruited during fracture repair, and that BMP2-dependent osteogenic differentiation requires CXCL12 downregulation. We hypothesize that BMP2-CXCL12 axis regulates Prx1 expression during osteoblast differentiation and such regulation is critical for fracture repair. To support our hypothesis we found that mice haploinsufficient for BMP2 in Prx1 expressing cells (BMP-2cKO/+), that have impaired fracture healing, have increased Prx1 mRNA levels and such increase positively correlated with increased levels of CXCL12. Immunofluorescence analysis of calluses from BMP2cKO/+ mice showed an increase of CXCL12+/Prx1+ cells, surrounding endothelial CD31+ cells and co-expressing pericyte markers. Tracing studies using Prx1-GFP-CreER-Rosa26-LacZ mice confirmed that Prx1 expressing cells are pericytes and they lose Prx1 expression with osteo-chondrogenic differentiation. Furthermore, in fractured calluses, Prx1 mRNA expression increased rapidly right after fracture, peaked by day 7, decreased by day 10 and continued to decline by day 14. Impaired fracture healing of BMP-2cKO/+ mice was rescued when mice were systemically treated with AMD3100, an inhibitor of CXCL12 signaling, that led to a downregulation of both CXCL12 and Prx1 mRNA expressions (Fig). Isolated endosteal cells from BMP2cKO/cKO mice failed to differentiate into osteoblasts and showed increased Prx1 and CXCL12 mRNA levels; AMD3100 treatment restored osteogenic differentiation and normalized both CXCL12 and Prx1 mRNA expressions (Fig). Interestingly, FACS-sorted GFP+ endosteal cells from Prx1GFPCreER+ mice cultured under osteogenic conditions differentiated in osteoblasts (Fig) and differentiation was associated with a decrease of Prx1 mRNA expression. Taken together, our in vitro and in vivo studies suggest that Prx1 is a downstream target of CXCL12 signaling during BMP2-induced fracture healing, and a downregulation of Prx1 is required for osteoblast differentiation.

CXCL12 signaling regulates Prx1 expression during osteoblast differentiation in fracture repair. A) AMD3100 reduces CXCL12 and Prx1 expression in fractured BMP2cKO/+. qRT-PCR, *p<0.05, **p<0.01, vs Day14=1. N=4, t-test. B) AMD3100 reduces CXCL12 and Prx1 expression in isolated endosteal cells of BMP2cKO/cKO. qRT-PCR, *p<0.05, **p<0.01, vs Day14=1. N=4. C) Prx1 expression in fractured Prx1GFPCreER+ mice. qRT-PCR, *p<0.05, **p<0.01, ***p<0.001, vs Unfractured=1. N=4, t-test. Methylation Of 4-aminobutyrate Aminotransferase (Abat) by Dnmt3b Regulates Chondrocyte Metabolism and the Development of OA Jie Shen*, Cuicui Wang, Daofeng Li, Ting Wang, Audrey Mcalinden, Regis O'Keefe. Washington University in St Louis, United States

Recent GWAS studies have implicated a distinct DNA methylation signature in OA patients, suggesting that DNA methyltransferases (Dnmt) have a role in regulating cartilage homeostasis. Our work further established that loss of Dnmt3b in articular chondrocytes (ACs) leads to OA progression, at least in part, due to accelerated TCA cycle and elevated mitochondrial respiration. The goal of this study is to determine the downstream targets of Dnmt3b potentially involved in regulating chondrocyte energy metabolism and in the pathogenesis of OA.RNA-seq and Methyl-seq were performed to investigate the downstream targets of Dnmt3b and integrative analysis revealed an enrichment in genes and pathways that regulate cellular energy metabolism in Dnmt3b LOF ACs. Among these gene targets was Abat. Direct analysis of the Abat promoter confirmed that Dnmt3b LOF resulted in reduced methylation in ACs (50% methylation in Control; and 3% methylation in Dnmt3b LOF). qPCR and western blot further showed that Abat gene and protein expression were induced in Dnmt3b LOF ACs and OA patients.Since Abat catalyzes the metabolism of GABA to succinate, HPLC mass spectroscopy validated an increase in succinate (300%) level in Dnmt3b LOF ACs. We further evaluated if Abat was involved in regulation of OXPHOS and AC hypertrophy and found that Abat siRNA resulted in a decrease in OXPHOS as reduced basal OCR (50%), maximal OCR (60%), and ATP production (50%). Abat inhibition in Dnmt3b LOF ACs by Vigabatrin blocked the increase in the expression of Col10a1, Mmp13, and Runx2 observed in the Dnmt3b LOF ACs. In contrast, Abat overexpression led to a marked increase in basal OCR (300%), maximal OCR (500%), and ATP production (500%). Overexpression of Abat stimulated AC hypertrophy as reflected by upregulation of Runx2 (250%) and Mmp13 (600%). The deleterious role of Abat was further confirmed in vivo by intraknee overexpression of Abat via lenti virus. Histological analysis revealed that Abat overexpression led to advanced osteoarthritic changes with loss of cartilage and development of osteophytes at 6 weeks post DMM surgery (n=10). More importantly, mice treated with Abat inhibitor, Vigabatrin displayed a protective effect against injury-induced OA progression at 6 and 10 weeks post DMM surgery (n=5). OARSI scoring showed marked lower scores in Vigabatrin treated mice.Taken together, Abat is a target of Dnmt3b and Abat mediated energy metabolism plays a critical role in OA progression.

Burosumab Improved Serum Phosphorus, Osteomalacia, Mobility, and Fatigue in the 48-Week, Phase 2 Study in Adults with Tumor-induced Osteomalacia Syndrome Suzanne Jan De Beur*[1], Paul D. Miller[2], Thomas J. Weber[3], Munro Peacock[4], Karl L. Insogna[5], Rajiv Kumar[6], Frank Rauch[7], Diana Luca[8], Christina Theodore-Oklota[8], Kathy Lampl[8], Javier San Martin[8], Thomas O. Carpenter[5]. [1]Johns Hopkins University School of Medicine, United States, [2]Colorado Center for Bone Research, United States, [3]Duke University, United States, [4]Indiana University School of Medicine, United States, [5]Yale University School of Medicine, United States, [6]Mayo Clinic College of Medicine, United States, [7]McGill University, Canada, [8]Ultragenyx Pharmaceutical Inc., United States

Tumor-induced Osteomalacia (TIO) Syndrome, including Epidermal Nevus Syndrome (ENS), is a rare condition in which tumor-produced fibroblast growth factor 23 (FGF23) leads to decreased renal phosphate reabsorption, impaired 1,25(OH)2D synthesis, and osteomalacia resulting in pain, weakness, fatigue, decreased mobility, and fractures. Burosumab is a fully human monoclonal antibody against FGF23.In the ongoing open-label Phase 2 CL201T study (NCT02304367), 16 adults with TIO and 1 adult with ENS were treated with burosumab for 48 weeks. All subjects received 0.3-2.0 mg/kg every 4 weeks with the exception of 1 subject that received only 1 dose of 0.3 mg and then 2 doses of 0.15 mg/kg at Weeks 8 and 32. Key endpoints were change in serum phosphorus and histomorphometric indices assessed from paired trans-iliac crest bone biopsies. Fatigue, quality of life, and mobility were also assessed.At baseline, mean age was 53 years, mean serum intact FGF23 was 381 pg/mL, and mean serum phosphorus was 1.6 mg/dL. One subject with TIO discontinued treatment prior to Week 48 to treat tumor progression. Mean (SD) serum phosphorus level averaged across the mid-point of the dose interval through Week 24 was 2.73 mg/dL (0.81). Histomorphometric analysis is reported for 11/13 subjects with paired biopsies that showed osteomalacia at baseline. At Week 48, histomorphometric indices improved as demonstrated by increases in mineralizing surface/bone surface (mean percentage change +227%) and decreases in osteoid thickness (-24%), osteoid volume/bone volume (-24%) and mineralization lag time (-45%). Mean (SD) Global Fatigue Score decreased from 5.7 (2.7) at baseline to 3.8 (2.9) at Week 48 (p=0.0008). The mean (SD) physical component summary score on the Short-Form 36 health assessment increased from 33 (11) at baseline to 39 (11) at Week 48 (p=0.009). Additionally, mean (SD) vitality score increased from 41 (14) to 47 (12) (p=0.0057). The mean (SD) number of sit-to-stand repetitions increased from 6.9 (4.2) at baseline to 8.5 (4.2) at Week 48 (n=13; p=0.0006). All subjects experienced ≥1 adverse event (AE). There were 13 drug-related AEs in 6 subjects, none were serious. There were 11 serious AEs in 5 subjects, none of which were drug-related.In adults with TIO Syndrome, burosumab was associated with increases in serum phosphorus; improvements in osteomalacia, mobility, and quality of life; and reductions in fatigue.

Table 1. Histomorphometric Assessments in UX023-CL201T

Assessment	All Subjects[a] Mean [Median] (SD)	Normal Range (Recker et al. 1988)
Osteoid V / Bone V, % Baseline Week 48	19.82 [11.00] (18.47) 13.62 [8.10] (15.09)	0.30 - 3.10
Osteoid Thickness, μM Baseline Week 48	17.63 [13.60] (11.07) 12.17 [8.20] (9.03)	5.50 - 12.00
Osteoid S / Bone S, % Baseline Week 48	64.27 [57.00] (28.06) 63.00 [64.00] (24.98)	7.0 - 25.0
Mineralizing S / Bone S, days Baseline Week 48	2.18 [1.75] (1.70) 6.13 [5.10] (4.83)	0.5 - 8.0
Mineralization Lag Time, days Baseline Week 48	2138.43 [1567.40] (1865.58) 994.53 [329.00] (2137.32)	23.0 - 80.0

[a]11 subjects with paired biopsies who also showed osteomalacia at baseline are included in the histomorphometric analyses. S, surface; V, volume

Efficacy and Safety of Burosumab, a Fully Human Anti-FGF23 Monoclonal Antibody, for Children 1-4 Years Old with X-linked Hypophosphatemia (XLH) Michael P. Whyte*[1], Erik Imel[2], Gary S. Gottesman[1], Meng Mao[3], Alison Skrinar[3], Javier San Martin[3], Thomas O. Carpenter[4]. [1]Shriners Hospitals for Children, United States, [2]Indiana University School of Medicine, United States, [3]Ultragenyx Pharmaceutical Inc., United States, [4]Yale University School of Medicine, United States

In children with X-linked hypophosphatemia (XLH), high circulating levels of fibroblast growth factor 23 (FGF23) cause hypophosphatemia with consequent rickets, skeletal deformities, and growth impairment. We have reported that treatment with burosumab, a fully human monoclonal antibody against FGF23, improved phosphate homeostasis and rickets in 5-12 year-old children with XLH.Study CL205 (NCT02750618) is an open-label, multicenter investigation of the efficacy and safety of burosumab in 13 1-4 year-old children with XLH. Each child received burosumab 0.8 mg/kg SC Q2W, increased to 1.2 mg/kg if hypophosphatemia persisted, for 64 weeks with the option to enroll in an extension study. The primary endpoint was change from baseline in serum phosphorus at Week 40. Other key endpoints included change in rickets severity at Weeks 40 and 64 based on the Thacher Rickets Severity Score (RSS) and the Radiographic Global Impression of Change (RGI-C).All 13 children (mean age 2.9 years; 69% male) completed 64 weeks of burosumab treatment. Though all children had received conventional therapy before enrollment (mean duration 16 months), rickets was apparent at baseline (85% of children had Total RSS $\geq$ 2.0). Rickets, as assessed by RSS, RGI-C, and serum alkaline phosphatase (ALP) activity, significantly improved (Table 1). At Weeks 40 and 64, mean RSS decreased by 59% and 69%, respectively. All children achieved substantial healing (RGI-C Global Score $\geq$ +2.0) by Week 40. Lower limb bowing improved, with 2 and 4 children achieving a lower extremity RGI-C $\geq$ +2.0 at Weeks 40 and 64, respectively. Significant decreases in ALP at Week 40 (-39%) were maintained at Week 64. Consistent with our findings in older children with XLH, serum phosphorus and 1,25(OH)2D levels increased, with mean values reaching within the normal range. All children experienced $\geq$ 1 adverse event (AE). One child had a serious AE, dental abscess, that was considered unrelated to treatment. All other AEs were mild or moderate, except for a Grade 3 food allergy unrelated to study drug. No child discontinued therapy, showed hyperphosphatemia, or had clinically meaningful increases in circulating calcium or PTH.Consistent with findings in older children with XLH treated with burosumab, Q2W burosumab significantly improved phosphate homeostasis and rickets in 1-4 year-old children with XLH.

Table 1. Burosumab through Week 64 for 1-4 Year-old Children with XLH

Assessment	Q2W (N=13)
Serum Phosphorus, mg/dL, mean (SE)	
Baseline	2.51 ± 0.08
Week 40	3.47 ± 0.14[a]
Week 64	3.40 ± 0.13[a]
Serum 1,25(OH)₂D, pg/mL, mean (SE)	
Baseline	45 ± 5
Week 40	57 ± 3[b]
Week 64	56 ± 3[a]
Serum ALP, U/L, mean (SE)	
Baseline	549 ± 54
Week 40	335 ± 24[a]
Week 64	334 ± 22[a]
RSS Total Score, mean (SE)	
Baseline	2.9 ± 0.4
Week 40	1.2 ± 0.1[a]
Week 64	0.9 ± 0.1[a]
RGI-C Global Score, LS mean (SE)	
Week 40	+2.33 ± 0.07[a]
Week 64	+2.23 ± 0.11[a]
RGI-C Lower Limb Score, LS mean (SE)	
Week 40	+1.26 ± 0.13[a]
Week 64	+1.56 ± 0.12[a]

[a]p<0.0001 and [b]p<0.001 based on LS mean change from baseline.
Lower RSS and Higher RGI-C values indicate improvement.

Incidence of Malignancies in Fibrous Dysplasia: Data from a National Pathology Cohort Marlous Rotman*, Neveen Hamdy, Bas Majoor, Michiel Van De Sande, Judith Bovee, Sander Dijkstra, Olaf Dekkers, Natasha Appelman-Dijkstra. LUMC, Netherlands

Fibrous dysplasia(FD) is reported to be associated with increased risk for breast and thyroid cancer and for the pre-malignant intraductal papillary mucinous neoplasm (IPMN), possibly due to extra-skeletal tissue distribution of GNAS-mutations. Data on further associations of FD with malignant tumors are scarce. Since these associations may have significant clinical implications, we performed a cohort study on tumor occurrence in FD.Pathology reports from patients with confirmed FD were retrieved from the Dutch National pathology registry (PALGA). Incidence rates for malignant tumors were estimated and compared between FD patients and the general Dutch population by calculating standardized morbidity ratios (SMR). In this study, SMRs were calculated for all histologically confirmed FD/GNAS-associated and bone tumors. We also studied the FD associated risk for the three most common malignancies in the Netherlands, e.g. prostate, colorectal and skin cancer; our data on breast cancer have been reported previously.Of the 1146 PALGA FD patients, 177 (M/F; 79/98) also had histological evidence for a malignant tumor. Mean age at FD diagnosis was 47.0 years (1-86yr) and mean age at diagnosis of malignancy was 49.7 years (2-92yr). 207 malignant tumors were documented. Among known GNAS-related and bone tumors, SMR was increased for thyroid cancer (3.71[95%CI 1.13-7.76]) and for osteosarcoma (26.31[95%CI 6.58-59.20]). For the three most prevalent malignancies in The Netherlands, SMRs were increased for prostate cancer (3.08[95%CI 1.82-4.63]) and melanoma (1.99[95%CI 1.05-2.94]), but not for colorectal cancer.Our data confirm that patients with FD have an increased risk for thyroid cancer and osteosarcoma. We also report for the first time an increased risk for a number of other malignancies in FD such as melanoma and prostate cancer, which both have not priviously been associated with GNAS-mutations, but no increased risk for pancreatic cancer was found. Our findings raise awareness for the risk of malignancy in FD, although caution should be exerted in the interpretation of these data, as true incidence rates of malignancy might have been underestimated by the inclusion in this study of only patients with histologically-confirmed FD, and the specific role of GNAS mutations in the pathophysiology of FD-related tumors is as yet to be unraveled.

Abnormal Monocyte Responses in Fibrodysplasia Ossificans Progressiva Emilie Barruet*[1], Blanca M Morales[1], Tania Moody[1], Corey J Cain[1], Kelly Wentworth[1], Tea V Chan[1], Amy Ton[1], Tom Hm Ottenhoff[2], Mariëlle C. Haks[2], Judith Hellman[1], Mary Nakamura[3], Edward C Hsiao[1]. [1]UCSF, United States, [2]Leiden University Medical Center, Netherlands, [3]UCSF/VAMC, United States

Heterotopic ossification (abnormal bone formation in soft tissue) is known to be triggered in inflammatory settings, although the underlying mechanisms are poorly understood. Diseases of heterotopic bone formation such as fibrodysplasia ossificans progressiva (FOP) give valuable insights into human-specific mechanisms of increased bone formation. FOP is associated with mutations in the Activin A type I receptor (ACVR1), a BMP receptor that increases ACVR1 signaling activity and response to both BMP and Activin A ligands. FOP is characterized by progressive and debilitating heterotopic ossification, often occurring in inflammatory flares with pain, erythema, swelling, and localized edema. The forming bone lesions contain multiple cell types, including large numbers of macrophages that may play a key role in modulating osteogenesis. We previously showed that FOP patients have increased serum cytokine levels associated with a chronic inflammatory state. We hypothesized that patients with FOP are in a pro-inflammatory state that increases their sensitivity to inflammatory insults. Using carefully-obtained samples of blood from FOP subjects and relatives, we tested the activation of CD14+ primary monocytes with toll-like receptor (TLR) ligands including lipopolysaccharide (LPS), and used immunofluorescence quantification analyses to assay the BMP and NFB pathways. We also analyzed the different subtypes (classical, intermediate and non-classical) of monocytes present in whole blood of FOP patients and found a significant increase in the intermediate monocyte population that is thought to be pro-inflammatory. TLR4 activation by LPS of FOP CD14+ primary monocytes increased CCR7 and CXCL10 expression as well as pro-inflammatory cytokine (IL-1RA, IL-3, IL-15, IL-17A), chemokine (MIP-1α, CCL1), and growth factor (EGF, VEGF) production via prolonged activation of the NFB pathway. Together, these results suggest a pro-inflammatory state at baseline in FOP patients that can be detected in primary monocytes from FOP patients. The insights gained from these studies indicate that modulation of the inflammatory state may be a key strategy for mitigating the devastating progression of FOP. Further study of the inflammatory responses will help identify how disruptions of the normal bone-regulating roles of monocytes and macrophages trigger heterotopic bone formation, and whether these immune targets may be amenable to modulation as part of a comprehensive treatment strategy.

Albright Hereditary Osteodystrophy (AHO): autosomal dominant shortening of metacarpals and -tarsals caused by a novel splice-site mutation in PTHLH Monica Reyes*[1], Bert Bravenboer[2], Harald Jüppner[1]. [1]Endocrine Unit, Massachusetts General Hospital, United States, [2]Department of Endocrinology, Universitair Ziekenhuis Brussel, Belgium

Shortening of metacarpals and/or -tarsals is typically observed in pseudohypoparathyroidism (PHP) type Ia (PHP1A) or pseudo-PHP (PPHP), related disorders that are caused by GNAS mutations involving those exons that encode the α-subunit of the stimulatory G protein (Gαs). PHP1A patients also develop PTH-resistant hypocalcemia and often resistance to other hormones, while PPHP patients show no hormonal abnormalities. We now investigated a large Caucasian family with shortened metacarpals and -tarsals, as well as reduced adult height. The proband (190/II-1) had normal serum calcium and phosphate levels (2.34 mmol/L and 1.18 mmol/L, respectively), PTH was slightly elevated (75.7 pg/ml) despite a normal 25-OH vitamin D level (39.1 ng/ml); TSH was normal. Nucleotide sequence analysis of GNAS exons 1-13 provided no evidence for a mutation and no epigenetic GNAS changes were detected. Skeletal abnormalities were present also in the proband's sister (190/II-2), one of this sister's daughters (190/III-1) and two of her three grandchildren (190/IV-1, 190/IV-2), who all had normal calcium, phosphate, PTH, and TSH levels. Whole exome sequencing of the proband's genomic DNA revealed a heterozygous A>G change at nucleotide -3 of PTHLH exon 3 that encodes the last two amino acids of the Pre-Pro sequence and the secreted PTHrP(1-139). The same nucleotide change was also found in the four available family members with similarly shortened metacarpals and -tarsals, but not in two unaffected family members and unrelated spouses. Furthermore, the nucleotide change in PTHLH was not found in public databases thus raising the possibility that it causes the skeletal abnormalities. Complementary DNA derived from immortalized lymphoblastoid cells of the affected male 190/IV-2 and his unaffected sister 190/IV-3 was PCR-amplified using forward primers located in either PTHLH exon 1 or 2, and a reverse primer located in the 3'-non-coding region of exon 3. Nucleotide sequence analysis of both amplicons from 190/IV-2, but not 190/IV-3, revealed a heterozygous insertion of genomic nucleotides -2 and -1 at exon 3, which causes a frame-shift after residue 34 of the PrePro sequence thus encoding 29 novel amino acids that share no homology with PTHrP or any other protein. Our findings extend previous reports indicating that PTHrP haploinsufficiency causes of AHO-like features, which are similar to those observed with GNAS mutations, but do not affect the regulation of mineral ion homeostasis.

Bone marrow-derived CXCL12 is indispensable for the loss of cortical bone mass caused by estrogen deficiency Filipa Ponte*, Aaron Warren, Ha-Neui Kim, Iyer Srividhya, Li Han, Maria Almeida, Stavros Manolagas. UAMS, United States

The protective effects of estrogens against cortical and cancellous bone loss result from ERα signaling on distinct cell types: mesenchymal cells (targeted by Prx1 or Osx1-Cre) and cells of the myeloid lineage (targeted by LysM-Cre), respectively. However, functional evidence for the ERα gene targets and the molecular changes and mediators of the adverse effects of estrogen deficiency in the two bone compartments is lacking. CXCL12 is a C-X-C motif containing chemo-attractant abundantly expressed in Prx1 cells of the bone marrow and indispensable for B-lymphopoiesis. The mRNA and secreted protein levels of CXCL12 are increased in ERα null bone marrow cells from female ERαf/f;Prx1-Cre mice; and so is osteoclastogenesis in co-cultures of ERα null BM stromal or calvaria cells with macrophages. Furthermore, ovariectomy (OVX) increases CXCL12 in the bone marrow plasma in mice and administration of E2 prevents it.To functionally determine whether the increase of CXCL12 with estrogen deficiency contributes to the loss of cortical bone mass and/or the increase in B-cells, we have generated mice with conditional deletion of a CXCL12 allele in mesenchymal progenitors expressing Prx1 (CKO mice). CXCL12- floxed (control) and CKO littermate mice were ovariectomized (OVX) at 4.5 months of age and 6 weeks later sacrificed for analysis. CXCL12 mRNA in bone marrow-derived stromal cell cultures from CKO mice was decreased by more than 90%. Total body weight and cortical thickness (measured by micro-CT) in the mid-shaft of the femur were indistinguishable between estrogen-sufficient control and CKO mice. The number of CD19+ B cells was, however, dramatically decreased in the CKO mice. Loss of estrogens caused the expected decrease in cortical thickness in the control mice. This effect was completely prevented in the CKO mice. OVX increased B cell number in the bone marrow of control mice, but in spite of the low number of B cells in the CKO mice, B cell number increased following OVX. These results demonstrate that mesenchymal/stromal cell-derived CXCL12 is an indispensable mediator of the loss of cortical bone mass, but not the increase in B-cells, caused by estrogen deficiency in mice.

Marrow adiposity and vascular morphology are regulated by EBF1 in adult bone Seham Alruwaili*[1], Steven Tommasini[2], Ben-Hua Sun[2], Jackie Fretz[2]. [1]Quinnipiac University, United States, [2]Yale School of Medicine, United States

EBF1-KO mice have a low bone phenotype. These global knockouts, however, are heavily influenced by the consequences of EBF1-loss from extra-skeletal tissues including kidney development and systemic adiposity changes. Although Osx- and Runx2- driven deletion models of EBF1 have been described with relatively modest phenotypes, we present here that Prx1-driven conditional deletion of EBF1 to the entire mesenchymal lineage results in a prolific increase in marrow adiposity, and aberrations to the cortical vascular network. Young mice, up to 3 months of age had no overt bone phenotype when they were examined by μCT for bone quality and osmium staining for quantification of marrow adiposity. By contrast, 6 month old animals developed a significant increase in marrow adiposity (increased over 10 fold) without any alteration of the BV/TV, TbN, TbTh, TbSp, cortical radii or thicknesses, nor BS/BV in either the trabecular or cortical region. Upon histological examination, marrow adiposity was greatly increased, and large portions of the marrow space was occupied by dilated sinusoids. Using FACS the CD45-CD34+ endothelial population was increased in Prx1-cre:Ebf1fl/fl mice. Higher resolution nano-CT revealed that small voids representing osteocyte lacunae were present in both genotypes at equal number and quantity. Larger voids in the bone that trace the vascular network were expanded in the Prx1-cre:Ebf1fl/fl animals (0.55 + 0.07% vs. 0.95 + 0.40%). Their pathway through the cortex were more distended and torturous in Prx1-cre:Ebf1fl/fl mice, and large diameter vessels (50-200 μm) vertically traversing the cortex were uniquely present in the knockouts. FACS separation of various mesenchymal progenitors in 6 month old animals revealed that the abundance of PDGFRα+ and PDGFRβ+ perivascular cell number increased. Markers of other populations, like αSMA were unchanged. This suggests a selective shift in the identity of the MSCs populating Prx1-cre:Ebf1fl/fl bones. Taken together these data indicate that EBF1 has an integral role in regulating the formation of marrow adipocytes from perivascular progenitors, and functions through these support cells to regulate the bone vascular network of the adult skeleton. It also illustrates a situation where marrow adiposity can increase without a decrease in bone volume. Future research into the mechanism of this phenotype may be useful in enhancing our understanding and treatment of vascular bone diseases.

Conditional ablation of Prx1 expressing cells impairs endochondral ossification in postnatal bone repair Lai Wang*[1], Alessandra Esposito[1], Joseph Temple[1], Tieshi Li[1], Jie Jiang[1], Xin Jin[1,2], Anna Spagnoli[1]. [1]Department of Pediatrics, Rush University Medical Center, Chicago, United States, [2]Department of Orthopaedics, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, 430022, P.R. China

Fracture healing is a complex process involving endochondral and intramembranous ossification. Cells from the periosteum and endosteum contribute significantly to callus formation through endochondral ossification. Prx1 is postnatally expressed in the periosteum and endosteum, and Prx1CreER transgene-expressing cells are confirmed as osteochondral progenitor cells. In this study, we used Prx1CreER;R26tdTomato to trace the Prx1 expressing progenitor cells, and used Prx1CreER;R26DTA mice to determine the effect of cell ablation of Prx1 expressing cells in fracture healing. Male mutant mice and their littermate controls were subjected to tibia fracture at postnatal age 10-12 weeks. 4-hydrotamoxifen was administered for 6 days started two days before fracture. Mice were euthanized 14 days after fracture. Immunofluorescence analysis showed co-expression of Sox9 and Osx with tdTomato in the callus of Prx1CreER;R26tdTomato mice, confirming that chondrocytes and osteoblasts in the callus are derived from Prx1 progenitor cells. Contrast-enhanced microCT imaging was performed using contrast agent phosphotungstic acid (PTA) to analyze the callus cartilage. MicroCT-PTA imaging analyses revealed that the volume of soft callus was significantly decreased in Prx1CreER;R26DTA mice compared to their control littermates (13.23±3.48 vs. 8.23±1.39 mm3, n=3 of each group, p<0.05). Immunofluorescence analyses by confocal microscopy showed that tdTomato fluorescence was decreased in the callus of Prx1CreER;R26DTA;R26tdTomato mice, so did the expression of chondrocyte marker Sox9 and osteoblast marker Osx. In Prx1CreER;R26DTA mice, the decrease in cartilage formation was also detected by Safranin O/Fast Green staining. Interestingly, the fracture callus of Prx1CreER;R26DTA mice showed an increased neovascularization. Quantification with PECAM1+ vessel counting showed a 31.9% of increase in microvessel density in calluses from Prx1CreER;R26DTA mice [1.00±0.11 for control group (n=5), vs. 1.32±0.25 for DTA group (n=7), the numbers of PECAM1+ vessels per field were normalized to the control group, p<0.05]. These data indicate that the Prx1-progenitors mediate endochondral ossification. The increased angiogenesis in the callus of Prx1CreER;R26DTA mutant mice may indicate that the failure in bone repair is compensated with increased vascularization.

LRP5-deficiency in OsxCreERT2 mice recapitulates intervetebral disc degeneration from aging and mechanical compression Jiannong Dai*[1], Matthew Silva[2], Nilsson Holguin[1]. [1]IUPUI, United States, [2]Washington University in St. Louis, United States

Intervertebral disc (IVD) degeneration putatively activates differentiation of prehypertrophic chondrocyte-like cells. Osterix is a critical transcription factor in mesenchymal stem cell fate, where its loss or loss of WNT signaling diverts differentiation to a chondrocytic lineage, but its role in IVD degeneration and aging is unclear.Using immunofluorescence, osterix was expressed in (pre)osteoblasts of 5 mo and 12 mo vertebra and in the cells of the outer annulus fibrosus (AF) and nucleus pulposus (NP) of healthy 5 mo IVD, but declined with aging (Fig. 1A). IVD degeneration and aging inactivated WNT signaling. Therefore, we suppressed LRP5 (WNT ligand receptor) in 4 mo mice that inducibly targeted osterix-expressing cells (OsxCreERT2) and report WNT signaling (TOPGAL, LRP5 cKO, n=10). Wild-types served as controls (LRP5fl/fl/TOPGAL, WT, n=9). LRP5 cKO and WT were analyzed by histology, qPCR and mechanical testing. In IVDs, depletion of LRP5 in osterix-expressing cells inactivated WNT signaling (Fig. 1B) in the NP by 95% and AF by 45%, reduced osterix expression by 75% (Fig. 1C), degenerated the IVD (Fig. 1D, E) and reduced the compressive and tensile stiffness by 45%. Using RNA-sequencing, LRP5-deficiency in osterix-expressing cells upregulated notochordal cell markers in the IVD.Next, we determined the histological score of young-adult (5 mo) and aged IVD (18 mo) subjected to 1 week of tail compression (model of IVD degeneration, n=5/age). QPCR quantified the expression of genes related to transcription factors (Osterix, RUNX2) and hypertrophic chondrocyte marker MMP13 in 5 mo and 12 mo IVDs subjected to tail compression (n=5-7/age). Adjacent, non-compressed IVD served as controls. Similar to LRP5 cKOs, aging and mechanical compression induced IVD degeneration, but with the most degeneration noted in compressed 18 mo IVD (Fig. 1E). Similarly, aging and compression reduced osterix expression with superposition effects (Fig. 1C). MMP13 expression, and similarly RUNX2, was elevated by compression of IVD, but less so in 12 mo IVD, suggesting a muted expansion of hypertrophic chondrocyte-like cells with aging. Overall, these data show that IVD cells express osterix and inactivation of WNT signaling in these cells can lead to IVD degeneration similar to aging. These data suggest that aging may limit regeneration by depleting the cells necessary to differentiate and/or proliferate prehypertrophic chondrocyte-like cells during IVD degeneration.

Figure 1. Loss of osterix-expressing cells via loss of WNT signaling contributes to intervertebral disc degeneration. (A) Fluorescence (OsxCreERT2-Ai9/td) of osterix (red, arrows) in the nucleus pulposus (NP) and outer annulus fibrosus (OAF) decreased with aging between 5 and 12 months of age. (B) WNT signaling (blue) in WT (TOPGAL/Lrp5[f/f]) and LRP5 cKO (TOPGAL/Lrp5[f/f]/Osx-CreERT2) mice showing loss with Lrp5-deficiency. (C) Gene expression of osterix declines with inactivated WNT, aging and compression. (D) Safranin-O images of LRP5 cKO and WT IVD. (E) Greater intervertebral disc degeneration in LRP5 cKO than WT. Aging (5 vs 18 mo), mechanical compression (Control vs Loaded) and in combination induce intervertebral disc degeneration in a respectively increasing order. Scale: (A, D) 100 µm, (B) 50 µm. *: vs Control and bar: vs 5 mo, p<0.05

LB-1163

Childhood Obesity and Fracture Risk: A Region-wide Longitudinal Cohort Study of 466,000 Children and up to 11 Years of Follow-up Daniel Prieto-Alhambra*[1], Katherine Butler[2], Jose Poveda[3,4], Daniel Martinez-Laguna[3,4], Carlen Reyes[3,4], Jennifer Lane[1], Jeroen De Bont[3,4], M Kassim Javaid[1], Cyrus Cooper[1,5], Jennifer Logue[6], Talita Duarte-Salles[3,4], Dominic Furniss[1]. [1]NDORMS, University of Oxford, United Kingdom, [2]Stoke Mandeville Hospital, United Kingdom, [3]Institut Universitari d'Investigació en Atenció Primària Jordi Gol (IDIAP Jordi Gol), Spain, [4]CIBERFes, Universitat Autònoma de Barcelona and Instituto de Salud Carlos III, Spain, [5]MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, [6]University of Glasgow, United Kingdom

Objectives.As childhood obesity increases, there is growing interest in the impact of Body Mass Index (BMI) upon bone health. This study investigated if there is an association between childhood BMI and fracture risk.Methods.A prospective cohort of children with a valid primary care BMI measurement in Catalonia, Spain at age 4 years (±6 months) between 1/1/2001 and 31/12/2013 were identified in SIDIAP database, and followed up until they turned 15, migrated, died, or until 31/12/2016. Fractures were defined using validated ICD10 codes recorded in primary care. Childhood cumulative incidence (age 4 to 15 years) was calculated by anatomical location and stratified by BMI category (WHO 2007 growth reference). Cox models were used to estimate Hazard Ratios (HR) according to BMI. Results.Of 466,997 children, 9250 (2.0%) had obese range BMIs, 26526 (5.7%) overweight, and 540 (0.1%) underweight range BMIs. We identified 20878 incident fractures. The cumulative incidence of upper limb fracture for children with obese range BMIs was 76.1 per 10,000 (95%CI 58.4-81.1), compared to 62.1 (59.8-63.4) for normal BMI. Lower limb fracture cumulative incidence was 28.7 per 10,000 (18.0-34.1) in those with obese range BMIs and 15.1(13.9-15.7) in children with normal range BMI. Using BMI as a continuous variable, adjusted hazard ratios (HR; (95%CI)) were 1.05 (1.03-1.06) per 1 standard deviation increase for forearm fractures, 1.08 (1.05-1.12) for hand fractures, 1.14 (1.09-1.20) for ankle fractures and 1.15 (1.10-1.19) for foot fractures.Divided by WHO categories, compared to those with normal range BMI, children with obese range BMIs had an adjusted HR (95%CI) of 1.14 (1.0-1.29) for forearm fractures, 1.37 (1.14-1.66) for hand fractures, 1.66 (1.32-2.10) for foot fractures and 1.81 (1.37-2.37) for ankle fractures. Further adjustment for birthweight (available for 310,751 children) did not affect these estimates. Conclusions. Childhood obesity is associated with a significantly increased risk of forearm, hand, ankle, and foot fractures. The effect of increased BMI upon fracture risk in adults appears to extend to the paediatric population.

LB-1164

Does Cortical Porosity Predict Incident Fractures in Postmenopausal Women? Camilla Andreasen*[1], Åshild Bjørnerem[2]. [1]Department of Clinical Medicine, UiT The Arctic University of Norway, Tromsø, Norway, Department of Orthopaedic Surgery, University Hospital of North Norway, Tromsø, Norway, [2]Department of Clinical Medicine, UiT The Arctic University of Norway, Tromsø, Norway, Department of Obstetrics and Gynecology, University Hospital of North Norway, Tromsø, Norway

Measurement of areal bone mineral density (aBMD) using dual-energy x-ray absorptiometry, online Fracture Risk Assessment Tool (FRAX) and the Garvan Fracture Risk Calculator based on clinical risk factors are commonly used approaches for assessment of fracture risk. However, these approaches have limitations and additional bone measurements may enhance the predictive ability of these existing tools. In cross-sectional studies, women with fracture have higher cortical porosity, thinner cortices and smaller cortical cross-sectional area (CSA) than controls. Cortical porosity and thickness are associated with fracture risk independent of aBMD and FRAX, and cortical porosity improved net reclassification of women with fracture compared with FRAX alone. Whether cortical porosity predicts inci-

dent fractures in unclear. We wanted to examine whether cortical porosity of the proximal femur predicts incident fractures (non-vertebral and vertebral) independent of aBMD during 5 years follow-up of postmenopausal women. In this prospective study we pooled 211 postmenopausal women aged 54-94 years at baseline, with prevalent nonvertebral fractures (181 wrist, 26 proximal humerus and 4 hip), and 232 fracture-free controls in a nested case-control study from the Tromsø Study in Norway. We assessed femoral neck (FN) aBMD, and calculated FRAX 10-year probability of major osteoporotic fracture and Garvan 10-year risk for any fragility fracture, and quantified femoral subtrochanteric cortical porosity, thickness, and CSA from CT images using StrAx software. During a mean follow-up of 5.2 years, 80 (18.1%) of 443 women had an incident fracture (28 forearm, 7 proximal humerus, 4 clavicula, 1 rib, 7 hand, 9 hip, 2 patella, 7 ankle, 8 foot, 7 spine). Per standard deviation (SD) higher cortical porosity, thinner cortices, and smaller cortical CSA, hazard ratio (HRs) (95% confidence interval) for fracture were 1.07 (0.86-1.33), 0.97 (0.77-1.21), and 1.15 (0.92-1.44), respectively, all p > 0.10. Cortical porosity of the inner transitional zone predicted incident fractures marginally, HR was 1.23 (0.96-1.56), p = 0.081 adjusted for age, height, weight and prior fracture, and 1.16 (0.91-1.47), p = 0.231 when additionally adjusted for FN aBMD. Per SD higher FN aBMD, FRAX and Garvan estimates, HRs were 1.40 (1.06-1.86), 1.21 (1.01-1.45), and 1.31 (1.11-1.55), respectively, all p < 0.05. Based on this data, FN aBMD, FRAX and Garvan estimates predicted incident fractures in women but cortical porosity did not.

LB-1165

Nursing Home Trends in Hip Fracture Rates Follow the Plateau Observed in U.S. Women Sarah Berry*[1], Lori Daiello[2], Andrew Zullo[2], Kevin Mcconeghy[2], Tingting Zhang[2], Yoojin Lee[2], Jeffrey Curtis[3], Nicole Wright[3], Vincent Mor[2], Douglas Kiel[1]. [1]Hebrew SeniorLife, Institute for Aging Research, United States, [2]Brown University School of Public Health, United States, [3]University of Alabama at Birmingham, School of Public Health, United States

Purpose: A recent U.S. population-based study suggested a decline in the incidence of hip fracture (fx) between 2002-2012 among women in Medicare, followed by a leveling in the rate from 2013-2015. Newly admitted nursing home (NH) residents are particularly vulnerable to hip fx, and it is unclear whether that trend is observed in this high risk group. The purpose of our study was to describe trends in hip fx rates among 2.6 million newly admitted U.S. NH residents from 2007 to 2015, and to examine whether these trends could be explained by differences in resident characteristics. Methods: Medicare claims data were linked with the Minimum Data Set (MDS), a federally mandated clinical assessment performed quarterly on NH residents. In each year (2007-2015) we identified newly admitted long-stay (≥100 days in the same facility) NH residents. We restricted the sample to residents aged ≥ 65 years enrolled in Medicare Part A. Hip fx was defined using Part A diagnostic codes (ICD-9 & ICD-10). Follow-up time was calculated from the index date until the first hospitalized hip fx event, Medicare disenrollment, death or one year. Incidence rates were calculated as the number of hip fx divided by follow-up time. Poisson regression was used to adjust rates for age, sex, cognition, and transfer dependence. Results: The number of newly admitted NH residents decreased from 324,508 in 2007 to 261,550 in 2015. Mean age was similar across the years, but residents were more dependent in transfers over time (50% in 2007 to 64% in 2015). The unadjusted incidence rate of hip fracture decreased from 3.55/100 person-years in 2007 to 3.16/100 person-years in 2013 (Table), with a leveling or modest increase in the rate in 2014-2015. Mortality was relatively constant over time. The adjusted hip fracture rates were lower in magnitude with overlapping confidence intervals, but followed a similar trend as the unadjusted rates with a leveling of the decline in 2013. Conclusions: We observed a recent plateau in the incidence rates of hip fx among NH residents, similar to the trend observed in a sample of community-dwelling U.S. women. NH residents have become more functionally dependent, which might be expected to reduce the risk of fx. However, our findings may not be fully explained by differences in mortality, cognition, or transfer dependence. More investigation is required to understand the reason for the leveling in hip fx rates in a high risk NH population.

Year	N	Age Mean(SD)	Female n (%)	Dependent in transfers n (%)*	1 year mortality n (%)	1 year hip fx n (%)	Unadjusted IR/ 100 person yrs (95% CI)	Adjusted IR**/ 100 person yrs (95% CI)
2007	324,508	84 (8)	223,154 (69)	161,853 (50)	89,940 (28)	9,580 (3.0)	3.55 (3.48, 3.62)	2.70 (2.58, 2.83)
2008	315,270	84 (8)	215,855 (69)	164,024 (52)	84,794 (27)	9,242 (2.9)	3.54 (3.47, 3.61)	2.72 (2.59, 2.85)

Fracture Prevention in Osteopenic Postmenopausal Women with Zoledronic Acid Every 18 Months, a Randomized Controlled Trial Ian Reid*, Anne Horne, Borislav Mihov, Mark Bolland, Sonja Bastin, Greg Gamble. University of Auckland, New Zealand

Bisphosphonates prevent fractures in patients with osteoporosis but their efficacy in women with osteopenia is unknown. Most fractures in postmenopausal women occur in

osteopenic individuals, so if pharmaceutical intervention is to impact significantly on total fracture numbers, therapies with efficacy in osteopenic postmenopausal women are needed. We report a 6-year, double-blind trial of 2000 osteopenic (i.e. hip T-scores between -1.0 and -2.5) postmenopausal women aged >65 years recruited using electoral rolls. They were randomly assigned to receive 4 infusions of either zoledronic acid 5mg, or normal saline at 18-month intervals. Supplements of vitamin D, but not calcium, were provided. Baseline mean age was 71 (SD 5) years, femoral neck T-score -1.5 (0.5), and median 10-year hip fracture risk 2.3% by FRAX.The primary endpoint of osteoporotic fracture (i.e. osteoporotic non-vertebral fractures or vertebral fractures) occurred in 190 women in the placebo group (227 fractures) and in 122 women in the zoledronic acid group (131 fractures), hazard ratio (HR) 0.63 (95%CI 0.50, 0.79; P<0.0001). The number needed to treat to prevent one woman fracturing was 15. Anti-fracture efficacy was unaffected by baseline BMD, prevalent fracture, calculated fracture risk, age, BMI, or calcium intake. Non-vertebral osteoporotic fractures (HR 0.66, P=0.0014), symptomatic fractures (HR 0.73, P<0.0027), vertebral fractures (odds ratio 0.45, P=0.0018), and height loss (P<0.0001) were also reduced in the zoledronic acid group. There were 41 deaths in the placebo group and 27 in the zoledronic acid group (odds ratio 0.65, 95%CI 0.40, 1.05). Rate ratios for other pre-specified adverse events were: myocardial infarction 0.58 (0.35, 0.94), composite vascular endpoint 0.72 (0.53, 0.98), and cancer 0.68 (0.52, 0.89). Rate ratio for breast cancer was 0.59 (0.35, 0.98).Zoledronic acid prevents fractures in osteopenic women aged >65 years, substantially broadening the target population for pharmaceutical intervention to prevent fractures. The beneficial effects on cancer and vascular disease are consistent with data from some previous studies and suggest that zoledronic acid should be formally trialled for the prevention of these conditions.

Cumulative Incidence Osteoporotic Fracture (%)

Background: Endocrine therapy with aromatase inhibitors (AI) for at least 5 years is standard of care in patients with early hormone receptor (HR+) positive breast cancer. ABCSG-18 has shown (1) a high fracture risk in patients on AI treatment, (2) a significant reduction of clinical and vertebral fractures by 6-monthly denosumab (HR=0.5, p<0.0001, Lancet 2015). Recent reports indicate an elevated risk of rebound-associated fractures - especially multiple vertebral fractures - after stopping denosumab. Here we present data on fracture risk >6 months after the last dose of denosumab or placebo for patients with HR+ early breast cancer.Methods: In the prospective, double-blind, placebo-controlled phase III ABCSG-18 trial, 3,425 postmenopausal HR+ patients treated with adjuvant AI were enrolled to denosumab 60mg or placebo s.c. q6 months until the prespecified number of 247 first clinical fractures was reached. All patients received at least 2 doses of denosumab (median: 7 doses), the primary trial endpoint was time to first clinical fracture risk.Results: 2,451 patients stopped AI later than 6 months after the last dose of denosumab/placebo. 387 patients ended their AI intake prior to, and 295 patients within 6 months after the last dose of denosumab/placebo. During a median off-treatment follow-up of 36 months, 318 fractures in 199 patients (subject incidence rate 6.2%) have occurred. No difference in overall fracture risk in patients who stopped denosumab compared to patients who stopped placebo could be detected (163 vs 155 fractures in 98 vs 101 patients, time to first fracture: HR 0.92 (0.70,1.22)). However, when looking specifically at clinical fractures, patients who stopped denosumab had a significantly higher risk of clinical vertebral fractures and multiple clinical vertebral fractures compared to patients who stopped placebo (39vs14 fractures in 22vs9 patients, HR 2.44 (1.12,5.32); 28vs8 fractures in 11vs3 patients, HR 3.52 (0.98,12.64)). This increased risk of clinical vertebral as well as multiple clinical vertebral fractures in patients who stopped denosumab, only occurred in patients who ended AI treatment prior to or >6 months after the last dose of denosumab/placebo, whereas no difference was seen in patients who ended AI treatment within 6 months of stopping denosumab/placebo.Conclusion: Rebound-associated fractures after termination of adjuvant denosumab therapy may be avoided when stopping bone-compromising AI therapy within 6 months.

Burosumab Improved Rickets, Phosphate Metabolism, and Clinical Outcomes Compared to Conventional Therapy in Children with XLH

Erik Imel*[1], Michael P. Whyte[2], Craig Munns[3], Anthony A. Portale[4], Leanne Ward[5], Ola Nilsson[6], Jill H. Simmons[7], Raja Padidela[8], Noriyuki Namba[9], Hae I. Cheong[10], Meng Mao[11], Chao-Yin Chen[11], Alison Skrinar[11], Javier San Martin[11], Francis Glorieux[12]. [1]Indiana University School of Medicine, United States, [2]Shriners Hospitals for Children, United States, [3]The Children's Hospital at Westmead, Australia, [4]University of California, San Francisco, United States, [5]University of Ottawa, Canada, [6]Karolinska Institutet, Sweden, [7]Vanderbilt University School of Medicine, United States, [8]Royal Manchester Children's Hospital, United Kingdom, [9]Osaka Hospital, Japan Community, Healthcare Organization; Osaka University Graduate School of Medicine, Japan, [10]Seoul National University Children's Hospital, Republic of Korea, [11]Ultragenyx Pharmaceutical Inc., United States, [12]Shriners Hospital for Children-Canada, McGill University, Canada

In children with X-linked hypophosphatemia (XLH), high circulating levels of fibroblast growth factor 23 (FGF23) cause hypophosphatemia with consequent rickets, skeletal deformities, and growth impairment. Conventional therapy has consisted of multiple daily doses of oral phosphate and active vitamin D (Pi/D). Burosumab is a fully human monoclonal antibody against FGF23 indicated for the treatment of XLH.In the Phase 3 randomized active-control study CL301 (NCT02915705), 61 children with XLH (1-12 years old) were randomized 1:1 to receive open-label subcutaneous burosumab starting at 0.8 mg/kg every 2 weeks (Q2W) or standard XLH doses of Pi/D as prescribed by investigators. Eligibility criteria included a Total Rickets Severity Score (RSS) ≥2.0 and prior receipt of Pi/D. The primary endpoint was the radiographic global impression of change (RGI-C) global score for rickets assessed by radiologists blinded to treatment at Week 40 (RGI-C 7-point ordinal scale: worsening of rickets [-3, -2, -1], no change [0], or improvement [+1, +2, +3]). At Week 40, burosumab significantly improved rickets compared with Pi/D. More subjects in the burosumab group had a RGI-C global score ≥+2.0 at Week 40, indicating substantial healing, compared with the Pi/D group (21/29, 72% vs 2/32, 6%; odds ratio of 39.1; p<0.0001). Further evidence of rachitic improvement with burosumab included decreased alkaline phosphatase, decreased RSS, and improved lower limb deformity RGI-C compared with Pi/D. Increases in serum phosphorus and TmP/GFR occurred rapidly with burosumab and these values were significantly greater at Week 40 compared with Pi/D. Standing height Z-score increased in both groups, with a least squares mean change (95% CI) of +0.15 (0.05, 0.25) for burosumab and a change of +0.08 (-0.02, 0.19) for Pi/D. The Six Minute Walk Test percent predicted distance increased with burosumab (Baseline to Week 40: 62% to 72%) and was unchanged with Pi/D (76% to 75%). Pre-defined adverse events (AEs) of interest, including hypersensitivity and injection site reaction, were higher in the burosumab group, but were mild to moderate in severity overall, with no discontinuations. There were 4 serious AEs (3 with burosumab, 1 with Pi/D); none were related to treatment and all resolved.In this Phase 3 randomized controlled trial, burosumab Q2W resulted in significantly greater improvement in rickets and serum phosphorus compared with conventional therapy in 1-12 year-old children with XLH.

In adults with XLH, excess FGF23 causes hypophosphatemia with consequent fractures/pseudofractures (Fx/PFx), osteomalacia, pain, stiffness, and impaired physical function. In an ongoing, Phase 3, double-blind, multicenter study, we examined the efficacy and safety of burosumab in adults with XLH.Subjects were randomized 1:1 to receive burosumab 1 mg/kg or placebo subcutaneously every 4 weeks. At Week 24, subjects in the placebo group crossed-over to receive burosumab, and all subjects continued treatment for an additional 24 weeks, remaining blinded to prior treatment. The primary endpoint was the proportion of subjects achieving mean serum phosphorus above the lower limit of normal (LLN) at the midpoint of the dosing intervals from Weeks 0-24.A significantly greater percentage of burosumab subjects than placebo subjects attained the primary endpoint (94% vs 8%; p<0.0001). Between Weeks 24-48, 84% (57/68) of burosumab-continuation subjects and 89% (59/66) of crossover subjects were above the LLN at the midpoint of the dosing intervals. At baseline, 65 active Fx/PFx were present in 47% (32/68) of burosumab subjects and 91 Fx/PFx in 58% (38/66) of placebo subjects. At Week 24, 43% (28/65) of Fx/PFx healed with burosumab and 8% (7/91) healed with placebo (odds ratio 16.8, p<0.0001). By Week 48, the burosumab-continuation group showed additional Fx/PFx healing and the crossover group showed healing similar to that of the burosumab-continuation group at Week 24. At Week 24, the burosumab group showed greater reductions than the placebo group in stiffness scores (p=0.011), and non-significant reductions in pain (p=0.092) and physical functioning (p=0.048) scores. At Week 48, both groups showed significant decreases from baseline (or Week 24 for crossover) in stiffness (both p<0.0001), physical functioning (both p<0.001), and pain (both p<0.0001) scores. There was no meaningful difference in subject-reported pain medication use (Week 0→48 opioid: burosumab-continuation 25%→21% of subjects, crossover 20%→18%; non-narcotic: 69%→57%, 65%→52%). Serious AEs were reported in 15 subjects, none were drug-related. There were no meaningful changes in serum calcium, iPTH, nor nephrocalcinosis scores.In adults with XLH, burosumab was associated with

improvements in serum phosphorus, pain, stiffness, and physical functioning, and healing of Fx/PFx. Improvements seen in the burosumab group at Week 24 were replicated in subjects who crossed over from placebo to burosumab.

Oral Iron Therapy Normalizes Fibroblast Growth Factor 23 (FGF23) in Patients with Autosomal Dominant Hypophosphatemic Rickets Erik Imel*[1], Ziyue Liu[2], Melissa Coffman[1], Dena Acton[1], Michael Econs[1]. [1]Indiana University School of Medicine, United States, [2]Indiana University School of Public Health, United States

Autosomal dominant hypophosphatemic rickets (ADHR) is a rare bone disease caused by mutations impairing cleavage of fibroblast growth factor 23 (FGF23). FGF23 gene expression increases during iron deficiency. In both humans and mice with the ADHR mutation, increased intact FGF23 concentrations and resulting hypophosphatemia occur in the setting of iron deficiency. This clinical trial tested the hypothesis that oral iron administration would normalize FGF23 concentrations in ADHR subjects.Subjects with ADHR were recruited to receive oral iron replacement for 12 months, at a starting dose of 65 mg daily and titrated based on serum iron concentration. Eligibility criteria included: confirmed FGF23 mutation; and either serum iron < 50 mcg/dl; or serum iron 50-100 mcg/dl combined with hypophosphatemia and intact FGF23 >30 pg/ml. Key exclusion criteria were CKD or pregnancy. The primary outcome was decrease in fasting intact FGF23 ≥20% from baseline. All laboratory samples were collected fasting.Six adults (3 male, 3 female) having the R176Q mutation were enrolled. Four subjects completed 12 months and one completed 4 months to date; 1 was lost to followup. At baseline 3/5 subjects had severely symptomatic hypophosphatemia (phosphorus <2.5 mg/dl). Due to symptoms, these 3 subjects also received calcitriol with or without phosphate, concurrent with oral iron: 1 began prior to enrollment, 1 began at the baseline visit, 1 began at month 2. Baseline laboratories included [median (minimum, maximum)]: fasting serum phosphorus 2.1 (<1.0, 2.7 mcg/dl), iron 69 (22, 83 mcg/dl), intact FGF23 171.7 (20.3, 222.6 pg/ml) (See Table). Within 4 months, 4 out of 5 subjects already met the primary outcome, decreasing FGF23 by ≥20% from baseline, and 3 had normalized FGF23 (<70 pg/ml in our laboratory). Overall, median FGF23 concentrations decreased from 171.7 pg/ml at baseline to 47.2 pg/ml at 4 months and 50.1 pg/ml at 12 months. Median ferritin increased from 18.6 mg/ml at baseline to 46.1 ng/ml at month 4 and 143.5 ng/ml at month 12. All 3 subjects with baseline hypophosphatemia normalized serum phosphorus, had markedly improved symptoms, and were able to discontinue calcitriol and phosphate (2 at 4 months, 1 at 9 months).Oral iron treatment normalized serum FGF23 and phosphorus in ADHR subjects. Since iron repletion is necessary to treat iron deficiency, and oral iron treatment was also able to normalize FGF23, oral iron should be the standard therapy for ADHR.

Table

	N	FGF23 (pg/ml)	Phosphorus (mg/dl)	Iron (mcg/dl)	Ferritin (ng/ml)	Alkaline phosphatase (U/L)	Creatinine (mg/dl)
Screening	5	52.6 (34.8, 182.2)	2.3 (1.4, 2.9)	53 (10, 81)	-	80.5 (56.0, 235.0)	0.82 (0.53, 1.03)
Baseline	5	171.7 (20.3, 222.6)	2.1 (<1.0, 2.7)	69 (22, 83)	18.6 (7.7, 82.5)	93.0 (82.5, 211.0)	0.70 (0.55, 1.01)
Month 4	5	47.2 (17.3, 77.3)	2.9 (2.1, 3.6)	76 (39, 94)	46.1 (28.8, 92.1)	91.0 (68.0, 195.0)	0.74 (0.52, 0.97)
Month 6	4	25.8 (16.3, 44.8)	3.1 (2.3, 4.2)	95 (44, 133)	86.7 (54.3, 127.0)	89.5 (60.0, 157.0)	0.76 (0.66, 0.86)
Month 12	4	50.1 (19.4, 62.9)	2.9 (2.5, 4.0)	66 (43, 88)	143.5 (49.6, 261.0)	78.0 (60.0, 120.0)	0.75 (0.56, 0.86)

Values are median (minimum, maximum); for Month 6, N=3 for FGF23.

Digenic Inheritance of Heterozygous SLC34A3 and SLC34A1 Mutations in Hereditary Hypophosphatemic Rickets with Hypercalciuria Rebecca Gordon*[1], Daniel Doyle[2], Joshua Zaritsky[2], Michael Levine [1]. [1]The Children's Hospital of Philadelphia, United States, [2]Alfred I. duPont Hospital for Children, United States

Hereditary Hypophosphatemic Rickets with Hypercalciuria (HHRH) is an autosomal recessive disorder characterized by renal phosphate wasting due to mutation of SLC34A3 encoding the NPT2c sodium-phosphate cotransporter in the proximal renal tubule. Patients manifest hypophosphatemia with rickets and/or osteomalacia plus low serum levels of FGF23, with consequent elevated 1,25(OH)2D that leads to hypercalciuria and often renal stones. We evaluated a non-consanguineous kindred with apparent dominant transmission of HHRH by next generation sequencing (NGS), and identified digenic heterozygous mutations in both affected sisters: a known missense mutation in SLC34A3 (exon 13, c.1535G>A; p.R512H) and a novel frameshift mutation in SLC34A1 (exon 13, c.1561dupC), which encodes the NPT2a sodium-phosphate cotransporter that is expressed in the proximal renal tubule. Evaluation of all available family members over four generations demonstrated that the mother with bowed legs and short stature also had the same two digenic heterozygous mutations as her two affected daughters; the affected short father and short paternal grandmother carried only the SLC34A3 missense mutation, which was also present in an unaffected short older brother. Another presumed affected older brother, given his bowed legs, refused to participate in these studies. Because both parents carried the identical SLC34A3 mutation it was not possible to determine the parent of origin for this allele in generation V carriers. Therefore, both mutations, on different chromosomes, could have come from the mother. Both affected daughters and the father had clinically significant nephrolithiasis. All available affected family members had low to low-normal serum phosphorus levels with elevated 1,25(OH)2D levels and low serum 25(OH)D levels. Subjects with digenic heterozygous mutations had a more severe phenotype than subjects with only one heterozygous mutation, with variable penetrance. There appeared to be an attenuation of renal phosphate wasting with aging. We conclude that these two affected siblings and their family members demonstrate a novel, digenic basis for pseudo-autosomal dominant inheritance of HHRH. We suggest that NGS of multiple genes involved in phosphate regulation provides a more comprehensive genetic evaluation of patients with hypophosphatemic rickets, and can provide novel insights into the pathogenesis of renal phosphate wasting.

LRP6 Mutation: A New Cause of Autosomal Dominant High Bone Mass Michael P. Whyte*[1,2], Gary S. Gottesman[1], Elizabeth L. Lin[1,2], William H. Mcalister[3], Angela Nenninger[1], Vinieth N. Bijanki[1], Margaret Huskey[2], Shenghui Duan[2], Steven Mumm[1,2]. [1]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospital for Children, United States, [2]Division of Bone and Mineral Diseases, Department of Internal Medicine, Washington University School of Medicine at Barnes-Jewish Hospital, United States, [3]Mallinckrodt Institute of Radiology, Washington University School of Medicine at St. Louis Children's Hospital, United States

Autosomal dominant gain-of-function mutation of the gene encoding LDL-related receptor protein 5 (LRP5) causes high bone mass (HBM). Clinical expressivity ranges from non-syndromic to overt with oropharyngeal exostoses and neurological complications including Chiari I malformation and cranial nerve palsies. LRP5 is a transmembrane receptor with four extracellular YWTD β-propeller domains, which bind WNT, SOST, and DKK1 to regulate osteoblast-mediated bone formation via the canonical WNT pathway. LRP5 activating mutations, which cause HBM by diminishing inhibitory ligand (SOST and DKK1) binding, lie within β-propeller 1. Notably, the LRP6 receptor protein is ~70% homologous to LRP5, and similarly binds LRP5 ligands. Nevertheless, mutations in LRP6 leading to HBM have not been reported. In two HBM American families, we discovered LRP6 mutations that encode alterations within regions homologous to the LRP5 β-propeller 1. In Family 1, two teenage sisters were found by their dentist to have dense mandibles. An 8-year-old boy in Family 2 developed Bell's palsy after suffering trauma to his face and CT imaging revealed increased density of his calvarium and skull base. Subsequent radiographic skeletal surveys of affected individuals from both families showed generalized osteosclerosis and endosteal hyperostosis that mimicked LRP5 HBM. Family 1 (mother and 2 daughters) DXA BMD Z-scores ranged from +5.2 to +9.4 in the spine and +7.8 to +10.1 in the hip, which increased with age. In family 2 (3 generations), Z-scores ranged from +7.3 to +10.3 in the spine and +6.4 to +8.8 in the hip. We found acquired torus palatinus, a variably broad jaw, and an inability to float in our LRP6 HBM families, akin to our LRP5 HBM families. Although serum P1NP and CTX were elevated, other studies of bone and mineral metabolism were normal. In family 1, our Ion Torrent HBM platform identified an LRP6 missense mutation c.602C>T, p.A201V confirmed by Sanger sequencing, which is precisely homologous to the previously reported LRP5 HBM mutation c.641C>T, p.A214V. In family 2, Sanger sequencing showed the LRP6 mutation c.553A>C, p.N185H when LRP5 analysis proved negative. This second LRP6 mutation occurs at another homologous LRP5 HBM mutation site but results in a different amino acid change (c.593A>G, p.N198S). Both mutations co-segregated with the HBM phenotype in their respective families. Thus, LRP6 mutations also cause HBM.

Figure: Family 1 radiographs show generalized osteosclerosis. **A** (Daughter): Lateral skull shows marked diploic thickening with a sclerotic base. Floor of the maxilla is especially dense, as is the expanded mandibular body with a prominent mental protuberance. Cervical vertebrae are similarly sclerotic. **B** (Mother): Pelvis, lower lumbar spine and femora are diffusely osteosclerotic. **C** (Mother): Marked cortical thickening encroaches on the femoral medullary cavity.

Multi-omics approach reveals novel pathogenic indicators of DISH Matthew Veras*[1], Neil Tenn[1], Miljan Kuljanin[2], Gilles Lajoie[2], James Hammond[3], S. Jeffrey Dixon[1], Cheryle Séguin[1]. [1]Bone & Joint Institute, The University of Western Ontario, Canada, [2]The University of Western Ontario, Canada, [3]University of Alberta, Canada

Background: Mice lacking equilibrative transporter 1 (ENT1) develop ectopic spinal calcifications mirroring diffuse idiopathic skeletal hyperostosis (DISH) in humans. Calcifications affecting fibrocartilaginous tissues including the annulus fibrosus (AF) of the intervertebral disc are detected at 2 months-of-age, increase in severity and progress caudally with age. This novel preclinical model allows for unprecedented studies of the molecular mechanisms underlying ectopic calcification at the onset and throughout disease progression; an approach not possible in the clinical population where diagnosis is limited to late stage disease. To decipher the mechanisms driving DISH, we developed an unbiased strategy applying transcriptomic, proteomic, and metabolomic analysis of the ENT1 KO mouse to identify novel pathogenic indicators of DISH.Methods & Results: To identify pathways associated with ectopic calcification, we assessed AF tissue from WT and ENT1-/- mice prior to (2 months-of-age) and following (6 months-of-age) AF calcification. Microarray analysis

revealed massive dysregulation of transcription in the AF of ENT1-/- mice compared to WT. Gene ontology analysis showed deregulation of pathways regulating bone mineralization, bone cell development, and biomineral tissue development; surprisingly, cell cycle processes were the most highly affected pathways. The E2f family of transcription factors and proliferating cell nuclear antigen (PCNA) were implicated in the deregulation of cell cycle progression. Proteomic analysis quantified the expression of over 5000 proteins and identified subsets of dysregulated proteins in ENT1-/- tissues. Analysis confirmed transcriptomic data and implicated known modulators of mineralization such as bone sialoprotein and matrix Gla-protein in disease progression. Notably, we confirmed dysregulation of cell-cycle regulators PCNA (7.5-fold increase), CDK1 (5.8-fold increase), and a remarkable 19.7-fold increase in MCM5 expression in ENT1-/- vs WT at 6 months-of-age.Significance: This is the first study to associate dysregulation of cell cycle with disorders of ectopic calcification, suggesting a causative link with DISH. This multi-omics analysis using a preclinical model of DISH has provided novel insight into the pathways regulating disease pathogenesis. Combined with ongoing metabolomic analysis, these studies will identify therapeutic targets to prevent or delay the onset of ectopic calcification in DISH patients.
Figure 1. Loss of ENT1 dysregulates cell cycle-associated proteins in the annulus fibrosus of the intervertebral disc.
A) 6-month-old WT and ENT1-/- mid-coronal T2/T3 vertebral discs (IVDs) stained with hematoxylin & eosin. ENT1-/- sections show disrupted organization of annulus fibrosus (AF) tissue whereby AF cells no longer line concentric collagen lamellae. Furthermore, there appears to be a larger proportion of rounded AF cells. B) Counts of AF cells in the right lateral aspect of 6-month-old ENT1-/- intervertebral discs. There is no significant difference in the number of AF cells between WT and ENT1-/-. C) 6-month-old WT and ENT1-/- mid-coronal T2/T3 intervertebral disc immunostaining for proliferating cell nuclear antigen (PCNA). There is an absence of PCNA positive cells in the AF of WT intervertebral discs, but numerous PCNA-positive cells in the outer AF of ENT1-/- intervertebral discs. D) Proteomic analysis of 6-month-old WT and ENT1-/- thoracic AF tissue. Proteomics revealed significant upregulation of PCNA, MCM5, and CDK1 protein expression in ENT1-/- thoracic AF tissue compared to WT control. Images are representative of n=3 mice per genotype. AF cell counting was performed on n=3 tissue sections per genotype. Proteomics was performed on n=2 mice per genotype (AF tissue from 4 thoracic IVDs per mouse).

Cathepsin K (Ctsk) restrains the periostin (Postn)-mediated increase in cortical size induced by RANKL Nicolas Bonnet*[1], Eleni Douni[2], Serge Ferrari[3]. [1]University Geneva Hospital (HUG), Switzerland, [2]Biomedical Sciences Research Center "Alexander Fleming", 2Department of Biotechnology, Agricultural University of Athens, Greece, [3]University Geneva Hospital (HUG), Switzerland

Failure of periosteal apposition to compensate for endosteal resorption may contribute to age-related bone fragility, however this mechanism remains poorly understood. We previously reported that Postn, -expressed by osteocytes and lining cells in response to mechanical forces-, stimulates bone formation, and is eventually degraded by Ctsk. We hypothesized that RANKL would increase mechanically-driven periosteal apposition but these effects be limited by Ctsk-dependent Postn degradation.For this purpose, femur microstructure, periosteal bone formation and cortical strength were evaluated in mice overexpressing huRankL and eventually subjected to limb immobilization (IL) by botox injection, as well as in the progeny of huRANKLTg+ x Ctsk-/- and huRANKLTg+ x Postn-/- mice.huRANKL Tg+ exhibit low BV/TV and CtBV vs WT (1.5±0.2% vs 11±0.9; 0.39±0.02mm3vs 0.52±0.01, p<0.001) but a high CtTV (1.58±0.05mm3 vs 1.17±0.04, p<0.01). Immobilization further decreased BV/TV and CtBV in huRANKLTg+ (-97% & -43% vs the non-IL, p<0.05), and prevented the increase in CtTV (-12% vs non-IL, p<0.05). Accordingly, Postn mRNA levels are increased and Sost decreased in cortical bone of huRANKLTg+ (+73% and -69%, p<0.01), while Postn mRNA and protein decreases and Ctsk mRNA increases in IL (+53% and -34%, p<0.05). In turn genetic deletion of Postn in huRANKL-Tg+ mice prevented the compensatory periosteal growth and aggravated bone fragility.In contrast, in Tg5519-Ctsk-/- mice, Ctsk ablation improved BV/TV but also increased CtTV (+24% vs huRANKLTg+, +67% vs WT, both p<0.05). PsBFR was stimulated vs huRANKLTg+ (+215%), and WT (+1533%), with an increased Postn protein levels. mRNA levels of Runx2, ALP, Coll1a and PDGFB were also increased (+100%, +86%, +23%, +191% vs huRANKLTg+, p<0.05). As a consequence, ultimate force was improved in huRANKLTg+-Ctsk-/- (14.7±0.8 vs 9.9±1.3N in huRANKLTg+, p<0.05), reaching cortical strength levels similar to WT.In conclusions, endosteal bone loss induced by high levels of RANKL is accompanied by an increased periosteal bone formation and diameter that is mechanically driven and mediated by Postn. However, the larger bones of huRANKL mice remain weaker than WT because Postn is degraded by Ctsk. In turn, Ctsk inhibition improves periosteal growth and fully restores

bone strength. These findings further delineate the molecular mechanisms that couple bone remodeling / modeling.

Short-Term Intermittent PTH (1-34) Administration, Angiogenesis, and Matrix Metalloproteinase-9 in Femora of Mature and Middle-Aged C57BL/6 Mice Seungyong Lee*, Rhonda Prisby. The University of Texas at Arlington, United States

Intermittent parathyroid hormone administration (iPTH) increases bone volume and matrix metalloproteinase (MMP)-9 secretion. In addition, iPTH alters bone blood vessels by increasing vasodilator capacity, augmenting bone perfusion, and relocating bone marrow blood vessels closer to osteoid seams. Discrepancies exit, however, as to whether iPTH elicits angiogenesis. Since MMP-9 participates in cellular homing and migrating, we theorized that it aides in relocating bone marrow blood vessels. We examined the influence of short-term (i.e., 5- and 10-days) iPTH on angiogenesis, MMP-9 secretion, and the distance between blood vessels and bone in mature (6-8mon; n=30) and middle-aged (10-12mon; n=30) male and female C57BL/6 mice. Mice were divided accordingly: control (CON), 5-days iPTH (5dPTH) and 10-days iPTH (10dPTH). Mice were given a placebo (i.e., PBS; 50 μl/d) or PTH 1-34 (43 μg/kg/d). Right femora were collected and prepared for histology. Frontal sections (5μm) were triple-immunolabeled to identify endothelial cells (i.e., anti-CD31), vascular smooth muscle cells (i.e., anti-αSMA), and MMP-9 (i.e., anti-MMP9). Sections of the distal femoral metaphysis were imaged to determine vascular density, MMP-9 localization, and blood vessel distance to bone. Blood vessels were analyzed according to diameter: 1-29μm, 30-100μm, and 101-200μm. Trabecular bone microarchitecture (i.e., BV/TV [%], Tb.Th [μm], Tb.N [/mm2], and Tb.Sp [μm]) and bone static (i.e., OS/BS, %, Ob.S/BS, % and Oc.S/BS, %) and dynamic (MAR, mm/day; sLS/BS, %; dLS/BS, %; MS/BS, % and BFR, mm3/mm2/day) properties were examined. Gender-related differences were not observed with this sample size, so female and male data were pooled. The density of 1-29μm and 30-100μm CD31-labeled blood vessels was significantly (p<0.05) higher and tended (p=0.055) to be higher, respectively, in 10dPTH vs. 5dPTH and CON. Further, 30-100μm and 101-200μm αSMA-labeled blood vessels tended (p<0.10) to be higher in 10dPTH vs. 5dPTH. MMP-9 was augmented (p<0.05) in 10dPTH vs. the other groups and MMP-9 was closer (p<0.05) to 1-29μm blood vessels and furthest (p<0.05) from trabecular bone. No differences were observed in distances between blood vessels and bone, bone microarchitecture, and bone static and dynamic properties. In conclusion, bone angiogenesis occurs by 10 days of iPTH (i.e., quicker than changes in trabecular bone), coinciding with augmented MMP-9 secretion closer to the smallest (1-29μm) blood vessels.

LB-1176

Identification of a Novel Selective Small-Molecule Inhibitor of the BMP Type I Receptor Kinase ACVR1/ALK2 with Disease-Modifying Potential for On-Target Therapy of Fibrodysplasia Ossificans Progressiva (FOP) Ina Kramer*[1], Luca Arista[2], Victoria Head[3], Michaela Kneissel[1], Thomas Ullrich[2], Sabine Guth-Gundel[1]. [1]Musculoskeletal Disease Area, Novartis Institutes for BioMedical Research, Switzerland, [2]Global Discovery Chemistry, Novartis Institutes for BioMedical Research, Switzerland, [3]Translational Medicine, Novartis Institutes for BioMedical Research, Switzerland

Fibrodysplasia ossificans progressiva (FOP) is a devastating ultra-rare disease of painful progressive soft tissue heterotopic ossification (HO) causing ankylosis and immobility of patients with no treatment available to date. It is caused by a recurrent autosomal dominant gain-of-function mutation in the bone morphogenetic protein (BMP) type I receptor ACVR1/ALK2 [[ALK2(R206H)] rendering the receptor hypersensitive to BMP ligands and conferring aberrant responsiveness to Activin A-mediated BMP pathway activation. While clinical trials in FOP are ongoing with therapeutic principles blocking upstream or further downstream events of the mutated ALK2-induced signaling cascade, a direct and selective on-target therapy to normalize the aberrant ALK2 receptor activity is still missing.Here, we describe a novel small-molecule ALK2 kinase inhibitor, SF-86-HL84, which is selective for ALK2 relative to the related BMP type I receptors ALK1, 3 and 6, but also the TGFb receptor ALK5, in biochemical kinase as well as cellular reporter gene assays. Moreover, SF-86-HL84 demonstrates excellent oral pharmacokinetic and overall drug formulatability properties. We hence tested its therapeutic potential in an inducible mouse model of pediatric FOP (Acvr1tnR206H;R26-CreERT2 mice) in which we induced expression of the mutated Alk2(R206H) allele by tamoxifen dosing starting at about one week of age followed by induction of the disease phenotype by unilateral hind limb skeletal muscle injury at about 10 days of age. Irrespective of whether oral treatment was started in a preventive mode 3 days after injury or a therapeutic setting 2.5 weeks after injury when heterotopic bone was alreday present, SF-86-HL84 fully suppressed HO following 6 weeks of dosing as assessed by in vivo and ex vivo computed tomography.We also assessed the bone phenotypic consequences of SF-86-HL84 therapy on the growing and aged skeleton by determining structural and functional biomechanical parameters in skeletally growing Acvr1tnR206H;R26-CreERT2 mice as well as intact aged female rats. Neither skeletal long bone growth nor skeletal bone loss during aging were impacted by SF-86-HL84 therapy at doses demonstrating full ther-

apeutic efficacy.Together, our findings reveal that the novel ALK2 inhibitor SF-86-HL84 shows superior in vitro selectivity and compound properties while holding disease-modifying potential for FOP based on its demonstrated in vivo efficacy in a preclinical mouse model of pediatric FOP.

LB-1177

Activin A (ActA) Expression by Fibroadipoprogenitors (FAPs), But Not Myeloid Cells, Is Necessary for Endochondral Heterotopic Ossification (HO) in Fibrodysplasia Ossificans Progressiva (FOP) Mice Cody M. Elkins*, Chuanmin Cheng, Heather Durai, Nikash Hari, Daniel S. Perrien. Vanderbilt Center for Bone Biology, Division of Clinical Pharmacology, Department of Medicine, Vanderbilt University Medical Center, United States

FOP is a rare, currently untreatable disease, characterized by episodic skeletal muscle inflammation, or 'flares', leading to endochondral heterotopic ossification (EHO), causing pain, joint fusion, loss of mobility, and eventual premature death. The classic causal mutation, ALK2R206H, sensitizes the Type 1 BMP receptor ALK2/ACVR1 to Activin A (ActA)-induced signaling. Expression of ALK2R206H in intramuscular FAPs (CD45-/CD34-/Sca1+/PDGFR1α+ cells) is necessary and sufficient to induce EHO in mice. However, the in vivo sources of ActA driving this process are unknown. Pro-inflammatory mac-rophages (MΦ) express high levels of ActA, play critical roles in innate sterile inflammation and tissue repair, and depletion reduces HO in FOP mice. Thus, we hypothesized that MΦ-derived-ActA is required for injury-induced EHO in FOP. To test this hypothesis, EHO was initiated in FOP mice (R26creERt2;ALK2R206H-FlEx/WT) by tamoxifen-induced expression of ALK2R206H followed by injury of the gastrocnemius with cardiotoxin or crush injury. The area and volume of EHO were measured by plain radiographs and μCT at 14-21 days after injury. To demonstrate MΦ involvement, CCR2DTR/+ mice, which allow selective killing of MΦs by treatment with diphtheria toxin (DT), were crossed with FOP mice (CCR2DTR/+;FOP mice). DT treatment depleted >90% of MΦs and completely prevented the EHO seen in CCR2+/+;FOP mice (p<0.001). Histological examination confirmed that MΦ depletion also blocked muscle repair and led to the formation of small scattered intram-embranous dystrophic HO. In contrast, global deletion of ActA prevented EHO in FOP mice without dystrophic ossification, demonstrating that ActA is necessary for EHO in FOP. Next, FAPs from uninjured muscles of FOP mice were injected into injured muscles of ALK2wt/wt recipient mice. Extensive EHO formed in wildtype and Rag2 recipient mice. Surprisingly, myeloid-specific deletion of ActA in Lysmcre/cre;ActAfl/fl recipients did not prevent EHO compared to Lysm+/+;ActAfl/fl recipients, suggesting that M/MΦ expression of ActA is dispensable. In contrast, deletion of ActA in donor FOP FAPs (ActA-/-;FOP) completely prevented EHO without blocking muscle repair or causing dystrophic HO in Rag2 or WT recipients. These data provide the first direct evidence that the autonomous expression of ActA and its autocrine signaling in FAPs is necessary for EHO in FOP mice, while suggesting the critical role of MΦs in FOP is independent of their ActA expression.

Acute Kidney Injury in Primary Hyperparathyroidism Cristiana Cipriani*[1], Jessica Pepe[1], Federica Biamonte[1], Valeria Fassino[1], Luciano Colangelo[1], Valentina Piazzolla[1], Carolina Clementelli[1], Luciano Nieddu[2], Salvatore Minisola[1]. [1]Sapienza University of Rome, Italy, [2]UNINT University, Italy

Purpose. The endpoint of the study was to establish the potential role of biomarkers of acute kidney injury in detecting subtle renal damage in patients with primary hyperparathyroidism (PHPT).Methods. We studied 69 post-menopausal patients with PHPT and 41 healthy age and sex-matched subjects. Exclusion criteria were: GFR<60 ml/min, chronic inflammatory disease, diabetes, infection, cancer. We measured serum IL-18, calcium (Ca), phoshorus (P), 25(OH)D, PTH, Klotho, plasma intact FGF23, Monocyte Chemoattractant Protein-1 (pMCP-1); urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL), Kidney injury molecule-1 (KIM-1), uMCP-1, creatinine clearance (CrCl), calcium excretion (CaEx) and renal tubular reabsorption of phosphate (TmPO4/GFR).Results. Our data showed, as expected, significantly higher mean serum Ca, PTH and CaEx (p<0.001) and lower 25(OH)D (p<0.05), P and TmPO4/GFR (p<0.0001) in PHPT compared to control subjects. Mean FGF23 and Klotho were higher in PHPT (72±48 pg/ml and 811±366 pg/ml, respectively) compared to controls (53±23.5 and 668.6±17; p<0.02 and p<0.05, respectively). KIM-1/uCr was significantly higher in PHPT (1.4-6±1.3-6) than in controls (9.2-7±7-7; p<0.05). Results were confirmed when the analysis was adjusted for CrCl and the presence of hypertension. Significant differences in mean values of NGAL/uCr (1.8-5±1.4-5 and 1-5±8-6, respectively; p<0.0001) were observed between PHPT with (n=28) and without kidney stones (n=35). Six PHPT refused kidney ultrasound. Considering together patients and subjects according to the CrCl, difference in Klotho levels were significant between PHPT (956.3±453) and controls (679±219) in those with CrCl > 90 ml/min (p<0.05). In the CrCl 60-89 ml/min class, we observed a significant difference in KIM-1/uCr between PHPT (1.3-6±9-7) and controls (8.2-7±3.6-7; p<0.02). We found significant positive associations between NGAL/uCr and Ca (R=0.292, p<0.02) and KIM1/uCr and PTH (R=0.329, p<0.01).Conclusions. There is a subtle kidney injury in patients with PHPT as detected by the use of sensitive biomarkers, particularly KIM-1 and NGAL, well before the deterioration of GFR. Since these molecules are elevated in patients with proximal tubular necrosis, they could reflect an intra-renal damage in PHPT. At present it is unclear if the increased FGF23 levels represent a compensatory mechanism, are expression of PTH-driven effects on bone cells or are related to parathyroid resistance.

Changes in Skeletal Microstructure Through Four Years of rhPTH(1-84) Therapy in Hypoparathyroidism Natalie Cusano*[1], Mishaela Rubin[2], John Williams[2], Sanchita Agarwal[2], Gaia Tabacco[2], Yu-Kwang Donovan Tay[2], Rukshana Majeed[2], Beatriz Omeragic[2], John Bilezikian[2]. [1]Lenox Hill Hospital, United States, [2]Columbia University Medical Center, United States

Hypoparathyroidism is characterized by low bone turnover, above average areal bone mineral density (BMD), and abnormal structural indices by bone biopsy. We previously reported that patients with hypoparathyroidism on conventional therapy have altered skeletal parameters including elevated cortical BMD using high resolution peripheral quantitative computed tomography (HRpQCT, Scanco Medical) of the distal radius and tibia. No data are available regarding the effects of rhPTH(1-84) on these microstructural indices by HRpQCT. We now report HRpQCT results for 34 hypoparathyroid patients 1, 2, and 4 years after rhPTH(1-84) in comparison to baseline values. The group was comprised of 25 women/9 men; age 47 ± 14 (SD) years; etiology: 20 postsurgical, 14 idiopathic; duration 12 ± 13 years. Prior to therapy with rhPTH(1-84), serum calcium was 8.7 ± 1 mg/dL and PTH 1.4 ± 4 pg/mL. A linear mixed model approach was used, controlling for effects of age, gender, and disease duration.At baseline, areal BMD by DXA was normal/above average: lumbar spine T-score +1.4, femoral neck +0.7, total hip +0.9, 1/3 radius 0.0, ultradistal radius +0.2. Areal BMD demonstrated the following changes at 4 years (p<0.05 for all): lumbar spine: +4.7 ± 0.9%, femoral neck +2.1 ± 0.9%, total hip -2.5 ± 0.8%, ultradistal radius -2.8 ± 0.8; no significant change at the 1/3 radius.The HRpQCT results are presented in Table 1. There were declines in volumetric BMD and cortical area, cortical BMD, and cortical thickness at both the radius and tibia but no significant changes in trabecular indices from baseline.Age was a significant negative predictor at the radius in volumetric and cortical BMD and at the tibia in volumetric BMD, cortical area, cortical BMD, and cortical thickness; gender and disease duration had no effect.Using HRpQCT, these data are the first to show changes in cortical parameters in hypoparathyroid patients after therapy with rhPTH(1-84). The data contrast with the BMD data by DXA that seem to mimic the effects of PTH therapy in osteoporosis. Rather, by this high resolution technology, we provide support for the hypothesis that PTH corrects unusually dense cortical bone in this PTH deficient setting by starting the transition towards trabecularization.

Table 1. Changes in Cortical (Ct) HRpQCT indices after 4 years of rhPTH(1-84)

Index	Radius	Tibia
Volumetric BMD	-2.8 ± 0.6	-1.9 ± 0.5
Ct area	-3.8 ± 0.8	-2.9 ± 0.8
Ct BMD	-3.6 ± 0.5	-3.9 ± 0.5
Ct thickness	-3.2 ± 0.9	-2.8 ± 0.8

% change from baseline ± SE
p<0.05 for all

Greater Visceral Adipose Tissue is Associated with Impairment of Bone Strength Assessed with HR-pQCT : the OFELY Study Francois Duboeuf*, Elisabeth Sornay-Rendu , Roland Chapurlat. INSERM UMR 1033, Université de Lyon, France

Purpose : The relationship between visceral (VFAT) and subcutaneous(SFAT) fat mass with bone mineral density and microarchitecture is still controversial. Although obesity has been reported not to be protective against fracture, a recent study from the Framingham cohort (1), showed that visceral fat assessed by computed tomography was positively associated with bone quality assessed by HRpQCT. Our aim was to analyze this relationship using the DXA technique to evaluate abdominal fat mass.Subjects and methods : 815 women (mean ± SD : age : 60 ± 15 years; BMI : 24 ±4 kg/m2) from the OFELY study with both whole body DXA (Discovery A, HOLOGIC Inc; Bedford, MA) and HR-pQCT (Xtreme CT, Scanco Medical AG, Switzerland) at the radius and tibia have been included. Abdominal visceral fat (VFAT) and subcutaneous fat (SFAT areas were assessed using the APEX 4.0.2 software. The bone microarchitectural considered parameters from the HR-pQCT were :Total area (Tt.Ar) , cortical area (Ct.Ar) , trabecular area (Tb.Ar), Total VBMD (Tt. vBMD), Cortical VBMD (Ct. vBMD), Trabecular vBMD (Tb. vBMD), Cortical thickness (Ct. Th), Cortical porosity (Ct.Po), Trabecular Number (Trab.N), Standard deviation of Trabecular separation (Tb.Sp.SD), Failure Load (FL) and strength (K). We performed multiple linear regression analysis (HR-pQCT parameters as the dependent variable and VFAT or SFAT quartiles as the primary independent variable). All analyzes were adjusted for age and BMI.Results : At the radius, Ct.Ar (p=0.035), FL (p=0.006)and K (p=0.005) were significantly lower in the highest quartile of VFAT compared with the other quartiles. At the tibia, Ct.Ar (p=0.0001), Tb.Sp.SD (p=0.001) , FL (p=0.002)and K (p=0.003)were significantly lower in the highest quartile of VFAT.At the radius Tt.Ar (p=0.001) and Tb.Ar (0.006) were significantly lower in the highest quartile of SFAT compared with the other quartiles At the tibia, Ct.Ar (p=0.008) and Tt. Ar (p=0.016) were significantly lower in the highest quartile of SFAT.Conclusion : We found that highest VFAT and SFAT values are associated with smaller bone size. Highest values of VFAT-but not SFAT are associated with lower bone strength supporting the deleterious effect of VFAT on bone . This could be explained by both a smaller size of the bone and some metabolic effect, such as low-grade inflammation from the VFAT compartment.1.Visceral Adipose Tissue Is Associated With Bone Microachitecture…, J Bone Miner. Res., 252:10.

Effects of parathyroidectomy on the biology of bone tissue in patients with chronic kidney disease and secondary hyperparathyroidism Geovanna O. Pires*[1,2], Itamar O. Vieira[1], Fabiana R. Hernandes[3], Andre L. Teixeira[1], Ivone B. Oliveira[1], Wagner V. Dominguez[1], Luciene M. Dos Reis[1], Fabio M. Montenegro[4], Rosa M. Moyses[1,5], Aluizio B. Carvalho[3], Vanda Jorgetti[1,2]. [1]Laboratório de Investigação Médica 16, Hospital das Clinicas da Faculdade de Medicina da Universidade de São Paulo, Brazil, [2]Hospital Samaritano Américas Serviços Médicos, Brazil, [3]Nephrology Division, Federal University of São Paulo, Brazil, [4]Disciplina de Cabeça e Pescoço, Hospital das Clinicas da Faculdade de Medicina da Universidade de São Paulo, Brazil, [5]Pos-Graduate Medicine Program, UNINOVE, Brazil

Secondary hyperparathyroidism (SHP) is a complication of chronic kidney disease that compromises skeletal integrity. In patients with SHP undergoing parathyroidectomy (PTx), parathyroid hormone (PTH) levels dramatically fall. The effects of PTx are poorly understood, especially regarding proteins expressed by osteocytes, such as fibroblast growth factor 23 (FGF23), dentin matrix protein 1 (DMP-1), matrix extracellular phosphoglycoprotein (MEPE), sclerostin (Scl), receptor activator of nuclear factor kappa β ligand (RANKL) and osteoprotegerin (OPG), which regulate bone turnover. We aimed to characterize the bone expression of these proteins by immunohistochemistry and correlate them with those of bone histomorphometry before and after PTx. We studied bone biopsies, before and 12 months after PTx, from 23 patients. The attached table reports the results. We observed an improvement in biochemical parameters (Calcium, Phosphorus, Alkaline Phosphatase, and PTH). Also, we observed an improvement in trabecular thickness (TB.Th), trabecular separation (Tb.Sp), and trabecular number (Tb.N); a decrease in osteoid volume (OV/BV), osteoid thickness (O.Th), osteoid surface (OS/BS), osteoblast surface (Ob.S/BS), eroded surface (ES/BS), osteoclast surface (Oc.S/BS), total osteocytes per bone area (Ost total/B.Ar), total osteocytes per tissue area (Ost total/T.Ar), and fibrosis (Fb.V/TV). But, an impaired mineralization [bone formation rate (BFR/BS), mineralizing surface (MS/BS) and mineralization lag time (Mlt)], after PTx. We found significant increases in Scl and OPG expression and a decrease in the RANKL/OPG ratio after PTx. We detected also correlations in the relative changes before (Δ) and 12 months after PTx between osteocytes proteins and bone histomorphometric parameters: ΔScl and ΔBV/TV, ΔTb.N, ΔO.Th and ΔTb.Sp; ΔRANKL and ΔBV/TV, ΔTb.N, and ΔTb.Sp; ΔRANKL/OPG ratio and ΔOb.S/BS, suggesting the involvement of these proteins in the improvement of bone lesions due to SHP. We conclude that after PTx, significant changes in the bone expression of osteocyte proteins occur and these proteins may potentially regulate bone remodeling.

Overweight and Underweight Are Risk Factors for Vertebral Fractures in Patients with Type 2 Diabetes Mellitus Ippei Kanazawa*, Masakazu Notsu, Ken-Ichiro Tanaka, Toshitsugu Sugimoto. Shimane University Faculty of Medicine, Japan

Purpose: Several studies suggest that obesity may be a risk factor for fracture although the relationship between body mass index (BMI) and fracture risk is unknown in type 2 diabetes (T2DM). We thus aimed to examine the association between BMI and the prevalence of vertebral fracture (VF) in Japanese patients with T2DM.Methods: In this cross-sectional study, 798 subjects (500 men and 298 women) with T2DM were enrolled. Bone mineral density (BMD) of femoral neck (FN) was measured by the dual-energy X-ray absorptiometry. VF was defined by semi-quantitative method using lateral X-ray films of the thoracic and lumbar spine. The association of BMI quartiles (Q1; < 21.2 kg/m2, Q2; 21.3 – 23.4 kg/m2, Q3: 23.5 – 25.8 kg/m2, Q4; 25.9 < kg/m2) with the presence of VF was examined.Results: According to BMI increase, urinary N-terminal cross-linked telopeptide of type-I collagen (uNTX), a bone resorption marker, was significantly decreased, and FN-BMD, FN-T score, and FN-Z score were significantly increased. Subjects in Q2 quartile had less prevalence of VF (29.4%) compared to others in Q1 (43.1%), Q3 (28.6%), and Q4 (41.5%). Multiple logistic regression analyses adjusted for age, gender, duration of diabetes, HbA1c, estimated glomerular filtration rate, and serum albumin showed that Q1, Q3, and Q4 were significantly associated with an increased VF risk compared to Q2 as a reference [Q1; odds ratio (OR) = 1.91, 95% confidence interval (CI) 1.24 – 2.95, p = 0.004, Q3; OR = 1.65, 95%CI 1.07 – 2.55, p = 0.023, and Q4; OR = 2.18, 95%CI 1.39 – 3.41, p <0.001]. Moreover, these associations remained significant after additional adjustment for femoral neck T score and uNTX (Figure). When the associations were examined separately in men and women, same tendencies were observed as the results of total subjects although some associations became insignificance because the number of the subjects was reduced.Conclusions: This is the first study to show that both overweight and underweight were associated with the BMD-inde-

pendent risk of VF in patients with T2DM. Therefore, body weight modification should be considered to protect diabetes-related bone fragility.

Association between BMI quartile and the risk of VF in patients with T2DM

Multiple logistic regression analysis adjusted for age, gender, duration of diabetes, HbA1c, eGFR, albumin, FN-T score, and uNTX was performed with the presence of VF as a dependent variable and BMI quartile as an independent variable.

Cinacalcet restores bone quality in CKD-MBD mice by modulating Wnt10b and klotho signaling in bone cells Jia-Fwu Shyu*[1], Tzu-Hui Chu[1], Yi-Jun Lin[1], Lo-Wei Chen[2], Cheng-Yuan Hsiao[1], Wen-Chih Liu[4]. [1]Department of Biology and Anatomy, National Defense Medical Center, Taiwan, [2]Department of Biology and Anatomy, National Defense Medical Center, United Republic of Tanzania, [4]Graduate Institute of Clinical Medicine, College of Medicine, Taipei Medical University, Taiwan

Chronic kidney disease (CKD) is a global health problem of growing incidence that affects 5 to 15% of the world's population. The mineral and bone disorder (MBD) begins early in CKD consisting of vascular calcification, osteodystrophy, loss of klotho and increased FGF23 secretion. Progress has been made into the causes of CKD-MBD, but they remain largely unknown. Recent studies have suggested that adding a calcimimetic agent, namely cinacalcet, can reduce the risk of fractures in CKD-MBD patients. Further insights into the action of cinacalcet in bone cells might lead to calcium sensing receptor-based drugs that maximize not only the effects of the receptor on the parathyroid glands and kidneys but also on bone. Two-step 5/6 nephrectomy protocol was performed in 8-wk-old male mice. Four weeks later these CKD mice were treated with cinacalcet for 4 more weeks. μCT images demonstrated obvious deterioration of bone microstructure in CKD mice as compared with the control mice. Moreover, the CKD mice exhibited decreased cortical bone thickness, increased cortical porosity, impaired trabecular bone volume and bone surface density, and decreased trabecular number in comparison with the control mice. Cinacalcet-treated CKD mice revealed significantly increased cortical thickness and significantly reduced cortical porosity compared with saline-treated CKD mice. The roles of Wnt ligands and klotho involved in skeletal physiology and disease is not fully understood yet. We hypothesize that cinacalcet increases bone formation by inducing Wnt10b and klotho expression in bone cells. To test this hypothesis, bone marrow hematopoietic mononuclear cells were isolated from rat femur and tibia. They were induced into osteoclasts by M-CSF and RANKL treatments. In these cells, cinacalcet induced an increase of Wnt10b expression as examined by confocal and Western blot analysis. ELISA analysis also showed increase of Wnt10b expression in supernatant (condition medium) collected from the cinacalcet-treated osteoclasts. Culture of osteoblasts (isolated from neonatal rat calvarias) with the cinacalcet-treated osteoclasts condition medium increased mineralization as indicated by alizarin red staining. In addition, increased klotho expression was found in cinacalcet-treated osteoblasts. Taken together, these results indicate that upregulated Wnt and klotho signaling may be involved in the underlying mechanisms of using cinacalcet to restore bone quality in CKD-MBD mice.

Bone Material Strength Index as Measured by Impact Microindentation in Patients with Primary Hyperparathyroidism and Hypoparathyroidism Jessica Starr*[1], Gaia Tabacco[2], Rukshana Majeed[1], Beatriz Omeragic[1], Maximo Gomez[1], Leonardo Bandeira[3], Mishaela Rubin[1]. [1]COLUMBIA UNIVERSITY, United States, [2]University Campus Bio-Medico, Italy, [3]Instituto FBandeira de Endocrinologia, United States

PTH is a regulator of cortical bone properties. Increased levels in primary hyperparathyroidism (PHPT) lead to cortical bone loss while deficient levels in hypoparathyroidism (HypoPT) increase cortical thickness. Yet the effects of PTH excess and deficiency on cortical bone tissue properties as assessed by in vivo impact microindentation are unknown. We hypothesized that bone material strength index (BMSi) would be decreased in PHPT and increased in HypoPT as compared to euparathyroid controls. Impact microindentation was performed in 50 subjects (PHPT, HypoPT and Control) to assess BMSi at the anterior surface of the mid-tibia diaphysis. Areal bone mineral density (aBMD) (g/cm2) of the lumbar spine (LS), femoral neck (FN), total hip (TH) and distal 1/3 radius (DR) were measured by dual-energy X-ray absorptiometry (DXA) in PHPT and HypoPT. Controls were selected to match either PHPT or HypoPT subjects by age (PHPT [n=13]: 59.3±15 yrs; HypoPT [n=15]: 44.3±12.5 yrs; Controls [n=22]: 49.2±17 yrs) and gender (proportion female: PHPT: 69%; HypoPT: 73%; Controls: 77%). Serum calcium differed between the groups (PHPT: 10.7±1 mg/dl; HypoPT: 8.6±1 mg/dl; Controls: 9.5±1 mg/dl; p<0.001), as did PTH levels (PHPT: 73.6±40 pg/ml; HypoPT: 8.0±4 pg/ml; Controls: 31.4±22 pg/ml; p<0.001). As compared to controls, BMSi was 12% lower in PHPT (Controls: 77.2 ± 8 vs PHPT: 67.8 ± 9; p=0.01) and 11% lower in HypoPT (Controls 77.2 ± 8 vs HypoPT 68.4 ±10; p=0.02); the differences persisted after adjusting for age and gender. BMSi in PHPT and HypoPT did not differ (p=0.98). DXA T-scores were higher in HypoPT than in PHPT at the FN (HypoPT: -0.13 ± 2 vs PHPT: -1.24± 2; p=0.06), TH (HypoPT: 0.03 ± 1 vs PHPT: -0.83 ±1; p=0.06) and DR (HypoPT: -0.03 ± 1 vs PHPT: -1.38 ± 1; p=0.01), although not at the LS (HypoPT: -0.14 ± 1 vs PHPT: -0.63 ± 2; p=0.45). In conclusion, PHPT and HypoPT subjects have worse cortical bone indentation properties as measured by in vivo impact microindentation of the tibial diaphysis when compared to controls. BMSi is reduced in HypoPT to a similar extent as in PHPT, despite higher aBMD T-scores. These data suggest that measurement of BMSi may reflect a different aspect of skeletal behavior than that assessed by aBMD. The results provide a rationale for future investigations aimed at assessing mechanisms by which abnormal PTH levels impact cortical bone tissue properties and at determining whether BMSi can predict fracture in PHPT and HypoPT patients.

FRI-0008

Parathyroid Gland Localization in Primary Hyperparathyroidism: Evaluation of a Novel Imaging Protocol and Direct Head-to-Head Comparison of Parathyroid 4D-CT and Sestamibi SPECT/CT Randy Yeh*, Yu-Kwang Donovan Tay, Gaia Tabacco, Laurent Dercle, Jennifer Kuo, Leonardo Bandeira, Catherine Mcmanus, James Lee, John Bilezikian. Columbia University Medical Center, United States

BackgroundAccurate preoperative imaging is critical to the success of minimally invasive parathyroidectomy. At most institutions, technetium 99m (99mTc) sestamibi scintigraphy and ultrasound, often used in combination, are the imaging modalities of choice. A more recent approach, 4-dimensional computed tomography (4D-CT) has demonstrated excellent accuracy in preoperative localization of abnormal parathyroid tissue. In some studies, 4D-CT has appeared to be superior to sestamibi. We evaluated the accuracy of the combined use of 4D-CT and sestamibi SPECT/CT and performed a direct head-to-head comparison of each modality using a one-stop imaging protocol performed on a single SPECT/CT scanner. MethodsFour hundred consecutive patients with primary hyperparathyroidism (PHPT) who had parathyroidectomy (PTX) first underwent the combined imaging protocol. The imaging protocol consisted of dual-phase sestamibi SPECT/CT and 4D-CT, with 4D-CT acquired immediately after the delayed phase sestamibi SPECT/CT acquisition and the patient in the same position and SPECT/CT scanner. Using a 4-quadrant analysis, sensitivity, specificity and area under the curve (AUC) for localization were compared for sestamibi SPECT/CT and 4D-CT, alone and in combination. The reference standard for successful PTX was an intraoperative drop in PTH > 50% and pathological confirmation of an adenoma or hyperplasia. ResultsCombination of 4D-CT/Sestamibi and 4D-CT alone had the highest AUCs of 0.879 [95% CI 0.857 – 0.900] and 0.875 [0.853-0.897] and were not statistically different from each other. Both had a significantly higher AUC than sestamibi alone of 0.784 [0.756-0.811]. 4D-CT had higher sensitivity than sestamibi (79% vs. 58%) and demonstrated sensitivity equal to combined 4D-CT/Sestamibi (80%). While sestamibi showed the highest specificity (99%), both 4D-CT and combined 4D-CT/Sestamibi still demonstrated very high specificity at 96% and 95%, respectively. In a subset analysis, 4D-CT had higher sensitivity than sestamibi in single gland (92% vs. 75%) and multigland disease (58% vs. 31%). ConclusionThe combination of 4D-CT/Sestamibi did not improve the accuracy of 4D-CT alone, but was superior to sestamibi alone. 4D-CT provides superior preoperative localization compared to sestamibi in patients with single and multigland disease. 4D-CT should be considered as a first-line modality in the preoperative localization of abnormal parathyroid tissue in primary hyperparathyroidism.

Fracture susceptibility is currently predicted by assessment of bone mineral density (BMD) but is also determined by bone quality. Bone quality describes the material properties of the skeleton that contribute to strength independently of BMD, and has recently emerged as an important research priority as it cannot currently be integrated into the clinical prediction of fracture risk. Phosphate (Pi) is a major ion component of the bone matrix and its uptake by mineralizing cells is considered a pre-requisite for mineralization. In vertebrates, the type III co-transporters (PiT1/SLC20A1 and PiT2/SLC20A2) are the only sodium-Pi co-transporters known to be expressed in skeletal tissues, and are thought to be essential for Pi delivery during mineralization.To determine the physiological role of PiT2 in tissue mineralization, we performed detailed characterization of the skeletal phenotype of Slc20a2-deficient mice (n=3-6 Slc20a2-/- and wild-type mice per age, per sex) and evaluated the bone phenotype of 21 patients with heterozygous pathogenic variants in SLC20A2 leading to Primary Familial Brain Calcifications (PFBC). We showed that juvenile Slc20a2-/- mice had abnormal endochondral (decreased height of the growth plate, p<0.01) and intramembranous ossification (reduced cranial length (p<0.001), zygomatic width (p<0.01) and mandibular length (p<0.01)), decreased BMD (p<0.001), impaired mineral accrual and short stature. In adult mice, µCT analysis, quantitative back-scattered electron-scanning electron microscopy (qBSE-SEM) and biomechanical testing revealed small reduced trabecular and cortical volumes (p<0.05 and p<0.001, respectively) and mineralization (p<0.001) but a profound impairment of bone strength (reduced bone stiffness and strength, p<0.001 and p<0.01, respectively). Bone quality was therefore investigated by comparing bone mineral content (BMC) and biomechanical parameters in Slc20a2-/- mice and 320 age and sex-matched wild-type controls. This analysis showed that bone quality was severely impaired in Slc20a2-/- mice. In human, we showed that mean bone density in occipital condyle and thickness of parietal bone spongiosa were decreased in PFBC patients compared to controls, suggesting they may also have impaired skeletal tissues. Altogether, these studies identify Slc20a2 as a physiological regulator of tissue mineralization and highlight a critical role for phosphate transport in the determination of bone quality and strength.

FRI-0054

Bone strength and mineralization are regulated independently of bone mass by ephrinB2-dependent autophagic processes in osteocytes Vrahnas Christina*[1], Toby Dite[1], Yifang Hu[2], Huynh Nguyen[3], Mark R Forwood[3], Keith R Bambery[4], Mark J Tobin[4], Gordon K Smyth[2], T John Martin[1], Natalie A Sims[1]. [1]St. Vincent's Institute of Medical Research, Australia, [2]Walter and Eliza Hall Institute of Medical Research, Australia, [3]Griffith University, Australia, [4]Australian Synchrotron, Australia

Bone formation has two phases: a rapid initiation (primary mineralization), followed by slower accrual of mineral (secondary mineralization) that continues until that portion of bone is renewed by remodeling. Initiation of bone mineralization, and late stage osteoblast differentiation, requires expression of EphrinB2 (Efnb2) in the osteoblast lineage, but the function of EphrinB2 in matrix-embedded osteocytes is not known.We previously reported at this meeting that osteocyte-specific EphrinB2 null mice (Dmp1Cre.Efnb2f/f) exhibit an intrinsic defect in material strength. Their brittle bone phenotype was not associated with any change

in moment of inertia, osteoblast numbers, nor any defect in the initiation of osteoid mineralization. However, secondary mineralization was significantly accelerated: after initiation of mineralization, mineral:matrix ratio, and carbonate:matrix ratio increased more rapidly in EphrinB2-deficient bones than controls (detected by synchrotron-based Fourier-transform infrared microspectroscopy). This indicated that osteocytic ephrinB2 suppresses mineral accumulation in bone.To identify novel mechanisms by which osteocytes regulate secondary mineralization bone mass, we carried out RNA sequencing of marrow-flushed cortical bone from Dmp1Cre.Efnb2f/f brittle-bone mice and Dmp1Cre control littermates. This revealed 782 significantly up-regulated genes and 1024 down-regulated genes (FDR < 0.05). Genes previously known to regulate mineralization (e.g. Dmp1, Mepe, Sost, Phospho1, Enpp1, Enpp2) were not significantly modified by EphrinB2 deletion, and no regulation of the collagen type I genes (Col1a1 or Col1a2) was detected. By a literature search, we identified that >30% of the top 30 differentially expressed genes are associated with autophagy, a mechanism that mediates intracellular recycling and exocytic secretion. We therefore generated stable ephrinB2-deficient osteocyte cell lines (Ocy454) using shRNA. EphrinB2-deficient osteocytes deposited greater amounts of mineral in vitro than controls. They also showed a significantly greater increase in autophagic flux than control cells (the increase in LC3-II:I ratio in response to chloroquine treatment was increased by 30% compared to controls). This suggests that secondary mineralization of the bone matrix is controlled by autophagic processes in osteocytes, in a manner that is limited by ephrinB2. Such processes may be disrupted in conditions of bone fragility that are independent of bone mass.

FRI-0055

Non-invasive Localized Cold Therapy as a New Mode of Bone Repair Enhancement Marianne Comeau-Gauthier*, Daniel Castano, Jose Luis Ramirez-Garcia Luna, Justin Drager, Jake Barralet, Geraldine Merle, Edward Harvey. McGill University, Canada

It has been observed that frequent cold-water exposure results in ectopic bone formation visualized in the outer ear[1,2]. Local cold therapy has been a time-honored treatment for inflammatory and painful musculoskeletal afflictions, but its effect on bone defect healing has never been studied. In vitro studies revealed that although osteoclastogenesis is enhanced upon cold application[3], the effect of hypothermia on osteoblasts is conflicting[4,5]. This project used repeated cold-water exposure as a novel non-invasive adjunct therapy to stimulate bone growth in a bilateral cortical defect model.Bilateral femoral window defects were drilled in 18 adult wild-type male mice. Starting postoperative day 1, one lower extremity was immerged daily in an ice bath for 15 minutes (temperature at bone level=19°C), whereas the other was used as control. ?Mice were euthanized at postoperative day (POD)-7 (early inflammatory phase) (n=6) and POD-28 (remodeling phase) (n=12). Bone formation was assessed ?using micro CT and histological analysis for alkaline phosphatase (ALP), tartrate resistant acid phosphatase (TRAP), CD34, and vascular endothelial growth factor (VEGF) to identify osteogenic cells, osteoclasts, endothelial vascular cells and angiogenesis respectively.Lowering the temperature at the defect site during the healing course resulted in a significant increase in bone volume (Fig.1), despite a decrease of the osteoblast activity at 4 weeks. Interestingly, immunohistochemical analysis demonstrated higher expression of VEGF and a greater number of CD34+ stained cells during the inflammatory healing stage (POD-7) accompanied with higher expression of TRAP. Interestingly, at 4 weeks this trend was inverted, and the expression of VEGF and CD34+ was decreased compared to the non-treated group.Our results demonstrate that daily local cold therapy for 4 weeks accelerates/enhances bone healing in a murine model of intramembranous bone repair. Further, our study suggests that this increase in osteogenesis is mediated by the upregulation of the VEGF pathway. Further studies exploring the mechanism of action of local cooling on bone healing, as well as the optimal treatment dose, duration, and frequency are warranted based on the results of this pilot study. If proven effective, local cold therapy can be introduced as a novel, cost effective, and non-invasive treatment modality to enhance bone healing in a clinical setting.

4 weeks postoperative

Figure 1. Macroscopic evaluation of bone repair in the window defect. Cold-treated and control femora were scanned at a resolution of 5μm on a Skyscan 1172 instrument. Representative 3D models from paired femora were reconstructed from 2D images to display healing of the defect at 4 weeks postoperative. Significant new bone (white) is seen at the level of the defect in the cold group (C,D,G,H,K,L,O,P) compared to the control group (A,B,E,F,I,J,M,N). The difference in percent bone volume (% BV/TV) in the window defect between the experimental and control group is displayed in the graph below (Q) p<0.001. Cold significantly different from control at *p<0.001.

FRI-0056

A Novel FEM Approach for Evaluating the Fracture Resistance of Human Cortical Bone Demonstrates that Material Heterogeneity Distributes and Attenuates Damage in Cortical Bone from Human Iliac Crest Biopsies Ahmet Demirtas*[1], Erik Taylor[2], Eve Donnelly[2], Ani Ural[1]. [1]Villanova University, United States, [2]Cornell University, United States

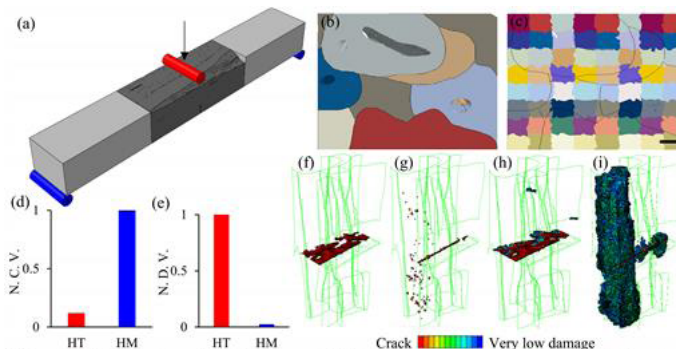
Pathologic or therapeutic compositional changes at the microscale alter fracture resistance at larger length scales. However, the relative importance of these modifications on fracture risk has not been quantified. The aim of this study is to establish a finite element (FE) model capable of simulating the influence of material property alterations on the fracture resistance of human cortical bone biopsies. In particular, we examined the effect of material heterogeneity on the fracture behavior of cortical bone. An FE model was generated of a notched beam excised from an iliac crest biopsy (gender: F, age: 75y) loaded in three-point bending (Fig. 1a) by: (1) micro-computed tomography (μCT) imaging of the beam at 1.4μm resolution, (2) processing the μCT image via a MATLAB script to identify the location of cement lines and osteons, and (3) generating the 3D FE model using an image processing software, and a second MATLAB script (Fig. 1b). The model simulated fracture via cohesive extended finite elements (osteons and interstitial bone) and interface elements (cement lines). The influence of material heterogeneity on the fracture behavior of cortical bone was investigated by generating two models with distributions of material properties measured by nanoindentation (1) heterogeneous (HT) (Fig. 1c) and (2) homogeneous (HM), average material properties assigned to all osteons and interstitial bone. The fracture behavior was assessed by comparing the crack and damage volume at the same load. The HT material distribution increased the damage volume but reduced the crack volume compared to the HM material distribution (Fig. 1d,e). A major crack formed following the initial notch in the HM model (Fig 1f) whereas the fractured elements were distributed in the HT model without the formation of a macrocrack (Fig. 1g). In addition, HT model resulted in greater amounts of low-level damage compared to the small amounts of high-level damage in the HM model (Fig. 1h,i). In conclusion, the current study developed a novel modeling approach that is capable of assessing the influence of material property distribution in human biopsies on their fracture response. The results demonstrated that material heterogeneity promoted energy dissipation and prevented crack growth in the bone. This approach has the potential to provide additional insight into the patient-specific effects of treatments and diseases which can improve fracture risk assessment and therapeutic interventions.


Figure 1: (a) Planar view of three point bending specimen where the dark grey section is the detailed microstructure region. The arrow on red cylinder shows the applied displacement and the blue cylinders show the fixed boundary conditions (span length = 3mm). (b) Cross-sectional view of the detailed model showing the osteons and interstitial bone. (c) Material assignment in HT model based on nanoindentation measurements. Each color represents a different value of material property (Scale bar = 50 μm). Normalized (d) crack volume (NCV) and (e) damage volume (NDV). Crack formation in (f) homogeneous (HM), and (g) heterogeneous (HT) models. Damage formation in (h) HM, and (i) HM models. In (f-i) the cement lines are highlighted with green.

Aging and Chronic Kidney Disease differently diminish bone mechanics from the nano- to whole-bone scales Chelsea M Heveran*[1], Charles Schurman[2], Claire Acevedo[3], Eric Schaible[4], Eric W Livingston[5], Moshe Levi[6], Ted Bateman[5], Tamara Alliston[2,7], Karen B King[8], Virginia L Ferguson[1]. [1]Department of Mechanical Engineering, University of Colorado at Boulder, United States, [2]Department of Orthopaedic Surgery, University of California San Francisco, United States, [3]Department of Mechanical Engineering, University of Utah, United States, [4]Lawrence Berkeley National Laboratory, United States, [5]Department of Biomedical Engineering, University of North Carolina, United States, [6]Department of Biochemistry and Molecular &Cellular Biology, Georgetown University, United States, [7]UC Berkeley/UCSF Graduate Program in Bioengineering, United States, [8]Department of Orthopaedics, University of Colorado School of Medicine, United States

Aging and chronic kidney disease (CKD) commonly co-occur and both increase fracture risk. We hypothesized that aging and CKD, which each affect systemic mineral homeostasis and bone turnover, would differently diminish bone strength and toughness. Male C57Bl/6 mice received Sham or 5/6th nephrectomy (to induce CKD) surgeries and were killed after 3 mo at 6 mo (Sham: n = 6; CKD: 7), 18 mo (n = 8; 10), and 24 mo (n = 8; 8). Whole femur mechanics were evaluated via three-point bending (3PB). The femur mid-diaphysis was then dehydrated, embedded, sectioned, and polished. Nanoindentation arrays spanning the cortical thickness assessed reduced modulus (Er). Tissue tensile stress and strain were studied in the ulna-radius complex; collagen nanomechanics were monitored via change in d-spacing from synchrotron Small-Angle X-ray Scattering (SAXS). MicroCT evaluated cortical (midshaft femur) and trabecular (proximal tibia) microarchitecture. For Sham, aging (6 mo to 24 mo) reduced 3PB ultimate stress (-40.2%, p<0.05), modulus (-48.4%, p<0.05), and microscale Er (-9.2%, p<0.05) (Fig 1A-B). Adjusting for age (ANCOVA), higher Er corresponded with lower 3PB ultimate stress (r2 = 86%, p<0.05). Aging reduced SAXS tissue tensile ultimate stress and collagen strain at max strain (p<0.05), with no correlation to 3PB outcomes (Fig 1C). Cortical (↑Ct.Po, ↓Ct.Th) and trabecular (↓Tb.N, ↓Tb.Th) microarchitecture were lost with aging. Lower Ct.Th contributed to lower ultimate stress (ANCOVA r2 = 88%; p<0.05). CKD at 18 mo vs Sham reduced 3PB toughness (-49.9%, p<0.05), but not ultimate stress or modulus, and microscale variance in Er (-19.8%, p<0.05) (Fig 1D-E). SAXS tissue tensile strain declined with CKD (p<0.05), and collagen fibers assumed greater % total strain (p<0.05) (Fig 1F). Increased % collagen strain reduced 3PB toughness (ANCOVA r2 = 27%; p<0.05). CKD also impacted cortical (↑Ct.Po, ↓Ct.Th) and trabecular microarchitecture (↓Tb.N, ↓Tb.Th). Lower Tb.Th reduced 3PB modulus and strength (ANCOVA r2 = 79-83%, p<0.05). We show for the first time that aging and CKD differently diminish multiscale bone mechanics. Aging reduced whole bone strength and modulus, which is explained by altered tissue-scale stiffness and microarchitecture but not collagen mechanics. CKD reduced toughness, which is best explained by increased collagen strain burden. Our results demonstrate that aging and CKD may separately contribute to loss of skeletal strength and fracture resistance.

The Effect of Vitamin D3 Supplementation on Distal Radius Fracture Healing: A Randomized Controlled HR-pQCT Trial F.L. Heyer*[1], J.J.A. De Jong[1], P.C. Willems[1], J.J. Arts[2], S.M.J. Van Kuijk[1], J.A.P. Bons[1], M. Poeze[1], P.P. Geusens[1], B. Van Rietbergen[3], J.P. Van Den Bergh[1]. [1]Maastricht University Medical Center, Netherlands, [2]Eindhoven University of Technology, Netherlands, [3]Technical University of Eindhoven, Netherlands

Enhancing fracture healing using systemic therapies is gaining interest. Vitamin D3 is an important factor to consider in bone metabolism, especially in the population at risk for osteoporotic fractures in which there is a substantial prevalence of vitamin D deficiency. Animal studies have shown a positive effect of vitamin D3 supplementation on fracture healing, but evidence from clinical trials is scarce and inconclusive. We performed a randomized controlled trial to assess the effect of vitamin D3 supplementation on distal radius fracture healing using high-resolution peripheral quantitative computed tomography (HR-pQCT) and micro-finite element analysis (µFEA) based outcome parameters.Thirty postmenopausal women with a conservatively treated distal radius fracture were included within two weeks post-fracture and randomized in a control group, a low-dose and a high-dose intervention group receiving 30 000 IU and 75 000 IU vitamin D3 per six weeks equivalent to 700 IU/day and 1 800 IU/day, respectively. After the baseline visit 1-2 weeks post-fracture, follow-up visits were scheduled 3-4, 6-8 and 12 weeks post-fracture. At each visit, HR-pQCT scans of the fractured radius were performed. Cortical and trabecular bone microarchitectural parameters and µFEA derived torsion, compression and bending stiffness were assessed. In addition, venous blood samples were collected to assess serum markers of bone resorption (C-terminal telopeptide of type I collagen; CTX) and bone formation (N-terminal propeptide of type I procollagen; PINP).Serum levels of 25(OH)D3 were <50 nmol/L in 30-40% and <75 nmol/L in 60-90% of included patients. No statistically significant differences were observed between control and low-dose intervention groups in any of the outcome parameters (all p>0.05). High-dose vitamin D3 supplementation resulted in a decreased trabecular number (B -0.22; p<0.01) and lower compression stiffness (B -3.63; p<0.05), together with an increase in the bone resorption marker CTX (B 0.062; p<0.05), after correction for baseline 25(OH)D3-levels.We conclude that vitamin D3 700 IU/day supplementation does not improve distal radius fracture healing and that a dose of 1 800 IU/day may be detrimental to restoring bone stiffness during the first 12 weeks of fracture healing.

Differences in Microarchitectural and Nano-mechanical Properties of Bone Between Patients with and without Atypical Femoral Fracture after Prolonged Bisphosphonate Treatment Shijing Qiu*[1], Lanny Griffin[2], George Divine[1], Mahalakshi Honasoge[1], Arti Bhan[1], Shiri Levy[1], Elizabeth Warner[1], Sudhaker Rao[1]. [1]Henry Ford Hospial, United States, [2]California Polytechnic State University, United States

It is well-known that a small group of patients on long-term bisphosphonate (BP) therapy are predisposed to sustain atypical femoral fracture (AFF). However, the mechanism(s) resulting in AFF remains unclear. The purpose of this study is to determine the association of AFF with bone microarchitecture and remodelling, and its mechanical propertiesIliac bone

biopsies were obtained after double tetracycline labeling from 20 age-matched postmenopausal women with ≥2-year BP treatment, 10 with AFF (aged 67.4 ± 5.36) and 10 without AFF (aged 67.3 ± 6.83). The 5 µm sections were used to measure bone microarchitecture and remodeling status. Nanoindentation was performed on each bone block.As shown in Table, there was very little difference in cortical bone volume (BV/TV), and the nominal difference in cancellous BV/TV between patients with and without AFF was not statistically significant. Interestingly, wall thickness (W.Th) in all bone compartments (cancellous, cortical and endosteal) was significantly decreased in AFF patients. In contrast, erosion surface (ES/BS) and osteoclast surface (Oc.S/BS) in all bone compartments were numerically increased in AFF patients, but only the increase in OcS/BS in cortical bone reached statistical significance. Based on numerical data, the insignificant results may have been due to small sample size. Nano-indentation showed that the elastic modulus (E) of cortical bone was significantly increased in AFF patients.In summary, two morphological changes of bone (especially cortical bone) were noted in AFF patients: decreased W.Th and increased osteoclasts and bone resorption areas. Others have reported increased number of osteoclasts after 3 years of alendronate treatment, but approximately 1/3 were giant hyper-nucleated osteoclasts detached from bone surface (NEJM 2009;360:53-62). These osteoclasts have low capacity for bone resorption, producing shallow resorption cavities. Accordingly, accumulation of such abnormal osteoclasts may increase resorption area, but decrease resorption depth. The shallow resorption cavities would reduce W.Th, leading to an expansion of interstitial bone area with higher mineralization degree that may raise elastic modulus. Our previous work indicated that microdamage are much more likely to accumulate in the interstitial areas of cortical bone. Therefore, the increase in fragile interstitial bone is probably a crucial factor for the development of atypical fracture in femoral diaphysis.

Effect of Exercise and Weight on Bone Health in 8-9 Year Old Children Sandra Shefelbine*[1], Vineel Kondiboyina[1], Lauren Raine[1], Arthur Kramer[1], Naiman Khan[2], Charles Hillman[1]. [1]Northeastern University, United States, [2]University of Illinois at Urbana-Champaign, United States

Obesity has reached epidemic proportions around the world. One in every six children in the United States is obese. It has been observed in various studies that when adjusted for their weight, obese children have lower bone mineral content (BMC) and bone mineral density (BMD), which may explain their high rates of fracture. BMD is an areal estimate and does not take into account the effect bone thickness. Bone mineral apparent density (BMAD=BMC/Area1.5) is a volumetric estimate and has been recommended for assessing bone density in children.The objective of this study was to evaluate the effect of a 9-month physical activity intervention on BMC, bone area, and BMAD of children based on their pretrial weight class (normal weight, NW, and overweight/obese, O/O).Participants included overweight and obese (BMI> 85%, n=148) and healthy weight (n=203) preadolescents (8-9years old). Their whole body bone mineral density (BMC), area, and bone mineral apparent density were recorded using dual X-ray absorptiometry (DXA).O/O children had a higher total BMC (p<0.001) than normal weight children but when adjusted for their weight BMC was lower in O/O children compared to normal weight children (p<0.001) in both pre-trial and post-trial assessments. Interestingly, pre-trial and post-trial whole body BMAD of O/O children was higher than normal weight children irrespective of adjustment by weight (p<0.001). Nine-months of exercise significantly increased BMC (p<0.001) and area (p=0.006) in both O/O and normal weight, but had no effect on BMAD. BMAD increased more in normal weight children than in O/O children in both the exercise and non-exercise groups (p=0.017). The change in BMAD and BMC due to exercise within weight groups was not significantly different from each other (p=0.53 and p=0.54). Therefore, due to exercise, the increase in the bone mineral content and area for normal weight and O/O children is similar but there is no significant change in the volumetric density.In summary, obesity in 8-9 year olds results in bones with higher BMC, area, and BMAD compared to normal weight bones. Exercise increases BMC and area but not volumetric density (BMAD) in both normal and O/O children. The greater increase in BMC and BMAD over the 9 months in normal weight compared to obese children indicates a slower rate of bone mass accrual, which may have implications for bone health during skeletal growth.
Figure 1: Change in BMAD over a 9 month period by weight class and treatment. Increase in BMAD is greater in normal weight than in O/O in both exercise and control groups. The increase in BMAD in the exercise group is not significantly different from the control group for either O/O or normal weight.

Uncontrolled hyperglycemia delays bone healing and disrupts the microstructure and gene expression of cartilaginous and bony cells at the growth plate, metaphyseal and subchondral bone in diabetic rats Ariane Zamarioli*[1], Beatriz P Trani[1], Maysa S Campos[1], João Paulo B Ximemez[2], Raquel A Silva[3], José B Volpon[1]. [1]School of Medicine of Ribeirão Preto, Brazil, [2]School of Pharmaceutical Sciences of Ribeirão Preto, Brazil, [3]School of Dentistry of Ribeirão Preto, Brazil

The aim of this study was to assess the effects of hyperglycemia on the growth plate, bone quality and fracture healing in diabetic and non-diabetic rats. For this, 112 female Wistar rats (200±10g) were assigned to four groups: (1) SHAM, (2) sham with vibration therapy (SHAM+VT), (3) diabetes mellitus (DM), and (4) DM+VT. Diabetes was induced with a single intravenous injection of streptozotocin. Thirty days after diabetes induction, animals underwent closed bone fracture at the right mid-femur, followed by surgical stabilization of bone fragments. Three days after bone fracture, DM+VT and SHAM+VT rats were subjected to whole-body vibration therapy (50 Hz, 3x/wk, 20 minutes). On days 14 and 28 post-fracture (representing two distinct phases of normal bone healing: soft and hard bone callus formation, respectively), the rats were euthanized, blood was collected for serum bone marker analysis, and both femurs were collected for real time PCR, micro-computed tomography and histological analysis. The left femur was used to assess the quality of growth plate, and both subchondral and metaphyseal bone. The right fractured femur was used to follow bone healing. Diabetes caused detrimental effects on the growth plate, metaphyseal and subchondral bone, as well as a delay in bone healing in hyperglycemic rats, with a decrease of 93% in circulating IGF-1 and an increase in CTX-I level. In intact bone, diabetes caused detrimental changes in growth plate (tridimensional volume, thickness, area of proliferative, hypertrophic and ossification zones and reduction in cells of the ossification and calcified zones), in metaphyseal bone microarchitecture (reduced BV by 90%, BV/TV by 87%, TbN by 85% and Conn.D by 77%) and in subchondral bone (reduction in BV/TV and Tb.Th and, increment in BS/BV and SMI). In bone healing, diabetes caused a delay in cell proliferation, 81% in callus volume and 69% in callus mineralization. The osteoblast differentiation marker RUNX-2 was less expressed in diabetic rats when compared to non-diabetics after 28 days of fracture. Conversely, vibration therapy exerted an osteogenic effect in accelerating bone healing and in increasing bone and cartilage quality, but only in diabetic rats. VT significantly increased the IGF-1 and decreased the RANK-L level. VT was effective at increasing growth plate thickness and at ameliorating metaphyseal microarchitecture (augmented BV by 494%, BV/TV by 386%, TbN by 394% and Conn.D by 233%, Fig 1), but no changes were seen in the subchondral bone. In bone callus, VT accelerated osteogenic and chondrogenic cell proliferation at the fracture callus (Fig 2), thus increasing callus volume by 52%. We concluded that diabetes had detrimental effects on both non-fractured bone quality and fracture healing. Vibration therapy was very effective at counteracting the significant disrup-

tion in bone metabolism, mass and microarchitecture on both non-fractured and fractured femurs of diabetic rats.

Identification of a Non-Linear Maturational Trajectory During Adolescence Melanie Boeyer*, Emily Leary, Dana Duren. University of Missouri, United States

Assessments of a child's growth trajectory is of critical importance for clinicians treating skeletal growth and/or developmental disorders (e.g., leg length inequality). Current growth trajectory estimates are based on a child's chronological age and current height, with improvement occurring with the addition of a skeletal age assessment. Unfortunately, the precision of these estimates is rarely narrow, with implications for clinical outcomes. Variability in these estimates may be due, in part, to non-linear developmental patterns (i.e., maturational spurt). To assess the contribution of a maturational spurt to longitudinal growth, we assessed serial left hand-wrist radiographs, using the Fels Method, in 345 healthy boys and girls between 3 and 20 years of age from the Fels Longitudinal Study. The shape of individual developmental trajectories was examined to determine if skeletal age tracked linearly or curvilinearly (4th order fixed effect polynomials) with chronological age. Trajectories that exhibited a curvilinear relationship were further assessed for maturational spurt parameters (e.g., onset, peak, and cessation) using the first and second derivative of the polynomial model. All parameter estimates were determined separately for early, average, and late maturing boys and girls, defined based on the mean relative skeletal age at the parameters of the maturational spurt. Differences in the chronological age and the rate of maturation attained at each parameter were compared among maturity groups using a one-way ANOVA. Most (81%) boys and girls exhibited a curvilinear relationship between chronological age and skeletal age, with the maturational peak occurring most frequently in adolescence. Significant differences (p < 0.001) were observed in the chronological age of cessation, with early maturers reaching this milestone 10.8 and 15.2 months earlier than average maturing boys and girls, respectively. Late maturing boys failed to reach cessation prior to 20 years of age. No late maturing girls were identified. Although the parameters of the maturational spurt appear variable, when used in conjunction with other developmental milestones, such as peak height velocity or menarche, finer resolution in growth trajectory estimates will likely be achieved. These results highlight the curvilinear relationship between chronological age and skeletal age and combat the current paradigm that skeletal maturation is a linear process.

Sexual Dimorphism in Cortical and Trabecular Bone Microstructure Appears During Puberty in Chinese Children Ka Yee Cheuk*[1], Xiao-Fang Wang[2], Ji Wang[3], Zhendong Zhang[3], Fiona Wp Yu[1], Vivian Wy Hung[1], Wayne Yw Lee[1], Ali Ghasem-Zadeh[2], Roger Zebaze[2], Tracy Y Zhu[1], X Edward Guo[3], Jack Cy Cheng[1], Tsz Ping Lam[1], Ego Seeman[2]. [1]Department of Orthopaedics and Traumatology, The Chinese University of Hong Kong, Hong Kong, [2]Departments of Endocrinology and Medicine, Austin Health, University of Melbourne, Australia, [3]Bone Bioengineering Laboratory, Department of Biomedical Engineering, Columbia University, United States

Distal forearm fractures during growth are more common in males than females. As metaphyseal cortical bone is formed by coalescence of trabeculae emerging from the periphery of the growth plate, we hypothesized that the later onset of puberty in males produces a longer delay in trabecular bone formation and coalescence resulting in a transient phase of higher cortical porosity, lower matrix mineral density and higher trabecular density than in females. We quantified the non-dominant distal radial microstructure in 433 healthy Chinese boys and girls aged 7 to 17 years using high-resolution peripheral quantitative computed tomography in Hong Kong. Measurements of 110 slices (9.02 mm) were acquired 5 mm proximal to the growth plate of the non-dominant distal radius. Porosity was measured using StrAx1.0; trabecular plate and rod structure were measured using Individual Trabecula Segmentation (ITS). Mechanical properties were estimated using finite element analysis (FEA). Results were after adjusted for age, total bone area, dietary calcium intake and physical activity level. In boys, total bone area was 14.7-18.6% larger throughout puberty, cortical area/total bone area was 5.6% smaller in Tanner stage 2 only, cortical porosity was 8.6-14.9% higher and matrix mineral density was 1.0-2.5% lower in Tanner stage 2 to 5, than in girls. Boys had higher rod BV/TV in Tanner stage 3 and 4, higher plate BV/TV and plate to rod ratio in Tanner stage 5 and 20.4% lower apparent modulus than girls in Tanner stage 2 (p <0.05). A transient phase of higher porosity due to dissociation between bone mineral accrual and linear growth may contribute to higher distal radial bone fragility among Chinese males than females during growth.

Elucidating the Mechanism of JAGGED1-mediated Osteoblast Commitment during Maxillary Development Archana Kamalakar*, Melissa Oh, Samir Ballestas, Yvonne Coretha Stephenson, Steven Goudy. Emory University, United States

Maxillary bone deficiency (MBD) results from changes in cell signaling mechanisms during maxillary bone development, trauma or surgery. While in adults, bone morphogenetic protein (BMP2) is commonly used to ameliorate MBD, in pediatric cases, it leads to significant pain, erythema and inflammation. Therapies based on stimulation of bone formation without triggering painful inflammation in children with MBD are lacking. JAGGED1 (JAG1), a membrane-bound NOTCH ligand, is required for normal craniofacial development, and Jagged1 mutations in humans are known to cause maxillary bone hypoplasia and Alagille Syndrome, associated with bone demineralization and fractures. We previously demonstrated deficient maxillary osteo- and vasculo- genesis in Wnt1-cre;Jagged1f/f (Jag-1CKO) mice by conditional deletion of Jagged1 in maxillary mesenchymal stem cells. We hypothesize that a JAG1-NOTCH1 pathway is essential for maxillary development and for differentiation of neural crest cells (osteoblast precursors) during intramembranous ossification. In this study, we investigated the JAG1 signaling pathways in a cranial neural crest cell line, O9-1. We observed significant increase in Notch1 gene expression within 3hrs of JAG1 treatment (5 fold>control) compared to untreated and BMP2-treated cells. As expected, treatment with DAPT, a γ-secretase inhibitor of NOTCH intracellular domain (NICD) cleavage, ± JAG1, resulted in increased Notch1 gene expression, suggesting a compensatory mechanism in response to lack of NOTCH activity. Furthermore, osteoblast differentiation and maturation markers, Runx2 and OCN, respectively, as well as classic NOTCH1 targets, Hes1 and Hey1, were increased with JAG1 treatment. While Hes1 and Hey1 expression levels were predictably decreased after DAPT treatment, Runx2 and OCN levels were surprisingly constant in the presence of DAPT, indicating that JAG1 effects are independent of NICD cleavage. JAG1 treatment also led to increased JAK2 phosphorylation, which was refractory to DAPT treatment, further implicating the NICD cleavage-independent effects of JAG1. Pharmacologic inhibition of JAK2 phosphorylation upon JAG1 induction reduced Runx2 and OCN gene expression. Collectively, these data suggest that JAK2 is an essential component downstream of a non-canonical JAG1-NOTCH1 pathway through which JAG1 stimulates expression of osteoblast-specific gene targets that contribute to osteoblast differentiation and bone mineralization in maxillary development

Menstrual abnormalities and cortical bone deterioration in young female athletes: an analysis by HR-pQCT Yuriko Kitajima*[1], Ko Chiba[2], Yusaku Isobe[2], Narihiro Okazaki[2], Naoko Murakami[1], Michio Kitajima[1], Kiyonori Miura[1], Makoto Osaki[2], Hideaki Masuzaki[1]. [1]Department of Obstetrics and Gynecology, Nagasaki University Graduate School of Biomedical Sciences, Japan, [2]Department of Orthopedic Surgery, Nagasaki University Graduate School of Biomedical Sciences, Japan

Purpose Young female athlete such as long-distance runners and rhythmic gymnasts sometimes have menstrual abnormalities, that causes problem with bone metabolism. HR-pQCT is a high resolution quantitative CT which enables us to investigate a patients' bone microstructure non-invasively. The purpose of this study is to investigate bone microstructural changes in young female athletes by HR-pQCT. Method Nineteen female athletes (middle and long-distance runners and rhythmic gymnasts, ages 15-21) and 29 female non-athletes (control, ages 15-23) participated in this study. A questionnaire survey was performed to obtain menstrual history. Distal radius and tibia were scanned by HR-pQCT at the voxel size of 61 μm (XtremeCT II, Scanco Medical, Switzerland), and cortical and trabecular bone micro-structures were analyzed. Results 84.2% of female athletes had abnormal menstruation. BMI was lower in athletes than in the control group (18.4 and 20.9, respectively, p<0.01). Cortical BMD was lower in athletes than in the control group (880.4 and. 920.9 mg/cm3 at the radius, p<0.03; 935.2 and 956.5 mg/cm3 at the tibia, p<0.01). Cortical porosity at the radius was increased in athletes (0.34 and 0.20%, p=0.01). Trabecular BMD, number, and thickness were not significantly different. Conclusion Young female athletes seem to be high risk population of abnormal menstruation and deteriorated cortical bone. Our study suggest that to maintain bone health in young female athletes, monitoring menstrual cycles is important.

Body mass is important, but so is its distribution: associations between body composition and bone health measures in 11-12 year old children Peter Simm*[1], Dorothea Dumuid[2], Susan Clifford[3], Grace Gell[3], Timothy Olds[2], Melissa Wake[3]. [1]Dept of Endocrinology, Royal Children's Hospital Mlebourne, Australia, [2]Alliance for Research in Exercise, Nutrition and Activity, University of South Australia, Australia, [3]Murdoch Children's Research Insitute, Australia

The drivers of bone mass accrual in childhood remain unclear, with conflicting data about the role of body composition, and the relative impact of the underlying components such as fat mass and fat-free mass.The Child Health Checkpoint is a cross-sectional study of 11-12 year old Australian children, drawn from the national Longitudinal Study of Australian Children (LSAC). 1874 children attended for a single-day session involving multiple health measures, including peripheral quantitative computerised tomography (pQCT) of the non-dominant tibia, and body composition analysis (truncal fat, non-truncal fat, fat free mass) measured by bio-impedance. Compositional multiple linear regression explored the relationship between body composition and bone health measures (trabecular/cortical density and geometry). Novel isocompartmental substitution modelling quantified the differences in bone health associated with the reallocation of mass between body compartments. Models were adjusted for age, height, pubertal stage, socioeconomic status and moderate-vigorous physical activity.843 subjects (49.3% male) with complete data participated in these analyses. In non-compositional analyses of bone parameters, higher fat-free mass was associated with overall improved skeletal geometry and trabecular density, but lower cortical density.

However, higher truncal and nontruncal fat had the opposite effect. Figure 1(a) shows that polar stress-strain index (SSI) increases linearly with overall mass, consistent with previous studies showing body mass drives improved bone health parameters in young people. Compartmental substitution modelling revealed profoundly opposing effects of different elements of body composition (see figure 1 (b)). For example, a 6% absolute increase in fat-free mass was associated with a 1 SD increase in SSI while a 3% absolute reduction in truncal fat was associated with an approximately 1 SD increase. Effects for non-truncal fat were similar in pattern, but much weaker, to those for truncal fat.These findings emphasize that while heavier children in general have stronger bones, it is higher lean mass combined with lower truncal fat that drives improved outcomes at any given total body mass. The role of non-truncal fat seems less important. If these relationships are confirmed in experimental studies, interventions that maximise fat-free mass and minimise truncal fat could lead to long term, population-wide skeletal health benefits.

Osteocalcin is necessary and sufficient to mount an acute stress response
Julian Berger*, Lori Khrimian, Karsenty Gerard. Columbia University, United States

While trying to identify a common thread between the diverse functions of the hormone we noticed that memory, adaptation to exercise, energy expenditure and male fertility that are all favored by osteocalcin, are survival functions for animals living in hostile conditions such as in the wild. This observation prompted us to ask whether osteocalcin contributes to a quintessential survival function, the acute stress response (ASR). This investigation revealed that osteocalcin exhibits two major features of a stress hormone. First, circulating bioactive osteocalcin levels increase two to four times within 5 to 15 minutes in wild type (WT) mice exposed to any type of stressors. The same is true in rats and humans. The bone's response to stress is specific to osteocalcin, independent of transcriptional events, sympathetic tone or the adrenal glands, but requires the integrity of neurons of the amygdala. Second, analysis of mice lacking Osteocalcin (Ocn -/-) or its receptor in peripheral organs (Gprc6a-/-) demonstrates that osteocalcin signaling in peripheral organs, is necessary for the full development of the following manifestations of the ASR: increased heart rate, hyperventilation, and enhanced energy expenditure. Anatomical, molecular, genetic, and electrophysiological evidence obtained in WT and Gprc6a-/- mice or cells shows that to favor these physiological processes osteocalcin signals in post-ganglionic parasympathetic neurons to inhibit their activity thereby leaving the sympathetic tone unabated. Next to assess the respective contribution of osteocalcin and glucocorticoid signaling in triggering an ASR we analyzed the stress manifestations mentioned above in WT mice that had been adrenalectomized (Adx). Surprisingly, we observed that WT Adx mice have an ASR that is identical in intensity to the one of WT mice. Since corticosterone inhibits Osteocalcin expression, WT Adx mice also display a two- to three-fold increase in circulating osteocalcin. We reasoned that if osteocalcin was sufficient to mount an ASR, the hyperosteocalcinemia of the WT Adx mice might explain why they can mount a full fledge ASR. In support of this hypothesis we observed that Ocn+/- Adx mice that yield normal circulating osteocalcin levels, could not mount an ASR. Taken together these results identify osteocalcin as a bona fide stress hormone and reveal that unlike other vertebrates, bony vertebrates use a bone-centric mode of response to an acute stress.

Mice with reduced visceral and bone marrow adipose tissue have increased bone mass Louise Grahnemo*[1], Karin L. Gustafsson[1], Klara Sjögren[1], Petra Henning[1], Vikte Lionikaite[1], Antti Koskela[2], Juha Tuukkanen[2], Claes Ohlsson[1], Ingrid Wernstedt Asterholm[3], Marie K. Lagerquist[1]. [1]Centre for Bone and Arthritis Research, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Sweden, [2]Medical Research Center, University of Oulu, Finland, Sweden, [3]Unit of Metabolic Physiology, Department of Physiology, Institute of Neuroscience and Physiology, The Sahlgrenska Academy, University of Gothenburg, Sweden

Although obesity is associated with metabolic comorbidities such as diabetes and atherosclerosis, obesity has long been thought to protect against osteoporosis, possibly due to a higher mechanical load. However, these findings are under debate since fat mass – especially visceral fat mass – has been negatively associated with bone mass. Also bone marrow adipose tissue (BMAT) has been negatively associated with bone mass; a suggested mechanism is the competitive differentiation of osteoblasts and marrow adipocytes from bone marrow mesenchymal stromal cells. To further investigate the link between fat and bone mass, we used a mouse model, the RID transgenic mice (Wernstedt Asterholm et al., Cell Metab, 2014), with reduced capacity for adipogenesis in visceral fat. We hypothesized that RID transgenic mice, compared with wild type mice, would develop reduced BMAT in response to high-fat diet (HFD), for 11 weeks, leading to increased bone mass. As expected, RID transgenic mice had reduced HFD-induced weight (-7%, P < 0.001) and fat mass (-39%, P < 0.001, determined by dual-energy X-ray absorptiometry) gain compared with controls. Furthermore, the bone marrow adiposity, as judged by histological analysis of femur, was decreased in RID transgenic mice and this finding was associated with smaller bone marrow adipocytes than in controls (-20%, P < 0.05). In line with our hypothesis, HFD-fed RID transgenic mice displayed an increased bone mass, in long bones and vertebrae, affecting trabecular and cortical parameters. For example, as determined by high-resolution micro-computed tomography, RID transgenic mice had increased percent bone volume (BV/TV) (+11%, P < 0.05) and cortical thickness (+10%, P < 0.01) in femur and increased trabecular thickness (+6%, P < 0.01) in L5 vertebra compared with controls. Furthermore, HFD-fed RID transgenic mice had an increased humeral toughness (+44%, P < 0.01), determined by 3-point bending, compared with controls. In conclusion, mice with reduced visceral and bone marrow adipose tissue have increased bone mass.

An Osteocyte Protective Metabolite, β-aminoisobutyric Acid, BAIBA Mediates Survival Signals through MRGPRD/Ca2+/CaMKKβ/AMPK pathway. Yukiko Kitase*, Lynda Bonewald. Indiana University, United States

Osteoporosis and sarcopenia are age-related diseases that frequently occur together. Evidence is accumulating for molecular crosstalk between muscle and bone that may reciprocally enhance the function of the other tissue in healthy individuals and may reduce degenerative processes with aging. We have previously shown that β-aminoisobutyric acid, BAIBA, a contracting skeletal muscle-derived metabolite, prevents bone loss induced by hindlimb unloading in mice while inhibiting osteocyte apoptosis in vivo. In vitro, L-BAIBA protects MLO-Y4 osteocyte-like cells from oxidative stress-induced cell death by preventing mitochondrial fission/depolarization (ASBMR2016). We validated that the Mas-related G-protein coupled receptor, type D (MRGPRD) mediates the protective effects of L-BAIBA by both siRNA and CRISPR/Cas9 mediated gene editing. MRGPRD is known to be coupled to the Gαq subunit that induces cytoplasmic calcium ion flux when activated. Since AMPK is critical in maintaining mitochondrial homeostasis and calcium signaling activates AMP-activated protein kinase (AMPK) via the calcium/calmodulin-dependent protein kinase β (CaMKKβ), we hypothesized that L-BAIBA activates calcium signaling pathways downstream of MRGPRD leading to activation of AMPK to protect osteocytes from oxidative stress. Pharmacological inhibition of phosphatidylinositol bisphosphate (PIP2) hydrolysis leading to inositol triphosphate (IP3)/Ca2+ release using gentamycin blocked the protective effect of L-BAIBA on cell death induced by hydrogen peroxide-mediated oxidative stress in MLO-Y4 cells, as did STO-609, a CaMKKβ inhibitor. Treatment with L-BAIBA increased phosphorylation of AMPK indicating an increase in the active form. An AMPK inhibitor, compound C, inhibited L-BAIBA protective effects while the AMPK activator, AICAR, protected MLO-Y4 from oxidative stress-induced cell death. Together these data suggest that the muscle-derived factor, L-BAIBA works to protect osteocytes from cell death induced by oxidative stress through binding to the MRGPRD receptor which leads to stimulation of calcium release followed by CaMKKβ-mediated activation of AMPK. This study has revealed a novel pathway for muscle-bone crosstalk by which BAIBA, produced by exercising muscle, has beneficial effects on osteocyte survival.

Fam210a is a Novel Determinant of Bone and Muscle Ken-Ichiro Tanaka*[1], Yingben Xue[1], Loan Nguyen-Yamamoto[1], John A Morris[2], Ippei Kanazawa[3], Toshitsugu Sugimoto[3], Simon S Wing[4], J Brent Richards[2], David Goltzman[1]. [1]Calcium Research Laboratory, Metabolic Disorders and Complications Program, Research Institute of the McGill University Health Centre, Canada, [2]Departments of Medicine, Human Genetics, Epidemiology and Biostatistics, McGill University, Jewish General Hospital, Canada, [3]Internal Medicine 1, Shimane University Faculty of Medicine, Japan, [4]Division of Endocrinology, Department of Medicine, McGill University, Canada

Background: Osteoporosis and sarcopenia are common comorbid diseases, however their shared mechanisms are largely unknown. Genome-wide association studies (GWAS) in humans have identified SNPs intronic to FAM210A (family with sequence similarity 210, member a), which are strongly associated with the risk of fracture, but less or with decreased bone mineral density (BMD) [Nat Genet 2012]. Although Fam210a is expressed in a variety of tissues involving muscle, the skeletal function of Fam210a remains unknown. Methods: We investigated the effect of FAM210A on bone and muscle using human genetic association data and Fam210a knockout mice. We first examined whether SNPs mapping to FAM210A were associated with bone and muscle traits in adults and children. Next, we examined phenotypes of two-month-old tamoxifen-inducible Fam210a knockout (TFam210a-/-) and tamoxifen-inducible Fam210a muscle-specific knockout (TFam210aMus-/-) mice. The expression and localization of Fam210a were investigated using X-gal staining and immunofluorescence. Their BMD, biomechanical strength, bone micro-architecture using micro-computed tomography (μCT), bone formation, osteoclast activity, grip strength, and limb lean mass were evaluated. Microarray analysis of muscle cells from TFam210aMus-/- mice was performed. Results: We found that genetic variation near FAM210A was associated, through large-scale GWAS studies, with fracture, BMD, and appendicular and whole body lean mass, in humans. In mice Fam210a was localized to muscle mitochondria and cytoplasm, as well as in heart and brain, but not in bone. Grip strength and limb lean mass were reduced in TFam210a-/- mice and TFam210aMus-/- mice. Decreased BMD, bone biomechanical strength and bone formation, and elevated osteoclast activity with micro-architectural deterioration of trabecular and cortical bones, were observed in TFam210a-/- mice. BMD of male TFam210aMus-/- mice was also reduced and osteoclast numbers and surface in TFam210aMus-/- mice were increased. Microarray analysis of muscle cells from TFam210aMus-/- mice identified candidate musculoskeletal modulators involving MMP-12. Conclusions: Fam210a has a crucial role in regulating bone structure and function, and may impact osteoporosis through a biological pathway involving muscle as well as through other mechanisms. Funding Support: the Canadian Institutes of Health Research (CIHR), MSD Life Science Foundation, Public Interest Incorporated Foundation, The Uehara Memorial Foundation, Mochida Memorial Foundation and by a Richard and Edith Strauss Postdoctoral Fellowship in Medicine from the Research Institute of the McGill University Health Centre

FRI-0139

The direct transdifferentiation of tendon cells into bone cells during bone modeling and remodeling Ke Wang*[1], Chi Ma[1], Minghao Zheng[2], Xiaohua Liu[1], Jian Feng[1], Yan Jing[1]. [1]Texas A&M University College of Dentistry, United States, [2]The University of Western Australia, Australia

For many years, bone is considered to be exclusively formed by its own cells, whereas tendon is thought to assist muscles in body movement. The purpose of this study is to test the direct transdifferentiation of tendon cells into bone. First, we demonstrated that in addition

to long fibrous tendons (commonly observed in literature), there are many mini-tendons that attach muscles to bone, resulting in a huge contact area between tendon and rough/uneven bone compared to smooth and even bone that has no tendon attachment (Fig 1). In these massive junction areas, the histological analyses showed unique features in cell distribution pattern, cell shape, and gene expression profiles (such as high levels of Periostin, Vimentin, Biglycan, DMP1, and Col I) that differ from the non-tendon-attached bone. To address mechanical responses, we applied open-coil springs anchored on miniscrew implants in dog tibia with a force of 0g and 200 g separately. Sixty-day loading resulted in more robust new bone formation in the tendon-bone junction (including more osteons; Fig2a) compared to the periosteum-attached bone(Fig2b). Cell lineage tracing using Gli1-CreERT2-tdTomato mice (induced at 4-weeks old, harvested@5-, 6-, and 7-weeks, separately) displayed strong Gli1+ tendon cells mainly at the tendon-bone junction (including both long and short tendon cells) surrounded by strong aggrecan+ matrices. Initially, there were few red bone cells in the bone underneath. Later, however, more and more red bone cells are observed, which are co-localized with Runx2 and cartilage (aggrecan) and tendon (vimentin) markers (Fig 3), confirming that tendon cells directly transdifferentiate into bone cells. Interestingly, in the 3.2 Col 1-Cre-tdTomato mice (induced and harvested at the same time-frame as the Gli1 tracing line) many more red bone cells are identified in the tendon-bone junction, which are also co-localized with the above cartilage, tendon and bone markers. Furthermore, we used 2.3 Col 1-GFP young adult mice labeled with Alizarin Red for 4 hours to define a relationship between tendon, tendon-derived bone, and mineralization. Non-decalcified frozen confocal imaging revealed that those GFP+ tendon cells form bone cells, and that neither GFP+ tendon cells nor GFP+ osteoblast cells deposit mineral, whereas GFP+ osteocytes do. Thus we propose that the tendon-derived bone cells contribute to bone formation in the tendon-bone attached area, and directly respond to mechanical response.

Low bone mass and high marrow adiposity in congenic 6T mice are related to shifts in metabolic flexibility within the bone marrow niche. Sheila Bornstein*, Clifford Rosen, Victoria Demambro, Anyonya Guntur, Makoto Fujiwara. Maine Medical Center Research Institute, United States

C3H/HeJ mice have both high bone marrow adipose tissue (MAT) and BMD compared to B6. We made a congenic mouse, B6.C3H.6T (6T), with an inversion on mouse Chr6 from C3H, and backcrossed it into B6Bm (100%BL/6J) ten generations. 6T male and female mice on a high fat diet (HFD) had high BMAT but low trabecular BV/TV and reduced bone formation. We hypothesized that skeletal differences between B6Bm and 6T were related to altered metabolic regulation from genes near or at the inversion site (Chr 6 at ~ 120MB). To test that hypothesis, we measured body composition in B6Bm and 6T, energy expenditure (EE) on a 13 week regular (LFD) or HFD. We measured whole tibia bone + marrow gene expression (tibial MGE) and cultured bone marrow MSCs from both strains under adipogenic conditions. On a LFD, 16-week old male 6T and B6Bm mice had similar body weights and fat mass, but 6T had greater lean mass, higher RQ, greater daytime EE and were more active. There were no differences in aBMD or trabecular BV/TV between 6T and B6Bm on a LFD. But, on a HFD, 6T gained more weight and fat mass than B6Bm (p<0.0001). Similarly, femoral BV/TV in 6T was 50% lower than B6Bm (p<0.03) and had reduced cortical thickness and enhanced cortical porosity (p<0.006). On a HFD, tibia MGE revealed markedly reduced Sp7, Ocn, Sost, Runx2, and Rankl in 6T vs. B6Bm. 6T BMSCs showed enhanced adipogenic differentiation vs. B6 by Oil Red O staining and was associated with a 1.5 fold increase in Pparg, AdipoQ, and Ccrn4l. Two key regulatory factors for adipogenesis were markedly altered in tibia MGE on a HFD. Aebp1 which promotes adipogenic proliferation and inhibits differentiation, was lower in 6T vs B6Bm (p<0.004). And, Bcl2l13 mRNA, a mitophagy receptor that regulates mitochondrial fission was lower in 6T compared to B6Bm (p<0.001). Consistent with less mitochondria in 6T on a HFD there was lower Pdk4 (pyruvate dehydrogenase kinase 4) than B6Bm, (p=0.007); PDK4 is a mitochondrial enzyme that regulates metabolic flexibility by shifting metabolism from fatty acid to glucose oxidation. In sum, Bcl2l13 and Pparg, two genes located on either side of the Chr 6 inversion exhibited altered regulation and likely play a key role in the skeletal differences between 6T and B6 on a HFD. Metabolic flexibility, i.e. switching from fatty acid to glucose oxidation reflected by gene expression and energy expenditure could lead to impaired bone formation, lower bone mass and greater MAT in the congenic 6T.

Activation of β-catenin signaling in mature osteoblasts versus osteoblast progenitors defines a transcriptional and mutational profile for the transformation of MDS to AML Álvaro Cuesta-Domínguez*[1], Ioanna Mosialou[1], Junfei Zhao[2], Akihide Yoshimi[3], Konstantinos Panitsas[4], Richard A. Friedman[5], Omar Abdel-Wahab[3,6], Raúl Rabadán[7], Stavroula Kousteni[1]. [1]Department of Physiology and Cellular Biophysics, College of Physicians and Surgeons, Columbia University Medical Center, United States, [2]Department of Systems Biology, Columbia University Medical Center, United States, [3]Human Oncology and Pathogenesis Program, Memorial Sloan Kettering Cancer Center, United States, [4]Department of Physiology and Cellular Biophysics, College of Physicians and Surgeons, Columbia University, United States, [5]Biomedical Informatics Shared Resource, Department of Biomedical Informatics, Herbert Irving Comprehensive Cancer Center, College of Physicians and Surgeons, Columbia University Medical Center, United States, [6]Weill Cornell Medical College and Leukemia Service, Dept. of Medicine, Memorial Sloan Kettering Cancer Center, United States, [7]Department of Systems Biology and Department of Biomedical Informatics, Columbia University Medical Center, United States

A growing body of evidence indicates that osteoblasts have a pathogenetic role in the development of myelodysplasia (MDS), acute myeloid leukemia (AML) and transformation of MDS to AML. β-catenin activation in osteoblasts induces MDS progressing to AML in mice and is seen in more than 30% of MDS and AML patients. To examine whether the stage of osteoblast differentiation influences disease development or progression, we constitutively activated β-catenin in mature osteoblasts (βcat(ex3)OCN mice) and osteoblast progenitors (βcat(ex3)2.3Col1a1 mice). βcat(ex3)2.3Col1a1 mice develop MDS which rapidly transforms to AML characterized by multi-organ infiltration with myeloid blasts, hematopoietic deregulation and lethality by 6 weeks of age. However, βcat(ex3)OCN mice presented with thrombocytopenia, anemia and lymphocytopenia along with dysplasia in the erythroid and megakaryocyte lineage in the blood and bone marrow, and although they never developed more than 10% of blasts in the marrow they die by 6 weeks of age. These characteristics indicate the development of MDS in βcat(ex3)OCN mice. In agreement with this diagnosis, high throughput, targeted-DNA-sequencing of CD11b+/Gr-1+ myeloid cells from βcat(ex3)OCN mice, identified in-frame deletions in the histone methyltransferases Kmt2d and Setd1e, missense mutations in Cux1 and Braf splice site (previously reported in human MDS) and in the Fanconi anemia complementation group A (FancA) gene associated with defective DNA repair. RNA-seq analysis revealed that genes related to cell cycle (cycD), insulin signaling (InsR, Rtk, Shc) and the oncogene c-myc regulatory cascade (Jund, Ccnd2, Max, Ddx3x and Id2) were potently upregulated in LSK cells from βcat(ex3)OCN mice.

Spliceosome regulators Srsf5 and Prpf8 were downregulated in βcat(ex3)OCN LSK versus wild type LSK cells. Interestingly, spliceosomal mutations are the most common genetic alterations in patients with MDS. In addition, expression of the methyltransferases Kmt2a, Kmt2b and Ash1, which induce MLL rearrangement in AML, was increased in LSK cells from leukemic βcat(ex3)23Col1a1 mice as compared to LSK cells from MDS βcat(ex3) OCN mice. Notably, spliceosomal deregulation, as seen in LSK cells of βcat(ex3)OCN mice, is highly associated with MLL-rearranged AML, suggesting that increased expression of Kmt2a, Kmt2b and Ash1 may be crucial in the transformative mechanism leading from MDS in βcat(ex3)OCN mice to AML in βcat(ex3)2.3Col1a1 mice.

FRI-0171

Pharmacological Targeting of Osteoblast-Induced MDS and AML Ioanna Mosialou*, Marta Galan-Diez, Andrew Vandenberg, Abdullah Ali, Azra Raza, Stavroula Kousteni. Columbia University, United States

The bone marrow hematopoietic stem cell niche has emerged as a regulator and instigator of hematological myeloid malignancies. Activation of b-catenin signaling in osteoblasts, by deletion of exon3 or by inactivating mutations in APC, induces myelodysplasia (MDS), rapidly progressing to acute myeloid leukemia (AML) in mice. Activated b-catenin signaling is present in osteoblasts of one third of MDS and AML patients and it is the most active pathway in stromal cells of MDS patients suggesting that it may sustain dysplastic hematopoiesis and progression to MDS and AML in humans. Therefore, targeting this pathway may provide a new therapeutic approach for this subgroup of MDS/AML patients. To examine this hypothesis we searched for an FDA-approved compound with the ability to inhibit b-catenin signaling and identified all-trans-retinoic acid (ATRA) as a potential candidate. We show here that treatment of osteoblastic cells with ATRA inhibits the induction of b-catenin target genes by Wnt3a and abrogates nuclear localization of b-catenin, as shown by immunohistochemistry and western blot analysis. These effects are mediated by the retinoic acid receptor a (RARa) since silencing RARa, but not RARb or RARg, in osteoblasts abolishes the inhibitory effect of ATRA on Wnt3a-induced b-catenin signaling. Similarly, treatment of leukemic mice expressing constitutively active b-catenin in their osteoblasts with ATRA, inhibited b-catenin signaling as measured by expression of its target genes Axin2 and Lef1 in bone. At the same time, ATRA improved anemia and thrombocytopenia, decreased the percentage of blasts in bone marrow and blood and prolonged overall survival in these leukemic mice as compared to vehicle-treated mice. The response to ATRA treatment of two MDS patients with active b-catenin in their osteoblasts, and not responding to other treatments, was monitored. The hematologic phenotype of the patients improved and disease status stabilized so that patients remain transfusion independent and disease-related symptom-free with a good quality of life thereafter. The improvement in disease status coincided with absence of b-catenin in the nucleus as flow cytometry analysis showed a high percentage of patient osteoblasts expressing activated b-catenin in pre-therapy samples but not in on-therapy samples. These results suggest that ATRA may find a new use in the treatment of the specific portion of MDS/AML patients with activated b-catenin in their osteoblasts.

Single-cell proteomics reveal bone marrow stromal cell drivers of blood regeneration Nicolas Severe*[1], Murat Karabacak[2], Karin Gustafsson[1], Ninib Baryawno[1], Gabriel Courties[1], Youmna Kfoury[1], Elizabeth Scadden[1], Matthias Nahrendorf[1], Mehmet Toner[2], David Scadden[1]. [1]Massachusetts General Hospital, United States, [2]Shriners Hospital for Children, United States

The relationship between bone and blood is ancient in evolutionary terms. All animals since the divergence of fish that have both bones and blood, make blood in their bones. This long history of co-evolution has led to complex interrelationships that are still being defined. The non-hematopoietic compartment, also called stroma, is increasingly recognized as a regulator of hematopoietic stem and progenitor cells (HSPCs) function, but its cellular complexity remains poorly defined. Mass Cytometry (CyTOF) permits quantitation of up to 40 proteins simultaneously at single-cell resolution, thus enabling multi-dimensional analysis of the bone marrow stromal compartment.Using this approach, we identified 28 distinct populations of mouse bone marrow stromal cells. To define the potential hematopoietic relevance of specific clusters of bone marrow stromal cells, we analyzed their cytokine profile enabling us to select 14 candidate clusters. In addition, assessing the response of these groups to systemic challenges of medical relevance, we evaluated cells prior to whole body lethal irradiation and one day later (the time of bone marrow transplantation). We showed that most bone marrow stromal cells were damaged by radiation. Only 3 clusters preserved their cell number despite irradiation and each expressed the extracellular ecto-5'-nucleotidase, CD73. In order to further explore the function of the adenosine-producing enzyme CD73, we used a CD73-knockout mouse model and found that CD73 expressed by stromal cells is a functional driver of HSPCs engraftment and blood regeneration. Furthermore, cytokine profiling analysis one day post-irradiation reveals a unique cluster of CD73+ persisting cells, producing higher level of hematopoietic niche factors, that can be defined by NGFRhigh expression and support hematopoiesis ex-vivo.These data demonstrate that using single-cell multi-dimensional protein analysis with sequential steps of filtering based on cytokine profiling and resistance to radiation enables identification of novel subset of bone

marrow stromal cells capable of regulating HSPCs transplantation and blood regeneration, mediated in part by an interesting adenosine-producing mechanism.

ERRa in primary breast tumours promotes tumour cell dissemination to bone by regulating RANK Geoffrey Vargas*[1], Mathilde Bouchet[2], Casina Kan[3], Claire Benetollo[4], Martine Croset[1], Martine Mazel[5], Laure Cayrefourcq[5], Sophie Vacher[6], Francesco Pantano[7], Keltouma Driouch[6], Ivan Bieche[6], William Jacot[5], Jane Aubin[8], Catherine Alix-Panabieres[5], Philippe Clezardin[1], Edith Bonnelye[1]. [1]INSERM-U1033, France, [2]ENS-Lyon, France, [3]INSERM U1033, Australia, [4]INSERM U 1028-CNRS UMR 5292-UCBL Lyon 1, France, [5]Institut Universitaire de Recherche Clinique (IURC)- Montpellier, France, [6]Institut Curie, France, [7]University Campus Bio-Medico-Roma, Italy, [8]University of Toronto, Canada

Bone is the most common metastatic site for breast cancer. Because Estrogen-Related-Receptor alpha (ERRα) has been implicated in cancer cell invasiveness and bone metastasis progression, we determined whether ERRα expression in primary breast tumours could modulate the molecular mechanisms that drive breast cancer cell dissemination to bone. In breast cancer patients, we showed that high ERRα expression level in primary tumours (n=295) was associated with relapse to bone but not to lungs. ERRα expression was also detected in the circulating tumour cells from metastatic breast cancer patients. Using a murine 4T1 breast cancer cell line that spontaneously metastasizes to lung and bone when inoculated orthotopically to animals, we found that ERRα overexpression in 4T1 cells (4T1-ERRα) promoted spontaneous bone micro-metastasis formation whereas lung metastasis formation remained unchanged. RANK was identified as an ERRα regulated gene in 4T1-ERRα primary tumours both as transcriptomic and protein levels. Concomitantly, we showed that RANKL stimulated 4T1-ERRα cells migration as well as the phosphorylation of mTOR in vitro. In line with these data, RANK was up-regulated in human MCF7 breast cancer cells overexpressing ERRα. A positive correlation was also observed between high ERRα/RANK expression levels in primary tumours from patients with breast cancer (n=446) and occurrence of bone metastases (n=248). Furthermore, in order to determine whether inhibition of ERRα abrogates primary tumour outgrowth and tumour cell dissemination to bone, the pharmacological effect of the ERRα inverse agonist C29, which is known to block ERRα transcriptional activity, was studied. We first showed that C29 inhibited RANK mRNA expression in 4T1 and MCF7 breast cancer cells in vitro. Then, 4T1-ERRα cells were inoculated orthotopically and mice were treated with the C29. Reinforcing our data, we found that the pharmacological inhibition of ERRα reduced primary tumour growth, bone micro-metastasis formation in vivo, and decreased RANK expression in situ. In conclusion, our results reveal a novel ERRα/RANK axis through which ERRα in primary breast cancer promotes dissemination of tumour cells to bone. We propose that ERRα may be a useful biomarker to identify breast cancer patients at high risk of relapse in bone.

S100A4 Released from Highly Bone-metastatic Breast Cancer Cells Plays a Critical Role in Osteolysis Haemin Kim*[1], Sang Il Kim[2], Hyung Joon Kim[3], Brian Y. Ryu[2], Junho Chung[2], Zang Hee Lee[2], Hong-Hee Kim[2]. [1]Hospital for Special Surgery, United States, [2]Seoul National University, Republic of Korea, [3]Pusan National University, Republic of Korea

Bone metastasis affects more than 80% of patients with breast cancer at advanced stages of the disease and causes severe pain, fracture, hypercalcemia, and nerve compression, leading to increased morbidity and mortality. Communication between cancer cells and skeletal cells in metastatic bone microenvironments is a principal element that drives tumor progression and osteolysis. In this communication, tumor-derived factors play fundamental roles. To identify key molecules associated with breast cancer bone metastasis, we analyzed the gene expression profiles of the bone-metastatic MDA-MB-231 (MDA) and the nonmetastatic MCF7 breast cancer cell lines. Among the genes that were highly differentially expressed, the signal for S100A4 was higher in the MDA than in the MCF7 cell line. Furthermore, a search of NCBI GEO microarray data sets of tumor samples from 65 breast cancer patients (GSE 14020) revealed a significantly higher expression of S100A4 in bone-metastasized tumors than in tumors metastasized to other organs. To further validate in vivo relevance in an animal model of bone metastasis, we established a highly bone-metastatic subline of MDA by utilizing the in vivo selection method previously described. Briefly, MDA cells were injected into the left ventricle of immune-deficient mice and collected from bones after eight weeks. The in vivo selection method was repeated twice to obtain more homogenous bone metastatic MDA population. This subline (mtMDA) showed a markedly elevated ability to secrete S100A4 protein than its parental partner, which directly stimulated osteoclast formation via the receptor for advanced glycation end products. Recombinant S100A4 stimulated osteoclastogenesis in vitro and bone loss in vivo. Conditioned medium from mt-MDA in which S100A4 was knocked down had a reduced ability to stimulate osteoclasts. Furthermore, the S100A4 knockdown cells elicited less bone destruction in mice compared with the control knockdown cells. In addition, administration of an anti-S100A4 monoclonal antibody that we developed attenuated the stimulation of osteoclastogenesis and bone loss

by mtMDA in mice. Taken together, our results suggest that S100A4 released from breast cancer cells is an important player in the osteolysis caused by breast cancer bone metastasis.

Granulocyte Colony Stimulating Factor impacts on osteomacs and bone marrow macrophages – implications for prostate cancer osteoblastic lesion formation Susan Millard*, Andy Wu, Simran Kaur, Yaowu He, Lena Batoon, John Hooper, Allison Pettit. Mater Research - UQ, Australia

Macrophages are key participants in the tumor cell-environment interaction and disruption of this is being investigated as a therapeutic strategy. Both resident macrophages and recruited tumor associated macrophages (TAM) contribute to the prostate cancer (PC) bone-bone marrow (BM) environment interactions. However, it is unclear whether the numerous functionally distinct resident macrophage subsets of bone and BM have opposing roles in the evolution of PC metastasis within bone. Granulocyte colony stimulating factor (G-CSF) drives HSC mobilization and reduces endosteal bone formation indirectly via impacts on BM and osteal (osteomacs) macrophages. G-CSF is used clinically to treat neutropenia subsequent to chemotherapy and prophylactic G-CSF was recently shown to also improve response to chemotherapy. Consequently, we characterized G-CSF bone and BM macrophage population impacts in both naive mice and in the context of PC bone metastasis, modelled by growth of RM1(BM) murine PC cells in immune-competent mice. Naive C57Bl/6 mice were treated with bi-daily G-CSF (125ug/kg) or saline for up to 6 days. Histological and flow cytometric assessments were performed at day 4, 6, 8, 10 and 12. In the PC model, G-CSF treatment was initiated 1 day after intratibial injection of RM1(BM) cells and continued until harvest at day 7. Flow cytometry confirmed expansion of F4/80-Ly6G+ granulocytes (neutrophils) and collapse of the F4/80+Ly6G+ macrophage subset during G-CSF treatment of non-tumor bearing mice. Monocytes (F4/80+Ly6G-CD115hi) were increased by more than 2-fold and Ly6C+ macrophages (F4/80+Ly6G-CD115loLy6C+) were increased by 3-fold at the expense of Ly6C- macrophages which decreased by 6-fold. In non-tumor bearing mice G-CSF treatment resulted in loss of F4/80+ endosteal osteomacs, which was accompanied by loss of endosteal osteoblasts, suggestive of osteomacs being capture within either the F4/80+Ly6G+ or Ly6C- macrophage subsets. Interestingly within G-CSF treated tumor-bearing limbs, F4/80+ resident macrophages in adjacent BM were reduced but TAM were minimally affected. Tumor-associated woven bone formation was reduced more than 2-fold in G-CSF treated animals compared to saline-treated controls (p<0.05), but there was no impact on tumor growth. These observations support the PC osteoblastic response occurs through tumor-mediated subversion of normal osteomac function rather than a de novo pathological mechanism driven by either the tumor or TAM.

Serum levels of RANKL are increased in primary breast cancer patients in the presence of disseminated tumor cells in the bone marrow. Tilman Rachner*[1], Martina Rauner[2], Andy Göbel[2], Oliver Hoffmann[3], Lorenz Hofbauer[2], Rainer Kimmig[3], Sabine Kasimir-Bauer[3], Ann-Kathrin Bittner[3]. [1]Universitätsklinik Dresden, Germany, [2]University Hospital Dresden, Germany, [3]University Hospital Essen, Germany

Background: Receptor activator of nuclear factor kappa-B ligand (RANKL) is an essential protein for osteoclast regulation that is associated with benign and malignant bone disease. The activity of RANKL is controlled by its soluble decoy receptor osteoprotegerin (OPG). There is increasing evidence that RANKL may also directly affect breast cancer progression and metastasis to bone. This study was aimed to assess the levels of RANKL and OPG in 509 newly diagnosed breast cancer patients with regard to the presence of disseminated tumor cells (DTCs) in the bone marrow (BM), circulating tumor cells (CTCs) in blood and clinical parameters.Patients and Methods: 509 patients with first diagnosis of breast cancer between Aug 2006 and Dec 2009 were included in our study. Blood and BM sampling was performed before surgery in an adjuvant setting. Blood was collected from each patient and sRANKL and OPG in the serum was measured by ELISA (Biomedica, Vienna, Austria). Two BM aspirates were analyzed for DTCs by immunocytochemistry using the pan-cytokeratin antibody A45-B/B3. In a subgroup of 364 patients, 2 x 5 ml blood was studied for CTCs using the AdnaTest BreastCancer (AdnaGen AG, Hannover, Germany) for the detection of EpCAM, MUC-1, HER-2, and beta-Actin transcripts.Results: Mean serum values for RANKL and OPG were 0.23±0.20 pmol/l and 4.24±1.70 pmol/l, respectively. RANKL levels were significantly lower in women above 60 years of age (0.19 pmol/l vs 0.26 pmol/l; p < 0.0001). This finding was reflected by higher RANKL serum levels and RANKL/OPG ratios in premenopausal patients compared to peri- (p<0.05) and postmenopausal patients (p<0.001), respectively. RANKL/OPG ratios were also higher in patients with lymph node involvement (N1-N3, p=0.03). All other clinical parameters did not influence RANKL or OPG levels. DTCs were detected in 213/509 (42%) patients and CTCs in 81/364 (22%) patients, respectively. However, while RANKL levels were unchanged in patients with detectable CTCs, they significantly increased by 33% (p<0.0001) in patients with DTCs. There was no difference in OPG levels, resulting in an increased RANKL to OPG ratio in patients with DTCs in the bone marrow (0.087 vs. 0.060; p < 0.0001)Conclusion: In conclusion, we show that RANKL serum levels and RANKL/OPG ratios are increased in patients with detectable DTCs in the BM, prior to the establishment of detectable bone metastases. This

finding warrants further investigation as it may provide a rational for novel diagnostic or therapeutic approaches.

Suppression of Breast Cancer Bone metastasis by Osteocytic Connexin Hemichannels, a Potential Therapeutic Target Manuel Riquelme*[1], Sumin Gu[1], Zhiqiang An[2], Jean Jiang[1]. [1]Department of Biochemistry and Structural Biology, University of Texas Health Science Center at San Antonio, United States, [2]Brown Foundation, Institute of Molecular Medicine, UT Health Houston, United States

Bone is the most preferred site for metastasized breast cancer cells. Osteocytes consist of over 95% of bone cells and play a central role in coordinating the bone formation, re-modeling and extracellular environment composition. Mechanical stimulation induces the opening of osteocytic hemichannels formed for connexin43 (Cx43), which mediates the communication between the intracellular and extracellular space. These channels are perme-able to molecules like ATP, PGE2, glutamate and others. It has been shown that mechanical loaded tibias inhibit intratibial breast cancer growth. Additionally, we have shown that ATP, released by osteocytic hemichannels through the activation of tumor P2X7 receptor, inhibits cancer cell growth and migration. In this study, we determined if Cx43 hemichannels are a potential therapeutic target for treatment of breast cancer bone metastasis and the un-derlying inhibitory mechanism of ATP. Mechanical loading reduced tumor growth in mice. Interestingly, tumor growth was reduced in osteocyte-specific transgenic mice expressing Cx43R76W, a dominant negative mutation that blocks gap junctions with the enhancement of Cx43 hemichannels. However, mechanical loading increases tumor growth and this in-crease was inhibited with Cox-2 inhibitor, which blocks prostaglandin synthesis. This data suggest that increased prostaglandin synthesis by mechanical loading associated with exac-erbated activity of hemichannels promotes tumor growth. Our lab develops a monoclonal antibody (MC2), which binds to extracellular domain of Cx43 and increases the activity of osteocytic hemichannels in vitro and in vivo. This antibody was immune-reactive in HeLa cells transfected with Cx43, osteocytic MLO-Y4 cells and mouse osteocytes in situ. The weekly injection of MC2 reduced the breast cancer growth in the WT mouse tibia, but not in osteocyte-specific Cx43 knockout mice. As is known, osteocytes Cx43 hemichannels are permeable to ATP. P2X7 specific agonist benzoyl ATP reduced in vitro breast cancer cell mi-gration, increased cytoplasmic free Ca2+ and induced formation of tubulin bundles, indica-tor of cytoskeleton reorganization. The effect of benzoyl ATP required functional CamKII to elicit these phenomena. Our results suggest that Cx43 hemichannels are likely a new target for treating breast cancer, probably through the enhancement of the extracellular ATP levels and the activation of P2X7/CamKII axis to inhibit breast cancer bone growth and metastasis.

HDAC inhibitors directly stimulate LIFR and induce pro-dormancy effects in breast cancer cells Miranda Sowder*[1], Lauren Holtslander[1], Vera Mayhew[1], Samuel Dooyema[1], Rachelle W. Johnson[2]. [1]Vanderbilt University, United States, [2]Vanderbilt University Medical Center, United States

Breast cancer cells often metastasize to the bone, where they may remain dormant for years. Our laboratory previously found that loss of leukemia inhibitory factor recep-tor (LIFR) in breast cancer cells results in poor patient survival and tumor cell exit from dormancy in the bone marrow. Based on our previous finding that the histone deacetylase (HDAC) inhibitor (HDACi) valproic acid (VPA) promotes LIFR expression in breast can-cer cells, we hypothesized that HDACi (romidepsin, panobinostat, vorinostat, entinostat) can be used to directly stimulate LIFR through histone acetylation on the LIFR promoter and maintain tumor cell dormancy. HDACi dramatically induced LIFR mRNA (up to 9.5-fold, p<0.05-0.0001) and protein levels by 24 hours in breast cancer cells with low (MCF7, SUM159, D2.0R) and high (MDA-MB-231b, D2A1, 4T1BM2) metastatic potential. MCF7 cells treated with HDACi showed enrichment of acetylated-H3K9 on the LIFR promoter (up to 10.9-fold, p<0.05-0.001), indicating that HDACi directly stimulate LIFR transcrip-tion. HDACi also induced other pro-dormancy genes including AMOT and TGFB2 (up to 5.5-fold, p<0.05-0.0001) independent of LIFR, but did not enhance promoter acetylation, suggesting indirect regulation by HDACi. MCF7 cells labeled with CellTrace Violet prolif-eration dye showed increased dye retention following 8 days of HDACi treatment (4.1-fold, p=0.019), with similar results observed in MDA-MB-231b cells, indicating that HDACi slow tumor cell proliferation. We next investigated LIFR expression in a dataset of prima-ry breast tumors (n=20; Accession: GSE83530) before and after 8 days of VPA treatment. Patients with increased peripheral blood histone acetylation, an indicator of therapeutic effi-cacy, showed increased LIFR levels in the primary tumor (p=0.0513) compared to patients with unchanged/decreased acetylation levels. To determine whether HDACi promote tumor dormancy in vivo, mice were treated with VPA (~2mg/kg; 3x/wk) following intracardiac in-oculation of MCF7 cells, but no significant difference in tumor-induced osteolysis or tumor burden was observed. However, VPA-treated naïve mice exhibited a significant decrease in bone volume (1.3-fold, p=0.037), suggesting that VPA negatively impacts bone remodeling and should be combined with a bone protective agent. Together, our results indicate that

HDACi slow breast cancer cell proliferation and may be therapeutically useful to maintain tumor cells in a chronic dormant state.

Pharmacological Inhibition of Sclerostin Protects From Breast Cancer-induced Osteolytic Disease and Muscle Weakness Eric Hesse*, Saskia Schröder, Diana Zarecneva, Jenny Pamperin, Hiroaki Saito, Hanna Taipaleenmäki. Molecular Skeletal Biology Laboratory, Department of Trauma, Hand and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Germany

Patients with breast cancer bone metastases present with osteolytic lesions and often suffer from muscle weakness. Current treatment includes chemotherapy, irradiation and anti-resorptive drugs that restrict bone destruction. Although patients benefit from these therapies, the disease remains irreversible and additional treatments are needed. Recent evidence suggests a role of the Wnt inhibitor sclerostin in cancer-induced bone disease. We therefore hypothesized that targeting sclerostin in metastatic breast cancer may restrict disease progression and restore muscle function. In support of this hypothesis, we deter-mined a significantly higher sclerostin expression in metastatic MDA-MB-231 breast cancer cells (BCCs) compared to non-metastatic MCF-7 BCCs. Osteoblast differentiation and the activity of Wnt signaling in osteoblasts was inhibited by conditioned medium (CM) from MDA-MB-231 BCCs in a dose-dependent manner. Repression of Wnt activity by CM was partially abolished upon antagonizing sclerostin in BCCs using siRNA. Reduction of scle-rostin expression in BCCs also restricted cancer cell migration. This indicates that BCC-de-rived sclerostin impairs bone formation but supports metastatic features. To test whether sclerostin inhibition restores osteoblast function and attenuates metastatic breast cancer, MDA-MB-231 BCCs stably expressing the luciferase gene were delivered by cardiac in-jection in female SCID mice and metastases were allowed to form prior to treatment with vehicle or anti-sclerostin antibody (Scl-Ab, 100 mg/kg). Weekly bioluminescence imaging revealed a reduced growth of bone metastases in Scl-Ab-treated mice compared to controls. Inhibition of sclerostin did not change the abundance of BCCs at extra-skeletal sites, indi-cating that BCCs did not relocate to other organs. In addition, sclerostin inhibition prevented breast cancer-induced bone destruction determined by microCT and histological analyses. Interestingly, although Scl-Ab treatment had no effect on muscle function in naïve mice, it protected from cancer-induced reduction of muscle fiber area and loss of muscle function in tumor-bearing mice, and expanded the life span of these animals. In summary, our data demonstrate that pharmacological inhibition of sclerostin reduces bone metastatic burden and reliefs from the suppression of bone formation and muscle weakness with a potential future implication in treating musculoskeletal complications in breast cancer patients.

DDRGK1, an essential component of the ufmylation process, regulates osteochondroprogenitor fate determination Yangjin Bae*, Adetutu Egunsola, Monika Weisz-Hubshman, Ming-Ming Jiang, Brendan Lee. Baylor College of Medicine, United States

DDRGK1 has been identified as a novel substrate of ufmylation process, a post-trans-lational modification mediated by one of ubiquitin-like proteins. The physiological role of DDRGK1 is varied in multiple tissue types based on others' studies. Moreover, our recent study underscored the critical role of DDRGK1 in cartilage. In brief, we uncovered ho-mozygous mutation of DDRGK1 as a causative mutation of one of rare form of chondro-dysplasia, Shohat-type SEMD (spondyloepimetaphyseal dysplasia). We demonstrated that DDRGK1 loss-of-function mutation led to defects in cartilage development in zebrafish. Furthermore, Ddrgk1-/- mutation was embryonic lethal (E11.5) in mice and also resulted in delayed chondrogenic mesenchymal condensation in the limb buds. Mechanistically, we showed that DDRGK1 forms a complex with SOX9 and inhibits ubiquitination-mediated proteasomal degradation of SOX9. Hence, our discovery of DDRGK1 as a causative gene in Shohat-type SEMD provides unprecedented evidence that ufmylation may be required for proper chondrogenesis. Here, to elucidate the cartilage-specific role of DDRGK1, we generated Prx1-Cre; Ddrgk1f/f mice, where Ddrgk1 is deleted in limb bud mesenchymal cells. Unlike Ddrgk1-/- mice, Prx1-Cre; Ddrgk1f/f mice survive. We observed progressive shortening of the limbs with an abnormal growth plate phenotype in Prx1-Cre; Ddrgk1f/f mice compared to Ddrgk1f/f mice. The typical columnar structure of chondrocytes in the proliferating zone in Prx1-Cre; Ddrgk1f/f mice was mildly disrupted, with shortening of the proliferating zone, while the hypertrophic zone was elongated and also disorganized. Fur-thermore, we performed RNA-seq analysis from the limb buds of Prx1-Cre; Ddrgk1f/f and Ddrgk1f/f mice (E13.5). Among the Top Canonical Pathways affected, Role of Osteoblasts, Osteoclasts and Chondrocytes in Rheumatoid Arthritis was significantly regulated (p-val-ue=1.43E-0.3) based on the Ingenuity Pathway Analysis (IPA) of differentially expressed genes (adj. p value <0.05). Consistent with the IPA result, we found that osteoblast-specific genes such as Alp and Col1a1 were upregulated in the limb buds of Prx1-Cre; Ddrgk1f/f by qRT-PCR analysis. These preliminary data suggest that the loss of DDRGK1 in early mesen-

chymal progenitor cells promotes osteoblastic lineage fate determination. The investigation of DDRGK1 role in osteochondroprogenitor fate determination is underway.

The role of mitochondrial dysfunction in the development of post-traumatic osteoarthritis Katherine Escalera-Rivera*, Sarah Catheline, Roman Eliseev, Jennifer Jonason. University of Rochester, United States

Osteoarthritis (OA), a debilitating degenerative joint disease characterized by an irreversible loss of articular cartilage, is currently the most common cause of chronic disability in adults. Among the most important risk factors associated with the onset of OA is prior traumatic joint injury. The molecular mechanisms underlying onset and progression of post-traumatic OA (PTOA), however, are still unclear. While mitochondrial dysfunction plays a causative role in a number of degenerative processes following traumatic injury, a relationship between mitochondrial dysfunction and PTOA has not yet been established. Using electron microscopy, we find a greater percentage of swollen mitochondria in joints subjected to meniscal/ligamentous injury (MLI) than in sham joints. Mitochondrial swelling is a consequence of mitochondrial permeability transition pore (MPTP) opening, a process that results in loss of the mitochondrial chemiosmotic membrane gradient. Cyclophilin D (CypD) is currently the only protein genetically proven to be essential for MPTP opening. To test whether inhibition of CypD/MPTP can protect against PTOA, we performed MLI in wild type (WT) C57BL/6J and age-matched CypD knockout (KO) mice and harvested knee joints 8 weeks later for histology. Histomorphometry revealed a ~50% loss of the unmineralized tibial articular cartilage in WT joints while cartilage was maintained in the CypD KO joints. OARSI scoring further revealed that the integrity of the cartilage from the CypD KO joints was significantly better than that of the WT MLI joints. To begin to elucidate the effects of MPTP opening in chondrocytes, we transfected ATDC5 chondrogenic cells with a vector encoding a constitutively active K166Q mutant of CypD (CypDCA). CypDCA expression disrupted mitochondrial membrane integrity leading to release of mtDNA into the cytosol and induction of TLR9 gene expression. Activation of NF-kB signaling as well as increases in gene expression of pro-inflammatory cytokines, TNFa and IL6, were also observed in the CypDCA cells. Our data, therefore, lead us to propose that chondrocyte mitochondrial dysfunction via MPTP opening and mtDNA-initiated damage-associated molecular pattern (DAMP) signaling causes cartilage catabolism and loss of cell viability following traumatic joint injury. We further suggest that CypD inhibition should be explored as a novel therapeutic strategy for the prevention of PTOA.

MLI leads to mitochondrial swelling in articular chondrocytes while CypD deficiency protects from MLI-induced cartilage loss. (A) WT C57BL/6J were subjected to MLI or sham surgery at 12 wks of age and tibial articular cartilage was harvested 4 wks later for EM. Arrows depict mitochondria (M). N, nucleus. (B) WT and CypD KO mice underwent MLI or sham surgery and were sacrificed 8 wks later for Safranin O/Fast Green staining. (C) Cartilage preservation in CypD KO knees was confirmed by histomorphometric analysis where MLI cartilage was normalized to corresponding sham cartilage (**$p<0.01$, Student's t-test; n=4). (D) Mouse OARSI scoring confirmed protection of CypD KO knees from MLI-induced cartilage loss. ****$p<0.0001$, *$p<0.05$ vs WT Sham; #$p<0.01$ vs WT MLI (ANOVA with Tukey's post-hoc analysis, n=5 for WT, n=4 for CypD KO).

Postnatal inactivation of Dot1L histone methyltransferase in growth plate cartilage impairs longitudinal bone growth Sangita Karki*, Rosa M. Guzzo. UConn Health, United States

Epigenetic regulation by histone modification enzymes is an important component of the regulatory mechanisms controlling skeletal growth and development. Disruptor of telomeric silencing-1 (Dot1L) is the sole histone methyltransferase that catalyzes the methylation of lysine residue 79 in histone 3 (H3K79), an established epigenetic mechanism associated with gene transcription. A recent study showed that Dot1L activity is critical for maintaining joint cartilage homeostasis, however the function of Dot1L in skeletal growth and growth

plate chondrocyte differentiation has not been thoroughly examined. Thus to evaluate the significance of Dot1L function in early postnatal skeletal development, we generated a new inducible, genetic loss of function mouse model using Dot1Lfl/fl;Aggrecan-CreERT2. Mice were injected with tamoxifen at postnatal day five, and we examined their skeletal phenotype between 3 weeks and 4 months of ages. X-ray imaging showed shortening of the long bones in mice with conditional disruption of Dot1L in growth plate cartilage (Dot1LΔ/Δ mice) by 3 weeks of postnatal development. Alcian blue staining of hindlimbs harvested from Dot-1LΔ/Δ mice revealed the presence of lesions and breaks within the cartilage growth plates of the distal femora and proximal tibia, which were not observed in control mice. To explore the molecular basis underlying the growth plate dysplasia in Dot1LΔ/Δ mice, we examined the contribution of Dot1L enzymatic activity on the transcriptional regulation of cartilage genes in vitro. Treatment of mouse primary chondrocytes with a Dot1L specific inhibitor (EPZ 5676, 10uM) resulted in global reduction of H3K79 mono- and di-methylation levels by immunoblot analyses. Quantitative PCR analyses further revealed down-regulation of cartilage genes (ie. Sox9, Col2a1) in Dot1L inhibitor-treated chondrocytes as compared to vehicle treated cells. Moreover, inhibition of H3K79 methylation in primary chondrocytes promoted a mature chondrocyte phenotype, as seen by increased type X collagen expression. Together, our data point to a critical role for Dot1L in maintaining growth plate cartilage integrity and in regulating chondrocyte differentiation during postnatal development. Our findings provide an important step toward a deeper understanding of the epigenetic mechanisms that dictate normal skeletal development, and may provide novel insights into the pathophysiology of growth plate dysplasias.

FRI-0229

Ciliary IFT80 Plays a Critical and Necessary Role in Fracture Healing through Regulating IGFβ Signaling Pathway Min Liu*[1], Mohammed Alharbi[2], Jormay Lim[1], Dana Graves[2], Shuying Yang[1]. [1]Dept. of Anatomy and Cell Biology, School of Dental Medicine, University of Pennsylvania, United States, [2]Dept. of Periodontics, School of Dental Medicine, University of Pennsylvania, United States

Rationale: Primary cilia are essential cellular organelles projecting from cell surface to sense and transduce signaling. Intraflagellar transport (IFT) proteins are indispensable for cilia formation and function. However, the precise role and mechanism of IFT protein in regulating bone repair after fracture has not been studied. In this study, we investigated the effect of conditional deletion of IFT80 in chondrocyte on fracture healing in mice. Materials and Methods: IFT80f/f mouse model, which has two LoxP sites flanking exon 6 of IFT80, has been generated in our lab. IFT80f/f mice were crossed with Col2α1-CreER mice to produce Col2α1; IFT80f/f mice. Femur fracture was performed in 12wk old mice from both Col2α1; IFT80f/f and IFT80f/f mice groups. Tamoxifen was injected at Days 3, 5, and 7 post fractures to delete IFT80 in chondrocytes. Femur samples were collected at day 9, 21 post fractures for analysis. Primary chondrocytes were isolated from IFT80f/f mice and infected with adenovirus, which overexpress either Cre or GFP. IF staining was performed to visualize cilia structure and alcian blue staining was used to detect the sulfated proteoglycan deposits. mRNA and protein levels of the markers of ciliogenesis, chondrogenesis and TGFβ signaling were measured. Results: Conditional knockout of IFT80 in chondrocytes significantly delayed the fracture healing. Col2α1; IFT80f/f mice formed smaller fracture calluses than IFT80f/f mice. Radiographic analysis revealed that fracture gap of Col2α1; IFT80f/f mice were clearly observed and partially covered mostly by low-density/porous woven bony tissue with significantly lower BV/TV, Tb-N, Tb-Th and greater Tb-Sp. In vitro study showed that IFT80 deletion dramatically reduced cell differentiation, proliferation, and cilia formation. In addition, IFT80 deletion down-regulated TGF-βI, TGF-βR, and Smad-7 mRNA expression and IF staining revealed a significant reduction of P-Smad2/3 expression in fracture callus. Similarly, primary chondrocytes failed to respond to TGFβ stimulation after IFT80 deletion. Finally, we found Foxo1 deletion up-regulated IFT80, Pcm1 and Kdm3a expression and restored diabetes-reduced cilia formation in chondrocytes. Conclusions: Ciliary IFT80 plays a critical and necessary role in fracture healing through regulating IGFβ signaling pathway. IFT proteins and cilia formation might be regulated by Foxo1.

PTHrP Targets Salt-induced Kinases to Regulate Chondrocyte Differentiation Shigeki Nishimori*[1], Marc Wein[1], Kei Sakamoto[2], Marc Foretz[3], Rebecca Berdeaux[4], Henry Kronenberg[1]. [1]Massachusetts General Hospital, United States, [2]Nestlé Institute of Health Sciences, Switzerland, [3]INSERM, France, [4]University of Texas, United States

Background: Parathyroid hormone-related protein (PTHrP) inhibits chondrocyte hypertrophy. We have demonstrated in vivo that Histone deacetylase (HDAC) 4 and 5 are mediators of PTHrP signaling in chondrocytes. We have further shown in vivo that PTHrP leads to lower phosphorylation of HDAC4 at the 14-3-3 binding sites and induces subsequent nuclear translocation of HDAC4 (submitted). In the nucleus, HDAC4/5 block Myocyte Enhancer Factor 2 (MEF2) that drives chondrocyte hypertrophy. How PTHrP action leads to lower phosphorylation of HDAC4/5 is not known. Methods: Salt inducible kinase (Sik) 3 influences chondrocyte hypertrophy (Sasagawa, Development, 2012). Sik2 and Sik3 phos-

phorylate HDAC4 and HDAC5 at the 14-3-3 binding sites in vitro (Walkinshaw, JBC, 2013). Here, we investigated the roles of SIK family proteins in the PTHrP signaling pathway using mouse genetic models.Results: Surprisingly, the lethal phenotype of the PTHrP-KO mouse is rescued by knocking out the Sik3 genes. This result is consistent with the model that the PTHrP-KO phenotype requires HDAC4 phosphorylation induced by Sik3 action.Cyclic AMP signaling leads to protein kinase A-mediated phosphorylation and inactivation of Sik3 at T467, among other sites. We showed that PTHrP leads to phosphorylation of this site by adding PTH 1-34 (50 nM) to primary rib chondrocytes harvested at birth and using Western blots to assess phosphorylation of Sik3 T467 by a specific antibody (Patel et al Nature Comm, 2014). The Col2-Cre: Sik3 conditional KO (Sik3-cKO) mouse shows a long proliferating chondrocyte (PC) region, due to delayed chondrocyte hypertrophy. However, it is not as severe as the delay of hypertrophy in the chondrocyte-specific PTHrP transgenic mouse (Weir, PNAS, 1996) that exhibits only round chondrocytes at birth. The more severe phenotype with PTHrP over-expression suggests that other SIK family proteins (Sik1 or Sik2) may control chondrocyte hypertrophy in addition to Sik3.By additional deletion of the Sik1 or Sik2 gene in the Sik3-cKO mouse, we observed longer PC regions and delayed separation of proximal and distal growth plates at birth. These results suggest that Sik1 and 2 also regulate chondrocyte differentiation, but Sik2 deletion exhibits more obvious effects. Effects of Sik1 deletion were more obvious at Embryonic Day 17. Sik1-cKO, Sik2-cKO, and Sik1&2 double cKO exhibited normal bone phenotypes.By deleting the HDAC4 gene in the Sik3-cKO mouse, stepwise shorter PC regions were observed at birth, consistent with the idea that HDAC4 acts downstream of Sik3 to delay chondrocyte hypertrophy. The longer PC region in the Sik2/Sik3/HDAC4 triple KO mouse compared to the Sik3 and HDAC4 double KO mice suggests that Sik2 can block actions of HDAC5, thereby accelerating hypertrophy. Conclusions: These genetic and in vitro studies suggest that PTHrP acts on growth plate chondrocytes through a Sik1, 2, 3-HDAC4/5 dependent pathway.

FRI-0231

Direct transdifferentiation of ligament cells into articular chondrocytes that is regulated by Indian hedgehog (IHH) signaling and phosphate levels Jun Wang*[1], Chi Ma[1], Hui Li[1], Zhanjun Li[2], Liangxue Lai[2], Yan Jing[1], Jian Q. Feng[1]. [1]Texas A&M College of Dentisty, United States, [2]Jilin Provincial Key Laboratory of Animal Embryo Engineering, Jilin University, China

Articular cartilage is considered to be formed by its own chondrocytes, and currently, the known function of ligaments is to assist muscles in controlling body movement and stabilizing joints. Pathologically, ectopic ossification occurs in ligaments. The aim of this study is to propose a new ligament function: ligaments directly form articular cartilage and subchondral bone during normal development. To test this hypothesis, we first used the Rosa26-tdTomato (tdT) mouse line separately crossed with Gli-CreERT2 and Aggrecan (Acan)-CreERT2 with one-time tamoxifen induction at P5 and harvested at 4-weeks. Both the Gli1 and Acan tracing lines displayed a similar pattern: a) in the distal ligament region there were scattered tdT+ ligament cells, but there were numerous tdT+ cells at the ligament insertion site; b) many tdT+ cells became dendritic cells followed by flat spindle cells, pre-hypertrophic, and then hypertrophic chondrocytes (Fig a). Next, we used the 3.2kb Col1-CreERT2-tdT tracing line with one-time tamoxifen induction for 4-days (P5-P9). A strong tdT+ signal was observed in cells at the ligament insertion site and their daughter chondrocytes, which were co-localized with Sox9 and no longer expressed ligament markers (Periostin and Vimentin; b). In a 2.3kb Col1-GFP mouse line, a strong GFP+ signal was confirmed in the ligament insertion site and adjacent chondrocytes, in which a high level of alkaline phosphatase was documented (c). To study molecular regulation of direct cell transdifferentiation of ligament into chondrocytes, we deleted Ihh in the tdT background using Gli1-CreERT2 and Acan-CreERT2 at P5 and harvested at 4-weeks, separately. These two cKO lines displayed a very similar phenotype, being slightly stronger in the Acan-Cre line: a) a great expansion of the epiphysis but a shortened long bone and b) a sharp increase in the ligament-derived chondrocytes and bone mass, as well as a complete loss of growth plate and metaphysis (d). Finally, in our studies of the newly developed Dmp1 null rabbit (a hypophosphatemic rickets model), there was a severe reduction in ligament mass and Safranin O levels in ligament at the junction site. These Safranin O+ chondrocytes failed to form

mature subchondral bone, leading to expanded knee joint heads (e). Together, our studies support a novel theory: ligament cells directly transdifferentiate into knee chondrocytes and subchondral bone cells, which is regulated by IHH signaling and Pi levels.

Undercarboxylated Osteocalcin Downregulates Pancreatic Lipase Expression in CREB2-Dependent Manner in Pancreatic Acinar Cells Danbi Park*[1], Ye-Won Kwon[1], Jeong-Hwa Baek[2], Kyunghwa Baek[1]. [1]Department of Pharmacology, College of Dentistry and Research Institute of Oral Science, Gangneung-Wonju National University, Republic of Korea, [2]Department of Molecular Genetics, School of Dentistry and Dental Research Institute, Seoul National University, Republic of Korea

Osteocalcin is an osteoblast-specific secreted protein that has been associated with endocrine roles on multiple aspects of energy metabolism. We explored whether undercarboxylated osteocalcin (ucOC) downregulates pancreatic lipase (PNLIP) expression in pancreatic acinar cells and then identified the downstream signaling pathway. We previously demonstrated that β adrenergic blockade attenuates the body weight/fat mass gain in high fat diet fed mice and such an effect is associated with decrease in PNLIP expression in pancreatic acinar cells. In the present study, we first confirmed that serum ucOC level is inversely correlated with PNLIP expressions, i.e., those mice exhibiting the high level in serum ucOC had the low PNLIP in pancreas. In vitro experiment using primary pancreatic acinar cells and 266-6 cells, ucOC downregulated PNLIP expressions in mRNA and protein level. ucOC increased cellular cAMP level. Rp-cAMPs, KT5720 and H89, cAMP/PKA signaling inhibitors significantly reversed ucOC-induced downregulation of PNLIP expression. ucOC promoted the phosphorylation of cAMP response element-binding protein 2 (CREB2), but not of CREB1. Overexpression of CREB2 significantly suppressed PNLIP expression. The knockdown of CREB2 by siRNA reversed the ucOC-induced downregulation of PNLIP expression. Luciferase reporter assay showed that ucOC suppressed PNLIP promoter transactivation. Overexpression of CREB1 stimulated, but CREB2 suppressed PNLIP promoter activity. Knockdown of G protein-coupled receptor 6A (GPRC6A), a candidate receptor for mediating the response to ucOC in the bone-pancreas endocrine loop, by siRNA reversed the downregulating effect of unOC on PNLIP expressions. Targeting GPRC6A in 266-6 cells by CRISPR/Cas9 also blocked the suppression effect of unOC on PNLIP expressions. Taken together, ucOC downregulates pancreatic lipase expression in a cAMP/protein kinase A/CREB2-dependent manner. GPRC6A is a functional osteocalcin sensing receptor that regulate PNLIP expression in pancreatic acinar cells.This work was supported by the National Research Foundation of Korea Grant (NRF-2013R1A1A3008564 and NRF-2017R1A2B1006203).

Pparγ inhibition in osteoblast / osteocyte (OB/OCY) restores PTH bone anabolism in high fat diet model, importance of glycolysis versus mitochondrial oxidation ratio Lucie Bourgoin*[1], Beatrice Desvergne[2], Nicolas Bonnet[1]. [1]Service of Bone Diseases, Faculty of Medicine (UNIGE), Switzerland, [2]Genopode Science & medical University, Switzerland

High fat diet (HFD) is known to induce Pparγ upregulation as well as disturb glucose metabolism, known to contribute in the inhibition of bone anabolic response to PTH. We hypothesized that specific ablation of Pparγ in OB/OCY would restore PTH anabolic effects partially by maintaining proper mitochondrial/glycolysis activity. For this purpose, WT females and OB/OCY-specific Pparγ KO mice (i.e. Dmp1-Cre/Lox-Pparγ-deficient mice mice) at 16 weeks of age, received either a high fat or chow diet (HF 60% vs CD 10% of fat) for 8 weeks. Half of the mice were treated by intermittent PTH (40μg/kg/day) or vehicle (Veh). Bone structure at distal and midshaft femur, bone formation rate (BFR) and osteocalcin were evaluated by microCT, histomorphometry and ELISA. Using the seahorse XFe96 system, we measured glycolysis and mitochondrial activity in primary OB from WT and

Ppαγ KO mice.In WT, HFD increased Ppαγ expression in bone (+126% vs CD, p<0.001) and decreased BV/TV (-50.6% vs CD, p<0.05). Anabolic effects of PTH in CD, illustrated by increased BV/TV, cortical thickness (Ct.Th), EcBFR and PsBFR (respectively +92%, +7.9%, +2400% and +290% vs Veh, all p<0.05) were abolished in HFD. In contrast, PTH effects in KO mice under HFD were similar to those obtained in WT under CD. In KO under HFD mice, PTH increased BV/TV, CtTh, EcBFR, PsBFR and osteocalcin respectively by +98%, +18%, +580%, +90%, +39% vs Veh, all p<0.05). In Ppαγ KO primary OB, gene expression indicated a reduction in mitochondrial activity (-27% of PDHa1, p<0.01) and an upregulation of Glut1 and Glut4 (+394% and +157%, both p<0.001). Increased in glucose transporter was translated with an increased in glycolysis rate (ECAR, +75% vs WT, p<0.01). Hence, in vitro, osteocalcin response to PTH was magnified in KO vs WT (+97% vs +12.2%, p<0.001).In conclusion, HFD abolishes PTH effects both at the trabecular and cortical structure, suggesting that PTH-based bone fragility treatment in obese and diabetic patients would be less efficient. In contrast, by restoring glycolytic rates, Ppαγ ablation in OB/OCY could maintain the PTH anabolic efficacy. How Ppαγ inhibition in OB/OCY rescue HFD defects remains to be elucidate.

Allocation of Bone Marrow Stromal Cells into the Adipogenic Lineage is Marked by Enhanced Expression of the Mitophagy Receptor Bcl2l13

Makoto Fujiwara*[1], Anyonya Guntur[1], Phuong Le[1], Victoria Demambro[1], Mark Horowitz[2], Clifford Rosen[1]. [1]Maine Medical Center Research Institute, United States, [2]Yale University School of Medicine, United States

As with a host of specific transcription factors, metabolic programming may influence the lineage determination of bone marrow stromal cell (BMSC). We previously reported that C3H/HeJ (C3H) mice have higher bone mass yet markedly more marrow adipose tissue than C57BL/6J (B6) mice. We also noted that pre-adipocytes predominantly utilize oxidative phosphorylation (OxPhos) whereas pre-osteoblasts utilize glycolysis. Thus we hypothesized that C3H BMSCs were metabolically programmed to increase bone marrow adipogenesis via enhanced OxPhos.First, we cultured BMSCs from both strains in adipogenic media (AM) and osteogenic media (OM). C3H BMSCs differentiated into more adipocytes at day 9 and osteoblasts at day 14 than B6 BMSCs as measured by Oil Red O and Von Kossa staining respectively. Gene expression patterns in C3H BMSCs also showed greater Pparg, Cebpa, and Adipoq in AM and more Alpl, Runx2, and SP7 in OM. Next we asked whether genetic determinants could be responsible for the cellular phenotypes. C3H mice have an inversion in Chromosome 6 leading to dysregulation in genes at the breakpoint, which include Pparg proximally and Bcl2l13 distally. Bcl2l13 is the mammalian homolog of the yeast ATG32, the mitochondrial receptor protein essential for mitophagy. Gene and protein expression of Bcl2l13 in B6 BMSCs increased 9-fold and 4-fold, respectively at day 9 of adipogenesis, but unchanged in OM. We confirmed a similar pattern in 3T3-L1 cells and in primary cells from the stromal vascular fraction of the inguinal depot. In addition, in BMSCs, a mitochondrial fusion protein Mfn2 was also markedly increased in AM but not changed in OM, and mitochondrial/nuclear DNA ratio (Mt/N DNA) tended to increase in AM. siRNA of Bcl2l13 in 3T3-L1 cells led to more than 80% reduction in protein production, a significant impairment in adipocyte differentiation by Oil Red O staining but not induced apoptosis. Compared to negative control, the Bcl2l13 knock down decreased Mt/N DNA. Interestingly, in silico analysis showed that there are PPARG binding sites in the promoter of Bcl2l13 at full differentiation of 3T3-L1 cells, suggesting that the Pparg-Bcl2l13 interaction leads to enhanced adipogenesis.In sum, we found that the mitophagy receptor Bcl2l113 is essential for adipocyte differentiation, but not osteogenesis, and reflects increased OxPhos. Importantly, mitophagy is essential for adipogenesis and Bcl2l13 reflects how metabolic programming may influence lineage allocation.

Metformin Facilitates Fracture Healing in Type-2 Diabetes Mice Yuqi Guo*, Xin Li. NYU College of Dentistry, United States

Diabetes mellitus is a group of chronic diseases characterized by high blood glucose levels. Diabetic patients have a higher risk of sustaining osteoporotic fractures than their non-diabetic counterparts. The fracture healing is usually impaired in diabetics and our understanding of the detrimental effects of hyperglycemia on fracture healing is still inadequate. Effects of diabetes treatments on bone metabolism and fracture are varied. Metformin is the first-line medicine for type-2 diabetes (T2D) and has not been documented with any negative effects on bone. In contrast to most other medicines for T2D, it exhibits a favorable effect on diabetic bone by increasing bone mineral density and decreasing fracture in patients. Here we demonstrated that metformin preserved bone mass and facilitated fracture healing in T2D mice. Closed femoral fracture was induced to the right femur of age-matched normoglycemic and hyperglycemic mice. An intramedullary pin was inserted prior to fracture for stabilization. After fracture, mice were randomly assigned to treatment groups receiving vehicle or metformin daily by intraperitoneal injection. We conducted a temporal histologic analysis to track the healing process by collecting the fractured femora at 14, 23 and 31 days post-fracture. Our results demonstrated that the fracture healing was delayed in T2D mice and metformin rescued the delayed bone healing by facilitating osteogenesis and chondrocytogenesis. The cartilage formation in the endochondral ossification under hy-

perglycemic condition revealed by Safranin O staining was significantly increased at day 14 post-fracture in T2D mice receiving metformin treatment. Serum P1NP levels and double-fluorescent labeling exhibited that metformin stimulated the bone formation at day 23 post-fracture in T2D mice. In vitro culture of human and mouse BMSCs suggested that the impaired osteogenic capacity by hyperglycemia was associated with an impaired mitochondrial respiration. Metformin treatment ameliorated the impairment through stimulating the expression levels of Nrf-1, PGC1a and Ostrix in pre-osteoblasts.Taken together, our study demonstrated the favorable effects of metformin on bone metabolism in a T2D mouse model and revealed a mechanism by which osteogenesis of BMSCs can be improved.

Metformin facilitates fracture healing in T2D mice. A) Longitudinal µCT views of femurs on days 14, 23 and 31 post-fracture in WT and MKR (T2D) mice treated with PBS and metformin (MET). B) Safranin O staining on fracture sections at 3 different time points post surgery.C) Callus areas and D) cartilage areas within the healing site. E) Serum P1NP levels. F) Double-fluorescent labels were given to mice with a five days interval and samples were collected at day 23 post surgery.

KLF10 regulates skeletal muscle metabolism in mice Malek Kammoun*[1], Vladimir Veksler[2], Jérôme Piquereau[2], Lydie Nadal-Desbarats[3], Philippe Pouletaut[1], Molly Nelson Holte[4], Malayannan Subramaniam[4], Sabine Bensamoun[1], John Hawse[4]. [1]Université de Technologie de Compiègne, France, [2]Univ. Paris-Sud, France, [3]Université de Tours, France, [4]Mayo Clinic, United States

KLF10 is a member of the Krüppel-like family of transcription factors that regulates gene expression in multiple cell and tissue types. Loss of KLF10 expression results in tissue dysfunctions and diseases, many of which present in a sex-specific manner. Deletion of KLF10 in mice leads to an osteopenic bone phenotype only in female mice and polymorphisms in the KLF10 gene are associated with osteoporosis in humans. While KLF10 is well-known for its functions in bone, it is most highly expressed in skeletal muscle. To elucidate the impact of this transcription factor in skeletal muscle, we performed histochemical and electron microscopic analyses of both slow and fast twitch muscles in WT and KLF10 KO mice. The results of these studies revealed a lack of succinate dehydrogenase activity, decreased mitochondrial numbers and changes in mitochondrial shape, enzymatic activity and respiration rates in female, but not male, KLF10 KO mice. We also assessed the activity of specific respiratory chain complexes in situ using saponin-permeabilized skeletal muscle fibers isolated from female WT and KLF10 KO soleus muscle. These studies revealed a significant decrease in respiration rates for complexes I, II and IV in KLF10 KO mice. Metabolite analyses using nuclear magnetic resonance revealed significant differences in multiple metabolites between WT and KLF10 KO muscle further indicating a novel role for KLF10 in muscle metabolism. To understand the molecular mechanisms that underlie these muscle phenotypes, we performed RNA sequencing analyses of WT and KLF10 KO soleus muscle. These studies identified 146 genes whose expression levels were significantly different in KLF10 KO mice, many of which are involved in mitochondrial metabolism and biogenesis. Suppression of KLF10 in C2C12 myocyte precursor cells resulted in decreased mitochondrial numbers and ATP levels. Further, the KLF10 knock-down C2C12 cells also exhibited defects in myocyte differentiation and fusion compared to parental C2C12 cells. In summary, these findings have implicated novel roles for KLF10 in regulating skeletal muscle metabolism and function through altered mitochondrial biogenesis and activity. These phenotypes observed in both KLF10 KO mice and KLF10 knock-down C2C12 cells resemble a number of human diseases associated with mitochondrial myopathies. These models will be useful in identifying novel therapeutic strategies to enhance mitochondrial function and treat such disorders.

Fatty acid oxidation is essential for osteoclast development and skeletal homeostasis Priyanka Kushwaha*[1], Conor Beil[2], Michael J. Wolfgang[1], Ryan C. Riddle[1]. [1]Johns Hopkins University School of Medicine, United States, [2]Johns Hopkins University, United States

Postnatal skeletal remodeling is an energy demanding process that is linked to nutrient availability and the levels of metabolic hormones. Previously, we demonstrated that mitochondrial long-chain fatty acid oxidation by osteoblasts is required for normal bone accrual and identified a role for the skeleton in whole-body lipid homeostasis. Dietary lipids may also fuel the contralateral arm of the bone remodeling cycle, but the requirement for fatty acid oxidation by osteoclasts has not been studied. To investigate the contribution of fatty acid oxidation to bone resorption, we specifically disrupted expression of carnitine palmitoyltransferase 2, an obligate enzyme in mitochondrial fatty acid ß-oxidation in osteoclasts by crossing Cpt2loxP/loxP mice with lysozyme2-Cre transgenic mice (ΔCpt2). MicroCT revealed that inhibition of long-chain fatty acid oxidation in osteoclasts significantly increased bone volume, secondary to increased trabecular thickness and trabecular number. On the cellular level, TRAP staining revealed dramatic reductions in osteoclast numbers in ΔCpt2 mice relative to wild-type littermate controls. Similarly, bone marrow cells isolated from ΔCpt2 mice exhibited a reduced capacity for osteoclast differentiation and pit formation after stimulation with RankL and M-CSF when compared to cells isolated from control mice. These data were further supported by a down-regulation of the expression of osteoclast marker genes, including RANK, Nfatc1, TRAF-6, TNFα and NF-κB in Cpt2-deficient cultures, despite a compensatory up-regulation of genes involved in glucose utilization. Our data demonstrate that mitochondrial long-chain fatty acid oxidation by the osteoclast is required for normal bone resorption that its inhibition produces an intrinsic defect in osteoclast differentiation.

Metabolic characterization of the OCN-Cre;iDTR mouse model supports a relationship between bone health, bone marrow adipose tissue, and overall fitness Heather Fairfield*[1], Samantha Costa[1], Calvin Vary[1], Victoria Demambro[1], Marie Demay[2], Clifford Rosen[1], Michaela Reagan[1]. [1]Maine Medical Center Research Institute, United States, [2]Center for Skeletal Research, Massachusetts General Hospital, United States

Background: Many physiological examples demonstrate an inverse correlation between bone marrow adipose tissue (BMAT) volume and bone volume in mice and humans, but few studies have examined this association directly. The question remains whether the skeleton or the adipose it contains drives the correlation, although it has often been postulated that BMAT accumulation causes deterioration of bone. Here we demonstrate for the first time that removing bone cells can induce changes in BMAT and behavior.Methods: We removed osteoblasts and osteocytes from bones using the osteocalcin-cre, inducible diphtheria toxin receptor mouse model (OCN-Cre;iDTR) treated with vehicle (PBS) or diphtheria toxin (DT) every other day for 2 weeks. Long bone cellular and architectural changes were assessed via μCT, static and dynamic bone histomorphometry, and H&E sections of femora. BMAT was quantified in tibia via OsO4 μCT and in femur histological sections. Serum was analyzed via mass spectrometry. Changes in body composition were quantified via DEXA PIXMIUS and/or qNMR, and behavioral phenotypes were characterized utilizing metabolic cages.Results: A significant reduction of osteoblasts (Ob.S/BS (%) and N.Ob/B.Pm) upon DT treatment (25-50%, p<0.05) was observed and no bone formation was detected. Many other bone parameters (BV/TV, p<0.01; BMD, p<0.001; and Tb.N, p<0.001) were decreased, while increases in Tb.Sp (p<0.001) and cortical porosity (p<0.01) were observed in DT-treated mice. OsO4 μCT revealed increased BMAT in DT-treated mice tibia (p<0.05, confirmed by H&E adipocyte counting in the femora) (see Fig 1). Mice had decreased total weight (p<0.05) and lean mass (p<0.05, females; p=ns, males). Lipidomic profiling revealed clustering of DT-treated mice based on blood composition of sphingomyelins and glycopeptidolipids; but not triglycerides or diacylglycerols. DT-treated mice also showed less energy expenditure, wheel usage, and food intake (all p<0.05). The majority of these changes, but not BMAT, were normalized after a 3 week recovery.Conclusion: The reciprocal relationship between bone and BMAT we observed mirrors that in osteoporosis, aging and anorexia. We found that removal of bone cells can directly increase BMAT; we will next interrogate the cause and other consequences of this. Our study has important implications in understanding the pathogenesis of elevated BMAT, and the crucial link between skeletal maintenance and overall health in mice and humans.

FRI-0262

Complexity in Neuropeptide Y's effects on the skeleton Natalie Ky Wee*[1], Benjamin P Sinder[1], Sanja Novak[1], Xi Wang[1], Brya G Matthews[2], Boris Zemelman[3], Ivo Kalajzic[1]. [1]Department of Reconstructive Sciences, University of Connecticut Health Center, United States, [2]Department of Molecular Medicine, University of Auckland, New Zealand, [3]Center for Learning and Memory, The University of Texas at Austin, United States

Neuropeptide Y (NPY) is involved in multiple processes such as behavior, energy and bone metabolism. Our lab has shown that NPY expression is highly enriched in osteocytes, yet a clear identification of NPY-expressing cells in the skeleton has not been done. Previous studies have relied on global NPY depletion to examine its effects on bone. However, this approach does not distinguish the source of NPY influencing bone. Our aims were to identify which cells within the skeleton express NPY and establish a model that will enable us to differentiate effects of specific NPY deletions.We used a lineage tracing approach (NPYcre x Ai14 TdTomato reporter) to detect NPY expression in bone and have developed the first NPY conditional knockout (NPYcKO) mouse using CRISPR. We crossed our NPYcKO with Hprt-cre to generate a global knockout (NPYKO) and have assessed femurs using microCT, mechanical testing, histomorphometry and flow cytometry.NPY is expressed locally in skeletal sites. In the femur, we observed TdTomato-positive cells in articular chondrocytes, osteocytes and few cells on endosteum and periosteum. Interestingly, NPY expression was heterogeneous within these cell populations. Although NPY is involved in the immune system; we observed no TdTomato positive cells in the bone marrow. We identified a large proportion of osteocytes embedded within calvarial bone were TdTomato positive.To examine NPY's effects, we generated the NPYcKO and confirmed depletion of transcript and protein in our global NPYKO. Male NPYKO mice had a significantly smaller femoral cross-section and impaired bone strength. A reduction in CD51+ osteoprogenitors in the endosteal fraction was observed; whilst dynamic labeling in cancellous bone showed a trend of reduced mineralizing surface in NPYKO. Osteoblast activity (MAR) was increased, consistent with increased BMSC differentiation observed in vitro. Cancellous BFR was unchanged. No skeletal changes were observed in female mice suggesting that there may be sex-specific effects of NPY on bone. Notably, both genders had increased adiposity and thus, metabolic changes were associated with global deletion.This work identified NPY expression in the skeleton and examined the effect of global NPY depletion to bone mass. The differential impact of NPY deletion in cortical and cancellous compartments highlights the complex nature of NPY signaling, which may be from distinct sources that can be dissected with our newly created NPYcKO model.

Biochemical and phenotypic characterization of mice constitutively expressing epitope-tagged PIT1 transporter in all tissues Clemens Bergwitz*, Sampada Chande, Bryan Ho, Shumayi Syed, Jonathan Fentene. Yale University School of Medicine, United States

Inorganic phosphate (Pi) has an essential role in cell signaling and metabolism and is tightly regulated by parathyroid hormone (PTH), 1,25-dihydroxy vitamin D (1,25-D), and fibroblast growth factor 23 (FGF23) to avoid excess or deficiency. The type III transporters PIT1 and PIT2 have recently emerged as candidates "transceptors" that mediate activation of ERK1/2 by Pi resulting in osteogenic differentiation of smooth vascular and bone cells while pharmacological and genetic inhibition of PIT1 and PIT2 blocks these effects. Because of lack of suitable in vitro models it remains unclear, whether PIT1 or PIT2 regulate PTH, 1,25-D or FGF23. Ablation of Pit1 in mice results in embryonic lethality at E12.5, hypomorphic Pit1 ablation is viable and reduces femur length, but no significant changes of Pi or calcium metabolism were observed. Pit1 transgenic rats on the other hand have reduced trabecular

number on uCT, hyperparathyroidism and hyperphosphatemia, but FGF23 and renal Pi handling were not assessed in these studies. Pit2 null mice have low bone mass, but normal Pi homeostasis at baseline and become hyperphosphatemic when fed a high Pi diet. This goes along with inappropriately low intact FGF23 levels in these mice suggesting that Pit2 is upstream and positively regulating FGF23. To further investigate the regulation of FGF23 and Pi by PIT1, we developed a transgenic mouse expressing epitope-tagged human PIT1 transporter under control of the CMV/chicken beta actin (CAG) promotor and a loxP-stop-loxP (LSL) cassette permitting Cre-mediated activation of transgene expression. Germline excision of the LSL cassette results in expression of the transgene in all mouse tissues (HA-hPit1+/tg). Recombination was confirmed using genomic DNA obtained from tail samples of these mice. Furthermore, expression of HA-hPIT1 was found to be approximately 10-fold above endogenous mouse Pit1 in cultured primary calvaria osteoblasts (PCOB) when assessed by Pit1 immunoblot and qRT-PCR. Also, sodium-dependent 32Pi-uptake was 1.3-fold higher in HA-hPit1+/tg PCOB cultures compared to wildtype (WT) (0.0014± 9.89E-05 vs. 0.0011± 8.52E-05, p=0.037). HA-hPit1+/tg mice showed 1.3-fold higher plasma Pi levels when compared to WT (10.2±0.89, n=11 vs. 7.8±0.62, n=17, p=0.032), while intact FGF23 and urine Pi excretion index (PEI) were normal. These observations are consistent with prior observations in Pit1 transgenic rats and suggest that regulation of Pi homeostasis by type III Pi transporters is more complex than initially expected. Further phenotypic characterization of HA-hPit1+/tg mice and mice with osterix (Osx)-Cre mediated bone-targeted expression of HA-hPit1 is currently underway.

The role of inorganic pyrophosphate in the pathogenesis of PXE caused by ABCC6 mutations Qiaoli Li*, Jouni Uitto. Thomas Jefferson University, United States

Pseudoxanthoma elasticum (PXE) is a prototype of heritable multisystem ectopic mineralization disorders. It is caused in most cases by loss-of-function mutations in the ABCC6 gene which encodes ABCC6, a putative transmembrane efflux transporter primarily expressed in the liver. Studies in murine models of PXE suggest a unique pathomechanism relating to reduced levels of plasma inorganic pyrophosphate (PPi) as a result of the lack of ABCC6-dependent ATP release in hepatocytes. PPi has been demonstrated, over four decades ago, to be a powerful anti-mineralization factor, which, when present in physiologic concentrations, prevents calcium hydroxyapatite formation in soft connective tissues. The reduced plasma PPi levels raises the possibility to develop pharmacologic approaches for PXE by targeting plasma PPi deficiency. We performed three experiments with attempts to restore plasma PPi levels for treatment of ectopic mineralization in the Abcc6-/- mouse model of PXE. First, the Abcc6-/- mice were administered with stable and non-hydrolyzable PPi analogues, bisphosphonates. The results suggested that selected bisphosphonates, such as etidronate, were able to inhibit ectopic mineralization. Second, the Abcc6-/- mice were crossed with a transgenic mouse overexpressing human ENPP1, an ectonucleotidase that generates PPi through hydrolysis of ATP. The results demonstrated that overexpression of ENPP1 significantly reduced but did not completely prevent ectopic mineralization in the Abcc6-/- mice despite that plasma PPi levels increased to the level of wild type controls. The third experiment focused on inhibition of tissue non-specific alkaline phosphatase (TNAP), the enzyme that degrades PPi. Inhibition of TNAP activity resulted in reduced amount of mineralization in the Abcc6-/- mice despite unchanged plasma PPi levels. The results from three complementary experiments suggest that ABCC6 has other mechanisms, independent of PPi, for prevention of ectopic mineralization under physiologic conditions.

BMP2 is Required for Entheseal Bone Formation in Antigen-Induced Arthritis Yukiko Maeda*, Catherine Manning, Ellen Gravallese. University of Massachusetts Medical School, United States

Ankylosing Spondylitis (AS) is a common rheumatic disease with a prevalence of ~0.5% in the general population. AS patients suffer from pain and disability due to inflammation and ossification at enthesial sites, the mechanism of which remains unclear. BMP2 is reported to be upregulated in mesenchymal stem cells derived from AS patients. We studied the role of BMP2 in enthesial bone formation using the antigen-induced arthritis (AIA) model, in which endochondral bone formation occurs at specific enthesial sites about the knee joint. We used limb mesenchymal cell-specific (Prx1-Cre) BMP2 knock out mice (KO) and littermate control mice (WT) to induce AIA in knee joints of 8 and 14 week-old mice. At 8 and 14 weeks of age, both KO and WT mice showed similar inflammation in arthritic knees. Histologic analysis of 8 week-old WT mice revealed endochondral bone formation, angiogenesis and presence of TRAP-positive osteoclasts at entheses by day 15. In contrast, KO mice developed only cartilage but not bone. Furthermore, angiogenesis and osteoclasts were absent at entheses in KO. To examine whether enthesial bone formation was simply delayed in KO mice, we prolonged AIA until day 36; however, enthesial bone formation was again not observed in KO. AIA induced in 14 week-old mice showed enthesial bone formation in WT by day 15. In contrast, KO mice did not develop cartilage or bone at the enthesis. We harvested enthesial cells and bone marrow stromal cells (BMSCs) from 14 week-old WT and KO mice. After 3 weeks in osteoblast differentiation media, enthesial cells and BMSCs from WT mineralized, but cells from KO mice did not mineralize.

To explore the molecular mechanism we dissected entheses from 14 week-old WT and KO mice with AIA (day 9) using laser capture microscopy. Gene expression was analyzed using Affymetrix whole transcriptome array. We found that the Wnt antagonist, Sfrp4, was upregulated but Chondroadherin and Cxcl5 were down regulated in KO entheses. Sfrp4 was also upregulated in BMSCs from KO. Signaling Pathway Impact Analysis (SPIA) detected a trend of the Wnt pathway being negatively regulated in KO entheses. These results demonstrate that mesenchymal cell-derived BMP2 regulates entheseal bone formation in the setting of inflammation, possibly through Wnt signaling. Thus may have implications for the pathogenesis of enthesophytes in AS.

COPB2 Loss of Function Leads to Disrupted Collagen Trafficking and Juvenile Osteoporosis Ronit Marom*[1], Lindsay C Burrage[1], Mahim Jain[2], Ingo Grafe[1], Daryl A Scott[1], Jill A Rosenfeld [1], Jason D Heaney[1], Denise Lanza[1], Xiaohui Li[1], Kyu-Sang Joeng[1], Yi-Chien Lee[1], I-Wen Song[1], Joseph M Sliepka[1], Dominyka Batkovskyte[1], Zixue Jin[1], Brian C Dawson[1], Shan Chen[1], Yuqing Chen[1], Ming-Ming Jiang[1], Elda M Munivez[1], Vernon R Sutton[1], Cole Kuzawa[3], Rossella Venditti[4], Maryann Weis[5], Aurélie Clément[6], Brenna Tremp[6], Bernardo Blanco-Sánchez[6], Monte Westerfield[6], David Eyre[5], Catherine G Ambrose[3], Antonella De Matteis[4], Brendan Lee[1]. [1]Baylor College of Medicine, United States, [2]Kennedy Krieger Institute, United States, [3]University of Texas Health Science Center at Houston, United States, [4]TIGEM (Telethon Institute of Genetics and Medicine), Italy, [5]University of Washington, United States, [6]University of Oregon, United States

Abnormal collagen trafficking has been implicated in a number of skeletal dysplasias. In a 7-year-old female patient with juvenile osteoporosis, we identified a de novo, heterozygous loss-of-function variant in COPB2, a component of the coatomer complex COPI that is involved with membrane trafficking in the Golgi complex and between the ER and the Golgi complex. The patient presented with recurrent fractures starting at 2 years of age, and low bone mineral density. RNA studies in the patient's lymphoblast cells showed decreased expression of COPB2, consistent with haploinsufficiency. To better understand the molecular consequences of COPB2 haploinsufficiency, we assessed collagen trafficking by immunofluorescence microscopy. In COPB2 siRNA-treated fibroblasts, we observed delayed collagen trafficking with retention of type I collagen in the ER and Golgi, and altered subcellular distribution of Golgi markers. To characterize the effect of COPB2 loss of function on skeletal development, we generated a zebrafish model carrying a frameshift variant (p.Lys10Thrfs*12) resulting in an early stop codon in the copb2 gene. copb2-null embryos showed early lethality. Alizarin-red staining of heterozygous larvae at 7 days post-fertilization was reduced, suggesting delayed mineralization. We then generated a mouse model carrying a Copb2 deletion by CRISPR technology. Copb2-/- mice were embryonic lethal. In the heterozygous female mice, uCT analysis showed a 15-20% reduction in spine BV/TV, trabecular number and trabecular thickness. Biomechanical testing of femurs by 3-point bending demonstrated decreased bone strength, with reduced maximal load, stiffness and rigidity in femurs of Copb2+/- female mice, that was associated with decreased cortical thickness and cross-sectional bone area. Interestingly, in spite of the delay in collagen trafficking observed in vitro, collagen post-translational modifications were not altered in bones of Copb2+/- mice.In summary, we identified a loss-of-function variant in COPB2 in a patient with juvenile osteoporosis. Cell studies, zebrafish and mouse models support COPB2 haploinsufficiency as the mechanism of low bone mass in this patient, via disruption of intracellular collagen trafficking. This study underlines the critical role of the COPI complex in bone development and suggests that pathogenic variants in COPB2 should be considered in the genetic differential diagnosis of early-onset osteoporosis.

PIN1 is a new therapeutic target of craniosynostosis Hye-Rim Shin*[1], Han-Sol Bae[1], Bong-Su Kim[1], Heein Yoon[1], Young-Dan Cho[1], Woo-Jin Kim[1], Kang Young Choi [2], Yun-Sil Lee[1], Kyung-Mi Woo[1], Jeong-Hwa Baek[1], Hyun-Mo Ryoo[1]. [1]Seoul National University, Republic of Korea, [2]Kyungpook National University, Republic of Korea

Gain-of-function mutations in fibroblast growth factor receptors (FGFRs) cause congenital skeletal anomalies including cranisynostosis (CS), which is characterized by the premature closure of craniofacial sutures. Apert syndrome (AS) is one of the severest forms of CS, and the only treatment is surgical expansion of prematurely fused sutures in infants. Previously, we demonstrated that the prolyl isomerase PIN1 plays a critical role in mediating FGFR signaling, and that Pin1+/- mice exhibit delayed closure of cranial sutures. In this study, using both genetic and pharmacologic approaches, we tested whether PIN1 modulation could be used as a therapeutic regimen against AS. In the genetic approach we crossbred Fgfr2S252W/+, a mouse model of AS, and Pin1+/- mice. Down-regulation of Pin1 gene dosage attenuated premature cranial suture closure and other phenotypes of AS in Fgfr2S252W/+ mutant mice. In the pharmacological approach, we intraperitoneally administered juglone, a PIN1 enzyme inhibitor, to pregnant Fgfr2S252W/+ mutant mice, and found that this treatment successfully interrupted fetal development of AS phenotypes. Primary cultured osteoblasts from Fgfr2S252W/+ mutant mice expressed high levels of FGFR2 downstream target genes, but this phenotype was attenuated by PIN1 inhibition. Post-translational stabilization and activation of RUNX2 in Fgfr2S252W/+ osteoblasts were also attenuated by PIN1 inhibition. Based on these observations, we conclude that PIN1 enzyme activity is improtant for FGFR2-induced RUNX2 activation and craniofacial suture morphogenesis. Moreover, these findings highlight that juglone or other PIN1 inhibitors represent viable alternatives to surgical intervention for treatment of CS and other hyperostotic diseases.

Identifying Genetic Modifiers in Patients with Mild Fibrodysplasia Ossificans Progressiva using Whole Exome Sequencing Kelly Wentworth*[1], Tania Moody[1], Kim Taylor[1], Niambi Brewer[2], Fred Kaplan[2], Robert Pignolo[3], Eileen Shore[2], Edward Hsiao[1]. [1]UCSF, United States, [2]UPenn, United States, [3]Mayo Clinic, United States

Fibrodysplasia ossificans progressiva (FOP) is an ultra-rare genetic condition characterized by excessive heterotopic bone formation that occurs in response to injury or inflammation. Classic FOP is caused by an autosomal dominant missense mutation in the ACVR1 gene (c.617 G>A; p.R206H), which encodes activin A receptor type 1. This mutation leads to abnormal signaling through the ACVR1 receptor and over-activation of the downstream BMP signaling pathway, resulting in ectopic bone formation in soft tissues and loss of joint function and mobility. FOP is progressive and debilitating disease with no effective medical treatment, and most patients are wheelchair-bound by the third decade of life. There is a wide spectrum of disease severity among FOP patients with the classical R206H mutation, including a very small number who exhibit an unusually mild phenotype, with minimal joint involvement and no significant mobility limitations. We hypothesize that these milder FOP patients may harbor genetic variants that act as modifiers of BMP signaling and confer a protective effect. To test this hypothesis, we performed whole exome sequencing (WES) on a cohort of 23 FOP patients with the ACVR1-R206H mutation. We stratified these patients by disease severity using the CAJIS score (cumulative analogue joint involvement scale), a validated tool for assessing FOP disease burden. Four of the 23 patients had a strikingly mild phenotype defined as a CAJIS score of < 5/30 at age 15 or older. We analyzed the WES data using Ingenuity Variant Analysis software and applied sequential filters to assess for pathogenicity, allele frequency, conservation, and predicted protein function. An additional filter was applied to capture gene variants that are directly involved in BMP signaling, and identified a variant in the BMP receptor BMPR1A in one mildly-affected patient. This variant is not present in the other 19 classically-affected FOP patients. The minor allele frequency of this variant is <1% and is considered rare compared to the general population. It is located in a highly conserved region in the protein kinase domain and is predicted to cause loss-of-function. Since BMPR1A signals through the SMAD 1/5/9 pathway, as does ACVR1, we hypothesize that this variant could potentially attenuate signaling through this pathway, explaining the milder observed phenotype. We are currently testing this hypothesis using human induced pluripotent stem cells derived from FOP patients to determine if this variant alters BMP signaling and to evaluate its potential as a target for pharmacologic treatment. In summary, this study highlights the benefits of using WES combined with a well-defined phenotype analysis to identify rare disease-modifying variants that could be targeted for drug development.

A high resolution Capture-C promoter 'interactome' implicates causal genes at BMD GWAS loci Alessandra Chesi*[1], Yadav Wagley[2], Matthew E. Johnson[1], Sumei Lu[1], Michelle E. Leonard[1], Kenyaita M. Hodge[1], James A. Pippin[1], Elisabetta Manduchi[1], Andrew D. Wells[1], Struan F.A. Grant[1], Kurt D. Hankenson[2]. [1]The Children's Hospital of Philadelphia, United States, [2]University of Michigan, United States

There is clear evidence for a genetic component to osteoporosis pathogenesis. Genome wide association studies (GWAS) have been successful in discovering key genetic variants robustly associated with bone mineral density (BMD), both in children and adults. However, it is known that GWAS only reports genomic signals and not necessarily the precise localization of culprit genes. Given the notable paucity of genomic data available on bone in the public domain, and to improve upon the low resolution of typical Hi-C approaches, we developed a massively parallel, high-resolution Capture-C based method to characterize the genome-wide interactions of all human promoters in osteoblasts. We designed a custom Agilent SureSelect RNA library targeting DpnII restriction fragments overlapping 36,691 promoters of protein-coding, noncoding, antisense, snRNA, miRNA, snoRNA and lincRNA genes. We applied our method of SPATIaL-seq (genome-Scale, Promoter-focused Analysis of chromaTIn Looping) to primary human mesenchymal stem cell (MSC)-derived osteoblasts. We also generated ATAC-seq open chromatin maps from the same MSC-derived osteoblast samples to determine informative proxy SNPs residing in open chromatin for each of 111 BMD GWAS signals at 108 candidate loci. By intersecting our sub-1kb SPATIaL-seq data with our ATAC-seq data, we observed consistent contacts for at least 33 loci. Some 'nearest' genes to the sentinel SNP were supported e.g. SMAD3, SMG6 and SOST1, while at other loci more distant genes were implicated, including EPDR1 at the 'STARD3NL' locus and ING3 at the 'CPED1-WNT16' locus. Remarkably, knockdown of both EPDR1 and ING3 in four primary hMSC donor lines had pronounced inhibitory effects on osteoblastogenesis, including impacting Alizarin red S and histochemical alkaline phosphatase staining. In conclusion, we observed consistent contacts to at least ~30% of BMD GWAS loci using the highest resolution promoter 'interactome' to date in a single, disease-relevant cell type, and revealed two novel genes involved in osteoblastogenesis. Only by identifying the correct genes at BMD loci can GWAS findings be translated to the development of efficacious treatments for osteoporosis.

Assessing Clinical Utility of Genetic Profiling in Fracture Risk Assessment: A Decision Curve Analysis Thao P. Ho-Le*[1,2], Jacqueline R. Center[1,3], John A. Eisman[1,3,4], Hung T. Nguyen[2], Tuan V. Nguyen[1,2,3,4]. [1]Bone Biology Division, Garvan Institute of Medical Research, [2]School of Biomedical Engineering, University of Technology, Sydney, Australia, [3]St Vincent Clinical School, UNSW Australia, Australia, [4]School of Medicine, Notre Dame University, Australia

Aims: Genetic profiling has emerged as a useful factor for assessing the distant risk of fracture in asymptomatic individuals. This study was aimed at determining whether adding genetic profiling to clinical risk factors improves clinical decision making for the early identification of individuals at high risk for fracture.Methods: The study involved 2188 women and 1324 men aged 60+ years, who have been followed up to 20 years. Bone mineral density (BMD) and clinical risk factors were obtained at baseline. The incidence of fracture and mortality was ascertained during the study period. Sixty-two BMD-associated SNPs were genotyped, and a weighted genetic risk scores (GRS) were constructed for each individual by summing the products of the number of risk alleles and the sex-specific regression coefficients [associated with BMD from GWAS]. We considered 4 Cox's proportional hazard models for predicting 10-year fracture risk: Model I (Base model) included only clinical risk factors (ie age, prior fractures, and fall in previous 12 months); Model II (Garvan model) included clinical risk factors and femoral neck BMD; Model III (Garvan+GRS) included clinical risk factors, femoral neck BMD and GRS; and Model IV (Base+GRS) included clinical risk factors and GRS. Decision curve analysis was used to evaluate the clinical net benefit of predictive models: one sums the weighted benefits (true positives) and substract the weighted harms (false positives), with the weights assigned to true positives and false positives were derived from the threshold probability of fracture.Results: In women, for risk threshold above 0.15, the Base+GRS model had a significantly higher net benefit than the Base model (Figure); however, for threshold below 0.15, there was no significant difference in net benefit between the two models. The Garvan model yielded the highest net benefit; adding GRS into the Garvan model did not substantially improve the net benefit. In men with fracture risk greater than 0.15, the Base+GRS model resulted in a better net benefit than the Base model. Interestingly, the Garvan+GRS model did improve the net benefit over and above the Garvan model.Conclusion: These results suggest that genetic profiling can provide additional prognostic information to that obtained from clinical risk factors, particularly in women at higher risk of fractures. However, in the presence of BMD in a predictive model, GRS does not further improve net clinical benefit.

Bioinformatics Informs GWAS: An Osteoporosis and Epigenetics Study Hui Shen*, Xiao Zhang, Fangtang Yu, Hong-Wen Deng, Melanie Ehrlich. Tulane University, United States

Most genetic variants for osteoporosis identified by genome-wide association studies (GWAS) are mapped to non-coding regions. It is challenging to pinpoint the disease-causal variants and understand their regulatory functions in disease. Here, we employed a novel bioinformatics approach to prioritize osteoporosis-associated genes and potential functional variants by leveraging cell-specific epigenomic and transcriptomic profiles across diverse human cell types. We compiled a list of 275 genes and 11,493 single-nucleotide polymorphisms (SNPs) that were associated with osteoporosis risk in previous GWAS (index SNPs) or that are in high linkage disequilibrium (r2> 0.8) with the index SNPs. Using comprehensive epigenomic annotations (histone modifications, chromatin segmentation states, DNase I hypersensitivity, and DNA methylation) along with RNA-seq data in osteoblasts and a diverse set of other types of human cells, we identified 16 osteoporosis-associated genes that are preferentially expressed in osteoblasts, and corresponding potential functional SNPs that are mapped to osteoblast-associated enhancer or promoter chromatin. These genes are CARMN (host gene for MIR143 and MIR145), CCDC170, GALNT3, GPC6, HOXA11, IGFBP7, KLF12, PAPPA, PDE7B, PDGFC, PPP6R3, PRRX1, RERE, TBX15, TRPS1, and TNFRSF11B (OPG). They include some well-known osteoporosis-related genes (e.g., TNFRSF11B) and genes that previously received little attention for their potential contribution to osteoporosis risk (e.g., PDGFC, PPP6R3 and RERE). Eleven of the genes had enhancer chromatin in the gene body in osteoblasts. Three had enhancer chromatin in intergenic regions. One (TNFRSF11B) even had the index SNP embedded in osteoblast-specific enhancer chromatin within the neighboring gene (COLEC10) that was silent in osteoblasts and almost all studied cell and tissue types. Some of the index or proxy SNPs also overlapped predicted allelic variation-sensitive binding sites for transcription factors present in osteoblasts. Our study shows how diverse epigenomic and functional annotations can be used to guide the prioritization of novel genes and functional variants in GWAS signals, and highlights a number of promising functional variants that may contribute to osteoporosis risk through influencing osteoblast-specific regulatory elements. Our findings form the basis for future biological studies of the osteoporosis-associated functional variants in model systems.

Regulation of FGF23 and Bone Mass by the Proprotein Convertase Furin
Omar Al Rifai*[1], Rachid Essalmani[1], John Creemers[2], Nabil G. Seidah[1], Mathieu Ferron[1]. [1]Institut de recherches cliniques de Montreal, Canada, [2]KU Leuven, Belgium

Fibroblast growth factor 23 (FGF23) is a hormone regulating phosphate metabolism, which is secreted by terminally differentiated osteoblasts. Specifically, FGF23 reduces phosphate reabsorption in the proximal tubule of the kidney by decreasing the expression of the sodium/phosphate cotransporters NaPi2a and NaPi2c. FGF23 proteolytic cleavage by a proprotein convertase (PC) inhibits its activity, since mutations that render FGF23 resistant to cleavage lead in humans to autosomal dominant hypophosphatemic rickets (ADHR), a rare phosphate wasting disorder characterized by increased FGF23 serum level, hypophosphatemia and osteomalacia. Yet, the identity of the PC(s) responsible for FGF23 cleavage in vivo remains undetermined, although it was suggested to be either furin or PC5 based on in vitro evidence. Hence, in the current study we investigate the role of furin and PC5 in the regulation of FGF23 in vivo, and assess their respective requirement for phosphate metabolism and bone mass accrual. OCN-Cre transgenic mice, expressing Cre recombinase under the control

of the human osteocalcin promoter, were crossed with Furinflox/flox or Pcsk5flox/flox mice to generated mice lacking furin or PC5 specifically in differentiated osteoblasts (i.e., Furinosb-/- and Pcsk5osb-/-). Circulating levels of intact FGF23 were significantly increased by more than 25% in Furinosb-/- mice, but remained unchanged in Pcsk5osb-/- mice. Despite this raise in active FGF23 there was no change in the expression of NaPi2a and NaPi2c in the kidney of Furinosb-/- mice, which maintained normal serum phosphate levels. In addition, bone histology did not reveal sign of osteomalacia in the same animals. These results are consistent with the observation that mice carrying the ADHR mutation (R176Q) in Fgf23 do not develop hypophosphatemic osteomalacia unless they are fed a low-iron diet [1]. Inactivation of furin in osteoblasts nevertheless resulted in a striking bone phenotype characterized by a 2-fold increase in trabecular bone volume combined with a 15% reduction in cortical thickness and in overall bone mineral density. In three-point bending tests Furinosb-/- femurs showed reduced bone stiffness. Of note, Pcsk5osb-/- mice displayed normal bone density. Together these results identify furin as a PC responsible of FGF23 cleavage in vivo, but also suggest that furin in osteoblasts influences bone density through FGF23-independent mechanisms. Bone-Targeted Pharmacological Inhibition of Notch Signaling Potentiates PTH-induced Bone Gain. Jesus Delgado-Calle*[1], Gerald Wu[2], Mathew E. Olson[1], Kevin Mcandrews[2], Jessica H. Nelson[1], Ashley L. Daniel[1], Noriyoshi Kurihara[1], Emily G. Atkinson[2], Venkat Srinivasan [3], Lifeng Xiao[3], Frank H. Ebetino[3], G. David Roodman[1], Robert K. Boeckman Jr[3], Teresita Bellido[2]. [1]Indiana University School of Medicine, Dept. of Medicine, Hematology/Oncology, United States, [2]Indiana University School of Medicine, Dept. of Anatomy and Cell Biology, United States, [3]University of Rochester, Dept. of Chemistry, United States

Daily injections of PTH (iPTH) cause bone anabolism by increasing osteoblast number and function. However, iPTH also increases bone resorption, which can limit bone gain. Earlier work demonstrated that iPTH activates Notch signaling in osteocytes; and that bone-targeted Notch inhibition using a Y-secretase inhibitor (GSI) conjugated to an alendronate-modified bone-targeting molecule (BT-GSI) decreases Notch signaling in bone, and reduces CTX (-40%) while preserving bone formation, leading to increases in BMD (4-7%) and cancellous bone volume (BV/TV; 30%). Here, we examined if combination of iPTH (anabolic) and BT-GSI (anti-catabolic) increases bone mass to a higher extent than either agent alone. BT-GSI (5mg/kg, 3x/wk) or saline was co-administered with iPTH (100 ng/g/day) or vehicle for 2wks to 4-mo-old mice (n=10/group). iPTH increased Hes1/5/7 and Hey1/L expression in bone, and BT-GSI decreased it to control levels. iPTH increased total (7%) and femoral (13%), and preserved spinal BMD (0%); and BT-GSI potentiated the increase at all bone sites (10, 17, and 7%, respectively). BT-GSI increased by 25% the gain in cancellous BV/TV (L4 and distal femur) and trabecular thickness induced by iPTH, but did not alter iPTH-induced increases in cortical bone area (8%). Co-administration of BT-GSI decreased serum P1NP (-30%); however, it preserved the increased bone formation rate (20%) and osteoblast surface (20%) induced by iPTH in cancellous bone. Further, mice receiving iPTH alone or combined with BT-GSI exhibited similar elevated Alpl, Runx2, Bglap, and Wnt target genes mRNA levels, and decreased Sost in bone. In contrast, co-administration of BT-GSI reduced the increased serum CTX (30%) and osteoclast surface (25%) induced by iPTH to values below those of control mice receiving vehicle. The increased Rankl/Opg expression ratio in bone (1.5-fold) induced by iPTH remained unchanged by BT-GSI, and no changes were found in M-Csf expression. However, unconjugated GSI reduced Rankl-induced osteoclast differentiation in vitro with an EC50 ~0.1μM. Importantly, the bone-targeting molecule alone required a dose 10 times higher than GSI to decreased osteoclastogenesis. These results demonstrate that bone-targeted inhibition of the Notch pathway in the frame of anabolic PTH signaling induces a superior bone gain compared to individual treatments and provide the bases for novel therapeutic strategies that reduce bone catabolism while simultaneously preserve bone anabolism.

FRI-0346

Overexpression of Sirt1 in Mesenchymal Stem Cells Protects against Glucocorticoid-Induced Osteoporosis by Inhibiting Oxidative Stress and Osteocyte Senescence Qinghe Geng*, Xiaoqing Hu, Jun Wu, Dengshun Miao. Nanjing Medical University, China

Glucocorticoid-induced osteoporosis (GIO) is the most common form of secondary osteoporosis, but molecular mechanisms for their harmful effects on bone are unclear. Although Sirt1 has been suggested as a protective molecule against osteoporosis, it is unknown whether Sirt1 overexpression in mesenchymal stem cells (MSCs) can protect against GIO. To answer this question, 12-week-old male Prx1-Sirt1Tg mice with Sirt1 overexpression in

MSCs and WT littermates were injected subcutaneous with either vehicle or dexamethasone (DEX) (1mg/kg/day) for 4 weeks. Bone phenotypes of all models were analyzed at 16 weeks of age. We examined the alterations of expression levels of Sirt1 in bony tissue and found that the mRNA and protein expression levels of Sirt1 were significantly up-regulated in Sirt1Tg mice and were significantly down-regulated in DEX-treated WT mice compared to WT mice, and they were returned to normal levels in DEX-treated Sirt1Tg mice. BMD, cortical and trabecular bone volume and bone mechanical strength, and osteoblastic bone formation parameters including osteoblast number, ALP+ and type I collagen+ areas, MAR, BFR, osteogenic gene expression levels and serum ALP and P1NP levels were all significantly decreased, whereas osteoclastic bone resorption parameters including osteoclast number and surface, RANKL/OPG ratio, serum TRAP-5b and CTX-1 levels were significantly increased in DEX-treated WT mice compared to WT mice, and were normalized in DEX-treated Sirt1Tg mice. To further explore the mechanism underlying the role of Sirt1 overexpression in MSCs in protecting against DEX-induced osteoporosis, we examined the alterations of oxidative stress and cell senescence parameters. Results showed that the ROS levels of bone marrow cells and serum malondialdehyde levels, β-galactosidase and p16 positive osteocytes, protein expression levels of γH2AX, 8-OHdG, p16, p21 and p53 and inflammatory factors, including TNFα, IL-1α/β, IL-6 and IL-8 gene expression levels were significantly increased, whereas T-AOC activity and SOD activity, protein expression levels of SOD1/2 and Prdx1/4 were significantly decreased in DEX-treated WT mice compared to WT mice, and were normalized in DEX-treated Sirt1Tg mice. Results of this study demonstrated that overexpression of Sirt1 in MSCs can protect against DEX-induced osteoporosis by inhibiting oxidative stress and osteocyte senescence, thus suggest that Sirt1 in MSCs is a therapeutic target for GIO.

FRI-0347

Sustained Klotho delivery reduces serum phosphate in a model of diabetic nephropathy Julia Hum*[1], Linda O'Bryan[2], Arun Tatiparthi[3], Erica Clinkenbeard[4], Pu Ni[4], Martin Cramer[2], Manoj Bhaskaran[2], Robert Johnson[2], Jonathan Wilson[2], Rosamund Smith[2], Kenneth White[4]. [1]Marian University, United States, [2]Eli Lilly and Company, United States, [3]Covance Inc, United States, [4]Indiana University School of Medicine, United States

Diabetic nephropathy (DN) is a primary cause of end-stage renal disease and is becoming more prevalent due to the global rise of type 2 diabetes. A model of DN, the db/db uninephrectomized (db/db-uni) mouse, is characterized by obesity, as well as compromised renal function. This model also manifests defects in mineral metabolism common in DN including hyperphosphatemia, which leads to severe endocrine disease. The FGF23 co-receptor, αKlotho (αKl), circulates as a soluble, cleaved form ('cKL') and may directly influence phosphate handling. Our study sought to test the effects of cKL on mineral metabolism in db/db-uni mice. Mice were placed into either mild or moderate disease groups based upon the albumin/creatinine ratio (ACR). Body weights of db/db-uni mice were significantly greater across the study compared to lean controls regardless of disease severity. Adeno-associated-cKL (AAV-cKL) administration was associated with increased serum Klotho, intact, bioactive 'iFGF23', and cFGF23 (p<0.05). BUN was improved after cKL administration, and cKL corrected hyperphosphatemia in the high and low ACR db/db-uni group. Interestingly, two weeks after cKL delivery blood glucose levels were significantly reduced in db/db-uni mice with high ACR (p<0.05). Several genes associated with stabilizing active iFGF23 were also increased in the osteoblastic UMR-106 cell line with cKL treatment. It remains to be determined whether increased cKL-FGF23 signaling or increased intact FGF23 acting on the diseased kidney mediates the effects on hyperphosphatemia in DN. In summary, delivery of cKL to a model of DN normalized blood phosphate levels regardless of disease severity.

FRI-0349

1,25-Dihydroxyvitamin D Retards Osteoporosis by Activating Nrf2-Antioxidant Signaling and Inactivating P16 Senescence Signaling Wanxin Qiao*[1], Lulu Chen[1], Weiwei Sun[1], David Goltzman[2], Dengshun Miao[1]. [1]Nanjing Medical University, China, [2]McGill University, Canada

Vitamin D deficiency has been identified as one of the factors associated with osteoporosis, however, the mechanism of vitamin D deficiency in accelerating the occurrence of osteoporosis is not yet clear. We first employed 1α (OH)ase heterozygous (1α (OH)ase+/-) mice as an animal model for 1,25 (OH)2D deficiency. In these mice, serum calcium and phosphorus levels were not reduced significantly, PTH levels were slightly increased, however, serum 1,25 (OH)2D levels were reduced by 30% compared to WT littermates. 1α (OH)ase+/- mice at 12 months of age displayed severe osteoporotic phenotype, including significantly reduced BMD, trabecular volume, ALP+ osteoblasts, and increased TRAP+ osteoclasts. Mineralization was normal. These mice also displayed an aging phenotype in bone, including significantly increased bone marrow ROS levels, p16+ and β-Gal+ osteocytes. Protein expression levels of nuclear factor erythroid 2-related factor (Nrf2), a mas-

ter regulator of cellular resistance to oxidants, and its target antioxidant enzyme genes, were down-regulated, and protein expression levels of γH2AX,a maker for DNA damage, and p16,p19 and p53 were up-regulated. Both the osteoporotic and bone aging phenotypes observed in 1α (OH)ase+/- mice were rescued by supplementation with exogenous 1,25(OH)2D3 or with the antioxidant N-acetyl-L-cysteine and by deletion of the p16 gene. Furthermore, we demonstrated that 1,25(OH)2D3 exerted an antioxidant role by transcriptional regulation of Nrf2 via VDR. Expression levels of Nrf2 gene were upregulated significantly in 1,25(OH)2D3-treated mouse embryonic fibroblasts (MEFs) from wild-type mice in a dose dependent manner, but not in MEFs from VDR knockout mice. Bioinformatic analysis suggested the presence, in the 5'-flanking region of the Nrf2 promoter, of a VDR response element-like sequence. Chromatin immunoprecipitation demonstrated that the VDR had the ability to physically bind the Nrf2 promoter. Luciferase assays showed that luciferase activity was increased significantly in MEFs transfected with Nrf2-PGL3 plasmid compared with the empty plasmid, and was more pronounced in 1,25(OH)2D3 treated MEFs transfected with Nrf2-PGL3 plasmid. Nrf2 knock-down significantly down-regulated the expression levels of Nrf2 antioxidant target genes. Taken together, current studies therefore, indicate that 1,25(OH)2D exerts an anti-osteoporosis role by activation of Nrf2-antioxidant signaling and inactivation of p16 senescence signaling.

FRI-0350

Estrogen-stimulated pleiotrophin functions to stimulate osteoblast differentiation and maintain bone mass in IGF binding protein-2 knockout mice Susan D'Costa*[1], Gang Xi[1], Victoria Demambro[2], Clifford Rosen[2], David Clemmons[1]. [1]University of North Carolina at Chapel Hill, United States, [2]Maine Medical Center Research Institute, United States

Pleiotrophin (PTN) is an extracellular heparin binding protein that contains a region of sequence that closely resembles IGFBP-2. Both PTN and IGFBP-2 bind to the cell surface receptor RPTPβ which leads to activation of AKT. Our previous studies showed that IGFBP-2 -/- male mice exhibited reduced trabecular bone mass while female null mice had no reduction but the explanation for this sexual dimorphism was not determined. Since estrogen has been shown to stimulate PTN, we hypothesized that estrogen maintains bone mass in the absence of IGFBP-2 via up-regulation of PTN. Our data showed that although PTN mRNA level was higher in female animals regardless of IGFBP-2 level, PTN mRNA levels in bone were significantly greater in IGFBP-2 knockout compared to wild type females. Analysis of calvarial osteoblasts isolated from IGFBP-2 knockout female mice showed a high level of PTN expression at day 3 and day 6 of differentiation. In addition, the temporal change in expression of PTN in MC-3T3 cells was quite similar to IGFBP-2, increasing from day 0 to day 9 and decreasing after day 12. Knockdown of PTN in MC-3T3 cells using RNAi inhibited osteoblast differentiation which could be rescued by adding back PTN or IGFBP-2. Similar to IGFBP-2, PTN was able to stimulate AKT activation, which is essential for osteoblast differentiation and addition of an anti-fibronectin 3 domain antibody which blocks IGFBP-2 binding to RPTPβ, inhibited PTN stimulation of AKT as well as differentiation. The addition of estrogen to MC-3T3 or IGFBP-2 silenced cells stimulated PTN expression and this resulted in enhanced osteoblast differentiation but estrogen had no effect on AKT induction or differentiation when PTN was knocked down. To further support this hypothesis, we also showed that estrogen loss following ovariectomy reduced serum PTN by > 50% while administration of estrogen to WT male mice increased PTN and RPTPβ mRNA 1.6 and 2 fold respectively in bone and it induced 1.9 and 2.9 fold increases in IGFBP-2 -/- mice. Consistently, our studies in male WT mice showed that estrogen treatment for 16 weeks resulted in a significant increase in aBMD but the response was significantly greater in male IGFBP-2 -/- mice. These results demonstrate that estrogen-stimulated PTN functions in a manner similar to IGFBP-2 to stimulate osteoblast differentiation and maintain the bone mass and that in the absence of IGFBP-2, estrogen stimulation of PTN maintains bone mass in female knockout mice.

FRI-0351

Overexpression of Sirt1 in Mesenchymal Stem Cells Protects against Estrogen Deficiency-Induced Osteoporosis Qian Zhang*, Rong Wang, Jianliang Jin, Dengshun Miao. Nanjing Medical University, China

Previous studies suggest that Sirt1 has a protective role against osteoporosis (OP), however, it is unknown whether overexpression of Sirt1 in mesenchymal stem cells (MSCs) can protect against estrogen deficiency-induced OP. To answer this question, 8-week-old female Prx1-Sirt1 transgenic (Sirt1Tg) mice and WT littermates were surgically ovariectomized (OVX) or sham operated. After 3 months, bone phenotypes of all models were analyzed. BMD, cortical and trabecular bone volume, and osteoblast number, ALP+ and type I collagen+ areas, ALP+ CFU-f forming efficiency and osteogenic gene expression levels were all reduced significantly, whereas TRAP+ osteoclast number and surface, and RANKL/OPG ratio were increased significantly in OVX-WT mice compared to sham-WT mice, however, they were normalized in OVX-Sirt1Tg mice. ROS levels of bone marrow cells, 8-OHdG and β-galactosidase positive osteoblasts and osteocytes, protein expression levels of p16, p21 and p53 were increased significantly, whereas protein expression levels of SOD1/2 and Prdx1/4 were reduced significantly in OVX-WT mice compared to sham-WT mice, however, they were normalized in OVX-Sirt1Tg mice. Furthermore, we demonstrated that estrogen

regulates Sirt1 expression at a transcriptional level mediated via ERα, subsequently, Sirt1 inhibits NF-κB signaling directly by deacetylating NF-κB. The mRNA and protein expression levels of Sirt1 in bony tissue were up-regulated significantly in Sirt1Tg mice and were down-regulated significantly in OVX-WT mice compared to sham-WT mice, however, they were returned to normal levels in OVX-Sirt1Tg mice. Bioinformatic analysis suggests the presence of a putative Esr1 response element in the Sirt1 promoter. ChIP demonstrated that the Esr1 had the ability to physically bind the Sirt1 promoter. Luciferase assays showed that luciferase activity was increased significantly in MEFs transfected with Sirt1-PGL3 plasmid compared with the empty plasmid, and was more pronounced in 17β-estradiol treated MEFs transfected with Sirt1-PGL3 plasmid. Immunoprecipitation demonstrated that Sirt1 could bind to NF-κB and Sirt1 overexpression in MSCs reduced the acetylation level of NF-κB and gene expression levels of IL-1β and IL-8, Mpp3/13. Taken together, current studies therefore, indicate that overexpression of Sirt1 in MSCs can protect against estrogen deficiency-induced OP by inhibition of oxidative stress and osteoblast/osteocyte senescence and inactivation of NF-κB signaling.

FRI-0392

Gambogic amide, a TrkA agonist, augments skeletal adaptation to mechanical loading through sensory nerve signaling Phuong Hua*, Ryan Tomlinson. Thomas Jefferson University, United States

The periosteal and endosteal surfaces of mature bone are densely innervated by sensory nerves expressing TrkA, the high-affinity receptor for nerve growth factor (NGF). In previous work, we demonstrated that inhibition of TrkA signaling diminished load-induced bone formation. Similarly, administration of exogenous NGF significantly increased load-induced bone formation through activation of Wnt signaling, albeit with the induction of substantial mechanical and thermal hyperalgesia in adult mice. Here, we tested the effect of gambogic amide (GA), a recently identified robust small molecule agonist for TrkA, on hyperalgesia and load-induced bone formation. The right forelimb of adult C57BL/6J mice (n = 7-8 per group) was subjected to non-damaging axial compression (3 N, 100 cycles, 2 Hz rest-inserted) for three consecutive days. GA (0.4 mg/kg) or vehicle (DMSO) was administered one hour prior to the first bout of loading. Behavioral analysis was used to assess pain up to one week after loading. Contrary to our expectations, GA treatment was not associated with diminished use of the loaded forelimb, by forelimb asymmetry testing. In fact, GA-treated mice used the loaded forelimb significantly more than control mice at two time points (1 and 4 days). To further examine GA-induced hyperalgesia, we performed hotplate sensitivity testing at 55 °C. Surprisingly, thermal sensitivity in GA-treated mice was unaffected or significantly decreased following loading. Calcein (10 mg/kg) and alizarin red (30 mg/kg) were administered 3 and 8 days after the initial bout of loading, respectively. Load-induced bone formation was assessed by dynamic histomorphometry using undecalcified sections from the mid-diaphysis of loaded and non-loaded forelimbs. Importantly, GA treatment was associated with a significant increase in relative periosteal bone formation rate (+63%) as compared to vehicle treatment. GA treatment was not associated with alterations in mechanical properties of non-loaded limbs (i.e. femur) as quantified by three-point bending. Furthermore, ulnar sections were stained for static histomorphometric analysis. We observed that GA treatment was associated with an increase in the number of osteoblasts per millimeter of bone surface in loaded limbs (+13%). In total, the results from our study demonstrate that gambogic amide has a beneficial effect on load-induced bone formation without inducing the hyperalgesia observed following exogenous administration of NGF.

Knockout p16 Protects against Unloading-Induced Intervertebral Disc Degeneration by Inhibiting Oxidative Stress And Cell Senescence Yongxin Ren*, Hui Che. The First Affiliated Hospital of Nanjing Medical University, China

Intervertebral disc degeneration (IVDD) is an integral part of age-related multi-organ aging. The p16 is not only a biomarker, but also an effector for aging, however, the role of p16 in the process of IVDD has not been investigated. In this study, we first examined alterations of p16 expression levels in degenerative human disc specimens and found that p16 expression at both mRNA and protein levels had a positive relationship with the degenerative severe degrees. Then we isolated nucleus pulposus (NP) cells from human discs, in which p16 was overexpression or knockdown, respectively. Our results demonstrated that p16 overexpression inhibited the proliferation of NP cells and induced the senescence of them, in contrast, p16 knockdown played an opposite action on the proliferation and senescence of NP cells. Next, we asked whether p16 knockout could rescued tail suspension-induced IVDD in mice, 3-month-old WT and p16-/- mice were performed with or without tail suspension (TS) for 4 weeks and the phenotypes of lumber intervertebral discs were analyzed using histopathological, cellular and molecular techniques. MRI evaluation based on Modified Thompson classification revealed that the degree of disc degeneration was increased to double levels of ground WT mice in TS-WT mice and returned to levels of ground WT mice in TS-p16-/- mice. Disc height index, the positive areas of safranin O staining and type II collagen immunostaining in the discs, and the percentage of PCNA+ cells were reduced significantly in TS-WT mice compared with ground WT mice and were largely rescued by p16 deletion. ROS levels, β-galactosidase+ senescence cells and senescence-associated secretory

phenotype (SASP) molecules including the gene expression levels of TNFα, IL-1α/β and IL-6 and the gene and protein expression levels MMP-3/13, p65-NF-κB, p19 and p53 were increased significantly, whereas the protein expression levels of Sirt1, SOD1/2, CDK4/6, pRB and E2F1/2 were down-regulated in the discs of TS-WT mice compared with those of ground WT mice, and were all largely rescued by p16 deletion. Our results indicate that p16 deletion can protect against unloading-induced IVDD by stimulating cell proliferation, inhibiting oxidative stress, cell senescence and SASP.

FAK expression in osteocytes is dispensable for bone accrual and for the anabolic response of cortical and cancellous bone to mechanical loading in female mice. Amy Y Sato*[1], Troy Li[1], Kevin Mcandrews[1], Alexander G Robling[2], Teresita Bellido[3]. [1]Department of Anatomy & Cell Biology, Indiana University School of Medicine, United States, [2]Department of Anatomy & Cell Biology, Indiana University School of Medicine, Roudebush Veterans Administration Medical Center, United States, [3]Department of Anatomy & Cell Biology, Department of Medicine, Division of Endocrinology, Indiana University School of Medicine, Roudebush Veterans Administration Medical Center, United States

A mechanosome composed of structural and signaling molecules, including the focal adhesion kinase (FAK), transmits mechanical stimuli into pro-survival signaling in osteocytes. Earlier studies showed that FAK activation is required for the anti-apoptotic effects of mechanical stimulation in osteocytes in vitro. However, whether FAK signaling in osteocytes is required for bone accrual or for bone anabolism induced by mechanical loading in vivo remains unknown. We addressed these questions by generating mice lacking FAK in osteocytes (FAKf/f;DMP1-8kbCre: FAKΔOT) and FAKf/f littermate controls and performed tibial loading in 5-7 mo. female mice. FAK deletion in osteocytes did not alter lean body mass (17 vs 16g), fat mass (8 vs 8g) or total (0.051 vs 0.050g/cm2), spine (0.057 vs 0.057g/cm2) or femur (0.062 vs 0.061g/cm2) BMD, quantified by DXA, or cortical or cancellous bone mass and architecture, quantified by μCT, for FAKΔOT vs FAKf/f mice (N=7-16). Body weight and the weight of soleus, gastrocnemius and tibialis anterior muscles were also similar in FAKΔOT vs FAKf/f mice. The force required to generate equivalent strains in the hindlimbs was 9.6 and 8N for FAKΔOT and FAKf/f mice, respectively, measured by strain gauges. Tibial loading consisted of a triangle waveform with 0.075sec loading at 4Hz, 0.075sec unloading, and 0.1sec rest, for a total of 5min (1200 cycles), once/d 5x/wk for 2wks. Mechanical loading effects were not detected at the BMD level, regardless of the genotype. However, loaded tibias from FAKf/f mice showed significant (*p<0.05) gain in the cortical bone fraction (BA/TA: 60 vs *64%) and area (BA: 0.12 vs *0.14mm2), tissue cross-sectional area (TA: 0.20 vs *0.23mm2), and cortical thickness (Ct. Th: 0.19 vs *0.21mm) without changes in marrow area (MA: 0.08 vs 0.08mm2), as detected by μCT in midshafts of non-loaded vs loaded tibia. Loaded tibia from FAKΔOT mice showed similar gains compared to control FAKf/f mice in BA/TA (60 vs *66%), BA (0.12 vs *0.15mm2), TA (0.20 vs *0.24mm2), and Ct.Th (0.19 vs *0.22mm), without changes in MA (0.08 vs 0.08mm2), in non-loaded vs loaded, respectively. Loading also led to similar increases in trabecular thickness of proximal tibia cancellous bone in both genotypes, non-loaded vs. loaded (FAKf/f: 0.05 vs *0.06mm; FAKΔOT: 0.05 vs *0.06mm). Taken together, these findings demonstrate that FAK signaling in osteocytes is not required for bone accrual or for bone anabolism induced by mechanical loading in vivo.

IGF1R Deficiency in Periosteal Osteoprogenitors Inhibits Bone Response to Mechanical Loading Tianlu Wang*, Faming Tian, Yongmei Wang, Daniel Bikle. Endocrine Unit, University of California, San Francisco and San Francisco VA Health Care System, United States

Previous studies demonstrated that insulin-like growth factor-1(IGF1) signaling in mature osteoblasts (OB) and osteocytes is critical for the bone response to mechanical loading. In this study, we investigated the role of IGF1 signaling in periosteal osteoprogenitor cells (POC) using POC specific IGF1 receptor (IGF1R) knockout mice (KO, floxed IGF1R X prx1promotor driven Cre) and their control littermates (Con, IGF1Rfl/fl no cre). At 12 wks, mice were divided into normal loading (NL), unloading (UL, 14 days tail suspension) and unloading combined with cyclic loading (CycL) group [14 days tail suspension combined with cyclic loading (10N compression, 40cycl/day for 10 days)]. Tamaxifen (Tam) was given 1 dose/day for the first 5 days. In NL group 14 day after tam, μCT revealed less cortical (Ct.) bone in the KOs compared with the Cons in both genders (male Ct.BV/TV:-11%, Ct.Th:-14%; female Ct.BV/TV:-13%, Ct.Th:-22%, Tb.Th:-8%.). Although in both genotypes, UL decreased bone mass compared with NL group, KOs exhibited less cortical bone loss than the Cons (KO male Ct.BV/TV:-6%, female Ct.BV/TV:-3%, Ct.Th: 0%; Con male Ct.BV/TV:-13%, female Ct.BV/TV:-33%, Ct.Th:-25%.). Consistently, bone histomorphometry showed reduced cortical and trabecular (Tb) bone formation in KOs in NL in both genders (male Ct.Ec.BFR:-49%, Tb.BFR:-48%; female Ct.Ec.BFR:-48%, Tb.BFR:-53%.). Periosteal (Ps) and endocortical (Ec) bone formation rate (BFR) in Cons decreased more dramatically than that in the KOs in response to UL (KO male Ct.Ps.BFR:-79%, female Ct.Ec.BFR:-48%; Con male Ct.Ps.BFR:-88%, female Ct.Ec.BFR:-70%). CycL induced a

greater increase in BFR in Cons than KO (KO male Ct.Ps.BFR:+0.7 fold, KO female Ct.Ec. BFR:+0.4 fold; Con male Ct.Ps.BFR:+2.6 fold, Con female Ct.Ec.BFR:+1.5 fold). In vitro, periosteal cells from each group were cultured in osteogenic medium for 14 days. In NL groups, in both genders, KO cultures formed fewer calcium containing nodules and expressed lower mRNA levels of RUNX2 and osteocalcin (OCN), as determined by QPCR. UL led to less nodule formation in both genotypes, but more dramatic reductions were observed in the KOs compared to the Cons. In response to cycL, more nodules were formed in the Cons than in the KOs, although both genotypes failed to reach significance. Our data indicate that IGF1R in the POC is critical for osteoprogenitor differentiation, bone formation and the skeletal response to mechanical loading, especially in the cortical bone.

Mechanical Loading Induces Bone Formation from Pre-Existing Osterix Expressing Cells Heather Zannit*, Matthew Silva. Washington University in St. Louis, United States

Cortical bone formation, which can be stimulated by mechanical loading, occurs when either existing osteoblasts are activated at the bone surface or new osteoblasts are recruited through differentiation or proliferation. The objective of this study was to begin to describe the identity of these bone forming cells. To do this, we utilized tamoxifen inducible Osx-Cre-ERT2;Ai9/TdTomato (iOsx-Ai9) reporter mice. All experiments used male and female mice aged to 5- and 12-mo subjected to unilateral axial tibial compression. First, the right tibia of iOsx-Ai9 mice (n=4/age group) were cyclically loaded for 5 days (1200 cycles/day; 7-14 N peak force) and processed for dynamic histomorphometry. We confirmed a significant increase in bone formation in loaded limbs compared to non-loaded controls (p<0.01). Then, to investigate the role of Osx lineage cells in this response, iOsx-Ai9 mice (n=6-15/age group) were pulse labeled with tamoxifen (followed by 3-wk clearance) and the right tibias were cyclically loaded for 5 consecutive days. Mice received BrdU in their drinking water daily, calcein was given 24 hours prior to euthanasia, and tibias were harvested and processed for frozen undecalcified histology. Periosteal compressive surfaces were analyzed in a 2mm region of the mid-diaphysis. Histology revealed both non-loaded and loaded tibias were covered in Osx+ cells (>95%) on the periosteum of both 5- and 12-mo animals. Additionally, there was a more than 2-fold increase in the mineralizing surface (calcein+) that is covered with Osx+ cells in loaded versus control limbs (p<.001). Furthermore, nearly all (>99%) of mineralizing surfaces were lined with Osx+ cells. We also observed both Osx and non-Osx cells proliferating (BrdU+) at sites of bone formation in 5- and 12-mo mice. These results show that, following mechanical loading, pre-existing cells of the Osx lineage cover the vast majority of surfaces where there is active loading-induced bone formation. This indicates that new bone formation shortly after mechanical loading primarily arises from Osx lineage cells, not the recruitment of earlier progenitor cells. Our findings of both Osx-lineage and non Osx-lineage cells proliferating at sites of bone formation validates previous work showing the importance of these cells to loading induced bone formation. To our knowledge, this is the first study to use an inducible reporter mouse to track the origin of bone forming osteoblasts following mechanical stimulation.
Figure1. A) Representative image in the ROI of an iOsx-Ai9 loaded tibia. Mineralizing surface (green) can be seen lined with non-proliferating Osx lineage cells (grey arrows) and proliferating Osx lineage cells (yellow arrows). B) Percentage of bone surface that is mineralizing with Osx lineage or non-lineage cells and just Osx lineage cells (Top-5 mo, Bottom-12 mo). Mu-Muscle, B-Bone

Short-term pharmacologic inhibition of RAGE suppresses bone turnover and muscle atrophy in aging Hannah M. Davis*[1,2], Mohammad W. Aref[1,2], Alyson L. Essex[1], Sinai Valdez[1], Alexandra Aguilar-Perez[1,2], Padmini Deosthale[1,2], Fletcher White[3,4,5], Jolene Windle[6], Matthew R. Allen[1,2,5], Lilian I. Plotkin[1,2,5]. [1]Department of Anatomy & Cell Biology, Indiana University School of Medicine, United States, [2]Indiana Center for Musculoskeletal Health, United States, [3]Department of Anesthesia, Indiana University School of Medicine, United States, [4]Stark Neuroscience Research Institute, Indiana University School of Medicine, United States, [5]Roudebush Veterans Administration Medical Center, United States, [6]Department of Human and Molecular Genetics, Virginia Commonwealth University, Richmond,VA, United States

Young RAGE (receptor for advanced glycation end products) KO mice exhibit increased bone mass and strength due to osteoclast (Oc) defects. Whether pharmacologic RAGE inhibition blocks Oc and prevents bone loss in aging is unknown. We assessed this question using female WT young 5mo and aged 16mo mice treated with Azeliragon (Az), a small molecule RAGE inhibitor being tested as treatment for Alzheimer's Disease and CRISPR/Cas9 global RAGE KO mice. WT mice were injected daily with Az 100μg/d (young), 110μg/d (aged), or vehicle (veh) for 28 days. In 16mo mice, expected age-induced changes in bone geometry and mechanics were observed; and bone formation was suppressed with lower serum P1NP (-39%) and mRNA expression of several osteoblast (Ob) genes. Az treatment did not affect bone geometry or mechanics at either age, but altered bone turnover at the cellular level. In particular, it reduced Oc number/surface on vertebral cancellous and femoral endocortical surfaces at both ages. Consistently, less mature (≥3 nuclei) Oc were obtained in vitro when wildtype bone marrow cells (BMC) were cultured with Az (-30%) or were generated from RAGE KO-derived BMC (-34%). Az also reduced Ob gene expression (OCN, Col1a1, and Osx) in bone, serum P1NP levels and vertebral Ob number/surface in both ages. These results suggest pharmacologic and genetic RAGE inhibition decreases Oc and Ob resulting in suppressed bone turnover. In addition, aged veh-treated mice exhibited altered body composition with greater fat mass and less lean mass vs 5mo mice. Consistently, aged veh-treated mice had reduced gastrocnemius (GA), tibialis anterior (TA), and quadriceps (QC) weight (wgt)/body wgt and lower TA mRNA levels of the muscle differentiation marker myoD; whereas muscle atrophy markers atrogin-1 and murf-1 were higher. Az reduced fat mass and increased lean mass; and increased GA (5%) and TA (14%) wgt in 5mo mice and GA (2%), TA (19%), and QC (10%) wgt in 16mo mice. RAGE inhibition also increased the expression of the myogenesis marker myogenin at both ages and restored myoD levels in 16mo mice. Moreover, Az reversed age-induced increased atrogin-1 levels. Overall, these findings reveal that while short-term pharmacologic RAGE inhibition suppresses bone turnover, it does not alter bone architecture or mechanical properties in 5 or 16mo mice. Further, we identified a novel protective effect of RAGE inhibition on skeletal muscle by preventing loss of muscle mass and muscle atrophy in aging.

Anti-Sost/Dkk1 Antibody Therapy Increases Bone Formation in Old Mice, but Does Not Enhance Their Modest Response to Tibial Loading Lisa Lawson*, Michael Brodt, Matthew Silva. Washington University in St. Louis, United States

Bone formation is regulated by the Wnt signaling pathway. Compressive axial loading of the skeleton has been shown to potently stimulate bone formation and induce expression of osteogenic markers including Sp7 and Col1a1, as well as many Wnt pathway genes. Compared to young-adult mice, however, aged mice exhibit reduced osteogenic responsiveness to skeletal loading. Recent studies suggest that loading-induced activation of the Wnt signaling pathway promotes bone formation in the adult skeleton, and that activation of this pathway may be impaired in the bones of aged mice. Recent work from our lab suggest that these changes may be related to a failure to potently downregulate Sost and Dkk1 in response to loading. Together, these data suggest that modulating the Wnt signaling pathway by targeting Sost and Dkk1 may be an effective strategy to restore the osteoanabolic effect of loading in aged mice. To investigate this possibility, 22-month old C57BL/6 mice were treated with neutralizing antibodies to Sost and Dkk1 (12.5mg/kg each of anti-Sost and anti-Dkk1, Amgen) or vehicle, and subjected to daily compressive loading on the right tibia (60 cycles, 2200ue); the left tibia served as a non-loaded control. Bone marrow was removed and tibias were harvested for mRNA isolation. Independent of loading, RT-qPCR showed a marked increase in the expression of Sp7, Runx2, Bglap, and Col1a1 in the non-loaded tibias of antibody-treated mice relative to the non-loaded tibias of vehicle-treated mice. Canonical Wnt pathway target Axin2 was also elevated in the non-loaded tibias of antibody-treated mice relative to controls. Dynamic histomorphometry showed that independent of loading, antibody treatment was associated with marked increases in measures of bone formation. In the non-loaded tibias of vehicle-treated mice, Ec.MS/BS and Ps.MS/BS were 14.6% and 0.6%, respectively, compared to 95.6% and 25.5%, respectively, in the non-loaded tibias of antibody-treated mice. Ps.MS/BS increased in response to loading in both groups, but antibody treatment did not further increase loading-associated bone formation. In sum, we found anti-Sost/Dkk1 antibody therapy to be a potent stimulator of bone formation, but that antibody therapy failed to restore a potent osteoanabolic response to tibial loading in aged mice.

Association of trajectories of change in bone, lean mass and physical performance with mortality in older men Jian Shen*[1], Neeta Parimi[2], Peggy Cawthon[2], Lisa Langsetmo[3], Kris Ensrud[3], Jane Cauley[4], Deborah Kado[5]. [1]University of California, San Diego, United States, [2]California Pacific Medical Center Research Institute, United States, [3]University of Minnesota, United States, [4]University of Pittsburgh Graduate School of Public Health, United States, [5]University of California, United States

Musculoskeletal deterioration is an important physiological change observed with aging. Biological cross-talk between bone and muscle may influence the rate of decline, and if so, patterns of concurrent change in musculoskeletal phenotypes may more precisely capture effects of accelerated aging and identify those at high mortality risk. Therefore, we conducted longitudinal analyses of change in bone, muscle and two physical performance parameters with subsequent mortality risk among 3232 men participating in the Osteoporotic Fractures in Men Study (MrOS) (mean age: 79 y). We measured: 1) total hip bone mineral density (BMD); 2) appendicular lean mass (ALM) by DXA; 3) grip strength by hand dynamometry; and 4) gait speed (usual pace over 6 meters, m/s) at up to 4 clinic visits between 2000 and 2009. Using multivariate proportional hazards analyses, all-cause mortality was assessed over an average of 7.1 years following the last clinic visit. We used group-based trajectory models (PROC TRAJ in SAS) to create trajectories based upon identifying patterns of change in each of the 4 parameters. All models were adjusted for age, site, weight loss, fracture history, and self-reported health. For each of the 4 parameters, 3 trajectory groups were identified, each with similar rates of decline. The "high" trajectory group included those with higher values across all visits; the "intermediate" group had values in the middle ranges, and the "low" group had the lowest values over time. Compared to men in the intermediate trajectory group, those in the low trajectory group had an increased mortality risk (HR (95%CI):1.16 (1.02-1.31) for BMD; 1.3 (1.14 -1.48) for ALM; 1.25 (1.1-1.42) for grip strength; and 1.33 (1.12 -1.57) for gait speed. Men in the high trajectory group for gait speed, but not the other 3 high trajectory groups, had lower mortality risk compared to those with an intermediate trajectory. We also found that for each parameter, the single measure at the last visit predicted mortality risk (Table). After adjusting for the last visit measure of each of the 4 parameters, the associations of each of the trajectory groups with mortality risk was no longer significant. These findings suggest that men with elevated mortality risk may follow distinct musculoskeletal trajectories; however, the most proximal musculoskeletal measure of either BMD, ALM, grip strength or gait speed exerts the most influence when estimating mortality risk.

Table. Multivariate adjusted hazard ratios of each musculoskeletal trajectory with all-cause mortality before and after adjusting for the last visit measure

Musculoskeletal trajectory	Full model	Full model + last visit measure
BMD		
Low	1.16 (1.02 to 1.31)	0.95 (0.80 to 1.14)
Intermediate	REF	REF
High	0.97 (0.83 to 1.13)	1.22 (0.98 to 1.52)
ALM

Fibroblast growth factor receptor 3 inhibits progression of degeneration in the intervertebral disc in mice Yangli Xie*, Xiaolan Du, Lin Chen, Zuqiang Wang. Department of Rehabilitation Medicine, Center of Bone Metabolism and Repair, State Key Laboratory of Trauma, Burns and Combined Injury, Trauma Laboratory, Daping Hospital, Army Medical University, China

Objective Intervertebral disc (IVD) degeneration is a common degenerative disease, to date the mechanisms during its pathogenesis is largely unknown. Herein we investigated whether FGFR3, a negative regulator of endochondral ossification, is associated with IVD.Methods Immunohistochemistry (IHC) was used to detect the expression of FGFR3 in IVD tissues in mice with different age and from human. Lumbar segmental instability (LSI) model was generated. Deleted FGFR3 in IVD tissue including annulus fibrosus (AF) and endplate (EP) in FGFR3flox/flox; Col2α1-CreERT2 mice by administering tamoxifen. Alterations in IVD structure were evaluated histologically using IVD degeneration scoring system. The expressions of genes associated with IVD homeostasis were analyzed by qRT-PCR and IHC.Results In degenerated IVD from human patients, we found that FGFR3 expression level is decreased in AF and NP, suggesting a possible role for FGFR3 in the IVD hemostasis. The levels of FGFR3 were downregulated in murine IVD tissue during aging process. Gain-of-Function mutation of FGFR3 can play protective role in IVD under LSI condition in mice. Moreover, FGFR3 conditional knockout mice exhibited early onset of IVD degeneration with accelerated IVD matrix degradation, abnormal bone formation in EP and increased bone resorption in vertebra with aging.The elevated Wnt/β-catenin signaling may be involved in this degeneration process.Conclusions FGFR3 may play a protective role in homeostasis of IVD, and may serve as a potential molecular target for treating disc degenerative diseases.

Novel Genetic Loci Control L5 Vertebral Trabecular Bone and the Response to Low Calcium Intake in Growing BXD Recombinant Inbred Mice Krittikan Chanpaisaeng*[1], Sarah Mace[2], Perla Reyes-Fernandez[1], James Fleet[1]. [1]Department of Nutrition Science, Purdue University, United States, [2]Department of Biological Sciences, Purdue University, United States

Epidemiological data show an inverse association between vertebral fractures and trabecular bone (Tb) microarchitecture. This highlights the importance of developing strong Tb microarchitecture to prevent osteoporotic fractures. Because Tb is modulated by genetics (G) and environment (e.g. diet, D), we studied the impact of GxD interactions on Tb at the L5 spine. Mice from 51 BXD recombinant inbred lines were fed either adequate (H, 0.5%) or low (L, 0.25%) Ca diets from 4-12 wks of age. We used micro-computed tomography (μCT) to measure: bone volume fraction (BV/TV) and Tb tissue mineral density (Tb.TMD), Tb thickness (Tb.Th), separation (Tb.Sp), and number (Tb.N), as well as connectivity density (Conn.D), and structure model index (SMI). The response to dietary Ca restriction (RCR) was calculated for each phenotype in each line. Body size (BS)-corrected residuals were used for statistical analysis. We found that genetics has an independent, strong influence on Tb traits (e.g. BV/TV, narrow sense heritability (h2)=0.57) but a more modest influence on the RCR (e.g. Tb.N, h2=0.28). ANOVA revealed significant main effects for genetics and diet for all traits. Similarly, the RCR was affected by genetics indicating a GxD interaction affecting all Tb traits. BS-corrected line means for each trait and RCR were used for quantitative trait loci (QTL) analysis by composite interval mapping (500 permutations, WinQTL-Cart). We identified 2-5 loci affecting each trait and 1-3 loci affecting the RCR for each trait. Loci controlling Tb.N (chr 2, 12), Tb.Sp (chr 2, 4), Conn.D (chr 1, 12), and SMI (chr 8) were seen in both diet groups providing replication of environmentally robust genetic effects. Loci on chr 2 (Tb.Sp, Tb.N, SMI RCR), chr 12 (Tb.N, Conn.D, Tb.Sp L) and chr 7 (RCR for BV/TV, SMI, Tb.TMD, Tb.Th, Tb.Sp) were found to control multiple phenotypes suggesting the existence of latent traits. Candidate genes underlying selected loci were identified with PROVEAN (protein coding effects) or eQTL analysis in The GeneNetwork (mRNA level effects). On chr 7, we found a non-synonymous coding (Cn) variant and a cis eQTL affecting Lrrk1, a gene that promotes bone resorption. On chr 2, we found a Cn variant of Wisp2, a mesenchymal cell activator of canonical WNT signaling. Within a chr 3 locus, Sec24d has a Cn variant and a cis eQTL that could affect the secretion of extracellular matrix in bone. Our work shows that genetics and diet interact to influence lumbar spine Tb.

The large variant of the stimulatory G protein alpha-subunit XLαs regulates bone formation by promoting Wnt signaling Qing He*, Julia Matthias, Lauren Shumate, Murat Bastepe. Massachusetts General Hospital and Harvard Medical School, United States

Mutations of the GNAS complex gene, encoding the alpha-subunit of the stimulatory G protein (Gsα) and its large variant XLαs, cause multiple diseases that involve bone development, such as Albright's osteodystrophy and progressive osseous heteroplasia. Gsα mediates the actions of many hormones or autocrine/paracrine factors primarily by stimulating the cAMP signaling pathway. Although overexpression of XLαs also stimulates cAMP signal-

ing, cellular actions of XLαs remain unclear. Moreover, XLαs is expressed in bone cells, but its roles in bone physiology and bone disease are poorly defined. By μCT and bone histomorphometry analysis, we have demonstrated that XLαs knockout (XLKO) mice have significantly decreased bone mass and thickness at postnatal day 10 because of impaired bone formation. While osteoblast numbers were decreased, osteoclast numbers remained unchanged; surprisingly, osteocyte density was increased in XLKO mice. Consistent with decreased bone formation in XLKO mice, the expression levels of osteogenic markers were dramatically reduced, including alkaline phosphatase, Runx2, osteocalcin, and bone sialoprotein. Calvarial cells isolated from neonatal XLKO mice displayed impaired osteogenic differentiation. Since Wnt signaling has been shown as an important regulator of bone formation and osteogenic differentiation, we examined Wnt signaling and found significantly increased expression of the Wnt inhibitor sclerostin, together with reduced expression of Wnt targets TCF1 and LEF1 in XLKO femurs. Western blot analysis demonstrated decreased skeletal levels of active β-catenin in XLKO mice. Moreover, XLKO calvarial cells showed reduced TOPflash activity at baseline and after Wnt3a stimulation compared to wildtype cells, further confirming repressed Wnt signaling in XLKO samples. Activation of the cAMP signaling pathway can enhance Wnt signaling in bone cells, but RANKL mRNA, a target of cAMP signaling, was increased in XLKO femurs, and CRISPR/Cas9-mediated ablation of XLαs in a mouse osteocyte-like cell line did not diminish cAMP generation, suggesting that the action of XLαs in bone does not occur via cAMP signaling. Taken together, these results imply that XLαs is essential for normal bone formation and osteogenic differentiation, and that its role in bone formation might involve Wnt signaling.

FRI-0440

BMP9 stimulates synovial joint regeneration in mice Ken Muneoka*, Ling Yu, Mingquan Yan, Lindsay Dawson. Texas A&M University, United States

Purpose: A major goals of regeneration science is to develop strategies to stimulate mammalian regeneration. The mouse digit tip is the only part of the limb that displays regenerative ability, amputations at proximal levels result in fibrotic scarring and skeletal truncation. We use the non-regenerating neonatal digit amputation as a test site for factors that can induce regenerative events. Previously we found that BMP2 treatment stimulates bone regeneration by inducing an endochondral ossification center at the amputated digit stump. We now show that subsequent treatment with another BMP family member, BMP9, stimulates the regeneration of a synovial joint.Methods: Neonatal digits are amputated mid-way through the sub-terminal phalangeal element (P2) removing the distal half of P2, the terminal phalangeal element (P3) and the intervening P2/P3 joint. After wound closure, a single agarose beads carrying either BMP2 or BMP9 protein is implanted between the wound epidermis and stump. In some experiments, a BMP2 bead implantation is followed by a BMP9 bead implanted 3 or 7 days later. Digits are analyzed using microcomputed tomography (μCT), histology, immunohistochemistry and in situ hybridization.Results: BMP9 treatment induces the regeneration of a skeletal element that articulated with the digit stump in 51% of the digits (n=96). Histological analyses identified an articular cartilage layer lining the regenerated skeletal element and a cavity separating the skeletal element from the stump. The regenerated skeletal element forms as a chondrogenic nodule within 3 days after BMP9 treatment and contains articular chondrocytes identified based on marker gene expression. A cavity lined with cells expressing Prg4 identifies the regenerated cavity as synovial. Studies using mutant mice indicate that BMP9-induced joint regeneration requires the Prg4 gene. Amputation wounds is first treated with BMP2 to induce skeletal regeneration, then treated with BMP9, we show that induced regeneration of bone can be coupled with synovial joint regeneration. Conclusions: We have demonstrated for the first time that synovial joint regeneration can be stimulated in a mammalian model of regenerative failure, and have identified BMP9 as a regeneration inducing agent. Combining BMP2 and BMP9 application to induce a complex regenerate establishes a novel strategy for engineering regenerative responses with targeted growth factor treatment.

Microtubule-Actin Crosslinking Factor 1 Is Essential for Bone Formation in Mice Fan Zhao*[1], Xiaoli Ma[1], Wuxia Qiu[2], Lifang Hu[1], Airong Qian[1]. [1]Northwestern Polytechnical University, China, [2]Northwestern Polytechnical, China

The spectraplakins are highly conserved crosslinking proteins that expressed widely in a variety of cell types. In lower animals such as fly, the spectraplakins are encoded by the Short stop (Shot) gene, while in mammals, it is encoded by microtubule-actin crosslinking factor 1 (Macf1). Numerous studies pointed out that MACF1 might serve an important molecular in crosslinking cytoskeletal components during cell migration, adhesion and differentiation.Previous studies also discovered that MACF1 partially colocalizes with the microtubules and microfilaments, has ATPase activity, and controls epidermal migration through regulating focal adhesion and cytoskeleton dynamics. Our previous data demonstrated that MACF1 expression level was lower in osteoporotic bone tissue in mice; In vitro data showed that knockdown of MACF1 in osteoblastic cells inhibited osteoblast differentiation through suppressing the β-catenin/TCF1-Runx2 signaling axis. However, the role of MACF1 in bone metabolism regulation is still poorly understood, no in vivo data are now available to depict its role and mechanism in regulating osteogenic differentiation and bone formation.Being a major factor in cytoskeletal dynamics regulation, increasing evidence have pointed out crucial roles of MACF1 in cellular metabolism. In the present study, we unveiled key roles of MACF1 in osteogenic differentiation and bone formation in vivo. By conditional gene targeting to delete MACF1 in mesenchymal stem cells in mice (panel A), we observed in bones of the MACF1 deficient mice obvious ossification retardation and bone loss (panel B, C and D), which we traced to a decrease of osteoblastic differentiation capability in MSCs (panel E, F and G). Further, we show that MACF1 is essential for the cytoskeleton to regulate osteoblastic differentiation of MSCs (panel H and I). By coupling the results obtained, we have identified key roles of MACF1 in cytoskeleton maintenance in MSCs and bone formation regulation in mice. The data would not only update our knowledge of the spectraplakins in osteoblastic functions, but also offer a new therapeutic target for bone degenerative diseases.

Epigenetic regulator, Uhrf1, positively controls skeletal muscle differentiation

Yuichiro Sawada*[1], Tadahiko Kikugawa[1], Iori Sakakibara[2], Yusuke Ono[3], Yuta Yanagihara[4], Noritaka Saeki[4], Hiroyuki Iio[1], Takashi Saika[1], Yuuki Imai[4]. [1]Department of Urology, Ehime University Graduate School of Medicine, Japan, [2]Research Center for Advanced Science and Technology, The University of Tokyo, Japan, [3]Musculoskeletal Molecular Biology Research Group, Nagasaki University Graduate School of Biomedical Sciences, Japan, [4]Division of Integrative Pathophysiology, Proteo-Science Center, Ehime University, Japan

Regulation of homeostasis of various cells and tissues requires epigenetic regulation such as DNA methylation and histone modifications, however, the effect of epigenetic regulatory factors on skeletal muscle is still largely unknown. To investigate the relationship between muscle regeneration and epigenetic regulation, we analyzed gene expression levels of various DNA methylation-related factors in mouse skeletal muscle regeneration models induced by cardiotoxin (CTX) injection for TA muscles. As a result, gene expression of Uhrf1 (Ubiquitin-Like PHD And Ring Finger Domain 1), which is responsible for maintenance DNA methylation, was significantly increased at day 4 after muscle injury. To evaluate the function of Uhrf1 in skeletal muscle differentiation and regeneration, Uhrf1 knockout for C2C12 cells, which is a representative myoblastic cell line, were established using CRISPR/Cas9 system and single cell sorting, then, myotube formation and expression of muscle differentiation marker genes were examined. As a result, Uhrf1 knockout C2C12 cells showed remarkably impaired myotube formation, significantly reduced expression of myogenic genes and increased expression of Myh3, an embryonic type myofiber gene. In addition, to investigate the physiological role of Uhrf1, satellite cells, which are stem cells of skeletal muscle, specific Uhrf1 knockout (scKO) mice were generated by crossing Pax7CreERT2 and Uhrf floxed mice. Then, the muscle regeneration ability of control and scKO mice were analyzed using CTX model with or without 5-straight-days Tamoxifen injection. Fourteen days after CTX, TA muscles of scKO mice exhibited significantly reduced muscle weight recovery and decreased cross-sectional area of myofibers (n = 3-5) when compared to that of control mice. To examine the potential of satellite cells lacking Uhrf1, single muscle fibers were isolated from EDL muscle of control and scKO mice and cultured for analyses of differentiation and proliferation of satellite cells on the muscle fibers. Immunocytochemistry against Pax7 and MyoD for single muscle fibers revealed that satellite cells on myofibers of scKO mice showed significantly decreased proliferation and impaired differentiation (n = 5 mice, more than 10 fibers/mouse) when compared to that of control mice. These data indicate that Uhrf1 play an important role in proliferation and differentiation of satellite cells, followed by skeletal muscle regeneration and skeletal muscle fiber maturation.

Targeted epigenetic modulation of bone-specific enhancers regulates mesenchymal cell fate and controls osteoblastic differentiation

Jonathan Gordon*[1], Coralee Tye[1], Joseph Boyd[1], Andre Van Wijnen[2], Janet Stein[1], Gary Stein[1], Jane Lian[1]. [1]Department of Biochemistry, Larner College of Medicine, University of Vermont, United States, [2]Department of Orthopedic Surgery, Mayo Clinic, United States

Adult bone formation requires a highly regulated program of differentiation from a mesenchymal-derived osteoprogenitor to a mature osteocyte. Epigenetic mechanisms control mesenchymal stromal cell (MSC) commitment to a mature osteoblast through facilitating of binding of transcriptional regulators to promoter regions of genes, however less well understood are inter- and intra-genic regulatory regions that control cell-type-specific gene expression programs. These regulatory elements called cis-regulator modules, are bound by transcription factors (TFs) and specific post-translationally modified histones, and play key roles in the control of tissue morphogenesis. To define novel regulatory regions during osteogenesis, pluripotent CD45-/Ter119-/SCA1+/CD29+/Nestin+/CD146+/aSMA+ MSCs and analogous human MSC populations, were isolated by FACS to obtain a homogenous population of cells that were differentiated to mature osteoblasts. We then used ChIP-seq to develop genome-wide enrichment profiles of intergenic genomic regions of occupied by TFs, cofactors, chromatin regulators, and transcription apparatus occupying osteogenic enhancers in MSCs. Supervised pattern discovery was performed using ChromHMM to segment genomic regions into active, quiescent, TF-bound, transcribed and super-enhancer regions. From this analysis, we identified novel enhancers near genes that are involved in osteogenesis (e.g. SP7, Runx2, Fgfr1). Further novel enhancers for bone formation were predicted in intragenic regions of several osteoblast-related genes. Using a CRISPR-based strategy for targeted epigenetic modification, dCas9 protein fused to the catalytic core of the human acetyltransferase p300 or LSD1/KDM1A was used to alter histone acetylation or histone methylation (respectively) at SP7 enhancer regions. Alterations of histone post-translational modifications at these enhancer regions by targeted dCas-p300 or dCas9-KDM1A were sufficient to alter expression of SP7 (osterix) and inhibit commitment of progenitors to the osteoblast lineage (dCas9-KDM1) or increase osteoblast-related markers (dCas9-p300). From these studies, we have demonstrated novel regulatory regions, denoted by histone modifications and transcription factor binding sites functioning as enhancers critical for osteogenic differentiation. In addition, we have used a novel epigenetic modification strategy to increase osteoblast-related gene expression. These strategies may be used to modify or enhance osteogenic potential of mesenchymal cells for therapeutic bone regeneration.

Glutamine metabolism is required in skeletal stem cells for appropriate bone regeneration.

Yilin Yu*, Anthony Mirando, Leyao Shen, Matthew Hilton, Courtney Karner. Duke University, United States

Skeletal stem cells (SSC) are multipotent progenitor cells postulated to regulate bone mass and regeneration by providing a source of osteoblasts throughout life and in response to injury. With age, the SSC population can be exhausted, resulting in reduced osteoblast formation, decreasing bone mass, and diminished bone regeneration in response to injury. Recent work has focused on defining cell markers of the SSC population, however little is known about the molecular mechanisms regulating the proliferation or maintenance of the SSC population. Glutamine metabolism has emerged as a critical regulator of proliferation and cellular activity in diverse systems. In addition to direct incorporation in polypeptide chains, glutamine is an important oxidative fuel and a precursor of non-essential amino acids, nucleotides, and glutathione. The enzyme glutaminase (GLS) catalyzes the deamination of glutamine to form glutamate, the rate-limiting first step in glutamine metabolism. Here we demonstrate GLS is required in SSC to regulate postnatal bone homeostasis and regeneration. Using GLS activity assays, we discovered GLS activity declines with age in wild type SSC and significantly correlates with depletion of SSC and reduced bone mass observed with aging. Importantly, genetic deletion of a conditional (floxed) Gls allele (Glsfl/fl) in SSC using LeprCre significantly reduces bone mass in vivo due to decreased osteoblast numbers and bone formation. Moreover, LeprCre;Glsfl/fl mice had diminished bone regeneration in a non-stabilized tibia fracture model. LeprCre;Glsfl/fl fracture calluses had reduced cartilage callus formation, diminished bone volume as well as persistent fibrosis at the fracture site. Colony forming unit assays and Brdu incorporation studies demonstrated a significant reduction in proliferation in LeprCre;Glsfl/fl SSC. Mechanistically, glutamine dependent glutathione and nucleotide biosynthesis are dispensable for SSC proliferation, whereas amino acid transaminase dependent α-ketoglutarate production is critical for SSC proliferation. Collectively, these data highlight the critical role for GLS and glutamine metabolism in SSC to maintain the SSC population and promote postnatal bone mass accrual and bone regeneration in response to fracture. Our data indicate stimulating GLS activity may provide a valuable therapeutic approach to maintain or expand SSC in aged individuals to repair or regenerate bone.

FRI-0466

Zinc Finger Protein 467 Is a Major Determinant of Lineage Allocation and Bone Turnover in Female Mice Phuong Le*[1], Weiqing Liu[2], Tj Martin[3], Beate Lanske[4], Roland Baron[2], Clifford Rosen[1]. [1]Maine Medical Center Research Institute, United States, [2]Harvard School of Dental Medicine, United States, [3]St. Vincent's Institute Medical Research, Australia, [4]Radius Health, Inc, United States

Zinc finger protein 467 (Zfp467) was originally isolated from mouse endothelial LO cells as an oncostatin M-inducible mRNA. It belongs to the Kruppel-like family of transcription factors and its expression is relatively ubiquitous. Preliminary work implicated Zfp467 as a novel regulator of cell fate by inhibiting osteoblast commitment and stimulating adipocyte differentiation. We (Fan, et al.) reported that Zfp467 is up-regulated 8-fold in RANKL-producing marrow adipocytes from Prx1cre;PTH1Rfl/fl mice while Quach, et al. noted that Zfp467 mRNA was suppressed by PTH suggesting that Zfp467 positively influences adipogenesis and is negatively regulated by PTH. In this study, we hypothesized that genetic loss of Zfp467 would lead to an increase in bone mass by shifting marrow cell fate towards osteogenesis. We generated Zfp467-/- mice and performed skeletal and adipose phenotyping. At 16wks of age, Zfp467-/- mice (-/-) were significantly smaller than Zfp467+/+ mice (+/+) due to lower fat mass and lean mass (p< 0.03). uCT of tibial trabecular (Tb.) bone showed that Tb.BV/TV, Tb.BMD, Tb.N, and Conn.D were significantly higher in -/- vs. +/+ (p<0.002) and lower SMI (p=0.005). Cortical (Ct.) parameters showed smaller Ma.Ar and higher Ct.Ar/Tt.Ar (p<0.03) in -/-. Additionally, Ct.Porosity was significantly lower (p=.003) in -/-. Consistent with uCT, histomorphometry showed higher structural parameters of Tb.BV/TV, Tb.N, and Tb.Th (p<0.0175) in -/-. Furthermore, MS/BS, MAR, BFR/BS, and BFR/BV were higher in -/- vs. +/+ (p<0.005). However, Oc.S/BS was also significantly higher in -/- vs. +/+ (p<0.05) indicating an overall increase in bone turnover. Adipocyte ghosts were reduced in the marrow of -/- vs. +/+ mice. Femoral gene expression including Alpl, Sp7, and Acp5 were increased (p< 0.018) in -/- . In vitro, BMSCs from -/- showed more positive ALP and Von Kossa staining and a decrease in ORO droplets from BMSCs and eMSC. Adiponectin, Cebpa, Lepr, and Pprag mRNA were also lower in -/- vs. +/+ (p<0.01). Similarly, Fabp4 and Lep in the inguinal depot were also decreased in -/- vs. +/+ (p<0.05). Taken together, absence of Zfp467 leads to greater bone remodeling with high bone formation and bone mass, together with a decrease in BMAT in female mice. These data support a critical role for Zfp467 in early lineage allocation and provide a novel potential mechanism by which PTH acts in an anabolic manner.

FRI-0467

Effects of Notch1 signaling on bone fracture healing Sanja Novak*[1], Emilie Roeder[1], Brya G Matthews[1], Douglas J Adams[2], Ivo Kalajzic[1]. [1]Department of Reconstructive Sciences, University of Connecticut Health Center, United States, [2]Department of Orthopaedic Surgery, University of Connecticut Health Center, United States

Notch signaling exhibits different effects at different stages of the osteoblast lineage. Notch signaling in progenitor cells increases their proliferation but also inhibits osteogenic differentiation potential. We hypothesize that Notch signaling regulates the expansion, migration and differentiation of mesenchymal progenitor cells and modulates the fracture healing process.Fracture healing was assessed in 8-9-week-old male and female mice. Forced expression of Notch1 intracellular domain (NICD1) was targeted to osteoprogenitor cells using αSMACreERT2 during fracture healing. Stabilized closed transverse femur fractures were generated in experimental mice and littermate controls and Cre activity was induced by injecting tamoxifen on day 0, 2 and 4 post fracture. Increased expression of Hes1 and Hey1 in periosteal cell culture (PPC) and callus tissue confirmed NICD1 overexpression. In vitro experiments using PPC overexpressing NICD1 showed increased proliferation and migration compared to controls, but decreased osteogenic differentiation.Histological evaluation of fracture healing in male mice showed that targeted NICD1 overexpression decreased cartilage area 10 days after fracture (p<0.05) and increased mineralized content 14 days after fracture (p<0.01). Fracture calluses with NICD1 overexpression had increased bone mass (p<0.05) with no difference in callus volume compared to controls 3 weeks after fracture. Furthermore, NICD1 overexpression in male animals increased fractured femur strength and stiffness (p<0.001), but also strength and stiffness of intact contralateral femur compared to controls (p<0.05). Overexpression of NICD1 in female mice did not alter callus volume or bone content 3 weeks after fractures, and biomechanical properties of intact contralateral femurs did not differ compared to the controls.Furthermore, using RBPjκ floxed mice and crossing them with αSMACreERT2, we evaluated the effect of Notch signaling deletion on fracture healing. We did not observe changes in callus volume and callus bone mass 3 weeks after fracture.Overexpression of Notch1 signaling in osteoprogenitors following fracture has anabolic effects and leads to increased bone mass and improved biomechanical properties of the fractured femur, while deletion of Notch signaling in αSMA osteoprogenitor cells did not affect the healing process. Further studies are required to understand the discrepancy between in vitro and in vivo effects of NICD overexpression.

FRI-0468

Aberrant muscle tissue repair by mutant ACVR1 FOP muscle stem cells – implications for heterotopic ossification Alexandra Stanley*[1], Elisia Tichy[2], Foteini Mourkioti[3], Eileen M. Shore[4]. [1]Perelman School of Medicine, University of Pennsylvania, Department of Orthopaedic Surgery, Cell and Developmental Biology Graduate Program, United States, [2]Perelman School of Medicine, University of Pennsylvania, Department of Orthopaedic Surgery, United States, [3]Perelman School of Medicine, University of Pennsylvania, Departments of Orthopaedic Surgery and Cell and Developmental Biology, United States, [4]Perelman School of Medicine, University of Pennsylvania, Departments of Orthopaedic Surgery and Genetics, United States

In the rare genetic disease fibrodysplasia ossificans progressiva (FOP), progenitor cells are mis-regulated to differentiate to heterotopic extra-skeletal bone in connective tissues. Mutations in the BMP type I receptor ACVR1/ALK2 cause FOP, with the R206H mutation as the most prevalent. Our lab previously identified that ACVR1R206H increases both BMP ligand-dependent and ligand-independent signaling and promotes increased downstream chondro-/osteogenic gene expression and heterotopic ossification (HO) in FOP patients. HO formation in FOP is often initiated by injury within skeletal muscle. The regenerative potential of skeletal muscle is dependent on the function of muscle stem cells (MuSCs). Quiescent MuSCs are activated within 1-2 days after injury, quickly followed by proliferation, and then differentiation of cells until muscle architecture is restored. We developed an Acvr1R206H mouse model that forms HO after cardiotoxin (CTX) injury to skeletal muscle. By 14 days, while muscle of CTX-injured WT animals is fully repaired, muscle tissue from Acvr1R206H mice is fibrotic and has not repaired, indicating that muscle healing is impaired by the Acvr1R206H mutation. Impaired muscle regeneration is accompanied by a substantial amount of HO within Acvr1R206H muscle. BMP signaling has been shown to promote MuSC proliferation and repress their differentiation, leading us to hypothesize that Acvr1R206H in MuSCs impairs their ability to regenerate muscle after injury. We examined the effect of the Acvr1R206H mutation on MuSC proliferation specifically by isolating MuSCs using fluorescent activated cell sorting. No significant differences between proliferation of MuSCs from WT and FOP injured muscle tissue post-cardiotoxin (CTX) injury were detected, and the number of MuSCs isolated from FOP mice were comparable to that from WT mice. We next investigated the ability of WT and FOP MuSCs to differentiate. We cultured isolated WT and FOP MuSCs in myogenic fusion media and while WT MuSCs differentiate normally to form branching myofibers (high fusion index), FOP MuSCs form underdeveloped fibers that fail to fuse (low fusion index) (Figure One). These data indicate that the Acvr1R206H mutation does not alter MuSC proliferation but has a negative impact on their ability to undergo myogenesis. On-going in vivo experiments will further elucidate the role of the MuSCs in response to the Acvr1R206H mutation during muscle regeneration in response to tissue injury.

FRI-0469

New Insight into SHP2 regulation of Osteogenic Commitment of Mesenchymal Progenitors Lijun Wang*[1], Jiahui Huang[2], Chunlin Zuo, Douglas Moore[2], Matthew Warman[3], Michael Ehrlich[1], Wentian Yang[1]. [1]Department of Orthopaedics, Brown University Alpert Medical School and Rhode Island Hospital, United States, [2]Brown University Alpert Medical School and Rhode Island Hospital, United States, [3]Orthopaedic Research Laboratories and Howard Hughes Medical Institute, Boston Children's Hospital and Harvard Medical School, United States

Chondrocytes and osteoblasts differentiate from mesenchymal stem cells via a common osteochondroprogenitor (OCP). The signaling pathways that control lineage decisions for OCPs are incompletely understood. SHP2 is a ubiquitously expressed protein tyrosine phosphatase and has been identified as an important regulator of the development and homeostasis of multiple tissue and/or organ. The role SHP2 in the skeletal system, however, remains incompletely defined. We conditionally deleted SHP2 in mouse limb and head mesenchyme (using Prrx1-Cre), which yielded SHP2-deficient mice with increased cartilage mass and deficient intramembranous and endochondral ossification, suggesting SHP2-deficient OCPs become chondrocytes and not osteoblasts (Fig 1). Consistent with these observations, the expression of the master chondrogenic transcription factor Sox9 and its target genes Acan, Ihh, Col2a1, and Col10a1 are increased in SHP2-deficient chondroid cells, as revealed by gene expression arrays, qRT-PCR, in situ hybridization, and immunostaining. Mosaic SHP2 deletion at E13.5 in Prx1-CreERt2-expressing OCPs leads to the growth of osteochondromas and enchondromas. Mechanistic in vivo and in vitro studies demonstrated that SHP2 regulates fate determination of OCPs via the post-translational phosphorylation and SUMOylation of SOX9, at least in part via the PKA signaling pathway. These data indicate that SHP2 is critical for skeletal cell lineage differentiation and thus may be a pharmacologic target for bone and cartilage regeneration.
Fig. 1 SHP2 deficiency in the PRRX1+ osteochondroprogenitors (OCPs) impairs osteogenic differentiation. Fluorescent images of P1.5 tibia frozen sections demonstrate that ZsGreen+ OCPs robustly differentiate into OSTERIX+ (red) osteoblasts (green+red=yellow) in SHP2_Prrx1CTR;R26^ZSG;Sp7^mCherry mice. This process, however, is markedly compromised in SHP2_Prrx1KO;R26^ZSG;Sp7^mCherry mice. Bottom panels are the enlarged view of the corresponding boxed areas on the top panel.

PDGFRβ signaling regulates osteogenesis of αSMA labeled periosteal cells. Xi Wang*[1], Sanja Novak[1], Danka Grcevic[2], Brya G Matthews[1], Ivo Kalajzic[1]. [1]UConn Health, United States, [2]University of Zagreb, Croatia

The goal of our study is to better understand molecular mechanisms that regulate commitment and differentiation of progenitor cells during bone regeneration. We have shown that alpha smooth muscle actin (α?SMA) is a marker for mesenchymal stem cells that contribute to the majority of osteoblasts and chondrocytes in fracture healing. While intact periosteum shows 2.5% α?SMA+ cells by flow cytometry, this proportion dramatically increases to 18±3% on day 4 and 34.8±5% on day 10 post fracture. Over 60% of the ?SMA+ population expresses PDGFRβ.We investigated the effect of PDGFRβ signaling on α?SMA labeled periosteal progenitor cells (PPCs). PPCs were isolated from α?SMA-CreERT2/Ai9/Col2.3GFP mice and treated with 4-OH Tamoxifen to induce Cre activity. We treated PPCs with 10ng/ml PDGF-BB and observed a significant increase of EdU+ proliferative cells. PDGF-BB also increased cell migration in a wound healing assay. PDGF-BB also inhibited osteogenic differentiation shown by osteogenic gene expression and GFP expression.To further understand the role of PDGFRβ signaling in PPCs, we conditionally deleted PDGFRβ using α?SMA-CreERT2 crossed with PDGFRβ flox/flox mice. In vitro deletion of PDGFRβ in PPCs resulted in significantly enhanced osteogenic differentiation indicated by ALP and Von Kossa staining.We then performed femur fracture on 12 week old mice and examined the proliferation of periosteal cells upon injury. 4 days after fracture, in the periosteal regions

proximal to fracture site, there was a significant decrease of EdU+ proliferative cells in α?S-MA PDGFRβdel/del mice. 14 days after fracture, there was a trend of more mineralization area/callus area in Cre+ mice (N=8).Overall, PDGFRβ is widely expressed in progenitor cells that contribute to fracture healing in vivo. Using a conditional deletion mouse model, we have demonstrated that PDGFRβ signaling regulates osteogenic differentiation of PPCs. Deleting PDGFRβ? impaired periosteal cell proliferation, while promoting differentiation. Studies are ongoing to assess the functional outcome of this perturbation on fracture callus composition and biomechanics.

Drug-induced modulation of gp130 signaling prevents articualr cartilage degeneration and promotes repair Ruzanna Shkhyan*, Ben Van Handel, Jacob Bogdanov, Denis Evseenko. University of Southern California, United States

Introduction. Human adult articular cartilage has little capacity for repair, and joint surface injuries often result in osteoarthritis (OA), characterized by loss of matrix, hypertrophy and chondrocyte apoptosis. Inflammation mediated by IL-6 family cytokines has been identified as a critical driver of pro-arthritic changes in mouse and human joints, resulting in a feed-forward process driving expression of matrix degrading enzymes and IL-6 itself. Methods. Medial meniscal tear and focal injury rat models of osteoarthritis. Statistical methods: Student t-test, one-way ANOVA followed by the Newman-Keuls test. All animal experiments were conducted in accordance and under the supervision of the University of Southern California Department of Animal Resources. Results. Human adult articular cartilage has little capacity for repair, and joint surface injuries often result in osteoarthritis (OA), characterized by loss of matrix, hypertrophy and chondrocyte apoptosis. Inflammation mediated by IL-6 family cytokines has been identified as a critical driver of pro-arthritic changes in mouse and human joints, resulting in a feed-forward process driving expression of matrix degrading enzymes and IL-6 itself. Here we show signaling through gp130, the common receptor for IL-6 family cytokines, can have both context- and cytokine-specific effects on articular chondrocytes and that a small molecule gp130 modulator can bias signaling toward anti-inflammatory and anti-degenerative outputs. High throughput screening of 170,000 compounds identified a small molecule gp130 modulator termed Regulator of Cartilage Growth and Differentiation (RCGD 423) that promotes atypical homodimeric signaling in the absence of cytokine ligands, driving transient increases in MYC and pSTAT3 while suppressing oncostatin M- and IL-6-mediated activation of ERK and NF-κB via direct competition for gp130 occupancy. This small molecule increased proliferation while reducing apoptosis and hypertrophic responses in adult chondrocytes in vitro. In a rat partial meniscectomy model, RCGD 423 greatly reduced chondrocyte hypertrophy, loss and degeneration while increasing chondrocyte proliferation beyond that observed in response to the injury. Moreover, RCGD 423 improved cartilage healing in a rat full-thickness osteochondral defect model, increasing proliferation of mesenchymal cells in the defect and also inhibiting breakdown of cartilage matrix in de novo generated cartilage. Conclusion. These results identify a novel strategy for articular cartilage remediation via small molecule-mediated modulation of gp130 signaling.

Tissue Mechanical Deficiencies Detected in Both Articular Cartilage and Subchondral Trabecular Bone in Osteoarthritic Human Knees Yizhong Hu*[1], Eric Y. Yu[1], Ariana Moini[1], Zexi Wang[1], Matthew Scott Heller[2], Akshay Lakra[2], Herbert John Cooper[2], Roshan Pradip Shah[2], Jeffrey Albert Geller[2], X. Lucas Lu[3], X. Edward Guo[1]. [1]Bone Bioengineering Laboratory, Columbia University, United States, [2]Department of Orthopaedic Surgery, Columbia University Medical Center, United States, [3]Department of Mechanical Engineering, University of Delaware, United States

Cartilage and subchondral bone are key mechanical components in the knee joint and highly vulnerable in osteoarthritis (OA). Histology and specialized MRI sequences reported biochemical deterioration of proteoglycans in OA cartilage. Microstructural analyses of subchondral trabecular bone revealed loss of rod number despite trabecular thickening and bone sclerosis. The biomechanical properties of human OA cartilage and subchondral bone tissue, however, have rarely been examined collectively. In this study, we used microindentation testing to directly quantify tissue mechanical properties in human OA cartilage and subchondral trabecular bone simultaneously.OA (n = 6) and control (n = 4) tibial plateaus were collected from knee replacement patients and cadaver donors. Osteochondral cores were harvested from moderate and severe regions from OA samples and corresponding control regions. From the μCT scan of each core, cartilage thickness was measured, and subchondral trabecular bone was subjected to Individual Trabecula Segmentation (ITS) for identification of trabecular type and orientation. Each core was subjected to 3 cartilage indentation tests. Aggregate modulus and permeability were calculated based on poroelastic theory. Subchondral bone was then isolated and embedded for microindentation. A total of 212 plates and 156 rods were indented. Bone tissue modulus was calculated from the unloading curve. Cartilage thickness was lower in severe OA regions but remained intact in moderate regions. Cartilage indentation found significantly reduced modulus in all regions. Increased permeability was found only in severe OA regions. Trabecula microindentation revealed consistent and drastic reductions in tissue modulus in OA subchondral bone. On average, a 30% decrease in modulus was found in all regions for longitudinal plates, oblique plates and rods, and transverse plates and rods.The reduced modulus and increased permeability in OA cartilage may be attributable to disintegration of collagen/proteoglycan solid matrix and reduced resistance to fluid flow. Tissue modulus reduction in the subchondral bone despite trabecular thickening indicates increased bone remodeling but compromised mechanical integrity, likely due to poor mineralization. Furthermore, persistent bone changes beneath moderately and severely damaged cartilage may indicate their precedence in OA progression, or different sensitivity of microindentation to cartilage and bone tissue changes.

FRI-0503

Reliable change index in the evaluation of joint space loss: a novel method for assessing osteoarthritis progression data from the Osteoarthritis Initiative Camille Parsons*[1], Andy Judge[2], Kirsten Leyland[2], Hazel Inskip[1], Cyrus Cooper[1]. [1]MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, [2]University of Bristol, United Kingdom

The reliable change index (RCI) allows for identification of whether observed change between knee joint space width (JSW) measurements is statistically reliable in the presence of measurement error. We aimed to assess the effectiveness of the RCI as a novel approach to estimating osteoarthritis (OA) progression using longitudinal knee JSW measurements, while accounting for the presence of measurement error.Data for these analyses are from the Osteoarthritis Initiative (OAI) public-use data sets. Measurements from 3,469 participants were included. Knee JSW measurements were taken from radiographic images at baseline, and at 12, 24, 36, 48, 72 and 96 months, using a semi-quantitative method. A RCI score was calculated, using the version developed by Christensen and Mendoza, between each OAI study visit for each study participant. The resulting RCI is a continuous score that follows a standard normal distribution, with larger (RCI greater than 1.96) and smaller (RCI less than -1.96) values indicating that the change observed is statistically significant and therefore more than the fluctuations of the measurement.Between consecutive study visits, 53 to 64% of participants had a crude decrease in JSW between study visits. Implementation of the RCI indicated that considerably fewer participants had a statistically reliable decrease in JSW, e.g. 3.1% participants were identified between baseline and 12 month study visits as having meaningful change compared to 53% crude decrease. Similar proportions of statistically reliable decreases were observed between all other OAI study visits. Around 40% of participants had crude increase in JSW between the pairs of study visits under consideration. Use of the RCI dramatically reduced the number of participants that were identified as having an increase, e.g. between 72 and 96 month study visits only 1.4% were identified compared to 39% that were identified using crude differences. As increases in JSW are biologically extremely rare, this shows the impact of measurement error if crude differences are assessed without accounting for measurement error.The RCI provides a useful method to identify change in JSW, removing many of the apparent changes that are likely to be due to measurement error. This method appears to be useful for assessing change in JSW clinical and research settings from radiographs. This method appears to be useful for assessing change in JSW from radiographs in both a clinical and research setting.

FRI-0504

Predicting total hip replacement for symptomatic osteoarthritis using radiographs or clinical computed tomography; a prospective case-control study Kenneth Poole*[1], Ilya Burkov[1], Graham Treece[1], Andrew Gee[1], Thomas Turmezei[1], Fjola Johannesdottir[1], Sigurdur Sigurdsson[2], Tamara Harris[4], Helgi Jonsson[3], Vilmundur Gudnason[5]. [1]University of Cambridge, United Kingdom, [2]The Icelandic Heart Association, Iceland, [3]Public Health Sciences, University of Iceland, Iceland, [4]Laboratory of Epidemiology and Population Sciences, United States, [5]Faculty of Medicine, University of Iceland, Iceland

Expert osteoarthritis guidance now advises clinicians not to request imaging when managing patients with hip pain. We evaluated how well a single pelvic radiograph predicted total hip replacement (THR) compared with pain symptoms.From a prospective nested case-control study of 3133 healthy adults, 74 individuals underwent THR for osteoarthritis approximately 3 years after a baseline assessment comprising validated pain questionnaire and hip computed tomography (CT). Each case destined for THR was matched by age and sex to two control individuals. Mean age was 74±5yrs (range 67-89). Baseline variables were performance-tested using receiver-operating-characteristic curve analysis (AUC): hip pain, osteoarthritis grade or minimal joint space width (mJSW) from coronal plane reconstructed radiograph or 3D cortical bone thickness. The location and magnitude of bone thickening associated with THR was highlighted using statistical parametric mapping.Combining hip pain, radiographic osteoarthritis grade and CT gave excellent discrimination of THR (0·90; 0·85,0·95, figure 1). Conversely, hip pain was a poor to marginal predictor (AUC=0·70; 95%CI 0·62,0·78). The AUC for radiographic Kellgren and Lawrence (K&L) osteoarthritis grade alone was 0·87 (0·81,0·92), irrespective of hip pain, with single mJSW being a reasonable discriminator (0·80;0·73,0·87). Osteoarthritis was also associated with a CT-defined crescent of femoral head surface bone thickening (Odds Ratio for THR; 5 per SD thicker; 3·2,7·7, 0·85 (0·79, 0·91)). In a typical clinical presentation with hip pain, all of the imaging parameters measured ranged from good to excellent in terms of clinical utility. Imaging unequivocally predicted THR for osteoarthritis, whether or not pain had become apparent. Contrary to current guidance, images of patients with hip pain have good to excellent clinical utility for selecting surgically-relevant presentations. If patients with definite hip pain had definite radiological osteoarthritis, 85% went on to THR within 3 years.

Figure 1: Predicting total hip replacement for osteoarthritis within 3 years (+/-2yrs); using baseline hip pain alone versus adding imaging tests (comparison of area under the ROC curve of the various models)

Model	AUC (95% CI)	Cross-validated AUC*	OR per SD (95% CI)	Hip pain only versus hip pain + imaging (χ^2)	prob>χ^2

Beneficial effects of Denosumab on bone loss and bone erosion from results of long-term treatment in the phase 3, DESIRABLE study in patients with rheumatoid arthritis (RA) on background csDMARDs Yoshiya Tanaka*[1], Satoshi Soen[2], Hisashi Yamanaka[3], Toshiyuki Yoneda[4], Sakae Tanaka[5], Takaya Nitta[6], Naoki Okubo[6], Harry Genant[7], Désirée Van Der Heijde[8], Tsutomu Takeuchi[9]. [1]University of Occupational and Environmental Health, Japan, [2]Kindai University Nara Hospital, Japan, [3]Institute of Rheumatology Tokyo Women's Medical University, Japan, [4]Osaka University Graduate School of Dentistry, Japan, [5]The University of Tokyo, Japan, [6]Daiichi Sankyo Co. Ltd, Japan, [7]University of California, United States, [8]Leiden University Medical Center, Netherlands, [9]Keio University School of Medicine, Japan

Background:The DESIRABLE study demonstrated in RA patients that the first 12 months of treatment with denosumab (DMAb) 60 mg every 6 months (Q6M) or every 3 months (Q3M) significantly inhibited the progression of joint destruction and increased bone mineral density (BMD) compared to placebo. The purpose of this study is to evaluate the safety and efficacy of DMAb 60 mg Q6M or Q3M in RA patients on long-term treatment in the DESIRABLE study.Methods:Upon completion of the 12 months of the double-blind phase (DB) all patients were to receive DMAb 60 mg/Q6M or Q3M and daily supplements of calcium and vitamin D during the following 24 months of the open-label extension phase. Patients were randomized in a 1:1:2:2 ratio to receive one of four treatments (Figure 1). In this analysis, the continuous administration group received 36 months of DMAb treatment,

and the crossover group received 24 months of DMAb treatment (12 month of placebo in DB and 24 months of DMAb treatment). The radiographic evaluation used the van der Heijde modified total Sharp score (mTSS) and BMD of the lumbar spine was measured by dual energy X-ray absorptiometry at 0, 12, 24 and 36 months. Serum CTX-I was also monitored during the study.Results:667 (placebo/Q6M (P/Q6M), n=113; placebo/Q3M (P/Q3M), n=110; Q6M, n=222; Q3M, n=222) patients received at least one dose of study drug, and 607 (P/Q6M, n=105; P/Q3M, n=103; Q6M, n=199; Q3M, n=200) completed the DB period and entered the long-term extension. In the continuous and the crossover administration groups, sustained inhibition of mTSS and erosion score (mES) progression was observed during long-term treatment phase. No effect on joint space narrowing was observed. In the continuous administration group, increases from the baseline in BMD after 36 months of continued DMAb treatment were 8.9% in Q6M and 9.9% in Q3M group. In the crossover group, BMD changes at 36 month (24 months after the first dose of DMAb) were 6.7% in P/Q6M and 7.6% in P/Q3M group (Figure 2). And similar increases in BMD were observed regardless of glucocorticoid use. In both groups, serum CTX-I was decreased at 1 month after the first dose of DMAb with relatively sustained reductions.Conclusions:A 24 months extension phase of the DESIRABLE study showed that 36 months of DMAb treatment for RA was associated with suppression of mTSS and mES progression, continuous BMD increases, persistent CTX-I reductions and a favorable over all benefit risk profile.

Conditional deletion of Dock7 in the early limb bud results in reduced trabecular bone in both sexes with increased fat mass only in male mice Kathleen A Becker*[1], Daniel J Brooks[2], Anne Harrington[3], Mary L Bouxsein[2], Lucy Liaw[3], Clifford J Rosen[3]. [1]Maine Medical Center Research Insitute, United States, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, United States, [3]Maine Medical Center Research Institute, Maine Medical Center, United States

Dock7 is guanine nucleotide exchange factor involved in GTP-loading of small GT-Pases. While global loss of the Dock7 protein leads to low bone density predominantly in female mice, it is unclear in what cells and tissues Dock7 may function to control bone

metabolism. In order to determine whether Dock7 expression in bone cells is important for development of normal bone density and micro-architecture, Dock7 was conditionally deleted in the early limb bud by breeding a novel model, the floxed exon 3-4 Dock7 allele on the C57BL/6J background, with Prrx1-Cre expressing mice. Femurs from 16 wk old female mice expressing the Prrx1-Cre (Dock7fl/fl;Prrx1-Cre) (n=9) were analyzed by micro-computed tomography and compared to female Dock7fl/fl mice (n=8). Female Dock7fl/fl;Prrx1-Cre mice displayed a reduction in femur length (P=0.002), BV/TV (P=0.035), trabecular (Tb) BMD (P=0.038), and Tb number (P=0.002) with an increase in Tb separation (P=0.0028). Body composition was not altered. The decrease in Tb bone with conditional deletion of Dock7 is similar to what has been previously observed with global loss of the Dock7 protein in Misty mice. Therefore, these data suggest that the Tb bone loss observed in the Dock7fl/fl;Prrx1-Cre mice was, in part, mediated through loss of Dock7 directly in bone. Unlike Misty mice, cortical thickness (P>0.9999) was unaffected in the Dock7fl/fl;Prrx1-Cre mice indicating that loss of Dock7 in tissues outside the limb bud may regulate cortical thickness with global loss of Dock7. Similarly, femoral micro-architecture was analyzed in male Dock7fl/fl;Prrx1-Cre mice (n=9) and compared to Dock7fl/fl mice (n=12). BV/TV (P=0.0003), Tb BMD (P=0.0002), Tb number (P<0.0001), and connectivity density (P<0.0001) were reduced in Dock7fl/fl;Prrx1-Cre mice with an increase in Tb separation (P<0.0001). No change in femur length was observed. Unlike female mice, the 16 wk old male Dock7fl/fl;Prrx1-Cre mice had an increase in body mass (P=0.020) and fat mass (P=0.0058) with a reduction in fat free mass (P=0.0036) by DXA. Furthermore, the weight of brown (P=0.0155), inguinal (P=0.0743), and gonadal adipose depots were increased in Dock7fl/fl;Prrx1-Cre mice compared to Dock7fl/fl mice showing for the first time a sexual dimorphic fat phenotype with deletion of Dock7. Taken together, these data suggest that Dock7 may play a cell autonomous role in controlling bone metabolism warranting further investigation for a role of Dock7 in lineage determination.

The Role of VEGFA from Osteoblast Lineage Cells during Fracture and Cortical Defect Repair Evan Buettmann*, Nicole Migotsky, Susumu Yoneda, Pei Hu, Jennifer Mckenzie, Matthew Silva. Washington University in St. Louis, United States

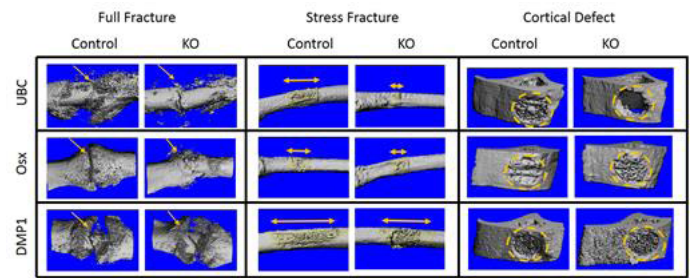
The molecule vascular endothelial growth factor A (VEGFA) has been shown to be indispensable for endochondral and intramembranous ossification following bone injury. However, the dispensability of VEGFA from osteoblast lineage cells at the time of injury in models of endochondral (full fracture) and intramembranous (stress fracture and cortical defect) bone repair remains unknown. Therefore, we sought to determine if inducible genetic deletion of 1) ubiquitous VEGFA and 2) osteoblast lineage VEGFA impairs injury-induced bone formation in mice. First, inducible Cre specificity in our models of fracture and defect repair was verified using an Ai9 (tdTomato) reporter under the Ubiquitin C (UBC), Osterix (Osx) and Dentin Matrix Protein1 (DMP1) CreERT2 driver. Next, these inducible Cre lines were crossed to mice containing floxed VEGFA alleles (VEGFAfl/fl) and either given a femoral fracture, ulnar stress fracture, or tibial defect at 12 weeks of age. Controls were littermate mice without Cre. All mice were given tamoxifen (TAM) continuously starting 2 weeks pre-injury.1) UBC CreERT2 VEGFAfl/fl (UBC KO) displayed a 96% reduction in VEGFA mRNA from cortical bone that manifested in dramatically reduced bone formation in all injury models. 2) Osx CreERT2 VEGFAfl/fl (Osx KO) and DMP1 CreERT2 VEGFAfl/fl (DMP1 KO) mice both displayed a 35% reduction in VEGFA mRNA from cortical bone. Despite similar deletion efficiencies, only the Osx KO mice displayed a significant reduction in callus bone volume versus controls following full fracture (-27%; p = 0.02; 14 days post-injury) and stress fracture (-58%; p = 0.01; 7 days post-injury). However, neither Osx KO nor DMP1 KO mice demonstrated significant impairments in bone formation following cortical defect (7 days post-injury). Our UBC KO results reaffirm previous pharmacological studies that ubiquitous VEGFA is necessary for injury induced bone formation. The impaired healing in Osx KO but not DMP1 KO animals after fracture suggests that VEGFA from early (osteoprogenitor) but not mature osteoblasts/osteocytes is necessary for maximal periosteal bone formation. On the other hand, the normal healing in the defect model in the Osx and DMP1 KO lines suggests that osteoblast lineage VEGFA is dispensable for intramembranous bone formation. In conclusion, our results show that the requirement for VEGFA varies depending on the injury model and differentiated state of the osteoblast.


Figure 1. MicroCT reconstructions (10 micron isotropic resolution) of full fracture (day 14), stress fracture (day 7) and tibial defect (day 7) in the littermate control and VEGFA knockout (KO) animals. Ubiquitin C (UBC) CreERT2 VEGFAfl/fl animals (top row) demonstrated greatly diminished bone formation across all injury models (top row). Osterix (Osx) CreERT2 VEGFAfl/fl animals (middle row) demonstrated impaired bone formation following full fracture and stress fracture only. DMP1 (DMP1) CreERT2 VEGFAfl/fl animals (bottom row) demonstrated no differences in healing. Arrows mark the sites of full fracture. Double arrow denotes the stress fracture region in each specimen. Dashed ovals are used to highlight outline of tibial defect.

Gene regulatory landscape in primary human mesenchymal stem cell (MSC) during BMP2-induced osteoblast differentiation Alessandra Chesi*[1], Yadav Wagley[2], Matthew E. Johnson[1], Sumei Lu[1], Michelle E. Leonard[1], Kenyaita M. Hodge[1], James A. Pippin[1], Elisabetta Manduchi[1], Andrew D. Wells[1], Kurt D. Hankenson[2], Struan F.A. Grant[1]. [1]The Children's Hospital of Philadelphia, United States, [2]University of Michigan, United States

Proper bone formation requires the differentiation of osteoblasts from mesenchymal stem cells (MSCs), a process mediated by bone morphogenetic protein (BMP) signaling. To understand the gene regulatory landscapeduring osteoblast differentiation, we performed ATAC-seq on undifferentiated MSCs and BMP2-differentiated osteoblasts from four human donors to obtain genome-wide maps of open chromatin regions (OCR), where gene regulation is most likely to occur. Of the overall 102,696 OCRs, 56,964 (55%) were common to the two cell types, 36,578 (36%) were osteoblast-specific and only 9,154 (9%) were MSC-specific. Thus, chromatin accessibility increased upon differentiation, and although more than half of the accessible landscape of these two cell types was maintained, more than a third was remodeled de novo to become accessible in the osteoblast lineage. Next, we leveraged a novel chromatin conformation capture technique we developed to investigate the genome-wide 3D contacts of all the promoters in the human genome at high resolution. Our custom Agilent SureSelect RNA library targets DpnII restriction fragments overlapping 36,691 promoters of protein-coding, noncoding, antisense, snRNA, miRNA, snoRNA and lincRNA genes. We applied our SPATIaL-seq (genome-Scale, Promoter-focused Analysis of chromaTin Looping) method to both cell types coming from the same donors. In both settings, interacting regions were significantly enriched for open chromatin regions as detected by our ATAC-seq experiments, suggesting a potential regulatory role. They were also enriched for histone marks associated with active chromatin regions in human primary osteoblasts from ENCODE, such as enhancer regions (H3K27ac and H3K4me1), active promoters (H3K4me3), actively transcribed regions (H3K36me3) and transcription factor binding sites (H3K4me2); they also associated with CTCF binding sites and the repressive mark H3K27me3, but not with the repressive mark H3K9me3.We went on to characterize 164,508 chromatin loops specific to the MSC-derived osteoblasts, 136,631 specific to MSCs, and 148,753 loops present in both. Of these, about 10% (15,882, 11,551, and 14,613, respectively) involved open chromatin regions in the corresponding cell type. When intersected with RNAs-seq, these data revealed specific pathways operating in each setting.These unique and high resolution complimentary datasets provide key insights in to the 3D regulatory architecture of human osteoblast differentiation.

Ablation of Gjc1 in the Chondro-Osteogenic Lineage Inhibits Osteoclastogenesis Leading to High Trabecular Bone Mass Francesca Fontana*, Marcus Watkins, Song Dah Woon, Giulia Leanza, Roberto Civitelli. Washington University School of Medicine, United States

The connexins family of gap junction proteins comprises 20 members. Each connexin confers specific permeability and electric conductance to the gap junction they form. Although connexin43 (Cx43) is the most abundant connexin expressed in bone, connexin45 (Cx45) and Cx37 are also present. Missense mutations of the Cx45 gene (Gjc1) in humans have recently been found in families with congenital arrhythmias and skeletal abnormalities. To test the role of Cx45 in bone, we generated Gjc1flx/flx; Tw2-cre mice, where Gjc1 is conditionally inactivated Gjc1 in chondro-osteogenic cells driven by the Dermo1/Twist2 promoter (cKO). Whereas Cx43 deficiency results in a primarily cortical phenotype, female Gja1 cKO mice have high trabecular bone mass by μCT, with >50% higher BV/TV, 75% higher trabecular thickness, and 20% lower trabecular spacing relative to control Gjc1flx/flx mice. Cortical bone mass and geometry are normal. By contrast, male Gjc1 cKO mice

showed no significant abnormalities in trabecular or cortical bone. Using a calcein diffusion assay and FACS analysis to test gap junctional intercellular communication (GJIC), we confirmed that bone marrow stromal cells (BMSC) from Gjc1 cKO mice exhibited higher capacity to transfer calcein from cell to cell. Since these cells abundantly express Cx43, higher GJIC in Cx45 deficient BMSC suggest that Cx45 inhibits Cx43-mediated GJIC, confirming previous data. Furthermore, Gjc1 cKO BMSC were less effective than control BMSC in supporting osteoclastogenesis in co-culture with bone marrow macrophages. This was associated with decreased RANKL expression, without changes in OPG mRNA. Corroborating this finding, histologic analysis revealed 40% decrease in osteoclast number on trabecular surfaces by TRAP-staining of Gjc1 cKO tibiae relative to controls. In vitro, Cx45-deficient BMSC exhibited no obvious osteogenic differentiation defects, consistent with no difference in P1NP levels between Gjc1 cKO and control littermates. Thus, while Cx43's major role is to modulate cortical modeling, Cx45 is a negative regulator of trabecular bone mass, albeit with genetic dysmorphism. Both connexins control osteoclastogenesis by modulating the RANKL/OPG system in osteogenic cells, but in opposite ways and in different bone compartments.

FRI-0541

A novel role for tissue nonspecific alkaline phosphatase in cranial bone progenitor cells.
Hwa Kyung Nam*, Iva Vesela, Nan Hatch. University of Michigan, School of Dentistry, United States

Introduction: Bone growth is dependent upon the presence of self-renewing osteoblast progenitor cell populations. While the contribution of Tissue Nonspecific Alkaline Phosphatase (TNAP) enzyme activity in promoting bone mineralization when expressed in differentiated bone forming cells is well understood, little is known regarding the role of TNAP in bone progenitor cells. Here we investigated the function of TNAP in cranial bone progenitor cells. Methods: Synchronized MC3T3E1 cranial osteoblast progenitor cells stably expressing TNAP shRNA and cranial progenitor cells isolated from TNAPko mice were analyzed for cell cyclin and cytokinesis protein expression, FACS based cell cycle progression, cell size, binucleation and FGFR expression when compared to control cells. Erk1,2 phosphorylation was assessed in cranial progenitor cells and tissues of TNAPko mice. Results: We find that TNAP is essential for expression of cyclin B1 and D1, as well as for activated forms of the cytokinesis proteins Aurora B and Histone 3. We also find that TNAP functions to promote cranial osteoblast progenitor cell cycle progression, cytokinesis and FGFR2 expression; and that these effects are mediated by erk1,2. Conclusions: We propose a model in which TNAP stimulates erk1,2 activity via both phosphate dependent and independent mechanisms, which promotes cell cycle progression, cyokinesis and cell proliferation, and concomitantly feeds back to inhibit FGFR2 expression. Together, our results suggest that the cranial bone abnormalities seen in humans and mice with TNAP deficiency may occur due to diminished erk1,2 activity leading to diminished cranial bone progenitor cell renewal.

Global Expression of miR-29 Decoy Decreases Bone Formation and Alters Cortical Bone Morphology in Young Mice
Henry Hrdlicka*, Bongjin Shin, Anne Delany, Sun-Kyeong Lee. UConn Health, United States

The miR-29 family of miRNAs positively regulates both osteoblast and osteoclast differentiation. In the osteoblast lineage, miR-29 levels increase as osteoblasts mature and matrix mineralizes; it is thought that miR-29 promotes this process by targeting multiple negative regulators of differentiation. In the osteoclast lineage, miR-29 levels increase in RANKL treated precursors as cells start to fuse; it is thought that miR-29 promotes osteoclastogenesis at least in part by regulating lineage commitment and cell motility.To examine function of miR-29 in normal skeletal physiology in vivo, we created mice globally expressing a miR-29 competitive inhibitor (tough decoy). Specifically, a cassette containing 3 copies of a miR-29 tough decoy within the 3'UTR of the tdTomato reporter was knocked into to the Rosa26 locus using CRISPR/Cas9. These mice are viable and fertile. In the current study, we examined the skeletal phenotype of mice carrying one copy of the miR-29 decoy cassette.MicroCT analysis of femurs from 8 week old female mice showed that cortical morphology was significantly altered in miR-29 decoy mice compared with littermate controls. Both endosteal area and perimeter were significantly larger in miR-29 decoy mice (7% increase, p<0.01, n=8), with a trend toward an increase in periosteal area and perimeter (p=0.053 and p=0.063, respectively) in miR-29 decoy mice. Thus, whereas miR-29 decoy mouse bones were larger in diameter, the cortical bone area was not significantly increased. Although trabecular bone volume in the femurs of female miR-29 decoy mice was not altered compared to littermate controls, miR-29 decoy mice had a 60% decrease in bone formation rate (p=0.03, n=4). Unaltered bone volume in the presence of decreased bone formation suggests a decrease in osteoclast number or activity.Investigating the osteoclast potential of bone marrow monocytes from the miR-29 decoy mice in vitro, we found that decoy cells formed 50-70% fewer osteoclasts (p<0.01) compared to controls. miR-29 decoy cells had decreased NFATc1 protein, a transcription factor critical for osteoclastogenesis, and decreased in cathepsin K mRNA, indicating decreased osteoclast differentiation and activity.We hypothesize that global inhibition of miR-29 activity decreases bone remodeling,

resulting in relatively mild changes in bone morphology. Whether this decreased remodeling has a significant impact on bone quality will be determined.

TNAP Deficiency Is the Major Contributor to the Loss of the Mineralization Potential of Trps1 Deficient Osteogenic Cells
Sana Khalid*, Byongsoo Chae, Daisy Monier, Mairobys Socorro, Victoria Smethurst, Dobrawa Napierala. Center for Craniofacial Regeneration, Dept. of Oral Biology, McGowan Institute for Regenerative Medicine, University of Pittsburgh School of Dental Medicine, United States

Tissue-Nonspecific Alkaline Phosphatase (TNAP) is critical for mineralization, as evident by hypomineralized skeletal and dental tissues in hypophosphatasia. TNAP is a membrane bound enzyme that generates inorganic phosphate (Pi) by hydrolyzing the mineralization inhibitor pyrophosphatase (PPi), and therefore, maintains a Pi/PPi balance conducive for mineralization. Pi is necessary not only for formation of hydroxyapatite, but also acts as a signaling molecule, which regulates osteogenic gene expression. Previous work from our lab demonstrated that 17IIA11 osteogenic cells deficient for the Trps1 transcription factor (Trps1-KD) showed impaired initiation of mineralization in comparison with WT cells. On the molecular level, Trps1-KD cells have significantly decreased expression of several osteogenic genes, including TNAP and, consistently, show reduced TNAP enzymatic activity. We hypothesize that TNAP deficiency in TRPS1-KD cells is the major contributor to the impaired mineralization of these cells. To test our hypothesis, we restored the expression of TNAP in Trps1-KD cells using transposon-mediated genomic integration of a TNAP-expressing construct. We selected 3 clonal cell lines in which TNAP expression was restored to the same level as in WT 17IIA11 cells on the Trps1 deficient background (Trps1-KD;TNAP+ cells) for further analysis. We analyzed the effect of restoring TNAP expression on mineralization, osteogenic gene expression and Pi signaling (as determined by activation of Erk1/2 kinases) employing alizarin red staining, qRT-PCR and Western blot, respectively. Results revealed that restoration of TNAP expression in Trps1 deficient osteogenic cells resulted in increased mineralization. Interestingly, significant upregulation of osteogenic genes Smpd3, Phospho 1, Runx2 and Sp7 (without changing Trps1 expression), and increased Erk1/2 activation in response to elevated exogenous Pi was detected in Trps1-KD;TNAP+ cells in comparison with Trps1-KD. Of note, there was no difference in Pi transporter (PiT1) expression between WT 17IIA11, Trps1-KD and Trps1-KD;TNAP+ cells. On the basis of these results we conclude that impaired mineralization of Trps1 osteogenic cells results mostly from the loss of TNAP expression. Furthermore, our data suggests that TNAP facilitate mineralization not only as a Pi provider but also plays a critical role in expression of osteogenic genes and cellular response to available exogenous Pi.

Macrophage-secreted Emilin2 Stimulates Chemotaxis and Differentiation in Stromal/Osteoblastic Cells
Yukihiro Kohara*, Atsushi Watanabe, Noboru Ogiso, Sunao Takeshita. National Center for Geriatrics and Gerontology, Japan

It was recently reported that in vivo depletion of macrophages resulted in significant reduction in bone formation, suggesting that macrophages have the potential to support bone formation by osteoblasts and contribute to bone metabolism. However, the molecular mechanisms underlying how macrophages stimulate osteogenesis and regulate bone remodeling have not been characterized.In this study, we found that bone marrow macrophage-conditioned medium stimulated chemotaxis in bone marrow stromal ST2 cells. To purify the chemotactic activity from the macrophage-conditioned medium, we performed successive anion-exchange column chromatography by monitoring the chemotactic activity of ST2 cells and identified Emilin2 by LC-MS/MS analysis. Emilin2, a 116 kDa extracellular matrix glycoprotein, is known to regulate cardiac development. Emilin2 mRNA was abundantly expressed in macrophages, but not in the other bone cells. Recombinant Emilin2 protein stimulated chemotaxis in ST2 cells, indicating that macrophages regulate the migration of bone marrow stromal cells through the production of Emilin2. Furthermore, enforced Emilin2 expression in calvaria-derived stromal cells increased calcium deposition, as assessed by Alizarin red staining, and the expression of osteoblast marker genes such as Runx2 and Osteocalcin, as assessed by quantitative RT-PCR. However, increased Emilin2 expression in 3T3-L1 preadipocytes inhibited adipogenesis. These results, taken together, suggest that Emilin2 functions in stromal cells as a mediator of cell fate determination into osteoblasts, while inhibiting the differentiation into adipocytes. Interestingly, the expression of Emilin2 mRNA in macrophages was up-regulated by treatment with IL-4, but not IFNγ and IL-10, which modulate macrophage polarization. IL-4-activated M2a macrophages are known to support tissue repair, including in bone fracture. Therefore, we hypothesize that M2a macrophages regulate bone fracture healing through the production of Emilin2. In fact, Emilin2 expression was transiently up-regulated in repaired tissue after bone injury in 8-week-old male mice. In order to gain insight into the in vivo functions of Emilin2 in bone metabolism, the analysis of Emilin2 knockout mice is now underway.

Trapidil induces osteogenesis by upregulating the signaling of bone morphogenetic proteins Bongjun Kim*, Hong-Hee Kim, Zang Hee Lee. Department of Cell and Developmental Biology, School of Dentistry, Seoul National University, Republic of Korea

Platelet-derived growth factor receptor (PDGFR) signaling has been shown to inhibit osteogenesis. However, the specific mechanisms by which PDGFR signaling inhibits osteogenic differentiation remain unclear. In the present study, we examined the effect of inhibiting PDGFR with trapidil, a PDGFR antagonist, on osteogenesis in vitro and in vivo. A rat calvarial defect model was analyzed by micro-computed tomography and histology to determine the pro-osteogenic effect of trapidil in vivo. In addition, primary mouse calvarial osteoblast precursors were cultured in osteogenic differentiation medium with trapidil to study the activity and expression of osteogenic markers in vitro. We showed that trapidil greatly promoted bone regeneration in a rat calvarial defect model. Further study demonstrated that trapidil induced Smad1/5/9 phosphorylation, MAPK phosphorylation, Runx2 expression, and ALP activity, leading to enhanced osteogenic differentiation in vitro. The pro-osteogenic effects of trapidil were inhibited in vitro by depletion of ALK3, type I bone morphogenetic protein receptor (BMPR), or treatment with noggin, an antagonist of BMPs. Finally, trapidil showed a synergistic effect with BMP2 on osteogenic differentiation. Trapidil induced BMPR activity through upregulation of BMP signaling, leading to promoted osteogenesis in vitro and in vivo. Attenuated BMPR activity may be involved in the inhibition of osteogenesis by PDGFR signaling.

FRI-0546

Regulator of G protein signaling protein 12 is required for osteoblast differentiation through controlling calcium channel/Gαi-calcium oscillation-ERK signaling Ziqing Li*[1], Tongjun Liu[2], Alyssa Gilmore[2], Néstor Más Gómez[1], Claire H Mitchell[1,3], Yi-Ping Li[4], Merry J Oursler[5], Shuying Yang[1,2]. [1]Department of Anatomy and Cell Biology, University of Pennsylvania, School of Dental Medicine, United States, [2]Department of Oral Biology, School of Dental Medicine, University of Buffalo, State University of New York, United States, [3]Department of Physiology, University of Pennsylvania, School of Medicine, United States, [4]Department of Pathology, University of Alabama in Birmingham, United States, [5]Department of Medicine, Endocrine Research Unit, Mayo Clinic, United States

Background: Bone homeostasis is intimately relied on the balance between osteoblasts (OBs) and osteoclasts (OCs). Our previous studies revealed that regulator of G protein signaling protein 12 (Rgs12), the largest protein in the Rgs super family, is essential for the terminal differentiation of OCs. However how Rgs12 regulates OB differentiation and function is poorly understood.Methods and materials: OB-targeted Rgs12 conditional knockout (CKO) mice model was generated by crossing Rgs12fl/fl mice with Osterix (Osx)-Cre transgenic mice (Osx; Rgs12fl/fl). Bone architecture changes of 12 weeks old mice were evaluated via micro CT, histology and histomorphometric analyses. For in vitro study, OB precursor cells (OPCs) from control mice (Rgs12fl/fl) were transfected with CRE (ad-RGD-Cre) adenovirus, leading a deletion of Rgs12 in OPCs. Molecular events and OB differentiation markers were examined using qPCR, western blot, immunofluorescence and histochemical staining. Calcium (Ca2+) oscillation, extracellular Ca2+ influx and Ca2+ release from endoplasmic reticulum (ER) were detected by live cell imaging.Results: We found that Rgs12 was highly expressed in both OPCs and OBs of Wide Type (WT) mice, and gradually increased during OB differentiation, whereas conditional Rgs12 CKO mice (OSX; Rgs12fl/fl) exhibited a dramatic decrease in cancellous bone mass, evidenced by reduced percentage of trabecular bone volume (BV/TV, 68%), trabecular number (Tb.N, 29%), trabecular thickness (Tb.Th, 81%), bone formation rate (BFR) and increased in trabecular space (Tb.Sp, 340%). Loss of Rgs12 in OPCs in vitro significantly inhibited OB differentiation and expression of OB marker genes, resulted in suppression of OB maturation and mineralization. Further, deletion of Rgs12 in OPCs significantly inhibited GTPase activity and impaired Ca2+ oscillations via restraints of major Ca2+ entry sources (extracellular Ca2+ influx and intracellular ER Ca2+ release), partially contributed by the blockage of L-type Ca2+ channel mediated Ca2+ influx. Downstream mediator ERK was also inactive in Rgs12-deficient OPCs, while overexpression of Rgs12 or application of pertussis toxin (PTX) could partially rescue the defective OB differentiation and function via activation of ERK.Conclusion: Our findings reveal that Rgs12 is an important regulator in OB differentiation and function, and highlight Rgs12 as a potential therapeutic target for bone disorders.

Lnc-DIF inhibits bone formation via targeting mir-489-3p Zhiping Miao*, Yong Yin, Yan Zhang, Ye Tian, Lifang Hu, Airong Qian. Northwestern Polytechnical University, China

IntroductionLong noncoding RNAs (lncRNAs) are a class of transcripts longer than 200 nucleotides. Recently lncRNAs have been focused as important novel regulators for

development, carcinogenesis and osteoporosis. For the purpose of discovering lncRNAs involved in osteogensis, we initiated characterization of lncRNAs by gene expression profiling analysis.Methods and ResultsWe performed RNA-seq assay on femur tissues from 12 month and 24 month aging C57BL/6 mice. Functional lncRNAs were further screened by correlation analysis to obtain the lncRNAs that were up-regulated by aging and closely related to osteogensis.We have assessed the expression of lncRNAs in bone-derived mesenchymal stem cells (MSCs) isolated from 12 to 24 month C57BL/6 mice. The expression of Lnc-DIF increased with aging process. Besides, the expression of Lnc-DIF decreased during osteoblastic differentiation processes. We further explored that down-regulation of Lnc-DIF in MC3T3-E1 cell line increased osteogenic gene ALP and RUNX2 expression, ALP activity and calcium nodules.We have found 12 binding sites of mir-489-3p in the sequence of Lnc-DIF through prediction by RNA22. Moreover, luciferase reporter assay proved that Lnc-DIF bond with mir-489-3p. We consistently found that agomir-489-3p increased ALP and RUNX2 expression as well as ALP activity and calcium nodules.For further clarify the mechanism of mir-489-3p, we have predicted its target gene PTPN6 by Gene Coexpression Networks and miranda. Luciferase reporter assay proved that mir-489-3p regulate PTPN6. We have also found the down-regulation of PTPN6 enhanced ALP expression, ALP activity and calcium nodules.To investigate whether the therapeutic inhibition of Lnc-DIF would prevent osteoporosis, we administrated si-Lnc-DIF with osteoblast targeting delivery system in ovariectomy (OVX) C57BL/6 mice model. Micro CT assay have proved that BMD, BV/TV, and Tb.N of OVX mice femurs were all significantly recovered by si-Lnc-DIF treatment.ConclusionIn conclusion, we have discovered Lnc-DIF as a novel osteogenic inhibitor. Lnc-DIF inhibits osteoblast differentiation and bone formation through Lnc-DIF - mir-489-3p - PTPN6 pathway. Inhibition of Lnc-DIF recovers bone formation in OVX mice. The finding has revealed a new mechanism of bone formation and provided potential targets for treatment of skeletal disorders.

Conditional Deletion of the Glucocorticoid Receptor in Osteoprogenitors Reveals Complex Roles for Glucocorticoid Signaling in Caloric Restriction-Induced Bone Marrow Fat Accumulation Jessica Pierce*, Ke-Hong Ding, Jianrui Xu, Kanglun Yu, Anuj Sharma, Mark Hamrick, William Hill, Xing-Ming Shi, Carlos Isales, Meghan Mcgee-Lawrence. Augusta University, United States

Bone marrow fat storage can be driven by stressors such as aging, inflammation, and increased circulation of glucocorticoid (GC) signaling. For example, increased circulation of endogenous GC with age is concurrent with an age-related decline in Hdac3 activity in BMSC-derived osteoblasts, allowing for upregulated GC signaling which may promote marrow fat. GC can induce phenotypic changes by binding and activating the glucocorticoid receptor (GR). Because the metabolic stress of caloric restriction (CR) drives marrow fat accumulation, we sought to test the role of the GR under caloric restriction to further elucidate its role in this model of metabolic stress and determine whether the GR is required for marrow fat storage. Additionally, as sympathetic tone can drive caloric restriction-induced marrow fat storage, we sought to test the role of sympathetic tone as a potential compensatory factor in the response of GR-deficient bone to CR. We hypothesized that blocking sympathetic tone in GR-deficient mice would inhibit the exacerbated marrow adiposity and cortical bone loss induced by CR. GRfl/fl mice were crossed with Osx1-Cre to generate GR conditional knockout mice (GR-CKO) and Cre-negative WT controls (6 mo old, n=7 to 8/group) that were subjected to ad libitum (AL), CR (25% reduction), or CR + 0.01% propranolol hydrochloride (administered in drinking water) for 8 weeks. Deletion of the GR within osteoprogenitors protected against osteoblastic lipid accumulation in vitro but augmented marrow adiposity in vivo (+75% adipocyte density) following caloric restriction. Additionally, DXA analysis (Kubtec Digimus) showed that GR-CKO mice had less femoral cortical bone than GR-WT mice following caloric restriction in vivo, while impaired in vitro matrix deposition (-81% Alizarin Red fraction) by BMSC-derived osteoblasts isolated from GR-CKO + AL

mice was rescued to GR-WT levels in cells derived from mice subjected to CR. Importantly, GR-CKO mice had decreased femoral cortical bone mass and significantly more marrow fat (+8-fold vs. GR-WT) under ad libitum conditions—with propranolol treatment rescuing bone mineral content but not preventing lipid accumulation induced by CR—indicating a baseline bone phenotype in GR-CKO mice and a potential role for sympathetic tone in rescuing CR-induced bone loss but not marrow adiposity. This work highlights the complex roles of GC signaling in bone health and in the effects of physiological stressors on marrow fat.

BAF Chromatin Remodelling Epigenetically Controls Osteogenesis in vivo
Tanner Godfrey**, Mohammad Rehan*, Benjamin Wildman, Yuechuan Chen, Quamarul Hassan. University of Alabama at Birmingham, United States

The precise assembly and coordinated function of Brg1 Associated Factors (BAF) complex plays an indispensable role for formation and maintenance of cell-type-specific patterns of accessible DNA, ultimately controlling cellular phenotypic fate. This BAF complex consists of 11 protein subunits encoded by 22 different genes, where different combinations of BAF restrict cell-type specificity. Our lab has identified BAF45a to be a key osteogenic BAF factor required in osteoblasts. Protein-protein interaction studies in vitro established the osteoblast specific BAF composition and in vivo studies show that BAF is a key osteogenic BAF factor required for osteoblastogenesis. We continue to explore the osteoblast specific function of other BAF subunits with the objective to define the osteoblast BAF complex composition and the specific role of different BAF subunits in osteoblasts. The osteoblast-specific BAF complex composition was investigated in differentiating pre-osteoblast cells using anti-BRG1 Immuno-precipitation (IP) mass spectrometry (MS). Osteogenic responsive factors were determined by RT-qPCR following BMP-2 and TGF-β treatment of MC3T3-E1 cells. IP-MS and expression analysis suggest a group of unique and define osteoblast-specific BAF composed of BAF180 (PBRM1), BAF250B and BAF170 interacted with SWI/SNF catalytic subunit BRG1 at day 4 and 14 of differentiation. Treatment with BMP2 resulted in a >2.5 fold increase in Baf45a expression, while TGF-β decreased expression by 50%. BAF45A was found to interact with osteoblast master transcription factor RUNX2 and together regulates osteogenic promoter activity. We developed an osteoblast specific Baf45a knockout model. Osteoblast specific deletion of Baf45a using Osteocalcin-Cre mouse significantly reduced bone volume of the trabecular bone, bone formation rate and bone strength. ChIP experiment was performed to study the epigenetic modification at promoter. Deletion of Baf45a in osteoblasts resulted in drastic decreases in activating histone modification H3K27ac at osteoblast-specific genes. Our data reveal the osteoblastic BAF composition, as well as the osteogenic role of Baf45a. We are in the process of investigating the role of different BAF subunits in the osteoblast development. By understanding these epigenetic mechanisms regulating osteoblasts and bone formation, we hope to uncover potential therapeutic targets to aid the treatment of bone-diseases.

The N6-methyladenosine demethylase FTO functions in bone to protect osteoblasts from age-related DNA damage Qian Zhang*[1], Ryan Riddle[1], Marie-Claude Faugere[2], Clifford Rosen[3], Charles Farber[4], Thomas Clemens[1]. [1]Department of Orthopaedic Surgery, Johns Hopkins University, United States, [2]Department of Medicine, University of Kentucky, United States, [3]Maine Medical Center, United States, [4]University of Virginia, United States

The fat mass and obesity-associated gene (FTO) was originally linked to both obesity and bone mineral density in humans by genome wide association studies but its function has remained elusive. FTO encodes a mRNA demethylase that controls mRNA stability via m6Am demethylation of the 5' mRNA cap. To examine the role of FTO in bone, we characterized the phenotype of mice lacking Fto globally (Fto KO) or selectively in osteoblasts (Ftooc-cre/-). Fto KO mice exhibited reductions in body length and body weight at maturity, and developed age-related reductions in bone volume in both the trabecular and cortical compartments. Ftooc-cre/- mice developed similar age-related bone deficits with enhanced marrow adiposity but did not exhibit changes in body composition. To explore the mechanism of Fto action in osteoblasts, we examined the impact of Fto loss of function on primary osteoblasts. RNA profiling in osteoblasts following acute disruption of Fto revealed changes in transcripts of genes in the DNA repair pathway including Hsp70, the RNA of which contains a Fto binding motif, and NF-κB. Fto KO osteoblasts showed increased basal and UV-induced DNA damage as assessed by γH2AX both in vitro and in vivo. Importantly, inhibition of NF-κB signaling rescued the phenotype in Fto KO osteoblasts in vitro. These findings suggest that DNA damage in osteoblasts lacking Fto is regulated by Hspa1a-NFκB signaling. Together, our results indicate that FTO functions intrinsically in the osteoblast to enhance the stability of mRNA products of proteins that function to protect cells from DNA damage.

Direct reprogramming of mouse fibroblasts into functional osteoblasts by defined factors Hui Zhu*[1], Bogdan Conrad[2], Fan Yang[3], Joy Wu[1]. [1]Division of Endocrinology, Stanford University School of Medicine, United States, [2]Program of Stem Cell Biology and Regenerative Medicine, Stanford University, United States, [3]Department of Orthopaedic Surgery, Stanford University School of Medicine, United States

While induced pluripotent stem cells hold promise for skeletal regeneration as a potential source of osteoblasts, the induction of pluripotency followed by directed differentiation into osteoblasts is time-consuming and low yield. In contrast, direct lineage reprogramming without an intervening stem/progenitor cell stage would be a more efficient approach to the generation of osteoblasts. We screened combinations of osteogenic transcription factors and identified a combination of four factors, Runx2, Osx, Dlx5, and ATF4, that rapidly and efficiently reprogram mouse fibroblasts derived from 2.3 kb type I collagen promoter-driven green fluorescent protein (Col2.3GFP) transgenic mice into induced osteoblast cells (iOB). iOB cells exhibit osteoblast morphology, form mineralized nodules, and express both Col2.3GFP and gene markers of osteoblast differentiation. The global transcriptome profiles of iOB cells are similar to primary osteoblasts. Genome-wide DNA methylation analysis demonstrated that within differentially methylated gene loci, the methylation status of iOB cells more closely resembles primary osteoblasts than mouse fibroblasts. We further demonstrate that GFP+ iOBs have transcriptome profiles similar to GFP+ cells harvested from Col2.3GFP mouse bone chips. Functionally, iOBs contribute to bone healing after transplantation into immunodeficient mice in a critical-sized cranial defect model. These findings provide a robust and reliable system to derive osteoblasts for skeletal regeneration.

Cell Autonomous Sfrp4-Dependent Inhibition of Non-Canonical Wnt Signaling in Osteoclasts Prevents Osteoclastogenesis, Ensuring Normal Cortical Bone Development Kun Chen*[1], Pei Ying Ng[1], Dorothy Hu[1], Roland Baron[1,2], Francesca Gori[1]. [1]Division of Bone and Mineral Research, Harvard Medical School and Harvard School of Dental Medicine, United States, [2]Endocrine Unit, Massachusetts General Hospital, United States

Pyle Disease is a rare skeletal disorder caused by loss of function mutations in the Wnt inhibitor Secreted Frizzled Receptor Protein 4 (Sfrp4). In cortical bone, Sfrp4 is a key regulator of periosteal bone formation and endosteal bone remodeling. The increase in Rankl/Opg ratio and number of endosteal osteoclasts (OCs) in Sfrp4-/- mice, indicate that Sfrp4-mediated signals are involved in osteoblast (OB)-dependent regulation of OC differentiation. We however found that Sfrp4 is also expressed by bone marrow macrophages (BMMs) and its expression increases during Rankl-induced OCgenesis, suggesting that Sfrp4 may be secreted by OCs and regulate OCgenesis in a cell autonomous manner. To test this hypothesis, we explored the mechanisms whereby Sfrp4 and its interference with Wnt signaling regulate OCs. OC differentiation and function were significantly enhanced in Sfrp4-/- BMMs, as indicated by the increase in TRAP+ multinucleated cells, pit assay and OC-specific gene expression. Confirming these findings, Sfrp4-treated wt BMMs were significantly inhibited in their ability to respond to Rankl-induced OC differentiation. Moreover, mix-and-matched co-culture assays demonstrated that Sfrp4 deletion in both OBs or BMMs favors OCgenesis. It is established that while canonical Wnt (cWnt)/Lrp5/6 signaling suppresses OCgenesis, activation of the non-cWnt/Ror2/Jnk cascade is a potent activator of OC differentiation. As expected Sfrp4 deletion resulted in an increase in both cWnt and non-cWnt/Ror2/Jnk signaling in Rankl-induced BMM differentiation. Pharmacological inhibition of cWnt signaling had no effect on the Sfrp4 deficiency-dependent increase in OCgenesis. In contrast, blocking the Ror2/Jnk cascade markedly inhibited OCgenesis. Similarly, while in vitro excision of Lrp5/6 did not alter the effect of Sfrp4 on OCgenesis, in vitro excision of Ror2 significantly impaired it. All together these data reveal a new mechanism whereby combined cell-autonomous effects of Sfrp4 and effects from OB-secreted Sfrp4 regulate OCgenesis. These results are consistent with a paradigm in which the increase in OCs in Sfrp4-/- mice is a consequence of non-cWnt signaling activation overriding the negative effect that activation of cWnt signaling has on OCgenesis. Since deregulated endosteal bone remodeling is a determinant for cortical thickness and porosity, these studies might have implications for the generation of novel therapeutic approaches for the treatment of bone fragility.

Autocrine actions of high mobility group box1 protein (HMGB) on osteocytes and osteoclasts regulate osteoclastogenesis Hannah M. Davis*[1,2], Sinai Valdez[1], Leland J. Gomez[1], Angela Bruzzaniti[1,2,3], Lilian I. Plotkin[1,2,4]. [1]Department of Anatomy & Cell Biology, Indiana University School of Medicine, United States, [2]Indiana Center for Musculoskeletal Health, United States, [3]Biomedical and Applied Sciences, Indiana University School of Dentistry, United States, [4]Roudebush Veterans Administration Medical Center, United States

Old age and Cx43 deletion in osteocytes (Ot) increase Ot apoptosis and osteoclastogenesis. Further, prevention of apoptosis in Cx43-deficient MLO-Y4 cells (Cx43def) blocks Oc differentiation induced by Cx43def conditioned media (CM), and blocks the release of the cytokine high mobility group box1 protein (HMGB1) from Cx43def Ot. Inhibition of HMGB1, in turn, lowers RANKL in Cx43def Ot, raising the possibility that HMGB1 mediates osteoclastogenesis induced by apoptotic Ot. We now report that addition of a neutralizing HMGB1 antibody (Ab) to bone marrow cells (BMC) treated with RANKL/MCSF reduces Oc formation. The role of RAGE or TLR4, two HMGB1 receptors, on osteoclastogenesis was tested by adding 1nM HMGB1 plus 100ng/ml RAGE (Azeliragon, Az) or TLR4 (LPS-RS) inhibitors. HMGB1 added during d1-3 increases Oc number, and LPS-RS, but not Az blocks this effect. HMGB1 added during d1-5 or d3-5 did not alter Oc number. Further, while Az or LPS-RS alone during d1-5 did not affect Oc, the combination of both inhibitors decreased Oc number. Moreover, RAGE but not TLR4 inhibition in mature Oc (d3-5) reduced Oc number. This suggests that HGMB1 produced by Oc has autocrine effects on differentiation through TLR4 activation in pre-OCs, followed by RAGE activation. We next tested if RAGE mediates the effects of apoptotic Ot on Oc. Co-culturing Cx43def Ot with WT or RAGE-KO BMC increased Oc number 2 and 4X, respectively vs Cx43+ Ot. Further, Cx43def CM induced 1.6X more Oc than CM from Cx43+ Ot, with or without Az. Similar to Cx43def CM, more Oc were obtained when CM from Ot-enriched long bone cultures of old (21mo) vs young (4mo) mice was added to BMC; an effect that was lost when bones were pre-treated with DEVD, an apoptosis inhibitor. Further, addition of CM from old bones to BMC from WT or RAGE-KO mice increased Oc by 1.3 and 1.7X, respectively, vs young bone CM. Taken together, our findings suggest that apoptotic Ot increase Oc independent of HMGB1/RAGE activation in Oc. Consist with this, immunodepletion of HMGB1 from Cx43def CM does not prevent Oc formation. However, treatment of Cx43def Ot with HMGB1 Ab followed by HMGB1 immunodepletion, reduced Oc differentiation induced by Cx43def CM, suggesting that autocrine HMGB1 actions stimulate the release of osteoclastogenic signals from Ot. We conclude that HMGB1 exerts dual effects on bone cells, directly promoting Oc differentiation via RAGE and TLR4 activation in Oc and increasing pro-Oc cytokine release from Ot.

EOMES is a novel and essential co-partner of PU.1 and MITF in regulating osteoclast differentiation Blake E. Hildreth Iii*[1], Heather A. Carey[2], Devadoss J. Samuvel[1], Katie A. Thies[1], Jennifer A. Geisler[2], Thomas J. Rosol[3], Ramiro E. Toribio[3], Julia F. Charles[4], Michael C. Ostrowski[1], Sudarshana M. Sharma[1]. [1]Medical University of South Carolina Department of Biochemistry and Molecular Biology and Hollings Cancer Center, United States, [2]Ohio State University Department of Cancer Biology and Genetics and Comprehensive Cancer Center, United States, [3]Ohio State University College of Veterinary Medicine, United States, [4]Brigham and Women's Hospital and Harvard Medical School Department of Medicine, Division of Rheumatology, Immunology and Allergy, United States

Osteoclasts (OCs) differentiate from myeloid precursors (MPs) and are essential for bone remodeling. Multiple transcription factors (TFs) expressed in MPs and OCs are essential for this process, including PU.1 and MITF. We have shown that PU.1 and MITF physically interact and regulate the transcription of multiple genes essential for OC differentiation and function. However, the full extent of TFs involved, and their hierarchical architecture and interplay, are not well known. Therefore, our goal was to further define the TF network regulating OC differentiation. Functional genomics analysis of OC ChIP-Seq data revealed PU.1/MITF peaks were enriched for the T-box TF EOMES, including many TF loci regulating OC differentiation. ChIP-Seq of EOMES from murine trophoblasts indicated significant overlap with PU.1 at gene loci. Conventional ChIP in MPs and OCs confirmed that EOMES is directly recruited to key PU.1- and MITF-bound TF loci essential for OC differentiation, including Nfatc1 and cFos. Subsequent co-IP demonstrated that EOMES interacts with both PU.1 and MITF. We then evaluated the effects of myeloid-specific deletion of EOMES (EomesΔMP/ΔMP) on OC differentiation and function. EomesΔMP/ΔMP mice had increased bone mass as shown by μCT. Most notably, there was a significant increase in 1) BV/TV and Tb.V/TV in the distal femoral metaphysis; 2) Ct.Th in the distal femoral metaphysis and diaphysis and 3) cumulative BMD. While there was a trend towards an increase in Tb.N (P = 0.065) in EomesΔMP/ΔMP mice, Tb.Sp was significantly reduced. Histomorphometry revealed significantly reduced Oc.N/BS and Oc.S/BS in EomesΔMP/ΔMP mice. EomesΔMP/ΔMP OCs had significantly lower expression of the osteoclastogenic TFs Nfatc1, Fosl2, Prdm1, Jun-B, and Myc, with a significant increase in Ppar-gamma expression. In addition, EomesΔMP/ΔMP OCs had significantly lower expression of the OC marker genes Acp5, Ctsk, Calcr, and Oscar. These findings indicate that 1) MP-specific deletion of EOMES decreases OC differentiation and function and 2) EOMES binds with PU.1 and MITF in both MPs and OCs to TF loci essential for OC differentiation and function. In summary, we have determined that a novel PU.1/MITF binding partner, EOMES, also possess functionality in cells of the OC lineage, of which it is essential for OC differentiation. This is the first evidence of EOMES having a functional role in any cell of the myeloid lineage, and more specifically, OC differentiation.

RANKL-Sensitive Super-Enhancer Activities Determine Cell Identity During Osteoclastogenesis Min Joon Lee*[1], Sungho Park[2], Keunsoo Kang[4], Jiyoung Ahn[3], Ye-Ji Lee[3], Sehwan Mun[3], Seyeon Bae[3], Kaichi Kaneko[3], Kyung-Hyun Park-Min[2]. [1]University of Toronto Faculty of Medicine, Canada, [2]Arthritis and Tissue Degeneration Program, David Z. Rosensweig Genomics Research Center, Hospital for Special Surgery, United States, [3]Arthritis and Tissue Degeneration Program, Hospital for Special Surgery, United States, [4]Department of Microbiology, Dankook University, Republic of Korea

Homeostatic osteoclastogenesis from progenitor cells requires precise coordination of cell-type- and site-specific gene expression. Despite substantial advance in the identification of osteoclast master regulators, developing therapeutic interventions for pathologic osteoclasts (e.g. in rheumatoid arthritis, RA) has been challenging due to off-target effects. Targeting tissue-specific and diseases-specific enhancers, a regulatory code located in distal elements, has recently emerged as a new therapeutic potential. Osteoclast-specific transcription is highly organized and is proposed to be driven by enhancers. However, the osteoclast-specific enhancer program is poorly understood and its role in osteoclastogenesis remains unclear. In this study, we profiled enhancers in human osteoclasts by combining bioinformatics and transcriptomics approaches using ChIP-, ATAC-, and RNA-sequencing, and validated the pathophysiological importance of our findings in RA patients. We treated human osteoclast precursors with RANKL for 1 or 3 days, and found that RANKL dynamically regulates super-enhancers, which are large regulatory regions of enhancers previously reported to control cell identity in other cell types. We further identified a new class of RNAs transcribed from super-enhancers (SE-RNAs) in human osteoclasts by integrated analysis of RANKL-regulated transcriptome with osteoclast-specific super-enhancers. These SE-RNAs were associated with the transcription of several key genes important for osteoclastogenesis. Among them, Osteolinc, a RANKL-inducible SE-RNA, was found to promote osteoclastogenesis by regulating RANKL-induced NFATc1 gene expression. Knock-down of Osteolinc by siRNA suppressed human osteoclastogenesis. Strikingly, we found that Osteolinc is only expressed in osteoclasts and not in other cell types. Synovial CD14+ cells isolated from RA patients had significantly elevated Osteolinc expression, while those from control CD14+ cells had low, undetectable baseline expression. To the best of our knowledge, our finding

provides the first example of enhancers and super-enhancers in human osteoclasts and highlights the importance of RANKL-induced epigenetic regulation in human osteoclastogenesis. Our results show that RANKL-regulated RNAs transcribed from super-enhancers play an important role in osteoclastogenesis and suggest that manipulating SE-RNAs may offer a novel, cell-specific therapeutic strategy for treating osteoclast-mediated bone diseases.

IDH2 is a novel regulator of osteoclast differentiation and function through osteoblastic modulation of ATF-NFATc1-RANKL signaling axis Suk-Hee Lee*, Seung-Hoon Lee, Soon-Young Kim, Eun-Hye Lee, Yeon-Ju Lee, Jung-Eun Kim. Department of Molecular Medicine, CMRI, BK21 Plus KNU Biomedical Convergence Program, School of Medicine, Kyungpook National University, Republic of Korea

Mitochondrial NADP+-dependent isocitrate dehydrogenase (IDH2) is an evolutionarily conserved protein that regulates mitochondrial redox balance and energy metabolism via generation of NADPH and α-ketoglutarate, respectively. IDH2 deficiency promotes the mitochondrial dysfunction in multiple cell types and various organs including heart, kidney, and brain. However, the function of IDH2 in bone tissue has not been studied. Here, we investigated the role of IDH2 in bone formation and remodeling using mice with targeted disruption of IDH2. MicroCT demonstrated that the femur of IDH2-/- mice exhibited a 39% (p<0.05) increase in trabecular BV/TV due to a significant increase in Tb.Th and Tb.N and a decrease in Tb.Sp compared to that of wild-type mice. In parallel, a significant reduction of osteoclast number/bone surface was observed in both of vertebrae and long bones from the IDH2-deficient mice, whereas there was no significant change of osteoblast number/bone perimeter between two genotypes. Serological analysis revealed that CTX-1, the marker of osteoclast activity and bone resorption, was reduced in IDH2-/- mice. The RANKL expression level in whole bone marrow from IDH2-deficient mice was decreased in comparison with that of wild-type mice. The RANKL/OPG ratio due to low RANKL was also significantly diminished in the serum of IDH2-/- mice. To investigate the inhibitory effect of IDH2 on the osteoclast differentiation and the associated underlying mechanism of action, bone marrow stromal cells (BMSC) and osteoclast progenitors isolated from IDH2-/- and wild-type mice were used. RANKL gene expression in primary BMSC was significantly decreased at the early stage of IDH2-deficient osteoblast differentiation. Consistent with these findings, the treatment of the serum derived from IDH2-deficient mice remarkably lowered the differentiation capacity of bone marrow-derived osteoclast progenitors. This inactivation of IDH2 was linked to reduced RANKL expression through the ATF4/NFATc1-dependent manner in BMSC, partly via a mitochondrial ATP generation. In the present study, we showed that mice targeted disruption of IDH2 exhibit high bone mass associated with down-regulation of RANKL expression which leads to the inhibition of osteoclast differentiation and bone resorption. Our findings suggest that IDH2 may be a novel positive regulator of osteoclast function and provide a rational of IDH2 as a therapeutic target against bone loss and osteoporosis.

Cortistatin Directly Binds to RANK and Protects Against Osteoporosis in Mice Weiwei Li*[1], Ruize Qu[2], Xiaomin Chen[2], Wenhan Wang[2], John Hayball[3], Krasimir Vasilev[3], Yunpeng Zhao[1]. [1]Shandong University Qilu Hospital, China, [2]Shandong University, China, [3]University of South Australia, Australia

INTRODUCTION: It is known that RANKL/RANKL signaling pathway plays a critical role in development of osteoporosis[1]. A neuropeptide, cortistatin (CST), is recently reported to be associated with bone metabolism. However, whether CST plays a role in osteoporosis is still unknown.METHODS: CST knockout mice (CST-/- of C57BL/6 strain), OPG-/- mice (C57BL/6 strain), micro CT, BMDM, OVX model, CST recombinant protein, co-immunoprecipitation (Co-IP), Solid phase binding assay, Western blot, real time PCR, Histology, immunohistochemistry, unpaired t-tests (Mann-Whitney), paired t-tests, ANO-VA.RESULTS SECTION: The interaction between CST and RANK was implied by Co-IP (Fig. 1A) and solid phase binding assay (Fig. 1B). BMDM was isolated from WT mice, and RANKL mediated production of osteoclast-associated genes were attenuated by CST (Fig. 1C). Moreover, OVX model was established in WT mice, with or without treatment of 20μg CST (twice a week). At 8-week time point, micro CTof vertebra (Fig. 2A) and the parameters, including BV/TV, BMD, Tb.Th and Tb.Sp (Fig. 2B-2E) showed that CST inhibited osteoporosis in OVX model, which was in line with TRAP staining of vertebral body (Fig. 2F). Furthermore, age associated osteoporosis was compared between 10-month old female CST-/- mice and WT mice (N=7 for each group). As a result, loss of CST exaggerated bone loss in tibia, as indicated by TRAP staining (Fig. 3A) and HE staining (Fig. 3B). Micro CT assay (Fig. 3C-3D) as well as its associated statistical analysis of parameters revealed more severe bone loss in CST-/- mice (Fig. 3E-3H). In addition, 2-month old OPG-/- mice were treated with 20μg CST (twice a week) for 2 months. As indicated by micro CT image (Fig. 4A), BV/TV, BMD, Tb.Th and Tb.Sp (Fig. 4B-4E), osteoporosis in OPG-/- mice was suppressed by CST treatment. TRAP staining revealed that osteoclast activity in OPG-/- mice was diminished by exogenous CST (Fig. 4F). The values are the mean±SD. *p<0.05, ** p<0.01 and *** p<0.005 vs. control group.DISCUSSION: These results reveal CST as a potential antagonist for osteoporosis through suppressing RANK/RANKL signaling. More

experiments are required to testify the specific mechanisms involved in this process.SIGNIFICANCE/CLINICAL RELEVANCE: CST may shed light on treatment of osteoporosis in the future. REFERENCES: [1] Luo J, et al, Nature Medicine, 2016

Hdac3 promotes bone robustness by suppressing osteoclast responsiveness to RANKL and enhancing bone formation Anna Mattson*[1], David Molstad[1], Dana Begun[1], Jennifer Westendorf[1], Merry Jo Oursler[1], Meghan Mcgee-Lawrence[2], Bradley Elizabeth[1]. [1]Mayo Clinic, United States, [2]Augusta University, United States

Hdac3 is a lysine deacetylase and functions to remove acetyl groups from histones and additional nuclear proteins. HDAC3 levels decline in human bone samples from old as compared to young women; thus, when bone mass decreases with age in humans HDAC3 levels are suppressed. To determine if Hdac3 levels impact osteoclast differentiation and bone resorption, we conditionally deleted Hdac3 in mature osteoclasts by crossing Hdac-3fl/fl mice with Ctsk-Cre expressing mice. Hdac3 cKOCtsk mice exhibit reduced femoral and tibial bone robustness (bone width relative to length) and increased cortical periosteal osteoclast number and osteoclast size. Trabecular bone volume fraction, bone mineral density, trabecular number and connective density are suppressed with a corresponding increase in trabecular spacing in Hdac3 cKOCtsk mice. Hdac3 suppression in mature osteoclasts also reduced healing in a cortical bone defect model. We previously showed that Hdac3 deacetylates the p65 subunit of the NFκB transcriptional complex to increase DNA binding and transcriptional activity. We hypothesized that elevated NFκB transcriptional activity of Hdac3 deficient osteoclasts would enhance RANKL signaling. Hdac3 deficient osteoclasts demonstrate increased K310 NFκB acetylation and NFκB transcriptional activity. Two downstream transcriptional targets of RANKL-induced activity, NFATc1 and the p65 NFκB gene locus itself, are likewise elevated in Hdac3 deficient osteoclasts. Hdac3 deficient osteoclasts were hyper-responsive to RANKL and showed elevated osteoclast number and size at all concentrations. Toluidine blue staining of dentin disks cultured with Hdac3 deficient cells was increased by 60%. Osteoclast-specific Hdac3 deficiency decreases cortical and trabecular bone parameters, suggesting that Hdac3 regulates coupling of bone resorption and bone formation. We surveyed a panel of osteoclast-derived coupling factors and found that suppression of Hdac3 diminished S1P production. Osteoclast-derived S1P acts in paracrine to promote bone mineralization. Alizarin red staining of wildtype bone marrow stromal cells cultured with conditioned medium from Hdac3 deficient osteoclasts was markedly reduced. Expression of Alkaline phosphatase, Type Collagen 1a1 and Osteocalcin was also suppressed, but no change in Runx2 expression was observed. Our results demonstrate that Hdac3 controls bone robustness by suppressing osteoclast responsiveness to RANKL and coupling to bone formation.

Collagen Type VI α2 Chain Deficiency Causes Trabecular Bone Loss by Promoting Osteoclast Differentiation through Enhanced TNFα Signaling Hai Pham*[1], Ainnie Dar[1], Vardit Kram[2], Li Li[1], Tina Kilts[1], Marian Young[1]. [1]Craniofacial and Skeletal Diseases Branch, National Institute of Dental and Craniofacial Research, National Institutes of Health, United States, [2]Collagen Type VI α2 Chain Deficiency Causes Trabecular Bone Loss by Promoting Osteoclast Differentiation through Enhanced TNFα Signaling, United States

Collagen type VI monomers are composed of three α-chains (α1, α2, α3) that align in a triple helix that assembles into larger fibrils found in many musculoskeletal tissues. Collagen type VI is widely known for its role in muscular disorders, however its function in bone is still not well understood. Using immunohistochemistry, we examined the expression of collagen type VI during fracture healing, and found that it was enhanced in the callus of healing bone. We further examined all three collagen type VI chains by qPCR and found Col6α2 mRNA highly upregulated at day 14 post-fracture, suggesting it could have a role in bone remodeling. To determine the role of collagen type VI α2 in bone function we analyzed bone mineral density of femora and whole mice's body by DEXA and found it significantly reduced in mice deficient in collagen type VI α2 (Col6α2 KO). Further micro CT analysis of both femora and vertebrae showed significant decreases in bone volume/total volume and trabecular number in Col6α2 KO mice compared to wild-types (WT). To try to understand the cellular basis for the decreased bone mass, we performed double labeling assays by calcein injections, and found no difference in trabecular bone formation between WT and Col6α2 KO mice judged by the mineral appositional rate, bone formation rate, and mineralizing perimeter. This experiment indicated that collagen type VI α2 deficiency does not affect bone formation in vivo. When we examined femora sections for the abundance of TRAP positive osteoclasts we discovered that mutant mice exhibited 2.4 times more osteoclasts compared to WT mice, indicating that the primary effect of collagen type VI α2 is on osteoclastogenesis. Since TNFα is well known to promote osteoclastogenesis, we hypothesized that TNFα may be involved in collagen type VI α2 regulation of osteoclastogenesis. To test this, solid phase binding assays were performed and showed specific binding of collagen type VI α2 to TNFα. When we treated bone marrow stromal cells (BMSCs) from WT and Col6α2 KO mice with rmTNFα protein, we found that Col6α2 KO cells expressed higher levels of TNFα mRNA compared to WT cells, suggesting BMSCs from Col6α2 KO mice are highly sensitive to TNFα signaling. Taken together, our data indicate that collagen type VI α2 chain deficiency causes trabecular bone loss by enhancing osteoclast differentiation through enhanced TNFα signaling.

Dual specificity of the Inpp4b phosphatase in bone remodeling Lina Saad*, Monica Pata, Jean Vacher. IRCM, Canada

Bone remodeling relies on a strict balance between bone formation by the osteoblast and bone resorption by the osteoclast. The differentiation and activation mechanisms of these cells are regulated by multiple signaling cascades including the PI3kinase pathway. Upon external stimulation, phosphatidylinositol kinases and phosphatases are activated and produce short-lived phospholipids second messengers essential in intracellular signaling for cell growth, survival and activation. We isolated and characterized the mouse homologue of the human and rat inositol polyphosphate 4-phosphatase b (Inpp4b) that is highly expressed in osteoclast and to a lower extent in osteoblasts. To gain insight into the role of Inpp4b in bone remodeling, we produced a null allele of Inpp4b. The systemic Inpp4b ablation resulted in an increase in osteoclast number and activity leading to low bone mass and osteoporosis. Inpp4b-/- mice also display an increase in mature osteoblast population resulting in enhancement of bone mineral apposition rate. However, a complete understanding of these regulatory mechanisms was missing. Among several osteoclast signaling cascades responding to RANKL stimulation and upstream of Nfatc1, only the PKCb pathway was modulated in absence of Inpp4b. We show that Inpp4b regulates bone marrow cells differentiation toward mature osteoclasts through the PKCβ/GSK-3β/Nfatc1 pathway and similarly, the PKCβ/GSK-3β/β-catenin pathway was modulated along Inpp4b-/- osteoblast differentiation. Importantly, pharmacologic inhibition of PKCβ in Inpp4b-/- cells results in a significant reduction of NFATc1 gene expression that was associated with a decrease in the level of GSK-3β inactive phosphorylated form. In addition, co-IP experiments suggest that Inpp4b can interact directly with the phosphorylated forms of PKCβ and GSK-3β. These results provide evidence that the lipid phosphatase Inpp4b is an active protein phosphatase that can modulate PKCβ and GSK-3β protein kinase activities during osteoclast and osteoblast differentiation to control bone remodeling.

An Unanticipated Role for Sphingosine Kinase-2 in Bone Anabolism Joanne Walker*, Gang-Qing Yao, Meiling Zhu, Ben-Hua Sun, Christine Simpson, Karl Insogna. Yale University School of Medicine, United States

Release of clastokines may be one mechanism by which osteoclasts modulate bone remodeling. Sphingosine-1-phosphate (S-1-P) is a clastokine with important bone anabolic

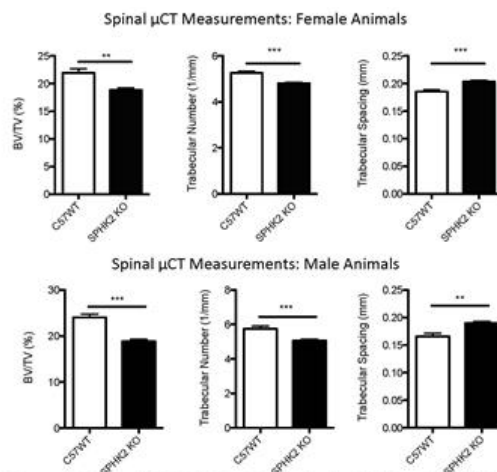
functions. Increased S-1-P production by osteoclasts results in increased bone formation in vivo (JCI 123:666; Nat. Comm. 5:5215). In vitro, S-1-P augments osteoblast differentiation and function. SPHK is the rate-limiting enzyme in S-1-P production and has two isoforms. SPHK1 is a cytoplasmic enzyme that generates S-1-P at the cell membrane for export. SPHK2 is localized to the endoplasmic reticulum, the nucleus, and mitochondria and is thought to generate S-1-P for intracrine actions. To evaluate the roles of SPHK1 and SPHK2 in bone, we examined the skeletal phenotype of mice with selective deletion of SPHK1 in osteoclasts (SPHK1-Oc-/-) mice and mice in which the SPHK2 gene was deleted (SPHK2-/-). Selective deletion of SPHK1 in osteoclasts was accomplished by crossing SPHK1flox/flox mice with Cathepsin K-Cre+/ mice and back-crossing these animals to SPHK1flox/flox mice to yield animals with the genotype SPHK1flox/flox-CtskCre /+. BMD by uCT was quantified at 12-weeks of age in 16 SPHK1-Oc-/- (9F, 7M) and 12 controls (9 F, 3 M). There were no differences in any of the trabecular or cortical parameters based on genotype or in serum CTx. By contrast SPHK2-/- female mice had a 14% lower spinal BMD (p<0.002) and males a 22% lower BMD at the same site (p<0.001; Fig 1). Trabecular number was reduced in the both male (p=0.0004) and female animals (p=0.0002) and trabecular spacing increased (M: p=0.002; F: p=0.0006). If generation of osteoclast-derived S-1-P is part of the anabolic program in bone entrained by single daily dose PTH, then limiting production of S-1-P should attenuate that anabolic response. SPHK2-/- animals (8 F, 8 M) were treated either with daily (1-34)PTH 80 ng/kg/d or vehicle for 28 days. Wild type controls (8 F, 9 M) were treated in the same manner. At 28 days femoral trabecular BMD increased by 133% in female controls and by 38% in male controls. In SPHK2-/- males, femoral trabecular bone only increased by 7% and in the females by only 54%. In the spine, control females had a 27% increase and the males a 29% increase in BMD while in the SPHK2-/- animals the values were 39% and 17% respectively in the female and male animals. Based on our data we conclude that SPHK2 has an important role in mediating both normal bone remodeling and the anabolic response to PTH.


Figure 1. BMD by uCT was quantified at 12-weeks of age in SPHK2-/- mice. Female and male mice had a low spinal BMD (p<0.002) and (p<0.001), respectively. Trabecular number was reduced in both male (p= 0.0004) and female animals (p= 0.0002) and trabecular spacing increased (M: p=0.002; F: p= 0.0006).

Osteocyte Sirt6 has crucial roles in bone and phosphate metabolism Aikebaier Aobulikasimu*[1], Zulipiya Aibibula[1], Jinying Piao[1], Shingo Sato[2], Hiroki Ochi[2], Kunikazu Tsuji[3], Atsushi Okawa[1], Yoshinori Asou[1]. [1]Department of Orthopedics Surgery, Tokyo Medical and Dental University, 1-5-45 Yushima Bunkyo-Ku Tokyo Japan, 113-8519, Japan, [2]Department of Physiology and Cell Biology,Tokyo Medical and Dental University, 1-5-45 Yushima Bunkyo-Ku Tokyo Japan, 113-8519, Japan, [3]Department of Cartilage Regeneration, Tokyo Medical and Dental University, 1-5-45 Yushima Bunkyo-Ku Tokyo Japan, 113-8519, Japan

Aging is a pivotal risk factor for osteoporosis in association with declined activity of vitamin D. FGF23 reduces serum phosphate levels by repressing intestinal phosphate absorption through downregulating 1,25-dihyroxyvitamin D and proximal tubular phosphate resorption. The stress-response and chromatin-silencing factor Sir2, a yeast sirtuin, is a NAD+-dependent histone deacetylase. in mammals the sirtuin family contains seven genes encoding sirtuin proteins. Among them, Sirt6 is localized to the nucleus and is involved in transcriptional silencing, genome stability, and longevity. Sirt6 is implicated in the regulation of life span and ageing. We have shown Sirt6 plays roles in the maintenance of the articular cartilage. However, the precise role of Sirt6 in bone metabolism is poorly understood. Here we aimed to examine the role of Sirt6, a mammalian homologue of Sir2, in the osteocyte by analyzing mice lacking Sirt6 in DMP1 expressing cells (DMP1cre::Sirt6 f/f mice;CKO). Mice grew normally and the body weight was not affected by Sirt6 deletion in osteocytes. Five months old male and female CKO have lower trabecular bone volume compared with the control mice both in the femur and the lumber spine. Serum osteocalcin, a bone formation marker, was decreased in CKO, wheras urine CTX-1, a bone resorption marker, was in-

Friday Posters

creased in CKO, Bone histomorphometry analysis indicated MAR and BFR were decreased in CKO. TRAP staining indicated osteoclast number and osteoclast surface were increased in CKO. To elucidate the target of Sirt6 in the osteocyte, qPCR analysis of the cortex bone was employed. As we previously found Sirt6 deficiency enhanced expression of PAI-1, a cell senescence marker, in the chondrocytes, mRNA level of PAI-1 was evaluated with sevral factors expressed in osteocytes. The results indicated mRNA expression of SOST, FGF23 and PAI-1 was increased in cortical bone of CKO. increased FGF23 levels was associated with reduced phosphate concentration in CKO and also in Sirt6 null mice. Elevated FGF23 in association with reduced phosphate were ameliorated when Sirt6 null mice were crossed with PAI-1 null mice (Sirt6-/-::PAI-1-/- mice). In cultured osteocyte -link MLO-Y4 cells, SOST and PAI-1 were increaced by Sirt6 knock down using siRNA. These results indicated Sirt6 regulate bone and phosphate metabolism through, at least in a part, regulation of SOST and FGF23 in osteocytes.

PPARα is a negative regulator of sclerostin production in osteocytes Amit Chougule*, Lance Stechschulte, Beata Lecka-Czernik. University of Toledo, United States

The nuclear receptor PPARα is a major regulator of energy production and lipid metabolism, and a pharmacologic target to treat dyslipidemia. Mice deficient in PPARα are metabolically impaired in response to fasting and high-fat diet, however PPARα role in maintenance of bone mass has not been studied in details. We have showed that sclerostin protein is under negative control of PPARα. PPARα global KO mice (αKO) have larger long bone cavity and thinner cortex, as compared to WT animals. Loss of PPARα results in decreased bone formation and decreased number of osteoblasts (OB), and increased bone resorption accompanied with increased number of osteoclasts (OC), along with an increase in marrow fat volume (MFV). We analyzed endosteal OB and cortical osteocytes (OT) freshly isolated from femora of WT and αKO mice. OT from αKO have 5-fold increased expression of Sost, while OB have decreased expression of Wnt10b, Wnt16 and CyclinD. Increased Rankl expression in OT corelates with a significant increase in OC, thinner trabeculae and thinner cortex in αKO mice. Consistently, there is 2-fold increase in sclerostin protein levels in αKO femur. Conditioned media (CM) collected from primary cultures of αKO OT have significantly higher sclerostin levels as compared to CM from WT OT. In co-cultures, αKO CM increased expressions of adipogenic markers aP2, CD36 and LPL in recipient WT marrow mesenchymal stem cells (MSC). Depleting sclerostin from αKO CM, decreased adipogenic markers in recipient MSCs, and increased Wnt signaling markers, Wnt10b and Axin2, in MSCs committed to OB lineage. We have identified a PPARα-specific PPRE sequence (αP-PRE) in the Sost promoter located -1.8 kb upstream from the transcription start site. ChIP assay confirmed that PPARα binds to this αPPRE in basal conditions, and this binding is increased following activation of PPARα with WY14643 agonist, while it is decreased in the presence of GW6471 antagonist, and is absent when αPPRE is mutated. Increased PPARα binding correlated with a decreased promoter activity of Sost and its mRNA expression. The effect of OT-specific PPARα deficiency on bone and energy metabolism is currently tested in 8kb Dmp1CrePPARαfl/fl mice. In summary, PPARα acts as a negative regulator of sclerostin expression in OT, which in αKO mice results in decreased bone formation and increased resorption, and increase in MFV. These findings position PPARα as a pharmacological target controlling sclerostin expression in OT.

Microgravity exposure in growing mice is detrimental to osteocyte lacunar volume and shape Jennifer C. Coulombe*[1], Zachary K. Mullen[2], Ashton M. Weins[2], Louis S. Stodieck[3], Virginia L. Ferguson[1]. [1]Department of Mechanical Engineering, University of Colorado, Boulder CO, United States, [2]Department of Applied Mathematics, University of Colorado, Boulder CO, United States, [3]BioServe Space Technologies, University of Colorado, Boulder, CO, United States

Osteocytes, the primary strain-sensing cell type within bone, perform osteolysis and undergo apoptosis with disuse which may lead to bone fragility in astronauts. Yet the effects of microgravity on osteocyte lacunar morphology and network organization are unknown. This study seeks to evaluate how individual and networks characteristics of osteocyte lacunae are altered by microgravity in regions of tensile and compressive strain in mouse cortical long bone.Female C57Bl/6N, skeletally immature 9 week old mice, n=4/group, were assigned to ground control (GC) and flight (FL; 12.8 days of microgravity, Space Shuttle Endeavour STS-118 mission). GC mice were housed in identical conditions. Tibiae were harvested and matched volumes were scanned with high resolution X-Ray microscopy (XRM; 0.6 μm voxels, Zeiss, Xradia 520) at 3 mm proximal to the tibiofibular junction. Anterior medial (tensile1) and posterior lateral (compressive1) regions assessed for influence of in vivo strain. Osteocyte lacunae were evaluated using DragonFly Pro. Osteocyte network characteristics, individual lacunar morphometry, and kriging models of local correlation (i.e., comparing individual measures lacunae to those of their neighbors) were analyzed in R. Two-way ANOVA and Tukey's HSD assessed data for effects of microgravity and strain; significance reported for p < 0.05.Under normal gravity, lacunar volumes were significantly greater in tensile (305.96 ± 20.1 μm3) as compared to compressive regions (245.98 ± 26.17

μm3). Lacunar stretch2, Lc.St, and Oblateness2, Lc.Ob, were also greater in tensile (0.77 ± 0.01, 0.58 ± 0.03) than in compressive regions (0.79 ± 0.01, 0.61 ± 0.03). Overall, lacunae under compressive strain had -19.6% volume, +3.44% Lc.St and +5.49% Lc.Ob. FL mice showed only -3.1% difference in volume, -0.5% Lc.St, -7.1% Lc.Ob. Kriging demonstrated that lacunar measures were similar to those of neighboring lacunae within each compressive and tensile region.Osteocyte networks remain the same despite exposure to microgravity and strain region. Osteocyte lacunar morphologies undergo shape and volume changes after exposure to microgravity in a strain-dependent manner. These differences in individual lacunae are consistent with those observed in aging3, and may be predictive of diminished osteocyte sensitivity to strain and diminished bone formation4.Citations:1) Patel, TK et al., J. Sex divergent role of osteocytic miR21 in the maintenance of osteocyte viability and regulation of bone turnover Hannah M. Davis*[1,2], Rafael Pacheco-Costa[1,2], Mohammad W. Aref[1,2], Alyson L. Essex[1], Emily G. Atkinson[1,2], Julian E. Dilley[1], Carmen Herrera[1], Padmini Deosthale[1,2], Mircea Ivan[3], Matthew R. Allen[1,2,4], Teresita M. Bellido[1,2,4], Lilian I. Plotkin [1,2,4]. [1]Department of Anatomy & Cell Biology, Indiana University School of Medicine, United States, [2]Indiana Center for Musculoskeletal Health, United States, [3]Department of Hematology/Oncology, Indiana University School of Medicine, United States, [4]Roudebush Veterans Administration Medical Center, United States

The microRNA miR21 regulates bone metabolism by acting directly on osteoblasts (Ob) and osteoclasts (Oc); but its role in osteocytes (Ot) is not completely known. Ot miR21 expression is low in bones from old female mice; and low miR21 levels increase Ot apoptosis. Because Ot apoptosis triggers osteoclastogenesis, we investigated whether Ot miR21 removal increases Oc formation. Surprisingly, high Ot apoptosis in 4-mo female miR21f/f;8kbDMP1-Cre mice with miR21 deletion in Ot (miR21Δot) was accompanied by low bone resorption (and formation) compared to miR21f/f littermates. We now report that Ot miR21 deletion has sex-divergent effects in bone and that the disconnect between Ot apoptosis and Oc number also occurs in 4-mo male miR21Δot (n=12) vs miR21f/f (n=12) mice. However, unlike females, male miR21Δot mice had reduced expression of apoptosis-associated genes (CHOP, Foxo3 and p27) and trends towards lower apoptotic Ot numbers vs miR21f/f mice. Further, Ot miR21 removal had sex-specific effects on femur cortical bone, with lower endocortical turnover in female but higher in male miR21Δot mice (89% more endosteal Oc and 42% higher periosteal BFR). Consistent with these cellular effects, females had no change in bone mass/geometry, whereas miR21Δot males had higher total, spinal and femoral BMD; and increased femoral cortical [10% marrow cavity area, 4% thickness, and 11% MMI] and trabecular [32% BV/TV, 10% thickness, and 20% number] architecture vs miR21f/f mice. To further examine the mechanisms underlying the sex-specific Oc effect of Ot miR21 removal, we generated Oc from wildtype bone marrow cells (BMC) cultured with conditioned media (CM) from Ot-enriched miR21Δot and control bone cultures. Consistent with our in vivo results, addition of CM from miR21Δot females and males led to 0.7-fold less and 3.8-fold more Oc, respectively; independently of whether female or male BMC were used. Further, we found sex-specific changes in Ot-enriched bone lysates with ~60% lower pro-osteoclastogenic cytokines IL6, MCP1, and MCSF mRNA in miR21Δot females, whereas IL1β and its target DKK1, an Ob inhibitor, were ~80% lower only in miR21Δot males. Collectively, our findings suggest that miR21 exerts a sex-divergent role in Ot, regulating bone mass and architecture through non-cell autonomous effects on Ob and Oc.

Further, we reveal a potential mechanism by which miR21 removal from Ot differentially alters bone turnover by sex-specific regulation of Ot cytokine production.

FRI-0659

Osteocyte Density and Viability in Postmenopausal Women after Long-term Bisphosphonate Therapy Shijing Qiu*, George Divine, Mahalakshi Honasoge, Arti Bhan, Shiri Levy, Elizabeth Warner, Sudhaker D Rao. Henry Ford Hospital, United States

Our previous study indicated that short-term (1 year) bisphosphonate (BP) treatment did not affect osteocyte viability in postmenopausal women, but the effect of long-term BP treatment on osteocytes remains unclear.Iliac bone biopsies were obtained from 80 age-matched white postmenopausal women (43 normal volunteers and 37 BP treated patients). The duration of BP exposure was 2 – 17y (median: 7y). Five μm Goldner & trichorome stained sections were used to measure trabecular bone osteocyte density [Ot.Dn (/mm²)], empty lacunar density [EL.Dn (/mm²)], total lacunar density [(TL.Dn (/mm²)], and percent empty lacunae [EL.Dn/TL.Dn (%)]. The difference in each osteocyte-related variable was compared between the 2 groups.As shown in the Table, Ot.Dn was significantly lower in patients with BP treatment than in normal women. In contrast, EL.Dn in BP treated patients was >3 times higher than in the normal women. The extremely increased EL.Dn in BP treated patients resulted in a 4 times higher EL.Dn/TL.Dn ratio. There was also a significant 14% reduction in TL.Dn in the BP treated group. There was no significant correlation between the duration of BP exposure and any osteocyte-related variable.In conclusion, we found that osteocyte viability is dramatically reduced after long-term BP treatment. The significant decrease in total lacunar density and a very high empty lacunar density suggest that part of empty lacunae resulting from osteocyte death are obliterated by mineralized tissue. Combined with our previous work, we postulate that the loss of osteocytes after long-term BP treatment is not due to BP toxicity but rather caused by prolonged and sustained inhibition of bone remodeling. Accumulation of unremodeled old bone characterized by low osteocyte density and hypermineralization will increase bone fragility.

Table 1. Difference in osteocyte-related variables between normal postmenopausal women and BP treated patients

	Normal (n = 43)	BP treated (n =37)	p
Age	64.0 (4.13)	65.7 (4.29)	NS
Ot.Dn	168 (24.2)	119 (31.4)	<0.001
EL.Dn	17.5 (6.52)	58.2 (18.2)	<0.001
TL.Dn	206 (24.1)	177 (30.3)	<0.001
EL.Dn/TL.Dn	8.67 (3.13)	33.3 (10.1)	<0.001

Normative Data for Trabecular Bone Score in Men and Women Kara Anderson*, Kara Holloway-Kew, Mark Kotowicz, Natalie Hyde, Julie Pasco. Deakin University, Australia

PurposeTrabecular bone score (TBS) is a novel tool for indirectly assessing trabecular microarchitecture at the lumbar spine, providing information complementary to areal BMD. However, limited reference ranges exist for TBS, particularly in men. The aim of this study was to develop such reference ranges for Australian men and women.MethodsThis study included 910 men and 780 women (aged 24-98yr) enrolled in the Geelong Osteoporosis Study. TBS was determined by retrospective analysis of lumbar spine DXA scans (Lunar Prodigy) using TBS iNsight software (Version 2.2). Multivariable regression techniques were used to determine best-fit models for TBS incorporating age, height and weight. T-score based classifications were used to assess differences in fracture risk between TBS and BMD using attribute agreement analysis, with partially degraded microarchitecture defined as TBS T-scores of -1.0 to -2.5, and degraded microarchitecture as T-scores below -2.5. Similarly, BMD T-scores of -1.0 to -2.5 indicated osteopenia and T-scores below -2.5 indicated osteoporosis.ResultsMean TBS decreases with age in both sexes (Table). Age-related differences in TBS were best modelled with a linear relationship in men (R2=21.5%, p<0.001) and a cubic relationship in women (R2=25.4%, p<0.001). Best models for TBS included linear age and weight in men, and cubic age and linear height in women. The attribute agreement analysis found that 56.2% (95%CI 52.9-59.4) of the men and 55.9% (95%CI 52.2-59.5) of the women had agreements in T-score based classifications of lumbar spine BMD and TBS, meaning that almost half of the men and women were discordant for TBS and BMD categories. Of those considered to have normal lumbar spine BMD, 39.2% of men and 38.5% of women had partially degraded or degraded microarchitecture on the basis of TBS. ConclusionThis study provides normative data for TBS in Australian men and women.

Table Mean trabecular bone score in men and women per age decade, given as mean±SD.

Age (years)	Men (n=910)	Women (n=730)
20-29	1.362±0.113	1.412±0.090
30-39	1.324±0.137	1.397±0.102
40-49	1.289±0.113	1.366±0.124
50-59	1.259±0.127	1.286±0.153
60-69	1.180±0.152	1.243±0.136
70-79	1.149±0.141	1.207±0.136
80+	1.138±0.144	1.180±0.152

FRI-0681

Time since fracture and number of previous fractures are independently associated with risk of new clinical fracture Kristian Axelsson*[1], Dan Lundh[2], Mattias Lorentzon[1]. [1]Department of Geriatrics, Sahlgrenska Academy, Gothenburg University, Sweden, [2]School of Bioscience, University of Skovde, Sweden

BackgroundPrevious fracture is one of the most important predictors of future fracture. However, previous fracture (yes/no) does not take into account number of fractures and the imminent fracture risk seen during the time period just following a previous fracture. The purpose of this study was to investigate if time since fracture and number of previous fractures are independently associated with risk of new fracture.MethodsA total of 429 313 patients (mean age 80.8 (SD 8.2), 58% women, 32% with a previous fracture) were included when visiting a healthcare facility in Sweden during 2008-2014. Patients with previous fracture were divided in three groups depending on number of previous fractures (1, 2, 3 or more) and three groups depending on time since last fracture (0-3 months, 3-24 months, 2 years or more). Each of the nine groups was compared to patients without previous fracture. During a median follow-up time of 1.3 years (IQR 0.6-2.3 years), the risk of any fracture was investigated using a Cox regression model adjusted for several known clinical risk factors (age, sex, weight, height, osteoporosis diagnosis, secondary osteoporosis, rheumatoid arthritis, alcohol related diseases and previous glucocorticoid treatment ($\geq$ 5 mg/day, $\geq$3 months)). To investigate if time since last fracture and number of previous fractures were independently associated with risk of new fracture, a Cox regression model was used.ResultsAmong patients without previous fracture, the number of incident fractures was 18550 (6.4%). Patients with one previous fracture more than 2 years ago had 5527 (9.7%) incident fractures which corresponded to a 1.4 times increased fracture risk (Hazard Ratio (HR) 1.40 (95% CI 1.36-1.44), p<0.001) in an adjusted Cox model compared to patients with no previous fracture, whereas patients with three or more previous fractures and the last fracture within three months had 1111 (22.6%) incident fractures corresponding to a 3.3 times increased fracture risk (HR 3.27 (95% CI 3.06-3.48), p<0.001). Adjusted HR for all the nine groups are presented in Figure 1. Both time since fracture and number of fractures significantly predicted any clinical fracture when used simultaneously in an adjusted Cox model.ConclusionsWe conclude that time since last fracture and number of fractures are independent predictors of new fracture, indicating that the use of these risk variables could improve fracture risk prediction in existing prediction calculators.

Adjusted HR using Cox regression. Patients with no previous fracture were used as reference (HR=1.00). All p<0.001

Development of Thresholds for Assessing Radius and Tibia Fragility Fracture Risk Using HR-pQCT – The CaMos Cohort Syed Jafri*[1], Lauren Burt[2], Leigh Gabel[2], David Hanley[3], Steven Boyd[2]. [1]University of Calgary, Canada, [2]McCaig Institute for Bone and Joint Health, Department of Radiology, Cumming School of Medicine, University of Calgary, Calgary, Canada, [3]McCaig Institute for Bone and Joint Health, Departments of Community Health Sciences and Oncology, Cumming School of Medicine, University of Calgary, Calgary, Canada

Fracture risk assessment tools are important for clinicians to identify patients at risk of fragility fractures. Current densitometry tools do not incorporate bone microarchitecture obtained from 3D imaging devices, which can be leveraged to provide estimates of bone strength using finite element analysis (FEA). Development of thresholds from bone microarchitecture and FEA measures may provide a novel approach to utilizing new high resolution peripheral quantitative computed tomography (HR-pQCT) technology to assess fracture risk.We aimed to develop thresholds that correspond to low bone density (formally known as osteopenia) and osteoporosis using FEA measures based on patient-specific microarchitecture. We then validated our thresholds using fracture data from the Calgary Canadian Multicentre Osteoporosis Study (CaMos). We estimated failure load (N) at the distal radius and tibia by solving FEA models based on HR-pQCT. DXA was assessed to acquire hip aBMD and derive T-scores. Scans were obtained from 866 participants in the Calgary CaMos cohort. A linear regression modeled aBMD-derived T-scores as a function of failure load. Predicted FEA failure load values at -1 and -2.5 T-score cut-offs were used to define thresholds for ranges relevant to low bone density and osteoporosis, respectively. We assessed classification accuracy of our predicted fracture risk thresholds using data from 35 individuals in CaMos who sustained fragility fractures.For women, our model predicted low bone density thresholds at the radius ($\leq 1600N$) and tibia ($\leq 4800N$) and osteoporosis thresholds at the radius ($\leq 700N$) and tibia ($\leq 2800N$). Predicted thresholds were consistently higher in men, with low bone density thresholds at the radius ($\leq 2000N$) and tibia ($\leq 5700N$) and osteoporosis thresholds at the radius ($\leq 800N$) and tibia ($\leq 3400N$). Fracture data from our cohort identifies the efficacy of these thresholds to single out individuals at high-risk of fracture (data not shown).These thresholds are the first proposed for interpreting FEA-based failure load estimates from HR-pQCT at the distal radius and tibia. Our future work will validate the use of these thresholds for assessing radius and tibia fragility fracture risk in other cohorts.

Automated Identification of Vertebral Compression Fractures Using Artificial Intelligence Convolutional Neural Networks Predicts Incident Non-vertebral and Hip Fracture: The Manitoba BMD Registry Sheldon Derkatch*[1], Christopher Kirby[2], Douglas Kimelman[2], Mohammad Jafari Jozani[1], J Michael Davidson[1], William Leslie[1]. [1]University of Manitoba, Canada, [2]St-Boniface Hospital Albrechtsen Research Centre, Canada

Purpose: Detection of vertebral compression fractures aids in future fracture risk assessment and targeting of fracture prevention therapies. Vertebral fracture (VF) recognition can be challenging due to a wide spectrum of appearances and non-fracture deformities. Vertebral fracture assessment (VFA) performed at the time of DXA is often performed by non-radiologists with limited imaging expertise.Aim: To determine if convolutional neural networks (CNNs) can be trained to identify clinically relevant VFs on VFA.Methods: Routine clinical VFA images 2010-2017 from the Manitoba Bone Density Program (GE Lunar Prodigy and iDXA, N=12742) reported by experienced imagers as VF present/absent fol-

lowing the algorithm-based qualitative (ABQ) method were used for CNN training. Criteria for VFA were T-score $\leq$-1.5 and (a) age $\geq$70 years; or (b) age $\geq$50 years plus historical height loss >5 cm, measured height loss >2.5 cm, or chronic systemic glucocorticoid therapy. Scans were randomly divided into independent training (60%), validation (10%) and test (30%) sets. The training and validation sets were used to discover effective CNN architectures and training hyperparameters. The best architectures (Inception-ResNetV2 and DenseNet) were then trained on the pooled training and validation sets using the optimized training hyperparameters, and fracture probability predictions were generated using these finalized CNNs as an ensemble. The independent test population (N=3822) was then used to assess CNN concordance with the human "gold standard", and prediction of incident non-vertebral and hip fractures in the subset with linkage to population-based administrative data (N=2813, mean follow up 2.8 years).Results: The CNN ensemble demonstrated AUC 0.94 (95% CI 0.93-0.95) for VF detection in the test data (continuous output, range 0-1); sensitivity 87.4%, specificity 88.4%, accuracy 88.3%, prevalence-adjusted, bias-adjusted kappa 0.77 (dichotomized output, cutoff 0.5). Performance was similarly high for scanner generations, sex, age, body size, and T-score category. "Heatmaps" of regional significance to the CNNs showed strong fracture localization capability. CNN and human detected VF were similarly predictive of any non-vertebral fracture and hip fracture, before and after adjustment for baseline risk (FRAX probability with BMD) (Table).Conclusions: CNNs can identify VFs on VFA images with high accuracy. VFs detected by CNNs in turn predict clinical fracture outcomes.

Table. Hazard ratios (HR) with 95% confidence intervals (CI) for incident fracture in 2813 subjects.

	Model 1: Unadjusted	Model 2: Adjusted for FRAX with BMD
Outcome: Any non-vertebral fracture (N=137) *	HR (95% CI)	HR (95% CI)
Fracture vs No fracture, CNN	2.03 (1.53-2.70)	1.73 (1.29-2.31)
Fracture vs No fracture, Human	2.12 (1.56-2.88)	1.81 (1.33-2.48)
Outcome: Hip Fracture (N=68)	HR (95% CI)	HR (95% CI)
Fracture vs No fracture, CNN	2.76 (1.71-4.46)	1.97 (1.20-3.21)
Fracture vs No fracture, Human	3.08 (1.88-5.07)	2.29 (1.38-3.80)

Clinical Performance of a Beta Version of Trabecular Bone Score (TBS) Including Thickness-based Correction for Soft Tissue Effects: The Manitoba BMD Cohort William D. Leslie*[1], Enisa Shevroja[2], Lisa M. Lix[1], Didier Hans[2]. [1]Department of Medicine (W.D.L.), University of Manitoba, Canada, [2]Center of Bone Diseases, DAL-RHU - Lausanne University Hospital, Switzerland

Introduction: Lumbar spine TBS is a texture measurement computed from DXA scans that predicts osteoporotic fractures independently of BMD. The amount of soft tissue in the abdomen impacts the signal to noise ratio and hence has an effect on TBS measurement. To address this, the current software (TBS iNsight®) includes a correction that relies on body mass index (BMI). This correction may be improved by using soft tissue thickness directly estimated by the DXA machine which should be a better indicator of patient morphology.Aim: To test a new TBS calculation based on a correction that relies directly on soft tissue thickness (TBSth) and compare its performance for fracture prediction with the current TBS algorithm (TBSv3). Methods: From a clinical registry of all DXA results for Manitoba, Canada, we identified women and men age >40 years with baseline spine DXA (GE Prodigy) from 1999-2011. Spine TBS were measured using TBSv3 and a beta version (non-calibrated) of the TBSth algorithms by researchers at the University of Lausanne blinded to clinical outcomes. Incident major osteoporotic fractures (MOFs) and hip fractures (HFs) were obtained from population-based health services data. Fracture prediction was estimated from area under the ROC curve (AUC), and comparisons were made (i.e., ΔAUC) using the DeLong method for correlated measures. All analyses were sex-stratified.Results (cf table): 3,827 men (mean age 61.4 years, BMI 26.6 kg/m2) and 34,905 women (mean age 63.3 years, BMI 26.1 kg/m2) met inclusion criteria. TBSv3 exhibited a negative correlation with BMI for both men (r= -0.04) and women (r = -0.02) while TBSth was now positively correlated (r = 0.21 for men, r = 0.23 for women), consistent with expectations. Reversals in correlations (from negative to positive) were observed for tissue thickness and abdominal fat percent in both sexes. During a mean follow up of 7.7 years in men, there were 317 incident MOFs and 89 HFs; during 8.9 years in women there were 3,338 incident MOFs and 1,052 HFs. Improvements in fracture prediction were seen with the new TBS algorithm in both men (ΔAUC for MOFs +0.05, p<0.001; HFs +0.03, p NS) and women (ΔAUC for MOFs +0.03, p<0.001; HFs +0.04 p<0.001).Conclusion: The new TBSth algorithm including thickness-based correction for soft tissue effects: (1) is positively associated with BMI (negatively before), and (2) improves fracture prediction in both men and women compared to the current algorithm.

Comparison of clinical performance for current (TBSv3) vs. new TBS (TBSth)

	Men (n=3827)	Women (n=34,905)
Fracture prediction	AUC (95%CI)	AUC (95%CI)
MOF: L1-L4 TBSv3	0.58[0.54-0.61]	0.63[0.62-0.64]
MOF: L1-L4 TBSth	0.63[0.59-0.66]*	0.66[0.65-0.67]*
Hip : L1-L4 TBSv3	0.62[0.56-0.68]	0.67[0.65-0.69]
HF: L1-L4 TBSth	0.65[0.59-0.70]	0.71[0.70-0.73]*

*p<0.001 for TBSv3 vs TBSth. MOF, Major osteoporotic fracture. HF, hip fracture.

FRI-0685

Usefulness of the Trabecular Bone Score in dialysis patients Oliver Malle*, Astrid Fahrleitner-Pammer. Medical University of Graz, Dpt. of Internal Medicine, Div. of Endocrinology and Diabetology, Austria

Introduction: The number of patients on dialysis is steadily increasing. Associated co-morbidities include cardiovascular diseases and an impaired mineral and bone metabolism leading to a higher fracture possibility, increased morbidity and mortality rate and decreased quality of life. Representing the structural condition of the bone microarchitecture dual-energy X-ray absorptiometry (DXA) is often used in combination with Trabecular Bone Score (TBS) to assess metabolic bone disorders. The aim of this study was to evaluate the clinical relevance of DXA and TBS with regard to fracture prediction in dialysis patients. Methods: 82 patients, who underwent dialysis at the university hospital of Graz, were included. All patients were interviewed for prevalent fractures and musculoskeletal pain. Statistical analysis was performed to correlate the results of DXA and TBS with musculoskeletal pain and fracture rate considering the kind and duration of dialysis as well as the number of kidney transplantations. Results: 36 out of 82 patients (43.9%) patients suffered from musculoskeletal pain and 32 out of 82 patients (39%) had a positive history of fracture. There was a significant linkage between dialysis duration and fracture rate (p<0.05) as well as musculoskeletal pain (p<0.01). No significant correlation between the DXA- and TBS-parameters and musculoskeletal pain could be established. DXA scores did not correlate with fracture history with the exception of DXA radius measurements. However, a high fracture rate in patients on dialysis significantly correlates with a low TBS (p < 0,001). Conclusio: DXA has a limited role in fracture prediction in patients on dialysis. However, the TBS seems to be a better predictor regarding the fracture risk in this patient population.

Assessment of Age Related Changes in Bone Metabolism Using 18F–Sodium Fluoride PET/CT Sylvia Rhodes*, Alexandra Batzdorf, Austin Alecxih, Jonathan Guntin, Matthew Peng, Amanda Jankelovits, Justin Kim, Julia Hornyak, Poul Flemming, Abass Alavi, Chamith Rajapakse. University of Pennsylvania, United States

ObjectivesIntegrated Positron Emission Tomography (PET)/Computerized Tomography (CT) imaging with the use of 18F-sodium fluoride (NaF), a hybrid of functional and structural imaging, has the potential for detecting early metabolic changes in bone even in the absence of detectable structural changes [1]. The objective of this study was to investigate the feasibility of using NaF PET/CT as a clinical tool to assess bone metabolism in human subjects.Methods139 healthy subjects (68 females and 71 males with known weight, age range 21-75 years old, BMI 18-43 kg/m2) were administered with the radiotracer NaF, and a PET/CT scan was conducted 90 minutes afterwards.The entire skeleton, vertebra, and femoral neck were segmented from the CT image using an operator-guided semi-automatic algorithm which used Hounsfield threshold 100 for bone. On the fused PET/CT images, standardized uptake values (SUVs) of NaF were calculated at each voxel (Figure 1). SUVs were adjusted for BMI and dosage and then plotted against the age. Drop in SUV for each decade of life was calculated using values at age of 20 years as baseline.ResultsWhole skeleton bone metabolism was negatively correlated with age (females: 3.13% drop in SUV per decade of life, p = 0.004; males: 3.57% drop in SUV per decade of life, p = 0.03).Femoral neck bone metabolism was negatively correlated with age among males (6.88% drop in SUV per decade of life, p = 0.007), but not among females (p = 0.68).Spine bone metabolism was negatively correlated with age among females (5.33% drop in SUV per decade of life, p < 0.001), but not among males (p = 0.30).ConclusionsNaF PET/CT imaging could provide valuable functional insight regarding bone metabolism in the whole-body skeleton, proximal femur, and spine before conventional structural imaging can detect structural changes that result from substantial physical deterioration. NaF PET/CT based methodology described here has the potential to be an imaging tool that is more sensitive and can lead to earlier detection of metabolic bone diseases.[1] Raynor W, Houshmand S, Gholami S, Emamzadehfard S, Rajapakse CS, Blomberg BA, Werner TJ, Høilund-Carlsen PF, Baker JF, Alavi A. Evolving Role of Molecular Imaging with (18)F-Sodium Fluoride PET as a Biomarker for Calcium Metabolism. Curr Osteoporos Rep. 2016 Aug;14(4):115-25.

Serum levels of DKK2 and sFRP1 are associated to incident fragility fractures in older women Ana Maria Rodrigues*[1], Mónica Eusébio[2], Ana Catarina Rodrigues[3], Joana Caetano-Lopes[4], Inês Lopes[5], Jorge M Mendes[6], Pedro Simões Coelho[6], João Eurico Fonseca[5], Jaime Cunha Branco[7], Helena Canhão[1]. [1]EpiDoc Unit – Unidade de Epidemiologia em Doenças Crónicas, CEDOC, Nova Medical School, Lisboa, Portugal, [2]Sociedade Portuguesa de Reumatologia, Lisboa, Portugal, [3]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal, [4]Department of Orthopaedic Research, Boston Children's Hospital, Boston, MA, USA; Department of Genetics, Harvard Medical School, Boston, MA, United States, [5]Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa, Centro Académico de Medicina de Lisboa, Portugal, [6]NOVA IMS, Universidade Nova de Lisboa, Lisboa, Portugal, [7]Centro de Estudos de Doenças Crónicas (CEDOC) da NOVA Medical School, Universidade Nova de Lisboa (NMS/UNL), Lisboa, Portugal

Background: Secreted Frizzled-related protein-1 (sFRP-1), dickkopf-related protein 2 (DKK2), dickkopf-related protein 1 (DKK1) and sclerostin (SOST) are inhibitors of Wnt signaling and, consequently, inhibitors of osteoblast-mediated bone formation. Our aim is to evaluate the association of serum levels of SOST, DKK1, DKK2 and sFRP-1 with bone mineral density and incident fragility fractures.Methods: This longitudinal study analyzed 828 women, aged 65 years old and older, from EpiDoC a population-based cohort. A structured questionnaire was applied during baseline clinical appointment in order to capture prevalent fragility fractures, clinical risk factors for fracture and Osteoporosis diagnosis. Blood was collected to measure serum levels of markers of bone fragility and serum levels of WNT regulators. Vertebral and hip bone mineral density (BMD) were determined by DXA. Two follow-up assessments were performed through a phone call interview and incident fragility fractures were defined by any new self-reported low impact fracture. Multivariate Cox proportional hazards regression models were used to analyze fracture risk, adjusted for clinical risk factors for fracture.Results: During a mean follow-up of 2.3±1.0 years, a total of 62 fragility fractures were sustained in 58 women. High serum levels of sFRP-1 were associated with a 1.4-fold increase in fracture risk. Association between sFRP-1 and fracture risk was not independent of BMD. Low serum levels of DKK2 were associated with a 1.6-fold increase of fracture risk in our multivariate model. Association between low levels of DKK2 and fracture risk were independent of BMD. Women in the two lowest quartiles of DKK2 had a fracture rate incidence of 32 per 1000 person-year, while the ones in the highest two quartiles of DKK2 had 14 fragility fractures per 1000 person-year. Serum levels of SOST (r=0.191; p=0.0025) and DKK1(r=-0.1725; p=0.011) were correlated with hip bone mineral density, but not with incident fragility fractures.Conclusion: Low serum levels of DKK2 are an independent risk factor for fragility fractures. High serum levels of sFRP-1 are significantly associated with fractures although this association is not independent of BMD. SOST and DKK1 were associated with BMD but not with incident fractures however, the number of new fractures recorded may not allow to detect this association.

During aging, changes in cortical bone endosteal and periosteal contours have been reported and it was proposed that differences in bone fragility between men and women relate to such changes. However, so far it was not possible to reliably detect these changes in-vivo due to limitations in image resolution and registration. In this study we use High Resolution peripheral Quantitative CT (HRpQCT) scanning in combination with an advanced 3D rigid registration technique to obtain a highly sensitive quantification of periosteal and endosteal changes in-vivo at the distal radius and tibia over time. Goals were first to test the reproducibility of this approach and second to assess differences between men and women in a large cohort.Default periosteal contouring and automatic endosteal autocontouring were applied first to all images. Rigid 3D registration then was used to align follow-up (FU) to baseline (BL) images. To avoid that cortical changes are obscured by the registration, only the cancellous bone compartment was used for registration. Periosteal and endosteal expansion/ retraction volumes were determined by overlaying cortical compartments (Fig. 1). The net volume was divided by the BL periosteal or endosteal surface area to calculate an average expansion distance. To test the reproducibility, images from a short-term reproducibility study were used (15 female, 21-47 years, scanned 3 times). To test differences between men and women, images from a subset of the Geneva Retirees Cohort were used (246 female, 60 male, average age 65 years, 3.5 and 7 years FU).Results of the short-term reproducibility study indicated that the least detectable significant change in average periosteal/endosteal expansion was 38/30 microns for the radius and 15/21 microns for the tibia.Results of the cohort study showed significant endosteal expansion at both radius and tibia after 3.5 years that is further increased at 7 years FU (Table 1). The expansion in females was significantly and much higher (1.7 – 4.8 times) than in males. Periosteal changes were much smaller and changes significantly different from zero were found only for the tibia. Differences between male and female were significant (p<0.01) for all endosteal measures and for none of the periosteal measures.Although some of the changes found were close to the detection limit, highly significant differences were found between men and women that could explain the development of increased fragility in women
Fig 1: BL-FU overlay image for the cortex

Off-Treatment Bone Mineral Density Changes in Postmenopausal Women after 5 Years of Anastrozole Ivana Sestak*, Jack Cuzick. Centre for Cancer Prevention, Queen Mary University London, United Kingdom

Background: Anastrozole (A) has been shown to prevent breast cancer in postmenopausal women at increased risk of developing the disease, but has been associated with substantial accelerated bone mineral density (BMD) loss during active treatment. Here, we investigate changes in BMD assessed by dual energy X-ray absorptiometry (DXA) 2 years after treatment cessation in women included in the IBIS-II breast cancer prevention trial. Methods: IBIS II randomly assigned 3864 postmenopausal women to A 1mg/day or placebo (P) for 5 years. 1410 were included in a BMD sub-study and stratified into three strata ac-

cording to their baseline T-score at spine or femoral neck (stratum I (N=760): T-score>-1.0 and observed; stratum II (N=500): -1.0<T-score>-2.5 and randomised to weekly risedronate or placebo; stratum III (N=150): -2.5<T-score>-4.0 or/and two fragility fractures and all on risedronate). The primary objective of this analysis was to investigate whether DXA BMD at the spine and hip changed 2 years after stopping A or P. All results are presented as mean % BMD changes (95% CI) between 5 and 7 years of follow-up.Results: 5 and 7-year BMD data were available for a total of 529 women who did not receive risedronate. In stratum I, cessation of A (N=205) led to an increase in BMD at the spine that was larger than in those on P (N=206) (A=1.29% (95% CI 0.78 to 1.79) vs. P=0.2% (-0.23 to 0.62), p=0.001). At the hip, BMD remained unchanged between 5 and 7 years after cessation of A but continued to a decrease in those who had been on P (A=-0.07% (-0.51 to 0.37) vs. P=-1.31% (-1.67 to 0.94), p<0.0001). Similar results were observed for women with osteopenia (stratum II). Those previously on A (N=53) had a significantly larger BMD increase at the spine after treatment cessation compared to those stopping P (N=64) (A=2.81% (1.40 to 4.23) vs. P=0.57% (-0.36 to 1.50); p=0.007). Loss of BMD at the hip continued in women who had been on P but increased slightly following cessation of A (A=0.47% (-0.42 to 1.36) vs. P=-1.33% -2.12 to -0.54); p=0.003).Conclusions: These are the first results reporting BMD changes after stopping A in a breast cancer prevention setting. BMD at the lumbar spine improved significantly more in women who were originally randomised to A compared to those who received P. Our results show that the negative effects of A on BMD in the preventive setting are partially reversible.

Microvascular Complications and Risk of Incident Hip Fracture in Type 2 Diabetes: A National Cohort Po-Yin Chang*[1], Yi-Ting Wang[2], Rodrigo J. Valderrábano[4], Yi-Wen Tsai[2], Jennifer S. Lee[1]. [1]Stanford University School of Medicine, United States, [2]National Yang-Ming Univeristy Institute of Health and Welfare Policy, Taiwan, [4]Univeristy of Miami Miller School of Medicine, United States

Background: Adults with type 2 diabetes (T2D) have a two-fold hip fracture risk; microvascular complications may further increase the risk.Methods: We followed 90% of all adults with newly diagnosed T2D in Taiwan, from 2001-2005 to 12/31/2013. We compared adults, ages 35 or older, who developed any (n=130,403), two or more (n=46,469), or three (n=9,093) microvascular complications to those who had no complications, matched on age, sex, and T2D duration. The outcome was hospitalized incident hip fractures accompanied by internal fixation or hemiarthroplasty. We reported hazard ratios (HRs) and 95% confidence intervals (CIs) from sex-specific Cox models adjusted for age, T2D duration, comorbidities, T2D medications, and fracture risk factors.Results: During a median 5.7-years of follow-up, 2,999 of 111,747 women and 1,686 of 135,914 men had a hip fracture. Incidence (/10,000 person-years) increased from 41.9 in women with no complications to 91.8 in women with three complications, and in men, from 20.5 to 49.1. Individuals with three complications had an incidence approaching to or greater than those 10 years older with no complications (Fig). Women with one only, two, and three complications had a 1.23-fold (CI: 1.14-1.34), 1.79-fold (CI: 1.54-2.08), and 2.59-fold (CI: 1.77-3.98) greater risk of hip fracture, respectively, than those with no complications; for men, the corresponding HRs were 1.33 (CI: 1.19-1.49), 1.92 (CI: 1.58-2.32), and 2.16 (CI: 1.40-3.35). Excluding individuals with cardiovascular diseases did not alter these estimates.Conclusions: Hip fracture risk increased with the number of microvascular complications in T2D adults. Fracture prevention strategies may warrant including T2D adults with multiple microvascular complications.

Cancer Patients who Suffer Fractures are Rarely Assessed or Treated for Osteoporosis: Population-based Data from Manitoba Beatrice Edwards*[1], William Leslie[2], Saeed Al-Azazi[2], Lin Yan[2], Lisa Lix[2], Piotr Czaykowski[3], Harminder Singh[3]. [1]Central Texas Veterans Healthcare System, United States, [2]University of Manitoba, Canada, [3]University of Manitoba, CancerCare Manitoba, Canada

Background: A care gap has been previously described in the general population whereby individuals with fractures are seldom evaluated or treated for osteoporosis. It is unknown if a similar gap exists for cancer patients.Methods: We linked population-based data (cancer registry, health administrative data, population registry) from Manitoba, Canada to identify cancer cases (first cancer diagnosis excluding non-melanoma skin cancer between 1987 and 2013) with a subsequent major osteoporotic fracture 1997 or later (MOF: hip, clinical spine, forearm, humerus). Performance of a bone mineral density (BMD) test or initiation of osteoporosis therapy over the 12 months post-fracture was analyzed using multivariate logistic regression. Only those who survived for a year after the fracture diagnosis were included. Results: There were 20,656 subjects with a cancer diagnosis who sustained a MOF (females 72.9%, males 27.1%). BMD testing was performed in 11.4% (females 12.8%, males 7.3%), osteoporosis therapy initiated in 22.1% (females 26.1%, males 10.6%), and either BMD or treatment in 28.5% (females 33.0%, males 15.7%). The likelihood of receiving a BMD test or receiving treatment increased from 1997 -2000 (15.4%) through 2007 – 2013 (32.5%). Oncologists were less likely to order BMD or initiate therapy than other clinicians. Logistic regression (Table) showed that BMD testing was more likely to be ordered in cancer patients aged 50-70 years and in those 70 years and older, and in those who sustained fractures between 2007-2013. Osteoporosis therapy was more likely to be initiated in females, in patients who were 50 years of age and older, if fractures occurred in 2001 or later and after vertebral fractures. Finally, either BMD testing and/or osteoporosis therapy initiation was more likely if patients were 50 years of age and older, had a higher socio-economic status, if fractures occurred in 2001 or later, had melanoma, or after vertebral fractures.Conclusions: In cancer patients who sustain a fracture, a care-gap exists whereby the evaluation or treatment for osteoporosis is seldom conducted. This care-gap seems more pronounced in oncologists as compared to other clinicians. We have identified several predictors of testing or initiation of therapy. Care maps need to be developed to reduce variation in care.

Table 1. Likelihood of having a BMD test or osteoporosis treatment initiation

BMD testing	Odds Ratio (95% C.I.)	Treatment initiated	Odds Ratio (95% C.I.)	BMD and/or treatment initiated	Odds Ratio (95% C.I.)
50 – 70 years of age	6.24 (2.8, 13.4)	Female gender	4.7 (3.6, 6.2)	50 – 70 years	7.3 (3.8, 14.3)
70 years and older	2.5 (1.1, 5.4)	50 – 70 years of age	6.2 (2.6, 14.5)	70 years and older	7.7 (3.9, 14.9)
Fracture in 2007-2013	4.7 (3.1, 7.1)	70 years and older	9.9 (4.2, 22.9)	Higher SES	1.4 (1.1, 1.8)
		Fracture in 2000-2006	2.1 (1.7, 2.8)	Fracture in 2001-2006	2.3 (1.8, 2.9)
		Fracture in 2007-2013	2.1 (1.6, 2.7)	Fracture in 2007-2013	7.7 (3.9, 14.9)
		Vertebral fractures	3.9 (3.2, 14.3)	Skin cancer	1.5 (1.1, 2.0)

Risk Factors for Atypical Femur Fractures in a Large, Prospective Cohort Study: A Multivariable Analysis from the Southern California Osteoporosis Cohort Study (SOCS) Erik J. Geiger*[1], Dennis M. Black[1], Bonnie H. Li[2], Denison S. Ryan[2], Richard M. Dell[2], Annette L. Adams[2]. [1]University of California, San Francisco, United States, [2]Kaiser Permanente Southern California, United States

Atypical femur fractures (AFFs) are rare but serious events. While evidence suggests an increased risk with long-term bisphosphonate (BP) use, examination of other risk factors has been limited. This analysis aimed to assess AFF clinical risk factors together with BP duration in multivariable (MV) analysis in a large, diverse cohort of post-menopausal women. This prospective cohort study included women aged ≥50 years who were members of Kaiser Permanente Southern California (KPSC) during the period 1/1/2007-9/30/2015. Using the 2014 ASBMR criteria, AFFs were adjudicated by expert review (RD) of all X-rays identified from ICD9-coded subtrochanteric or femoral shaft fractures and adjudication verified by a 2nd expert (EG). In addition to age and race, we collected information from KPSC EMRs on the following potential risk factors dating back up to 10 years prior to cohort entry: alcohol use, smoking history, height, fracture history, diabetes, glucocorticoid (GC) use, Charlson score, BP duration and time since BP discontinuation. Time-dependent, MV Cox models were used to estimate hazard ratios (HR) and 95% CIs including all risk factors found significant in unadjusted models. This analysis includes women with any BP use.The overall cohort included 913,367 women with 233 AFFs. In the analysis cohort with any BP use, there were 175,709 women with 206 AFFs. In the MV model, significant risk factors for increased AFF risk included younger age (HR 1.11/5 yr decrease, CI 1.04-1.18) Asian race (HR 3.83, CI 2.79-5.25), shorter height (HR/inch 1.09 CI 1.02-1.15), GC use >1 yr (HR 2.3 CI 1.4-3.6) and history of prior fracture (HR 1.56 CI 1.14-2.14) (see Table). In this fully adjusted model, AFF risk increased with increasing duration of BP use compared to those with < 1 year BP use. For 1-4 years of use, the HR was 3.56 (CI 1.53-8.28); for 4-8 years the HR was 19.10 (CI 8.57-42.57); for > 8 years the HR was 41.99 (CI 18.47-95.48). Of note, the relationships of Asian race, shorter height and BP duration to AFF risk were attenuated after MV adjustment (Table).Using radiographically-defined AFF and rigorous prospective, multivariable analysis, we identified a number of independent AFF risk factors including Asian race, GC

use and fracture history. Longer BP duration remained strongly associated with AFF risk, even after full adjustment. These results will be used to develop risk prediction tools to help clinicians individualize BP therapy duration.

Key Risk Factors in MV Model for Increased AFF Risk in 175,709 women >50 years who had used bisphosphonates[A]		
Risk factor	Unadjusted HR (p)	Multivariable Adjusted HR (p)
Younger Age (-5 yrs)	1.02 (0.42)	1.11 (0.003)
Asian race	5.15 (<0.001)	3.83 (<0.001)
GC use > 1 year	2.34 (<0.001)	2.29 (0.0004)
Any fracture hx	1.32 (0.06)	1.56 (0.006)
Shorter Height (-1 inch)	1.16 (<0.001)	1.09 (0.007)
BP duration (vs ≤ 1 year)		
1-4 years	5.6 (<0.001)	3.56 (0.003)
4-8 years	36.4 (<0.001)	19.10 (<0.001)
> 8 years	79.8 (<0.001)	41.99 (<0.001)

[A]Smoking and time since BP continuation was also included in model

Treatment with Statins Is Associated with Higher Volumetric Bone Mineral Density and Lower Cortical Porosity in Older Women Berit Larsson*[1], Anna Nilsson[1], Dan Mellstrom[1], Daniel Sundh[1], Mattias Lorentzon[2]. [1]Department of Geriatric Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Sweden, [2]Head of Geriatric Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Sweden

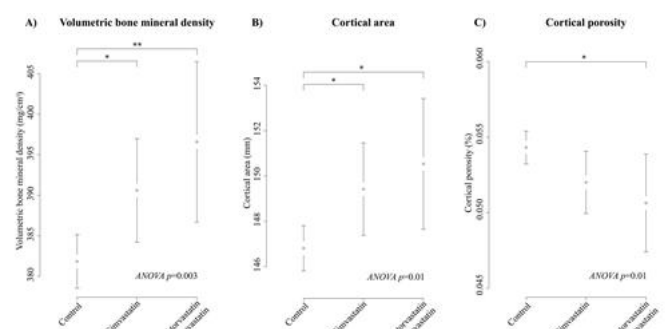
IntroductionThere are conflicting results in the literature whether treatment with statins have an effect on areal bone mineral density and fracture risk. The aim of this study was therefore to investigate if treatment with statins was associated with better bone geometry and microstructure and if these associations were dependent on statin potency.MethodsIn a large population-based study on older women (75-80 years) a standardized questionnaire was used to assess information regarding diseases, medications and lifestyle. Statin treatment was analyzed as yes/no, and according to statin potency (non-treated vs. simvastatin or atorvastatin/rosuvastatin). Bone geometry and microstructure were measured at the standard site (ultradistal) and at a more proximal section at 14% (distal) of the bone length on radius and tibia using a high-resolution peripheral quantitative computed tomography.ResultsIn the whole cohort of 3028 women (77.8±1.63 [mean±SD]), 803 (26.5%) women were treated with statins. Within this group, 551 (18.2%) took simvastatin, 201 (6.6%) atorvastatin, and 38 (1.3%) took rosuvastatin. Treated women were of similar age (77.9±1.6 vs. 77.8±1.6) and BMI (26.9±4.4 vs. 26.0±4.4) but had higher prevalence of heart disease and other comorbidities than non-treated women. Treatment was associated with a higher total bone mineral density (Tot.vBMD) (3.0%; p<0.001) and with cortical bone parameters, as reflected by a greater cortical area (Ct.Ar) (2.2%; p=0.001), volumetric bone mineral density (Ct.vBMD) (0.6%; p=0.002), and lower cortical porosity (Ct.Po) (-5.2%; p=0.01) at the distal tibia. Similar findings were found for the distal radius with higher Tot.vBMD (4.1%; p<0.001), Ct.Ar (3.2%; p<0.001), Ct.vBMD (0.6%; p<0.001), and lower Ct.Po (-9.7%; p=0.01). Statin use was also associated with greater trabecular bone volume fraction measured in the ultradistal tibia (2.6%; p=0.01) and radius (4.3%; p=0.01). Adjustments for confounders did not substantially alter these associations. Increased statin potency was associated with higher Tot.vBMD, larger Ct.Ar, and lower Ct.Po (Figure 1A-C) at the distal tibia.ConclusionOlder women treated with statins had better bone geometry and microstructure at both the tibia and radius, with differences persisting after adjustment for confounders. These associations were dependent on statin potency.


Figure 1 Treatment with statins in categories of potency was associated with increasing volumetric bone mineral density (A) and cortical area (B) as well as decreasing cortical porosity (C). Differences were compared with ANOVA and following post hoc analyses were performed with least significant difference (LSD) and significant levels are presented as: *p<0.05, **p<0.01

Osteoporotic Fracture Trends in a Population of US Managed Care Enrollees: 2007-2017 E. Michael Lewiecki*[1], Benjamin Chastek[2], Kevin Sundquist[2], Setareh A. Williams[3], Deane Leader, Jr.[3], Richard J. Weiss[3], Yamei Wang[3], Lorraine A. Fitzpatrick[3], Jeffrey R. Curtis[4]. [1]New Mexico Clinical Research & Osteoporosis Center, United States, [2]Optum, United States, [3]Radius Health, Inc., United States, [4]UAB Arthritis Clinical Intervention Program, University of Alabama at Birmingham, United States

Osteoporosis-related fractures (fractures) are a leading cause of morbidity and disability in the US. Epidemiological data on the occurrence of fractures are limited and required to inform healthcare providers, payers, and policymakers on the scope of this disease. The objective of this analysis was to assess the incidence of fractures in a population of managed care enrollees over the past decade.The study included commercial and Medicare Advantage health plan members who had evidence of a qualifying fracture between Jan 2007 and May 2017 (identification period). Fractures were considered qualifying if they were either identified during an inpatient stay or were identified in an outpatient setting based on primary or secondary ICD-9 or ICD-10 accompanied by a repair procedure code. Patients ≥50 years of age with evidence of a qualifying fracture were included. The denominator population comprised of members who were ≥50 years of age during the year of interest. The number of days the member was enrolled in the health plan during the year was calculated and was used to determine the total person-years (py) of enrollment for the denominator. Incidence rate is reported as number of events per 1000 py of enrollment during each year from 2007-May 2017. Rates are presented stratified by age category (50-64 vs ≥65) and gender (male vs. female). Patients were categorized by 5-year age increments and gender, and an overall age-gender adjusted rate was calculated.Of 1,841,263 members with fractures in the identification period, 513,176 met the eligibility criteria. The overall age-gender adjusted rate fell from 14.67/1000 py in 2007 to 11.80/1000 py in 2012, and then did not decrease from 2013- May 2017. Among females ≥65 years old the incidence of fractures declined from 27.49/1000 py in 2007 to 22.08/1000 py in 2013, and then did not decrease from 2014- May 2017. Similarly, among males ≥65 years old incidence decreased from 12.00/1000 py in 2007 to 10.72/1000 py in 2013 and then did not decrease from 2014- May 2017. For males and females ages 50-64 the rates were consistent across years, approximately 4.2 and 7.2 fractures per 1000 py, respectively.The current study findings suggest fracture incidence has remained the same and potentially rising since 2014. The current study results may reflect insufficient osteoporosis diagnosis and treatment and supports the call to action to increase diagnosis and treatment especially in older adults.

Identifying the genetic determinants of osteoporosis will help to highlight drug targets and understand its biological causes. We therefore performed genome-wide association studies (GWAS) of estimated bone mineral density measured by quantitative heel ultrasound (eBMD, N=426,824) and of bone fracture (Ncases=53,184) in White-British UK Biobank participants. Fracture findings were replicated using 23andMe participants (Ncases=367,900, Ncontrols=363,919). Candidate target genes were identified using functional genomics data and validated with an in-depth mouse screening pipeline.We found 1,106 lead SNPs (P<6.6x10-9) associated with eBMD, mapping to 518 loci (301 novel) and explaining 20% of variance in eBMD. For fracture, we found 14 lead SNPs (P<6.6x10-9), all of which were associated with eBMD. An integrative analysis of human genomic data featuring primary osteoblast and osteocyte Hi-C contact domains, osteoblast open chromatin sites, gene proximity and coding variation enabled us to map genetic associations to a total of 538 target genes. These target genes were enriched for known osteoporosis drug targets and genes involved in bone disorders (OR=58, P=10-75). We next undertook skeletal phenotyping of murine knockouts of 126 target genes and found an increased frequency of abnormal skeletal phenotypes (P<0.0001), compared to unselected genes. Multiple lines of evidence converged to suggest a role of DAAM2 in osteoporosis. We therefore generated Daam2 knockout mice for skeletal phenotyping with X-ray microradiography, microtomography and biomechanical testing. We observed large decreases in bone strength in knockout mice (2.14 standard deviations below control strength) likely due to increased cortical porosity and impaired bone quality, despite otherwise normal bone mineral content, bone length, trabecular and cortical parameters.In summary, this atlas of human and murine genetic determinants of osteoporosis has increased the number of associated BMD loci from previous studies 2.5-fold to 518, increasing the variance explained by genetic factors 1.5-fold to 20%. The identified target genes were strongly enriched for genes with known roles in bone biology. Moreover, validation of the DAAM2 target gene in mice led to marked reductions in bone strength and increased cortical bone porosity. This set of identified genes greatly improves our understanding of the genetic determinants of osteoporosis and is expected to identify osteoporosis treatment targets.

FRI-0744

Risk of fracture after bariatric surgery in France: population based, retrospective cohort study Julien Paccou*[1], Niels Martignène[1], Eric Lespessailles[2], Bernard Cortet[1], Grégoire Ficheur[1]. [1]Lille University Hospital, France, [2]Université d'Orléans, France

The long-term consequences of bariatric surgery on fracture risk are unclear but are likely to vary by procedure type. Moreover, studies have only been performed in younger

populations than population at risk of osteoporotic fractures. This study aimed to investigate the fracture risk in patients after bariatric surgery versus matched controls.The authors used the National Health Insurance Research Database of France and identified 16,840 patients aged 40 years or older who underwent bariatric surgery with a body mass index (BMI) ≥40 kg/m², during January 1, 2011 to June 30, 2012. We paired the cohort of bariatric surgery patients in a one to one ratio with obese people on the following factors: age, sex, Charlson Comorbidity Index; BMI≥50 kg/m². The primary outcome was any diagnosis of major osteoporotic fracture (MOF: hip, humerus, forearm, and vertebral) during the 4.5 years following surgery. Conditional logistic regression was used to investigate the relationships between bariatric surgery and the occurrence of at least one MOF. Similarly, the relationship between bariatric surgery and the risk of forearm fractures and hip fracture was investigated. We also assessed the risk of MOF stratified by surgery type.The mean ± SD age was 49 ± 7 years, and the groups were predominantly female (78%). The cumulative follow-up was 149,178 person-years. At the end of the study period, there were 174 MOF in the surgical group and 123 MOF in the matched control group. Compared with the control group, the risk of MOF in the surgical group was significantly increased (Odds-Ratio (OR) [95% confidence interval (CI)] = 1.42 [1.13-1.80]). In fracture site–specific analyses, patients with bariatric surgery had an increased risk of forearm fractures (OR=1.73, 95% CI [1.21-2.47]) while it was not the case regarding hip fracture (OR=1.30, 95% CI [0.76-2.24]). For the analysis stratified by surgery type, compared with the control group, the risk of MOF was significantly increased for the malabsorptive bariatric surgery (OR=2.29, 95% CI [1.57-3.36]) whereas no association was found regarding restrictive surgery (OR=1.10, 95% CI [0.71-1.71]) (Figure 1).In patients aged 40 years or older, bariatric surgery was significantly associated with an increased risk of MOF, mainly with malabsorptive procedures. These results provide further evidence that malabsorptive bariatric surgery dramatically increases the risk of fractures.

Secular trends in the initiation of therapy in secondary fracture prevention: widening treatment gaps in Denmark and Spain Daniel Prieto-Alhambra*[1], Martin Ernst[2], Katrine Hass Rubin[2], Daniel Martinez-Laguna[3], M Kassim Javaid[1], Cyrus Cooper[4], Cesar Libanati[5], Emese Toth[5], Bo Abrahamsen[6]. [1]Nuffield Department of Orthopaedics, Rheumatology, and Musculoskeletal Sciences (NDORMS), Oxford NIHR Biomedical Research Centre, University of Oxford, United Kingdom, [2]OPEN, Institute of Clinical Research, University of Southern Denmark, Denmark, [3]GREMPAL Research Group (Idiap Jordi Gol Primary Care Research Institute) and CIBERFes, Universitat Autònoma de Barcelona and Instituto de Salud Carlos III, Spain, [4]Lifecourse Epidemiology Unit, Southampton University, United Kingdom, [5]UCB Biopharma Sprl, Belgium, [6]Holbæk Hospital, Dept of Medicine, Denmark

Purpose: There is a recognised gap in the initiation of anti-osteoporosis therapy for secondary fracture prevention. We used population-based databases in Spain and Denmark to quantify the treatment gap amongst fractured patients in 2005-2015.Methods: Data were extracted from primary care records in Catalonia (SIDIAP) and the national hospital database from Denmark, linked to pharmacy dispensation/s from 2005 (2007 for SIDIAP) to 2016. Patients with an incident fracture (any but skull/face/digits) in 2005-2015 and aged over 50 years were eligible. Those with prostate, breast, or bone cancer were excluded, as were users of anti-osteoporosis therapy in the year before fracturing. Numbers and % with at least one prescription of anti-osteoporosis treatment in the year following fracture were reported, and treatment gap (those not starting any such therapy) over calendar years depicted. Analyses were stratified by country and fracture site.Results: A total of 131,959 (31,908 wrist, 9,773 hip, 7,664 spine, and 13,230 proximal humerus) and 284,375 (74,911 wrist, 46,171 hip, 8,331 spine, and 29,367 proximal humerus) fracture participants were included from Spain and Denmark respectively. Overall, secondary fracture prevention was more often started

after clinical spine (S 18.3%, DK 15.7%), followed by hip (S 11.5%, DK 10.1%), wrist (S 8.1%, DK 4.4%) and proximal humerus (S 6.9%, DK 3.5%) fractures. Hence treatment coverage was similar for clinical spine and hip, but halved for wrist and proximal humerus in Denmark compared to Spain.Already large treatment gaps increased further in the study period in Spain, from 89.6% for all fractures (80.5% for spine, 89.6% for proximal humerus) in 2007 to 94.7% (86.0% for spine, 94.9% for proximal humerus) in 2015. In Denmark, treatment gaps widened for spine (81.1% in 2005 to 87.6% in 2015), and remained stable for other fractures [Figure 1].Conclusions: Despite the known imminent fracture risk following a first fracture, unacceptable treatment gaps remain, and have widened in Spain, from 80% to 86% for clinical spine and from 90% to 95% for proximal humerus between 2007 and 2015 respectively. Data from DK suggest a similar trend in treatment gap for clinical spine, but not for other fracture/s. This compares to a 76% treatment gap overall in the 2017 UK Fracture Liaison Service audit. Effective secondary fracture prevention services that can demonstrate closing the treatment gap are urgently required in Europe.

Temporal Trends and Factors Associated with Bisphosphonate Drug Holidays Jeffrey Curtis*, Rui Chen, Tarun Arora, Shanette Daigle, Robert Matthews, Huifeng Yun, Nicole Wright, Ayesha Jaleel, Elizabeth Delzell, Kenneth Saag. University of Alabama at Birmingham, United States

BackgroundSafety concerns related to osteoporosis (OP) medication use and temporary or permanent cessation of bisphosphonate therapy (e.g. 'drug holidays') have generated appreciable attention in the lay media and medical community. We examined trends and factors associated with BP drug holidays.MethodsWe assembled a cohort of women ('OP cohort') who had osteoporosis as diagnosed by a physician, fragility fracture, or were treated with any OP therapy using 2009-2015 Medicare data (100% sample). Women with Paget's or malignancy were excluded. Use of any OP therapy was examined in 6 month calendar time intervals during which women had to remain alive with full medical & pharmacy coverage. We identified the subgroup of women ('long term BP user cohort') who had initiated BP therapy and were >=80% adherent with any BP for >=3 years. Women were considered to have taken a BP holiday if they had a gap in BP use > 12 months. We examined patterns of BP drug holidays over time, stratified in 6 month intervals and by cumulative duration of BP drug use.ResultsFrom a source population of more than 3 million women with osteoporosis, declining trends in use of all OP therapies were observed. Overall oral BP use fell by more than 50% from 2010 to 2014, although declines plateaued between 2012 and 2104. A total of 160,369 long-term BP users were identified, with mean (SD) age of 78.5 (7.5) years; 71% used alendronate and 51% used alendronate exclusively. Of these, 58,046 (36.2%) women had a BP drug holiday of >12 months. Approximately 10% of long term BP users discontinued each 6 month interval, reaching a peak in 2012 and continuing in a stable fashion thereafter (Figure). The timing of BP drug holidays peaked at a cumulative duration of 5-5.5 years of BP exposure. Numerous factors differed significantly between women taking drug holidays and those who did not including age, fragility fracture, and recent DXA.ConclusionLong term cessation of bisphosphonate therapy after 3-5 years of prior use has become increasingly common in the U.S. The impact on fracture risk and the optimal timing to restart remains of high importance.

Type 2 Diabetes and HR-pQCT Parameters in Older Men Ann Schwartz*[1], Neeta Parimi[1], Andrew Burghardt[1], Mary Bouxsein[2], Elsa Strotmeyer[3], Eric Vittinghoff[1], Eric Orwoll[4], Gina Woods[5], Dennis Black[1], Nancy Lane[6], Kristine Ensrud[7], Nicola Napoli[8]. [1]University of California, San Francisco, United States, [2]Harvard Medical School, United States, [3]University of Pittsburgh, United States, [4]Oregon Health and Science University, United States, [5]University of California, San Diego, United States, [6]University of California, Davis, United States, [7]University of Minnesota and Minneapolis VA Health System, United States, [8]Uniersita Campus Bio-Medico di Roma, Italy

Type 2 diabetes (T2D) may be associated with deficits in bone structure and microarchitecture that contribute to higher fracture risk. Previous studies of high resolution pQCT (HR-pQCT) parameters and T2D have not reported separate results for men. Our study determined associations between T2D and HR-pQCT parameters in older men using data from the Osteoporotic Fractures in Men (MrOS) study, including the diaphyseal tibia as well as the distal tibia and radius. At visit 4, on 1801 MrOS participants at 6 clinical sites, HR-pQCT scans were acquired with SCANCO XtremeCT II scanners at the distal radius (9mm from articular surface), distal tibia (22 mm from articular surface) and diaphyseal tibia (30% of tibia length) and analyzed centrally. Diabetes (DM) was ascertained by self-report of DM diagnosis or use of DM medication. Two men were excluded for lack of data on DM status, and two for possible type 1 DM. Analyses included 1797 men, 288 (16%) with T2D. Linear regression models, adjusted for age, race, BMI and clinic site, were used to compare HR-pQCT parameters by DM status. Mean age was 84 (±4) years in DM and non-DM. Mean weight was greater in DM (83±14 kg) than non-DM (79±12 kg) (p<0.001). Mean height was similar in DM (172±6.7 cm) and non-DM (172±6.9 cm). At all three scan sites, total cross-sectional area was significantly lower in DM than non-DM (Table). Cortical and trabecular area tended to be lower in DM than non-DM as well. Consistent with prior reports, trabecular vBMD and microstructure were either similar between groups, or more favorable in DM compared to non-DM. Total vBMD was similar between groups. However, in contrast to prior reports, there was no difference in cortical porosity between DM and non-DM. At the distal sites, cortical vBMD was similar between groups, but was significantly higher in DM than non-DM at the diaphyseal tibia (1003 vs 995 mg/cm3, p=0.001). Estimated failure load was similar between groups at the distal radius and distal tibia, but was significantly lower in DM than non-DM at the diaphyseal tibia (-2.3%, p=0.010). In summary, in older men T2D was associated with smaller total cross-sectional area at the radius and tibia. Both cortical and trabecular areas appeared to be proportionally smaller as well. At the diaphyseal tibia, smaller total area resulted in lower estimated bone strength despite no deficits in total or cortical vBMD. Smaller bone area may contribute to increased fracture risk in older men with T2D.

Table. Adjusted* Means for Selected HR-pQCT Parameters by Diabetes Status

HR-pQCT measure	DM	No DM	p
Distal Radius			
Estimated failure load (kN)	4.84	4.87	0.755
Total vBMD (mg/cm^3)	277	274	0.510
Total area (mm^2)	**389**	**398**	**0.033**
Cortical area (mm^2)	64.8	66.3	0.095
Cortical porosity (%)	1.3	1.4	0.200
Distal Tibia			
Estimated failure load (kN)	13.3	13.5	0.164
Total vBMD (mg/cm^3)	280	279	0.854
Total area (mm^2)	**874**	**897**	**0.010**
Cortical area (mm^2)	**134**	**139**	**0.019**
Cortical porosity (%)	4.0	4.0	0.981
Diaphyseal Tibia			
Estimated failure load (kN)	**19.6**	**20.1**	**0.010**
Total vBMD (mg/cm^3)	734	730	0.473
Total area (mm^2)	**430**	**441**	**0.004**
Cortical area (mm^2)	**305**	**313**	**0.004**

Cluster Analysis of High Resolution Peripheral Quantitative Computed Tomography Parameters Identifies Bone Phenotypes Associated With High Rates of Prevalent Fracture Kate Ward*, Mark Edwards, Leo Westbury, Cyrus Cooper, Elaine Dennison. MRC Lifecourse Epidemiology, University of Southampton, United Kingdom

With increasing use of high-resolution peripheral quantitative computed tomography (HRpQCT) and the extended phenotypic data the technique provides, it is important to assess whether the measurements are associated with fracture risk. The aim of this study was to identify clusters of bone microarchitecture and strength in older men and women from the Hertfordshire Cohort Study and relate them to fracture prevalence and aBMD.We studied 171 women and 188 men, aged 72.1-81.4 years, with HRpQCT (XtremeCT I) images of the distal radius. Standard image analyses were performed for assessment of macrostructure, regional densitometry, cortical (Ct) and trabecular (Tb) microarchitecture, and finite element analysis. K-means partitioning cluster analysis was used to identify four clusters in women and four in men. Prevalent fracture rates and femoral neck aBMD were determined for each cluster. Fifty women and 45 men had fractures. Using microarchitecture and FEA parameters together, in women, there were two phenotypes with fracture risk greater than the reference (lowest fracture prevalence) cluster. Cluster A contained 23 women (10 fracture) with Ct.Ar, Ct.Th, Ct.BMD, Tr.BMD, Tr.Th, stiffness, failure load, and Young's modulus (YM) more than 1SD below the sex-specific cohort mean, and % Tb load (distal) more than 1SD above. The relative risk of fracture [95% confidence interval]) was 2.55 [1.28, 5.07], p=0.008 in that cluster. Cluster B (39 women, 14 fracture) had a % Tb load proximal >1SD below the sex-specific cohort mean; relative risk of fracture was 1.93 [0.98, 3.78], p=0.06. Using FEA parameters alone, 3 clusters had significantly greater fracture risk compared to the lowest risk cluster. Two were similar to clusters A and B above, relative risks of fracture were: A 2.40 [1.12, 5.15], p=0.03; B 2.74 [1.46, 5.13], p=0.002; though in B none of the FEA parameters were >1SD below the mean. The third had % Tb load (distal and proximal) >1SD above the sex-specific cohort mean; relative risk of fracture was 2.31 [1.11, 4.78], p=0.02. Fracture rates did not differ significantly by cluster in men, though similar phenotypes to clusters A and B were identified in the analyses.We have demonstrated clusters with cortical and trabecular phenotypes associated with a higher proportion of fractures in women. In men, who had fewer fractures, significant differences in fracture rates were not identified despite similar phenotypes being identified.

The Long-term Impact of Incident Low-trauma Fractures on Health-related Quality of Life of Older People: The Canadian Multicentre Osteoporosis Study Asm Borhan*[1], Alexandra Papaioannou[1], Olga Gajic-Veljanoski[2], Courtney Kennedy[1], George Ioannidis[1], Claudie Berger[3], Wilma Hopman[4], David Goltzman[5], Robert Josse[6], Christopher S Kovacs[7], David A Hanley[8], Jerilynn C Prior[9], Suzanne N Morin[5], Stephanie M Kaiser[10], Angela M Cheung[13], Lehana Thabane[12], Jonathan D Adachi[12], The Camos Research Group[3]. [1]McMaster University & GERAS Centre, Canada, [2]GERAS Centre, Canada, [3]Camos – McGill University, Canada, [4]Kingston General Hosptial, Canada, [5]McGill University, Canada, [6]St. Michael Hospital, Canada, [7]Memorial University of Newfoundland, Canada, [8]University of Calgary, Canada, [9]University of British Columbia, Canada, [10]Dalhousie University, Canada, [12]McMaster University & St. Joseph's Healthcare Hamilton, Canada, [13]University of Toronto & University Health Network, Canada

BackgroundAlthough the short-term impact of incident fractures on health-related quality of life (HRQL) of older people has been confirmed, we lack long-term data. We explored the impact of incident low-trauma fractures on HRQL (measured by Health Utility Index-HUI2/3), among people aged 50 years and older, using 10-year prospective data from the Canadian Multicentre Osteoporosis Study. Both HUI2/3 can capture the general health status and specific domains including mobility, ambulation and pain.MethodThis study included 2187 men and 5566 women. The HUI2/3 was measured at baseline and year 10, while fragility fractures were ascertained yearly over 10 years and specified by sites (clinical spine, hip, rib, humerus, pelvic, forearm and any). Multivariable regression was used to measure the mean difference, adjusted for baseline HUI score and age, for those with and without fractures. The effect of time periods (years 1 to 5 vs. 6 to 10) and multiple fractures on year 10 HUI score were also examined.ResultsThe median age (men/women: 66/67 years) and baseline HUI scores (0=death, 1=perfect health) for both men (mean±SD: HUI2:0.87±0.13; HUI3: 0.82±0.21) and women (HUI2:0.85±0.15; HUI3:0.80±0.22) were similar. Women and men with incident hip fractures had significant deficits in HRQL: HUI2: -0.11[-0.16, -0.07]; HUI3: -0.15[-0.21, -0.10] and HUI2: -0.19[-0.28, -0.12]; HUI3: -0.15[-0.28, -0.02], respectively. Similarly, clinical spine fractures had substantial deficits on HUI2 among women (-0.07, p<0.001) and men (-0.07, p=0.04). In both sexes, hip fractures had statistically significant negative impact on mobility (men: -0.18, p<0.001; women: -0.16 p<0.001), self-care (men: -0.09, p=0.01; women: -0.18; p<0.001), and ambulation (men: -0.17, p<0.001; women: -0.18; p<0.001). Like hip, clinical spine fractures had substantial deficits on mobility (men: -0.09, p=0.02; women: -0.07; p<0.001), and ambulation (men: -0.10, p=0.02; women: -0.10, p<0.001). Fractures that occurred closer to the follow-up assessment had greater impact on HRQL. However, the impact of hip fractures lasted 5 years or longer (Figure). Multiple hip (-0.15[-0.28, -0.01]) and spine fractures (-0.14[-0.27, -0.004]) significantly impacted the overall HRQL of women only. Humerus and wrist fractures had no long-term impact on HRQL.ConclusionOur analysis suggests that incident low-trauma fractures, in particular hip and clinical spine impact the HRQL of people aged 50+ years for at least 10 years.

Figure: Effect of incident fractures occurred between year 1 to 5 and 6 to 10 on multi attribute HUI scores at year 10 among women ages 50+ years in the CaMos cohort.

Inappropriate Use of Cost-effectiveness Thresholds as Intervention Thresholds – Potential for Overtreatment of Low Risk Individuals Eugene Mccloskey*[1], Helena Johansson[2], Nicholas Harvey[3], Juliet Compston[4], Cyrus Cooper[3], John Kanis[2]. [1]Mellanby Centre for Bone Research, University of Sheffield, United Kingdom, [2]Centre for Metabolic Bone Diseases, University of Sheffield, United Kingdom, [3]MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, [4]Department of Medicine, Cambridge Biomedical Campus, United Kingdom

Purpose: Cost-effectiveness analysis have traditionally been used to determine appropriate use of relatively expensive treatments. In the UK, the National Institute of Health and Care Excellence (NICE) recently found generic oral bisphosphonates to be cost-effective when prescribed for patients fulfilling screening criteria laid out in NICE CG146 with a 10 year risk of major osteoporotic fracture (MOF) of 1% or more. This 1% threshold has mistakenly been interpreted by some as an intervention threshold; we have compared the impact of this threshold with that advocated by the National Osteoporosis Guideline Group (NOGG).Methods: In a simulated age-matched population of 50,633 UK women aged 50-90 years, with risk factor distribution similar to European FRAX derivation cohorts, the NICE and NOGG thresholds were compared including impacts on treatment recommendation and numbers needed to treat (NNT) to prevent a hip fracture.Results: All women in the population had a 10-year FRAX MOF probability of ≥1%. As 40,537 fulfilled the NICE CG146 screening criteria, treatment would be recommended in 80.1% of women under the NICE threshold. In contrast, NOGG guidance recommended treatment in 20,465 women (40.8%). At ages 50-54 years, NOGG recommended treatment in 30.8% of women, rising to 63.7% in those aged 85-90 years. In contrast, the NICE threshold treated 61% of 50-54 year olds and 100% of those aged 65 years or older. The median 10-year FRAX hip fracture probability in those identified by NICE for treatment at ages 50-54 years was significantly lower (0.42%) than that in those identified by NOGG (1.07%), suggesting that the NNT would be 2.55 times higher under NICE, assuming the same treatment efficacy in both groups. At 80-85 years, the ratio was 1.32.Conclusions: When osteoporosis treatments are very inexpensive, misapplication of cost-effectiveness thresholds as intervention thresholds markedly increases the proportion of postmenopausal women eligible for osteoporosis treatment, an effect that is more marked at younger ages. The higher number needed to treat to prevent a hip fracture, especially at younger ages, is likely to adversely alter the benefit-risk ratio.

Bending the Curve with Patient Identification and Treatment in Osteoporosis E. Michael Lewiecki*[1], Jesse D. Ortendahl[2], Jacqueline Vanderpuye-Orgle[3], Andreas Grauer[3], Amanda L. Harmon[2], Andrea J. Singer[4]. [1]New Mexico Clinical Research & Osteoporosis Center, United States, [2]Partnership for Health Analytic Research, LLC, United States, [3]Amgen Inc., United States, [4]Georgetown University Hospital, United States

Purpose: Two million US women and men suffer an osteoporotic fracture every year, often with significant ensuing morbidity, reductions in quality of life, loss of independence, and mortality. Such fractures also contribute to high costs for private payers and Medicare. Given demographic trends, there is an urgent need for better diagnosis and treatment strategies to reduce the clinical and economic burden to the individual and to society. In this study, we aimed to model the expected growth in osteoporotic fractures and simulate the impact of increased case finding and treatment.Methods: A microsimulation model was developed to project annual osteoporotic fracture rates and related costs among US women ages 65+ years from 2018-2040. Fracture rates were estimated using FRAX, a commonly used fracture prediction tool, and risk factor prevalence estimates from NHANES, a nationwide survey. Direct and indirect cost inputs were based on published literature and pricing databases. Scenarios, which varied by incorporation of policies aiming to increase diagnosis and treatment, were compared to estimate the potential benefits of encouraging and improving methods of case finding, and incentivizing the appropriate use of treatment.Results: Given anticipated population aging and growth, osteoporotic fractures were projected to increase by 68% from 2018 to 2040. The societal costs related to fracture prevention and treatment were expected to rise from $52 billion in 2018 to over $87 billion in 2040. Policy-driven increases in diagnosis and treatment of at-risk women could substantially decrease the clinical burden, with increases in treatment preventing up to 6.1 million fractures over the next 22 years. At the same time, efficient methods of case finding leading to higher treatment rates could reduce payer costs by $21 billion and total societal costs by $44 billion over the same time period. Conclusions: Given a growing population of postmenopausal women in the US population and increasing longevity, there is an expected rise in the economic and clinical burden of osteoporotic fractures. To prevent this rapid growth in fractures, emphasis must be placed on osteoporosis-related interventions. Our analysis found that such measures would simultaneously reduce the clinical burden while reducing costs, a rare combination given the current landscape.

Table 1. Model Projected Clinical and Economic Outcomes

Scenario	Total Fractures (2018-2040)	Fractures Reduced (vs. Base Case)	Total Costs (2018-2040)[a]	Cost Savings (vs. Base Case)[a]
Base Case (11% DXA, 9% Treatment)	61,603,120	-	$1,674,639.3	-
Increased Case Finding (61% DXA, 31% Treatment)	57,449,128	4,153,993	$1,635,873.2	$38,766.0
Increased Treatment (61% DXA, 53% Treatment)	55,457,460	6,145,661	$1,630,424.9	$44,214.4

The Calgary Vitamin D Study: Safety of Three-Year Supplementation With 400, 4000 or 10000 IU Daily Emma O Billington*[1], Lauren A Burt[1], Erin M Davison[1], Marianne S Rose[2], Sharon Gaudet[1], Michelle Kan[1], Steven K Boyd[1], David A Hanley[1]. [1]McCaig Institute for Bone and Joint Health, Cumming School of Medicine, University of Calgary, Canada, [2]Research Facilitation, Alberta Health Services, Canada

The Institute of Medicine set the tolerable upper intake level (TUL) for vitamin D at 4000 IU/day. Some suggest the TUL could be 10,000 IU/day. More than 3% of US adults report vitamin D intakes >4000 IU/day, but the safety of this practice is unknown.We conducted a 3-year double-blind RCT to investigate the dose-dependent effects of vitamin D supplementation on bone density and strength; safety was a pre-specified secondary outcome. Healthy adults aged 55-70 with serum 25(OH)D 30-125 nmol/L were randomized to receive 400, 4000 or 10000 IU vitamin D3 daily for 3 years. Calcium supplementation was initiated if dietary calcium intake was <1200mg/day. Fasting blood samples were collected (baseline, 3, 6, 12, 18, 24, 30, 36 months) and serum analyzed for 25(OH)D and calcium. Hypervitaminosis D was defined as 25(OH)D >450 nmol/L; hypercalcemia as serum calcium >2.55 mmol/L. Hypercalciuria was defined as 24-hour urine calcium >7.50 mmol or >0.1 mmol/kg body if weight >75kg, measured at baseline, 12, 24, 36 months. Calcium intake was reduced if hypercalciuria occurred. At visits, adverse events (AEs) and serious adverse events (SAEs), including fractures and falls were reported. Fisher Exact Tests were used to examine relationships between categorical variables.373 participants (mean [SD]: 62 [4] years, 52% women) were randomized and 343 (92%) completed the study. Drop-outs were similar among groups. Mean (SD) serum 25(OH)D levels at 3 months were 76 (17), 114 (22), 187 (38) nmol/L in the 400, 4000 and 10000 IU groups respectively. No 25(OH) D levels >450 nmol/L were observed at any time point. A total of 2725 AEs occurred in 365 participants, including 66 SAEs in 52 participants (Table 1). The number of participants with AEs (p= 0.999) and SAEs (p = 0.199) were not significantly different between groups. Incidence of hypercalcemia (range: 2.56-2.64 mmol/L) varied significantly between the 400 IU (0%), 4000 IU (3%) and 10000 IU (9%) groups (p<0.001). Hypercalciuria occurred in 87 participants; incidence varied significantly between the 400 IU (17%), 4000 IU (22%) and 10000 IU (31%) groups (p = 0.040).In conclusion, vitamin D supplementation for 3 years was not associated with any SAEs or AEs; however, there was a dose-response increase in hypercalcemia which resolved on repeat testing, and hypercalciuria which usually resolved with reduction in calcium intake.

Table 1. Incidence of adverse events in a randomized controlled trial comparing vitamin D3 400, 4000 and 10000 IU taken daily for 3 years

	400 IU (n=124)		4000 IU (n=125)		10000 IU (n=124)

Natural history of maternal urinary β-C-terminal telopeptide of type I collagen (CTX) in pregnancy, and response to cholecalciferol supplementation: findings from the MAVIDOS trial Elizabeth Curtis*[1], Camille Parsons[1], Kate Maslin[1], Stefania D'Angelo[1], Rebecca Moon[1], Sarah Crozier[1], Fatma Gossiel[2], Nicholas Bishop[3], Stephen Kennedy[4], Aris Papageorghiou[4], Robert Fraser[5], Saurabh Gandhi[5], Ann Prentice[6], Hazel Inskip[1], Keith Godfrey[1], Inez Schoenmakers[6], M Kassim Javaid[7], Richard Eastell[2], Cyrus Cooper[1], Nicholas Harvey[1]. [1]MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, United Kingdom, [2]Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom, [3]Academic Unit of Child Health, Sheffield Children's Hospital, University of Sheffield, Sheffield, United Kingdom, [4]Nuffield Department of Women's & Reproductive Health, John Radcliffe Hospital, University of Oxford, Oxford, United Kingdom, [5]Department of Obstetrics and Gynaecology, Sheffield Hospitals NHS Trust, University of Sheffield, Sheffield, United Kingdom, [6]MRC Human Nutrition Research, Elsie Widdowson Laboratory, Cambridge, United Kingdom, [7]National Institute for Health Research (NIHR) Oxford Biomedical Research Centre, University of Oxford, United Kingdom

Markers of maternal bone turnover in pregnancy are poorly characterised. In a randomised trial we investigated i) changes in maternal urinary beta-C-terminal telopeptide of type I collagen (CTX) concentrations in pregnancy, and the effect of gestational vitamin D supplementation thereon; and ii) associations between CTX and maternal postnatal bone indices.MAVIDOS is a randomised, double-blind, placebo-controlled trial of 1000 IU/day cholecalciferol vs placebo from 14 weeks gestation to birth. At 14 and 34 weeks gestation, maternal second void urinary CTX was measured using an ELISA (Immunodiagnostic Systems, Boldon, UK) and expressed relative to creatinine (Cr). Maternal bone indices were assessed by DXA (Hologic Discovery) within 2 weeks after delivery. Median CTX concentrations were compared using the Wilcoxon signed-rank test. CTX values were log transformed and standardised to an SD scale. Correlation and linear regression methods were used to explore associations. Beta coefficients represent change in outcome per 1 SD increase in CTX.636 women (314 placebo, 322 cholecalciferol) were studied. CTX increased overall from 14 to 34 weeks in both groups (median 14 and 34 week CTX: placebo 223.8 and 445.3 µg/mmol Cr; cholecalciferol 217.5 and 420.0µg/mmol Cr; both p-diff 14 to 34 weeks<0.0001; p-diff for supplementation effect at 34 weeks=0.06); 14 and 34 week values were correlated in both the placebo (r=0.32) and treatment (r=0.45) groups (both p<0.0001). In groups combined, 34 week CTX was associated with lower postpartum maternal femoral neck bone area [-0.43cm2/SD (-0.80, -0.07), p=0.02], bone mineral content (BMC) [-0.001g/SD (-0.001, 0.000), p=0.03] and lumbar spine BMC [-0.001g/SD (-0.002, 0.000), p=0.03]. There was no interaction between treatment group and CTX on bone outcomes (p-interaction all > 0.6).Urinary CTX rises from early to late pregnancy, appears to be reduced by gestational cholecalciferol supplementation, and is inversely associated with maternal bone mass post-partum. These findings inform our understanding of bone resorption in pregnancy and the potential relationship with vitamin D metabolism.

The association of breastfeeding, maternal smoking, birth weight and maternal diet with bone density and microarchitecture in young adulthood: a 25-year longitudinal study Yi Yang*[1], Feitong Wu[1], Terry Dwyer[2], Tania Winzenberg[1], Graeme Jones[1]. [1]Menzies Institute for Medical Research, University of Tasmania, Australia, [2]The George Institute for Global Health, University of Oxford, United Kingdom

Objective: We have previously shown that early life exposures are associated with bone mass assessed by densitometry at age 8 and 16. This study aimed to describe whether these associations persisted to young adulthood and extended to microarchitecture.Method: There were 201 participants followed from birth to age 25. Outcomes measured were bone mineral density (BMD) at the spine, hip and total body (by dual-energy X-ray absorptiometry (DXA)). Trabecular and cortical bone measures were obtained by high resolution peripheral quantitative computerized tomography (HRpQCT) at radius and tibia. Other factors measured were anthropometrics, breastfeeding status, maternal smoking, birth weight and Food Frequency Questionnaire (FFQ) during the third trimester of pregnancy.Result: For participants born prematurely, breastfeeding was associated with improvements in volumetric density (vBMD), porosity in cortical and inner transitional zones, trabecular number (Tb.N) and trabecular bone volume fraction (Tb.BV/TV) at radius or tibia at age 25. Maternal smoking during pregnancy was not associated with participants' porosity and trabecular microarchitecture at age 25. Low birth weight was a positive predictor for spine areal BMD, trabecular vBMD and trabecular separation (Tb.Sp). Maternal meat intake during pregnancy was associated with higher total vBMD and lower porosity at compact cortical, outer and inner transitional zones. Other nutrients (protein, fat, carbohydrate, calcium, magnesium and phosphorus) and food (fish, vegetable, fruit and milk) intake were not associated with any bone measures. For participants born at term, the beneficial effect of breastfeeding was no longer present. Smoking during pregnancy was associated with higher Tb.Sp and inner transitional zone porosity, lower trabecular vBMD, Tb.N and Tb.BV/TV. There was no sig-

nificant association between maternal nutrient and food intake during pregnancy with participants' vBMD and microarchitecture at age 25.Conclusion: There were long-term beneficial associations of breastfeeding, low birth weight, meat intake during pregnancy and vBMD as well as bone microarchitecture in participants born prematurely. Maternal smoking was an early life marker for suboptimal bone trabecular spacing and porosity in those children born at term. This study suggests that early life exposures may have affect bone development until the time of peak bone mass.

Effect of High-Dose Vitamin D on Bone Microarchitecture assessed via High Resolution Peripheral Quantitative Computed Tomography (HR-pQCT): a Double-Blind RCT Ursina Meyer*[1], Ursula Heilmeier[1], Robert Theiler[2], Andreas Egli[1], Heike A. Bischoff-Ferrari[2]. [1]Centre on Aging and Mobility, Department of Geriatrics and Aging Research, University Hospital Zurich and Zurich of University, Switzerland, [2]Department of Geriatrics and Aging Research, University Hospital Zurich and Zurich of University, Switzerland

Vitamin D (VitD) is a well-recognized key player in bone and mineral metabolism and VitD supplementation has been widely attributed beneficial effects on musculoskeletal health. However, to date, the optimal supplemental dose remains controversial. In addition, the detailed effect of VitD on bone microarchitecture in humans is still largely unknown as most clinical trials use DXA to assess bone outcomes, a 2D technique that cannot resolve bone microstructure. With the advent of HR-pQCT, a promising, non-invasive imaging tool has emerged which allows for in vivo 3D characterization of human bone microstructure at a spatial resolution of 82 µm. Therefore, the purpose of this study was to evaluate the effect of two different dosages of daily, 2-year long VitD supplementation (800 IU vs. 2000 IU) on bone microarchitecture using HR-pQCT in elderly seniors.This was a 2-year randomized, double-blind clinical trial. 273 patients aged ≥ 60 y were randomized to receive daily doses of either 2000 IU VitD (HD-group) or the standard-dose of 800 IU VitD (SD-group), and all received 500 mg calcium supplement per day. At baseline and 24 months, aBMD by DXA was measured at the hip and lumbar spine and bone microarchitecture of the distal radius and tibia was imaged by HR-pQCT. Bone structural parameters (0m, 24m, Δ) were computed. General linear models adjusted for age, sex, BMI and baseline bone parameters were employed to compare bone changes over time between treatment groups.At baseline, both groups were similar with respect to mean age, sex, BMI, and serum 25(OH)D levels (Tab 1). After 2 years, higher 25(OH)D levels were observed in the HD-group compared to the SD-group (35.7±6.8 vs. 28.8±6.0 ng/ml; p≤0.001). While DXA showed similar, small, but not significant increases in mean aBMD over the 2-y-follow up for both groups, we noted via HR-pQCT a significant increase in trabecular number in the HD-group (ΔTb.N 0.056 (SE 0.016) vs. 0.008 (0.016) 1/mm, p = 0.03) at the tibia. No statistical significant differences were found in other structural parameters [trabecular (Tb.Th) or cortical thickness (Ct.Th)], and volumetric BMDs at both sites.We conclude that a high dose VitD supplementation of 2000 IU daily for 2 years might have a slight beneficial effect on bone microarchitecture in seniors by increasing the trabecular number. Further microfinite element analyses are necessary to determine if this translates into improved biomechanical bone properties.

Table 1: Baseline characteristics of n= 196 seniors with HR-pQCT-derived bone microstructure measurements acquired at baseline and after 2 years of Vit D supplementation with either a daily standard dose or high dose Vit D regimen. Values are given as means (standard deviations) unless stated differently. Statistical significance is assumed at a p < 0.05. P-values were calculated using either Student's t-tests or X2 tests, as appropriate.

	Standard Dose Vitamin D: 800 IU	High-Dose Vitamin D: 2000 IU	p-value

Vitamin D Status, Bone Quality and Long-Term Risk for Fracture-related Hospitalization in Older Women Kun Zhu*[1], Joshua Lewis[2], Marc Sim[2], Richard Prince[3]. [1]Department of Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Australia, [2]School of Medical and Health Sciences, Edith Cowan University, Australia, [3]Medical School, University of Western Australia, Australia

Aims: We examined the association between plasma 25-hydroxyvitamin D (25OHD) with bone quality and 14.5-year fracture-related hospitalizations in a cohort of older women. Methods: The study participants were 1,348 women aged 70-85 years at baseline (1998) from the Perth Longitudinal Study of Aging in Women Study. Assessments include plasma 25OHD concentration using LC-MS/MS at baseline, hip DXA bone mineral density (BMD) at year 1, trabecular bone score (TBS) at year 5, and fracture-related hospitalizations over 14.5 years obtained from the Western Australian Hospital Morbidity Database Collection.Results: The mean plasma 25OHD was 66.9 (SD 28.2) nmol/L, and 384 (28.5%), 491 (36.4%) and 473 (35.1%) women had plasma 25OHD <50, 50-75 and ≥75 nmol/L, respectively. Accounting for season of blood sampling, baseline age, BMI and lifestyle factors, women with 25(OH)D ≥75 nmol/L had significantly higher total hip and femoral neck BMD at year 1 (3.3-3.9%) and TBS at year 5 (2.4%) than those with plasma 25OHD <50 nmol/L (all P<0.05). Generalized additive regression models showed that the values for total hip and femoral neck BMD and TBS increased with the increase of plasma 25OHD up to about 100 nmol/L, then levelled off. In the multivariate-adjusted Cox proportional hazards regression analyses, compared with women who had plasma 25OHD <50 nmol/L, those with 25OHD 50-75 and ≥75 nmol/L had significantly lower risk for any fracture (hazard ratio (95% CI): 0.75 (0.58, 0.97) and 0.69 (0.53, 0.90), respectively) and hip fracture-related hospitalization (hazard ratio (95% CI): 0.60 (0.40, 0.91) and 0.61 (0.40, 0.93), respectively). Restricted cubic spline regression models showed that plasma 25OHD below 75 nmol/L was associated with higher risk of any fracture-related hospitalization (Figure) and below 50 nmol/L hip fracture-related hospitalization.Conclusions: Our prospective study suggests maintaining serum 25OHD levels of at least 50 nmol/L and ideally up to 75 nmol/L could confer benefit for the long-term prevention of fracture-related hospitalization in community-dwelling older women.

Any fracture-related hospitalization

High dietary calcium intakes in men, not women, are associated with increased all-cause mortality: the Melbourne Collaborative Cohort Study Alexander Rodriguez*[1], David Scott[1], Belal Khan[2], Allison Hodge[3], Dallas English[2], Graham Giles[3], Bo Abrahamsen[4], Peter Ebeling[1]. [1]Monash University, Australia, [2]University of Melbourne, Australia, [3]Cancer Council Victoria, Australia, [4]University of Southern Denmark, Denmark

Context: The association of dietary calcium with mortality is controversial. A study of older women from the Swedish Mammography Cohort (SMC) suggested higher calcium was associated with a higher mortality risk; while a study of Australian adults from the

Melbourne Collaborative Cohort Study (MCCS) suggested higher intakes were associated with lower mortality risk.Objective: Perform a sex-specific re-analysis of MCCS to evaluate the association of dietary calcium with mortality outcomes and directly compare hazard estimates [95% confidence intervals] in women with those from SMC.Design: Prospective, co-hort studySetting: Community-dwelling adultsPatients: 34,627 individuals (women: 20,834 [60.2%], mean±SD age = 54±8 years) at baseline after excluding those with prevalent CV disease, cancer or incomplete dataExposure: Energy adjusted dietary calcium categorised into levels of consumption (mg/day): <600; 600-999; 1000-1399; ≥1400Main outcome: Mortality from all-causes, any CV disease and myocardial infarction. Mortality hazards estimated relative to intakes of 600-999mg/dayResults: In women, hazard estimates for calcium intake of ≥1400mg/day did not reach significance for all-cause [HR=0.83; 0.64, 1.08] or CV [HR=1.10; 0.68, 1.78] mortality in adjusted models. In men, intakes of ≥1400mg/day were associated with a 41% increased all-cause mortality risk [HR=1.41; 1.01, 1.97]. There was a trend toward increased CV mortality [HR=1.77; 0.92, 3.13]. In sensitivity analyses excluding those with calcium intakes three standard deviations above the sex-specific mean, for men there was a 54% increased risk of all-cause mortality [HR=1.54; 1.08, 2.19] associated with intakes above 1400mg/day. For women, no hazard estimate reached significance for any outcome. Conclusion: Contrary to findings from a similar study conducted in Swedish women, Australian women showed no increase in mortality risk with high calcium intakes. This may reflect differences in calcium handling dynamics, diet or lifestyle factors between the two countries. We identified an increased mortality risk for men.

FRI-0859

A greater weight loss reduces lumbar spine trabecular bone score in the obese, and this is not influenced by vertebral body structural defects Julia Amariti*[1], Stephen Schneider[2], Karen Hansen[3], Yvette Schlussel[1], Sue Shapses[1]. [1]Rutgers University, United States, [2]Rutgers Robert Wood Johnson Medical School, United States, [3]University of Wisconsin School of Medicine and Public Health, United States

Purpose: Obesity is a risk factor for osteoarthritis and spinal stenosis. Clinicians often recommend weight loss to reduce pain related to osteoarthritis and improve other health outcomes. However, weight loss can result in declines in bone mineral density (BMD), although this is not consistently observed at the lumbar spine (LS). It is hypothesized that this may be due to a higher prevalence of vertebral structural defects, and that LS trabecular bone score (TBS) may be a more sensitive indicator of bone changes due to WL. Methods: In this study, we retrospectively examined changes in BMD and trabecular bone scores (TBS) in 88 older overweight/obese women and men (body mass index, BMI, 32.0 ± 4.5 kg/m2; 57 ± 5 years old) who participated in weight loss studies (1-3). We classified weight loss as <5% (mild; n=44) or >5% (moderate; n=44). Because spine osteoarthritis leads to artifacts that spuriously measure the lumbar spine BMD, we assessed dual energy x-ray absorptiometry lumbar spine images for vertebral body exclusion criteria (4). Results: Repeated measures ANOVA (group by time) indicated that the trabecular bone score (TBS) was significantly affected by both time (p < 0.001) and degree of weight loss (p= 0.027). Moderate weight loss (-8.4 ± 4.0%) was associated with greater declines in TBS (-3.0 ± 5.5%) than mild weight loss (-2.7 ± 2.2% weight loss, TBS changed by 0.8 ± 4.6%). As expected, BMD decreased (p < 0.05) over time at multiple skeletal sites (ultradistal radius, 33% radius, total body), but this did not differ by weight loss category. By contrast, BMD did not decrease significantly at the lumbar spine, hip or femoral neck. Approximately 40% of subjects had ≥1 vertebrae with focal structural defects prompting vertebral body exclusion. However, when excluding vertebrae with such defects, we still found no association between weight loss and changes in spine BMD. Women experienced a greater decline in TBS than did men, despite similar degrees of weight loss (p < 0.001). Conclusion: Weight loss was associated with a decline in TBS, with women experiencing greater declines in TBS than men, despite similar degrees of weight loss. References: 1. Sukumar D JBMR 2011; 2. Identification of Cellular Senescence and Senescent Secretory Markers as Major Etiologies Underlying Radiotherapy Related Bone Damage Abhishek Chandra*, Joshua Farr, David Monroe, Rebekah Samsonraj, Haitao Wang, Susan Law, Sundeep Khosla, Robert Pignolo. Mayo Clinic, United States

Radiotherapy reduces cancer burden and improves survivorship, but by-stander effects on healthy tissues such as bone causes insufficiency fractures, and increases risk of morbidity and mortality. Despite extensive efforts, the exact mechanism(s) underlying radiotherapy-induced osteoporosis (RIO) are unclear, and an FDA approved drug to alleviate RIO is still elusive. In our mouse model of RIO, 3-month-old wild-type mice received 16Gy of focal radiation (R) to the metaphyseal region of the right femur, while the contralateral left leg was non-radiated (NR). We demonstrated in this model that loss in vBMD due to R begins at 2wks and peaks at 4wks. However, since osteoclasts were reduced by 2wks post-R, the exact mechanism behind RIO at 4wks is still incompletely understood. We recently identified cellular senescence and the senescence-associated secretory phenotype (SASP) as causal factors in the pathophysiology of age-related osteoporosis. However, possible roles for cellular senescence and the SASP in RIO have not been defined. Therefore, we performed gene expression profiling of the R bone in comparison to contralateral NR bones from RIO mice and compared markers for senescence and the SASP that were significantly expressed in enriched bone cell populations from old (O) mice as well. Among the senescence-related genes, p15, p16, p21, p27 and their regulator, FoxO1, as well as 12 SASP genes were markedly upregulated in response to R. Strikingly, among the 23 Wnt-pathway genes examined, Wnt-2, -2b, -3, -3a, -5b, -10a, -11, -16, Wif1 and Wisp2 decreased significantly with R; while Axin2, a negative Wnt-regulator had an elevated expression in the R bones. RIO is also associated with bone marrow adiposity (BMA), and we observed increased BMA markers Fabp4, Lpl, ApoE, Plin1, Cebp-α and PPAR-γ in R-bones. In order to identify the bone marrow cells that contributed towards the senescence and SASP observed in R bones, we performed gene expression analysis on magnetic sorted CD14+ myeloid cell population 2-weeks post-R. We observed significant increases in Wnt inhibitor, Axin2, the senescence marker, FoxO1 and SASP factors, Ccl2, Ccl4, Ccl5, Ccl6, Ccl7, Cxcl1, Cxcr5 and Mmp12, further confirming that myeloid cells were the major contributors of SASP factors in R bones as compared to NR bones. In conclusion, we have identified that cellular senescence and the SASP are the major etiologies underlying RIO, possibly due to down-regulation of the Wnt-pathway.

Identification and Characterization of lncRNA-DBD in Diabetic Bone Metabolism Zhekai Hu*[1], Qisheng Tu[1], Jake Chen[1,2]. [1]Division of Oral Biology Tufts University School of Dental Medicine, United States, [2]Department of Developmental, Molecular and Chemical Biology Sackler School of Graduate Biomedical Sciences Tufts University School of Medicine, United States

Objective:Mammalian genome contains loci that transcribe long noncoding RNAs (lncRNAs), which can function as essential regulators in diverse cellular processes including stem cell differentiation, cancer development and tissue regeneration via different mechanisms. However, their functions in diabetic bone diseases are largely unknown. In this study, we planned to use a diet induced obesity (DIO) mouse model to identify lncRNAs that attribute to the abnormal skeletal phenotypes under a diabetic condition. Methods:We first generated DIO mouse model and performed histologic staining and computerized tomographic scanning of lumbar vertebra and femur bones from the DIO mice and wide type (WT) mice. In vitro studies included the induction of osteoblast and osteoclast differentiation, quantitative RT-PCR, TRAP and alizarin red S staining. We screened the expression of mRNA and lncRNA in mouse bones through a microarray assay and analyzed the expression profile using bioinformatics. Results:Assessed by the structure model index we found that there was an imbalance between bone formation and bone resorption. Bone microarchitecture was found to be altered, and bone loss increased in lumbar vertebra and femurs of the DIO mice mainly because of impaired remodeling in bone architectures (Fig. A). In vitro experiment findings confirmed the observation (Fig. B). We also screened mRNAs and lncRNAs, and functionally identified a novel candidate lncRNA, termed DBD (Diabetic Bone Disorders), which functioned as an essential regulator in diabetic bone diseases. We further found that DBD highly expressed in osteoblastogenic differentiation and decreased in osteoclastogenic differentiation. In addition, DBD showed a dose-dependent correlation with a neighboring gene Bmp4. Bmp4 plays a pivotal role in osteogenic differentiation and bone formation. Here we showed that Bmp4 regulated the expression of Bmp2, Smad1, Smad2, Shh and Foxh1, potentially through DBD regulation (Fig. C and D). Conclusion:Using RNAs extracted from DIO bone tissues and a microarray assay we have initially identified and characterized a specific lncRNA DBD. DBD level was significantly elevated in diabetic bones. DBD also regulates a neighboring osteogenic gene Bmp4. Currently we are further studying the epigenetic mechanism and molecular signaling of how DBD affects bone metabolism in diabetes. These have great potential to advance our understanding of diabetic related bone disorders.

FRI-0862

Estrogen depletion alters regulation of mineralization at actively forming osteonal surfaces in a monkey animal model Eleftherios P. Paschalis*[1], Sonja Gamsjaeger[1], Stamatia Rokidi[1], Keith Condon[2], Klaus Klaushofer[1], David Burr[2]. [1]Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK and AUVA Trauma Centre Meidling, 1st Medical Department, Hanusch Hospital, Heinrich Collin Str. 30, A-1140, Austria, [2]Indiana University, School of Medicine, United States

Ovariectomized animal models have been extensively used in osteoporosis research due to the resulting loss of bone mass. The purpose of the present study was to test the hypothesis that estrogen depletion alters mineralization regulation mechanisms in an ovariectomized monkey animal model. We used Raman microspectroscopy to analyze humeri from monkeys that were either SHAM-operated or ovariectomized (N=10 per group). Measurements were made as a function of tissue age based on the presence of multiple fluorescent double labels. Briefly, natural habitat-derived adult female cynomolgus monkeys (Macaca fascicularis) were imported from Indonesia, quarantined for 3 months, and screened radiographically to ensure absence of open growth plates and skeletal abnormalities. Double fluorochrome labels were given (calcein, 10 mg/kg, iv) using a 1–12-1 schedule, with sacrifice 7 days after administration. In the present work we focused on osteonal osteoid seams (defined as a surface with evident calcein labels, 1μm distance away from the mineralizing front, and for which the Raman spectra showed the presence of organic matrix but not mineral), as well as the youngest mineralized tissue between the second fluorescent label and the mineralizing front, 1μm inwards from the front (TA1). The spectroscopically determined parameters of interest were the relative glycosaminoglycan (GAG) and pyridinoline (Pyd) contents in the osteoid, and the mineral content in TA1.In the SHAM animals, there was a significant negative correlation between osteoid GAGs and mineral content (Pearson's r = -0.83, p<0.0001), and a positive one between osteoid Pyd and mineral content at TA1 (Pearson's r = 0.91, p<0.0001). No significant correlations were evident in the OVX animals (Pearson's r = -0.26, and – 0.35, respectively).GAGs are known negative modulators of mineralization. The strong negative correlation between osteoid GAGs and the earliest deposited mineral agrees with previous reports. Pyd is an enzymatic collagen cross-link, involved in collagen fiber formation/stabilization. The highly significant correlation between these two organic matrix attributes in the osteoid and the mineral content of the newly formed bone mineral in the SHAM but not in the OVX animals suggests that in addition to the well-established effects on turnover rates and bone mass, estrogen depletion alters the regulation of mineralization by GAGs and Pyd.

Low bone mineral density remains highly prevalent in adolescents despite height adjustment: results from the Sickle Cell Clinical Research and Intervention Program (SCCRIP) pediatric cohort Oyebimpe Adesina*[1], Guolian Kang[2], Martha Villavicencio[3], Jason Hodges[3], Wassim Chemaitilly[4], Sue Kaste[5], James Gurney[6], Babette Zemel[7], Jane Hankins[3]. [1]Division of Hematology, University of Washington School of Medicine, United States, [2]Department of Biostatistics, St. Jude Children's Research Hospital, United States, [3]Department of Hematology, St. Jude Children's Research Hospital, United States, [4]Department of Pediatric Medicine, Division of Endocrinology, St. Jude Children's Research Hospita, United States, [5]Department of Radiological Sciences, St. Jude Children's Research Hospital, United States, [6]School of Public Health, University of Memphis, United States, [7]Division of Gastroenterology, Hepatology and Nutrition, Children's Hospital of Philadelphia, United States

PurposeLow bone mineral density (BMD) disproportionately affects people with sickle cell disease (SCD), with reported prevalence of 30-50% in children and adolescents. Growth delay is common in SCD, but most BMD studies in pediatric SCD patients fail to account for their short stature.MethodsWe examined low BMD prevalence and clinical correlates in 6 to18-year-old patients enrolled in the Sickle Cell Clinical Research and Intervention Program (SCCRIP), an ongoing multi-center lifespan SCD cohort study initiated in 2014. SCCRIP participants undergo areal BMD (aBMD) screening from age 6 years, and every 6 years thereafter, using a Hologic dual-energy X-ray absorptiometer (DXA). We stratified subjects into school age children (6-12 years), and adolescents (>12-18 years). Using results of their most recent total body less head DXA scan, we calculated aBMD-for-age and height-adjusted aBMD (Ht-aBMD) Z-scores, based on published values for healthy African American children and adolescents from the Bone Mineral Density in Childhood Study. We defined low BMD as aBMD-for-age Z-score or Ht-aBMD Z-score ≤-2; and, evaluated its associations with demographics and clinical characteristics. Statistical analyses included chi-square, t-test, and multivariate regression analyses. ResultsWe examined 308 African American subjects (mean age 12.5 years, 50% female, 73% HbSS/Sβ thalassemia genotype), and found that 99 (32%, 24 children and 75 adolescents) had low aBMD-for-age, while 58 (19%, 4 children and 54 adolescents) had low Ht-aBMD Z-scores (Figure). In females, low Ht-aBMD Z-scores associated with vitamin D status: 54% deficient, 35% insufficient, and 11% replete (p=0.069). Hip avascular necrosis (AVN) was 5-times more prevalent in males with low versus normal Ht-aBMD Z scores. In multivariate analyses for all patients, low Ht-aBMD Z-scores independently associated with adolescence, chronic pain, and hemoglobin (odds ratios 7.1, 6.9, and 0.8 respectively, p<0.05), not hip AVN (odds ratio 4.5, p=0.11). ConclusionsLow aBMD is highly prevalent in pediatric SCD. Adjusting for height accounts for the effects of delayed growth on aBMD in children with SCD, yet nearly 20% of subjects (mostly adolescents) still had very low Ht-aBMD Z-scores. Low Ht-aBMD Z-scores associate with older age, chronic pain, and anemia. As the SCCRIP longitudinal cohort matures, future studies will prospectively investigate the association between low Ht-aBMD and markers of SCD severity and morbidity.

Hyponatremia Induced Osteoporosis Julianna Barsony*, Qin Xu, Joseph G. Verbalis. Georgetown University, United States

Growing evidence indicates that chronic hyponatremia represents a significant risk for bone loss, osteoporosis, and fractures in humans. Our prior studies using a rat model of the syndrome of inappropriate antidiuretic hormone secretion (SIADH), demonstrated that hy-ponatremia causes osteoporosis primarily by increasing osteoclastic bone resorption, thereby liberating stored sodium from bone. Cellular studies have demonstrated increased osteoclast formation and resorptive activity in primary rodent bone marrow macrophages and murine RAW264.7 pre-osteoclastic cells in response to low extracellular fluid (ECF) sodium concentration ([Na+]). These studies indicated that osteoclasts can respond to low ECF [Na+]. In the present studies, we characterized this response in more detail using gene expression and protein phosphorylation arrays and osteoclast functional assays. We compensated for the osmolality change by adjusting the media osmolality to normal levels with the addition of mannitol. Pathway-specific gene expression array results demonstrated activation of the RANK/PI3K/Akt/mTOR pathway after 24-h exposure to low [Na+] (120 mmol/l), compared to normal [Na+] (140 mmol/l) media. Phospho-kinase array results supported the findings of the gene expression study. This survival pathway activation generated a burst in osteoclast energy production, as evidenced by ATP measurements in differentiated RAW264.7 cells after culturing in normal and low [Na+] for 24 h. Moreover, differentiated osteoclast migration was facilitated through the membrane in a Boyden chamber in low [Na+] media compared to migration in normal [Na+] media. The potential clinical relevance of osteoclast activation in patients with chronic hyponatremia (131 - 134 mmol/L), having osteoporosis by bone density criteria and prior fractures, was assessed by comparing serum [Na+] before and 6 months after starting treatment with denosumab. Administration of denosumab sc reduced serum [Na+] by 2-5 mmol/l (range) compared to baseline in all 4 treatment-naive patients. No change in serum calcium was found. These combined results therefore support our hypothesis that osteoclast-mediated bone resorption serves to stabilize serum [Na+] in hyponatremic patients by releasing sodium from bone stores, and that mTOR inhibitors may be effective in reversing the bone loss in hyponatremic patients without risking aggravation of their hyponatremia.

Bone histomorphometric effects of HIV infection and Antiretroviral therapy Janaina Ramalho*[1], Csw Martins[1], Rmr Pereira[1], Thomas Nickolas[2], Mt Yin[2], J Galvão[3], Margareth Eira[4], Lm Reis[1], Luzia Furukawa[1], Vanda Jorgetti[1], Rm Moyses[1,3]. [1]Universidade de São Paulo, Brazil, [2]Columbia University, United States, [3]UNINOVE, Brazil, [4]Instituto de Infectologia Emilio ribas, Brazil

Background: Reduction in bone mineral density (BMD) is a known metabolic complication of HIV infection and antiretroviral therapy (ART). We aimed to investigate changes in bone-related proteins and bone histomorphometry in ART-naïve HIV+ men initiating treatment with tenofovir disoproxil fumarate (TDF), lamivudine (3TC) and efavirenz (EFV). Methods: In 16 HIV+ men we evaluated bone structure, turnover and mineralization by iliac crest bone biopsy with histomorphometry before and 12 months after ART initiation. BMD was assessed by DXA. RANKL, OPG, SOST, FGF23, IL-6, IL-1β and TNFα levels in serum and bone were determined using multiplex assays. Results: Mean age was 29.8 ± 5.8 years, mean BMI was 24.4 ± 2.4, with median HIV RNA level of 28,685 (5,628 – 68,540) copies/mL and mean CD4 of 478 ± 189 cells. After 12 months, mean CD4 was 739 ± 232 cells, and all patients had HIV RNA below limit of detection. At baseline, 3 patients (19%) had Z score ≤ -2 at any site. There was a significant reduction in BMD at L1-L4 (0.981 vs. 0,960 g/cm3, p = 0.048), femoral neck (0.887 vs. 0.862 g/cm3, p = 0.001) and total hip (1,029 vs. 1,010 g/cm3, p = 0.04). We observed a trend of increase in 25-OH-vitamin D after 12 months (22.1 ± 7.4 vs 28.1 ± 9.2 ng/ml, p 0.06). Reduction in serum RANKL [15.2 (10.0 - 21.9) vs. 10.9 (7.5 – 16.8) pg/ml, p 0.049], TNFα [2.29 (1.78 – 3.37) vs. 1.61 (1.42 – 2.05) pg/ml, p 0.03] and FGF-23 [28.3 (26.2 – 34.9) vs 24.7 (22.1 – 28.3) pg/ml, p 0.04] levels were detected. No significant changes were observed in bone concentration of any protein. Low bone trabecular volume was seen in 25% before and after therapy;whereas the proportion with low bone formation rate and abnormal mineralization lag time increased, albeit not significantly (from 88 to 100%, and from 63 to 75%, respectively). At baseline, increased osteoclastic and eroded surface were seen in 44 and 31%, respectively. ART therapy was associated with an increase in osteoid volume (0.8 (0.3 – 1.4) vs. 2.2 (1.1 – 4.0) %, p 0.02), osteoblastic and osteoclastic surfaces [1.3 (0.5 – 2.3) vs 4.5 (2.5 – 6.8)%, p 0.02, and 0.1 (0.1 – 0.3) vs 0.3 (0.1 – 0.7) %, p 0.04, respectively], and cortical porosity and thickness (3.7 ± 1.7% vs. 6.3 ± 3.5%, p 0.049, and 663.5 ± 163.1mm vs. 886.9 ± 349.4mm, p 0.04, respectively). Conclusion: Abnormalities in bone volume, turnover and mineralization are common in HIV+ men even before ART exposure. These changes did not improve, but worsened after therapy with TDF, 3TC and EFV, which could explain the elevated fracture risk observed in these patients. Our findings emphasize the needing for an early detection and management of HIV-related bone disease.

Low daily dose of glucocorticoids induces trabecular and cortical bones impairment at the femur: a 3D analysis using DXA-based modeling. Arnau Manasanch Berengué *[1], Renaud Winzenrieth[1], Ludovic Humbert[1], Edward Leib[2]. [1]Galgo Medical SL, Spain, [2]Dept. of Medicine, University of Vermont College of Medicine, United States

INTRODUCTION: The aim of this study was to evaluate the effects of glucocorticoids (GCs) on trabecular and cortical bones at proximal femur using DXA-based 3D modeling.METHODS: 402 men and women receiving GCs (≥5 mg/day, for ≥3 months, predni-

sone equivalent) were included in this study. They were randomly gender-, age- and BMI-matched with 1087 control subjects (1:2 to 1:3). Individuals were included in the control group if they had not received glucocorticoid therapy and if they had a Z-score within -2 to +2 at both spine and femur sites. Clinical data, common clinical risk factors, and dietary habits were available in the medical report of the participants. GCs subjects were stratified depending on their fracture status. Areal BMD (aBMD) was measured at lumbar spine (aBMDLS), total femur (aBMDTot) and femoral neck (aBMDFN). A software algorithm was used to derive QCT-like subject-specific 3D models from the hip DXA scans of the participants and controls and compute the trabecular volumetric BMD (Trabecular vBMD) and the cortical surface BMD (Cortical sBMD).RESULTS: GCs-treated patients had a significantly lower aBMDTot and aBMDFN (p<0.05) when compared with controls while, no difference was observed for aBMDLS (p=0.72). Using 3D modeling, a significantly lower cortical sBMD (p=0.02) at total femur and trabecular vBMD (p=0.012) at neck were observed in GC-treated patients (Figure 1). When stratified based on their fracture status, GCs-treated patients with fracture (all type of osteoporotic fracture) had a significantly lower aBMDTot, cortical sBMD at total femur, trabecular vBMD at both total femur and neck, compared to GCs-treated subjects without fracture (all p<0.05). Cortical sBMD has the strongest association with fracture events in the GCs group, as expressed by an odds ratio per standard deviation decrease of 1.42 [1.08-1.87] and an area under the roc curve of 0.59 [0.54-0.64]. CONCLUSIONS: We observed an impairment of both cortical and trabecular compartments in GCs-treated patients, at total femur for the cortical bone and localized at the neck for the trabecular compartment. Presence of fracture is associated with a low cortical sBMD.
Figure 1: a) 3D distribution of the differences (in %) observed in Cortical sBMD between controls and GCs subjects. Increases are presented in blue-green colour while decreases are presented in yellow-red colours. b) Distribution of the average changes in vBMD observed in both trabecular and cortical bone in the mid coronal between controls and GCs subjects.

Efficacy of Teriparatide Compared With Risedronate on FRAX®-defined Major Osteoporotic Fractures: A Post-hoc Analysis of the VERO Clinical Trial Jean-Jacques Body*[1], Fernando Marin[2], Piet Geusens[3], Cristiano Zerbini[4], Astrid Fahrleitner-Pammer[5], Ruediger Moericke[6], Enrique Casado[7], Jan Stepan[8], Salvatore Minisola[9], Eric Lespessailles[10], Pedro López-Romero[2], David Kendler[11]. [1]CHU Brugmann, ULB, Belgium, [2]Lilly Research Center Europe, Spain, [3]Maastricht University Medical Center, Netherlands, [4]Centro Paulista de Investigaçao Clínica, Brazil, [5]Division of Endocrinology, Medical University of Graz, Austria, [6]Institut Präventive Medizin & Klinische Forschung, Germany, [7]University Hospital Parc Taulí Sabadell (UAB), Spain, [8]Institute of Rheumatology and Faculty of Medicine 1, Charles University, Czech Republic, [9]Sapienza Rome University, Italy, [10]Regional Hospital, University of Orleans, France, [11]University of British Columbia, Canada

Background: The VERO trial is an active-controlled fracture endpoint clinical trial that recruited postmenopausal women with low bone mass and prevalent vertebral fractures (VFx). We have previously reported a 52% (p<.001) reduction in the relative risk of clinical fractures [a composite of clinical vertebral and non-vertebral fragility fractures] in patients randomized to teriparatide (TPTD) compared to risedronate (RIS).1 In this original analysis, non-spinal fractures were defined according to the European Guidelines for the Evaluation of Drugs for the Treatment of Osteoporosis. Here we present a post-hoc analysis of the fracture results of the VERO trial restricted to the FRAX®-defined "major" osteoporotic fractures (MOF) (i.e.; clinical vertebral, hip, humerus and forearm), a widely used efficacy endpoint in recent osteoporosis trials.Patients and Methods: 1360 postmenopausal women (mean age [SD]: 72.1 [8.7] years) with at least 2 moderate or 1 severe VFx and low bone mass (BMD T-score ≤-1.5) were randomized (1:1) to SC daily TPTD 20 µg or oral weekly RIS (35 mg) in a double-blind, double-dummy, 2-year trial. Based on the full analysis set (680 patients in each treatment group), we calculated the cumulative incidence of patients and between-treatment comparison based on Kaplan-Meier and stratified log-rank tests, adjusted for antecedent of a recent clinical vertebral fracture in the 12 months before entering the study and recent bisphosphonate use. Patients who were lost to follow-up, died, or completed the study without experiencing a fracture were censored at the last date of contact.Results: 16 patients (2.6%) had ≥1 low trauma MOF in the TPTD group compared with 40 patients (6.4%) in the RIS group (hazard ratio 0.40; 95% CI: 0.23-0.68; p=0.001). Table shows the individual fracture location. Absolute MOF risk reduction was 3.8%. Clinical vertebral

fractures were the most frequent fractures: 7 patients in the TPTD group (1.1%) compared to 24 patients (3.9%) in the RIS group (hazard ratio: 0.29; 95% CI: 0.14-0.58; p=0.002). Conclusion: In postmenopausal women with severe osteoporosis, TPTD treatment was more efficacious than RIS, with a 60% lower risk of FRAX-defined major osteoporotic fractures during the 24-month treatment period.1Kendler DL et al. Lancet (2018);391:230-40

Association of Alendronate and Risk of Cardiovascular Events in Patients with Hip Fracture Ching-Lung Cheung*[1], Chor-Wing Sing[1], Angel Wong[1], Douglas Kiel[2], Elaine Cheung[3], Joanne Lam[4], Tommy Cheung[1], Esther Chan[1], Annie Kung[1], Ian Wong[5]. [1]The University of Hong Kong, Hong Kong, [2]Hebrew SeniorLife, Harvard Medical School, United States, [3]United Christian Hospital, Hong Kong, [4]Queen Mary Hospital, Hong Kong, [5]UCL School of Pharmacy, United Kingdom

The risk of cardiovascular events (CVE) with alendronate use in real-world hip fracture patients is unknown. This study aimed to investigate the risk of CVE with and without use of alendronate in patients with hip fracture. We conducted a retrospective cohort study using a population-wide database managed by the Hong Kong Hospital Authority. Patients newly diagnosed with hip fracture from 2005 through 2013 were followed until November 6, 2016. Alendronate and other anti-osteoporosis medications use during the study period were examined. We matched treated and non-treated patients based on time-dependent propensity score. The risks of cardiovascular mortality, myocardial infarction, and stroke between treatment groups were evaluated using conditional Cox regression stratified by match pairs. To examine the associations over time, outcomes were assessed at 1-, 3-, 5- and 10-years. Among 34,991 patients with newly diagnosed hip fracture, 4,602 (13.2%) received anti-osteoporosis treatment during follow-up. Physical functioning or survival prospect was not significantly different between treated and non-treated patients. 4,594 treated patients were matched with 13,568 non-treated patients. Results of Cox-regression analysis revealed that alendronate was associated with a significantly lower risk of one-year cardiovascular mortality (HR: 0.33; 95% CI: 0.17-0.65) and incident myocardial infarction (HR: 0.55; 95% CI: 0.34-0.89), whereas marginally significant reduction in risk of stroke was observed at 5- and 10-years (HR at 5-years: 0.82; 95% CI: 0.67-1; p=0.049; HR at 10-years: 0.83; 95% CI:0.69-1.01; p=0.065). The strength of the association declined over time but remained significant. Similar results were observed when all nitrogen-containing bisphosphonates were analyzed together. These findings were robust in multiple sensitivity analyses. Additional studies in other population samples and randomized clinical trials may be warranted to further understand the relationship between use of various anti-osteoporosis medication and risk of CVE in patients with hip fracture.

FRI-0904

Exploring a Teriparatide and Denosumab Sequencing Option: 18 month Interim Results Felicia Cosman*[1], David Dempster[2], Donald Mcmahon[2], Jeri Nieves[4]. [1]Columbia University, United States, [2]Helen Hayes Hospital, United States, [4]Columbia University and Helen Hayes Hospital, United States

In order to maximize the early anabolic effect of teriparatide, and to avoid tachyphylaxis, cyclic therapy might be useful. However, we have previously shown that cyclic teriparatide, in the absence of an intervening antiresorptive agent, does not increase BMD more than standard daily therapy. Since denosumab is a potent antiresorptive agent with a rapid off-effect, it might be the optimal agent to help maximize bone gains with cyclic teriparatide. After baseline evaluation, 70 postmenopausal women with osteoporosis were randomized to a 3-year protocol with: 18 months teriparatide followed by 18 months denosumab (Standard) or 3 separate 12 month cycles of 6 months teriparatide followed by one denosumab dose (Cyclic). Supplements of calcium, if needed, were recommended to achieve total intake >1200mg/day and vitamin D to maintain serum 25OHD>30ng/ml. Fasting serum samples for biochemical markers were obtained every 3 months. BMD (DXA) measurements of lumbar spine (LS), total hip (TH), femoral neck (FN), trochanter (TRO) and proximal radius (RAD) were performed every 6 months. Interim results from a pre-planned analysis on women who completed the 18-month protocol (n=63; 30 Standard and 33 Cyclic) are presented here. Baseline descriptive characteristics did not differ between groups (mean age 63.5, LS T-Score -2.7, TH T-Score -1.7, BMI 23.1). BMD increments for LS, TH and RAD are shown in the figure below (mean+SEM). In the LS, BMD increased progressively and similarly in both groups. In the TH, BMD increased in both groups, with a numerically larger

gain at 12 and 18 months in the Cyclic group (p=0.13). Increments in FN BMD were also numerically larger (NS) in the Cyclic Group at 12 and 18 months. There was no precipitous decline in any of the hip sites in the Cyclic group after transition from a single denosumab treatment at 6 months back to teriparatide at 12-18 months. RAD BMD declined progressively over 18 months in Standard, but with Cyclic, RAD BMD increased modestly from 6-18 months. We conclude that over 18 months, the Cyclic regimen resulted in higher BMD than Standard at sites containing more cortical bone, possibly due to minimization of cortical porosity and enhancement of secondary mineralization. Whether this benefit will persist over 36 months is not yet known. Final BMD results from the full 3-year study, including biochemical marker results, will be presented.

Treatments for Osteoporosis Do Not Reduce Overall Mortality Steven R. Cummings*[1], Li-Yung Lui[1], Douglas C. Bauer[2], Dennis M. Black[2]. [1]San Francisco Coordinating Center, CPMC Research Institute, United States, [2]San Francisco Coordinating Center, University of California San Francisco, United States

Background: There has been controversy about whether treatments that reduce the risk of fracture also reduce total mortality. It is a very important issue because, if treatments reduce mortality, then it would be cost-effective for almost all older adults to take a treatment for osteoporosis. Methods: We performed a systematic search for published data from randomized placebo-controlled fracture endpoint trials of treatments for osteoporosis; estrogen therapy and strontium were not included. We included placebo-controlled trials with at least 50 participants in the placebo group and at least one death; trials among those with secondary causes, such as corticosteroid use, were excluded. If there was more than one type of treatment, each treatment arm was compared to the placebo group. The prespecified primary analysis excluded selective estrogen receptor modulators (SERMs) and tibolone that have known hormonal effects that influence conditions besides fractures. A secondary analysis included those agents. As there was no significant heterogeneity (I2 = 0% P = 0.73), eligible trials were pooled using a fixed effects model.Results: We identified 32 published trials that included 107,164 participants and 2,803 deaths. Excluding 8 trials of SERMs or tibolone left 24 clinical trials with 63,371 participants and 2,070 deaths. There was no significant effect of treatments on mortality in the primary analysis: risk ratio = 0.96; 95% confidence interval: 0.88 - 1.04 (Figure 1). Similarly, there was no significant effect on mortality when SERMs and tibolone were included (0.99; 0.92 – 1.06).Conclusion: Treatments for osteoporosis do not reduce overall mortality.

Effect of Denosumab Versus Risedronate on Cortical and Trabecular Bone Microarchitecture by High Resolution Peripheral Quantitative Computed Tomography (HR-pQCT) in Glucocorticoid-treated Individuals Piet Geusens*[1], Stefan Goemaere[2], Nico Pannacciulli[3], Nancy Lane[4], Eric Lespessailles[5], Osvaldo D. Messina[6], Roland Chapurlat[7], Xiang Yin[3], Rachel B. Wagman[3], Joop Pw Van Den Bergh[1]. [1]Maastricht University Medical Center, Netherlands, [2]Ghent University Hospital, Belgium, [3]Amgen Inc., United States, [4]University of California, Davis, United States, [5]University Hospital Orleans, France, [6]Cosme Argerich Hospital, Argentina, [7]Hôpital Edouard Herriot, France

Purpose: Glucocorticoid (GC)-induced osteoporosis (GIOP) is the most common secondary cause of osteoporosis, yet many patients with GIOP do not receive osteoporosis therapy. In a study of patients initiating or continuing GC therapy, areal bone mineral density (aBMD) gains were greater with denosumab (DMAb) vs with risedronate (RIS) at the lumbar spine and total hip at 12 and 24 months. This substudy evaluated the effects of DMAb vs RIS on cortical and trabecular bone microarchitecture by HR-pQCT.Methods: The phase 3, randomized, double-blind, double-dummy, active-controlled study enrolled women and men ≥18 years receiving GC (≥7.5 mg prednisone daily or equivalent) for <3 months (GC-initiating [GC-I]) or ≥3 months (GC-continuing [GC-C]) before screening. All subjects <50 years had a history of osteoporosis-related (OP) fracture. GC-C subjects ≥50 years had lumbar spine, total hip, or femoral neck BMD T-score ≤?2.0; or T-score ≤?1.0 with history of OP fracture. Subjects were randomized 1:1 to subcutaneous DMAb 60 mg every 6 months or oral RIS 5 mg daily for 24 months; all were to receive daily calcium (≥1000 mg) and vitamin D (≥800 IU). In a subset, HR-pQCT (XtremeCT I; Scanco) scans of the distal radius and distal tibia were performed at baseline, Month 12, and Month 24; 110 slices of 82 μm thickness each were acquired, resulting in scan length of ~9 mm. Pixel size of the reconstructed images was 82 μm. Treatment differences (DMAb–RIS) were estimated with an analysis of covariance (ANCOVA) model.Results: 111 subjects (57 DMAb and 54 RIS) enrolled in the substudy. DMAb was associated with significantly greater increases than RIS in cortical thickness, total volumetric BMD (vBMD), and cortical vBMD at the radius and tibia at 12 and 24 months, and in trabecular vBMD at the radius at 12 months and tibia at 24 months (Table). Change in cortical porosity was not different between DMAb and RIS at either timepoint (Table). Results in the GC-I and GC-C subpopulations were overall similar to those in the two subpopulations combined.Conclusion: DMAb was associated with sustained improvements in cortical bone structure, as assessed by HR-pQCT of the radius and tibia, as compared with RIS. It remains to be elucidated whether increased cortical thickness with DMAb is associated with improved bone strength in GIOP. These results provide further support for DMAb as a treatment option for GC-treated patients at increased risk for fracture.

Table. Percentage Change From Baseline and Treatment Difference (DMAb—RIS) at Months 12 and 24 in vBMD and Cortical Microarchitecture at the Distal Radius and Distal Tibia

		Distal Radius		Distal Tibia	
		Month 12	Month 24	Month 12	Month 24

Abaloparatide Effect on Bone Mineral Density and Fracture Incidence in Postmenopausal Women with Osteoporosis Aged 80 Years or Older: Results from the ACTIVExtend Phase 3 Trial Susan Greenspan*[1], Fitzpatrick Lorraine[2], Bruce Mitlak[2], Yamei Wang[2], Nicholas C. Harvey[3], Chad Deal[4], Felicia Cosman[5], Mike Mcclung[6]. [1]University of Pittsburgh, United States, [2]Radius Health, Inc., United States, [3]MRC Lifecourse Epidemiology Unit, University of Southampton, United Kingdom, [4]Cleveland Clinic Foundation, United States, [5]Columbia University College of Physicians and Surgeons, United States, [6]Oregon Osteoporosis Center, United States

The risk of fracture increases with increasing age. Thus, it is important to understand efficacy and safety of osteoporosis treatments in elderly patients. In the ACTIVE phase 3 study, 18 months (M) of abaloparatide (ABL) treatment significantly increased bone mineral density (BMD) and reduced the risk of new vertebral, nonvertebral, clinical, and major osteoporotic fractures vs placebo (PBO). Women receiving ABL or PBO in ACTIVE were offered enrollment in the ACTIVExtend extension study in which both groups received 24M open-label alendronate (ALN) 70 mg weekly for a total of 43M (18M ABL or PBO, 1M for reconsent, and 24M ALN). The objective of this post hoc analysis was to evaluate efficacy and safety of ABL followed by ALN (ABL/ALN) vs PBO/ALN in the subgroup of patients aged ≥80 years in ACTIVExtend.ACTIVExtend enrolled postmenopausal women with osteoporosis between the ages of 50 and 85; 558 were from the original ABL group and 581 from the PBO group of the ACTIVE study. Pre-specified endpoints, including BMD, new vertebral, nonvertebral, clinical, and major osteoporotic fractures, were assessed over the 43M period. Nonvertebral fracture endpoints were assessed using the Kaplan-Meier (KM) method, proportional hazard model, and logrank test.A total of 56 ACTIVExtend patients (29 ABL/ALN; 27 PBO/ALN) were aged ≥80 years at ACTIVE baseline. Mean age was 81.8 years in both groups. Mean percent changes from baseline in total hip, femoral neck, and lumbar spine BMD were all significantly greater with ABL/ALN vs PBO/ALN at all timepoints assessed, except for total hip at M6. At M43, BMD mean percent change from baseline was 5.3% ABL/ALN vs 3.1% PBO/ALN (P=0.024) at the total hip, 4.6% ABL/ALN vs 3.1% PBO/ALN (P=0.044) at the femoral neck, and 17.2% ABL/ALN vs 8.6% PBO/ALN (P<0.0001) at the lumbar spine. Fracture rates were very low in both groups in this small subset of women (new vertebral: 0 ABL/ALN, 1 PBO/ALN; nonvertebral: 1 ABL/ALN, 2 PBO/ALN). Adverse event rates were similar between treatment arms with 78.6% and 81.5% of patients in the ABL/ALN and PBO/ALN groups, respectively reporting ≥1 treatment-emergent adverse event.In conclusion, significant BMD gains were maintained through 43M with ABL/ALN vs PBO/ALN. This post hoc analysis suggests that an ABL/ALN treatment was effective in an elderly subgroup of ACTIVExtend, with a safety profile similar across treatment arms.

Treatment gap following clinical vertebral fracture in the International Cost and Utility Related to Osteoporosis Fractures Study (ICUROS) Mattias Lorentzon*[1], Helena Johansson[2,3], Nicholas C Harvey[4], Anders Odén[2], Kerrie Sanders[4], Fredrik Borgström[5], Axel Svedbom[6], Eugene Mccloskey[2,7], John Kanis[2,3]. [1]Geriatric Medicine, Department of Internal Medicine and Clinical Nutrition, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg and Geriatric Medicine Clinic, Sahlgrenska University Hospital, Mölndal, Sweden, [2]Centre for Metabolic Bone Diseases, University of Sheffield, Sheffield, UK, Sweden, [3]Institute for Health and Aging, Catholic University of Australia, Melbourne, Australia, United Kingdom, [4]MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton and NIHR Southampton Biomedical Research Centre, University of Southampton and University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom, [5]LIME/MMC, Karolinska Institutet, Stockholm, Sweden, [6]Mapi, Stockholm, Sweden, [7]Mellanby Centre for bone research, Department of Oncology and Metabolism, University of Sheffield, Sheffield, United Kingdom

BackgroundClinical vertebral fractures are among the most severe osteoporotic fractures and lead to increased risk of morbidity and mortality. A prior vertebral fracture increases the risk of a subsequent vertebral fracture by four to five times. The greatest risk reductions with osteoporosis medications have been observed for vertebral fractures. The aim of the present study was to determine the uptake of bone-specific treatment in patients following a clinical vertebral fracture.MethodsAdults 50 years or older with a low to moderate energy fracture were included from ten countries in three continents (Europe, S America, Australasia) to the international study on costs and utility for osteoporotic fracture (ICUROS). Patients with clinical vertebral fractures were included within 2 weeks after the fracture, and followed for 18 months. Information about osteoporosis medication (excluding calcium/vitamin D) was collected at 4, 12 and 18 months after the clinical vertebral fracture.Results750 clinical vertebral fracture cases, 50 years or older, had information on osteoporosis medication. Mean age was 70.3 years and 81% were women. The treatment gap or the proportion of individuals not having fracture preventing treatment, 18 months after the fracture was 67% (95% CI: 63-70). A substantial heterogeneity was observed between countries. For example, in Italy the treatment gap was 99% (95% CI: 97-100, n=116) and in Russia 33% (95% CI: 26-40, n=187). The treatment gap was not significantly different between men and women and did not increase with age. For women, 60-69 years, the treatment gap was 60% (95% CI: 51-67) and for women, 80-89 years, it was 67% (95% CI: 56-78). The corresponding numbers for men were 72% (95% CI: 52-92) and 67% (95% CI: 40-94), respectively.ConclusionsEven though a clinical vertebral fracture dramatically increases the risk of subsequent vertebral fracture, and current osteoporosis medications being highly effective in preventing vertebral fractures, most patients do not receive secondary preventive treatment, as demonstrated by the substantial treatment gap in this large international cohort study.

FRI-0909

A Pooled Analysis of Fall Incidence from Placebo-controlled Trials of Denosumab Eugene Mccloskey*[1], Richard Eastell[1], Michael Mcclung[2], Nico Pannacciulli[3], Christine Wang[3], Susan Yue[3], Steven R. Cummings[4]. [1]The University of Sheffield, United Kingdom, [2]Oregon Osteoporosis Center, United States, [3]Amgen Inc., United States, [4]San Francisco Coordinating Center, United States

Purpose: In the pivotal fracture trial of denosumab in postmenopausal women with osteoporosis (FREEDOM), treatment with denosumab, a RANK ligand (RANKL) inhibitor, resulted in a lower subject incidence of falls not associated with fracture (log rank P-value = 0.02) compared with placebo [1]. In addition to its role in osteoporosis, the RANK/RANKL pathway has also been shown to play a role in muscle stregth in a murine model [2]. In an ad hoc exploratory analysis, we pooled data from additional placebo-controlled trials of denosumab to determine the consistency across trials of the reduction in the incidence of falls.Methods: The five placebo-controlled trials that contributed data to the FDA approval of denosumab for the bone loss indication were analyzed. These trials included study populations with low bone mass/osteoporosis and those receiving hormone ablation therapy. Trials in postmenopausal women with osteoporosis (FREEDOM, Trial 1, NCT00089791, [1]) and low bone mass (Trial 2, NCT00091793, [3]), men with osteoporosis (Trial 3, NCT00980174, [4]), women receiving adjuvant aromatase inhibitors for breast cancer (Trial 4, NCT00089661, [5]), and men receiving androgen deprivation therapy for prostate cancer (Trial 5, NCT00089674, [6]) were analyzed. The analysis was stratified by trial and only included data from the placebo-controlled period of each trial. A time-to-event analysis of first fall and exposure-adjusted subject incidence rates of falls (data not shown) were analyzed. Falls were reported as adverse events and not prospectively collected.Results: Kaplan-Meier estimates showed an occurrence of falls in 6.5% of subjects in the placebo groups (N = 5006), compared to 5.2% in denosumab-treated subjects (N = 5030), with an HR (95% CI) of 0.78 (0.66, 0.93), P-value 0.0053. The forest plot of time-to-first occurrence of fall is shown for both the individual studies and overall (Figure), and exposure-adjusted subject incidence rates of falls showed similar results. Heterogeneity in study designs did not permit overall assessment of association with fracture outcomes.Conclusions: Denosumab may reduce the

risk of falls in postmenopausal women with osteoporosis, in addition to the established fracture risk reduction in these patients.

	Hazard Ratio (95% CI)	Denosumab 60 mg Q6M (N = 5030) n/N (%)	Placebo (N = 5006) n/N (%)	Hazard Ratio (95% CI)

Teriparatide accelerates proximal humerus fracture consolidation – the TERAFRAP study Christian Muschitz*[1], Judith Haschka[1], Georg Langs[2], Markus Holzer[2], Andreas Baierl[3], Christoph Pümpel[1], Zora Messner[1], Roland Kocijan[1], Xaver Feichtinger[4], Rainer Mittermayr[4], Jakob E. Schanda[4], Thomas Hausner[5], Robert Wakolbinger[1], Jochen Schmidsfeld[6], Christian Fialka[4], Wolfgang Schima[7], Heinrich Resch[1]. Purpose: Systemic teriparatide (TPTD) enhances callus formation and mechanical strength after fracture in animal models and in humans. Less data exist on three-dimensional (3D) structural effects at the proximal humerus, a specific non weight-bearing cortical and trabecular bone site with high fracture incidence.Methods: This prospective double-blind placebo-controlled study investigated the effects of daily subcutaneous 20 µg TPTD induced changes in 3D bone structure over a 12-weeks treatment period. Untreated postmenopausal women and men with a recent non-surgically treated proximal humerus fracture (≤ 8 days) and without any comorbidity known to affect bone metabolism participated. To quantify localized changes over time, affine and subsequent non-rigid registration of baseline and follow-up high-resolution CT scans (128-row scanner, Somatom Definition AS+, Siemens) were performed. Scans covered proximal and distal humerus, with the arm constrained. At baseline one region of interest at the fracture was annotated for each patient. This region was computationally mapped to the same location in the F/U scan, and average Hounsfield unit values (HU) were extracted in the same region. The II° objectives included changes of baseline adjusted values of bone turnover markers (BTM) of formation (P1NP) and resorp-

tion (CTX), areal BMD (aBMD: iDXA, DXL) at spine, hip, calcaneus, changes in upper arm mobility (Constant Shoulder Score), pain (VAS) and SF-36 quality of life (QoL) scores. Results: Fifty-three of 82 screened patients (42 f, 11 m; mean age 75 years) were randomized either to TPTD or placebo, with 13 patients excluded (surgery, withdrawal). Forty patients finished the trial. In the fracture regions of the TPTD patients superior increases of HU values from baseline to follow up (average delta, +176.1; p<0.001 vs. placebo +125.2; p=0.007) were observed. Simultaneously TPTD induced increases of P1NP levels by 59 µg/L, and CTX by 0.31 ng/mL (p<0.005 for both). Areal BMD improved at spine and hip (p<0.05 for both); QoL, VAS and mobility changes were more intense with TPTD compared to placebo (p<0.05 for all).Conclusion: After a proximal humerus fracture an early initiation of a daily 12-week administration of TPTD exerts favorable effects at the fracture region through rapid increases of BTM of formation. Additionally these patients benefit from enhanced upper arm mobility, a robust pain reduction and an improvement of their QoL after TPTD.

Localization of Prefracture Lesions in Atypical Femoral Fracture on Straight and Bowed Femurs Young Chang Park*[1], Kyu Hyun Yang[2]. [1]International St. Mary's Hospital, Catholic Kwandong University College of Medicine, Republic of Korea, [2]Yonsei University College of Medicine, Republic of Korea

PurposeThe aims of this study were to evaluate the clinical and radiological features of atypical femoral fractures (AFFs) in the straight group and anterolateral femoral bowing group, and to determine which factors were associated with the fracture height of AFFs in the total cohort and each subgroup.MethodWe separated the 99 patients into two groups according to the presence of anterolateral bowing (straight group vs. bowing group) using anterolateral bowing grading system. Therefore, 43 (43%) patients were classified into the bowing group and the remaining 56 (57%) patients were classified into the straight group. In the bowing group only, the estimated apex height was also measured on a standard anterior-posterior radiograph. The reference line, drawn from the tip of the greater trochanter to the center of the intercondylar notch, was moved parallel in order to touch the most curved (concave) site of the medial femoral cortex. Then, a perpendicular line to the reference line was drawn at the most curved site. The lateral cortex point where this perpendicular line reached was defined as the estimated apex. Clinical and radiological characteristics were compared between the groups. Multivariable linear regression analysis was performed to determine the effect of factors on fracture height.ResultsIn the straight group, 64% of AFFs occurred at the level of the lesser trochanter and subtrochanteric area. The remaining 36% of AFFs were distributed throughout the diaphysis, with decreasing prevalence from the proximal to distal diaphysis. On the other hand, all locations of AFFs in the bowing group were in the diaphyseal area, especially within the range from 40 to 60% of femoral length. The anterolateral bowing grade was not related with the fracture height of AFFs in the bowing group. Patients in the straight group were younger, heavier, and taller, and had a higher bone mineral density, smaller anterior and lateral bowing angles, and more proximal fracture height than those in the bowing group. Multivariable analysis showed that the presence of anterolateral bowing itself was the only factor associated with fracture height in the total cohort (p = 0.001). In the subgroup analysis, weight and lateral bowing angle in the straight group (p = 0.048 and p= 0.036, respectively) and the estimated apex height in the bowing group (p < 0.001) were associated with fracture height.ConclusionThe presence of anterolateral bowing and the level of apex of the bowed femur were important factors for the fracture height of AFFs.

Beta 2 Adrenergic Receptor Gene Deletion Enhances Periosteal Response to Mechanical Stimulation in Senescent Male Mice Sundar Srinivasan*, Dewayne Threet, Philippe Huber, Brandon Ausk, Leah Worton, Ron Kwon, Steve Bain, Ted Gross, Edith Gardiner. University of Washington, United States

Under physiological load, the sympathetic nervous system (SNS) directly suppresses trabecular bone formation through osteoblastic beta 2 adrenergic receptor (B2AR). Data in a previous report indirectly suggested adult (6 Mo) B2AR-deficient male mice might show an enhanced anabolic response to mechanical stimulation. Here, we tested that hypothesis directly, comparing periosteal mechanical response in B2AR-deficient (Adrb2-/-; KO) and Adrb2+/+ (WT) male mice, in aged (21 Mo) and young adult (5 Mo) animals. Prior to initiation of the study, KO and WT littermates underwent μCt scanning at right tibia mid-shaft for structural assessment and strain calculation. Then a 3d/wk, 3wk cantilever bending regimen of right tibia (50 cycles/bout) was applied using an established protocol (1700 με normal strain). Mice received calcein labels (d10, d19) for dynamic histomorphometry at periosteum of loaded and contralateral tibia midshafts.Baseline (contralateral) bone formation parameters were higher in tibias from young adult KO mice, with MAR, MS and BFR values +5%, +71%, +81% vs WT, respectively (all p<0.05); however, this difference was not observed in aged bones. On loaded bones of both aged and young adult B2AR KO and WT mice, periosteal MAR, MS and BFR were significantly increased by mechanical stimulation (all p<0.02; loaded vs contralateral). Similarly, in both age groups, bone formation on loaded KO tibias was significantly higher than on loaded WT bones: In aged mice, MS was 80% higher and BFR was 77% higher in KO vs WT; similarly, in young adult, MS and BFR were 96% and 122% higher, respectively, in the KO bones (all p<0.05). Adrb2 genotype was a significant factor in mid-shaft tibial geometry of young adult but not aged males, with periosteal and cortical areas about 9% smaller in KO mice (both p<0.02 vs WT). This size difference was associated with a higher calculated peak normal strain value for KO tibias vs WT in young adult (1993 ± 87 vs 1698 ± 66 με, p=0.004) but not in aged males (1604 ± 35 vs 1553 ± 48 με).Thus, B2AR KO enhances mechanical response in aged and young adult male mice, but the response in younger mice is confounded by altered structure and baseline modeling activity. In aged mice, enhancement of MS and BFR by B2AR KO is clear, and unconfounded by structural differences or baseline modeling activity. This genetic study therefore reveals distinct B2AR mediated effects on bone modeling and response to mechanical stimulation.

Plasminogen is Critical for Bone Fracture Repair by Promoting the Functions of Mesenchymal Progenitors Luqiang Wang*[1], Zhenqiang He[2], Duan Hao[2], Richard Mitteer[3], Yanqing Gong[2], Ling Qin[1]. [1]Department of Orthopaedic Surgery, Perelman School of Medicine, University of Pennsylvania, United States, [2]Division of Translational Medicine and Human Genetics, Perelman School of Medicine, University of Pennsylvania, United States, [3]Radiation Oncology and Neurosurgery, Perelman School of Medicine, University of Pennsylvania, United States

Plasminogen (Plg) is an inactive proenzyme that can be converted to the active serine protease plasmin for blood clot dissolution and plays a pivotal role in many physiological and pathological processes, such as embryogenesis, wound healing, fibrosis, tumor etc. To understand its function in bone regeneration, we compared the fracture healing process of Plg KO mice with their WT siblings and investigated the action of Plg on mesenchymal progenitors. MicroCT analysis revealed that Plg deficiency in 2-month old female mice causes 39%, 20%, 17%, and 15% decreases in tibial trabecular BV/TV, trabecular number, cortical area, and cortical thickness, respectively, and a 28% increase in trabecular separation (n=5/group). After a closed, transverse fracture on the tibial midshaft, Plg KO mice displayed drastically delayed fracture healing. In WT mice, callus formation normally peaks at 10 days and fracture site bridges at day 28. However, KO fractures displayed 66% and 57% decreases in callus volume and bone volume, respectively, and unchanged bone volume fraction compared to WT at day 7 post fracture (n=6 mice/group) and similar levels of decreases in callus and bone volumes at day 10 and 14 (n=6 mice/group/time point). KO fractures eventually reached a peak at 28 days but remained non-union at day 42. Histology showed that KO mice have 71% less cartilage formation at the early stage of healing, suggesting that Plg is required for the injury response of periosteal mesenchymal progenitors. In vitro, we found that 20 μg/ml Plg significantly increases the proliferation of periosteal mesenchymal progenitors by 1.5 fold and inhibits their cell death induced by ischemic condition (anoxia with low glucose). Plg also stimulated progenitor migration by activating MMP9 as shown by zymography analysis. To confirm the actions of Plg on mesenchymal progenitors in vivo, we injected Tomato+ WT mesenchymal progenitors into mice with hindlimb ischemia. Bioluminescence imaging showed that those cells were much less likely to survive and migrate at the injury site in Plg KO mice compared to those in WT mice. Taken together, we demonstrated a critical function of Plg in regulating mesenchymal progenitor proliferation, migration, and survival during the initiation stage of fracture healing. Our study also points out that drugs activating Plg might represent a novel direction for treating fracture non-union.

Strain-Specific Response of Inbred Mice to PTH Suggests Significant Genetic Control of the Bone Anabolic Response to Drug Therapy Douglas Adams*[1], Olivia Hart[2], Renata Rydzik[1], Dana Godfrey[2], Michael Zuscik[2], Cheryl Ackert-Bicknell[2]. [1]University of Connecticut, United States, [2]University of Rochester, United States

Teriparatide (human PTH:1-34) is an anabolic therapeutic used to treat osteoporosis, demonstrating reduced fracture incidence. However, clinical outcomes demonstrate variable response to PTH, with up to 44% of patients failing to achieve ≥3% bone mineral density (BMD) increase after at least 12 months of treatment. Collectively, studies in mice suggest that responses to intermittent PTH vary between strains and anatomical locations, but nearly all studies examined only one strain. Herein we directly compared the response of 3 inbred strains to 4 weeks of intermittent PTH (40 μg/kg/day) versus saline (control), initiating treatment at 8 weeks of age in male A/J, 129S1/SvImJ (129) and NOD/ShiLtJ (NOD) mice (n=5 mice per strain, per treatment). Whole body BMD was measured by DXA (PIXImus II, GE-Lunar). Architecture of femora and L4 vertebrae was measured via microCT imaging. Femora were subjected to 3-point flexure strength tests. Response to PTH was greatest in A/J mice, with significant increases in whole body (10%, P<0.001), femur (20%, P=0.001), and spine (19%, P=0.002) bone mass versus control, with concomitant increases in femoral strength (21%, P=0.007) and stiffness (17%, P=0.016). Nominal gains in whole body BMD occurred in the NOD (4%, P=0.062) and 129 (3%, P=0.088) animals. Modest increases in femoral mass were also observed (NOD = 9%, P=0.003, 129=13%, P=0.01). PTH had no effect on bone mass in the spine in either NOD or 129 mice. Femoral strength was increased in the 129 mice (13%, P=0.033), but not in the NOD animals (P=0.15). Reduction of mechanical test data to material properties demonstrated no effects of PTH on matrix material strength and stiffness for any of the three strains examined. This suggests that all gains in bone strength were due to changes in bone size and geometry and likely not due to improvement in material quality. This direct comparison between three commonly used inbred strains strongly reflects the clinical experience with response to PTH treatment ranging from the robust increases in bone seen in the A/J mice to the minimal response observed with the NOD mice. These data confirm that response to PTH is strongly genetically regulated. Identification of genes that control the response to intermittent PTH could provide clinical screening tools to prevent unnecessary Teriparatide treatment, and could elucidate pathways leading to novel or improved anabolic therapies for bone.

AZP-3404, a Short Peptide Derived from Insulin-like Growth Factor Binding Protein 2 (IGFBP-2), Ameliorates Metabolic Status and Trabecular Bone in Aged-Ovariectomized (OVX) Mice Thomas Delale*[1], Stephane Milano[1], Victoria Demambro[2], David R Clemmons[3], Clifford J Rosen[2], Thierry Abribat[1]. [1]Alize pharma 3, France, [2]Maine Medical Center, United States, [3]NPT Inc, United States

IGFBP-2 acts on osteoblast differentiation through its heparin-binding domain 1 (HBD-1) and is not dependent on its IGF-binding properties. AZP-3404, a short peptide analog of HBD-1, has been shown to increase trabecular bone formation and improve bone biomechanical properties in young OVX mice. Because bone metabolism, hormonal status and IGF-1/IGFBP system are altered in aging, the aim of this study was to evaluate AZP-3404 treatment on bone and body composition in aged OVX mice.This study was conducted in 13-month aged OVX or sham-operated C57BL/6J female mice. Ten-week treatment with AZP-3404 or vehicle (VHL) was started immediately after surgery (n=10/group). AZP-3404 was given s.c. twice daily at 1 or 3 mg/kg. During treatment, body composition was monitored by DXA. Post-mortem μCT was performed to evaluate metaphyseal trabecular and diaphyseal cortical parameters of the femur.At the end of VHL treatment, aged OVX mice gained more body weight and fat mass (g) than the sham-operated animals (+14% and +28% respectively, p<0.001). Femoral trabecular metaphyseal microarchitecture was markedly lower in the sham aged mice compared to young animals. In the aged mice, the farther from the epiphyseal region the scans were performed, the more the effect of OVX on bone was pronounced (VOI1: 0.3-1.05 mm: BV/TV -21%, ns; VOI2: 0.75-1.5 mm: BV/TV -37%, p<0.05). AZP-3404 at 1 mg/kg particularly improved trabecular bone at the VOI where the OVX effect was prominent (BV: +45%, p<0.05; BV/TV: +43%, p<0.05; Tb.Th: +22%, p<0.01; Tb. PF: -24%, p<0.01). In addition, AZP-3404 at 1 mg/kg decreased body weight gain (-6%; p<0.01, vs VHL) and this effect was associated with a decrease in body fat mass (-14%; p<0.05, vs VHL).In conclusion, AZP-3404 significantly improved trabecular microarchitecture at the femoral metaphysis and reduced body weight and fat mass gain in the aged OVX mice. These results support the continued development of AZP-3404 as a novel therapeutic approach for treating trabecular bone loss associated with metabolic disorders in elderly patients.

AZP-3404, a Short Peptide Derived from Insulin-like Growth Factor Binding Protein 2 (IGFBP-2), Improves Trabecular Bone in Ovariectomized (OVX) Mice Thomas Delale*[1], Stephane Milano[1], David R Clemmons[2], Clifford J Rosen[3], Thierry Abribat[1]. [1]Alizé Pharma 3, France, [2]NPT Inc, United States, [3]Maine Medical Center, United States

IGFBP-2 is a physiological regulator of osteoblast differentiation, a function that is not dependent on its IGF-binding properties. The heparin-binding domain 1 (HBD-1) of IGFBP-2 replicates this effect and stimulates bone formation in rodents. AZP-3404, a short peptide analog of HBD-1, designed for its osteoblast differentiation activity and improved pharmacokinetics properties is a drug candidate for treatment of bone disorders.This study was conducted to determine the effects of AZP-3404 on bone in ovariectomized (OVX) C57BL/6J female mice. A six-week treatment with AZP-3404 or vehicle (VHL) was initiated 3 weeks after OVX surgery in 8-week animals (n=10/group). OVX effects were confirmed by comparison with a sham-OVX group. AZP-3404 was given s.c. twice a day at 0.3, 1 or 3 mg/kg. rhPTH(1-34) was used as a reference anabolic drug and was injected s.c. at 40 µg/kg daily. During treatment, BMD was monitored by DXA. Post-mortem µCT was performed to evaluate metaphyseal trabecular and diaphyseal cortical long bone parameters. Static and dynamic femoral histomorphometry was also evaluated as well as biomechanical properties of femoral neck.Prior to treatment, OVX animals showed increased body weight (+8%, p< 0.001), decreased total (-12%, p< 0.001) and vertebral (-23%, p< 0.001) BMD compared to sham. Compared to VHL, AZP-3404 increased BMD, especially at the vertebral level (+16.7%, p<0.05) at 3 mg/kg, whereas PTH showed a 4.5% increase. At the distal femoral metaphysis (VOI: 0.3-1.05 mm from epiphysis), AZP-3404 improved trabecular microarchitecture, particularly at 1 mg/kg (BV: +23 %, p<0.01; BV/TV: +18 %, p<0.05; Tb.N: +16 %, p<0.05; Tb. PF: -15%, p<0.01). These effects were more pronounced (e.g.; BV/TV: +37.4 %, p<0.05) at a more proximal VOI (0.75-1.5 mm) and were also observed for tibia (e.g.; BV/TV: +32.0 %, p<0.01). At the same femoral VOIs, PTH showed only 6.5% and 9.7% increases, respectively. PTH also increased femoral cortex thickness by +6.1 % (p<0.01). Static histomorphometry confirmed µCT data. Like PTH, AZP-3404 tended to increase trabecular BFR/TV, while only PTH had an effect on MAR. Importantly, AZP-3404 at 1 mg/kg improved femoral neck strength (maximum load: +11.6%; work-to fracture: +43.3 %; p<0.05).In conclusion, AZP-3404 significantly improved trabecular bone and biomechanical properties in OVX supporting its use as a novel therapeutic agent for treating bone disorders associated with trabecular bone loss.

A Novel Bone Anabolic Conjugated Drug (C3) Can Rebuild Bone in an Ovariectomized (OVX) Rat Model: A Novel Approach for Reversing Osteoporotic Bone Loss Marc Grynpas*[2], Zeeshan Sheikh[1], Robert Young[3]. [1]University of Toronto, Canada, [2]Sinai Health System, Canada, [3]Simon Fraser University, Canada

Introduction: There is an unmet need to find new anabolic drugs to rebuild bone lost to osteoporosis. By linking a PGE2 receptor analog (EP4a) to a bisphosphonate (ALN) in a conjugated drug (C1), we have shown that bone loss can be recovered. However this conjugated drug does not allow for bone remodeling and results in overproduction of bone that renders bones mechanically weak. In this study we adopted a conjugate bone-targeting approach where a synthetic, stable EP4 agonist is covalently linked to an inactive alendronate (ALN) that still binds to bone and allow physiological bone remodeling (C3).Methods: In this curative experiment, the following 7 groups of rats were treated for 8 weeks via tail vein injection (after losing bone for 12 weeks). 1) Sham, 2) OVX, 3) OVX +C3 low and high (4), 5) OVX+C1, 6) inactive ALN alone and 7) mixture of unconjugated ALN and EP4a (to assess the effect of conjugation) (n=10 for each group). We used microCT to determine bone architecture; static and dynamic histomorphometry to determine bone turnover and biomechanics to measure bone mechanical properties.Results: This experiment demonstrated that C3 treatment significantly increased vertebral bone mineral density and trabecular bone volume versus OVX controls. Biomechanical testing showed that C3 treatment led to significant improvement in the load bearing abilities of the vertebrae compared to OVX controls; C3 stimulated bone formation and increased load bearing in femurs. We have shown in this research study that C3 led to significant anabolic effects on trabecular bone while the effects associated with C1 were beyond physiological levels. Conjugation between the EP4a and ALN components was crucial to the drug's anabolic efficacy as it allowed for the local delivery of EP4a via the bone targeting ability of ALN.Conclusion: The C3 conjugate demonstrated, for the first time, that a combined therapy using an anabolic agent linked to an inactive ALN has significant anabolic effects, yet allow bone remodelling. This would be clinically very useful in the future for treating patients suffering from post-menopausal osteoporosis linked bone loss
Treatment effects of the conjugate drug (C3) in the proximal tibial metaphysis. Representative images scanned using Back Scatter Electron Microscopy (X80 mag)

FRI-0977

Abaloparatide is as Effective as PTH (1-34) in Improving Bone Formation While PTHrP (1-36) Has Less Effect in Mice. Carole Le Henaff*[1], Florante Ricarte[2], Zhiming He[1], Joshua Johnson[1], Johanna Warshaw[1], Nicola Partridge[1]. [1]New York University, college of dentistry, United States, [2]Molecular Pharmacology Training Program, Sackler Institute of Graduate Biomedical Sciences, United States

Abaloparatide (ABL), a novel analog of parathyroid hormone-related protein (PTHrP) 1-36), has similar bone anabolic effects to teriparatide (PTH 1-34), but lesser bone resorption. As a result, ABL received FDA approval in 2017 and became the second FDA-approved osteoanabolic therapy for the treatment of osteoporosis. This study aims to elucidate the effects of PTH (1-34), PTHrP (1-36), and ABL on bone remodeling, in vivo, in mice. Intermittent daily subcutaneous peptide injections of 80ug/kg/day were administered to 4 month-old C57Bl/6 male mice for 6 weeks (n=10/group). DEXA was performed during the course of the treatment to assess changes in bone mineral density (BMD). Eighteen hours after the final injection, right femurs were harvested for µCT analyses and histomorphometry, sera were assayed for P1NP and CTX, and tibiae were separated into cortical, trabecular, and bone marrow fractions for RT-qPCR analyses. Here, we show that ABL resulted in a similar increase in whole body (+5%), femoral (+11.4%), and tibial BMD (+8%) compared with PTH (1-34) and no significant changes were seen with PTHrP (1-36). µCT analyses revealed similar increases in cortical thickness only with ABL (11.9%) and PTH (1-34, 10.7%). Assessment of serum P1NP and CTX levels showed that ABL (90ng/ml) was superior to PTH (1-34, 71ng/ml) and PTHrP (1-36, 49.5ng/ml) in stimulating greater levels of P1NP, and PTH (1-34, 26.5ng/ml) and ABL (24.5ng/ml) led to increases in CTX (control, 19.3ng/ml). Histomorphometry confirmed an increase in the MAR with PTH (1-34, +39%), ABL (+44%) and the BFR (+70% and +82%, respectively). PTHrP seemed to have no effect on P1NP and CTX levels but, surprisingly, had a significant effect on the MAR (+19%) and BFR (+44%). RT-qPCR analyses of trabecular bone showed that PTH (1-34) and ABL led to a similar rise in type-1 collagen, alkaline phosphatase, osteocalcin, and bone sialoprotein mRNA levels. These data show that ABL is equivalent to PTH (1-34) in increasing whole body, femoral, and tibial BMD. Also, PTH (1-34) and ABL exert similar effects on osteoblasts with an increase in osteoblastic gene expression and bone formation rate. Taken together, this study provides greater insight into the effects of PTH (1-34), PTHrP (1-36) and ABL in bone, and confirms that ABL is as effective on osteoanabolic as PTH (1-34).

FRI-0978

Vanadyl Acetylacetonate Increases Bone Formation and Inhibits Osteoclast Differentiation in a Diabetes-Related Osteoporotic Rat Model Jayenth Mayur*[1], Anthony Lin[1], Maximilian Muñoz[1], Kevin Mesina[1], Atharva Dhole[1], Savannah Roy[1], Daniel Coban[1], Suleiman Sudah[2], Joseph Benevenia[1], Jessica Cottrell[3], David Paglia[1], Sheldon Lin[1]. [1]Rutgers New Jersey Medical School, United States, [2]Robert Wood Johnson Medical School, United States, [3]Seton Hall University, United States

Osteoporosis is typified by deficits in osseous microstructure and cortical weakness. We evaluated Vanadyl Acetylacetonate (VAC), an organic Vanadium salt with an established anabolic role in bone healing, as a potential therapy. This study examined the phenotypic impact of VAC on Type 1 diabetes-related (T1DR) osteoporotic femurs and the cellular mechanism by which VAC controls bone homeostasis.A female T1DR osteoporotic rat model (Verhaeghe et al. 1990) was followed. Right femurs were injected with either 0.1 mL saline solution or 1.5 mg/kg VAC solution. At 4 or 8 weeks post-surgery, rats were sacrificed to evaluate micro-CT (n=6) and torsion testing (n=7) outcomes. At 8 weeks post-surgery, Calcein solution (Sims et al. 2014) was injected IP at 7 and 2 days prior to sacrifice to measure bone formation (n=5). To measure osteoclast (OC) differentiation, marrow was extracted 8-weeks post-surgery from contralateral femurs and cultured for 5 days in 3 different media: MCSF (control), MCSF + RANKL, and MCSF + RANKL + 3 mg/mL VAC (n=5; triplicate).

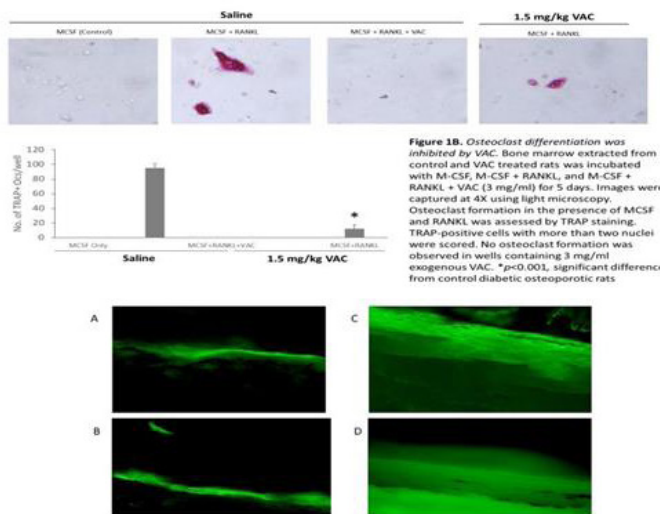
Cells were then fixed using 10% formalin and TRAP stained.At 8 weeks, VAC-treated femora showed a 10% decrease in percent cortical porosity (p<0.05), a 2.4% increase in cortical bone volume/tissue volume (BV/TV) (p<0.05), and a 45% increase in maximum shear stress (p< 0.005) (Figure 1A). At 4 weeks, there were no significant changes in cortical bone parameters or mechanical strength. Calcein labeling showed increased mineral apposition (31.4-fold; p< 0.05) and bone formation (26.9-fold) rates in VAC-treated femora compared to saline controls (Figure 2). OC quantification in MCSF + RANKL revealed a 91% reduction in OCs (p<0.001) in VAC-treated rats compared to saline controls. In cells extracted from saline controls and cultured in media containing VAC, there was a significant reduction in OCs (p<0.001) compared to cells cultured in the absence of VAC (Figure 1B).This study highlights VAC's effects on bone turnover and osteoclastogenesis in vivo. Calcein labeling suggests that VAC induces bone formation, thus normalizing cortical porosity in T1DR femora. We also found that VAC inhibited OC differentiation in vivo and in vitro, while not impairing supporting cells. An in vitro study (König et al. 2017) similarly showed that human OC differentiation was inhibited by Vanadium ions. In an aging T1DR osteoporotic population, VAC may prove to be an effective clinical adjunct in restoring bone porosity.
Figure 1A. Effects of VAC treatment on femoral biomechanical and microarchitectural parameters.
a. Values represent ratio of cortical porosity (Po(tot)) on operative side to that on contralateral non-operative side b. Effective shear stress of right femur c. Values represent ratio of cortical BV/TV on operative side to that on contralateral non-operative side
Data are expressed as mean±SE. *p<0.05, significant difference from control diabetic osteoporotic rats


Figure 1B. Osteoclast differentiation was inhibited by VAC. Bone marrow extracted from control and VAC treated rats was incubated with M-CSF, M-CSF + RANKL, and M-CSF + RANKL + VAC (3 mg/ml) for 5 days. Images were captured at 4X using light microscopy. Osteoclast formation in the presence of MCSF and RANKL was assessed by TRAP staining. TRAP-positive cells with more than two nuclei were scored. No osteoclast formation was observed in wells containing 3 mg/ml exogenous VAC. *p<0.001, significant difference from control diabetic osteoporotic rats

Low-intensity Pulsed Ultrasound (LIPUS) Prevents Development of BRONJ-like Pathophysiology in Rat Alveolar Bone Defect Induced by Tooth Removal after Alendronate and Porphyromonas Gingivalis Challenges
Kouki Hidaka*[1], Yuko Mikuni-Takagaki[1], Satoko Wada-Takahashi[1], Makiko Saita[2], Ryota Kawamata[4], Takenori Sato[1], Akira Kawata[1], Chihiro Miyamoto[1], Yojiro Maehata[1], Hirotaka Watabe[1], Nobuyuki Tani-Ishii[2], Nobushiro Hamada[1], Shun-Suke Takahashi[1], Shinji Deguchi[4], Ryohei Takeuchi[5]. [1]Kanagawa Dental University, Graduate School of Dentistry, Department of Oral Science, Japan, [2]Kanagawa Dental University, Graduate School of Dentistry, Department of Oral Interdsciplinary Medicine, Japan, [4]Kanagawa Dental University, Graduate School of Dentistry, Department of Dentomaxillofacial Diagnosis and Treatment, Japan, [5]Yokosuka City Hospital, Department of Joint Surgery, Japan

Bisphosphonate-related osteonecrosis of the jaw (BRONJ) was first observed in cases of multiple myeloma and metastatic bone cancer treated with nitrogen-containing bisphosphonates (N-BPs) and later in osteoporotic patients undergoing long-term treatment with oral N-BPs. Although the exact cause, induction, and the reason for its site-specific occurrence often after tooth extraction, remain unknown, the disease is often successfully treated with antibiotics. Involvement of human γδTCR to phosphoantigens, which can be provided by both certain bacteria and N-BPs, has been suggested (Kalyan S, J Bone Miner Res 2016).

In addition, we found site-specific mechanotransduction in isolated jaw bone osteoblasts which can promote bone remodeling. Namely, mandibular osteoblasts, which thrive under the constant challenge of oral bacteria are unique in expressing molecules such as Bcl-2 and RANKL only when mechanically loaded with LIPUS, and their expression is regulated by α5β1 integrin (Exp Cell Res 2011). Hypothesizing that the sudden loss of occlusal force after tooth extraction may increase the risk of BRONJ, we tested the protective effect of LIPUS as a surrogate occlusal force in a rat BRONJ model prepared in ovariectomized rats by subcutaneously administering 35 μg/kg/week alendronate (ALN), a common N-BP, for 5 weeks and then for another 3 weeks with additional periodontopathic Porphyromonas gingivalis (Pg) bacteria, by topical application targeting the maxillary first molars. After removing the tooth, LIPUS was applied extrabuccally to the extraction socket 5 times a week for 4 weeks for the experimental ALN+Pg+LIPUS group rats. Consequently, we found delayed healing only in the rats given both ALN and Pg but not in the rats with individual interventions, neither in ALN+Pg+LIPUS group rats. Exposure to daily LIPUS prevented development of deficiencies in ALN+Pg group such as lowered BMD in the alveolar bone, periosteal reaction of new bone formation as well as the eliminated expression of Hsp70, IL-6, Bcl-2 and RANKL mRNAs, all essential to bone regeneration, in the remote leg bone marrow cells. Development of BRONJ-like pathophysiology, at least in this model which is challenged by N-BP and periodontopathic bacteria, was avoidable with LIPUS exposure. In addition to the known effect of LIPUS of inhibiting local inflammation, normalization of the systemic humoral processes of regeneration is likely critical to the maintenance of alveolar bone.

FRI-0980

A Novel Cathepsin K Inhibitor Specifically Approaching Bone Resorption Surface to Suppress Osteoclastic Bone Resorption Xiaohao Wu*, Jun Lu, Jin Liu, Lei Dang, Aiping Lu, Ge Zhang. Hong Kong Baptist University, Hong Kong

Recently, the development of Merck's phase III Cathepsin K (CatK) inhibitor Odanacatib (ODN) has been terminated since increased risk for developing stroke was found in ODN-treated patients. Interestingly, our preliminary data revealed that this risk might be due to the non-specific delivery of ODN to non-target tissues. Thus, our study aimed to develop a new inhibitor to selectively approach bone resorption surface to inhibit CatK activity for suppression of osteoclastic bone resorption.The ODN was chemically conjugated with an osteoclast-targeted oligopeptide moiety D-Asp8 to synthesize the (D-Asp8)-ODN conjugate. The selectivity and Inhibitory efficiency of (D-Asp8)-ODN conjugate on CatK activity were determined by in vitro enzyme inhibition assay. In vivo distribution of the (D-Asp8)-ODN conjugate was analyzed by biophotonic imaging and histological analysis in an ovariectomized (OVX) mice model of osteoporosis. The CatK activity was measured by enzyme activity assay. In addition, the therapeutic effects of (D-Asp8)-ODN conjugate in OVX mice were measured by ELISA, micro-CT and bone histomorphometry and compared with ODN-treated (positive) as well as vehicle-treated (negative) controls.The (D-Asp8)-ODN conjugate exerted selectively inhibitory effect on CatK activity without off-target effects on other cathepsins (i.e. cathepsin B, S and L), and the inhibitory efficiency was comparable to ODN. Our data further demonstrated that the D-Asp8 could facilitate the conjugated ODN selectively approaching the bone resorption surface and selectively inhibiting the CatK activity in bone tissues without disturbing the CatK activity in non-bone tissues. Furthermore, the (D-Asp8)-ODN conjugate dramatically lowered the serum level of CTX-I (a marker of osteoclastic bone resorption) and attenuated deterioration of bone micro-architecture as compared with vehicle-treated controls in OVX mice during osteoporosis development. More importantly, the in vivo anti-resorptive effect of (D-Asp8)-ODN conjugate was also comparable to that of ODN.Collectively, we demonstrated that the osteoclast-targeted moiety D-Asp8 could facilitate the conjugated ODN selectively approaching bone resorption surface to inhibit the CatK activity for suppression of osteoclastic bone resorption during osteoporosis development in OVX mice. These findings indicate the (D-Asp8)-ODN conjugate as a novel osteoclast-targeted CatK inhibitor candidate for further translational development.

[18F]NaF PET/CT can identify a silent ''chronic'' state of Fibrodysplasia Ossificans Progressiva Esmée Botman*[1], Pieter Raijmakers[2], Maqsood Yaqub[2], Bernd Teunissen[2], Coen Netelenbos[1], Lothar Schwarte[3], Wouter Lubbers[3], Adriaan Lammertsma[2], Marelise Eekhoff[1]. [1]Department of Internal Medicine, section Endocrinology, Netherlands, [2]Department of Nuclear Medicine and Radiology, Netherlands, [3]Department of anesthesiology, Netherlands

Fibrodysplasia ossificans progressiva (FOP) is a rare, autosomal dominant disorder characterized by heterotopic ossification (HO) in muscles, tendons and ligaments. Flare-ups often precede the formation of HO. Due to progressive contractures without any clinical sings the existence of a chronic, smoldering progressive disease is assumed. Recently, [18F]NaF PET/CT was able to identify ossifying flare-ups, therefore we used the [18F]NaF PET/CT to search for the existence of this assumed but never confirmed "chronic" stage of FOP. Methods: a total of thirteen consecutive [18F]NaF PET/CT-scans from five FOP patients were analyzed. The scans were acquired over 0.5 – 2 years. An in-house tool was used for identifying and analyzing the heterotopic bone structures. Volume of HO and standardized uptake values (SUV) were assessed.Results:Two out of five patients experienced ≥1 active clinical flare-ups at the time of the [18F]NaF PET scan. In four out of five patients the serial scans showed progression of HO in the absence of a flare-up or any other clinical signs. This volumetric increase was present for over 10% of the identified HO structures, all were accompanied by increased 18F-sodium fluoride uptake (figure 1). In conclusion, HO may progress throughout the disease and the [18F]NaF PET/CT is a promising modality to identify these asymptomatic, chronically progressive HO lesions. [18F]NaF PET/CT appears to be an adequate imaging technique to detect and follow-up on HO formation both during active an chronic FOP disease. Importantly, future drugs should target both active and chronic HO activities in FOP.

Figure 1. Increased [18F]-Sodium Fluoride uptake in an asymptomatic, progressive heterotopic bone structure

Heterotopic ossification in the right thoracic region.
Consecutive [18F]NaF PET/CT-scans obtained within an eight months window showed a volumetric increase of >5cm³. Increased [18F]-sodium fluoride uptake was found compared to other, non-progressive structures.
NB. vertebrae exhibit the highest [18F]-sodium fluoride uptake in the body, due to, among others, mechanical stress

Sustained Efficacy and Safety of Burosumab, an Anti-FGF23 Monoclonal Antibody, for 88 Weeks in Children and Early Adolescents with X-Linked Hypophosphatemia (XLH) Thomas O. Carpenter*[1], Wolfgang Högler[2], Erik Imel[3], Anthony A. Portale[4], Annemieke Boot[5], Agnès Linglart[6], Raja Padidela[7], William Van'T Hoff[8], Gary S. Gottesman[9], Meng Mao[10], Alison Skrinar[10], Javier San Martin[10], Michael P. Whyte[9]. [1]Yale University School of Medicine, United States, [2]Birmingham Children's Hospital, United Kingdom, [3]Indiana University School of Medicine, United States, [4]University of California, San Francisco, United States, [5]University of Groningen, Netherlands, [6]APHP Hôpital Bicêtre Paris Sud, France, [7]Royal Manchester Children's Hospital, United Kingdom, [8]Great Ormond Street Hospital, United Kingdom, [9]Shriners Hospitals for Children, United States, [10]Ultragenyx Pharmaceutical Inc., United States

In children with X-linked hypophosphatemia (XLH), excess circulating fibroblast growth factor 23 (FGF23) causes hypophosphatemia with consequent rickets, skeletal deformities, and growth impairment. These skeletal abnormalities are associated with pain and impaired physical functioning. We previously reported that treatment with burosumab, a fully human monoclonal antibody against FGF23, improved phosphate homeostasis and rickets severity in children with XLH. Here, we report the long-term data from the Phase 2 Study CL201 (NCT02163577), including data from children who switched from every 4 (Q4W) to every 2 week (Q2W) dosing at Week 64.Fifty-two children with XLH (5-12 years old, Tanner ≤ 2) were randomized 1:1 to receive subcutaneous burosumab Q2W or Q4W for 64 weeks. Doses were titrated up to 2 mg/kg per dose to achieve serum phosphorus levels within 3.5-5.0 mg/dL. All subjects entered the long-term extension at Week 64, in which Q4W-treated subjects changed to the Q2W regimen; treatment continued through Week 88.The significant improvements in Total Rickets Severity Score (RSS) and the Radiographic Global Impression of Change (RGI-C) observed at Week 64 were maintained through Week 88. In the Q4W→Q2W group, 13 (50%) subjects demonstrated substantial healing of rickets (RGI-C ≥+2) by Week 64; 3 additional subjects in this group showed substantial healing of rickets by Week 88. Improvements in standing height Z score and distance walked in the 6-Minute Walk Test were sustained through Week 88. Significant increases in serum phosphorus (mg/dL) were maintained through Week 88 (mean [SE]: Q2W 3.36 [0.06]; Q4W→Q2W 3.26 [0.09]). For the 9 subjects who transitioned into adolescence (ranging from ~12 years of age at baseline to 14.6 years of age at Week 88), improvements in serum phosphorus and rickets severity were maintained. One subject had concurrent serious AEs (hospitalization for fever/muscle pain) which resolved within a day. Other AEs were generally mild to moderate in severity; no new serious AEs emerged between Weeks 64-88. No clinically meaningful changes in serum calcium or iPTH occurred. No subject discontinued therapy or developed hyperphosphatemia.Long-term burosumab treatment maintained improvements in clinical outcomes, including rickets severity, growth, and physical ability in children and early adolescents with XLH. Children that changed from the Q4W to Q2W regimen at Week 64 showed continued improvement in rickets severity.

Table 1. Evidence of Long-term Efficacy with Burosumab in CL201

Assessment	Q2W (n=26)	Q4W→Q2W[a] (n=26)
Serum Phosphorus, mg/dL, mean (SE)		
Baseline	2.38 (0.08)	2.28 (0.06)
Week 64	3.35 (0.09)	2.96 (0.07)
Week 88[a]	3.36 (0.06)	3.26 (0.09)
RSS Total Score, mean (SE)		
Baseline	1.92 (0.23)	1.67 (0.20)
Week 64	0.81 (0.12)[b]	0.94 (0.10)[b]
Week 88[a]	0.87 (0.14)[b]	0.84 (0.11)[b]
RGI-C Global Score, LS mean (SE)		
Week 64	+1.56 (0.11)[b]	+1.58 (0.11)[b]
Week 88[a]	+1.67 (0.14)[b]	+1.85 (0.09)[b]
Substantial Healing, (RGI-C ≥ +2.0), n (%)		
Week 64	15 (58)	13 (50)
Week 88[a]	15 (58)	16 (62)
Standing Height Z Score, mean (SE)		
Baseline	-1.72 (0.20)	-2.05 (0.19)
Week 64	-1.54 (0.22)[c]	-1.92 (0.16)[d]
Week 88[a]	-1.47 (0.20)[b]	-1.94 (0.16)[d]
6MWT, percentage predicted norm, mean (SE)		
Baseline	79.32 (2.60)	81.42 (2.96)
Week 64	85.00 (2.03)[c]	84.74 (2.67)[d]
Week 88[a]	85.55 (1.85)[d]	84.17 (2.70)

[a]At Week 64, Q4W regimen group changed to Q2W regimen through Week 88. [b]P<0.0001 LS mean change from baseline using the GEE model. [c]P<0.001 LS mean change from baseline using the GEE model. [d]P<0.05 LS mean change from baseline using ANCOVA. Decreases in RSS and increases in RGI-C indicate improvement.

FRI-1021

In a Randomized, Placebo-Controlled Trial Of Teriparatide (TPTD) For Premenopausal Idiopathic Osteoporosis (IOP), Tissue-Level Bone Formation Rate at Baseline and 3 Months Predicts Bone Density Response Adi Cohen*[1], Stephanie Shiau[2], Nandini Nair[1], John Williams[1], Robert Recker[3], Joan Lappe[4], David Dempster[1], Hua Zhou[5], Mafo Kamanda-Kosseh[1], Mariana Bucovsky[1], Julie Stubby[3], Elizabeth Shane[1]. [1]Columbia University Medical Center, United States, [2]Mailman School of Public Health, United States, [3]Creighton University Medical Center, United States, [4]Creighton University, United States, [5]Helen Hayes Hospital, United States

Premenopausal women with IOP (PreMenIOP) have marked deficits in bone mass, microstructure and stiffness. On tetracycline-labeled transiliac biopsies, bone formation rate (BFR) varies from very low to elevated. In a pilot study of teriparatide (TPTD) in 21 PreMenIOP, we observed marked increases in BMD, but 20% had no change at any site. We initiated a double-blind, placebo-controlled, single-switchover study of TPTD (20mcg SC QD) in 41 PreMenIOP. Subjects (37±8 yrs) were randomized to ActiveTPTD (n=28) or Placebo (n=13) pens. At 6M, those randomized to Active TPTD continued for 18M; those randomized to Placebo began ActiveTPTD and continued for 24M. Transiliac biopsy was performed at 3M, with tetracycline labelling before initiating and after 2.5M on TPTD or Placebo.Subjects had low lumbar spine (LS) Z scores (-2.2±0.9) and averaged 3±3 fractures. Age, BMI, serum CTX, PINP, LS and radius BMD were similar; total hip (TH) and femoral neck BMD were higher in the Placebo group (p<0.05). During the first 6M, LS BMD increased more in ActiveTPTD than Placebo (5.5±4.2% vs 1.8±4.0%; p=0.01) with no significant differences elsewhere. The ActiveTPTD group had larger 3M increases in cancellous (CAN), endocortical (ENDO) and intracortical BFR (p<0.01-0.001) and larger 3M rises in CTX (+270±420 vs -60±170 pg/mL; p=0.01) and PINP (+61±95 vs -6±9 ng/mL; p=0.02).During the first 12M on active TPTD, BMD increased by 8.2±6.4% at LS, 3.1±4.0% at TH and 2.2±3.8% at FN. As in the pilot study, 20% had no increase in BMD. Baseline BFR predicted 12M change in BMD at LS (CAN: r=0.4, p=0.03; ENDO: r=0.4, p=0.01) and TH (CAN r=0.5, p=0.004). 3M change in ENDO BFR predicted 12M change in BMD at LS and TH (both r=0.5, p=0.02) and in CAN BFR tended to predict TH BMD change (r=0.4;p=0.06). Baseline CTX (not P1NP) predicted LS BMD response to TPTD (r=0.4; p=0.03), while 3M changes in CTX and P1NP did not. Those randomized to Placebo first (received 12M of TPTD during M6-18) gained less LS BMD on ActiveTPTD than those randomized to ActiveTPTD first (4.1±6.5% vs 10.1±5.4%; p=0.005), but other sites did not differ. Compliance, assessed on returned pens, averaged >90%, did not differ during the 6M RCT or the first 6M or 12M on active TPTD, and did not predict BMD response.In conclusion, these results demonstrate that PreMenIOP have significant increases in lumbar spine BMD after 6 and 12 months of TPTD. They also confirm that a subset of affected women do not respond to TPTD. Both baseline and TPTD-induced 3M increases in tissue-level bone formation rate are significantly associated with BMD response in PreMenIOP.

Age-related Changes and the Effect of Bisphosphonates on Bone Turnover and Disease Progression in Fibrous Dysplasia of Bone Pablo Florenzano*[1,2], Kristen S Pan[1,3], Sydney M Brown[1], Lori C Guthrie[1], Luis Fernandez De Castro[1], Michael T Collins[1], Alison M Boyce[1]. [1]Skeletal Diseases and Mineral Homeostasis Section, National Institute of Dental and Craniofacial Research, National Institutes of Health., United States, [2]Department of Endocrinology, School of Medicine. Pontificia Universidad Catolica de Chile., United States, [3]NIH Medical Research Scholars Program (MRSP), United States

Fibrous dysplasia (FD) is a mosaic disease in which bone is replaced with fibro-osseous tissue, leading to fractures, disability, and pain. FD lesions manifest during the first years of life and expand during childhood, reaching final disease burden by age 15. In vitro data suggests that affected cells apoptose with age, leading to decreased disease activity in adulthood, however no clinical data is available to support this concept. This is relevant for interventional studies with bisphosphonates and other bone-altering medications, which frequently use change in bone turnover markers (BTMs) as surrogate endpoints. The aims of this study are to describe: 1) the natural history of bone turnover in FD, 2) the impact of bisphosphonates on BTMs in FD, and 3) the effect of bisphosphonates on FD lesion expansion and formation during childhood. Methods: Alkaline phosphatase, osteocalcin, NTx, FGF23, RANKL, and skeletal burden score (a validated marker of FD burden) from 179 total subjects were reviewed (mean age at enrollment 19y, range 2-80), including 75 total subjects treated with bisphosphonates. Results: In adults not treated with bisphosphonates, BTMs demonstrated a significant reduction with age: alkaline phosphatase (n=40, p<0.01, r=-0.5), osteocalcin (n=21, p=0.01, r=-0.5), NTx (n=35, p<0.01, r=-0.6), and RANKL (n=18, p<0.05, r=-0.5). FGF23 also demonstrated a significant reduction with age (n=57, p<0.01, r=-0.4). Bisphosphonate treatment (n=30) resulted in an 18% mean reduction in alkaline phosphatase, but in only 17% of subjects did it decline to within the age-specific normal range. Disease progression in children ≤ age 15 was not affected by bisphosphonate treatment [yearly increase in skeletal burden score of 18% for treated subjects (n=15) vs 14% for untreated subjects (n=20), p=ns]. Conclusions: FD is associated with an age-dependent decrease in BTMs in adulthood, with or without bisphosphonate treatment. Bisphosphonates can decrease, but infrequently normalize, BTMs. Bisphosphonate treatment does not prevent

the development or expansion of FD lesions in children. Consideration of the age-related decline in FD-related bone turnover, the lack of effect of bisphosphonates on disease progression, and established side effects in this population, should be made when evaluating use and response of antiresorptive medications in patients with FD.

Trabecular Bone Score in Osteogenesis Imperfecta. Is it useful? Helena Florez*[1], Africa Muxi[2], Eva Gonzalez[3], Ana Monegal[1], Núria Guañabens[1], Pilar Peris[1]. [1]Metabolic Bone Diseases Unit, Department of Rheumatology. Hospital Clinic. University of Barcelona, Spain, [2]Department of Nuclear Medicine. Hospital Clinic, University of Barcelona, Spain, [3]Department of Immunology. Hospital Clinic, University of Barcelona, Spain

The trabecular Bone Score (TBS) is a novel gray-level textural analysis measurement that can be applied to DXA images to estimate trabecular microarchitecture and has been shown to be related to direct measures of bone microarchitecture and fracture risk. Osteogenesis impefecta (OI) is a congenital bone disease characterised by a low bone mineral density (BMD) and poor bone quality and strength. The usefulness of TBS in OI has been scarcely evaluated.PURPOSETo analyse the clinical usefulness of TBS determination in patients with OI and its relation with anthropometric and clinical features (especially concerning skeletal fractures and BMD results).METHODSThirty-four patients (23F:11M) with OI with a mean age of 40±15 years (19-70) attending a Metabolic Bone Disease Unit were included. The clinical reports of the patients were reviewed, with especial attention to the clinical features (weight, height and body mass index [BMI]), previous fractures, disease severity, associated mutations and treatments received. Lumbar spine (LS), total hip (TH), and femoral neck (FN) BMD were measured using DXA equipment (Lunar) in all patients. TBS was analysed in LS, and the results were classified in three categories1: TBS>1.310 (normal), TBS 1.230-1.310 (partially degraded microarchitecture), TBS<1.230 (degraded microarchitecture). TBS values were compared with a healthy control group of similar age and gender.RESULTS6/31 patients (19%) had a degraded microarchitecture, 8 (26%) a partially degraded microarchitecture and 17 (55%) normal TBS. All patients with TBS<1.230 were over 40 years old. 97% had a previous history of fractures, most with multiple fractures. Regarding BMD, 61% of the patients had osteoporosis, 36% osteopenia and one had normal values. Most patients had mutations in the COL1A1 or COL1A2 genes (66% and 34%, respectively). No significant differences were observed in BMD or TBS values according to the COL1 gen mutation (COL1A1 vs. COL1A2). A correlation was observed between TBS and age (r=-0.6, p<0.01), LS BMD (r=0.4, p=0.03), TH BMD (r=0.4,p=0.04) and with BMI (r=-0.5, p=0.01). No significant differences were observed on comparing TBS in patients and controls (1.297 vs. 1.399, p=N.S.).CONCLUSIONSTBS measurement does not seem to be useful for evaluating bone strength in patients with OI. Despite most patients presenting a history of multiple fractures, only 19% showed degraded microarchitecture with TBS. 1 McCloskey EV. J Bone Miner Res. 2016

FRI-1024

Achondroplasia Natural History: a Large, Ongoing Multi-Center Cohort Study Julie Hoover-Fong*[1], Michael Bober[2], Syed Hashmi[3], Jacqueline Hecht[3], Janet Legare[4], Mary Ellen Little[2], John Mcgready[1], Peggy Modaff[4], Richard Pauli[4], David Rodriguez-Buritica[3], Kerry Schulze[1], Elena Serna[3], Cory Smid[4], Adekemi Alade[1]. [1]Johns Hopkins University, United States, [2]AI duPont Hospital for Children, United States, [3]University of Texas, United States, [4]University of Wisconsin, United States

Objective: Information lacks about adverse health outcomes related to poor physical function, pain and obstructive/central apnea, and earlier adult and higher infant mortality in achondroplasia. To define the natural history, a large multi-center database with retrospective and prospective functionality was built. Materials/Methods: All available medical records from achondroplasia patients at a skeletal dysplasia center (i.e. Johns Hopkins, AI duPont Hospital, University of Texas, University of Wisconsin) from 1957 to date were gathered. There were 4 primary study domains: 1. Mixed longitudinal anthropometry (i.e. length/ht, wt, head circ); 2. Surgical burden; 3. Sleep disordered breathing; and 4. Radiographic catalogue. Phase 1 was establishment of this well-phenotyped achondroplasia cohort (i.e. Primary Achondroplasia Cohort, PAC). In phase 2, multivariate analysis across study domains will occur. A clinically active sub-cohort from the PAC will participate in prospective studies related to craniofacial structure and obstructive sleep apnea; metabolic health and obesity; neurocognition; and pain/function related to surgery. There is IRB approval. Results: The PAC includes 1,377 subjects (704 M:673 F, mean 15.2±12.1 yr, 75.5% de novo). The Active subcohort includes 471 subjects (250 M:221 F). 5.7% of the PAC were adopted. 39,000+ mixed-longitudinal anthropometric data points were collected to examine length/ht, wt and head circ trajectories. 1,116 subjects had 4,934 surgeries in 5 categories; 151 (10.7%) had no surgery. There were 2,757 ENT procedures (tubes, T&A) in 885 subjects. 138 subjects had 329 brain surgeries (i.e. VP shunt, ventriculostomy) while 250 (18.2%) had a foramen magnum decompression + C1/C2 laminectomy. Spine surgery occurred 430 times in 182 subjects, and 289 had 654 lower extremity procedures (i.e. osteotomy, lengthening). Data from 1556 polysomnograms are available from 666 subjects; 423 (63.3%) have obstructive

sleep apnea. There are 10,354 images from 1,249 subjects. Conclusions: This is the first multi-center natural history study of achondroplasia. We made novel observations about growth velocity and final adult height, surgical burden, and sleep disordered breathing. We are now examining interactions among study domains. This cohort may serve as controls against subjects treated with novel pharmacologic, medical and surgical interventions, and participate in prospective studies.

FRI-1025

The Effect of Burosumab (KRN23), a Fully Human Anti-FGF23 Monoclonal Antibody, on Osteomalacia in Adults with X-Linked Hypophosphatemia (XLH) Karl L. Insogna*[1], Frank Rauch[2], Peter Kamenický[3], Nobuaki Ito[4], Takuo Kubota[5], Akie Nakamura[6], Lin Zhang[7], Matt Mealiffe[7], Javier San Martin[7], Anthony A. Portale[8]. [1]Yale School of Medicine, United States, [2]McGill University, Canada, [3]Université Paris-Sud, France, [4]University of Tokyo Hospital, Japan, [5]Osaka University Hospital, Japan, [6]Hokkaido University Hospital, Japan, [7]Ultragenyx Pharmaceutical Inc., United States, [8]University of California, San Francisco, United States

In adults with XLH, excess FGF23 causes hypophosphatemia, leading to persistent osteomalacia – a defect in bone mineralization due to chronically low serum phosphorus. Osteomalacia is associated with fractures, pseudofractures, delayed fracture healing, and bone pain. Burosumab is a fully human monoclonal antibody against FGF23 under investigation for treatment of XLH.UX023-CL304 is an ongoing, open-label, Phase 3 study investigating the effects of 48 weeks of subcutaneous burosumab, 1.0 mg/kg administered every 4 weeks, on osteomalacia in adults with XLH who have not received oral phosphate and vitamin D therapy within 2 years of enrollment. The primary endpoint is improvement in osteoid volume/bone volume assessed by transiliac bone biopsies obtained at baseline and Week 48. Additional assessments include serum phosphorus, markers of bone turnover, fracture/pseudofracture healing, patient-reported outcomes, and safety.Fourteen subjects enrolled (mean age 40 years, 57% female), 13 completed 48 weeks, and 11 completed paired biopsies. At baseline, subjects demonstrated severe osteomalacia. All osteomalacia-related histomorphometric measures improved significantly at Week 48 (percent change: osteoid volume/bone volume -54%, osteoid thickness -32%, osteoid surface/bone surface -26%, mineralization lag time -52%). Mean serum phosphorus concentration, averaged across the mid-point of the dose cycle between Weeks 0-24, increased by 48%, consistent with previous findings. Markers of bone formation and resorption increased at Week 48 (LS mean increase: P1NP +77%, CTx +36%; both p<0.0001). Of the 4 active pseudofractures detected at baseline, 3 were healed and 1 was missing at Week 48. There were significant reductions in pain (LS mean change -1.86 p=0.0054) and global fatigue (-1.20 p=0.0359) scores. All subjects had ≥1 treatment-emergent adverse event (AE). Two subjects experienced serious AEs (migraine; paraesthesia) that were unrelated to treatment and resolved. The safety profile of burosumab was similar to that seen in larger clinical trials, with most AEs mild to moderate in severity. Eleven subjects had 18 procedure-related AEs: 15 for pain and 1 each for itch, headache, and bandage irritation. There were no deaths or incidents of hyperphosphatemia; 1 subject withdrew consent at Week 44.We conclude that treatment with burosumab significantly improves osteomalacia in adults with XLH, which should ameliorate the skeletal complications of this disease.

Table 1. Efficacy Assessments in UX023-CL304

Assessment	All Subjects[a]
Osteoid Volume/Bone Volume, %	
Baseline	26.1 (12.4)

FRI-1026

An overview of the etiology, clinical manifestations, management strategies and complications of hypoparathyroidism from the Canadian National Hypoparathyroidism Registry Rafik El Werfalli*[1], Yasser Hakami[1], Manoela Braga[1], Adam Millar[2], Zubin Punthakee[1], Farhan Tariq[1], J.E.M. Young[1], Aliya Khan[1]. [1]McMaster University, Canada, [2]University of Toronto, Canada

The Canadian National Hypoparathyroidism Registry (CNHR) was formed in 2014 and enrolment of prevalent and incident cases began following approval by McMaster University Ethics Review Board.Objective(s):• identify the etiology and presenting symptoms of patients with hypoPTH.• evaluate current treatment practice in Canada.• assess differences in presentation based on etiology of the disease.• compare parameters of calcium homeostasis amongst those developing complications of nephrolithiasis or nephrocalcinosis versus those without complications.• assess fracture risk in Canadian patients with hypoPTH. Material and Methods:118 patients aged >18 years registered in the CNHR were reviewed as per the following inclusion criteria:1. Chronic HypoPTH (low PTH in the presence of low serum calcium total or ionized below normal reference range for at least 6 months prior to enrolment)2. HypoPTH (including post-surgery) requiring calcium/calcitriol replacement to maintain normal calcium (total or ionized calcium level for at least 6 months prior to enrolment3. Pseudohypoparathyroidism with elevated PTH and low serum calcium (total or ionized) normal vitamin D and hyperphosphatemia were included.We reviewed etiology, clinical presentation, biochemical profile, management strategies, markers of skeletal health including fractures, bone mineral density (BMD), fracture risk and complications including nephrolithiasis/nephrocalcinosis, and basal ganglia calcification.Results: Most patients (72%) had postsurgical hypoparathyroidism, followed byidiopathic/autoimmune disease (25%) and pseudohypoparathyroidism (3%). The mean age of onset was 42.0 years, with mean duration of follow-up of 4 years. All patients were taking calcium supplements (100%); calcitriol was taken by 82.2% and 6 patients were receiving parathyroid hormone. Nephrolithiasis or nephrocalcinosis were present in 24.6% of treated patients despite a mean calcium phosphate product <4.4 mmol2/L2.Basal ganglia calcification was present in 8 of the 30 patients reviewed.Hospitalization was required in 40 of the 118 patients for symptoms of hypocalcemia.Conclusion:1. HypoPTH is associated with a significant disease burden and leads to hospitalization in a large number of patients.2. Renal complications were present in 24.6% of treated patients despite maintenance of a calcium phosphate product in the desired range (<4.4 mmol2/L2). The ideal calcium phosphate product needs to be reconsidered.3. Fracture risk was low in the absence of traditional osteoporosis risk factors.

Bone Remodeling and Bone Mass in Patients with Hypophosphatasemia Laura Lopez-Delgado*[1], Leyre Riancho-Zarrabeitia[2], Maite Garcia-Unzueta[1], Carmen Valero[1,3], Jair Tenorio[4], Marta Garcia-Hoyos[1], Pablo Lapunzina[4], Jose A. Riancho[1,3]. [1]Hospital UM Valdecilla, Spain, [2]Hospital Sierrallana, Spain, [3]Univ Cantabria, IDIVAL, Spain, [4]Institute of Medical and Molecular Genetics, Spain

Purpose: Hypophosphatasia (HPP) is a rare genetic condition caused by loss-of-function mutations of the gene that encodes the tissue nonspecitific alkaline phosphatase (ALPL or TNSALP). It is characterized by low serum levels of ALP. The clinical spectrum of hypophosphatasia (HPP) is broad and variable within families. Adult forms with mild manifestations may be incidentally discovered by the presence of low alkaline phosphatase (ALP) activity in serum. However, it is still unclear whether individuals with persistently low levels of ALP, in the absence of overt manifestations of HPP, present subclinical abnormalities of bone remodeling or bone mass.Methods: The aim of this study was to obtain a better understanding of the skeletal phenotype of adults with low ALP by analyzing bone mineral density (BMD), bone microarchitecture (Trabecular bone score, TBS) and bone turnover markers (P1NP and ß-crosslaps). Results: We studied 36 individuals with persistently low serum ALP not related to drug therapy or other secondary cause. In about half of them we identified a heterozygous mutation of the coding region of the ALPL gene. We found that patients with persistently low ALP indeed have a reduced bone turnover. They showed lower levels of P1NP (32.0±14.4 versus 50.6±24.0 ng/ml; p=0.00089) and ß-crosslaps (0.22 ± 0.19 versus 0.34 ± 0.21 ng/ml, p=0.008) than individuals in the control group. However, there were no significant correlations between serum levels of ALP and either P1NP or ß-crosslaps among patients with low ALP. Similar levels were found in patients with mutations and those without detected mutations. Despite the decreased bone turnover, there were no significant differences in BMD, bone mineral content or TBS between both patients and controls.Conclusions: These results strongly suggest that patients with persistent hypophosphatasemia have low bone remodelling even though they do not present evident clinical skeletal alterations or decreased BMD. This might render them more susceptible to anti-resorptive-related adverse effects such as the development of atypical femoral fractures.

Clinical Features of Patients with Tumoral Calcinosis: The Mayo Clinic Experience Jad Sfeir*, Kurt Kennel, Matthew Drake. Mayo Clinic, United States

Background: Tumoral calcinosis (TC) is characterized by ectopic tumor-like peri-articular deposits of calcium that can infiltrate muscles and tendons. Epidemiological data is very limited. Primary TC is commonly familial and associated with hyperphosphatemia. Genetic and phenotypic heterogeneity is present, however, and thus patients can have sporadic disease especially when serum phosphate levels are normal. Here we review our experience with this disease.Results: We conducted a retrospective review of patients with radiographic and/or pathologic evidence of calcinosis from January 1985 to December 2016. After excluding secondary causes, such as renal and connective tissue diseases, 33 patients were identified to have primary TC.Patients were primarily Caucasian (78%) women (85%). Approximately half (45.5%) had hyperphosphatemia. Median age at diagnosis for hyperphosphatemic disease was 15.5 years (9.5 – 58.65) versus 66.3 years (55.6 – 75.9) in patients with normophosphatemia.Plain films were required in all patients for the diagnosis of TC. Disease was localized in larger joints sites [hips (27%), shoulders (24%) and elbows (18%)], but smaller joints were almost as common (21% feet and 18% hands). One-third of patients had disease in more than one joint.Surgical excision was performed in two-thirds of patients for symptomatic and/or cosmetic indications. Recurrence occurred in 38%, at a median of 3.5 years after surgery (2 – 8); 75% of those with recurrence had hyperphosphatemia. Only one patient had major complications from surgery including infection, delayed wound healing and prolonged drainage. Sevelamer normalized serum phosphate in 3 out of 4 patients. Etidronate showed no improvement in symptoms or extent of disease. Alendronate and zoledronate were prescribed to 5 patients, but the follow up period was too short to estimate their effect.Conclusion: Although TC was originally thought to primarily affect patients of African descent, our data suggests that Caucasians are at risk too, possibly with a higher prevalence. Hyperphosphatemia was associated with increased TC severity and earlier diagnosis, whereas adults with normophosphatemia have milder disease. Surgery appears to be safe, although the risk of recurrence is substantial. Medical treatment is mostly directed at serum phosphate normalization. Etidronate is largely ineffective but more time is needed to judge the efficacy of newer bisphosphonates.

Mechanisms Underlying Increased Osteoclastogenesis in the Mouse Model of Osteogenesis Imperfecta Due to Mutation in Collagen Type I Iris Boraschi*[1], Eréne C Niemi[2], Frank Rauch[1], Mary Nakamura[2], Svetlana Komarova[1]. [1]Shriners Hospital-Canada/ McGill University, Canada, [2]University of San Francisco California, United States

Introduction: Osteogenesis imperfecta (OI) is the most common heritable bone fragility disorder, usually caused by dominant mutations in genes coding for collagen type I alpha chains, COL1A1 or COL1A2. Although, osteoclasts do not express or produce collagen, stimulated osteoclastogenesis and bone destruction were reported in OI.Objective: The aim of this study was to examine the osteoclast phenotype in a mouse model of dominant severe OI caused by a Col1a1 mutation, Col1a1Jrt/+ mice.Methods: Bone marrow and spleen osteoclast precursors were extracted, characterized and differentiated into mature osteoclasts by culturing with macrophage colony-stimulating factor and RANKL in vitro.Results: We found that more and larger osteoclasts were formed in vivo from bone marrow and spleen precursors of Col1a1Jrt/+ (OI) mice compared to wild-type littermates (WT). However, expression of the osteoclast markers genes, or signaling by calcium or NFATc1 were not significantly different between WT and OI. Osteoclast precursor frequency was similar in Col1a1Jrt/+ and WT mice, however, OI precursors were more sensitive to RANKL compared to WT. No significant difference was found in the protein expression of RANKL, OPG or RANK between OI and WT bone extracts or in vitro generated osteoblasts or osteoclasts. We have previously established that osteoclast formation is inhibited by collagen type I degradation fragments. The molecular weight of isolated Col1a1Jrt/+ collagen type I was approximately 50 kDa and was easily degradable by cathepsin K. We have previously demonstrated that osteoclast formation is inhibited by collagen type I and, more robustly by its degradation fragments. OI full length collagen type I was more effective in inhibiting osteoclast formation compared to WT, while OI collagen degradation fragments lacked osteoclast-inhibitory activity.Conclusion: We demonstrate that Col1a1 mutation results in an osteoclast phenotype even though osteoclasts themselves do not express this protein. One of the potential mechanisms is rapid degradation of mutated collagen type I resulting in complete lack of fragments with osteoclast inhibitory activity, and thus an absence of a negative feedback for osteoclastogenesis in OI.

An antibody against ALK2 extracellular domain reveals a role of dimer formation for signal activation Takenobu Katagiri*[1], Shinnosuke Tsuji[2], Sho Tsukamoto[1], Mai Kuratani[1], Satoshi Ohte[1], Kiyosumi Takaishi[2,3], Yoshihiro Kawaguchi[4], Jun Hasegawa[4]. [1]Division of Pathophysiology, Research Center for Genomic Medicine, Saitama Medical University, Japan, [2]Rare Disease & LCM Laboratories, R&D Division, Daiichi-Sankyo Co., Ltd., Japan, [3]Kensuke Nakamura, Modality Research Laboratories, Biologics Division, Daiichi-Sankyo Co., Ltd., Japan, [4]Modality Research Laboratories, Biologics Division, Daiichi-Sankyo Co., Ltd., Japan

Fibrodysplasia ossificans progressiva (FOP) is a rare autosomal-dominant disorder characterized by heterotopic ossification (HO) in soft tissues. Trauma induces acute progressive ossification in patients with FOP. A recurrent R206H mutation in ALK2, a type I receptor for BMPs, was found in the patients with typical FOP. The mutant ALK2 induces BMP signaling by binding to non-osteogenic ligand, activin A. We have developed rat monoclonal antibodies bind to ALK2 extracellular domain and inhibit signaling in response to ligand stimulation. In the present study, we examined an effect of the ALK2 antibody on HO induced by the mutant receptor and the molecular mechanisms underlying the activity in vitro. We established a novel knock-in mouse line carrying the R206H mutation, in which the mutant ALK2 is induced by Cre-dependent recombination. In mice crossed with CAG-CreERt, trauma-induced HO was observed in tamoxifen-injected mice. Unexpectedly, however, the HO was increased by treatment with the ALK2 antibody. The increase in HO by the antibody was also observed in mice locally injected adenovirus-Cre in skeletal muscle. We carefully examined effects of the antibody on signaling in vitro through mouse and human ALK2 of WT and the R206H forms. We found that the antibody enhanced signaling by mouse R206H, but not human R206H, in the absence of ligands. The F(ab')2 fragment of the antibody also enhanced mouse R206H, but the Fab fragment did not show such capacity. In addition, the antibody and the F(ab')2 fragment, but not the F(ab) fragment, induced a dimer formation of ALK2 on the cell surface. By generating chimera and substitution mutations between mouse and human ALK2 sequences, we identified a single residue critical for the responses to the antibody. Substitution of the residue identified in mouse R206H to the human residue caused a suppression of signaling by the antibody. This finding was further supported in human R206H vice versa. Moreover, all of thirteen mutants of human ALK2 found in patients with FOP were suppressed by the antibody in vitro. Taken together, these data suggest that the 2 arms of the antibody form a dimer of ALK2 on the cell surface. The formed dimer of mouse ALK2(R206H) is able to activate signaling in the absence of ligands, although it is inhibited to response to ligands. It was also suggested that the ALK2 antibody inhibits HO in the patients with FOP.

Activation of the pro-fibrotic TGFβ pathway contributes to the multiorgan dysfunctions in the CLCN7-dependent ADO2 Antonio Maurizi*, Mattia Capulli, Anna Curle, Rajvi Patel, Nadia Rucci, Anna Teti. University of L'Aquila, Italy

The chloride channel type 7 (CLCN7) is a ubiquitous gene essential for lysosome function in different cell types. However, missense mutations of CLCN7 are associated only with autosomal dominant osteopetrosis type 2 (ADO2), considered a pure bone disease caused by defective osteoclast function. As a consequence of this classification, ADO2 patients are investigated only for the bone alterations even though the ubiquitous CLCN7 expression suggests that alterations in other organs could also contribute to the patients' morbidities. We tested this hypothesis in a mouse model of ADO2 carrying the heterozygous Clcn7G213R mutation and applied an unbiased large-scale approach. RNA deep sequencing analysis of lungs, muscles and kidney transcriptomes showed an enrichment in the macrophage gene signature and an upregulation of the pro-fibrotic Tgfβ pathway in ADO2 vs WT littermates (p<0.05). In line with these results, histopathological analysis revealed perivascular fibrosis in ADO2 lungs (+1.5fold;p=0.005), muscles (+1.7fold;p=0.04) and kidneys (+3fold;p=0.01), vs WT. Accordingly, upregulation of Col1α1 expression was detected in ADO2 lungs (+6.7fold;p=0.001), muscles (+2.6fold; p=0.001), kidneys (+8fold;p=0.002) and bone marrow (+3.5fold;p<0.01), associated with a higher number of F4/80+ macrophages (+6fold;p<0.01). Macrophages are known to be involved in the onset of fibrosis and are the candidate cells that could induce the observed multiorgan alterations. In line with this hypothesis, ADO2 macrophages revealed higher lysosomal pH (+1.64 pH units;p< 0.001), LC3bII accumulation (+1.7fold) and increased p62 expression (+2.7fold), suggesting altered autophagy, which is known to be induced by TGFβ. Real-time RT-PCR confirmed the upregulation of Tgfb1 and Tgfb2 in ADO2 lungs and muscles, respectively (+1.5fold;p=0.01 and +2.6fold;p=0.0026), while both Tgfb1 and Tgfb2 were upregulated in ADO2 kidneys (+2.4fold; p=0.0008 and +1.4fold;p=0.03). Of note, Tgfb1 overexpression was also found in the bone marrow (+10fold;p=0.004). Consistently, the TGFβ-activated factors, a-Sma and Grem1, were upregulated in ADO2 lungs (+2.9fold; p< 0.0001) and muscles (+11.4fold;p=0.01). Moreover, the activation of the TGFb pathway was confirmed by increased pSMAD+ cells in the ADO2 lungs (+20 fold;p<0.001). Our work indicates that ADO2 is a systemic disease and that tissue macrophages and activation of the pro-fibrotic TGFβ pathway could mediate ADO2 organ fibrosis.

Autologous Regulatory T Cell Transplantation Enhances Bone Repair in a Mouse Model of Osteogenesis Imperfecta Meenal Mehrotra*, Inhong Kang, Shilpak Chatterjee, Uday Baliga, Shikhar Mehrotra. Medical University of South Carolina, United States

Osteogenesis imperfecta (OI), most common hereditary bone disease, is characterized by reduction in quantity of bone matrix that leads to repeated fractures and bone deformity. Incidence of OI in United States is estimated to be 1/20,000 live births. Long-term treatment to prevent fractures have their own side effects; therefore several strategies are being tested to enhance bone remodeling. It is known that skeletal homeostasis can be dynamically influenced by the immune system. Recent studies have shown that T lymphocytes could be essential in regulating homeostasis, survival and function of not only osteoclasts but osteoblasts as well, thus playing an important role in bone turnover. A previous study demonstrates improved bone formation after delivery of anti-inflammatory regulatory T cells (Treg's) during mesenchymal stem cell based bone regeneration. However, whether T cells, specifically Treg's, play a role in OI, a disease with high turnover and high fracture rates, has never been investigated before. For our studies we used B6C3Fe a/a-Col1a2oim/J (oim) model, which resembles Type III OI, a non-lethal but severe form. Characterization of T lymphocytes demonstrated that splenic T cells from oim mouse exhibited activated phenotype as compared to wild type (WT) T cells, which in turn correlated with higher secretion of effector cytokines, IFN-g and TNF-α. Furthermore, we also observed that oim mouse exhibited a quantitative decrease in CD4+CD25+Foxp3+ Treg's. Thus, we hypothesized that quantitative restoration of Treg's in OI would inhibit the higher pro-inflammatory cytokine secretion by T cells and lead to better bone formation. Enhanced improvement in trabecular and cortical parameters was observed by Micro-CT when oim mice were transplanted with WT bone marrow (BM) + WT Treg's as compared to those transplanted with WT BM alone. Interestingly, significant improvement in trabecular and cortical parameters was also observed when oim mice were transplanted with Treg's from another oim mouse (auto-transplantation). To determine mechanism of how Treg's mediate healing of bone, we examined their effects on osteoclasts and osteoblasts from oim mice. Conditioned media from WT as well as oim Treg's, not only suppressed osteoclast formation, but also caused a remarkable increase in osteoblast mineralization. Thus, understanding the contribution of Treg's to osteogenesis in OI could help develop autologous immunotherapy based treatment modalities for OI.

BMP signaling and BMPR dynamics and interactions are restrained by cell surface heparan sulfate, a mechanism likely altered in Hereditary Multiple Exostoses Christina Mundy*, Evan Yang, Paul Billings, Hajime Takano, Maurizio Pacifici. The Children's Hospital of Philadelphia, United States

Heparan sulfate (HS) is a key component of cell surface and extracellular matrix molecules. The HS chains specifically interact with a variety of signaling proteins, including bone morphogenetic proteins (BMPs), and regulate protein distribution, availability and activity on target cells. A deficiency in HS characterizes the rare pediatric disorder Hereditary Multiple Exostoses. HME is caused by loss-of-function mutations in HS-synthesizing enzymes EXT1 or EXT2 and is characterized by cartilaginous tumors (exostoses/osteochondromas) forming along the growth plate, causing multiple health problems. Previously we showed that genetic or pharmacological interference with HS function rapidly increases canonical BMP signaling, suggesting that HS normally limits BMP signaling. However, the mechanisms of this action remained unclear. Thus, we investigated whether HS regulates cell surface BMP receptor (BMPR) mobility, interactions and signaling. We transfected cell lines with constructs encoding Snap-BMPRII and Snap-BMPRIa fusion proteins. Co-transfected cells rapidly responded to BMP2 treatment with major increases in pSMAD158 levels; interestingly, the same occurred after treatment with HS antagonist Surfen. Such increases were counteracted by Noggin co-treatment, suggesting that they reflected an increase in endogenous BMP at the cell surface. To assess BMPR dynamics, we carried out fluorescence recovery after photobleaching assays and found that receptor mobility decreased after treatment with BMP2 or Surfen, suggesting that the receptors had transitioned to lipid rafts for signaling. To verify such lipid raft re-localization, we separated lipid raft from non-lipid raft cell surface domains by ultracentrifugation and found that treatment with Surfen did in fact shift a significant amount of BMPRII to lipid raft domains compared to untreated cells. Lastly, we performed in situ proximity ligation assays to monitor BMPRIA and BMPRII interactions on live cells and found that treatment with Surfen promoted receptor-receptor oligomerization compared to control cells. In sum, our data indicate that cell surface HS chains restrain BMP signaling by limiting ligand availability and BMPR dynamics and interactions. The HS deficiency in HME could hamper these mechanisms, increasing BMP signaling and inducing osteochondroma formation. Ongoing studies are investigating BMP and BMPR expression and signaling levels in tissues derived from patient osteochondromas.

FRI-1082

Gene expression profiling of sclerostin antibody-induced therapeutic response in growing Brtl/+ mouse model of osteogenesis imperfecta Hsiao Hsin Sung*[1,2], Rachel Surowiec[3], Rebecca Falzon[2], Lauren Battle[2], Chris Stephan[2], Michelle S. Caird[2], Kenneth M. Kozloff[3]. [1]RIMLS, Department of Rheumatology, Radboudumc, The Netherlands; Department of Oral and Maxillofacial Surgery, University of Michigan, [2]Department of Orthopaedic Surgery, University of Michigan, United States, [3]Biomedical Engineering, University of Michigan; Department of Orthopaedic Surgery, University of Michigan, United States

Osteogenesis imperfecta (OI) is a genetic disorder caused by mutations in the genes that encode type I collagen. Brtl/+ mouse is a model for OI characterized by increased bone fragility and loss in bone mass. Sclerostin antibody (SclAb) is a novel anabolic bone agent that increases bone mass and improves bone fragility in Brtl/+ mouse. Unknown is the specific transcriptional response modulated by SclAb in the OI model. The purpose of this study was to assess the differential gene expression induced by SclAb in the trabecular and cortical bone of the Brtl/+ OI mouse model after 1 and 5 weeks of treatment.3 week-old female WT and Brtl/+ mice were randomly assigned to SclAb (Amgen) treatment or vehicle injection (PBS), and injected s.c. at 25 mg/kg, 2X/week. Femoral trabecular and cortical samples of Brtl/+ and WT mice treated for one and five weeks (Total=8 groups; n=3/group) were carefully dissected, and RNA extractions were processed with the Qiazol and RNeasy micro kit. The RNA integrity number for all samples was above 7.0. RNA-Seq data were analyzed by Funrich, ClustVis, and IpathwaysGuide. qRT-PCR was performed to validate select genes. Statistical analysis was tested with two-tailed unpaired Student's t-test p<0.05 considered as statistically significant.Untreated Brtl/+ and WT show high levels of differentially expressed genes (DEGs) at 4 week-old that gradually decrease by 8 week-old (Figure 1A). The length of treatment, type of bone and phenotype determine the SclAb-induced adaptive changes. SclAb-induced cortical response tends to be sustained during the time, unlike the higher-fold change (FC) of differences in the trabecular after 5 week of treatment, possibly due to the catch-up growth (Figure 1B). After 5 weeks of treatment, SclAb seems to restore the gene expression involved in bone remodeling, and collagen organization comparable to a WT level (Figure 1C). In Brtl/+ mouse, SclAb induced differential expression of Sost gene (FC>1.5; p<0.05) in both types of bone, and length of treatment (Figure 1 D-E). This is not observed in the trabecular of 1 week-treated WT, suggesting a compensatory mechanism.These data suggest that SclAb regulate differentially the gene expression of cortical and trabecular bone. Understanding the influence of genotype on the therapeutic response is critical for developing patient-specific treatment strategies. In this study, observations of DEGs suggest bone type- and genotype-specific response to therapy between Brtl/+ and WT.

Figure 1. A) Volcano plots showing the global transcriptional changes (>1.5 FC; p<0.05) in trabecular and cortical bone of Brtl/+ and WT at 4 and 8 week-old (treated with PBS). The log FC is represented on the x-axis and the y-axis represents the log 10 of the p value. B) Venn diagram showing the number of DEG (>1.5 FC; p<0.05) in all type of genotype, bone type, and treatment duration. Panel 5 shows the overlapping number of genes among the 4 comparisons. Panel 1, 7 shows the early SclAb-induced response in Brtl/+ and WT, respectively. Panel 3, 9 shows the late response in Brtl/+ and WT, respectively. C) Heatmap, a subset of osteogenic- and collagen-related genes from trabecular and cortical bone of non-treated and treated Brtl/+ and WT mice, exhibiting at least 1.5-FC. D-E) Venn diagram showing genes that are differentially expressed (>1.5 FC; p<0.05) in trabecular and cortical bone of Brtl/+ treated and WT untreated compared to Brtl/+ untreated at 1 and 5 weeks of treatment (SclAb/PBS).

FGF23 Regulates Wnt/β-catenin Signaling-mediated Osteoarthritis in Mice Overexpressing High Molecular Weight FGF2 Patience Meo Burt*, Liping Xiao, Marja Hurley. UConn Health, United States

Although humans with X-linked hypophosphatemia (XLH) and the Hyp mouse, a murine homologue of XLH, are known to develop degenerative joint disease, the exact mechanism which drives the osteoarthritic (OA) phenotype remains unclear. Mice that overexpress high molecular weight FGF2 isoforms (HMWTg mice) phenocopy both XLH and Hyp including OA with increased FGF23 production in bone and serum. Since HMWTg cartilage also has increased FGF23 and there is crosstalk between FGF23-Wnt/β-catenin signaling, the purpose of this study was to determine if OA observed in HMWTg mice is due to FGF23 mediated-canonical Wnt signaling in chondrocytes given that both pathways are implicated in OA pathogenesis. HMWTg OA joints had decreased Dkk1, Sost, and Lrp6 expression

with increased Wnt5a, Wnt7b, Lrp5, Axin2, phospho-GSK3b, Lef1, and nuclear β-catenin as indicated by immunohistochemistry or qPCR analysis. Chondrocytes from HMWTg mice had enhanced alcian blue and alkaline phosphatase staining and increased FGF23, Adamts5, Il-1β, Wnt7b, Wnt16, and Wisp1 gene expression and phospho-GSK3b protein expression as indicated by Western blot compared to chondrocytes of Vector control and chondrocytes from mice overexpressing the low molecular weight isoform, which were protected from OA. Canonical Wnt-inhibitor treatment rescued some of those parameters in HMWTg chondrocytes, seemingly delaying the initial accelerated chondrogenic differentiation. Neutralizing FGF23Ab treatment was able to partly ameliorate OA abnormalities in subchondral bone and reduce degradative/hypertrophic chondrogenic marker expression in HMWTg joints in vivo (Fig.1). These results demonstrate that osteoarthropathy of HMWTg is at least partially due to FGF23 modulated Wnt/β-catenin signaling in chondrocytes.

Figure 1. Effect of FGF23Ab on joints of HMWTg and Vector female mice. **A,** Digital radiographs show flattening of the tibial plateau and joint space narrowing (bracket) in Vehicle-treated HMWTg mice, while FGF23Ab-treated HMWTg knees have a similar phenotype to both Vector control groups. **B,** 3D reconstructive images show pitting and erosion of the surface (yellow arrows) in the HMWTg + Vehicle knees compared to the smooth contour of all other groups. High-resolution microCT sagittal images of HMWTg + Vehicle display flattened tibia (dashed arrow), thinning and abnormal morphology of subchondral bone (white arrow) and decreased trabecular number and thickness in the femoral and tibial epiphyses. HMWTg + Fgf23Ab phenotype resembles that of Vector + Vehicle and Vector + Fgf23Ab groups. **C,** 3D morphometric parameters revealed a significant decrease in BV/TV, Tb.N, and Tb.Th and increase in Tb.Sp in HMWTg + Vehicle femoral epiphyses compared with Vector + Vehicle group, while there is some rescue in the HMWTg + FGF23Ab knees. BV/TV, trabecular bone volume; Tb.Sp, trabecular separation; Tb.N, trabecular number; Tb.Th; trabecular thickness. **D,** qPCR analysis of mRNA taken from the knees shows increased expression of ColX, Mmp13, and Mmp9 in HMWTg + Vehicle mice, with some rescue in the HMWTg + FGF23Ab group. **E,** Safranin-O staining show decreased articular cartilage thickness (bracket) in HMWTg + Vehicle, which is restored in HMWTg + FGF23Ab. **F-G,** Representative immunohistochemical staining show increased MMP13 and MMP9 expression (arrows) in femoral articular cartilage of HMWTg + Vehicle, which is decreased in HMWTg + FGF23Ab. N=3-4/group. Values are the means ± SD. •:compared with Vector + Vehicle $p<.05$. ¢:compared with Vector + FGF23Ab $p<.05$. $:compared with HMWTg + Vehicle $p<.05$. #:compared with HMWTg + FGF23Ab $p<.05$.

FRI-1118

Three months of vitamin D3, 2,800 IU/d has an unfavorable effect on muscle strength and physical performance in vitamin D insufficient, hyperparathyroid women – a randomized placebo controlled trial Lise Sofie Bislev*[1], Lene Langagergaard Rødbro[1], Lars Rolighed[2], Tanja Sikjaer[1], Lars Rejnmark[1]. [1]Department of Endocrinology and Internal Medicine, Denmark, [2]Department of surgery, Denmark

Introduction: Low vitamin D levels and/or hyperparathyroidism has been associated with reduced muscle strength and postural stability. Methods: In a double-blinded placebo controlled randomized trial, we aimed to investigate effects of vitamin D3 supplementation (2800 IU/d vs. placebo) for three months during wintertime in 81 healthy postmenopausal women with high PTH- and low 25-hydroxy-vitamin D (25(OH)D) (<20 ng/mL) . Maximal voluntary isometric muscle strength and maximal force production at upper- and lower extremities was measured with an adjustable dynamometer chair. We assessed physical performance by Time Up to Go test (TUG) and Repeated Chair Stands (RCS). Postural stability was assessed by a stadiometer, body composition by DXA and physical activity by a Physical Activity Scale questionnaire.Results: Median age was 65 (range: 60-76) years. At baseline, p-25(OH)D was 13±3.7 ng/mL and p-PTH 58±13.5 ng/mL with no significant differences between groups. Compared with placebo, vitamin D3 supplementation significantly increased levels of 25(OH)D and 1,25(OH)2D by 230% (95% CI: 189% to 272%, p<0.0001) and 58% (190% to 271%, p<0.0001), respectively, and lowered PTH by 17% (-23% to -11%, p<0.0001). Compared with placebo, vitamin D3 had a significant detrimental effect on maximal handgrip strength; -9% (-15% to -3%, p<0.01), knee flexion; -13% (-24% to -2%, p=0.02) and TUG test; 4.4%; (0.1 to 8.6, p<0.05). Total lean body mass and appendicular lean mass index did not change in response to treatment and neither did degree of physical activity. Vitamin D3 supplementation did not affect postural stability or RCS. Changes in 25(OH)D correlated with changes in handgrip (r=-0.25, p=0.04), knee flexion (r=-0.30, p=0.01) and TUG (r=0.22, p=0.05), whereas changes in PTH did not correlate with any of the stated measurements. Conclusion: Compared with placebo, supplementation with vitamin D3 2800 IU/d had an unfavorable effect on maximal muscle strength and physical

performance. This is the first study to report an unbeneficial effect of a relatively high daily dose of vitamin D3 on muscle strength. Our data warrants against use of too high doses of vitamin D.

Analyzing Fall Risk using Smart Phone Application in Subjects with Osteoporosis with and without Falls Krupa Doshi*[1], Seong Moon[2], Michael Whitaker[1], Thurmon Lockhart[2]. [1]Mayo Clinic, AZ, United States, [2]Arizona State University, United States

Background: Fall risk evaluation in osteoporosis is of high priority for research and clinical interventions. Loss of balance and body sway can be important risk factor for falls. We explored use of a wearable smart phone application(SPA) sensor (Lockhart Monitor) capable of measuring postural sway and gait stability in real-time and compared it to traditional force plate sway measurements (AMTI Force Plate). We hypothesized that postural and gait stability measures will differentiate fallers and non-fallers among adults with osteoporosis. Methods: 31 ambulatory adults with osteoporosis (27F, 4M; age (yrs) = 72.4 ± SD 9.3; 8 fallers) were studied in outpatient endocrinology dept. Postural transition time and static postural stability were measured using force plate and SPA. Dynamic data was collected using the SPA. Subjects were asked to remain standing and follow voice commands from the app. Walking trials were conducted at a self-selected pace over a 10 meter walk-way. Thereafter, a continuous long walking trial was conducted for 120 sec, minimum of 150 gait cycles. Walking aids were allowed.Results: No significant sway differences were observed between fallers and non-fallers' postural stability as measured by sway area, sway path length, and sway velocity using both the force plate and the SPA. However, significant differences were observed between walking patterns of fallers and non-fallers using the SPA (Table1). Dynamic stability was significantly different (p=0.009) with fallers exhibiting less stable gait as compared to non-fallers. Multiscale entropy in medial-lateral directions during walking was also significantly different (p=0.034) with fallers exhibiting less complexity. Finally, harmonic ratio was significantly different (p=0.009) between fallers and non-fallers. Conclusion: In individuals with osteoporosis, fallers were less stable than non-fallers during walking and exhibited more robot like gait as measured by dynamic gait patterns (dynamic stability, multiscale entropy, and harmonics). Thus, fallers and non-fallers with osteoporosis can be differentiated using dynamic real-time measurements that can be easily captured by a SPA, while traditional postural sway and gait patterns were found to be less sensitive in our study. Thus, dynamic gait assessment promises to be a more sensitive tool to study fall risks and dynamics of walking in adults with osteoporosis as compared to traditional postural sway and gait measurements.

	Dynamic Stability	Multiscale Entropy	Harmonic Ratio
Fallers (n=8)	1.642	10.565	1.921
NonFallers (n=23)	1.48	11.399	1.339
P-value	0.0096	0.0342	0.0094

FRI-1120

Genetic Basis of Falling Risk Susceptibility Katerina Trajanoska*[1], Felix Day[2], Carolina Medina-Gomez [1], Andre G. Uitterlinden[1], John Perry[2], Fernando Rivadeneira[1]. [1]Department of Internal Medicine, Erasmus Medical Center, Rotterdam, The Netherlands, Netherlands, [2]MRC Epidemiology Unit, University of Cambridge School of Clinical Medicine, Cambridge, United Kingdom

Background: Falls and fall-related injuries are growing healthcare problem in elderly people. Approximately one out of three older adults will experience at least one fall. Multiple factors can increase the risk of falling. We aimed to determine how much of an individual's fall susceptibility can be attributed to genetics.Methods: We conducted the first genome-wide association study (GWAS) to evaluate the genetic variation in fall risk in 89,076 cases and 362,103 controls from the UKBiobank. Individuals were genotyped with the Afymetrix UKBiobank chip. Model included age and sex analysed with BOLT-LMM v.2.3.1. Next, we used LD score regression to: 1). Estimate falling risk heritability 2). Test for genetic correlation with other traits and 3). Identify tissues where expression of genes related to fall-associated variants are enriched.Results: We identified two novel fall loci mapping near PER4 on 7p21.3 (rs2709062, OR=1.03, p=3.4x10-08) and near TSHZ3 on 19q12 (rs2111530, OR=1.03, p=1.2x10-08). Falling risk heritability was modest (2.5%). Falls had strong positive genetic correlation with fracture risk (rg=0.35, se=0.05), insomnia (rg=0.42, se=0.05), neuroticism (rg=0.26, se=0.08) and ADHD (rg=0.44, se=0.14); and strong negative genetic correlation with muscle strength (rg=-0.24, se=0.04), intelligence (rg=-0.12, se=0.04) and social well-being (rg=-0.29, se=0.05). Brain and in particular cerebellum tissue showed the highest gene expression enrichment (FDR<5%) for fall-associated variants.Conclusions: Falling risk constitutes a heritable, heterogeneous and polygenic trait genetically

correlated with fracture risk and grip strength. The cerebellum tissue enrichment of falls-associated variants corroborates the mediation of postural balance in the etiology of falls.

FRI-1121

Effects of Music-based Multitask Exercise (Jaques-Dalcroze Eurhythmics) versus Multicomponent Exercise on Physical Function, Falls and Brain Plasticity in Older Adults: A Randomized Controlled Trial Mélany Hars*[1], Natalia Fernandez[2], François Herrmann[3], René Rizzoli[1], Gabriel Gold[3], Patrik Vuilleumier[2], Andrea Trombetti[1]. [1]Division of Bone Diseases, Department of Internal Medicine Specialties, Geneva University Hospitals and Faculty of Medicine, Switzerland, [2]Laboratory for Behavioural Neurology and Imaging of Cognition, Campus Biotech, University of Geneva, Switzerland, [3]Division of Geriatrics, Department of Internal Medicine, Rehabilitation and Geriatrics, Geneva University Hospitals and Faculty of Medicine, Switzerland

Currently, no robust evidence exists to support one exercise type over another for prevention of physical decline and falls among older adults, primarily because of the lack of comparative trials. The music-based multitask program Jaques-Dalcroze Eurhythmics (JDE) has been shown to increase physical performances and reduce falls [1], but also to improve executive functions, which play a crucial role in falls risk. In the EPHYCOS study, we aimed to i) determine the effectiveness of a JDE exercise intervention compared with a multicomponent (MULTI) exercise intervention —an evidence-based fall prevention program— on physical function and falls, and ii) explore to which extent these interventions are associated with changes in brain structure and brain activity during a cognitive executive task.We conducted a prospective, randomized, single blind comparative effectiveness trial involving 142 community-dwelling older adults (130 women; 74.3 ± 6.5 years) at increased risk of falling. Participants were randomized to i) a JDE exercise program (once weekly, group-based) or ii) a MULTI exercise program (twice weekly, mix of group- and home-based) that included balance, gait, and strength training activities, for 12 months. Physical and falls outcomes were assessed over 12 months. In an exploratory sub-study (n=34), brain structure and function were also assessed through magnetic resonance imaging (MRI).At 12 months, physical performances improved in both groups, but the JDE group improved more than the MULTI group in gait and balance tests (e.g.,Timed up & Go and Tinetti tests: p for interaction= 0.013 and 0.030, respectively). The JDE program reduced falls as compared with the MULTI program (adjusted hazard ratio, 0.50 [95%CI, 0.29-0.87]). Exercise-related changes in functional brain MRI showed a decreased activation in the executive network in the JDE group, while an over-recruitment of motor and salience networks was observed in the MULTI group (Figure 1). Finally, an increase of grey matter density across several brain areas was observed in the structural analysis for the JDE group only.In conclusion, JDE exercise results in greater benefits compared with MULTI exercise for a variety of physical outcomes and for falls reduction in older adults. The JDE exercise-related improvements are associated with brain plasticity, including both functional and structural changes in regions related to executive functions. [1] Trombetti et al. Arch Intern Med 2011.
FIGURE 1. ILLUSTRATION OF THE BRAIN AREAS ASSOCIATED WITH CONFLICT RESOLUTION (BASED ON A MODIFIED ERIKSEN FLANKER TASK)
a) In blue, the brain areas reduced after the intervention (i.e. activated at baseline but no more activated at 12-month).
b) In red, the brain areas increased after the training (i.e. not activated at baseline and recruited at 12-month).
All the clusters presented are significant at the peak-level at p < 0.001, uncorrected for multiple comparisons, with a minimum cluster size of 50.

FRI-1122

Effect of Vitamin D3 supplementation on muscle strength in HIV+ postmenopausal women Michael Yin*[1], Mariana Bucovsky[1], John Williams[1], Danielle Brunjes[1], Arindam Roychoudhury [3], Ivelisse Colon[1], David Ferris[2], Susan Olender[1], P.Christian Schulz[3], Anjali Sharma[4], Cosmina Zeana[2], Barry Zingman[4], Elizabeth Shane[1]. [1]Columbia University Medical Center, United States, [2]BronxCare Health System, United States, [3]Weill Cornell Medical College, United States, [4]Albert Einstein College of Medicine and Montefiore Medical Center, United States

Background: Both falls and fractures are increased in older HIV+ individuals. Low vitamin D (VitD) levels have been associated with falls, fractures and poor muscle strength in observational studies, and VitD supplementation is associated with increased strength in some treatment studies. We hypothesized that VitD supplementation would improve muscle strength in HIV+ postmenopausal women with low serum VitD (<32 ng/ml). Methods: In a 12-month prospective, randomized, double-blind, placebo-controlled study of 69 HIV+ black and Hispanic postmenopausal women on antiretroviral therapy, we investigated the effects of daily Low (1000 IU; n=31) and Moderate (3000 IU; n=38) VitD doses on muscle mass and strength. The main outcomes were change in lean body mass by DXA and isometric and isokinetic muscle strength in the dominant lower extremity using the Biodex System 4 Pro. Isometric peak torque (force in Kg) was measured in maximum knee extension and flexion held for 6 seconds at 60° and normalized to body weight (Torque/BW, %). Isokinetic measures, from 5 repetitions of knee extension and flexion at 60° per second, included peak torque, work (force x distance, normalized to body weight, Work/BW, %), and average power (work/time, watts). Results: Mean age was 56+5 years, median CD4 count 722 cells/mm3 and 74% had HIV RNA<50 copies/ml. Serum 25-OHD did not differ between groups at baseline, but was higher in the Moderate than Low VitD group at 6 months (33.1±10.3 vs 27.8±8.1 ng/ml, p=0.03) and 12 months (30.2±9.6 vs 24.3±7.6 ng/ml, p=0.007). Baseline lower extremity isometric and isokinetic parameters did not differ between groups. In the Moderate VitD group, there were significant increases in lower extremity isometric torque, and isokinetic torque, work and power at 12 months, with no change in lean mass (Table). In the Low VitD group, the same parameters improved to a lesser extent than the Moderate VitD group, with only 2 parameters reaching significance. There were no statistically significant between-group differences in strength parameters or lean mass.Conclusion: VitD supplementation with 3000 IU daily significantly increased lower extremity muscle torque, work and power in HIV+ postmenopausal women, without a concomitant increase in muscle mass. Future and larger studies will be required to determine the optimal dose of VitD to improve muscle strength and to determine whether supplementation reduces the risk of falls and fractures in HIV+ individuals.

Mean ± SD	Low VitD			Moderate VitD

Importance of Recognizing Low Alkaline Phosphatase Levels in a Patient with Decreasing Bone Mineral Density Nada Alhashemi*[1], Christine Derzko[2]. [1]University of Toronto, Canada, [2]University of Toronto, St Michael's Hospital, Canada

Introduction:Hypophosphatasia is a rare metabolic bone disorder resulting from mutations in the gene encoding tissue nonspecific alkaline phosphatase (TNSALP). The hallmark is a low alkaline phosphatase level.Case discussion:A 76 year old woman was referred to the Metabolic Bone Clinic in July 2017 with decreasing bone density despite being on denosumab since 2013. She had longstanding osteoporosis and was on bisphosphonate from 2004 until 2012 .She was switched to denosumab in 2013. She gave a history of right 3rd metatarsal - and right 5th digit fractures in the past, while on bisphosphonate . Her medications included denosumab and vitamin D supplements. Examination revealed a body mass index of 20.7 kg/m2, increased occiput to wall of > 10 cm, reduced rib to pelvis distance of 1 fingerbreadth. She has scoliosis of the spine with no spine tenderness. Sclera and dentition were unremarkable. Investigations showed a low ALP of 9 U/L. Ca was upper limit of normal at 2.56 mmol/L. Vitamin D was optimal at 100 nmol/L. CBC, Creatinine, TSH were unremarkable. She was noted to have low ALP since June 2016. All documented readings were less than 30 U/L. Dual energy xray absorptiometry from 2017 showed decreasing bone density at the total hip and lumbar spine, from -1.1 to -1.4 and from -1.1 to -2.3 respectively despite being on denosumab. We suspected hypophosphatasia. An elevated urine phosphoethanolamine (PEA) supported the diagnosis, and genetic testing confirmed the mutation. Discussion:Hypophosphatasia is a rare inborn error of metabolism resulting from loss of function mutations in the gene encoding TNSALP. TNSALP is expressed in skeleton and teeth. Hypophosphatasia leads to accumulation of TNSALP substrates, including inorganic pyrophosphate (PPi) which is a potent inhibitor of skeletal mineralization. The diagnosis is made by persistently low ALP levels and supported by increased TNSALP substrates including elevated urinary phosphoethanolamine (PEA) and elevated serum pyridoxal 5'-phosphate (PLP).It is important to recognize that persistently low ALP levels may indicate hypophosphatasia. Antiresorptive therapy in such cases may further impair bone mineralization. Treatment involves optimizing vitamin D and calcium. Enzyme replacement therapy with asfotase alfa has been successfully used to treat children and adults.

Fracture risk in Chronic B-cell Lymphocytic Leukemia: a historic cohort study Anupam Kotwal*, Jad Sfeir, Matthew Drake. Division of Endocrinology, Diabetes, Metabolism, and Nutrition, United States

Background: Chronic B-cell lymphocytic leukemia (CLL) is a common condition affecting older patients that is usually characterized by a prolonged asymptomatic phase. The effects of CLL on bone health have been limited to advanced disease following chemotherapy. In addition to bone marrow infiltration, increase in circulating levels of cytokines might lead to altered bone metabolism. We aimed to evaluate the rate of fractures and their possible risk factors in patients with CLL.Methods: We reviewed all patients with CLL evaluated at Mayo Clinic in Rochester, first diagnosed from 1/1/2000 through 12/31/2010. CLL associated fractures (CAF) were defined as those occurring up to 1 year prior to or any time after CLL diagnosis. Non-parametric tests were used to compare variables in those with or without CAF.Results: In this cohort of 107 patients with CLL, median age was 71 years (IQR 62 – 78), 58% (n=62) were males and all patients were Caucasian. No patient was on medication to target CLL. Median follow-up was 8.3 years (IQR 5.1 – 12.7). Thirty four patients (37%) had a CAF, of which 27% were vertebral and 18% proximal femur fractures. Fracture rate was higher in females (44%) as compared to males (23%). Only 3 had >1 fracture. Median time to 1st fracture was 2.5 years after CLL diagnosis (IQR -0.05 to 9.5). We also evaluated for potential risk factors for CAF. Thirty two women (71%) were post-menopausal and they showed a significantly higher rate of CAF compared to pre-menopausal women (46% vs. 25%, respectively; p=0.02). Spontaneous and fall from standing height or less accounted for 87% of CAF. Osteoporosis by BMD criteria was present in 73% of those who sustained a CAF vs. 85% in those who did not (p=0.3), however only 56% of those who fractured had DXA evaluation. Fifteen percent of patients with CAF had a prior fracture history compared to 20% of those without (p=0.5). There was no statistically significant difference in age (p=0.5), BMI (p=0.2), smoking status (p=0.9) and alcohol status (p=0.3) between the two groups. Activity status (only known for 1/4th of the cohort) did not differ between the two groups. There was also no difference between chronic conditions known to impact bone health (such as diabetes mellitus, thyroid disease, renal disease) between the two groups. Mortality was 53% in patients with CAF compared to 49% in those without (p=0.6). Median survival after CLL diagnosis was 5.5 years with no difference between the two groups. Median fracture-to-death time was 1.3 years (IQR 0.4 – 5).Conclusions: More than 1/3rd of patients with CLL not receiving targeted therapy had a fracture 1 year prior to or any time after diagnosis, most of which were spontaneous or due to minor trauma. Risk factors included women and post-menopausal status. Impact of CLL on bone metabolism may precede CLL diagnosis, and highlights the need to assess bone health in patients with CLL to reduce fracture risk.

SAT-0011

Evaluation of an optimal cutpoint of parathyroid venous sampling gradient for localizing elusive cases of primary hyperparathyroidism Jooyeon Lee*[1], Namki Hong[1], Sujin Lee[1], Jong Ju Jeong[2], Byung Moon Kim[3], Dong Joon Kim[3], Yumie Rhee[1]. [1]Department of Internal Medicine, Severance Hospital, Endocrine Research Institute, Yonsei University College of Medicine, Seoul 120-752, Korea, Republic of Korea, [2]Thyroid Cancer Clinic, Yonsei University College of Medicine, Severance Hospital, Seoul, Korea, Republic of Korea, [3]Department of Radiology, Yonsei University College of Medicine, Severance Hospital, Seoul, Korea, Republic of Korea

Preoperative localization of abnormal parathyroid tumor before surgery by parathyroid venous sampling (PVS) has been reported to provide useful information in selected recurrent, elusive, or complicated cases of primary hyperparathyroidism (PHPT). Although the 2-fold (2.0X) increase in intact parathyroid hormone (PTH) in PVS has been considered significant, the optimal cutoff for the positive gradient in PVS remains unknown. Among a total of 198 consecutive patients (mean age 58 years, female 75%) with PHPT presented to a tertiary center between 2012 and 2017, 56 subjects who underwent PVS for equivocal or negative results from noninvasive localizations studies or for further confirmation were analyzed. 99mTc-sestamibi SPECT/CT (MIBI) was performed in all subjects for initial localization study. First, the optimal cutoff for PVS gradient was developed from a dataset of subjects with a single gland disease (n=36) confirmed by MIBI and pathology (development set). Then, the performance of new vs. conventional cutoff (2.0X) for lateralization was compared in subjects with multiple gland uptakes (n=12) or diffuse or no focal uptake (n=8) in MIBI (validation set). In development set, concordant results between radiological/ surgical findings and PVS was observed in 25 subjects (right side 13; left side 12), whereas discordant results were found in 11 subjects (opposite direction or no differences in PVS gradient in both sides). Because peak PVS gradient of all subjects in concordant group had a value equal to or higher than 1.4 whereas most of subjects (n=8/11) in the inconsistent group had PVS gradient lower than 1.4, 1.4 fold gradient (1.4X) in PVS was set as a potential alternative threshold. In validation set, applying 1.4X improved correct lateralization of lesions in both multiglandular diseases (50% to 62%) and no focal uptake in MIBI (75% to 81%) compared to 2.0X (Fig.1). Sensitivity for correct lateralization increased from 37% to 53% in multiglandular diseases and 56% to 78% in no uptake in MIBI while the specificity remained high in both conditions (100% in multiglandular diseases and 86% in no uptake in MIBI). In conclusion, PTH gradient cutpoint 1.4X performed better than 2.0X in lateralization of lesions with higher sensitivity for preoperative localization. Our findings suggest that

1.4-fold PTH gradient might provide a more sensitive threshold for localizing parathyroid lesions in selected cases of PHPT, which merits further validation.

Parathyroid hormone (PTH) deficiency in patients with hypoparathyroidism is associated with reduced bone turnover and increased bone mineral density (BMD). In the phase III placebo-controlled REPLACE and dose-blinded RELAY studies, rhPTH(1-84) treatment improved mineral homeostasis and increased bone turnover markers (BTMs) in adults with hypoparathyroidism.In RACE (NCT01297309), an open-label extension of REPLACE and RELAY, treatment with subcutaneous rhPTH(1-84) was initiated at 25 or 50 µg/day. Dose adjustments in 25-µg increments were permitted (up to 100 µg/day) if oral calcium (Ca) and active vitamin D could be reduced and serum Ca maintained at 8.0–9.0 mg/dL. Albumin-corrected serum Ca, 24-h urine Ca, serum phosphate, and serum alkaline phosphatase were measured. Bone turnover was evaluated by serum levels of BTMs; BMD was assessed by dual-energy x-ray absorptiometry. Baseline (BL) was defined as the start of rhPTH(1-84) treatment. Data are presented as mean ± SD.Of 49 patients enrolled (81.6% women; duration of hypoparathyroidism, 15.9±12.49 y), 40 (81.6%) completed 60 months of treatment. Serum Ca was maintained within the target range (BL, 8.4±0.70 mg/dL [n=49]; Month 60 [M60], 8.5±0.78 mg/dL [n=40]). There was a numerical reduction in urinary Ca excretion (BL, 356.7±200.37 mg/24 h [n=48]; M60, 246.3±132.21 mg/24 h [n=40]) and serum phosphate (BL, 4.8±0.58 mg/dL [n=49]; M60, 3.9±0.66 mg/dL [n=40]). Serum alkaline phosphatase levels increased and remained above BL, but within the normal range, over the study (BL, 67.0±18.72 U/L [n=49]; M60, 89.7±29.82 U/L [n=40]). BTMs increased from baseline, peaked at ~1 year following rhPTH(1-84) treatment, and then declined but remained above pretreatment values to M60. BSAP and CTX remained within the normal range and P1NP higher than normal over 60 months. BMD was relatively stable, except at the distal one-third radius, where a decline within the normal range was observed at M60 (Table). The most frequently reported adverse events were hypocalcemia (36.7%; n=18); muscle spasms (32.7%; n=16); and nausea, paresthesia, and sinusitis (30.6% each; n=15).Over 5 years, rhPTH(1-84) was associated with an acceptable safety profile, and had sustained pharmacodynamic effects on mineral homeostasis and bone turnover, as shown by maintenance of serum Ca within the target range, decreases in urinary Ca excretion and serum phosphate, increases followed by stabilization in BTMs, and reduced or stable BMD.

Table. Effects of rhPTH(1-84) on Bone Parameters						
	Baseline		Maximum Value		Month 60	
BTM	Mean (SD)	n	Mean (SD)	n	Mean (SD)	n
BSAP, µg/L (Normal 6–30 µg/L)	9.6 (3.32)	48	20.7 (12.18)	45	17.8 (13.82)	37
CTX, ng/L (Normal ≤690 µg/L)	213.0 (172.34)	48	699.1 (469.5)	47	463.7 (388.30)	37
P1NP, µg/L (Normal 20–108 µg/L)	33.7 (19.72)	49	201.5 (160.72)	46	144.1 (153.73)	38
BMD, Z-score	Baseline Mean (SD)	n	Month 60 Mean (SD)	n	Change from Baseline at Month 60 Mean (SD)	n
Lumbar spine	2.13 (1.471)	40	2.13 (1.516)	35	0.10 (0.985)	33
Hip–total	1.57 (1.123)	40	1.54 (1.093)	34	−0.04 (0.583)	32
Hip–femoral neck	1.45 (1.240)	40	1.39 (1.274)	34	−0.02 (0.666)	32
Distal one-third radius	0.94 (0.833)	40	0.50 (1.193)	35	−0.48 (0.962)	33

BMD=bone mineral density; BSAP=bone-specific alkaline phosphatase; BTM=bone turnover marker; CTX=cross-linked c-telopeptide of type 1 collagen; P1NP=aminoterminal propeptide of type 1 collagen

SAT-0013

Normocalcaemic Hyperparathyroidism: Study Of The Prevalence And Natural History In A United Kingdom Referral Population Marian Schini*[1], Richard Jacques[1], Nicola Peel[2], Jennifer Walsh[1], Richard Eastell[1]. [1]University of Sheffield, United Kingdom, [2]Sheffield Teaching Hospitals, NHS, United Kingdom

Rationale: Normocalcaemic hyperparathyroidism (NHYPER) is characterised by persistently normal calcium levels, elevated PTH values on at least two consecutive measurements, after excluding other causes of secondary hyperparathyroidism. It is usually encountered during the evaluation of secondary osteoporosis. It was recognised by the Third International Workshop on Asymptomatic Primary Hyperparathyroidism (PHPT). The prevalence of the disease in the literature varies significantly due to various definitions used; it is reported to be between 0.1 and 8.9%. The data on the natural history of this disease are sparse and inconclusive.Objectives: to identify the prevalence of NHYPER in a UK referral population using the international criteria and study the variability of serum calcium. To compare the variability of serum calcium in NHYPER and PHPT.Methodology: We retrospectively evaluated data from 6280 patients referred for a bone mineral density measurement. Using a statistical method (Mahalanobis distance) subjects were identified as 'normal' or 'abnormal' and using the reference intervals for albumin-adjusted calcium and PTH, these patients were divided in different categories. In order to identify NHYPER patients, we excluded the ones having either eGFR<60 ml/min/1.73m2 or 25(OH)D<50nmol/l, or no measurements available. Repeated measurements of calcium were used to calculate the variability. Patients with high PTH and high calcium (PHPT) were also identified and their variability was calculated and compared with the NHYPER group.Results: Based on laboratory results on the index day and the evaluation of their medical files, we identified 8 patients (mean age 70y, 86% female) with NHYPER (prevalence 0.1%). These patients had laboratory results available for an average of 5 years and the natural history of this disorder was studied. Only 2 patients (0.03%) had consistent normocalcemia throughout their follow up. The SD for the NHYPER group was 0.101 mmol/L (CV 4.0%). Out of the 129 patients identified with high PTH and high calcium, 27 (mean age 73y, 85% female) fulfilled the above-named criteria. Only 48% had persistent hypercalcaemia. The SD of the PHPT patient group was 0.087 mmol/L (CV 3.2%). The comparison of the variances of the two groups showed no statistical difference (p>0.05).Conclusions: The prevalence of NHYPER in our UK referral population is low. NHYPER patients often have episodes of hypercalcemia, so they probably suffer from PHPT. The variability of NHYPER and PHPT patients is similar, and this results in about half of patients with PHPT having normal serum calcium at some point.

SAT-0014

Low Volumetric Bone Density is a Risk Factor for Complications after Spine Fusion Surgery Yi Liu*[1], Alexander Dash[1], Andre Samuel[1], Eric Marty[1], Harold Moore[2], Brandon Carlson[1], John Carrino[1], Donald Mcmahon[3], Alexander Hughes[1], Han Jo Kim[1], Matthew Cunningham[1], Frank Schwab[1], Richard Bockman[1], Emily Stein[1]. [1]Hospital for Special Surgery, United States, [2]Weill Cornell Medical College, United States, [3]Columbia University, United States

Over 250,000 spine fusion surgeries are performed annually in the US. Complications after fusion result in significant morbidity and healthcare costs. Multiple factors, including osteoporosis, have been suggested to contribute to risk of complication and reoperation. However, most studies have used DXA, which is subject to artifact in patients with spine pathology and may not accurately diagnose osteoporosis in this population. This study investigated volumetric BMD (vBMD) as a risk factor for complication and reoperation after fusion. We hypothesized that patients with low vBMD have higher rates of post-operative complications. Patients enrolled in this retrospective cohort study had initial lumbar spine (LS) fusion at our institution between 1/11 and 12/16, and had pre-operative LS CTs and post-operative imaging available for review. Cox regression analysis was used to relate demographic factors (age, sex, BMI), smoking status, vBMD (T12-L5, using MindWays QCTPro phantomless software), surgical procedure (fusion approach, number of levels, use of bone graft or bone morphogenetic protein), and osteoporosis medications to post-operative outcomes and time to complication. Among 118 patients, mean age was 60±14 years, 59% were women, mean BMI was 28±5 kg/m2. Median follow up time was 11 months. Complications occurred in 47 patients, 30% had pseudarthrosis or hardware failure, 26% adjacent degenerative changes, 21% persistent symptoms, and 15% adjacent level fractures. Thirteen patients (11%) required reoperation, 85% within 1 year (median time 4 months). The most common reasons for re-operation were hardware failure (38%), adjacent level fracture (24%) and persistent symptoms (24%). Candidate risk factors for post-operative complication in univariate logistic models (p<0.2) were tested with Cox time-to-event regression. Only vBMD (T12-L5) was a significant predictor of post-operative complication (p<0.02, Figure). For each decrease in vBMD of 10 mg/cm3, risk of complication increased by 9%. In summary, we found that low vBMD is a significant risk factor for complications in patients undergoing LS fusion. As CT scans are frequently performed on surgical candidates, this information is readily available and may be helpful to consider in risk stratifying patients prior to surgery. Prospective, controlled studies are needed to confirm our findings and to identify the best strategies for preventing bone loss and lowering risk of complications in this population.

SAT-0015

Quality of life in hypoparathyroidism improves with rhPTH(1-84) throughout 8 years of continuous therapy Gaia Tabacco*[1], Donovan Tay Yu-Kwang[1], Mishaela Rubin[1], John Williams[1], Beatriz Omeragic[1], Rukshana Majeed[1], Maximo Gomez Almonte[1], Natalie Cusano[2], John Bilezikian[1]. [1]Department of Medicine, Division of Endocrinology, College of Physicians & Surgeons, Columbia University, United States, [2]Department of Medicine, Division of Endocrinology, Lenox Hill Hospital, United States

Treatment of hypoparathyroidism with calcium and vitamin D does not improve reduced quality of life (QoL), a characteristic of the disease. rhPTH (1–84) therapy improves QoL metrics for up to 5 years. Information on QoL beyond 5 years has not been available, but is important because there are no limits on duration of rhPTH(1-84) in hypoparathyroidism. Aim of this study is to evaluate the effects of 8 years of continuous rhPTH(1-84) therapy on QoL and to evaluate factors associated with long term benefitProspective, open-label

trial. 20 hypoparathyroid subjects were treated with rhPTH(1-84) daily. QoL was evaluated by RAND 36-Item Short Form (SF-36) Health Survey at baseline and through 8 years of therapy.At baseline, all 8 domains of SF-36 were significantly lower than the normal population. rhPTH therapy was associated with a significant improvement in 5 of the 8 domains [vitality, social functioning(SF), mental health(MH), bodily pain(BP) and general health] throughout the study duration. 3 of the 5 domains that were improved at year 8, namely MH, SF and BP, improved to values that were no longer different from normal subjects. Improvement in the mental component summary(MCS) score was sustained through 8 years (p=0.009 vs baseline). Improvement in physical component summary PCS) score, improved through 6 years, and tended to be higher than baseline at years 7 and 8. Lower baseline MCS and PCS scores were associated with a greater likelihood for improvement. A baseline MCS score <238 predicted 90% of the cohort who improved in both MCS and PCS at year 8. A baseline PCS score <245 identified 100% of the cohort who improved at 8 years. There was an inverse relationship between reduction in calcium dosage and improvement in both PCS and MCS. In patients whose both requirement for calcitriol was reduced and duration of disease was shorter improvement in PCS was greater.rhPTH(1-84) improves QoL in hypoparathyroidism. Improvements were more evident in those whose baseline SF-36 levels were lower. Baseline MCS and PCS scores predicted the extent of QoL improvement, but did not explain the entirety of the change. A fall in requirements of calcium and active vitamin D was also associated with an improvement in QoL.The results may be useful for clinicians in deciding which HypoPT patients are likely to benefits from rhPTH(1-84). They also provide a framework for future randomized controlled studies of rhPTH(1-84) on QoL in chronic hypoparathyroidism.

Normative data, baseline and 8y scores for the 8 domains of SF-36 index: physical functioning (PF), role limitations caused by physical health problems (RF), role limitations due to emotional health problems (RE), vitality (VT), mental health (MH) social functioning (SF), bodily pain (BP) and perception of general health (GH).

SAT-0016

rhPTH(1-84) in Hypoparathyroidism Is Associated With Stable Renal Function Through 8 Years of Continuous, Uninterrupted Therapy Donovan Tay*[1], Gaia Tabacco[1], Natalie Cusano[2], John Williams[1], Beatriz Omeragic[1], Rukshana Majeed[1], Maximo Gomez Almonte[1], John Bilezikian[1], Mishaela Rubin[1]. [1]Columbia University Medical Center, United States, [2]Lenox Hill Hospital Department of Medicine, United States

Conventional management of chronic hypoparathyroidism (HypoPT) with calcium and active vitamin D (aVitD) is associated with renal complications such as worsening hypercalciuria, renal stones and renal insufficiency. With rhPTH(1-84) now available as an adjunct therapy in HypoPT, the need for high doses of supplemental calcium and aVitD is markedly reduced. We hypothesized that this reduction in the calcium burden by rhPTH(1-84) would stabilize long-term renal function. This report describes our open-label evaluation of renal function among 24 subjects (mean age: 46±3 years, 75% women; mean duration of disease, 22.9±3 years) treated with rhPTH(1-84) for 8 years of continuous therapy. With rhPTH(1-84), daily supplementation of calcium and aVitD fell progressively. Serum calcium (S.Ca) levels were maintained within the asymptomatic range. 24-hr urine calcium was reduced by 38% from 254±29 mg/d at baseline to 157±37 mg/d at 8 years (p=.01). Of the 11 subjects who were ever on thiazides, the mean dosage fell by 51% from 30±7 to 15±6 mg/day (p=0.01); 4 subjects eliminated thiazide use. Renal function was stable throughout the 8-year treatment period. Serum creatinine did not change (0.94±0.04 to 0.95±0.04 mg/dL; p=NS). Estimated glomerular filtration rate (eGFR) by MDRD was unchanged (88±4 to 85±4 mL/min/1.73m²; p=NS). When stratified according to baseline renal function, those with baseline eGFR <90 mL/min/1.73 m² (n=13) had no change in eGFR (74±5 to 78±4 mL/min/1.73m²; p=NS). In those whose eGFR was ≥90 mL/min (n=10), eGFR decreased from 107±6 mL/min to 93±5 mL/min/1.73m²; p<.01, while still remaining in the normal range. Within this stable framework of renal function, S.Ca levels predicted eGFR: for every 1 mg/dL decrease in S.Ca, there was a 5 mL/min/1.73 m² increase in eGFR (p<.01). There were

no associations between eGFR and age, duration of disease, serum phosphate, calcium phosphate product, PTH, or calcium and aVitD dose. One renal stone was reported by 1 patient at year 4.These data suggest that 8 years of continuous rhPTH(1-84) treatment in HypoPT is associated with stable renal function. The results support the idea that reducing the calcium burden by rhPTH(1-84) has salutary effects to maintain renal function, thus potentially addressing a major morbidity in HypoPT. S.Ca may be a surrogate for calcium burden (diet, PTH, Ca and aVitD dose) and a lower S.Ca achieved, may reflect shorter duration in the hypercalcemic range and be renal protective

SAT-0017

Recognition of persistent low serum alkaline phosphatase in hospitalized adults Justine Vix*[1], Thierry Hauet[2], Pascal Roblot[3], Francoise Debiais[1]. [1]Rheumatology department CHU, France, [2]Biochemistry department CHU, France, [3]Internal medicine department CHU, France

Introduction : Hypophosphatasia (HPP) is a rare genetic disease caused by loss-of-function mutations in the ALPL gene encoding the tissue-non-specific alkaline phosphatase (TNSALP). Mild HPP is usually misdiagnosed in adult age, but should be better recognized in case of low serum alkaline phosphatase (ALP).Methods : Patients were selected from the records of the biochemistry department of Poitiers University Hospital, France. The patients were hospitalized in the departments of rheumatology and internal medicine, between 2007 and 2017. Inclusion criteria were age ≥ 18 years and low serum ALP, with a requirement of 2 low-serum ALP and values ≤ 35 IU/l (normal range : 40-130 IU/l). The aim of this retrospective study was to determine number of patients from whom the persistent low serum ALP value was recognize, and to note if clinical or radiographic findings potentially related to HPP were reported.Results : 37857 hospitalized patients had a serum ALP dosage and 226 of these patients had a least 2 low serum ALP. However, 151 patients had fluctuating low values (mean age 68.9 years ; 56.2 % women) (related to bisphosphate therapy, severe septis, hepatic failure…)Among these 226 patients, 75 patients (51 patients from rheumatology department and 24 from internal medicine department) had persistent low value below 35 IU/l (mean 52.1 years ; 64% women). Mean serum ALP was 29 IU/l (9-35 IU/l) ; the low ALP value was notified in the hospitalization report in 14 patients. A history of fracture was present in 21 patients ; most common recorded fractures were lower limbs in 7 patients (metatarsus, femoral neck…) or vertebral fractures (9 patients). A history of crystalline arthritis or calcific periarthritis was noted in 28 patients; radiographic chondrocalcinosis was observed in 10 patients and apatite deposition in 18 patients ; dental abnormalities were reported in 6 patients. Genetic research was conducted in10 patients and ALPL mutation was found for 6 of them.Conclusion : In these 10 years retrospective study, we found that 0.2% of adult patients hospitalized in rheumatology and internal medicine departments had persistent low serum ALP. An elevated serum ALP value draws more attention than a low value. Physicians are to be aware of the importance of searching for HPP in case of recurrent fractures, musculo-squeletal pain, chondrocalcinosis, dental abnormalies, and to avoid antiresorptive treatments.

Coronary Artery Calcification Absence, Assessed by Computed-Tomography, Spanning One Year Of Asfotase Alfa Therapy For A 69-Year-Old Woman With Hypophosphatasia Michael P. Whyte*[1], Andy Bierhals[2]. [1]Division of Bone and Mineral Diseases, Department of Internal Medicine, Washington University School of Medicine at Barnes-Jewish Hospital; Center for Metabolic Bone Disease and Molecular Research, Shriners Hospital for Children, United States, [2]Mallinckrodt Institute of Radiology, Washington University School of Medicine at Barnes-Jewish Hospital, United States

Hypophosphatasia (HPP) is caused by mutation(s) of the gene that encodes the cell-surface tissue non-specific isoenzyme of alkaline phosphatase (TNSALP). In HPP, extracellular accumulation of the TNSALP substrate inorganic pyrophosphate (ePPi) blocks hydroxyapatite crystal (HA) formation and growth, often causing rickets during infancy or childhood or osteomalacia during adult life. However, seemingly paradoxical ectopic mineralization can occur in HPP, including from hypercalcemia and hyperphosphatemia causing nephrocalcinosis in severe HPP. More mild disturbances in mineral homeostasis in HPP may explain punctate, asymptomatic, corneal calcifications. Also, enthesopathy, osteophytosis, calcific periarthritis, and chondrocalcinosis are common in affected adults. In direct contrast, generalized arterial calcification of infancy (GACI) results from mutations in other genes that cause low ePPi levels leading to vascular calcification. In 2015, asfotase alfa (AA), a recombinant HA-targeted TNSALP replacement therapy, was approved for pediatric-onset HPP in the United States. Theoretically, excessive HA-targeted AA could provoke or exacerbate ectopic calcification. However, clinical trials of AA involving all patient ages have been reassuring despite the high on-treatment circulating ALP activity (sometimes, 5000-10,000 U/L). Reassurance has come from skeletal radiographs, retinal ophthalmoscopy, and renal sonography. Nevertheless, coronary artery calcium (C-Ca++) has not been studied in HPP, particularly in elderly patients. We investigated, using routinely available computed tomography (CT), a 69-year-old woman with HPP presenting in childhood, who was assessed for C-CA++ before and after one year of standard dose AA therapy. Image acquisition calculated

an Agaston Score and C-Ca++ volume using a prospective electrocardiogram (ECG)-gated method. Regions of interest were drawn for each coronary artery, as well as for the coronary artery vascular bed, to calculate the C-Ca++ score. No C-Ca++ was seen throughout the coronary artery tree at either time point (Figure). Adults with HPP will likely receive AA long-term. Our relatively brief experience with AA treatment for one woman with HPP is reassuring. Baseline and follow-up assessments of additional adult patients will help determine if the ePPi superabundance in HPP is protective against C-Ca++, and if AA is safe for adults with various forms of ectopic calcification.

After one year of asfotase alfa therapy, sequential CT cuts for coronary Ca++ show no accumulation that would appear as red areas resembling the normal skeleton.

PTH 1-34 Replacement Therapy has Minimal Effect on Quality of Life in Patients with Hypoparathyroidism Rachel I. Gafni*[1], Tiffany Hu[1], Lori C. Guthrie[1], Beth A. Brillante[1], Michaele Smith[2], Robert James[3], Michael T. Collins[1]. [1]National Institute of Dental and Craniofacial Research, National Institutes of Health, United States, [2]Rehabilitation Medicine Department, Clinical Center, National Institutes of Health, United States, [3]Rho, Inc, United States

Background: Hypoparathyroidism (hypoPTH) is characterized by hypocalcemia, hyperphosphatemia, and hypercalciuria. Patients with hypoPTH frequently experience neuromuscular irritability, extraskeletal calcifications, decreased bone turnover and poor quality of life (QOL), complaining of fatigue and "brain fog." Therapy with calcium/calcitriol or parathyroid hormone (PTH) can successfully manage the hypocalcemia, however, the effects of therapy on QOL are unclear. Methods: 31 hypoparathyroid subjects (25F, 6M) were treated in an open-label, uncontrolled study with full replacement doses of subcutaneous synthetic PTH 1-34 twice daily for up to 5 years, to maintain a blood calcium of 7.6-9 mg/dL. Subjects completed an SF-36 survey, Fatigue Symptom Inventory (FSI), and 6-minute walk test (6MWT) at baseline, every 6 months on PTH, and at a post-PTH follow-up visit (FU). As duration of therapy varied, analyses were also made using the last treatment time point for all subjects.Results: The SF-36 assesses 4 physical components: physical function (PF), physical role limitations (RP), bodily pain (BP), and general health (GH), and 4 mental components: vitality (VT), emotional role limitations (RE), social function (SF) and mental health (MH). Compared to the US population, subjects at baseline had worse scores in RP, GH, VT, and MH (p<0.05). Improvements in mean score were seen only for GH at 6 months and VT at 12 months compared to baseline (p<0.05). At the last treatment time point on PTH, there was an improvement in mean scores for RP, VT, and SF compared to baseline (P<0.05); however, scores at FU were not different from baseline or last treatment on PTH, except for SF, which was had decreased at FU compared to on-PTH (P<0.05). The FSI assesses fatigue severity, frequency, and perceived interference. There were no changes in fatigue frequency at any time point; perceived interference was improved at the 12 and 18-month time points and composite severity was improved only at 60 months (p<0.05). No differences were seen in the 6MWT. Conclusions: HypoPTH is associated with decreased QOL compared to the US population. Despite the inherent bias in open-label studies to predict positive effects on QOL, PTH therapy in this study had limited and non-sustained effects on QOL, inconclusive changes in fatigue experience, and no change in the 6MWT.

While PTH 1-34 can adequately manage the hypocalcemia in hypoparathyroidism, its effects on QOL appear to be minimal.

Second-generation HR-pQCT reveals minor size differences between right and left sides, but no major differences in density or microarchitecture Sanchita Agarwal*[1], Bin Zhou[2], Y Eric Yu[2], Kyle K Nishiyama[1], Fernando R Rosete[1], Mariana Bucovsky[1], Elizabeth Shane[1], X Edward Guo[2]. [1]Division of Endocrinology, Department of Medicine, Columbia University, United States, [2]Bone Bioengineering Laboratory, Department of Biomedical Engineering, Columbia University, United States

Second-generation high-resolution peripheral quantitative computed tomography (HR-pQCT, XCT2, isotropic voxel size 61 μm) permits 3D measurements of bone geometry, density and microstructure in cortical (Ct) and trabecular (Tb) compartments of the distal radius and tibia with high fidelity. Although it is customary to scan the non-dominant limb unless contraindicated (e.g., prior fracture), no study has assessed whether XCT2 measures differ between two sides of the same person.We scanned 68 people (40F, 28M) aged 24 to 80 (mean 40 ± 14), of diverse race (20 Asian, 9 Black, 24 White, 16 Other) and ethnicity (16 Hispanic) with XCT2 at the right (R) and left (L) radius and tibia. Based on the Waterloo handedness and footedness questionnaire, 57 were R dominant, 3 L dominant, 2 ambidextrous and 6 had missing data. As most were R dominant, we compared L versus R sides, without regard to dominance, with a separate analysis by gender. Data were analyzed by paired t-tests and p<0.05 was considered significant.The R radius was larger than the L (Table), with significantly greater Total Area (p=0.015) and Ct Perimeter (0.009) and non-significant trends for larger Tb (p=0.08) and Ct Area (p=0.053). There were no differences in total, Ct or Tb density or in Ct porosity. Tb number was slightly higher on the R (p=0.003). However, as the absolute difference was small (0.04) and below the LSC (0.18), this difference is unlikely to be relevant. Similarly, the R tibia was larger than the L, with significantly greater Total (p=0.01) and Tb Area (p=0.009), non-significant trends for larger Ct Perimeter (p=0.07) and no difference in Ct Area. Total, Ct and Tb density, Ct porosity and Tb number did not differ, though Tb thickness tended to be lower on the R (p=0.07). Analyses based on gender revealed similar trends but size differences were more prominent at the radius in men and the tibia in women (data not shown).In summary, in a group of people that was largely

right-dominant but diverse with respect to age, gender, race and ethnicity, we found that the right radius and tibia were slightly larger than the left, with no difference in total or compartmental densities and minimal differences in Tb microarchitecture. While it is possible that these size differences could affect estimated stiffness, the absence of significant differences in density and microstructure implies that measurements obtained at either site in a given subject will be essentially interchangeable.

Persistent activation of calcium-sensing receptor increases microcrack and decreases bone strength. Itsuto Endo*[1,2], Bingzi Dong[3], Yukiyo Ohnishi[1], Yukari Ooguro[1], Kiyoe Kurahashi[1], Masahiro Hiasa[4], Jumpei Teramachi[5], Hirofumi Tenshin[4], Seiji Fukumoto[6], Masahiro Abe[1], Toshio Matsumoto[6]. [1]Department of Hematology, Endocrinology and Metabolism, Tokushima University Graduate School of Medical Sciences, Japan, [2]Department of Chronomedicine, Tokushima University Graduate School of Medical Sciences, Japan, [3]Department of Endocrinology and Metabolism, the Affiliated Hospital of Qingdao University, China, [4]Department of Orthodontics and Dentofacial Orthopedic, Tokushima University, Japan, [5]Department of Tissue Regulation, Tokushima University, Japan, [6]Fujii Memorial Institute of Medical Sciences, Tokushima University, Japan

Background: Activating mutations of calcium-sensing receptor (CaSR) cause autosomal dominant hypocalcemia type 1 (ADH1). ADH1 patients exhibited similar to the clinical features of hypoparathyroidism with abnormal calcification of kidney or basal ganglia. However, it is not well known about bone phenotype including bone strength of ADH1 patients.Methods and Results: ADH1 model mice (hCaSR A843E knocked-in) mimicked almost all the biochemical features of ADH1 including low bone turnover with decreased PTH secretion, and these phenotype were recovered by subcutaneous injection of PTH(1-34) or oral administration of calcilytic JTT-305. ADH1 mice exhibited smaller body and bone size and lower BMD compared to age-matched WT, and these observations were reversed by PTH(1-34) or JTT-305. Breaking maximum load, stiffness and energy to peak load assessed by 3-point bending test were reduced in ADH1 mice femur regardless of correction by dimension of bone and/or BMD. These corrected bone strength parameters of ADH 1 mice were completely recovered by treated with PTH(1-34) or JTT-305. Microcracks assessed by Fuchsin staining were rarely detectable in WT mice, whereas there was a marked increase in both the number and density of microcracks in ADH1 mice femur. PTH(1-34) or JTT-305 reduced microcrack number and density to the similar levels to those in WT mice. Microcrack number and density in ADH1 mice were negatively correlated with the dimension of bone and/or BMD corrected bone strength parameters and were positively correlated with mice ages. The corrected bone strength parameters were negatively correlated with ages of ADH1 mice.Conclusion: Accumulation of microcracks due to aging mainly causes decreased bone strength in ADH1 mice. These observations demonstrate that the fracture susceptibility might be increased in aged patients with ADH1.

SAT-0064

Is cortical porosity associated with degraded material quality ? Aurelien Gourrier*[1], Delphine Farlay[2], Helene Follet[2], Georges Boivin[2]. [1]LIPHY CNRS Université Grenoble Alpes, France, [2]INSERM UMR 1033 Université de Lyon, France

The mineral nanoscale structure and organization are intrinsic determinants of bone quality. While these material characteristics have been shown to be altered in severe pathological state (e.g. fluorosis, OI), the extent of the fluctuations in healthy individuals is still not fully understood. This study aims to analyze the extent of nanoscale fluctuations that can be expected in a group of healthy individual which main morphological variability is cortical porosity.Transverse sections of 100 µm in thickness were prepared from the lateral quadrant of the femoral mid-diaphysis of 26 donnors aged 50–95 (12 men, 14 women). The samples were analyzed by quantitative scanning small-angle X-ray scattering (qsSAX-SI) using a synchrotron beam of 20 µm in diameter which allowed resolving histological features. Images of the mineral nanoparticle thickness and organization were thus reconstructed with nanoscale resolution over the full cortical shell (up to 5 x 11 mm2).The global

mineral nanoparticle thickness distributions reported in fig.1a fall in a range of 3.5 – 4.1 nm (interquartile range), in good agreement with values found in the literature. Significant shifts in average thickness were found between samples, but these remain in a limited range (0.2 – 0.3 nm) as compared to known pathological modifications (e.g. > 1 nm for fluorotic bone). However, a closer examination of the images reveals spatial fluctuations well correlated with histology. In particular, lower thickness values are encountered in the vicinity of the cortical pores/voids. Furthermore, significant perturbations of the mineral organization (higher interparticle distance and shorter correlation length) were also observed (fig.1b) indicating ultrastructural tissue modifications.Our preliminary analysis tends to indicate that cortical bone porosity may be associated with a degraded material quality. While the limited changes in nanoparticle thickness suggests that the global mineralization mechanisms are essentially conserved, the perturbation in their organization indirectly points to alterations of the structure and/or organization of the tissue at the microfibril level. Because microfibrils have been shown to be the main determinants of microelasticity at the lamellar level, these tissue modifications should have an impact on the micro- to macroscopic biomechanical properties.Fig.1: (a) nanoparticle thickness (SAXS) vs age; (b) short range order ($2\pi/\alpha$) vs interparticle distance ($2\pi/\beta$).

Chondroitin Sulfate and Biglycan Play Pivotal Roles in Bone Toughness via Retaining Bound Water in Bone Matrix Rui Hua*[1], Jie Bai[2], Xiaodu Wang[2], Jean X. Jiang[1]. [1]Department of Biochemistry, UT Health San Antonio, United States, [2]Department of Mechanical Engineering, University of Texas at San Antonio, United States

In extracellular bone matrix, proteoglycans (PGs) are one of the structural non-collagenous proteins (NCPs) which reside in the organic interface between hydroxyapatite crystals. Typically, PGs contain long unbranched glycosaminoglycans (GAGs) chains attached to core proteins. Our previous in vitro studies using human cadaveric bone samples showed that PGs might play a pivotal role in sustaining bone toughness via retaining bound water in bone matrix, and chondroitin sulfate (CS) was the major subtype of GAGs which correlated with age-related deterioration of bone toughness. In addition, biglycan, a major subtype of CS-containing PGs, also declined during aging. In this study, we examined the effect of CS and biglycan on the toughness of bone in vivo using WT and biglycan-deficient mouse model. A significant decrease of total GAGs amount was observed in the mineralized compartment of 6-month-old biglycan KO mouse bone matrix. Consistently, a semiquantitative Alcian blue histochemical staining method verified the similar GAG change in biglycan KO mice compared to WT. The tissue-level toughness was investigated using nanoscratch test techniques under both hydrated and dehydrated conditions. The results showed that biglycan deficiency led to a significant reduction of bone toughness for fresh bone specimens. However, after removal of bound water in the bone tissue, the difference between bone tough-

ness of WT and biglycan KO mice was diminished. Moreover, dehydration decreased bone toughness of WT and biglycan KO groups by 22% and 10%, respectively. We have shown that CS and biglycan are important molecules in bone fragility during aging process. Here, we injected CS in 10-month-old WT and biglycan KO mice to test whether supplemental GAGs could improve age-related loss of tissue-level toughness. After intradermal injection of CS (3 mg/kg) for 4 weeks, along with the significant increase of the GAG amount in mineralized matrix of WT group, the bone toughness was greatly improved. Interestingly, the increase of the GAG amount and bone toughness was not observed in biglycan KO mice, possibly caused by the lack of biglycan to retain supplemental CS. In summary, our results demonstrated that CS and biglycan in bone matrix play a pivotal role in retaining bound water in bone matrix, thus imparting the toughness to bone, and supplementation of CS to bone matrix may improve the toughness of bone in mice of 10-month-old.

SAT-0066

Quantitative Computed Tomography (QCT) Analysis of Bone Quality: Consideration of Hierarchical Levels of Variation for Predicting Fracture Risk. Randee Hunter*[1], Karen Briley[2], James Ellis[2], Amanda Agnew[1]. [1]Skeletal Biology Research Laboratory, United States, [2]Wright Center of Innovation in Biomedical Imaging, United States

The purpose this study is to investigate differential skeletal response to systemic and mechanical environments as the source of intra-individual and intra-element variation in bone quality using quantitative computed tomography (QCT). After controlling for patient demographics, a hierarchical consideration of sources of variation could provide clinicians with a mechanism for more discriminant assessments of fracture risk. QCT analysis was performed on ex vivo bilateral radii and tibiae from a cadaveric sample of 76 males (63.7±14.1 yrs) and 34 females (64.4±14.4 yrs). CT scans were acquired using optimized acquisition parameters on a Philips Ingenuity 64-channel system with resulting in-plane resolutions of 0.167mm (radius) and 0.335mm (tibia). Proxies for cortical bone strength, including robustness (Tt.Ar/Le) and area moment of inertia (I), were quantified for sites relative to total length (mm) in the radius (30, 50%) and tibia (38, 50%) using SkyScan CTAn (Bruker) software. Site-specific volumetric bone mineral density (vBMD) was calculated using a QRM cortical phantom. Multiple linear regressions indicate significant relationships for sex, age, and body size (kg) in all segments sites per element for both I and Tt.Ar/Le and (p<0.01). vBMD was not predicted by sex (p>0.05) but was significantly related to age and body size (p<0.01). ANCOVA results indicate significant differences in all variables between segment sites (p<0.01). Pearson correlation coefficients ranging from 0.45 to 0.71 between site-matched variables in both elements indicate a substantial amount of systemic influence. Understanding intra-individual and intra-element variation in cortical bone quality will help advance fracture risk predictions beyond limited areal BMD t-scores. Future work will include dynamic whole bone mechanical testing to determine the biological relevance of these sources of variation.

SAT-0067

Compressive Bone Strength Index (BSIc) Explains 85% Variance in Experimentally-Derived Distal Radius Failure Load James Johnston*[1], Matthew Mcdonald[1], Saija Kontulainen[2]. [1]Department of Mechanical Engineering, University of Saskatchewan, Canada, [2]College of Kinesiology, University of Saskatchewan, Canada

Background/Purpose: Peripheral quantitative computed tomography (pQCT) imaging is commonly used to estimate distal radius strength (i.e., failure load) via the compressive bone strength index (BSIc), where BSIc = (Total area)x(Total density)2 [1]. This equation is derived from prior research showing that the stress (force/area) required to fracture bone is proportional to density squared [2]. Although commonly reported to estimate distal radius failure load, BSIc has only been validated at the distal tibia (where BSIc explained 85% variance in distal tibia failure load) [1]. It may be possible to advance the BSIc method and apply composite beam theory to account for the relative effects of cortical and trabecular bone in resisting load. The purpose of this study was to assess variance in distal radius failure load predicted by BSIc and a new composite beam index (FCB), along with other bone properties. Methods: We evaluated 13 fresh-frozen cadaver forearms, all from female donors (mean age 82.4, SD 8.5 years). We scanned the distal radius using pQCT (0.2mm in-plane pixel size, 2.3mm thickness), and total, cortical and trabecular area and density were analyzed. We calculated BSIc using the equation above. FCB was calculated via FCB = (Strab)[(Etrab)x(A-trab) + (Ecort)x(Acort)]/Etrab, where Strab pertains to density-dependent trabecular bone compressive strength [3] and E pertains to density-dependent elastic moduli of trabecular [4] or cortical [5] bone. Forearms were experimentally tested in axial compression (3mm/s) onto the palm of the hand, and we recorded failure load. We report variance (R2) in experimental failure load predicted by BSIc, FCB and bone properties. Results: Variance in failure load appeared to be best predicted by BSIc (R2=85%), total bone mineral content (81%) and FCB (78%). Conclusions: BSIc predicted the same, 85% of variance in experimental failure load as previously reported at the distal tibia [1]. This study validates continued use of BSIc when estimating bone strength of the distal radius and for predicting fracture risk. The new FCB strength index explained less variance in failure load than BSIc, likely due to challenges associated with differentiating distal radius cortical from trabecular bone when using pQCT.

SAT-0068

Differences in bone quality between fresh bone and PMMA-embedded bone Hiromi Kimura-Suda*[1], Teppei Ito[1], Masahiko Takahata[2], Tomohiro Shimizu[2], Fumiya Nakamura[1], Masahiro Ota[2]. [1]Chitose Institute of Science and Technology, Japan, [2]Hokkaido University, Japan

Both Fourier transform infrared (FTIR) and Raman imaging are powerful tools for the assessment of bone quality, including parameters such as mineral-to-matrix ratio (mineral/matrix), carbonate-to-phosphate ratio (carbonate/phosphate), crystallinity, and mineral maturity. Conventional FTIR imaging requires the use of a poly(methyl methacrylate) (PMMA) embedding process to prepare thin sections of bone for the assessment of bone quality; however, the PMMA embedding process takes time and causes denaturation of proteins including collagen. Thin sections do not need to be prepared for Raman imaging, which provides information of the bone quality of fresh bone. On the other hand, FTIR imaging provides information on bone quality over a wider area and more quickly than Raman imaging. We have previously developed a quick and easy sectioning method using frozen sectioning instead of PMMA-embedded sectioning to assess the bone quality of fresh calcified bone using FTIR imaging in transmittance mode. We have demonstrated that the mineral/matrix and crystallinity of the thin sections prepared by PMMA embedding were higher than those of sections prepared by frozen sectioning, whereas the carbonate/phosphate of the thin sections prepared by PMMA embedding was lower than that of sections prepared by frozen sectioning. In this study, we clarified the differences in bone quality between fresh bone and PMMA-embedded bone. Femurs were removed from six 12-week-old BALB/cA mice after euthanasia, and thin sections from three mice were prepared by the PMMA embedding procedure, and the thin sections form the other three mice were prepared by the frozen sectioning procedure. In the trabecular bone in the fresh femurs, we found a positive correlation between the mineral/matrix and mineral maturity and a negative correlation between the carbonate/phosphate and mineral/matrix, between the carbonate/phosphate and mineral maturity, and between the carbonate/phosphate and crystallinity; however, no such correlations were observed in the trabecular bone in the femurs embedded in PMMA. Moreover, there was a marked difference in the carbonate/phosphate between the fresh femurs and PMMA-embedded femurs. The carbonate/phosphate of the PMMA-embedded femurs was 30% lower than that of the fresh femurs. We concluded that the carbonate/phosphate may afford a useful parameter for the comparison of bone quality between fresh bone and PMMA-embedded bone.

Osseointegrated implants for lower limb amputees: evaluation of bone mineral density Seamus Thomson*[1], William Lu[1], Munjed Al Muderis[2]. [1]The University of Sydney, Australia, [2]The Osseointegration Group of Australia, Australia

Background and aim(s)The use of dual-energy X-ray absorptiometry (DXA) is a standard clinical procedure for the evaluation of bone mineral density (BMD). Amputee patients are known to have decreased BMD and an increased risk of osteoporosis in the affected proximal femur and hip region. The major cause of these issues in these patients is the absence adequate loading leading to bone resorption in accordance to Wolff's law. In this paper, we present a prospective study reporting changes in BMD among amputees who received osseointegrated implants to determine if the loading through the Osseointegrated implant can overcome the bone resorption issues.MethodThis is a prospective study of 33 patients, consisting of 24 males and 9 females, aged 22-77 (mean = 51.0 ± -2.0) years with one and two-year follow-up. Selection criteria included age over 18 years, unilateral amputees with socket-related problems. All patients received osseointegrated implants press-fitted into the amputated limb. BMD was assessed using DXA in the femoral neck (operative and contralateral) and lumbar spine (L2-L4) regions, and corresponding Z-scores were generated. DXA scans were taken preoperatively as well as one-year and two-years following osseointegration surgery.Result(s)Mean BMD and Z-scores of spine, and operative and contralateral sides were generated for all patients. Dependent t-tests were used to test for significant differences (P<0.05) preoperative, one-year, and two-years for mean changes in BMD and Z-Scores following surgery. Analysis of the BMD and Z-scores indicated that patients showed improvements at one-year post-surgery.Conclusion(s)These results suggest that osseointegrated implants are effective at encouraging bone growth and restoring BMD levels for amputees within a short period of time post-surgery. Osseointegrated implants therefore have the potential to address stress distribution issues associated with socket prostheses and restore the normal bone loading regime in lower limb amputees.

Distal Radius Bone Microarchitecture: what happens between age 25 and old age? Canchen Ma*[1], Feng Pan[1], Laura Laslett[1], Kathryn Squibb[1], Roger Zebaze[2], Tania Winzenberg[1], Graeme Jones[1]. [1]Menzies Institute for Medical Research, University of Tasmania, Australia, [2]Austin and Repatriation Medical Centre, University of Melbourne, Australia

Purpose: The aim of this study was to describe the differences of bone geometry, volumetric bone mineral density (vBMD) and microarchitecture parameters at the distal radius between older and young adults.Methods: Bone geometry, trabecular and cortical parameters and vBMD at distal radius were collected using high-resolution peripheral computed tomography (HRpQCT) and analysed using StrAx in 201 participants from the prospective Tasmanian Older Adult Cohort study (mean age 72.2 years, range 61.9-89.4 years, female 46.8%) and 196 participants from the T-bone study (mean age 25.5 years, range 24.1-27.6 years, female 38.8%). Unpaired t-tests were used for comparison of means.Results: Older adults had a significantly larger cross-sectional area of the transitional zone (outer 30.96mm2 vs. 28.38mm2, inner 36.34mm2 vs. 32.93mm2) and thicker transitional zone bone area (outer 0.57mm vs. 0.54mm, inner 0.71mm vs. 0.65mm) compared with young adults. In addition, the prevalence of cortical porosity (54% vs. 49%) and porosity of the transitional zone (outer 42% vs. 37%, inner 82% vs. 81%) were significantly higher in older adults than in young adults. vBMD of total bone area (370.73 mg hydroxyapatite (HA)/cm3 vs. 424.57 mg HA/cm3), vBMD of transitional zone (outer 899.29 mg HA/cm3 vs. 959.52 mg HA/cm3, inner 385.47 mg HA/cm3 vs. 408.34 mg HA/cm3), cortical and trabecular vBMD (734.51 mg HA/cm3 vs. 801.04 mg HA/cm3 vs. 178.02 mg HA/cm3) were all significantly lower in older adults. There were no significant differences between older and young adults in total, cortical, and trabecular cross-sectional area or cortical and trabecular thickness.Conclusions: Compared to young adults at the time of peak bone mass, older adults have an increase in transitional bone size, decreased vBMD measures and substantially increased prevalence of porosity, with the most significant difference in the compact cortex.Keywords: bone microarchitecture; bone mineral density; high-resolution peripheral quantitative computed tomography

Osteoarthritis Correlates with High-Speed Exercise and Sesamoid Bone Fracture in Racehorses Heidi Reesink*[1], Erin Cresswell[2], Sean Mcdonough[1], Scott Palmer[1], Christopher Hernandez[1], Caroline Wollman[1], Bridgette Peal[3]. [1]Cornell University, United States, [2]LifeNet Health, United States, [3]North Carolina State University, United States

Fracture of the proximal sesamoid bones (PSBs) is a sudden, unexpected, catastrophic fracture representing the most common fatal musculoskeletal injury in U.S. racehorses. Here, we asked if computed tomography (CT)-measured bone morphologic parameters and macroscopic, micro-CT or histologic evidence of osteoarthritis were correlated with PSB fracture or high-speed exercise.PSBs (n=62) from New York racehorses that sustained a catastrophic fracture (n=8) and controls (n=8) were imaged using high resolution micro-CT.

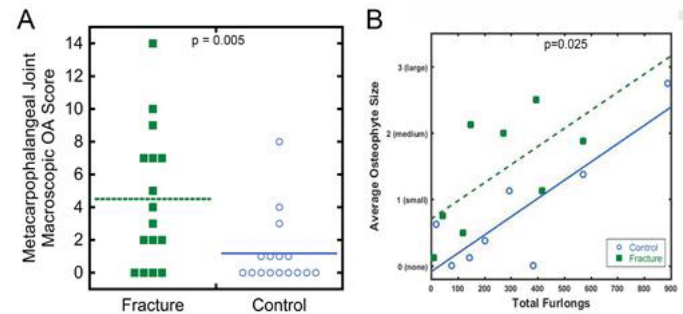
Each joint was assigned a macroscopic osteoarthritis score by a single board-certified veterinary pathologist, and sagittal PSB histologic sections were scored by 3 blinded observers using the OARSI scale. Logistic and linear regression were performed to identify parameters correlated with fracture and exercise history (measured as total furlongs of exercise). Horses sustaining PSB fracture had greater macroscopic osteoarthritis scores (p=0.005, Fig 1A). PSBs from the intact, contralateral forelimb of horses sustaining fracture had larger osteophytes (p=0.04, Fig 1B) as compared to controls. Fractured bones had increased bone volume fraction (90.39±1.76% vs. 87.20±2.79%, p<0.0001) as compared to controls. Histologic scoring and osteophyte micro-CT revealed strong associations between osteoarthritis and the amount of high-speed exercise (total furlongs, p=0.02 and 0.03, respectively). Catastrophic PSB fracture is associated with increased bone volume fraction, osteophytosis and more advanced macroscopic osteoarthritis in Thoroughbred racehorses. Both macroscopic and histologic osteoarthritis scores were associated with total high-speed furlongs. Monitoring bone volume fraction and osteophytosis in vivo could identify risk factors for catastrophic fracture. Longitudinal imaging studies are required to assess the potential benefit of in vivo CT imaging.


Figure 1. (A) Macroscopic OA scores were higher for horses that experienced fracture vs. controls (p=0.005). (B) Osteophyte size was significantly correlated with fracture (p=0.025) and total distance accrued during high-speed exercise (total furlongs, p=0.001).

Elevated RANKL Levels in Pediatric Patients with Metabolic Bone and Neuromuscular Disorders Sara Akhtar Ali*, Leigh Ramos-Platt, Senta Georgia, Pisit Pitukcheewanont. Children's Hospital Los Angeles, United States

Background: Metabolic bone and neuromuscular disorders are not uncommon in pediatrics, many of which lead to pediatric osteoporosis. In addition, the mechanism of bone loss in these conditions has not been established. RANKL (receptor activator of nuclear factor kappaB ligand) and osteoprotegerin (OPG) pathway is responsible for normal bone remodeling, however its role in pediatric metabolic bone and neuromuscular disorders has never been well described. Objective: To quantify RANKL levels in pediatric patients with metabolic bone or neuromuscular disorders compared to controls. Study Design: Subjects, 1-21 years of age, with a diagnosis of either metabolic bone or neuromuscular disorder were enrolled. Free soluble RANKL levels were quantified using a sandwich ELISA (Biomedica Immunoassays BI 20462) and compared to previously published healthy control data using the same assay. Results: One-hundred and twenty-two patients (34 female and 88 male)

from 16 months to 21 years of age were enrolled. Preliminary data showed an overall higher median RANKL level of 0.24 pmol/L (compared to a median level of 0.15 pmol/L in healthy children previously reported) with a mean of 0.28 ± 0.17 pmol/L. Subgroup analysis, when able, was performed using Kruskal-Wallis test showed no statistical significant difference in RANKL levels (p = 0.33) among patients with osteogenesis imperfecta (n = 19, median = 0.19 pmol/L), rickets (n = 10, median = 0.28 pmol/L), hypoparathyroidism (n = 10, median = 0.38 pmol/L), pseudohypoparathyroidism (n = 8, median = 0.25 pmol/L), steroid-induced osteoporosis (n = 5, median = 0.30 pmol/L), and Duchenne Muscular Dystrophy (DMD) (n = 42, median = 0.24 pmol/L), though sample size of each diagnosis was small. Mann Whitney U test revealed no significant difference between metabolic bone disorders and neuromuscular disorders (p = 0.29); males and females (p = 0.40); or history of multiple fractures (n = 45, median = 0.22 pmol/L) and no fractures (n = 77, median = 0.27 pmol/L, p = 0.25). RANKL level was negatively correlated with age (Spearman r = -.36, p <0.0001). Conclusions: RANKL levels were elevated in patients with metabolic bone and neuromuscular disorders. RANKL levels were highest in patients with hypoparathyroidism and steroid-induced osteoporosis, as well as DMD. Larger studies should be done to evaluate RANKL for potential targeted therapeutic intervention.

SITAR Models of Bone and Body Composition Growth: Prospective Longitudinal Data for U.S. White Girls from Childhood to Adulthood Jodi N Dowthwaite*[1], Stephanie A Kliethermes[2], Tamara A Scerpella[2]. [1]SUNY Upstate Medical University; Binghamton University, United States, [2]University of Wisconsin - Madison, United States

Purpose: We aimed to confirm key concepts in pediatric development by evaluating site- and tissue-specific growth patterns, using prospective, longitudinal data from a sample of white girls from Upstate New York. Methods: Data were collected during a study of bone growth in the context of gymnastic exposure; girls were healthy gymnasts or non-gymnasts at enrollment. Height and weight were recorded contemporaneous with annual whole body DXA scans, performed using 1 of 2 Hologic scanners (QDR4500W 1998-2012; Discovery A 2008-2018). A one-time scanner transition affected data for girls measured pre-2008 through post-2010. Cohort and scanner-specific, pediatric regression equations converted QDR data to Discovery-equivalent data before entry into Superimposition by translation and rotation models using "R" (SITAR, Cole et al. 2010). SITAR models use regression B-splines and random effects to produce mean and subject-specific growth curves defined by parameters as follows: size (growth magnitude), tempo (maturation timing) and velocity (growth rate), estimated for numerous outcomes (Table 1). Analysis inclusion criteria were: ≥3 annual DXA scans and white, non-Hispanic identification. Affected data were excluded for individuals who developed adverse conditions.Results: SITAR models explained 89% to 98% of variance for all outcomes in 141 girls, representing 3 to 20 annual observations per individual, age range 7.5-30.9 yrs. Mean chronological ages at peak velocity ranged from 12.14 yrs (lean mass) to 13.96 yrs (fat mass), with intermediate ages at peak velocity for all bone outcomes; peak height velocity (PHV) preceded peak velocity for arm bone mineral content (ARMBMC).Conclusion: Our data support the concept that peak lean mass velocity precedes peak BMC velocity at all sites. Furthermore, peak ARMBMC velocity lags ~1 yr post-PHV and ~0.6 yrs post-peak weight velocity; this lag may contribute to high upper extremity fracture risk during this growth phase, as theorized by pediatric bone researchers. Note that the ARMBMC lag may be moderated in this sample compared to the general population, as many participants were gymnasts exposed to unusual arm loading patterns during growth. Future work will address maturity-specific loading history as a factor in site- and tissue-specific growth curves.

Low Trabecular Bone Score in Adolescent Female Inpatients with Anorexia Nervosa Yael Levy-Shraga*[1], Liana Tripto-Shkolnik[2], Dana David[1], Iris Vered[2], Daniel Stein[3], Dalit Modan-Moses[1]. [1]Pediatric Endcrinology Unit, The Edmond and Lily Safra Children's Hospital, Chaim Sheba Medical Center, Tel-Hashomer, Israel, [2]Institute of Endocrinology, Chaim Sheba Medical Center, Tel-Hashomer., Israel, [3]Pediatric Psychosomatic Department, The Edmond and Lily Safra Children's Hospital, Chaim Sheba Medical Center, Tel-Hashomer, Israel

Background: Trabecular bone score (TBS) is an emerging technology that provides information regarding bone microarchitecture. A recent study showed that in healthy girls normal TBS (≥1.35) was achieved within the first year post-menarche. The aims of our study was to assess TBS in adolescents with anorexia nervosa (AN) and to evaluate correlations with clinical, laboratory and densitometric variables.Methods: A cohort study of 208 adolescent females (mean age 15.6±1.8y) hospitalized because of AN between 2003-2017 was retrospectively assessed. Demographic and clinical data, including age, weight, height, body mass index (BMI), laboratory parameters and bone mineral density (BMD) measurements by dual-energy X-ray absorptiometry (DXA) were retrieved from the medical charts. TBS was assessed by reanalyzing DXA spinal images. Results: Mean TBSwas 1.308±0.083, lower than the values previously described in healthy adolescents (p<0.0001). Compromised microarchitecture was found in 17 participants (8.2%) and partially compromised in 123 (59.1%). TBS was significantly correlated with age, weight standard deviation score (SDS), BMI SDS, BMD measurements of the lumbar spine and total body, luteinizing hormone (LH) and 17b-estradiol (E2) level, and was negatively correlated with cortisol (p=0.017). Participants with regular menstruation or secondary amenorrhea had higher TBS than participants who were pre-menarche or with primary amenorrhea (p<0.001).A stepwise linear regression analysis identified BMD L1-4 z score and log E2 as independent predictors of TBS.Conclusion: TBS of adolescent females with AN was found to be lower than TBS of healthy adolescents. Prospective longitudinal studies should be undertaken to investigate whether recovery may result in correction of bone microarchitecture.

SAT-0118

Polyhydramnios: sole risk factor for non-traumatic fractures in 3 infants Geneviève Nadeau*, Marie-Béatrice Saade, Patricia Olivier, Melissa Fiscaletti, Marie Laberge-Malot, Philippe Campeau, Nathalie Alos. CHU Sainte-Justine - University of Montreal, Canada

The mechanostat theory postulates that an increased muscle strain and loading will affect bone strength in a corresponding, dose-dependent manner. We now think of multiple mechanostats: their dynamic and set point been different for each bone. The set point adjusts to resist peak forces applied on a bone while allowing it to carry its function efficiently. Ultimately, the overall capacity of a bone to resist strain is not only a function of its mass, but also of its density and unique geometry. These characteristics may be modulated by multiple factors including mechanical usage. Voluntary muscle strain and ground reaction forces seem to have the most predictable impact on bone remodeling. Accordingly, unloading will lead to reduced muscle development (and muscle force) and have a negative effect on the mass, size, and strength of bone with lower fracture thresholds. Low strain has been shown to result in trabecular thinning and endosteal resorption of cortical bone. We present the cases of three patients now aged 2 to 3 years and seen in our Bone Clinic at Sainte-Justine University Hospital between 2013 and 2018. They all presented fractures of lower limbs at an early age (3 to 8 months), and were found to have low bone mineral density upon DXA testing, with Z score of lumbar BMD inferior to -2 SDs. A shared characteristic between patients was that all three pregnancies presented with a polyhydramnios of unknown etiology in the third trimester, as assessed by routine ultrasound. They presented no family history of bone disease, and genetic testing for neuromuscular diseases or bone fragility was negative in all patients. During follow-up, they all showed to be catching up on bone mineral density within the year following the onset of fractureswithout receiving antioteoporotic treatments. However, lumbar BMD remained lower than expected (< -1 SD) as based on their anthropometric parameters. Based on the mechanostat theory, we hypothesize that in those patients, polyhydramnios might have played as a significant risk factor for low bone mineral density. A larger amount of liquid in the amniotic cavity could limit the rate and intensity of limb loading, resulting in lower peak force applied on growing bones. No studies have yet investigated a connection between intra-uterine limb strain and bone strength in the perinatal period. This case series could lead the way to researches connecting pre-birth environmental factors to bone strength in infancy.

Nmp4 regulates bone physiology, obesity, and glucose metabolism Joseph Bidwell*, Ronald Wek, Alexander Robling, Sarah Tersey, Michele Adaway, Carmella Evans-Molina. Indiana University School of Medicine, United States

Recent studies indicate that the skeletal system plays a major role in the maintenance of blood glucose, which in turn can impact the onset of diabetes. The skeleton regulates global energy utilization, in part, by acting as a significant sink for glucose uptake since osteoblasts use glycolysis to fuel bone formation. The bone also acts as an endocrine organ through release of a variety of factors that regulate key aspects of metabolism. Nmp4 is a ubiquitous transcription factor, and Nmp4-/- mice have an unremarkable skeletal phenotype until challenged with any one of several anabolic stimuli (e.g. PTH, Bmp2), which elicits enhanced and accelerated bone formation and significantly elevated increases in serum osteocalcin compared to WT mice. Nmp4-/- mice harbor more bone marrow osteoprogenitors than WT animals and these cells exhibit enhanced mineralization in culture and a significantly increased capacity for metabolic conversion to glycolysis. Because bone-derived undercarboxylated osteocalcin has been reported to regulate pancreatic β cell function, we hypothesized that Nmp4-/- mice may also exhibit changes in glucose metabolism. Interestingly, Nmp4-/- mice displayed a significant reduction in pancreatic β cell mass and reduced glucose-stimulated insulin secretion. To test whether Nmp4 status impacted the β cell adaptive response to obesity, 8 week-old WT and Nmp4-/- male mice were randomly placed either on a high fat diet (HFD, adjusted calories diet, 42% from fat) or on a low fat diet (LFD, adjusted calories diet, 12.6% from fat) for 12 weeks. Endpoint parameters included body weight, echo magnetic resonance imaging (echo-MRI), intra-peritoneal glucose tolerance test (IPGTT), insulin tolerance test (ITT), and percent β cell area. As expected the WT mice exhibited a significant HFD-induced weight gain accompanied by a marked increase in percent body fat. The WT mice showed a significant HFD-associated glucose intolerance and insulin insensitivity that was associated with an adaptive increase in the β cell area. Remarkably the HFD-fed Nmp4-/- animals were resistant to weight gain and exhibited no significant changes in glucose tolerance, insulin sensitivity, or percent β cell area. We conclude that Nmp4 mediates a complex regulation of obesity, energy utilization, and bone formation.

Osteocalcin/Oxytocin and NGF/BDNF mRNA levels in bone mediate muscle phenotype dependent response to cold stress challenge in mice Claudia Camerino*, Elena Conte, Maria Rosaria Carratù, Adriano Fonzino, Domenico Tricarico. University of Bari, Italy

Osteocalcin (Ost), Oxytocin (Oxt) and NGF/BDNF exert a protective function on bone, reproduction and cognition under cold stress (CS). Oxt and Ost are also required for muscle regeneration, the latter triggering the increase of IL-6 in myofibers and BDNF in brain. Here, we explored the signaling regulating bone and muscle response to CS. The mRNA levels of Ngf, Ost, Oxt and their receptors (p75ntr, Ntrk1, Gprc6a, Oxtr), Bdnf, Ucp1 and Il-6 in bone, soleus (SOL) and tibialis (TA) muscles from 3 months-old mice exposed to CS were investigated. The expression of different Myosin heavy chain Mhc2b (fast-glycolytic), Mhc1 (slow-oxidative), Mhc2x and Mhc2a (fast-glycolytic-oxidative) were also investigated. Mice (n= 15) were divided into: controls maintained at room temperature (RT=23°C), exposed to CS at T=4°C for 6h and 5-days (5d). CS exposure for 5d enhanced Ngf, but not its receptors, and Ucp1 genes in bone. Ucp1 and Ngf genes were significantly upregulated by 2 and 1.5 folds respectively in TA after 6h CS. Ntrk1 was significantly upregulated by 4 and 22 folds respectively in the SOL muscle after 6h and 5d CS, while p75Ntr was downregulated in both muscles after 6h CS. Oxt was upregulated by 5-fold following 5d CS in bone. Oxtr and Il-6 genes were upregulated respectively by 1 and 1.5 folds after 5d CS in SOL. Ost increased by 16-fold in bone after 5d, Gprc6a was unaffected. Gprc6a was upregulated respectively by 3.5 and 2 folds after 6h and 5d CS in TA. Bdnf increased by 9.5-fold in bone after 5d CS while it was not affected in muscle. Mhc2b was significantly downregulated in SOL respectively by 0.96 and 0.88-folds after 6h and 5d CS vs controls; Mhc1 only by 0.32-fold after 5d CS in SOL. Mhc2a was significantly downregulated by 0.88-fold after 5d CS in TA. Mhc2x was not affected following CS. Our study confirms that Ngf and Ucp1 are activated in bone as well as in muscle. Oxt and Ost are highly expressed in bone and exert phenotype-dependent protective effects towards muscle through up-regulation of their receptors, Oxtr in slow-twitch and Gprc6a in fast-twitch muscles. CS induced a marked shift of SOL muscle toward the slow-twitch phenotype which is in line with the metabolic need of the slow-twitch oxidative muscle following thermogenic challenge. CS induced a mild shift of the TA muscle toward the fast-twitch phenotype. IL-6 up-regulation in muscle after CS is consistent with the concept of a coordinated axis between bone and muscle.

Bone Defect and Fracture Healing in Dystrophy/utrophin Double Knockout Mice Xueqin Gao*[1], Xuying Sun[1], Sarah Amra[1], Yan Cui[1], Zhenhan Deng[1], Haizi Cheng[1], Charles Huard[1], Bing Wang[2], Walter Lowe[1], Johnny Huard[1]. [1]University of Texas Health Science Center at Houston, United States, [2]University of Pittsburgh, United States

The dystrophin-/- (mdx) mouse is a model of Duchenne muscular dystrophy (DMD); however, mdx mice have normal lifespan and do not exhibit clinical manifestations seen in DMD patients. The dystrophin-/-/utrophin-/- (Hom) mouse model closely mimics human DMD, with a short life span, and is a more useful DMD model. This study investigated the role of muscle force in bone defect healing, using skull and tibial defects, and tibial fracture, in dystrophic mice. Four-week-old C57BL/10J (B10), mdx, dystrophin-/-utrophin+/- (Het), and Hom mice bred at UTHealth were used. MicroCT analysis showed that a 1-mm skull defect did not heal, whereas a tibial defect of the same size healed fully in 21 days. New bone volume (BV) in the skull defect area was similar among the four groups, although bone density was lower in the Hom group than in the other groups. Tibial defect healing was delayed at day 7 in Hom mice, as evidenced by the lower BV of newly formed bone in the defect area, compared to other groups. Tibial defects were nearly healed by day 21 in all the groups, but newly formed bone density was lower in Hom mice than in the other groups on days 14 and 21. New BV was significantly higher in the tibial defect than in the skull defect in all groups. Herovici's staining showed bone matrix collagen I was less dense in the Hom group than in the other groups. Osteoclasts were decreased in the defect area at day 21 in mdx, Het, and Hom mice, compared to the B10 group. MicroCT showed union of tibial fractures in all four groups at 21 days after fracture. Hom mice demonstrated significantly impaired fracture healing compared to B10, mdx, and Het mice, as revealed by lower TV, BV, BV/TV and trabecular thickness of callus, and higher mortality after fracture (6/12), whereas no mortalities occurred in the other groups after successful surgery. mdx and Het mice did not show impaired fracture healing, as demonstrated by the formation of larger calli (TV), BV, and higher BV/TV, BV density, and trabecular number, and lower trabecular separation, than in the B10 group. H&E staining showed mainly trabecular bone in the fracture site, and lower collagen 1 density, in Hom mice, compared to other groups. In conclusion, healing of tibial, but not skull, defects were delayed in Hom mice. This was attributed to the lower number of osteoclasts in Hom mice. Tibial fracture healing was also impaired in Hom mice but not in Mdx and Het mice. Further mechanistic studies are ongoing.

Annexin A5 prevents force-mediated bone ridge overgrowth at the enthesis Hisashi Ideno*[1], Yoshinori Arai[2], Koichiro Komatsu[1], Kazuhisa Nakashima[1], Satoshi Wada [3], Teruhito Yamashita[4], Ernst Pöschl [5], Bent Brachvogel[6], Yoichi Ezura[7], Akira Nifuji [1]. [1]Department of Pharmacology, Tsurumi University School of Dental Medicine, Yokohama, Japan, [2]Nihon University, School of Dentistry, Japan, [3]Department of Orthodontics, Tsurumi University School of Dental Medicine, Yokohama, Japan, [4]Division of Hard Tissue Research, Institute for Oral Science, Matsumoto Dental University, Japan, [5]School of Biological Sciences, University of East Anglia, Norwich Research Park, Norwich, United Kingdom, [6]Experimental Neonatology, Department of Pediatrics and Adolescent Medicine, Center for Biochemistry, Medical Faculty, University of Cologne, Germany, [7]Department of Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Japan

Tendons are connected to bones by a specialized tissue known as the enthesis. The enthesis transmits muscle contractile forces to the skeleton through the tendons. So far, little is known about the molecular mechanisms of enthesis formation in mature animals. We report here that annexin a5 (Anxa5), a member of the annexin family of calcium-dependent phospholipid-binding proteins, plays a critical role in the regulation of bone ridge outgrowth at the entheses. We found that Anxa5 is highly expressed in the entheses in postnatal and adult mice. In Anxa5-deficient (Anxa5-/-) mice, the sizes of bone ridge outgrowths at the entheses of tibiae and femur were increased after 7 weeks of age, although there were no obvious differences in the general morphology of long bones. Bone ridge overgrowth at entheses was also observed in muscle attachment sites of the mandibular bone in Anxa5-/- mice. This bone overgrowth was not observed at the fibrous enthesis where the fibrocartilage layer does not exist. To examine the effects of mechanical forces, we performed tenotomy in which transmission of contractile forces by the tibial muscle was impaired and hindlimb unloading by tail suspension in mice . In tenotomized mice, bone overgrowth at the enthesis in Anxa5–/– mice was decreased to a level comparable to that in WT mice at 8 weeks after the operation. Furthermore, the tail-suspended mice showed a decrease in bone overgrowth to similar levels in Anxa5–/– and WT mice at 8 weeks after hindlimb unloading, suggesting that bone overgrowth at the enthesis requires mechanical forces. Calcein and Alizarin

Red double labeling revealed more mineralized areas at the enthesis in Anxa5–/– mice than WT mice. In Anxa5–/– mice, more ALP-expressing cells were observed in the fibrocartilage layer outside of the bone. We further examined effects of AnxaA5 gene knockdown (KD) in primary cultures of chondrocytes and tenocytes in vitro. AnxaA5 KD increased ALP expression in tenocytes and chondrocytes, suggesting that increased ALP activity in the fibrocartilaginous tissue in AnxaA5 KO mice is directly caused by Anxa5 deletion in tenocytes or fibrocartilage cells. Taken together, these results suggest that Anxa5 prevents bone overgrowth at the enthesis, whose formation is mediated through mechanical forces brought by muscle loading.

Dysregulation of NF-kB in Intestinal Epithelial Cells Induces Osteopenia in Mice Ke Ke*, Manoj Arra, Gabriel Mbalaviele, Gaurav Swarnkar, Yousef Abu-Amer. Washington University School of Medicine, United States

Skeletal abnormalities are common co-morbidities of systemic inflammatory syndromes. Patients suffering from Intestinal bowel disease (IBD), including colitis and Crohn's disease, present with skeletal complications. The transcription factor NF-kB has been implicated in the pathogenesis of numerous inflammatory diseases and elevated NF-kB activity contributes to these pathologies. However, the mechanism underpinning intestinal inflammation associated bone loss remains vague. Intestinal inflammation generates an inflammatory milieu that leads to dysregulation of mucosal immunity through gut-residing, macrophages, innate lymphoid cells (ILCs) and other cells. ILCs are recently identified mucosal cells considered as the gatekeeper of gut immunity. In our current study we propose that under intestinal inflammation ILCs and other immune cells play a critical role in mediating IBD-induced bone loss. To generate intestinal inflammation we genetically expressed constitutively active IKK2 (IKK2ca) in intestinal epithelial cells (IECs) which represents a sterile non-erosive gut inflammation (IKK2caIEC mice). In addition, we used the well-established dextran sulphate sodium induced IBD (DSS-IBD) model for comparison. Histological staining of intestine sections showed mild intestinal inflammation in IKK2caIEC mice. Both experimental models lost approximately a third of their body weight. Micro-CT analysis showed significant bone loss in both models of IBD. Further Trichrome and TRAP staining in bone sections showed reduced mineralized compartments and increased OC in both models when compared with respective controls. Serum ELISA showed increases expression of inflammatory cytokines like TNFa, IL1b, IL6, IP10 etc along with increased expression of G-CSF, DKK1 and RANKL which can influence HSC niches and negatively impact osteoblasts. Moreover, ex-vivo cellular analysis in DSS-IBD model showed expansion of whole bone marrow myeloid cell lineage and alteration of intestinal innate lymphoid cell (ILCs) groups. Our finding buttresses the pathogenic role of NF-kB as the principal player that links gut inflammation with systemic bone loss. Thus, deciphering the cellular and molecular steps contributing to gut-inflammation-induced osteopenia will offer a valuable tool to treat this co-morbidity.

SAT-0145

Factors Secreted From MLO-Y4 Osteocyte-Like Cells under Inflammatory Conditions Inhibit C2C12 Myoblast Differentiation Dorit Naot*, Maureen Watson, Ally Choi, David Musson, Jillian Cornish. Department of Medicine, University of Auckland, New Zealand

The presence of healthy muscle adjacent to fracture sites accelerates healing. It has been suggested that muscle supports bone healing through secretion of myokines and by providing a source of stem cells that differentiate into osteoblasts. We developed a co-culture system that allows communication between bone and muscle cells through secreted factors. The aim of the current study was to investigate the effects of factors secreted from osteocyte-like cells on muscle cell differentiation under inflammatory conditions that model early stages of fracture healing.MLO-Y4 osteocyte-like cells were cultured in 6-well plates and C2C12 myoblasts were seeded on inserts (ThinCert™). Inserts were then suspended over the MLO-Y4 cultures and interleukin (IL)-1β was added at 10ng/mL. Four days later, C2C12 cells were fixed and stained with fluorescently-labeled myosin antibody and DAPI, and fusion index determined. Gene expression was analyzed in RNA from cells collected after 48 hours of co-culture, using real-time PCR with TaqMan® assays. The results present values pooled from three independent biological repeats.The differentiation into myotubes was similar in C2C12 cells cultured alone, treated with IL1β, or co-cultured with MLO-Y4 cells without IL1β (fusion index, mean±SEM: 27.9±2.7, 20.41±2.9 and 30.6±4.1, respectively). However, in the presence of MLO-Y4 and IL1β the fusion index was significantly lower; 9.35±2.7, (P=0.02 in comparison to media alone, one-way ANOVA with Bonferroni's post-hoc). Comparison of gene expression in C2C12 cells treated with IL1β and cultured alone or in co-culture with MLO-Y4, found lower expression of muscle differentiation markers in co-cultured cells: myogenin (Myog) was 2.4-fold lower and the myosin heavy polypeptides Myh1 and Myh8 were each 8.7-fold lower. In order to determine the specificity of the effect to the cytokine inducing the inflammatory environment, we repeated the experiments replacing IL1β with TNFα (40ng/mL). We found that the expression of differentiation markers was similarly inhibited; the expression of Myog, Myh1 and Myh8 were 13.7, 9.3 and 10.9-fold lower, respectively, in co-culture. We conclude that under inflammatory conditions, MLO-Y4 cells secrete factors that inhibit the differentiation of C2C12 myoblasts into myotubes. This inhibition may represent a stage in the process of recruitment of muscle progenitor cells that could potentially differentiate into osteoblasts and contribute to bone repair.

Region-specific differences in geometric parameters of cortical fibula structure and peroneal muscle forces in football players. Sergio Luscher*[1], Laura Marcela Nocciolino[1,2], Nicolas Pilot[3], Leonardo Pissani[3], Gustavo Roberto Cointry[1], Maria Rosa Ulla[4], Joern Rittweger[5], Alex Ireland[6], Jose Luis Ferretti[1], Ricardo Francisco Capozza[1]. [1]Center for P-Ca Metabolism Studies (CEMFoC), Natl Univ of Rosario, Argentina, [2]Musculoskeletal Biomechanical Studies Unit (UDEBOM), University Institute Gran Rosario (IUGR), Argentina, [3]Musculoskeletal Biomechanical Studies Unit (UDEBOM), University Institute Gran Rosario (IUGR), Argentina, [4]CEOM- Centro de endocrinología Osteología y Metabolismo de Córdoba, Argentina, [5]Institute of Aerospace Medicine, German Aerospace Center (DLR); Department of Pediatrics and Adolescent Medicine, University of Cologne, Germany, [6]School of Healthcare Science, Manchester Metropolitan University, United Kingdom

Structural differences have been described along the cortical human fibula, suggesting distinct, site-specific adaptations to its mechanical environment. The fibula shaft appears insensitive to disuse, whilst the fibula's response to exercise has been little studied. In this study, the cross-sectional moments of inertia concerning lateral and A-P bending (yMI, xMI) and torsion (pMI) and the cross-sectional area and vBMD of cortical bone (CtA, CtD) were pQCT-assessed in 18 serial scans of the fibula taken at every 5% of the 10-90% segment of tibia length, and the maximal strengths of the one-leg jump and the external rotation of the foot were dynamometrically assessed in the dominant (kicking) leg of 19 healthy male footballers (FB) who were trained for 4-8 years and of 15 untrained controls, aged 18-30 years. All MI's were adjusted to CtA to assess the efficiency of distribution of the available cortical tissue to resist each type of deformation.All MI's were consistently larger in FB than in controls throughout the bone (p<0.001), in the order yMI>pMI>xMI. All CtA-adjusted MI's correlated with the strength of the external rotation of the foot (not the one-leg jump) in all subjects, with highest values of both variables for FB, most significantly for the yMI (p<0.001), and with increasing adjustment (r values) toward the middle of the distal region. Correlations between the MI's (y) and CtD (x) ('distribution/quality', d/q curves, indicators of the efficiency of distribution of cortical tissue as a function of its stiffness) calculated for every site scanned were significant for all subjects (p<0.05 to p<0.01) only distally for the yMI and pMI, and nonsignificant for the xMI. Results suggest that FB training would significantly improve fibular resistance to lateral bending, torsion, and A-P bending in that decreasing order, in association with the strength of the lateral peroneal (not soleus/gastrocnemius) muscles only within their anatomic insertion area. The d/q curves suggest that all the above structural improvements (presumably resulting from the controlling work of bone mechanostat) would have been induced beyond the natural influence of cortical tissue stiffness on the easiness of stimulation of the system.This interpretation is in congruence with the observed influence of the strength of muscles which externally rotate or evert the foot on fibula robustness in hominid and predator species for which those movements have high selective connotations.

Osteocalcin and osteopontin mediate osteogenic differentiation of mesenchymal stem/stromal cells by controlling the maturation level of mineral species Marta Carvalho*[1], Joaquim Cabral[2], Cláudia Lobato Da Silva[2], Deepak Vashishth[1]. [1]Center for Biotechnology and Interdisciplinary Studies, Department of Biomedical Engineering, Rensselaer Polytechnic Institute, United States, [2]Department of Bioengineering and iBB - Institute of Bioengineering and Biosciences, Instituto Superior Técnico, Universidade de Lisboa, Portugal

Non-collagenous proteins in the bone extracellular matrix, such as osteocalcin (OC) and osteopontin (OPN) are known to control different aspects of mineralization, however their roles in mesenchymal stem/stromal cells (MSC) differentiation are still unknown. The aim of this study was to investigate the roles of OC and OPN in mineral species production during osteogenesis induced by differentiating MSC into osteoblasts.MSC were derived from tibia and femur of bone marrow of 6- to 8- week-old OC-/-OPN-/- mice and Wild-type (WT) control mice. We found that proliferation of OC-/-OPN-/- MSC was affected and their capacity to differentiate into osteoblasts was decreased, although OC-/-OPN-/- MSC were able to differentiate into adipogenic and chondrogenic lineages. After 21 days of osteogenic differentiation, calcium deposition and ALP activity levels of OC-/-OPN-/- MSC demonstrated a significant reduction compared with WT MSC.Using spectroscopic analysis, we found that the maturation of mineral species was affected by the suppression of OC and OPN levels. The minerals species maturation from OC-/-OPN-/- MSC was delayed compared with the control group. After 21 days of osteogenic differentiation, WT MSC presented the peak of hydroxyapatite (HAP) at 960 cm-1, however such a peak was not observed for OC-/-OPN-/- MSC.These results confirm that, at a cellular level, OC and OPN are important regulators of bone mineralization and provide new insights into forming high quality bone, relevant for treatment of fracture healing in older and osteoporotic bone.

SAT-0174

Osterix-cre expression by itself enhances adipogenic differentiation of stromal cells and affects hematopoiesis Katrin Huck*[1], Carla Sens-Albert[2], Inaam Nakchbandi[1]. [1]Max-Planck Institute for Medical Research, Germany, [2]University of Heidelberg, Germany

Osterix is a transcription factor in early osteoblast differentiation. It has been used to drive cre recombinase expression and delete floxed genes in cells of the osteoblastic lineage. Its expression in wildtype mice however led to skeletal defects including delayed calvarial calcification and craniofacial deformities. Therefore, the appropriate controls for genetic deletion using osterix cre are not those normally used (homozygous floxed genes in the absence of the promoter (+/+_fl/fl). Instead, mice expressing osterix-cre should be used (osx-cre/+_+/+). Several published reports deleting various genes using osterix-cre implicated these genes in early adipocyte differentiation and fat metabolism.We evaluated both osteogenic and adipogenic differentiation in vitro of newborn calvarial osteoblasts from mice only carrying osterix-cre and compared these to wildtype littermate controls. Nodule formation was diminished (30% of CT), as was osteocalcin mRNA expression (10% of CT) while the number of preadipocytes was increased (250% of CT). In line with this, PPARγ mRNA expression was increased (200%), as were other markers of adipocytic differentiation. BMD diminished by 18%, but no differences in dynamic or static bone histomorphometry parameters. Instead there was a 400% increase in the number of adipocytes on bone sections. Osmium tetroxide density was also increased (115% of CT) in the presence of osterix-cre (all results significant at p<0.05 or lower).Because several groups also proposed that bone marrow adipocytes represent part of the hematopoietic stem cell niche we evaluated hematopoiesis in the presence of osterix-cre. While peripheral blood values were normal, both the absolute number and the percentage of hematopoietic stem and progenitor cells were diminished (70% of CT), but administration of doxycycline to silence osterix and hence cre expression

normalized these values. Similarly, the common lymphoid progenitors were diminished, but these recovered after suppression of osterix-cre using doxycycline. In contrast, a decrease in mesenchymal stromal cells did not recover despite doxycycline administration.In summary, the expression of cre-recombinase under the control of osterix should not be used to evaluate mesenchymal stromal cell differentiation to either osteoblasts or to adipocytes. Furthermore, any findings using this promoter in evaluating hematopoiesis might be misleading unless a control containing osterix-cre is included.

Epigenetic targeting of the myeloma-bone microenvironment in 3D Juraj Adamik*[1], Yerneni S Saigopalakrishna [2], Sree H Pulugulla[3], Quanhong Sun[1], Philip E Auron[3], Phil G Campbell[4], Deborah L Galson[5]. [1]Department of Medicine, Hematology/Oncology, UPMC Hillman Cancer Center, University of PIttsburgh, United States, [2]Department of Biomedical Engineering, Carnegie Mellon University, United States, [3]Department of Biological Sciences, Duquesne University, United States, [4]Department of Biomedical Engineering, Engineering Research Accelerator, Carnegie Mellon University, United States, [5]Department of Medicine, Hematology/Oncology, UPMC Hillman Cancer Center, McGowan Institute for Regenerative Medicine, University of Pittsburgh, United States

EZH2, the methyltransferase subunit of Polycomb Repressive Complex 2 (PRC2), catalyzes H3K27me3 histone modificationsand epigenetically regulates genes involved in cellular pluripotency and differentiation. EZH2 regulates myeloma (MM) cell survival, and its elevated expression correlates with poor prognosis in MM patients. EZH2 inhibitors including GSK126 showed promising anti-MM effects. We showed that GSK126 rescued MM-induced suppression of BM-MSC osteogenic differentiation, indicating its potential to promote bone healing. We provide evidence that GSK126 blocks MM-induced hyper-activation of osteoclast precursors (OCLp). RNA-seq profiling revealed that inhibition of EZH2 re-activated 115 genes associated with bivalent and/or H3K27me3 promoter signatures including OCL inhibitory factors MafB, Irf8, Bcl6b and Arg1.In contrast, we found that OCLp expansion in MM1.S-conditioned media (MMCM) induced significant gene expression changes, which correlated with TNF and IKK signaling, inflammatory responses and CXC-chemokine receptor pathways. We evaluated the effectiveness of GSK126 in the context of the bone microenvironment in a novel 3-dimensional (3D) model of MM co-cultures (3D-MM).We combined basement membrane extract (BME) hydrogels with devital-ized bone slices to mimic the 3D setting of MM with the OCL-resorbing endosteal surface. This enabled us to test GSK126 alone or in combination with bortezomib simultaneously on MM survival and OCLp differentiation and resorption. While GSK126 exhibited potent anti-MM effects and blocked OCL differentiation, mature OCL added to 3D-MM co-cultures increased the IC50MM inhibition dose of both bortezomib and GSK126 by 40% and 50%, respectively. Their synergy on MM cells was further reduced by 70%. 3D-MM co-cultures with total bone marrows of differentially (1-12 months old) aged mice showed selective protection from GSK126, but not bortezomib, on MM viability. Furthermore, the resistance to GSK126 was age-dependent, with the 12-month-old bone marrows causing the greatest

protection of the MM cells. Using confocal microscopy, we found that the resistant MM cells were in close proximity to osteoprogenitor cells, suggesting that this interaction reduces the effectiveness of epigenetic drug targeting against MM.This novel 3D-MM system enables us to rapidly screen drug combinations, and simultaneously evaluate the influence of bone-microenvironmental interactions on MM drug resistance and BM cell responses to the drugs.

SAT-0195

Metastatic Lesion Types Predict Vertebral Bone Matrix Quality and Strength Stacyann Bailey*[1], David Hackney[2], Marc Stadelmann[3], Philippe Zysset[3], Ron Alkalay[2], Deepak Vashishth[1]. [1]Rensselaer Polytechnic Institute, United States, [2]Beth Israel Deaconess Medical Center, United States, [3]University of Bern, Switzerland

Tumor metastasis to the skeleton occurs in more than 80% of all cancer patients[1] and is associated with intractable pain, hypercalcemia, and pathological fractures[2]. Metastatic lesions disrupt normal bone turnover and appear radiologically as osteolytic (bone-destroying), osteoblastic (bone-forming), or mixed with features of both types. Metastatic cells induce oxidative stress within the bone microenvironment and can trigger the formation of molecular cross-links known as advanced glycation end-products (AGEs). AGEs have been shown to be detrimental to bone mechanical properties[3]. However, their role in metastatic bone disease and their contribution to bone fracture remains unclear. This study investigated whether AGE accumulation vary with type of metastatic lesion and whether AGEs in metastatic lesions are predictive of vertebral bone strength.Thoracic and lumbar vertebrae (n=14) were obtained from donors (age 59±7 yrs) with breast, kidney, lung, or prostate cancer. After removal of the endplates and posterior elements, each vertebra was scanned using micro-computed tomography at 24.5µm3 resolution for bone mineral density quantification (µCT100 Scanco, Switzerland). Vertebral bodies were tested in unconfined axial compression until failure and structural properties determined (MTS858 MiniBionix II). The type of lesion in each vertebra i.e. lytic, blastic, or mixed was characterized based on appearance from the µCT dataset. Trabecular bone cores demonstrating these range of lesions were then analyzed for total fluorescent AGEs [4]. Mixed model ANOVA was used to determine the relationship between lesion type and all measured parameters.A significant association with AGEs and lesion type was observed. More specifically, mixed lesions exhibited higher AGEs compared to lytic (p=0.018) and blastic (p=0.015) (Fig 1). A negative correlation between AGEs and BMD was observed for mixed (R2 = 0.36, p=0.023) and blastic (R2 = 0.44, p=0.0512) lesions. This association remained when the primary cancer was taken into account whereby breast (R2 = 0.43, p<0.01) and prostate (R2 = 0.58, p<0.01) metastases exhibited higher AGE content with low BMD. Independent of lesion type, AGE was negatively associated with vertebral strength (R2= 0.10, p=0.031). Our results indicate that metastatic bone is heterogeneously modified by AGEs and is lesion dependent. This study provides insight into the role of post-translational modification in bone metastases and may reveal new targets for predicting fracture risk.

Diacritic impacts of matrix stiffness and adhesion on osteosarcoma cells and osteoblasts Tongmeng Jiang*, Li Zheng, Jinmin Zhao. Guangxi Engineering Center in Biomedical Materials for Tissue and Organ Regeneration & Guangxi Collaborative Innovation Center for Biomedicine, The First Affiliated Hospital of Guangxi Medical University, China

The means of extracellular matrix (ECM) affects osteosarcoma cells and their normal counterparts (osteoblasts) is still unknown. Different natural materials with distinguishable characteristics were used as vehicles for two-dimensional (2D) and three-dimensional (3D) culture. Assays showed that matrix stiffness and adhesion are two main factors influenced on osteosarcoma cells and osteoblasts. We developed hydrogels with different ECM stiffness

and adhesion properties using poly (ethylene glycol) diacrylate (PEGDA) and methacrylated gelatin (GelMA). When cultured in 3D hydrogels, osteosarcoma cells are dependent on the matrix stiffness by regulating the integrin-mediated focal adhesion (FA) pathway, whereas osteoblasts are highly sensitive to the ECM adhesion via the integrin-mediated adherens junction (AJ) pathway. However, when seeded on the 2D hydrogels, osteosarcoma cells were similar to anchorage-dependent osteoblasts and behaved anomalously and became sensitive to the ECM adhesion because they were "forced" to attach to the underlayment. This study might provide new insights into rational design of scaffolds for tumor or tissue engineering.

SAT-0197

Identification of potential mediators of bone loss in cancer Jessica Dorschner*, Jennifer Westendorf, Theodore Craig, Xuewei Wang, Rajiv Kumar. Mayo Clinic, United States

Abstract: Bone loss occurs frequently in patients with breast, prostate, and lung cancer, and plasma cell dyscrasias such as multiple myeloma (MM) and is associated with considerable morbidity and reduced survival. Inhibitors of the Wnt signaling pathway such as Dkk1 are thought to contribute to bone loss of bone in MM patients, but the precise mediators of bone loss in other tumors has not been well defined. We sought to identify potential mediators of bone loss elaborated by Lewis lung cancer 1 cells (LLC1), a model of non-small cell lung cancer. Mice inoculated with LLC1 cells lost bone mass within three weeks of tumor cell injection as assessed by dual-energy x-ray absorptiometry and compared to vehicle injected mice. Micro-computed tomography of bone showed a reduction in bone trabecular volume, number and connectivity but no change in cortical bone thickness in mice injected with tumor cells.To identify modulators of bone density secreted by tumor cells, we performed whole transcriptome sequencing of LLC1 cell mRNAs and compared the information obtained from these cells with that obtained from non-tumorigenic distal respiratory epithelial cells (MLE12 cells). We identified several factors in the secretome of LLC1 cells that could alter bone formation and resorption. These factors include hedgehog interacting protein, Wnt modulators such as Dkk2, various interleukins, chemokines, and growth, differentitation factor 15 and PTH-like protein (Table 1) whose expression was significantly increased. We conclude that the "secretome" of non-small cell lung cancer cell line LLC1 encodes proteins that mediate bone remodeling. The mouse model of tumor-induced bone loss developed by us will allow the systematic examination of the role of these factors in vivo.

Table 1. Differentially Expressed mRNAs Encoding Secreted Proteins in LLC1 Compared to MLE12 Cells Determined by RNA-seq.

Top 10 mRNAs encoding secreted proteins whose expression is significantly increased in LLC1 cells

An Incomplete Atypical Femoral Fracture Associated with Bisphosphonate Therapy and Femoral Skeletal Metastasis Pamela Taxel, Md*, Adam Lindsay, Md. UConn Health, United States

Introduction: Atypical femoral fractures (AFFs) have been associated with long-term bisphosphonate (BP) use in patients with osteoporosis. BPs are also used in the prevention of skeletal-related events (SREs) in patients with skeletal metastases and cancer. Oncology trials have reported few AFFs with limited detail, and most fractures are classified as pathologic. We report the case of a patient treated for metastatic breast cancer with an incomplete AFF in an established area of skeletal metastasis. Case: A 58-year-old woman was referred for opinion about anti-resorptive therapy in the setting of skeletal metastases. She was diagnosed with breast cancer 8 years ago, and received neoadjuvant chemotherapy, lumpectomy, radiation therapy and treatment with anti-estrogen therapy for 5 years. She had no history of fractures or metabolic bone disease and received adequate calcium and Vitamin D. Shortly after completing anti-estrogen treatment she was diagnosed with metastases to bone (L1, right femur) and liver. She subsequently received IV zoledronic acid, 4 mg monthly, for a year and then every 3 months, for a total of 14 doses. She did well for a year, but then developed right hip pain, and imaging confirmed multiple new areas of skeletal involvement, but low concern for impending fracture of the right femur. A month later her right hip pain progressed and she was unable to bear weight. Repeat radiographs show a nondisplaced right subtrochanteric femoral fracture with cortical thickening, consistent with an incomplete AFF. She underwent prophylactic nailing and specimens from the area confirmed rare atypical cells consistent with breast cancer. BP therapy was discontinued. Within 6 months she developed left hip pain and inability to bear weight. Xray revealed metastatic lesion of the proximal femur with erosion into the soft tissue; therefore, prophylactic nailing of left femur was performed. Discussion: We report an incomplete AFF in an area of established skeletal metastasis. It is important to recognize that bone pain in an area of known metastasis may be due to an impending AFF versus a pathologic one. BPs concentrate in areas of high bone resorption such as skeletal metastases, and may increase risk of AFF. Prophylactic stabilization of the femur is recommended if the patient is experiencing functional pain with incomplete AFF; however, radiation would be the initial approach if underlying malignancy was the etiology of pain and dysfunction.

SAT-0199

Roles of membrane bound HB-EGF and EGF-Receptor interaction on osteoblast in melanoma induced bone resorption Kenta Watanabe*, Shosei Yoshinouchi, Keita Taniguchi, Michiko Hirata, Tsukasa Tominari, Chisato Miyaura, Masaki Inada. Tokyo University of Agriculture and Technology, Japan

Prostaglandin E2 (PGE2) is associated with inflammatory bone destruction in various infectious immune responses. We have reported that the bone metastasis of malignant melanoma induced PGE2 that caused by direct interaction with melanoma and host osteoblast. Although bone metastasis of malignant melanoma is accompanied with severe bone destruction increased by bone resorption, the triggered target molecule in melanoma that induced PGE2 production in osteoblast is still not known. We have been searching the key molecules that involved cell to cell interaction between melanoma and host osteoblast. Recently, we found several candidates of these target molecules for cellular interaction that mainly found in membrane bound proteins, and some of the molecules were screened by the criteria of PGE2 production capability in osteoblast. In this study, we examined the malignant melanoma (B16) induced bone destruction focusing on heparin-binding EGF-like growth factor

(HB-EGF) which is a ligand of EGFR. The ligand HB-EGF expression was detected in both B16 and osteoblast, however, the receptor EGFR expression was only found in osteoblasts. In HB-EGF treatment, COX-2 and mPGES-1 mRNA expression and PGE2 production were increased. Following RANKL expression was also increased that correlated the levels of PGE2 production induced by HB-EGF. Additional treatment of EGFR inhibitor clearly suppressed both PGE2 and RANKL expression that was induced by HB-EGF treatment. EGFR inhibitor also blunted EGFR and ERK phosphorylation. These data showed that cell to cell interactions between B16 and host osteoblast increased the production of PGE2 and RANKL in osteoblast, EGFR inhibitor attenuated all these of induction in osteoblast. Previous reports suggested that epidermal-mesenchymal interaction increased PGE2 production in many case of biological phenomenon. In this case, the interaction of epidermal melanoma among mesodermal osteoblast induced PGE2 production and sequentially leads to RANKL production in osteoblast that promoted following osteoclast functions. These results clearly indicated that the HB-EGF produced by melanoma activated EGFR/ERK signaling in osteoblast and increased RANKL production via PGE2 signaling. Targeting of HB-EGF/EGFR/ERK signaling is promising therapeutic candidate for the treatment of melanoma patients with bone metastasis.

Runx2 Deletion in Chondrocytes Fails to Disrupt Development of TMJ David Summerford*, Haiyan Chen, Harunur Rashid, Yang Yang, Amjad Javed. University of Alabama at Birmingham, United States

The development of the orofacial structure such as palate and the temporomandibular joint (TMJ) in mammals is a highly ordered process. The TMJ is a complex structure that is essential for normal jaw function and consist of glenoid fossa of the temporal bone, the condylar head of the mandible, and a fibrocartilagenous disk. Chondrocytes and osteoblasts work in close association during the development of the TMJ. Due to unavailability of suitable mouse models, very little is known about the function of Runx2 during the development of the TMJ. To elucidate Runx2 regulatory control distinctive to chondrocyte cell population, we ablated Runx2 gene using Col2a-Cre mice. Cellular, histological and immuno-histochemical approaches were utilized to evaluate developmental progression of TMJ and orofacial bone. Runx2Ch-/- mice exhibited failed endochondral ossification and die shortly after birth. The progressive differentiation of chondroprogenitors to proliferative and mature hypertrophic chondrocytes noted in long bones of wild-type mice was completely absent in the Runx2Ch-/- littermates. Runx2 activity in chondrocyte also contributes to the formation of craniofacial bones derived by endochondral ossification. Unlike the wild-type littermates, the basisphenoid and occipital skull bones were absent in the Runx2Ch-/- mice. Surprisingly, in spite of the loss of Runx2 in chondrocyte of Meckel cartilage, we observed normal maxilla, mandible and jaw formation, as well as odontogenesis in the Runx2Ch-/- littermates. RUNX2 insufficiency in humans has been linked to the lip and or palatal clefting. Interestingly, both the formation and fusion of palate was normal in the Runx2Ch-/- littermates. However, the palate size was significantly reduced in the newborn homozygous mice. Runx2 is expressed from embryonic to adult stages of TMJ cartilage. We first confirmed, Runx2 gene deletion in developing TMJ by using both tdTomato and Rosa reporter mice. Surprisingly, development of condylar cartilage, the major component of the TMJ was unaffected in the homozygous mice. Unlike growth plate, Runx2 deficient chondrocytes in the TMJ cartilage showed progressive hypertrophic maturation, mineralization, and endochondral ossification. Together these results indicate that in chondrocytes Runx2 exerts differential

roles, where it is obligatory in hyaline cartilage of long bone but not in chondrocyte that form Meckel or TMJ cartilage.

IL36α promotes chondrocyte maturation: is this a functional role in fracture repair? Xin Jin*, Tieshi Li, Alessandra Esposito, Jie Jiang, Lai Wang, Joseph Temple, Anna Spagnoli. Rush University Medical Center, United States

Introduction: IL36α, a proinflammatory cytokine, plays critical roles in psoriasis and osteoarthritis. However, the role of IL36α in endochondral ossification and in fracture repair has not been evaluated. Purpose: To investigate the role of IL36α in chondrocytes maturation during the endochondral ossification process and in the formation of the cartilaginous callus during fracture repair. Methods: 1) Fracture calluses were obtained from mice that underwent to a semi-stabilized tibia fracture and subjected to qRT-PCR and IHC analyses for IL36α, IL36 receptor (IL36R) and IL36 receptor antagonist (IL36Ra). 2) Isolated mesenchymal limb-bud cells obtained from E11.5 mouse embryos, were cultured in micromasses and treated with IL36α respectively for 7, 9 and 13 days, followed by Alizarin Red (AR) and Alkaline Phosphatase (AP) staining; mRNA and total protein were subjected to qRT-PCR and WIB analyses. 3) Primary chondrocytes, isolated from the humerus, radius and ulna of E15.5 embryos were treated with IL36α and respectively with inhibitors of p38 MAP kinase (SB203580), MEK1 (PD98059) and NFκB (JSH-23) that are downstream signaling pathways of IL36α. Results: mRNA expression levels of IL36α, IL36R and IL36Ra increased in the first few days after fracture compared with D0 (tissue collected few minutes after the fracture). IL36α and IL36R peaked at Day5 after fracture, IL36Ra peaked at Day3. IL36α, IL36R and IL36Ra gradually reached a nadir at Day21. IHC analyses showed that at Day0, IL36α, IL36R and IL36Ra were mainly detected in the periosteum. At Day1, Day3 and Day5, IL36α, IL36R and IL36Ra expressing cells localized within multiple regions including hematoma, periosteal and endosteal sites. At Day7 and Day10, IL36α, IL36R and IL36Ra were expressed in the cartilaginous callus by pre-hypertrophic and hypertrophic chondrocytes. In micromass cultures, IL36α increased AR staining, AP staining and expression of Runx2, Collagen 10 and Mmp13. Similarly, in primary chondrocytes, IL36α induced Runx2, Collagen 10 and Mmp13 expressions. JSH-23 significantly attenuated IL36α stimulated Mmp13 and Runx2 expressions, suggesting that IL36α signaling promotes chondrocyte maturation via NFκB-Runx2-Mmp13. SB203580 and PD98059 had no effects. Conclusions: In the endochondral ossification process, IL36α promotes chondrocytes hypertrophy. During fracture repair, IL36α, IL36R and IL36Ra are temporally-regulated and expressed by hypertrophic chondrocytes. Findings are supportive for a role of IL36α and its signaling in skeletogenesis and in fracture repair likely by regulating hypertrophy.

SAT-0234

Role of the A2B Adenosine Receptor in Inflammatory Degradation of Cartilage Meghan Kupratis*, Lauren Mangano Drenkard, Louis Gerstenfeld, Elise Morgan. Boston University, United States

Introduction: Adenosine receptors mediate multiple pathways that lead to joint destruction in rheumatoid arthritis and are involved in inflammation through cytokine activity. The goal of this study was to assess the relationship of the A2B adenosine receptor (A2BAR) to cartilage degeneration in collagen antibody-induced arthritis (CAIA).Methods: A2BAR knockout (KO) mice (n=16) were bred on a C57BL/6J background, along with wild type (WT) C57BL/6J mice (n=12). At four months of age, mice were injected with collagen antibody (ArthritoMab, MDBiosceinces) and lipopolysaccharide (Sigma-Aldrich) (CAIA) or saline (control). Proximal tibiae underwent contrast-enhanced microCT (CECT) with the contrast agent CA4+ to image cartilage. Quantitative real-time PCR was run in triplicate for primers for lubricin and aggrecan; expression was normalized to Rn18s. Molecular assessments of A2BAR function were carried out in ATDC5 chondrogenic cells seeded at 4.10x105 cells/well and cultured for two days in DMEM with 5% fetal bovine serum (FBS) and 1% penicillin/streptomycin (P/S), followed by 21 days in α-MEM with 5% FBS,

1% P/S, and 0.5% insulin transferrin selenium. Six treatment groups were established: no A2BAR ligands ± tumor necrosis factor (TNF; 10 ng/mL, BD Biosciences); NECA (A2BAR agonist; Tocris Bioscience) ± TNF; and PSB-1115 (PSB; A2BAR antagonist; Tocris) ± TNF. Cell viability was determined using a live/dead assay (Molecular Probes) and DAPI stain (Molecular Probes).Results: CECT attenuation (a measure of glycosaminoglycan content) in tibial cartilage decreased with CAIA at days 8 (p<0.05) and 10 (p<0.0001) in both KO and WT mice; however, there were no changes in cartilage thickness (p=0.44). Lubricin and aggrecan expression decreased four- to eight-fold with CAIA in both genotypes. The A2BAR agonist (NECA) and antagonist (PSB) had mild negative effects on chondrocyte viability; however, only the agonist combined with TNF reduced cell viability beyond the effects of TNF alone (p<0.001).Discussion: While loss of A2BAR in vivo leads to systemic elevation of TNF, it did not synergize the negative effects of CAIA on cartilage loss or chondrocyte function. Interestingly, activation of A2BAR in vitro increased TNF-mediated cell death while the antagonist had no effects. Taken together, these results suggest that A2BAR locally enhances actions of TNF, while systemically acting to inhibit TNF expression.
Figure 1: A) Sagittal CECT sections of the proximal tibia ("NU" = native attenuation units); B) CECT attenuation of tibia articular cartilage (*p<0.05, ** p<0.0001 CAIA vs. control); C) cell viability (live cells as a percentage of total cells) in the in vitro experiments. Non-matching letters indicate differences among groups (p<0.001).

Osteocalcin Null Mice Differ From Wildtype by Sex and Genotype in Response to Prolonged High Fat Diet Patricia Buckendahl*, Saad Ahmad, Nicholas Bello, Sue Shapses. Rutgers University, United States

Osteocalcin (OC), a bone-associated gamma-carboxyglutamic acid (Gla)-containing, vitamin K dependent protein, stimulates insulin and adiponectin synthesis in mice. Gla conveys calcium-binding capability to OC and numerous other proteins. Early reports indicated that OC null mutants (KO) were obese, hyperglycemic, and insulin resistant but did not specify gender or background strain. We studied WT and KO on the C57Bl/6 background under a variety of treatments, and had not observed genotypic differences in body mass or hyperglycemia. To investigate this discrepancy, we studied male and female WT and KO mice, bred at Rutgers under approved institutional care protocols as progeny of their respective homozygous parents, thus KO had no fetal or neonatal exposure to OC. All mice were previously provided normal Lab Diet chow. We performed oral glucose tolerance tests (OGTT) in 8 month-old male (5 WT, 10 KO) and female (7 WT, 8 KO) mice. We then provided high fat diet (HFD, Research Diets) for 14 weeks and monitored weight gain. We performed another OGTT after 10 weeks on HFD. Two days before termination, we quantified body fat mass by Echo MRI. At the end of the experiment, we collected blood and placed hind limb bones into 70% EtOH for later analysis. Results: Initial body weights did not differ by genotype. OGTT did not differ significantly by genotype in males, but did differ in females (area under the curve greater in KO than WT, p< 0.05). Both male and female mice gained significant body mass (53% and 51% of initial body mass respectively). Relative to initial body mass, KO males gained 3% more fat mass than WT males (p<0.05), but this difference was not observed in females. WT females gained 25% more fat mass than WT males (p<0.05). OGTT performed after prolonged HFD indicated no genotypic difference between males; however in females, KO had an impaired tolerance compared with WT (p<0.05). Analysis of femoral bone microstructure by microCT (SkyScan 1172) indicated no significant differences between male WT and KO in either trabecular or cortical parameters. Likewise, female cortical parameters did not differ by genotype; however, trabecular analysis did indicate adverse effects of diet. KO females had lower BV/TV and BS/TV than WT (p<0.01), no differences in TbTh, but higher TbSp and TbN (p<0.01).We conclude that HFD effects on weight gain, glucose tolerance and femoral morphology in aged osteocalcin KO mice are diet, gender and genotype specific.

Change In Body Composition And Mass In Relation To The Final Menstrual Period (FMP): Study Of Women's Health Across The Nation (SWAN) Gail Greendale*[1], Weijuan Han[1], Meihua Huang[1], Barbara Sternfeld[2], Kristine Ruppert[3], Carrie Karvonen-Gutierrez[4], Arun Karlamangla[1]. [1]Division of Geriatrics, David Geffen School of Medicine at UCLA, United States, [2]Division of Geriatrics, Emeritus, United States, [3]Epidemiology Data Center, University of Pittsburgh, United States, [4]School of Public Health, University of Michigan, United States

Purpose: Changes in body composition and mass in mid-life women are often attributed to aging rather than to the menopause transition (MT). Small sample sizes and few women transitioning from pre-to-postmenopause in prior studies raise the possibility that an apparent absence of an MT-effect results from type-II error. We examined rates of change in body composition and weight during 8 y before and 10.5 y after the FMP, to detect and quantify any acceleration or deceleration in changes in these characteristics during this time. Methods: We measured weight, height, and body composition by DXA in women initially aged 42-52 y and pre- or early perimenopausal. We used loess plots to estimate the functional form of each outcome's trajectory in relation to # of years before or after the FMP. We used multivariable mixed effects regression to fit piecewise linear models to repeated measures of baseline-normalized values of each outcome as a function of time before or after FMP, using linear splines. Covariates were age at FMP, race, study site and time-varying hormone therapy (HT) use. Results: 356 Black, 153 Chinese, 178 Japanese and 559 White women had mean baseline age 46.7 y and age at FMP 52.2 y. Mean # of DXA's per woman was 11 (max 14). Optimum knot locations were 2 y prior to and 1.5 y after FMP for body composition and 1 y prior to and 3 y after FMP for weight and BMI. Gain in total fat mass and the proportion fat (fat mass/total mass) were evident during pre-transmenopause along with a decline in the proportion lean (lean mass/total mass). In each case, onset of transmenopause (interval bracketing FMP, defined by the change knots) saw a 2-3 fold doubling of the rate of change. Body composition parameters stabilized (slopes did not differ from 0) in postmenopause. During pre-transmenopause, weight and BMI increased; however, slopes did not change at transmenopause. In postmenopause, weight stabilized and the rate of increase in BMI slowed. Conclusion: The MT exerts unfavorable effects on fat and lean mass, characterized by accelerated, adverse changes in these parameters. These metabolic alterations are not reflected in weight and BMI, which continue on the same linear, increasing trajectory as that observed in pre-transmenopause. In postmenopause, changes in body composition and weight cease. Supported by NIH/DHHS Grants U01NR004061, U01AG012505, U01AG012535, U01AG012531, U01AG012539, U01AG012546, U01AG012553, U01AG012554, U01AG012495, R21DK107211

Average annual rates of change of body composition and weight in relation to the date of the final menstrual period (FMP) Study of Women's Health Across the Nation (SWAN) [a,b,c,d,e]			
	Body weight or composition slopes (% per year) during each interval before and after the FMP (95% CI)		
	Pre-Transmenopause 8 to 2 y before FMP	Transmenopause 2 y before to 1.5 y after FMP	Postmenopause 1.5 to 10.5 y after FMP
Total fat (kg)	0.95% (<.0001)	1.70% (<.0001)	0.05% (0.60)
Total lean (kg)	0.16% (0.0002)	-0.15% (0.0073)	-0.05% (0.13)
Proportion fat	0.41% (<.0001)	1.03% (<.0001)	0.04% (0.37)
Proportion lean	-0.19% (<.0001)	-0.54% (<.0001)	0.01% (0.68)
	Pre-Transmenopause 8 to 1 y before FMP	Transmenopause 1 y before to 3 y after FMP	Postmenopause 3 to 10.5 y after FMP
Weight (kg)	0.46% (<.0001)	0.34% (<.0001)	-0.03% (0.59)
BMI (kg/m²)	0.49% (<.0001)	0.43% (<.0001)	0.11% (0.04)

[a] Values in table are model-predicted slopes for the average participant, (with age at FMP, clinical site, race and HT use set at sample mean) and are presented as the percentage of baseline level that is gained per year.
[b] Knots vary between body composition and anthropometric outcomes; intervals of time around the FMP which define the transmenopause are, therefore, different.
[c] Proportion fat = fat mass/subtotal mass; proportion lean = lean mass/subtotal mass
[d] Slopes in each interval that are statistically significantly different from 0 are shown in **bold italic typeface**.
[e] For each model, slopes in each interval are statistically significantly different from each other, except for the pre-transmenopause vs. transmenopause comparison in the instances of weight and BMI.

Hyperandrogenism is not associated with low bone mineral density in exercising women with menstrual disturbances Kristen Koltun*, Emily Southmayd, Nancy Williams, Mary Jane De Souza. Pennsylvania State University, United States

Exercise associated menstrual disturbances (EAMD) are associated with suboptimal bone health. A subset of women with EAMD also present with hyperandrogenism (HA), which may mitigate the risk for low bone mineral density (BMD). Our purpose was to determine if there were differences in BMD among exercising women with EAMD and concurrent HA (EAMD+HA, n=31), exercising women with EAMD without HA (EAMD, n=66), and exercising ovulatory controls (OV, n=45).Exercising women were recruited and menstrual status was assessed by self-reported history of menses and confirmed with daily urinary measures of estrogen and progesterone metabolites. Total testosterone (TT) and sex hormone binding globulin (SHBG) were measured in serum and used to calculate free androgen index (FAI) (FAI=TT/SHBG*100). HA was defined as FAI>2.92, representing the upper bound of the 95% confidence interval for all subjects. BMD (total body, L1-L4, femoral neck, total hip) and percent body fat (%BF) were assessed via DXA. One-way ANOVA was used to compare body composition and BMD among the groups with a Tukey post-hoc, as necessary.Subjects were 22.3±0.3 yrs old, 165.6±0.5 cm tall, had a body mass of 57.4±0.6 kg, a BMI of 21.1±0.2 kg/m2, and had 25.3±0.4 %BF. Groups were similar with respect to weight, but BMI (p=0.007) and %BF (p=0.019) were elevated in EAMD+HA (21.9±0.4 kg/m2; 27.0±1.0%) compared to EAMD (20.5±0.3 kg/m2; 24.1±0.6%). Groups were similar with respect to BMD for the total body (p=0.068; 1.12±0.01 g/cm2), femoral neck (p=0.404; 1.05±0.01 g/cm2), and total hip (p=0.107; 1.05±0.01 g/cm2). There was a significant main effect for group at the lumbar spine (p=0.001). Post-hoc analyses identified that L1-L4 BMD was significantly lower in EAMD (1.09±0.02 g/cm2) compared to OV (1.19±0.02 g/cm2) (p<0.001), however, L1-L4 BMD was not different in the EAMD+HA group (1.13±0.02 g/cm2) compared to either the EAMD or OV groups (p>0.05).Women with EAMD in the absence of HA presented with a significantly lower BMD at the lumbar spine compared to ovulatory controls. This difference was not apparent in women with EAMD and evidence of HA. This cross sectional study suggests that EAMD combined with HA is not associated with the commonly observed reduction in BMD reported in women with EAMD. It is possible that HA may be protective of BMD in the face of EAMD, likely because of the higher exposure to androgens, but additional prospective studies are required.

Thermoneutral housing exacerbates bone loss from atypical antipsychotic drugs Roni Kunst*[1], Megan Rue[2], Katherine Motyl[2]. [1]MMCRI, Netherlands, [2]MMCRI, United States

Risperidone (RIS) and olanzapine (OLA) are atypical antipsychotic (AA) drugs that are used to treat mental disorders, such as schizophrenia and bipolar disorder. AA drugs cause several metabolic side effects, such as hyperlipidemia and glucose intolerance. More recently, bone loss and increased fracture risk have been added to this list. We have previously shown that bone loss from RIS is mediated through the sympathetic nervous system (SNS) and accompanied by markers of thermogenesis in brown adipose tissue. However, room temperature housing in mice is sub-thermoneutral and accelerates age-related bone loss. This complicates preclinical studies because humans are thermoneutral around room temperature. In this experiment we aimed to explore the effect of thermoneutral housing on AA drug-induced bone loss. We housed 8-week-old female C57BL/6J mice at room temperature (22 °C) or thermoneutrality (28-30 °C) to better model clinical exposure. Mice were dosed daily for four weeks with 1.5 mg/kg RIS, 10 mg/kg OLA or vehicle by oral gavage. In thermoneutral conditions, OLA, but not RIS, caused a decrease in femoral bone mineral density (BMD) by dual X-ray absorptiometry (DXA), despite an increase in lean mass in both groups. At room temperature, we observed a similar increase in lean mass (p<0.05), but only in the RIS treated mice. Both RIS and OLA-treated mice had significantly decreased trabecular bone volume fraction and trabecular number, and increased trabecular separation com-

pared to vehicle treated mice housed at thermoneutrality (all p<0.05). Although, femur total cross-sectional area did not change, cortical thickness decreased due to both RIS (p<0.05) and OLA (p<0.0001) treatment. Expression of the osteoclast marker, Acp5, increased in tibia marrow of RIS treated mice (p<0.05), whereas the marrow adipocyte marker, fatty acid binding protein Fabp4, increased after both RIS (p<0.01) and OLA (p<0.05) treatments. This is contrary to the decrease in marrow adiposity we have seen before in RIS treated mice at room temperature. In contrast to thermoneutral conditions, AA treated mice housed at room temperature did not exhibit changes in cortical micro-architecture. In conclusion, we found bone loss with AA treatment was more severe at thermoneutrality, suggesting room temperature housing may mask some of the deleterious bone effects of treatments involving the SNS.

Metabolic, Anthropometric and Nutritional Profile of Girls with Adolescent Idiopathic Scoliosis: A Pilot Study Émilie Normand*, Anita Franco, Stefan Parent , Alain Moreau, Valérie Marcil. Centre de recherche CHU Sainte-Justine, Canada

Purpose of the study: Studies have shown that patients with adolescent idiopathic scoliosis (AIS) have anthropometrical differences compared to their peers, but results are inconsistent. While differences in energy metabolism and nutrition could explain these discrepancies, they have been poorly studied in AIS. This study aims to thoroughly characterize the metabolic profile, nutritional habits and level of physical activity of girls affected by AIS and to compare them to age-matched healthy controls.Methods: For this pilot study, 20 girls with AIS and 20 healthy controls are being enrolled. Fasting glucose, insulin and lipid profile (total cholesterol, LDL-cholesterol, HDL-cholesterol, triglycerides and apolipoprotein B) are assessed. Bone mineral density and body composition is determined by osteodensitometry scan. Anthropometric parameters (weight, standing and sitting height, body mass index (BMI), waist circumference and arm spam) are measured and questionnaires are administered to assess food intake and physical activity level.Results: To this day, 13 AIS and 9 healthy girls have completed the study. The mean age for AIS girls and controls was 14.8 ± 1.8 and 14.7 ± 1.7 yrs, respectively. The AIS group had a mean Cobb angle of $27.9 \pm 9.4°$ and a mean age at diagnosis of 12.6 ± 1.7 yrs. Preliminary results show that AIS girls were taller than controls and have lower weight, BMI, body fat percentage and bone mineral density, although differences were not statistically significant. Fasting glucose and insulin were not different between groups. We found a tendency for perturbed lipid profile in AIS girls with higher LDL-cholesterol (18%, P=0.065), apolipoprotein B (22%, P=0.087) and total cholesterol (12% P=0.0763). Calorie intake and physical activity levels were similar between groups, but AIS girls consumed more calories than their needs compare to controls. There was a tendency of higher calcium intake in AIS (28%, P=0.1437) and both groups had similar vitamin D intake.Conclusion: In this study, AIS girls tended to have differences in their anthropometrical features, lipid profile and energy balance when compared to age-matched controls. Increasing the number of participants might confirm these results.

A rat model of steroid-associated osteonecrosis Li-Zhen Zheng*[1], Jia-Li Wang[1], Ling Kong[1], Le Huang[1], Li Tian[1], Qian-Qian Pang[1], Xin-Luan Wang[2], Ling Qin[1]. [1]Musculoskeletal Research Laboratory, Department of Orthopaedics & Traumatology, The Chinese University of Hong Kong, Hong Kong SAR, PR China, Hong Kong, [2]Translational Medicine R&D Center, Institute of Biomedical and Health Engineering, Shenzhen Institutes of Advanced Technology, Chinese Academy of Sciences, Shenzhen, PR China, China

It is essential to establish a preclinical disease animal models to study etiology and/or pathophysiology of the relevant diseases and to test prevention and/or treatment concept(s). This study established an induction and assessment protocol for a preclinical steroid-associated osteonecrosis (SAON) animal model in rats with pulsed injections of lipopolysaccharide (LPS) and methylprednisolone (MPS).Twenty-eight 24-week-old male Sprague-Dawley rats were included in this study. Sixteen rats were used to induce SAON by one intravenous injection of LPS (0.2 mg/kg) and three intraperitoneally injections of large dose of MPS (100 mg/kg) with a time interval of 24 hours, and then low dose of MPS (40mg/kg) were intraperitoneally injected 3 times a week from week 2 to sacrifice. Additional twelve rats were used as normal controls. 2 and 6 weeks after induction, animals were scanned by a metabolic dual energy x-ray absorptiometry (DXA) for tissue composition, serum was collected for bone turnover markers, microfil perfusion was performed for angiography, liver was collected for histopathology, and bilateral femora and bilateral tibiae were collected for histological examination.Three rats died after LPS injection, with additional three supplemented, i.e. with 15.8% (3/19) mortality. All rats from SAON group showed SAON at week 2 with 100% incidence by histological evaluation. Rats from SAON group showed significantly higher fat percent and lower lean weight at week 6 by DXA, and significantly bone degradation at proximal tibia at 6 weeks by Micro-CT. Angiography showed significantly less blood vessels in proximal tibia and significantly more leakage particles in distal tibia 2 weeks after SAON induction. For bone turnover markers, serum PINP and OC were significantly lower at both 2 and 6 weeks after SAON induction, and serum CTX was significantly lower at 6 weeks after SAON induction. Histomorphometry showed significantly lower osteoblast surface,

and higher marrow fat fraction and edema area in SAON group. Hepatic edema appeared 2 weeks after SAON induction, and lipid accumulation appeared in liver of SAON rats 6 weeks after SAON induction.This SAON rat model induced with pulsed injection of LPS and MPS, which was well simulating the clinical feature and pathology, could be a cost-effective preclinical experimental model to study body metabolism, molecular mechanism of SAON and potential drugs developed for prevention or treatment of SAON.

No Indication for Increased Severity of the Sclerotic Bone Phenotype of Sost Knock-out Mice in the Presence of an Lrp4 Mutation. Eveline Boudin*[1], Timur Yorgan[2], Gretl Hendrickx[2], Ellen Steenackers[1], Michaela Kneissel[3], Ina Kramer[4], Geert Mortier[1], Thorsten Schinke[2], Wim Van Hul[1]. [1]Centre of Medical Genetics, University and University Hospital of Antwerp, Belgium, [2]Department of Osteology and Biomechanics, University Medical Center Hamburg, Germany, [3]Musculoskeletal Disease Area, Novartis Institutes for BioMedical Research, Basel, Switzerland., Switzerland, [4]Musculoskeletal Disease Area, Novartis Institutes for BioMedical Research, Basel, Switzerland., Belgium

Previously we showed that loss of function of sclerostin, encoded by SOST, and hypomorphic missense mutations in LRP4 can be the genetic cause underlying sclerosteosis, a rare sclerosing bone disorder marked by an increased bone mass especially at the skull and tubular bones. Sclerostin and LRP4 are shown to interact and the interaction is impaired in the presence of the sclerosteosis causing mutations in LRP4. Furthermore, it was shown that the sclerostin-LRP4 interaction is important for the inhibition of the canonical WNT signaling, a known regulator of bone formation.In addition, not only sclerostin but also other modulators of canonical WNT signaling and bone metabolism e.g. wise and dickkopf1 (DKK1) are reported to interact with LRP4. To investigate the importance of different bindingpartners of LRP4 in the regulation of bone formation, we crossed the previously described Sost knockout mouse (Sost-/-) with the recently described Lrp4 p.R1170Q homozygous knockin (Lrp4R1170Q) mouse model (Polygene, Switzerland) and compared the bone phenotype of the double mutant mice with that of the Sost-/- and Lrp4R1170Q mice. μ-CT analysis as well as structural histomorphometry data showed that the sclerotic bone phenotype of the Lrp4R1170Q mouse is milder compared to that of the Sost-/- and the Lrp4R1170Q;Sost-/-double mutant mice, the latter two showing no significant difference. Based on these data, it seems first that the skeletal phenotype observed in the Lrp4R1170Q mice is due to the impaired binding of LRP4 to sclerostin but at the same time that other binding partners of LRP4 do not contribute to the bone phenotype of the LRP4 mutant mice or that their action is not disturbed by the mutation. Measurement of DKK1 in serum of these mice demonstrated that the levels of DKK1 are, in contrast to sclerostin, not significantly increased in Lrp4R1170Q mice compared to wild type mice which confirms that their interaction is either not disturbed by the mutation or that LRP4 is not the main interaction partner of DKK1 in bone. Furthermore, the more severe phenotype observed in the Sost-/- mice indicates that there is still some residual inhibitory activity of sclerostin in Lrp4R1170Q mice. Based on the latter one could conclude that either the binding of Lrp4R1170Q with sclerostin is not completely lost or that sclerostin can inhibit bone formation via LRP5/6 independent of LRP4. Finally, additional studies will be needed to further investigate the mechanism whereby sclerostin and LRP4 regulate bone formation.

SAT-0302

Adgrg6 Is a Novel and Critical Regulator for Cartilage Homeostasis and Joint Stability Zhaoyang Liu*, Ryan Gray. University of Texas at Austin, Dell Medical School, United States

Osteoarthritis (OA) is a degenerative disease resulting in severe joint cartilage destruction and disability. Our previous studies have identified a role of Adhesion G-protein coupled receptor G6 (ADGRG6) for spine and intervertebral disc integrity. Here we identify a critical role for ADGRG6 in joint cartilage homeostasis and in the pathogenesis of OA, using a conditional Col2Cre;Adgrg6f/f mutant mouse model. These mutant mice exhibit normal joint and articular cartilage morphology at P21. However, joint integrity analysis in 1.5-, 6-, and 8-month-old mutants via microCT, histology, IHC, ISH, and histomorphometry showed an early onset and progressive OA-like pathology characterized by fibrosis and degeneration of articular cartilage and meniscus, synovial tissue hyperplasia, and progressive loss of extracellular matrix (ECM) components coupled with abnormally upregulated catabolic enzyme activities. To isolate the cellular role of ADGRG6, we generated a cartilage-specific mouse model ATC;Adgrg6f/f with the Acan enhancer-driven, Tetracycline-inducible Cre (ATC). Early postnatal induction (P1-P20) of these mutants recapitulate most phenotypes observed in Col2Cre;Adgrg6f/f mutants at 1.5 and 8 months. To obtain insight into the biological processes affected by ADGRG6, we engineered a stable Adgrg6KO mutation in the chondrogenic ATDC5 cell line with CRISPR-Cas9, and performed RNA-seq on WT and Adgrg6KO cells. 304 differentially expressed genes have been identified, including genes involved in apoptosis, ECM composition and structural constituent. In addition, several of the upregulated genes are associated with human or animal models of OA, including Aspn, Dmp1, Clu, Ctfg, Dkk-3, and RhoB. Interestingly, constitutive activation of STAT3 signaling is observed in Adgrg6KO cells and in vivo in the articular cartilage of ATC;Adgrg6f/f mutants prior to histopathological changes of the knee joint. Preliminary studies showed that STAT3 inhibitor (Stattic) treatment can partially rescue the OA-like cartilage degeneration phenotype in Col2Cre;Adgrg6f/f mutant mice, and restore some of the disrupted gene expression in Adgrg6KO cell culture. Collectively, these data have identified ADGRG6 as a novel and critical regulator for cartilage homeostasis and joint integrity potentially via regulation of ECM gene expression and of the STAT3 pathway, implicating ADGRG6 as a potential therapeutic target for the treatment of OA.

SAT-0303

Common and rare variants of WNT16, DKK1 and SOST and their relationship with bone mineral density Núria Martínez-Gil*[1], Neus Roca-Ayats[1], Anna Monistrol-Mula[1], Natàlia García-Giralt[2], Adolfo Díez-Pérez[2], Xavier Nogués[2], Leonardo Mellibovsky[2], Daniel Grinberg[1], Susana Balcells[1]. [1]Department of Genetics, Microbiology and Statistics, Faculty of Biology, University of Barcelona, IBUB, IRSJD, CIBERER, Spain, [2]Musculoskeletal Research Group, IMIM (Hospital del Mar Medical Research Institute), Centro de Investigación Biomédica en Red de Fragilidad y Envejecimiento Saludable (CIBERFES), ISCIII, Spain

Numerous studies have highlighted the role of the Wnt pathway in bone biology. Our objective has been to study the allelic architecture of three Wnt pathway genes: WNT16, DKK1 and SOST. We have resequenced the coding and some regulatory regions of these three genes in two groups with extreme BMD (n=~50, each) from the BARCOS cohort. Those predicted functional variants considered interesting have been genotyped in the full cohort (n=1490), and when appropriate (MAF>0.01), their association with BMD has been studied. We have found six variants associated with BMD. Three of them were missense (WNT16 rs2707466, WNT16 rs2908004 and SOST rs17882143) and three were putative regulatory variants (WNT16 rs55710688, in the Kozak sequence; WNT16 rs142005327, within a putative enhancer and DKK1 rs1569198 generating an alternative splice site). In addition, two rare variants in functional regions (rs190011371 in the WNT16b 3'UTR and rs570754792 in the SOST TATA box) were found only present in three women each, all with BMD below the mean of the cohort. We have carried out functional studies for the SOST variants rs17882143 and rs570754792, and WNT16 variants rs2908004 and rs2707466 to verify their association with BMD. The rs17882143 SNP is a missense change that substitutes an amino acid within the signal peptide of sclerostin. To assess whether the change might affect the subcellular localization of the mutated protein and/or its abundance, Western blot studies were performed and these showed that the amount of sclerostin excreted into the extracellular space was the same for the WT and the mutated protein. The rare variant

rs570754792 lies in the SOST extended TATA box. Reporter gene (luciferase) assays with constructs containing each of the variant alleles showed significant differences in luciferase activity between the two alleles tested, where the minor allele displayed lower transcription capacity. The WNT16 missense variants were shown to be eQTLs of CPED1 and FAM3C in artery tissue and Skin, respectively, according to GTEx. We tested whether these variants are eQTLs of these genes in primary osteoblasts (n = 45) and found an association between FAM3C RNA levels and the variant rs2908004. In conclusion, our results illustrate how functional analyses were necessary to sort out true form putative functional variants in these Wnt pathway genes.

Genetic variability and functionality of the FLJ42280 locus, a GWAS hit for osteoporosis Neus Roca-Ayats*[1], Darío G. Lupiáñez[2], Núria Martínez-Gil[1], Marina Gerousi[3], Mónica Cozar[1], Natàlia Garcia-Giralt[4], Xavier Nogués[4], Leonardo Mellibovsky[4], Adolfo Díez-Pérez[4], Susanna Balcells[1], Daniel Grinberg[1]. [1]Department of Genetics, Microbiology and Statistics, Facultat de Biologia, Universitat de Barcelona, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER), ISCIII, IBUB, IRSJD, Spain, [2]Epigenetics and Sex Development Group, Berlin Institute for Medical Systems Biology, Max-Delbrück Center for Molecular Medicine, Germany, [3]Department of Genetics, Microbiology and Statistics, Facultat de Biologia, Universitat de Barcelona, IBUB, Spain, [4]Musculoskeletal Research Group, IMIM (Hospital del Mar Medical Research Institute), Centro de Investigación Biomédica en Red en Fragilidad y Envejecimiento Saludable (CIBERFES), ISCIII, Spain

Genome-wide association studies (GWAS) have repeatedly identified variants associated with bone mineral density (BMD) and osteoporotic fracture in intronic regions of FLJ42280, a poorly studied gene of unknown function. The aim of the present study is to analyse the variability and functionality of this locus. Firstly, we resequenced the FLJ42280 genomic region in two extreme BMD groups from the BARCOS cohort of postmenopausal women. The number and frequency of variants between the two groups were compared and 110 variants were identified, of which 59 were rare and low frequency (MAF<0.05). Overall, the number of variants was balanced between the two groups and frequency differences did not reach statistical significance. Secondly, the overlap of the variants with functional elements from ENCODE was explored and 4 of them were found to be located in putative osteoblast enhancers. Next, taking into consideration both frequency and functionality, we genotyped 8 SNPs in the complete BARCOS cohort and tested them for association with BMD and fracture. Significant differences were obtained for 2 upstream SNPs, rs4342521 and rs10085588, in lumbar spine BMD (p-values=0.0031 and 0.0036, respectively) and in osteoporotic fracture (p-values=0.0391 and 0.0355, respectively). Finally, the possible role of these 2 SNPs as cis-eQTLs in primary human osteoblasts was studied, together with SNP rs4727338 (the GWAS hit in Estrada et al Nat Genet 2012;44(5):491-501). All 3 SNPs showed a statistically significant influence on the expression of the proximal neighboring gene SLC25A13 and a tendency on SHFM1 (distal). Further functional studies of a conserved putative regulatory element 4 kb upstream of FLJ42280, which contains rs10085588, are currently underway, namely 4C-seq (circular chromosome conformation capture) and luciferase assays. We also undertook functional analysis of an enhancer present in intron 2 of FLJ42280, which has been described as an active enhancer for Dlx5 and Dlx6 in embryonic mouse branchial arches (Birnbaum et al, Hum Mol Genet 21(22):4930-4938, 2012) and contains histone marks of active enhancers in osteoblasts (ENCODE data). We performed 4C–seq in mouse embryonic day (E) 12.5 developing limbs and a clear interaction between the enhancer and the Dlx5 promoter region could be detected, indicative of a role for this embryonic enhancer also in the developing bone. Further functional studies including CRISPR-Cas9 disruption in mouse are currently underway.

Comprehensive targeted LC-QTOF-MS metabolomics identifies novel metabolite changes associated with treatment of the rare bone disease Alkaptonuria Brendan Norman*[1], Andrew Davison[2], Gordon Ross[3], Anna Milan[2], Andrew Hughes[2], Norman Roberts[2], Lakshminarayan Ranganath[2], James Gallagher[1]. [1]Institute of Ageing & Chronic Disease, University of Liverpool, United Kingdom, [2]Liverpool Clinical Laboratories, Royal Liverpool University Hospitals Trust, United Kingdom, [3]Agilent Technologies UK Ltd, United Kingdom

Metabolomics involves studying the entire complement of small molecule metabolites in a biological system and is increasingly recognised as a powerful phenotyping strategy to understand the pathophysiology underlying a broad range of disease. Data processing and identification of 'unknowns' is the bottleneck in metabolomics. To resolve this an approach has been evaluated for comprehensive targeted metabolomics employing three complementary LC-QTOF-MS methods and accurate-mass retention time (AMRT) databases generated in-house from 619 metabolite standards. The strategy was then applied to Alkaptonuria (AKU), a rare inborn error of tyrosine metabolism also known as 'black bone disease'.619 standards (mw: 45-1354 Da) covering a broad range of primary metabolism, including carbohydrates, amino and organic acids and lipids, were analysed by three chromatographic methods (two reversed-phase, one normal-phase) coupled to an Agilent 6550 LC-QTOF-MS operated in positive and negative polarity. Data from the standards formed an in-house AMRT database for each method for identifying the structures of 'unknown' chemical entities detected from metabolic profiling of AKU urine. AMRT-based targeted feature extraction was performed on data of urine samples from 25 AKU patients (19-72 years) at baseline then at 3 (2mg every other day), 12 and 24 months (2mg daily) on nitisinone. AMRT matching employed windows of ±10ppm (mass) and ±0.3 minutes (retention time). Combining data from the three methods enhanced coverage of the metabolome, achieving a total of 243 unique AMRT compound identifications that passed quality control filtering. In total, 24 positively-charged AMRT matches showed significant profile differences (FDR p<0.05 and fold change >2) from the pre-treatment sampling time point; 12 decreased abundance, 12 increased abundance. The altered metabolites included changes which are known following nitisinone treatment, including homogentisic acid (decreased) and tyrosine (increased), but also some previously unreported changes: tyramine, 3-methoxytyramine, 4-hydroxyphenylacetic acid, 4-hydroxybenzaldehyde and ethylmalonic acid increased; tryptophan, kynurenine, methyl-histidine, cAMP, xanthosine and paraxanthine decreased.In conclusion, we have identified a number of novel metabolite changes in AKU urine following treatment with the promising drug nitisinone. The LC-QTOF-MS strategy will be an invaluable phenotyping tool for application to AKU and other rare bone diseases.
Principal components analysis plot from LC-QTOF-MS metabolic profiling of Alkaptonuria urine. The pre-nitisinone samples cluster separately from the post-treatment time points, showing that the profiling strategy has captured clear changes to the metabolome as a consequence of nitisinone therapy in Alkaptonuria.

SAT-0329

Identification of secreted factors coupling bone resorption to bone formation in humans using denosumab as a biological probe Megan Weivoda*, David Monroe, Josh Farr, Elizabeth Atkinson, Brittany Negley, Brianne Thicke, Ming Ruan, Louise Mccready, Matthew Drake, Merry Jo Oursler, Sundeep Khosla. Mayo Clinic, United States

Bone resorption is coupled to bone formation but the underlying mechanisms remain unclear. Anti-resorptive drugs (e.g., denosumab, DEN) are used to treat osteoporosis, but by reducing osteoclast numbers, these drugs also decrease bone formation. Thus, to identify novel coupling factors in humans, we employed DEN to eliminate osteoclasts in post-menopausal women, who were randomly assigned to placebo (PL) or DEN (N=24/group). Three months post-treatment, iliac crest bone biopsies were obtained, centrifuged to remove loosely-adherent marrow, and homogenized to obtain RNA for RNA-sequencing. DEN-treated patients showed significantly reduced serum CTX, TRAP, and P1NP. In addition, centrifuged bone showed significant reductions in known resorption (ACP5, CALCR, CTSK,

MMP9, MMP13, OC-STAMP, TNFRSF11A) and formation (ALPL, BGLAP, COL1A1, COL1A2, COL2A1, COL2A2, SP7, SPP1, SPARC) genes. Of interest, the rank means of the formation and resorption genes downregulated by DEN were significantly correlated in PL patients (R=0.81, P=0.0005), demonstrating coupling of bone resorption and formation at the gene expression level. Next we used Ingenuity Pathway Analysis to identify potential secreted coupling factors, which revealed 63 suppressed and 59 upregulated secreted genes in DEN-treated patients compared to PL. The rank means of the upregulated genes showed no correlation with formation or resorption genes in PL patients; however, the suppressed secreted genes correlated significantly with bone formation (R=0.95, P<0.0001) and resorption (R=0.87, P<0.0001) genes. To determine whether any of these genes may be osteoclast-derived factors, we performed RT-QPCR to compare expression of the DEN-suppressed secreted genes in human bone-marrow-derived osteoclast cultures vs human osteoblast lineage cells. We found that several secreted genes were expressed at significantly higher levels in osteoclasts vs osteoblasts, including CREG2, DPP4, TSPEAR, and LIF. Importantly, LIF has already been identified as an osteoclast-derived coupling factor in murine models, thus both validating this approach and establishing the role of LIF as a coupling factor in humans. Collectively, these data demonstrate for the first time the coupling of bone resorption to bone formation at the gene expression level in humans. In addition, we identify several candidate coupling factors in humans, as well as independently establish LIF as a coupling factor in human bone remodeling.

Integrative analysis of genetic and clinical risk factors affecting bone loss in Korean population Ji Hyun Lee*[1], Jooyong Park[2], Jung Hee Kim[3], Hyung Jin Choi[4], Eu Jeong Ku[5], A Ram Hong[6], Ji-Yeob Choi[2], Nam H. Cho[7], Chan Soo Shin[3]. [1]Department of Internal Medicine, Seoul National University College of Medicine, Department of Internal Medicine, VHS Medical Center, Republic of Korea, [2]Department of Biomedical Sciences, Seoul National University College of Medicine, Republic of Korea, [3]Department of Internal Medicine, Seoul National University College of Medicine, Republic of Korea, [4]Department of Anatomy, Seoul National University College of Medicine, Seoul, Republic of Korea, [5]Department of Internal Medicine, Chungbuk National University College of Medicine, Cheongju Si, Republic of Korea, [6]Department of Internal Medicine, Seoul National University College of Medicine, Boramae Medical Center, Republic of Korea, [7]Department of Preventive Medicine, Ajou University School of Medicine, Republic of Korea

Objective The relative contribution of genetic and clinical risk factors for bone loss is not well known. We investigated change of total hip bone mineral density (BMD) and risk of genetic and clinical risk factors for bone loss in Korean population. Methods In a Korean prospective cohort study, we included 645 men over 50 years old and 683 postmenopausal women who repeated BMD testing between 2007 and 2013. Accelerated hip BMD loss was defined as a slope ≤ -1 standard deviation (SD) below mean at total hip BMD. We showed the relationship between the rate of change in hip BMD and clinical risk factors such as age, body mass index (BMI), and change in lean mass and fat mass, menopause in women. We investigated the association between the rate of change in hip BMD and 2,614 single-nucleotide polymorphisms from 23 known BMD-related candidate genes: AKIN, SOX9, SOX6, ZBTB40, MEF2C, ESR1, VDR, P2RX7, TNFRSF11B, TNFSF11, TNFRSF11A, FOXL1, LRP5, SOST, WNT16, WNT4, WNT5B, SP7, CTNNB1, RUNX2, DKK1, SFRP4, and BMP2. Results BMI, baseline total hip BMD and lean mass loss over 10% were independent risk factors for estimating accelerated hip BMD loss of Korean men (BMI, Odds ratio (OR) = 0.91, 95% confidence interval (CI) = 0.83-0.99; baseline total hip BMD (per 1 SD increase), OR = 0.72, 95% CI = 0.55-0.94; lean mass loss (> 10%), OR = 2.74, 95% CI = 1.51-4.99). Age, years since menopause under 3 years, fat mass loss over 7%, and TNFSF11 rs931273 minor allele homozygote are significant risk factors for accelerated hip BMD loss in Korean women (age, OR = 1.05, 95% CI = 1.01-1.10; fat mass loss (> 7%), OR = 2.02, 95% CI = 1.07-3.83; rs931273, OR = 1.99; 95% CI = 1.08-3.68). In men, LRP5 rs4988300 was associated with rate of change in hip BMD (β = 0.127, P = 0.005). In women, two TNFSF11 SNPs were associated with the rate of change in hip BMD (rs7325635 and rs931273, β = 0.139, P = 0.007, β = -0.132, P = 0.001). The areas under the ROC curve (AUC) of accelerated hip BMD loss in men and women were 0.706 (95% CI = 0.642-0.770) and 0.711 (95% CI = 0.652-0.770) respectively. Conclusion BMI, baseline total hip BMD, and lean mass loss (>10%) were independent predictors to accelerated hip BMD loss in men. In postmenopausal women, age, fat mass loss (>7%), year since menopause under 3 years, and TNFSF11 rs931273 were important risk factors to accelerated hip BMD loss. Interaction of genetic and clinical risk factors affects bone loss.

Oxytocin treatment improves the femoral neck bone quality of the aging rats in periestropause Fernanda Fernandes*, Camila Tami Stringhetta Garcia, Melise Jacon Peres Ueno, Angela Cristina Nicola, Fabiana Fernandes, Mário Jefferson Quirino Louzada, Antônio Hernandes Chaves-Neto, Rita Cássia Menegati Dornelles. UNESP, Brazil

Introduction: Primary osteoporosis is a disease related to the hormonal changes that occur in the female organism in the transition to the aging. Research has shown an anabolic action of oxytocin (OT) on bone homeostasis and its possible potential in osteoporosis therapy where as OT receptors have been detected in human osteoblasts and osteoclasts. Although there are results that demonstrate this performance, the action of the OT in aging organisms that are in the transition period to menopause (perimenopause) is not established, so that this action happens in a preventive way. Objective: The present aimed to analyze whether OT performance in the femoral neck bone metabolism of aging acyclic Wistar rats (18 months) contributes to decrease the risks of osteopenia and primary osteoporosis. Material and method: Wistar rats (18 months old) was distributed in the groups: 1 - Control (Veh) and 2 - Treated/OT (Ot), with eight animals each, and it was analyzed the estrous cycle from all animals to test the estrous acyclicity (periestropause). The animals received two intraperitoneal injections of NaCl (0.15 M - control group) or OT (134 μg / kg - treated group), with a 12 hour interval. After 35 days of administration of the injections, the animals were decapitated for blood collection, which was used for the biochemical assays and surgical removal of the femurs was performed for cortical bone microtomography and biomechanical assay. Results: In the biochemical analysis, there was statistical difference between the groups for the enzymes Alkaline Phosphatase (FAL) and Tartarate Resistant Acid Phosphatase (TRAP), and the Ot group presented the highest FAL enzymatic activity (p=0.0138) and lower enzymatic activity of TRAP (p=0.0045). In the analysis of cortical bone microtomography was observed the highest cortical bone area (Ct. Ar) (p=0.00416), lower cortical pores percentage (Ct. Po) (p=0.0102) and greater polar moment (p=0.0480), maximum polar moment (MMI-max) (p=0.0480) and minimum polar moment (MMI-maxAv) (p=0.0035) in Ot group. In the mechanical assay analysis, greater maximal strength (p=0.0003) and bone stiffness (p=0.0145) were observed in the Ot group. Conclusion: Therefore, we conclude that OT administration is valid anabolic strategy for the prevention of primary osteoporosis in aging rats in the periestropause period. We also emphasize the importance of these data as the basis for the direction of pre and clinical research.

SAT-0353

The Phosphate Hypothesis: Divergent Roles for PTH and PTHrP Robert Fredericks*. Endocrine-Associates, United States

Models developed through experience with oral calcium challenge, immersion in water, and DXA in personalization of medical care are supported by recent clarification of downstream influences of the PTH/PTHrP receptor. These findings also validate the phosphate hypothesis that proposes phosphate to be the foundational signal of metabolism leading to models that organize basic and clinical data while facilitating repurposing of available interventions. 1 alpha Vitamin D was found to suppress leptin release from cultured adipose tissue and subsequently found to resolve symptoms in 5 of 5 patients with Behcet's syndrome. Suppression of salt inducible kinases, known targets of PTH and PTHrP, by 1 alpha D, also a downstream signal, is proposed to mediate effects on BMD and inflammation. Recent clarification of PTH/PTHrP downstream signaling reveals a complex system providing protection from elevation of the Ca x PO4 product. The observations include antagonism of PTH by PTHrP signaling mediated by endosomal docking of the receptor as amplified by calcium. Partitioning of PTH signals by NHERF and Scribble are found to be cell type and cellular location specific. Incorporating the influences of FGF23 into the modeling, including modulation of distal tubular calcium and sodium, generates an interface with PTH/PTHrP and Vitamin D signaling structures in the construction of coherent models. Previous work with mouse calvarial cultures and study of patients with hyperparathyroidism or humoral hypercalcemia of malignancy, utilizing oral calcium challenge, anticipated the recent molecular observations. Discoveries made through investigation of patients with renal responses to immersion in water (gravity subtraction) has contributed to understanding of salt balance in pathogenesis of metabolic disease, including skeletal phenotypes. Modeling causal relationships through engagement of case based discovery in the context of ethical practice provides insights for appropriate transformation of metabolic disease categories. When categories are discordant with basic science discoveries, use of digital technology, including AI, for cost-effective personalization of healthcare is compromised. Modeling causal relationships in the organization of metabolism by calciotropic signals also serves the historic mission to understand their biological roles in the metabolic manifestations and skeletal phenotypes recognized in human health and disease.

SAT-0354

Estrogen Attenuates Complex I Activity and Stimulates the Mitochondrial Apoptotic Death Pathway in Osteoclast Progenitors Ha-Neui Kim*[1,2], Intawat Nookaew[1], Nukhet Aykin-Burns[1], Kim Krager[1], Li Han[1,2], Robert Jilka[1,2], Stavros Manolagas[1,2], Maria Almeida[1,2]. [1]University of Arkansas for Medical Sciences, United States, [2]Central Arkansas Veterans Healthcare System, United States

Estrogens decrease the number of osteoclasts and the resorption of cancellous bone by stimulating osteoclast apoptosis, via ERα signaling in myeloid lineage cells. However, it remains unclear whether this effect occurs in osteoclast progenitors, mature osteoclasts, or both; and the molecular mechanisms are unknown. To determine the stage of differentiation at which estrogens act, we cultured osteoclast progenitors from wild type BL/6 mice for 5-days with RANKL. 10-8 M 17β-estradiol (E2) present during only the first 24 hours decreased osteoclast number as much as it did when it was present throughout the 5 days of culture. We next cultured macrophages, pre-osteoclasts and mature osteoclasts from the bone marrow of ERαΔLysM mice and ERαf/f littermate controls and performed microarray analysis in cells treated for 4 hours with E2. Principal-component and hierarchical clustering analysis indicated that the majority of genes affected by ERα were in osteoclast progenitors, not in mature osteoclasts. Osteoclast progenitors lacking ERα exhibited significant enrichment for the term "transmembrane electron transfer carrier". Specifically, they showed increased expression of several genes of the mitochondrial Complex I, including Ndufa1, 3, 4, 5, 6, 9, Ndufb2, 6, 8, 9, Ndufc1, 2 and Ndufs2, 6. Using extracellular flux analysis in osteoclast progenitors, we next determined that RANKL addition to cells from wild-type BL/6 mice caused an increase in basal oxygen consumption rate, maximum respiratory capacity,

and respiratory reserve, as well as ATP production. E2 had no effect in any of these mitochondrial function measures in the absence of RANKL, but it potently suppressed all the effects of RANKL. Furthermore, E2 stimulated caspase-3 activity in osteoclast progenitors by 2-fold. This effect was abrogated in cultures of progenitors lacking Bak and Bax – the two essential proteins for the mitochondrial apoptotic death pathway – isolated from Bak-/-;BaxΔLysM mice. Rotenone, an inhibitor of Complex I activity, also increased the apoptosis of osteoclast progenitors and decreased osteoclast number. Like estradiol, the proapototic effect of rotenone required Bak and Bax. Taken together, these findings suggest that the decrease of osteoclast number by estrogens is caused, in part, by a decrease in mitochondrial complex I activity in osteoclast progenitors and thereby activation of the mitochondrial apoptotic death pathway.

SAT-0355

The impact of dietary phosphate on acute renal phosphate and calcium excretion in healthy subjects. Tom Mazzetti*[1], Mandy E. Turner[2], Laura Couture[3], Jenny Munroe[4], Rachel M. Holden[5]. [1]Queen's University School of Medicine, Canada, [2]Queen's University Department of Biomedical and Molecular Sciences, Canada, [3]McGill University Faculty of Health Sciences, Canada, [4]Kingston General Hospital, Canada, [5]Queen's University Department of Medicine, Canada

The kidney eliminates excess phosphate from the body by preventing phosphate reabsorption acutely in response to changing levels of the counter-regulatory hormone parathyroid hormone (PTH). However, PTH influences calcium (Ca) homeostasis; which affects several crucial physiologic processes. Phosphate (Pi) intake modifies Ca and Pi homeostasis in rats - those exposed to a high-Pi diet respond adaptively by increasing excretion via PTH. Here, we conduct a translational experiment in healthy humans to determine whether the acute excretion of Ca and Pi changes in response to the prevailing level of dietary phosphate. This was a 2 week randomized crossover study. 16 participants were randomly assigned to the low- or high-Pi condition and put on a fixed low-phosphate diet for 5 days. The low-Pi condition was supplemented with 500mg CaCO3 daily and the high-Pi condition was supplemented with 500 mg CaCO3 daily and 3000 mg of Pi daily. Participants collected their urine for 24 hours prior to presenting fasted for baseline blood and urine assessments (Pi, Ca, PTH, FGF-23, creatinine). After a 1500 mg oral Pi challenge, bloodwork and urine studies were repeated every hour for 3 hours. The mean age of participants was 23.3; 64% were female, mean creatinine was 76.5.In the high-Pi condition, had significantly higher 24h-urine Pi (49.9 mmol vs 21.5 mmol,p<0.0001), higher baseline FGF-23 (63.7 vs 55.2 pg/mL, p<0.01) and PTH (4.6 vs 3.8, p<0.05). Serum Ca and Pi were similar between conditions. Fractional excretion (FE) of Pi and urinary Pi:creatinine ratio were significantly higher in the high-Pi condition. After the oral Pi challenge, serum Pi increased in both conditions at 1h (+0.15 mM, p<0.001) and returned to baseline at 2 hours. In the low-Pi condition, the participants had no change in PTH and a significant increase in FEPi over baseline at 2 and 3 hours. In the high-Pi condition, participants had a significant decrease in PTH at 1 and 2 hours (-0.7 and +1.1 pmol/L, p<0.05), and FEPi was significantly lower at 1 hour compared to baseline.Among healthy subjects, a high level of prevailing dietary phosphate decreases the kidneys' ability to respond to an acute oral phosphate challenge. This phenomenon appears to proceed through a PTH-mediated mechanism.

SAT-0356

Relative influence of serum ionized calcium and 25-hydroxyvitamin D in regulating PTH secretion in healthy subjects: an analysis of a large cohort Federica Ferrone*[1], Jessica Pepe[1], Cristiana Cipriani[1], Vittoria Danese[1], Veronica Cecchetti[1], Valeria Fassino[1], Federica Biamonte[1], Luciano Colangelo[1], Frank Blocki[2], Salvatore Minisola[3]. [1]Department of Internal Medicine and Medical Disciplines, "Sapienza" University of Rome, Italy, [2]diasorin inc, United States, [3]Department of Internal Medicine and Medical Disciplines, "Sapienza" University of Rome, Jamaica

Purpose: To evaluate the relative influence of serum ionized calcium (Ca++), ionized magnesium (Mg++), 25(OH)D and 1,25(OH)2D on PTH secretion.Methods: 2259 volunteer blood donors (1652 men and 607 women, age range 18-68 years) were enrolled. Ca++ and Mg++ were assayed by biochemical analyzer NOVA8; PTH, 25(OH)D and 1,25(OH)2D by chemiluminescence-immunoassay (LIAISON XL®). Three different statistical approaches were utilized to test effects among these parameters: regression tree analysis, general linear models and Anova type III errors.Results: In the whole population, significant inverse and direct correlations [between Ca++ and PTH (r=-0.223, p<0.001), 25(OH)D and PTH (r=-0.178, p<0.001) and between PTH and age (r=0.322, p<0.001), respectively] were found. Below or above 38 years, differential covariate effects on PTH levels were observed. For younger subjects, 25(OH)D values were the most important parameter in regulating PTH; subjects with 25(OH)D <14 ng/mL had average PTH values equal to 23 pg/mL, while subjects with 25(OH)D levels >14 ng/mL had average PTH values equal to 20. For subjects 38 years or older, both 25(OH)D and Ca++ levels were effective in regulating PTH secretion. However, 25(OH)D values had the strongest effect, since subjects with 25(OH)D < 13 ng/mL had average PTH values equal to 29 pg/mL, while those > 13 ng/mL had average PTH

values equal to 25 pg/mL. Variations of PTH levels, in this latter group only, disclose a Ca++ effect. Subjects with Ca++ levels ≥ 1.30 mmol/L show an average PTH value (23 pg/mL) that is lower than that observed (26 pg/mL) in subjects with Ca++ values < 1.30 mmol/l. Multivariate analysis using a linear model to quantitatively assess the most important parameters influencing PTH serum levels was performed. After stepwise selection, all variables retained in the model had a significant effect (p<0.001) on log transformed PTH values. Finally, Anova Type III errors contributed by 25(OH)D, Ca++, BMI and 1,25(OH)2D accounted for 32.1%, 18%, 14.3% and 11.1% of total PTH variance, respectively. Remaining percentages were attributable to age and sex.Conclusion: Under clinically stable conditions not challenged by acute calcium perturbation shifts, 25(OH)D plays a significant role regulating PTH secretion. Finally, under conditions of relative vitamin D sufficiency, serum Ca++ also plays an important role.

SAT-0357

Decrement of Dentin Matrix Protein 1 caused by Excessive Parathyroid hormone is one of the pathogenesis in elevating Fibroblast Growth Factor 23 expression in Bone Tissue on Primary Hyperparathyroidism Model Yuki Nagata*, Yasuo Imanishi, Tomomi Maeda, Daichi Miyaoka, Noriyuki Hayashi, Masanori Emoto, Masaaki Inaba. Osaka City University Graduate School of Medicine, Department of Metabolism, Endocrinology, and Molecular Medicine, Japan

Primary hyperparathyroidism (PHPT) is the endocrine disorder characterized by hypercalcemia, accompanied with excessive secretion of parathyroid hormone (PTH) from parathyroid tumor or hyperplasia. Although it is well known that PTH acts directly on bone to increases secretion of Fibroblast growth factor 23 (FGF23), which is a phosphaturic factor, expressed in mature osteoblast and osteocyte and so patients with PHPT represent hypophosphatemia with the high level of plasma FGF23, this mechanism has not been fully elucidated. Dentin matrix protein 1 (DMP1) is non collagenous bone matrix protein of small integrin-binding ligand, N-linked glycoproteins (SIBLINGs), mainly expressed in osteocyte, to contribute bone mineralization. In addition, DMP1 may regulate phosphate metabolism to suppress FGF23 expression, resulting from hypophosphatemic osteomalacia with increment of FGF23 secretion in Dmp1 knockout mice. To determine if DMP1 play a role on FGF23 expression via PTH regulation, we examined their alterations in bone tissue on PHPT model mice, which presented with hypercalcemia, hypophosphatemia and increased serum FGF23. The FGF23 and DMP1 expressions on calvaria in PHPT mice significantly increased and decreased respectively by quantitative PCR and immunohistochemistry, compared to WT mice. We then investigated its mechanism in vitro using primary osteoblast (OB) and the mature OB cell line UMR 106. We tested if 1-34 PTH (10-7 M) treatment affects both of FGF23 and DMP1 expressions. 1-34 PTH increased fgf23 expression, while it decreased dmp1 expression in primary OB as well as UMR-106. Not only 1-34 PTH but also forskolin increased fgf23 expression and decreased dmp1 expression in UMR-106 in a dose-dependent manner. Furthermore, PKA inhibitor H89 (10-5 M) reversed elevated fgf23 and reduced dmp1 expressions by 1-34 PTH treatment, respectively. Silence of dmp1 expression, besides treating with 1-34 PTH, elevated fgf23 expression additively as same as phosphorylated form of the transcriptional factor cAMP-response element-binding protein (CREB), stimulating FGF-23 promoter activity in OB. These results demonstrated that PTH increases and decreases FGF23 and DMP1 expressions via activation of PKA signaling. Furthermore, the regulation of DMP1 expression negatively via PKA Signaling would be in part of the mechanism which PTH increases FGF23 transcription on bone tissue in PHPT.

Vitamin D Metabolites and the Gut Microbiome in Older Men: The MrOS Study. Robert Thomas*[1], Lingjing Jiang[1], Zech Xu[1], Jian Shen[1], Stefan Janssen[1], Gail Ackermann[1], John Adams[2], Steven Pauwels[3], Dirk Venderschueren[3], Rob Knight[1], Eric Orwoll[4], Deborah Kado[1]. [1]University of California San Diego, United States, [2]University of California Los Angeles, United States, [3]UZ Leuven, Belgium, [4]Oregon Health Sciences University, United States

The vitamin D receptor (VDR) is highly expressed in the gastrointestinal tract where, when activated with 1,25-(OH)2D, it impacts local inflammation, immunity, epithelial function, and calcium/vitamin D absorption. In animal studies, gut microbiota have been shown to alter intestinal vitamin D metabolism (VDM), but human evidence is sparse. Thus, we tested the hypothesis that the human gut microbiome may interact with VDM using blood and stool samples collected from 599 U.S. MrOS men (mean age 84.2, SD = 4.1). To quantify 25(OH)D, 1,25-(OH)2D and 24,25(OH)2D levels, we used LC:MS:MS. From the raw 16S ribosomal RNA sequencing data, we used Deblur to define sub-Operational Taxonomic Units and Greengenes 13.8 to assign taxonomic labels; all analyses were conducted in QIIME. Men had an average BMI of 27 kg/m2, their mean 25(OH)D level was 35.2 ng/mL (SD = 12.5), 75% reported taking vitamin D supplementation, and 7.2% were D deficient (≤20 ng/mL). To determine which factors were important in determining within subject differences in stool microbiota, we used Faith's Phylogenetic Diversity (PD) and non-redundant covariate analyses. We found that 1,25-(OH)2D explained 5% of variance in α-diversity; the other non-redundant covariates of site, race, history of recent antibiotic

use, 25(OH)D and antidepressant use all combined explained another 8%. In multiple linear regression analyses adjusted for age, site, antibiotic use and antidepressant use, with higher 1,25-(OH)2D, there was greater α-diversity (standardized β-estimate 1.32, p = 1.08 X 10-6). Likewise, with higher levels of 24,25(OH)2D, there was greater α-diversity (standardized β-estimate 0.66, p = 0.016). In β-diversity analyses using unweighted UniFrac to assess between subject differences in stool microbiota, 1,25-(OH)2D was the strongest factor assessed, explaining about 2% of the variation (Figure). In older men, higher levels of the active vitamin D hormone 1,25-(OH)2D and the catabolic product 24,25(OH)2D, but not the pro-hormone 25(OH)D, were associated with greater α-diversity, concordant with numerous other studies suggesting that greater stool microbial diversity is associated with better health. Although directionality cannot be determined, our results suggest that the gut microbiota play an important role in host VDM.

Determination of reference ranges for parathyroid hormone in healthy individuals classified by vitamin D status using the Elecsys® PTH and Vitamin D total II immunoassays Richard Ostlund*[1], Naga Yalla[1], Gabriella Bobba[2], Ge Guo[3], Ann Stankiewicz[3]. [1]Washington University, St. Louis, MO, United States, [2]Roche Diagnostics International Ltd, Rotkreuz, Switzerland, [3]Roche Diagnostics Inc., Indianapolis, Indiana, United States

Intro/BackgroundParathyroid hormone (PTH) concentrations are routinely measured in the diagnosis and management of bone and mineral diseases and chronic kidney diseases. PTH secretion can be increased in individuals with vitamin D deficiency, which has an estimated prevalence of 41.6% among US adults. Reference ranges for PTH may be overestimated if determined in a population of otherwise healthy individuals for whom vitamin D deficiency was not evaluated. We aimed to establish distinct PTH reference ranges in apparently healthy, normocalcemic, normophosphatemic individuals according to vitamin D status.MethodsApparently healthy individuals aged ≥21 years with body mass index >18 and <30 were enrolled at three diverse geographical sites across the US during summer (August 2015 and June 2016) and winter (December 2015 and February 2016) months. Use of drugs influencing bone and calcium/phosphorus metabolism was an exclusion criterion. Serum PTH and vitamin D concentrations were measured with the Elecsys® PTH (cobas e 601) and Elecsys® Vitamin D total II electrochemiluminescence immunoassays (cobas e 411) at one central laboratory (Washington University, MO, USA). Samples with values outside of the reference ranges for calcium, phosphorus and creatinine were excluded. PTH reference ranges were calculated using a standard nonparametric analysis (CLSI EP28-A3c guidelines).ResultsSamples were collected from 653 individuals, and 490 evaluable serum samples were analysed (56.73% female; 68.16% white/Caucasian; 28.57% African American; median age 44 yrs [range: 21–83]). Across all samples, median (2.5–97.5th percentile) serum PTH concentration was 35.46 pg/mL (17.25–76.43). A significant inverse relationship was found between PTH and vitamin D (p<0.001). Median PTH concentrations decreased with increasing vitamin D concentration (Table), and all of the clinical categories of vitamin D (≤20, >20–<30 and ≥30 ng/mL) were significantly different from one another (p<0.01). Any additional effects of race or season as covariates were relatively small or absent.ConclusionWe provide reference ranges for PTH in serum from apparently healthy normocalcemic, normophosphatemic individuals, using the Elecsys® PTH and Elecsys® Vitamin D

total II assays, according to three categories of vitamin D concentration. Values for vitamin D replete individuals will support the accurate and reliable diagnosis and management of various diseases.

Table. PTH reference ranges by vitamin D class.

Median PTH concentration, pg/mL (2.5th to 97.5th percentile)	Vitamin D concentration, ng/mL			
	≤20	>20 and <30	≥30	Total
Summer	39.20 (16.69–74.13) n=71	37.43 (20.09–60.41) n=81	31.58 (14.32–51.86) n=94	35.12 (18.14–74.01) n=246
Winter	40.03 (19.49–86.55) n=112	33.01 (13.81–60.40) n=85	33.70 (17.66–68.33) n=47	35.78 (17.24–76.95) n=244
Total	39.78 (19.49–86.43) n=183	35.46 (16.96–60.41) n=166	31.90 (17.86–58.64) n=141	35.46 (17.25–76.43) n=490

Growth Hormone Effects on Bone Loss-Induced by Mild Traumatic Brain Injury and/or Hind Limb Unloading Nikita Bajwa*[1], Chandrasekhar Kesavan[1,2], Heather Watt[1], Subburaman Mohan[1,2]. [1]Musculoskeletal Disease Center, VA Loma Linda Healthcare System, United States, [2]Department of Medicine, Loma Linda University, United States

Disruption of the hypothalamus-pituitary axis in response to traumatic brain injury (TBI) is a key element in inducing bone loss and this effect is maximized during immobilization. To study if the skeletal consequence of mild repetitive TBI and/or hind limb unloading (UL) is rescued by growth hormone (GH) treatment, eighty-one 9-week old female C57BL/6J mice were randomly assigned to the following groups: Control-Sham-Vehicle (VH), Control-Sham-GH, Control-UL-VH, Control-UL-GH, TBI-Sham-VH, TBI-Sham-GH, TBI-UL-VH, and TBI-UL-GH. Mild TBI was induced experimentally using a weight drop model, once per day for four consecutive days. Unloading (right hind limb) and treatment (3 mg/day GH or vehicle) began two weeks after the first TBI episode and lasted for four weeks. We previously showed that TBI, UL and TBI-UL reduced tibia trabecular bone mass by 15%, 70%, and 75% respectively compared to control mice and that GH treatment significantly increased trabecular bone mass in all four (VH, TBI, UL and TBI+UL) groups. To determine if TBI and/or hind limb UL adversely affects other skeletal sites besides long bones, we evaluated the trabecular bone mass of vertebra in this study. Micro-CT analysis revealed 20% reduction in BV/TV (P=0.01) at the lumbar vertebra in the vehicle treated TBI-Sham-VH mice compared to VH treated Control-Sham mice. Hind limb UL caused a small reduction (15%) in trabecular bone mass at the vertebra compared to the tibia (70%). In TBI-UL-VH mice, vertebral trabecular bone mass was reduced by 40% (P<0.01) compared to VH group. While GH treatment increased trabecular bone mass of tibia in all four groups (VH, TBI, UL and TBI+UL) groups, GH treatment increased vertebral trabecular bone mass in VH and Control UL groups but not in the TBI or TBI+UL groups. Conclusions: 1) TBI significantly reduced trabecular bone mass at both long bone and vertebra several weeks post impact. 2) Hind limb UL reduced trabecular bone mass at the local (tibia) as well as distal (vertebra) site, suggesting involvement of both local and systemic mechanisms for

UL effects. 3) GH anabolic effect in the TBI and UL groups varied depending on the skeletal site studied.

Mechanical Stress-induced Intracellular Ca2+ Oscillations in Human Periodontal Ligament Fibroblasts Ei Ei Hsu Hlaing*[1], Yoshihito Ishihara[2], Ziyi Wang[1], Naoya Odagaki[1], Hiroshi Kamioka[1]. [1]Department of Orthodontics, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Japan, [2]Department of Orthodontics, Okayama University Hospital, Japan

Objective:Periodontal ligament (PDL) fibroblasts are the first cells to receive mechanical stress (MS) followed by alveolar bone remodeling in tooth movement. However, the role of intracellular calcium ([Ca2+]i)-based mechanotransduction is poorly understood in PDL fibroblasts. We examined the MS-induced [Ca2+]i mobilization in PDL fibroblasts to investigate its possible role in tooth movement-initiated bone remodeling as a clue to determine the optimum orthodontic force to apply to teeth.Methods:PDL fibroblasts were isolated from healthy donors' extracted premolars for orthodontic reasons. Static compressive force was applied to the PDL cells for 24 h. The oscillatory [Ca2+]i activity was measured by a live Ca2+ imaging system and evaluated by a wavelet analysis in the time and frequency domains. Responsive cells were identified by their displaying a transient increase in [Ca2+]i of at least 50% increase over the baseline. PDL fibroblasts were treated with various doses of the Ca2+-transporting ionophore A23187 for 6 and 24 h to further investigate the functional role of [Ca2+]i upregulation in PDL cell behavior. Reverse transcription polymerase chain reaction was used to examine the mRNA expression.Results:The percentage of responsive PDL fibroblasts was significantly increased in response to MS. Individual cells responded with a sudden elevation of [Ca2+]i followed by intermittent increases in the [Ca2+]i. The cell response frequency, waveform length and maximum amplitude were significantly different from the control group. According to the Moran index for evaluating the influence of MS on cell-cell communication, individual cells independently responded to MS. Treatment with A23187 induced the upregulation of the RANKL/OPG ratio and SOST expression.Conclusion:Our findings suggest that RANKL/OPG and canonical Wnt/β-catenin signaling via augmented MS-mediated [Ca2+]i oscillation may be involved as an early signaling process in tooth movement-initiated bone remodeling.

SAT-0399

Role of Parathyroid Hormone Receptor Type I and Pimary Cilia in Bone Mechanotransduction on Osteocytes and Osteoblast Arancha Gortazar*, Irene Buendia , Eduardo Martin-Guerrero, Irene Tirado, Juan Antonio Ardura. Bone Physiopathology Laboratory, Departamento de Ciencias Médicas Básicas, Facultad de Medicina, Universidad San Pablo CEU, CEU Universities, Spain

Effects of mechanical stimulus on osteocytes and osteoblasts are determinant to bone physiopathology. Multiple mechanosensing mechanisms, including the activation of primary cilia in osteocytes and osteoblasts have been proposed as modulators of bone remodeling. Recently, we have described the mechanosensing ability of parathyroid hormone receptor type 1 (PTH1R) in bone. We hypothesize that PTH1R and primary cilia constitute a mechanosensing signalosome that regulates osteocyte- and osteoblast-mediated bone remodeling. We aim to describe the role of PTH1R and primary cilia as the molecular tools that concomitantly act as mechanosensors in osteocytes and osteoblasts.MLO-Y4 osteocytes and MC3T3-E1 pre-osteoblasts were mechanically stimulated with fluid flow (FF) [10 min, 10 dynas/cm2] or with PTHrP (1-37) [a PTH1R agonist]. PTH1R or primary cilia siRNAs and a primary cilia specific inhibitor [chloral hydrate] were used to decrease receptor or primary cilia signaling. Gene expression of bone remodeling and formation markers including OPG, RANKL, Runx2, osteocalcin, alkaline phosphatase and osterix and phosphorylation of the MAP kinase ERK 1/2 was studied in MLO-Y4 and MC3T3-E1 cells.FF increased OPG and RANK-L expression and OPG/RANK-L ratio and induced phosphorylation of ERK 1/2 kinase in both osteocytes and pre-osteoblasts. In addition, FF overexpressed Runx2, osteocalcin, and alkaline phosphatase in MC3T3-E1 pre-osteoblasts. These effects were partially inhibited by PTH1R silencing. Moreover, PTHrP (1-37)-dependent increase of OPG/RANK-L ratio and ERK 1/2 phosphorylation in osteocytes and pre-osteoblasts and Runx2, osteocalcin, and alkaline phosphatase overexpression in MC3T3-E1 pre-osteoblasts were inhibited by primary cilia silencers or chloral hydrate.The osteogenic response of osteocytes and osteoblasts is mediated, at least in part, by a PTH1R and primary cilia combined mechanism.

SAT-0400

Adaptive Changes in Micromechanical Environment of Cancellous and Cortical Bone Following Mechanical Loading and Disuse Haisheng Yang*[1], Ran Liu[1], Whitney Bullock[2], Russell Main[2]. [1]Beijing University of Technology, China, [2]Purdue University, United States

Mechanical stimuli play an important role in bone (re)modeling for maintenance of the skeleton to resist fracture during habitual loading. It is known that extra mechanical stimuli (e.g. exercise) can increase bone mass while a reduction of mechanical stimuli (e.g. space flight or prolonged bed rest conditions) may lead to bone loss. Little is known how mechanical loading or unloading alter the micromechanical environments of cancellous and cortical bone, which may be associated with tissue-level failures. Sixteen-week-old female C57BL/6J mice were used in this study. Loading and unloading experiments were conducted. For the loading experiment, one group of mice underwent in vivo tibial compressive loading for two weeks with the left limb being loaded and the contralateral limb serving as nonloaded control (n=10). For the unloading experiment, a second group of mice underwent hindlimb disuse for 3 weeks via tail suspension and the third group of mice served as an age-matched control group for the disuse group and had normal cage activities for 3 weeks (n=10/group). Changes in bone mass and tissue-level mechanical environments following loading or unloading were determined using micro-computed tomography (microCT) and microCT-based finite element analysis, respectively. We found that loading or unloading significantly altered cancellous and cortical bone mass and the change in bone mass was more pronounced in the proximal metaphyseal cancellous than midshaft cortical bone of the tibia. These loading- or unloading-induced changes in cancellous and cortical bone mass and morphology were accompanied by altered bone tissue-level mechanical environments when the tibiae were virtually loaded in compression. In the metaphyseal cancellous or midshaft cortical bone, there was a shift in the amount of bone tissue from high towards low strain regions for the loaded relative to control tibiae (Fig. 1); with unloading there was a decrease in the amount of low strain tissues and an increase in the amount of high strain tissues (Fig. 1). In addition, regression analyses indicated that bone mass was a good predictor of bone tissue strain for the midshaft cortical bone but not for the metaphyseal cancellous bone. In summary, loading- or disuse-induced changes in bone mass lead to an overall reduction or increase in tissue-level strains, respectively, and micromechanics of the cancellous bone may not be correlated with bone mass.
Fig. 1. Changes in tissue strain distribution of the proximal metaphyseal cancellous bone of the tibia with applied compressive loading or hindlimb unloading. * p < 0.05 (paired t-test for control vs. loaded tibiae or unpaired t-test for control vs. unloaded tibiae). Bars: mean+SD.

The Vitamin D Receptor Expression in Skeletal Muscle of Women with Distal Radius Fracture Kahyun Kim*[1], Hyun Sik Gong[2]. [1]Department of Orthopaedic Surgery, Hallym University College of Medicine, Republic of Korea, [2]Department of Orthopaedic Surgery, Seoul National University College of Medicine, Republic of Korea

Introduction: We aimed to evaluate the relationship between the VDR expression in the muscle cell and the muscle mass in women with a distal radius fracture (DRF).Methods: We prospectively recruited 45 women over 50 years of age (mean age, 66 years) with DRF and acquired biopsy of the forearm flexor muscle. The muscle cross-sectional area (CSA) and VDR expression were measured using immunohistochemistry staining. The clinical parameters including grip strength, gait speed, body mass index (BMI), bone mineral density (BMD), and serum vitamin D levels were compared between patients grouped by appendicular lean mass index and were correlated with the VDR expression.Results: Twelve patients (27%) showed a decreased appendicular lean mass index, less than the cut-off value of 5.4 kg/m2 which was suggested by the Asian Working Group for Sarcopenia. Patients with a low appendicular lean mass index had significantly lower muscle CSA (p = 0.037), but a higher VDR expression (p = 0.045) than those with higher indices. VDR expression was negatively correlated with BMI (r = -0.417, p = 0.004) and appendicular lean mass index (r = -0.316, p = 0.044).Conclusions: DRF patients with low appendicular lean mass index presented high VDR expression and low CSA in forearm muscle cells. This suggests that the VDR expression might be up-regulated in the attempt to compensate for the decreasing muscle mass. Further studies are necessary to explore the role of VDR in the progression of sarcopenia.

Age-related Decline of Osteogenesis Depends on Regulation of Protein Kinase A (PKA) by the Protein Kinase Inhibitor Gamma (PKIγ) Bryan S. Hausman*[1], Xin Chen[2], Hyonmin Choe[3], Ozan Akkus[1], Edward M. Greenfield[1]. [1]Case Western Reserve University, United States, [2]University of North Carolina at Chapel Hill, United States, [3]Department of Orthopaedic, Yokohama City University, Japan

Aging bone is characterized by decreased osteogenesis and increased adipogenesis resulting in bone loss and diminished repair capacity. Stimulation of the cAMP/PKA pathway in osteoblast lineage cells is responsible for increased bone formation in response to PTH therapy as well as many endogenous anabolic factors. We previously showed that PKIγ terminates PTH-induced PKA activity in the nucleus of mesenchymal precursor cells and that the termination of anabolic primary PKA-response genes (c-fos, IL−6, and LIF) by PKIγ reduces osteogenesis and enhances adipogenesis in vitro. We, therefore, generated and characterized Pkig−/− mice, which were indistinguishable from wild-type littermates by body weight and fertility. μCT analysis revealed that vertebrae of female Pkig−/− mice are protected from age-related trabecular bone loss (see figure). As a result, female Pkig−/− mice have 32% and 67% higher vertebral BV/TV at 12 and 24 months of age than wild-type mice (12-month, n=15: 13.9±0.5% vs 10.5±0.4%, p=0.0006 and 24-month, n=10: 13.4±1.0% vs 8.0±0.5%, p<0.0001). The increased vertebral BV/TV results from increased Tb.N without changes in Tb.Th (see figure). Accordingly, Tb.Sp was decreased and Connectivity Density increased with more plate-like geometry (decreased SMI). Regulation of age-related bone loss by PKIγ occurs primarily in vertebral trabecular bone of female mice as there was little or no effect in femora of female mice, in vertebrae and femora of male mice, or in younger mice. Based on the age dependence of the μCT results, we speculated that the decline in osteogenesis with aging would also be lessened in Pkig−/− mice. We, therefore, investigated intramembranous bone formation 7 days after placing a unicortical titanium implant in the distal femoral metaphysis. Biomechanical pull-out testing showed the expected age-related decline in osteogenesis in wild-type but not in Pkig−/− mice. As a result, osseointegration in 12-month old Pkig−/− males was significantly greater than in 12-month old wild-type males: Ultimate Force (7.6±1.7 vs 3.8±2.7 N, p=0.02) and Average Stiffness (6.7±1.6 vs 3.4±2.4 N/m, p=0.005). The increased osseointegration in femora of male Pkig−/− male mice shows that inducing rapid osteogenesis reveals effects of PKIγ deletion that are obscured during

normal development and aging. Overall, our results show that preventing PKIγ regulation of PKA activity in aging bone enhances the effects of endogenous anabolic factors.

Lineage Tracing Studies Identify The Source Of Chondrocyte-Like Cells In Mouse Intervertebral Disc With Normal Aging Sarthak Mohanty*[1], Robert Pinelli[1], Chitra Dahia[2]. [1]Hospital for Special Surgery, United States, [2]Weill Cornell Medical College, United States

Intervertebral disc degeneration and associated back pain affects almost 1/7 individuals at some point in life and is a huge financial burden. Despite its high incidence, the current treatments are either palliative or surgical that are limited to taking care of the symptoms rather than treating the cause. This is due to limited understanding of the molecular mechanisms of disc growth and differentiation, and of the changes associated with its degeneration and aging. Our approach has been to use a mouse model to understand the normal postnatal growth and differentiation of the disc, and how that changes with disc degeneration and aging. One of the limitations in the development of treatment of the degenerated disc is knowledge about the cellular and molecular changes associated with physiological aging of the disc and its degeneration, this includes the morphological changes observed in the nucleus pulposus cells of aged or degenerated discs. With aging or degeneration, the disc undergoes pathological changes associated with the replacement of reticular and vacuolated notochordal/ nucleus pulposus cells with cells that resemble chondrocyte-like cells (CLCs). The presence of these CLCs in the disc space has been considered as an indication of disc degeneration. However, the source of these cells remains unknown. Identifying the lineage of the CLCs with disc aging and degeneration will provide a better understanding of the progression of disc degeneration. In normal mouse, these CLCs can be seen from 18 months of age. To understand the source of CLCs in the mouse disc with normal physiological aging, we did lineage tracing studies and identified that the reticular NP cells differentiation into CLCs with normal physiological aging. Using fate-mapping studies, we also observed that with aging all nucleus pulposus cells are lost from mouse lumbar disc as it fuses. The disc losses height and extracellular matrix as it ages and fuses. However, it is not clear that what causes the reticular nucleus pulposus to differentiate into the CLCs, and will require further studies.

Circulating MicroRNAs Are Negatively Associated with Bone Mineral Density in Postmenopausal Women Zhaojing Chen*[1], Debra Bemben[2], Michael Bemben[2]. [1]California State University, San Bernardino, United States, [2]University of Oklahoma, United States

MicroRNAs (miRNAs) are short, non-coding RNA molecules that fine tune posttranscriptional gene expression. Recent research has indicated that some miRNAs, such as miR-21 and miR-23a, target on genes of osteogenesis. Aging is accompanied with progressive declines in bone mineral density (BMD) and bone strength, which potentially may be regulated by these miRNAs. Additionally, miRNAs are found stable in body fluids such as blood, thus circulating miRNAs (c-miRNAs) may be useful as noninvasive biomarkers of bone metabolism. Purpose: To examine the relationships between specific c-miRNAs, BMD and bone strength in older postmenopausal women. Methods: Seventy-five postmenopausal women aged 60 to 85 years old participated in this study. Body composition and areal BMD (aBMD) at total body, lumbar spine, dual femur (total hip, femoral neck, trochanter) were measured by Dual Energy X-ray Absorptiometry (DXA). Volumetric BMD (vBMD) and bone strength at 4%, 38%, and 66% of the non-dominant tibia were measured by Peripheral Quantitative Computed Tomography (pQCT). Total RNA were extracted from serum, and relative expression levels of c-miRNAs (miR-21, -23a, -24, -100, -125b) were analyzed using miRNA assays and real-time PCR. Results: Osteopenia and osteoporosis were particularly common in this group of participants with a total percentage of 81% (n=61). MiR-21 was significantly negatively correlated with left trochanter BMC (r = -0.252, p = 0.048), right trochanter BMC (r = -0.294, p = 0.020), and cortical vBMD at tibia 38% site (r = -0.253, p = 0.047). There also was a trend for a significant correlation between miR-21 and lumbar spine aBMD (r = -0.249, p = 0.051). Conclusion: Our results suggest that a higher expression level of circulating miR-21 is associated with decreased BMD in relatively healthy postmenopausal women. Future investigations are needed to further explore circulating miRNAs in osteoporotic or fragile older adults.

SAT-0444

Comparing the epithelial-mesenchymal interaction effects in alveolar bone and long bone Chul Son*, Joo-Cheol Park, Dong-Seol Lee, Yeoung Hyun Park. Laboratory for the Study of Regenerative Dental Medicine, Department of Oral Histology and Developmental Biology, School of Dentistry and Dental Research Institute, Seoul National University, Republic of Korea

Epithelial-mesenchymal interaction (EMI) plays an essential role during the development of both alveolar bone and long bone. Especially, alveolar bone remodeling has re-

cently been reported to be affected by peripheral epithelial tissue that remains after tooth development. Remodeling occurs more actively by external stimuli in alveolar bone, making the condition of alveolar bone an important factor in various dental surgical processes. Therefore, understanding of alveolar bone development and remodeling procedure is critical. We aim to elucidate how the EMI affects alveolar bone and long bone differently during development and remodeling. We did histological analysis to elucidate alveolar bone and long bone development. We isolated cells from alveolar, femur and tibia bone tissues. The morphology of primary cultured mouse alveolar bone-derived cells (mABDC) and long bone-derived cells (mLBDC) looked similar. The expression level of Bsp was high in both types of cells. When the cells were cultured in osteogenic differentiation media, they manifested mineralized nodule formation. We focused on the difference between alveolar bone and long bone considering from cell and tissue level. The intramembranous ossification (IO) associated markers, Msx and Dlx family genes, which are also known to be involved in EMI were expressed higher in alveolar bone than in long bone. Interestingly, EMI related genes, Bmp family, Cpne7 and Nfic expression were different between alveolar bone and long bone. RNA sequencing data showed consistent results. Some other neural crest-derived cell marker and EMI related genes were also highly expressed in mABDC. When we analyzed the osteoblast marker genes, IO and EMI related genes during osteogenic differentiation, Bsp, OC and Bmp2 showed increasing expression patterns in both. Meanwhile Alp, IO and EMI related genes showed different expression patterns between mABDC and mLBDC. mLBDC showed more nodules stained during differentiation. Among the EMI related proteins we treated to each cells, BMP4 elevated the expression levels of osteoblast marker genes the most, more noticeably in mABDC than in mLBDC. Our data suggest that factors involved In EMI signaling may affect alveolar bone and long bone differently, possibly because of their different developmental origin and local environment. Especially BMP4 affects mABDC more than mLBDC; further investigation is needed to figure out the mechanism underlying the discrepancy.

SAT-0445

Gait and Scaling Effect on Bone Growth in Rat Tibia Hyunggwi Song*, Mariana Kersh. Department of Mechanical Science and Engineering, UIUC, United States

During growth, bones in the extremities have a preferential distribution of material and composition to sustain the loading cycles from everyday movement, but it is not clear how material and mechanical properties of bone are optimized. We aimed to understand how bone morphology and material properties change during growth, and whether they are related to gait dynamics using rats. Data was collected from 5 healthy female Sprague-Dawley rats at the age of 7 weeks. Rats were scanned using in vivo microCT (resolution = 35.8 μm) and gait analysis was performed at 8, 9, 10, 11, 12, 14, and 20 weeks. A custom walkway was created to measure ground reaction forces (GRF) with a force plate. Joint kinematics of the hindlimb were measured with two high-speed cameras. When the right foot steps on the force plate correctly, both kinematics and GRF were collected during one gait cycle at 240 Hz. The right tibia was segmented using Amira 5.6. Hounsfield unit to apparent density conversions were calculated for each scan with HA phantoms. Custom Matlab code was used to calculate cross-sectional area (CSA), density, bone area fraction (BA/TA), and polar moment of inertia (J) at distal, diaphysis, and proximal regions.Averaged peak GRF and joint angles at the time of the peak were obtained over time (Fig. 1A). The rate of increase in peak GRF decreased, but the peak GRF still increased during growth, while joint angles decreased until at ten weeks and then converged. The proximal region had a larger CSA and lower density compared to the other regions, since it has more trabecular bone (Fig. 1B). The proximal CSA kept increasing, while middle and distal CSA were stayed at a constant level, which indicated that growth in proximal CSA was affected by both GRF and joint angles during gait. Both GRF and joint angles influence density since density and BA/TA in all regions increased and converged, except for distal BA/TA. To investigate the scaling relationships, CSA and J were compared with body mass in log scale (Fig. 1CD). CSA and J in diaphysis showed higher slopes than the other regions and the slopes were close to the scaling relationships [1], implies that the diaphysis of tibia is getting stronger most to sustain the loading during growth.Bone properties change and relationships to gait strategy during the growth period were investigated. How muscle forces can change bone properties during growth remains to be understood.1. Spence, A. J. Current Biology, 19(2), 2009.

SAT-0446

Associations of Insulin-like Growth Factor-1, Insulin-like Growth Factor Binding Protein-3, Bone and Body Composition Variables in Children 2 to 8 y Olusola Sotunde*[1], Neil Brett[2], Sherry Agellon[1], Catherine Vanstone[1], Hope Weiler[1]. [1]School of Human Nutrition, McGill University, Canada, [2]School of Nutrition Ryerson University, Canada

Musculoskeletal growth is multifaceted and influenced by several hormones including insulin like growth factor-1 (IGF-1). The majority of IGF-1 is bound by insulin-like growth factor binding protein-3 (IGFBP-3) in circulation, with IGFBP-3 serving as a circulatory reservoir for IGF-1. However, very little is known about the interactions between IGF-1, IGFBP-3, muscle and bone geometry of healthy young children. Therefore, we examined the associations between bone variables, body composition, IGF-1 and IGFBP-3 in children. Healthy children 2 to 8 y (n = 49) from Montreal Canada were studied (NCT02387892) for demographics, physical activity and standardised anthropometry. Fasting venous blood samples were collected to assess plasma IGF-1 and IGFBP-3 (enzyme-linked immunosorbent assays) and serum 25-hydroxyvitamin D (25(OH)D; Liaison, Diasorin Inc). Body composition and bone densitometry (whole body, lumbar spine and radius) were measured using dual-energy X-ray absorptiometry (Hollogic 4500A: APEX version 13.3:3). Tibia geometry (4 and 66%) and muscle density (66%) were measured at the distal end of the tibia with peripheral quantitative computed tomography (pQCT, XCT-2000; Stratec). The ratio of IGF-1 to IGFBP-3 was calculated as a marker of free bioactive IGF-1. Linear regression analyses were carried out with adjustments for covariates. Participants were 4.71 ± 1.89 y with body mass index z- score of 0.65 ± 0.84 kg/m2, 59.2% were boys and 46.9% were white. All participants were within the reference ranges for IGF-1 and IGFBP-3 while 18.4% were vitamin D inadequate [25(OH)D < 50 nmol/L]. IGF-1 was positively associated with whole body lean mass and pQCT parameters (muscle density, muscle cross sectional area, trabecular density, cortical cross sectional area and cortical density; Table 1), with no association to fat mass. IGF-1/IGFBP-3 ratio had a positive association with total radius densitometry, and cortical density of tibia at the 66% site. The associations of IGF-1 with tibia bone geometry; IGF-1/IGFBP-3 ratio and total radius densitometry suggests an important role of IGF-1 on long bone growth. Though IGFBP-3 had an independent positive association with cortical cross sectional area, IGF-1 appears to have stronger independent associations with bone and muscle parameters compared to IGFBP-3.

Table 1: Association between IGF1, IGFBP3 or IGF1/IGFBP3 ratio and bone and muscle quality in 2 – 8 year olds

Interactions between protein phosphatases and potassium channels control chondrocytes proliferation and regeneration Earnest Taylor*, Elizabeth Bradley, Xiaodong Li, Jennifer Westendorf. Mayo Clinic, United States

Osteoarthritis (OA) is the most common form of arthritis and is characterized by degeneration of articular cartilage, a shock absorbing tissue between bones, as a result of injury or aging. The protein phosphatases Phlpp1 and Phlpp2 are aberrantly expressed in articular cartilage from OA patients and limit chondrocyte proliferation in vitro. Phlpp1 deficiency and Phlpp inhibitors limit OA disease progression and pain in mice. In a candidate screen of mitogenic factors, we found that Phlpp1 depletion increased expression of a number of factors that are now in OA trials: Fgf18, Tgfb, Wnts. The Pth receptor, PthR1, was also upregulated in Phlpp1-deficient and Phlpp inhibitor treated chondrocytes. To further understand how Phlpp inhibitors increase chondrocyte proliferation and matrix production, we performed an unbiased RNA-seq experiment on human OA tissues. OA tissue explants treated with Phlpp inhibitors expressed higher levels of Girk2. Girk2 is a component of G protein-gated inwardly rectifying potassium (GIRK) channels that regulate potassium ion transport across cell membranes via specific G-protein-coupled signaling mechanisms. Various neurotransmitters, dopamine, opioids and serotonin control GIRK channels and potassium efflux by stimulating their cognate G protein coupled receptors. Our preliminary data demonstrate that Girk2 knockout (KO) and Girk3 KO mice have normal limbs and that chondrocytes from Girk2 KO or Girk3 KO mice differentiate normally in vitro. However, mice lacking both Girk2 and Girk3 have longer bones and chondrocytes from Girk2/Girk3 double KO mice produce more matrix in vitro. These data suggest that there is greater chondrocyte formation and regenerative capacity when both Girk2 and Girk3, which together comprise more than 90% of Girk channels, are absent. We have also discovered that GIRK channels bind to Phlpp1 and Phlpp2. Thus Girks may play a role in cytoplasmic retention and positioning of these phosphatases in close proximity to key substrates such as Akt and PKC that limit chondrocyte proliferation and matrix production. These data identify novel relationships between potassium channels and kinase signaling pathways in chondrocytes. Inhibitors of Phlpp1 and/or Girk2/3 may enhance chondrocyte regeneration by promoting anabolic pathways through secretion of growth factors and/or releasing.

Human mesenchymal stromal cells in adhesion to cell-derived extracellular matrix and titanium: comparative kinome profile analysis Marta Baroncelli*[1], Gwenny Fuhler[2], Jeroen Van De Peppel[1], Willian Zambuzzi[3], Johannes Van Leeuwen[1], Maikel Peppelenbosch[2], Bram Van Der Eerden[1]. [1]Internal Medicine, Erasmus MC, Netherlands, [2]Gastroenterology, Erasmus MC, Netherlands, [3]Chemistry and Biochemistry, Institute of Bioscience, UNESP, Brazil

The extracellular matrix (ECM) is essential to physically support cells and actively influence cell behaviour by modulating kinase-mediated signalling cascades, key regulators of signal transduction. Cell-derived ECMs have recently emerged in the context of bone regeneration, as they reproduce physiological tissue-architecture and ameliorate the promising properties of mesenchymal stromal cells (MSCs). Titanium scaffolds show good mechanical properties and porosity to facilitate cell adhesion, and thus have been routinely used for bone tissue engineering applications. The aim of this study was to analyze the kinomic signature of human MSCs in adhesion to an osteoblast-derived ECM that we have previously shown to be osteopromotive, and to compare it to MSCs on titanium. PamChip kinase array analysis revealed 63 phosphorylated peptides on ECM and 59 on titanium, with MSCs on ECM exhibiting significant higher levels of kinase activity than those on titanium (Area under curve on ECM 34.1 vs 27.6 on titanium, P<0.0001). MSCs on the 2 substrates showed a substantial overlap of kinome profiles, with the activation of similar signalling pathways, such as FAK, ERK and PI3K signalling, as confirmed by immunoblot analyses. Inhibition of PI3K signalling in cells significantly reduced cell adhesion to the ECM (0.5-fold, P<0.001), and increased the number of non-adherent cells, both on ECM (2.4-fold, P<0.001) and on titanium (1.9-fold). The increase in non-adherent cell number in response to PI3K inhibition was not due to induction of apoptosis by PI3K inhibitors. In summary, this study comprehensively characterized the kinase activity in MSCs on cell-derived ECM and on titanium, highlighting the role of PI3K signalling in the kinomic changes regulating osteoblast viability and adhesion. Kinome profile analysis represents a powerful tool to select pathways for a better understanding of cell behaviour. Osteoblast-derived ECM could be further investigated as coating for titanium scaffolds, to improve bone tissue engineering applications.

SAT-0472

Requirement of the PDGFR-PI3K-AKT signaling axis in periosteal cells Laura Doherty*, Xi Wang, Jungeun Yu, Ivo Kalajzic, Archana Sanjay. UConn Health, United States

Insufficient fracture healing remains a significant public health problem with a large economic burden and limited therapeutic options. PI3K signaling, a major pathway involved in regulation of fracture healing, promotes proliferation, migration, and differentiation of osteoprogenitors. We have recently reported that knock-in mice with a global increase in PI3K signaling (gCblYF) show enhanced femoral fracture healing characterized by an extraordinary early periosteal response. Periosteal-derived progenitors are essential during fracture repair, as they expand at the fracture site and provide a template for new bone formation. Platelet-derived growth factor (PDGF) is a potent mitogen for mesenchymal progenitors, with expression highest during the earliest phases of injury. The effects of PDGF are mediated through receptors Pdgfr-α and -β, and we have established that Pdgfrβ is the predominant isoform expressed in the fracture callus. Treatment of periosteal cells with PDGF-BB, that activates all platelet derived growth factor receptors, resulted in increased proliferation and migration. By flow cytometry analysis we found that 75% of periosteal cells express Pdgfrβ. Interestingly, of all the growth factor receptors involved in fracture healing, only Pdgfr β directly bind to PI3K. Given these findings, we hypothesized that PDGFR-PI3K signaling is necessary for mediating robust periosteal cell proliferation.We found that mRNA and protein expression of Pdgfrβ was augmented during the proliferative phase of cell culture in gCblYF periosteal cells compared to WT. Western blots showed that relative to FGF2 or IGF1, PDGF efficiently increased AKT phosphorylation in gCblYF periosteal cells, and also augmented phosphorylation of AKT substrates containing RXXS*/T* motif. In contrast, induction of ERK phosphorylation was comparable among all treatment groups. Phosphorylation of Pdgfrβ and AKT substrates was reduced in cells treated with SU16f, a Pdgfrβ inhibitor, and deletion of Pdgfrβ in periosteal cells using a mouse model abrogated AKT phosphorylation. Additionally, we found that treatment of periosteal cells with SC79, a small molecule activator of AKT, increased phosphorylation of AKT substrates to the same extent as treatment with PDGF. These results suggest that increased PI3K-AKT activation is necessary for Pdg-

frβ signaling in periosteal cells, and presents the PDGF-PI3K axis as a novel therapeutic target in the context of regenerative medicine.

DPP-4-Cleaved SDF-1β Diminishes Migration and Osteogenic Differentiation Capacities of Bone Marrow Mesenchymal Stem Cells Ahmed Elmansi*[1], Khaled Hussein[1], Brian Volkman[2], Galina Kondrikova[1], Wendy Bollag[3], Sadanand Fulzele[4], Xingming Shi[5], Meghan Mcgee-Lawrence[1], Mark Hamrick[1], Carlos Isales[5], William Hill[1], Sudharsan Periyasamy-Thandavan[6]. [1]Department of Cellular Biology and Anatomy, Augusta University, United States, [2]Department of Biochemistry, Medical College of Wisconsin, United States, [3]Department of Physiology, Augusta University, United States, [4]Department of Orthopedic Surgery, Medical College of Georgia, United States, [5]DEPARTMENT OF NEUROSCIENCE AND REGENERATIVE MEDICINE, Augusta University, United States, [6]Cancer Center Pharmacy, Medical College of Georgia, Augusta University, United States

Mechanisms for age-related bone loss are poorly understood. In part it can be attributed to a decline in bone marrow mesenchymal stem cell (BMSC) osteogenic potential. Stromal cell derived factor-1 (SDF-1/CXCL12) is a chemokine responsible for activation of osteogenic differentiation pathways in BMSCs. Dipeptidyl peptidase-4 (DPP4) is a proteolytic enzyme that cleaves the two N-terminal amino acids Lysine and Proline from SDF-1. Intact SDF-1 has a very short half-life, and is cleaved by DPP4 within minutes of its release. SDF-1 cleaved by DPP-4 enzyme is referred to as SDF-1(3-67) for the α splice variant, or SDF-1(3-72) for the β splice variant. Both cleaved isoforms have been thought to be inactive, and reported to have no activity through CXCR4, the primary receptor for SDF-1.However, we propose the DPP4 cleaved isoforms are not inactive but possess a separate bioactivity. We tested the effect of both intact and DPP4-cleaved SDF-1β on inducing osteogenesis, adipogenesis, and migration in BMSCs. To be able to measure the difference in concentration between intact and cleaved SDF-1, we developed an antibody specific for cleaved SDF-1.We report the first known biological effects for DPP-4 cleaved SDF-1(3-67 and 3-72) to be inhibition of osteogenesis and migration of BMSCs. Using the Alizarin Red osteogenic assay, we show that SDF-1 significantly increased BMSCs osteogenesis by 48%, while cleaved SDF-1 significantly decreased it by 22% relative to controls. Adding both cleaved and intact SDF-1 to BMSCs lead to an effect similar to that of cleaved SDF-1 alone. In terms of migration, cleaved SDF-1 shows similar outcomes in transwell assays and microfluidic migration assays in that DPP4 cleaved SDF-1 inhibits BMSCs migration to SDF-1-gradients. Further, in young human BMSCs treated with DPP4 Cleaved SDF-1 there is an increase in expression of the anti-osteogenic miRNAs 29b1-5p and 141-3p, which are up-regulated in aged human BMSCs. In contrast intact SDF-1 reduces the expression of these miRNAs in BMSCs from aged humans. This suggests DPP4 cleaved SDF-1 modulates osteogenic gene expression potentially through epigenetic regulation, as well as more rapidly responsive signaling pathways. These results add to our understanding regarding roles of intact SDF-1 and its metabolites in bone homeostasis with age.

SAT-0474

Assessment of a new anabolic drug, picolinic acid, in MSC cultures using in vitro live-cell confocal imaging Damian Myers*, Ahmed Al Saedi, Gustavo Duque. University of Melbourne, Australia

Introduction: Mesenchymal stem cells (MSC) are pluripotent used for in vitro studies of both adipocytes and osteoblasts. Picolinic acid (PIC) has been proposed as an anabolic therapy for bone conditions and, in this study, we have utilized intracellular calcium ion ([Ca2+Int]) mobilization is an indicator of cell activation. The aims of this study were to assess whether addition of PIC to MSC cultures could induce changes (Δ) in [Ca2+Int] and, also, to characterise MSC cultures for both calcium ion responses and lysosomal expression in live-cell cultures.Methods: Bone marrow-derived MSC (Lonza Biosciences, Mt. Waverley, VIC, Australia) were cultured onto φ18mm coverglass and, after 7 days of culture, were loaded for 30 min using Fluo-4-AM and LysoTracker-Red (Invitrogen, Thermofisher), both at 2 μM in the medium. After washing, time-course experiments were performed using a Nikon A1Rsi CLSM (x20 lens). Fluo-4 fluorescence changes, proportional to Δ[Ca2+Int], were monitored over 10-20 min to monitor cell responses to PIC (20 μM). Ionomycin (10-8 M) was added for maximal Δ[Ca2+Int] response and MnCl2 (2 mM) was added to quench fluorescence signals for minimal fluorescence to establish dynamic range.Results: 5-10% of the cell population showed low-level transient oscillations (periodicity of 55.3±3.3 secs, mean±SD); in a field population of approx 220-240 cells. ROI assessment of single cells showed that MSCs expressing low levels of lysosomes exhibited a higher Δ[Ca2+Int] in response to PIC (20 μM) compared to cells with high levels of lysosomes (mean ratio change of 2.43 (range 2.0–2.8) compared to 1.50 (1.0-1.9); p<0.05 by Kruskal-Wallis with Bonferoni correction; n=6 per analysis. Maximal ratio response to ionomycin was a value of 10-12.Conclusions: MSCs in culture exhibited differential expression of lysosomes and cells responded to PIC exhibiting dynamic Δ[Ca2+Int]. The capacity of these cells to exhibit spontaneous [Ca2+Int] oscillations is a novel finding and the fact that higher expression of lysosomes may affect induced Δ[Ca2+Int] responses may be important in long-term cultures

Saturday Posters

and related bone studies. [Ca2+Int] dynamics are central to many cellular processes affecting bone cell function and lysosomes have been implicated in autophagy and cell survival so further studies are justified to characterize these responses and to investigate impacts of novel therapies.

SAT-0475

Validation of osteogenic properties of Cytochalasin D by high-resolution RNA-sequencing in mesenchymal stem cells derived from bone marrow and adipose tissues Rebekah Samsonraj*[1], Christopher Paradise[1], Amel Dudakovic[1], Buer Sen[2], Asha Nair[1], Allan Dietz[1], David Deyle[1], Simon Cool[3], Janet Rubin[2], Andre Van Wijnen[1]. [1]Mayo Clinic, United States, [2]University of North Carolina, United States, [3]Institute of Medical Biology, Singapore

Differentiation of mesenchymal stem cells involves a series of molecular signals and gene transcription events required for attaining cell lineage commitment. Modulation of the actin cytoskeleton using cytochalasin D (CytoD) drives osteogenesis at early time points in bone marrow-derived MSCs, and also initiates a robust osteogenic differentiation program in adipose-derived MSCs. To understand the molecular basis for these pronounced effects on osteogenic differentiation, we investigated global changes in gene expression in CytoD-treated murine and human MSCs by high-resolution RNA-sequencing analysis. A three-way bioinformatic comparison between human adipose-derived, human bone marrow-derived and mouse bone marrow-derived MSCs revealed significant upregulation of genes linked to extracellular matrix organization, cell adhesion and bone metabolism. As anticipated, the activation of these differentiation related genes is accompanied by a downregulation of nuclear and cell cycle-related genes presumably reflecting cytostatic effects of CytoD. We also identified eight novel CytoD activated genes – VGLL4, ARHGAP24, KLHL24, RCBTB2, BDH2, SCARF2, ACAD10, HEPH – which are commonly upregulated across the two species and tissue sources of our MSC samples. The up-regulation of these 8 CytoD-responsive genes was confirmed via RT-qPCR. We selected the Hippo-pathway related VGLL4 gene, which encodes the transcriptional co-factor Vestigial-like 4, for further study because this pathway is linked to osteogenesis. Depletion of VGLL4 via siRNA knockdown reduced the pro-osteogenic effect of CytoD in adipose-derived MSCs upon assessment of matrix mineralization. Together, our RNA-seq analyses and subsequent in vitro experiments suggest that while the stimulatory effects of CytoD on osteogenesis are pleiotropic and depend on the biological state of the cell type, a small group of genes including VGLL4 may be central mediators controlling MSC commitment towards the bone lineage.

SAT-0476

Activation of Mitochondrial OxPhos Drives Osteogenesis via β- catenin Brianna Shares*, Melanie Busch, Noelle White, Laura Shum, Roman Eliseev. University of Rochester, United States

Bone marrow mesenchymal stem cells (BMSCs) can differentiate into osteoblasts (OB), adipocytes, and chondrocytes. As BMSCs undergo OB differentiation, they upregulate use of mitochondrial oxidative phosphorylation (OxPhos). Our lab is investigating mechanism(s) connecting mitochondrial OxPhos to OB differentiation. First, we showed that treating osteoinduced BMSC-like C3H10T1/2 (C3H) cells with an OxPhos inhibitor reduced their osteogenic potential with no change in cell viability, underlining the importance of OxPhos in osteogenesis. Interestingly, ATP levels were not reduced as glycolysis compensated for the decreased OxPhos. Thus, mitochondria support OB differentiation not only by supplying ATP but by some other mechanisms. To uncover such mechanisms, our strategy was to stimulate OxPhos and study downstream signaling. Replacing glucose in cell culture media with galactose is a known strategy to stimulate OxPhos. We thus replaced media glucose with galactose and observed stimulation of both OxPhos and osteogenesis in C3H cells in the absence of osteoinducers. To elucidate signaling mechanisms responsive to galactose-mediated stimulation of OxPhos, we used various promoter reporters carrying luciferase. β-catenin is regulated by acetylation, and OxPhos generates AcCoA, a substrate for acetylation. AcCoA is then converted to citrate capable of exiting mitochondria. Cytosolic citrate is next converted back into AcCoA by ACLY enzyme. We found that inhibiting the conversion of citrate to AcCoA using an ACLY inhibitor, SB204990 (SB), reversed the galactose-induced β-catenin activity and OB differentiation. This indicates that acetylation is involved in β-catenin activation after forced stimulation of OxPhos. We also detected SB-dependent β-catenin acetylation using immunoprecipitation. Both β-catenin protein and acetylation levels increased during osteoinduction, again in a SB-dependent manner, showing the importance of OxPhos-dependent β-catenin acetylation for the osteogenic program. These data suggest that active OxPhos is required for OB differentiation not only because of ATP demands but also due to its effect on β-catenin acetylation and, thus activity.
Figure 1. Citrate, derived from Ac-CoA in active mitochondria, translocates to the cytosol where it is converted back to Ac-CoA by ACLY enzyme. This ACLY-dependent cytosolic Ac-CoA is then used to acetylate and, thus activate β-catenin. ACLY is inhibited by SB204990 (SB).

Subchondral cyst number is positively associated with proximal tibia bone mineral density, alignment and joint space narrowing in individuals with OA Wadena Burnett*[1], Saija Kontulainen[1], Christine Mclennan[2], Diane Hazel[2], Carl Talmo[2], David Wilson[3], David Hunter[4], James Johnston[1]. [1]University of Saskatchewan, Canada, [2]New England Baptist Hospital, United States, [3]University of British Columbia, Canada, [4]Kolling Institute of Bone & Joint Research, University of Sydney, Australia

Purpose/Background: Osteoarthritis (OA) is a debilitating joint disease marked by altered cartilage and underlying bony tissues. Subchondral cysts are a commonly observed, but poorly understood, feature of knee OA. Clinical quantitative computed tomography (QCT) has the potential to characterize cysts in vivo, but it is unclear which specific cyst parameters (e.g., number, size) are associated with clinical signs of OA. The purpose of this study was to use QCT and image-processing to explore relationships between proximal tibial subchondral cyst parameters and subchondral bone density as well as clinical characteristics of OA in patients with knee OA.Methods: The preoperative knee of 42 patients was scanned using QCT, scored for pain using the Western Ontario and McMaster Universities Arthritis Index (WOMAC) and classified for OA severity. We also included medial and lateral joint space narrowing (JSN) and CT-measured joint alignment in our analysis. Cysts were

identified as approximate elliptical or spherical volumes of lower greyscale surrounded by higher greyscale through visual inspection guided by subject-specific half-maximum-height threshold values, then manually segmented. Only cysts within the subchondral region (depth of 7.5mm from the subchondral surface) were evaluated. We used a custom algorithm to measure cyst parameters (total, maximum, average, minimum, and standard deviation of cyst volume; number of cysts; cyst volume and cyst number per subchondral volume) and proximal tibial bone mineral density (BMD) excluding cysts. Cyst parameters and BMD were evaluated over total, medial, and lateral subchondral regions of the proximal tibia. Pearson's and Spearman's rank correlation were used to determine associations between cyst parameters and clinical characteristics of OA.Results: Lateral cyst number was associated with lateral BMD (r=0.55, p<0.001), valgus alignment (r=0.60, p<0.001) and lateral JSN (r=0.66, p<0.001). Although most individuals had medial OA, there were no associations for the total or medial regions, or between cyst parameters and OA severity or pain.Conclusion: To our knowledge, this is the first study to provide evidence of a positive association between subchondral cyst number and BMD, valgus alignment, and JSN in individuals with knee OA. These findings suggest that there may be disease-associated changes in tibial loading distribution leading to cyst development.

SAT-0508

Establishing a Model to Investigate the Role of Non-Traumatic Bone Marrow Lesions in the Pathogenesis of Knee Osteoarthritis: 9.4T MRI and microCT in Dunkin-Hartley Guinea Pigs Alicia K Gabilondo*[1], John R Matyas[2], Jeffrey F Dunn[1], Sarah L Manske[1]. [1]McCaig Institute for Bone and Joint Health, Department of Radiology, Cumming School of Medicine, University of Calgary, Canada, [2]McCaig Institute for Bone and Joint Health, Faculty of Veterinary Medicine, University of Calgary, Canada

Purpose: Bone marrow lesions (BMLs), which appear as diffuse hyper-intense regions in the subchondral bone on fat-saturated MRI sequences, are one of few imaging findings strongly associated with pain in late-stage knee osteoarthritis (OA). However, the underlying pathogenesis of non-traumatic BMLs in knee OA is poorly understood. The Dunkin-Hartley guinea pig spontaneously develops degenerative changes with characteristics similar to human knee OA. The purpose of this study was to investigate the occurrence of subchondral BMLs and their underlying bone microarchitecture in older Dunkin-Hartley guinea pigs to establish a model of spontaneous BMLs.Methods: We extracted the left hind limbs of 4 (2F, 2M) 24-month old guinea pigs and completed scanning within 48 hours. We obtained 3 image sequences using a 9.4T MRI (Magnex and Bruker) and a cryogenic transceiver quadrature RF surface coil (CryoProbe, Bruker) to identify BMLs and cysts, as well as bony anatomy: 1) gradient echo (FLASH), 2) proton-density weighted rapid acquisition with relaxation enhancement (RARE) and 3) modified drive-equilibrium Fourier-transform (MDEFT). We also obtained microCT images (vivaCT40, Scanco Medical) and performed H&E staining.Results: All samples demonstrated diffuse hyper-intense regions in the central distal femoral epiphysis and the proximal tibial epiphysis anterior to the ACL insertion site. Hyper-intense regions were absent of trabecular bone. Three of four samples also displayed a small spherical cyst in the medial tibial condyle inferior to the calcified medial meniscus. On histological sections, these regions did not contain cells or tissue and likely corresponded with fluid-filled cavities.Conclusions: In 24-month old Dunkin-Hartley guinea pigs, we observed hyper-intense regions on MRI in anatomically similar locations. Based on the absence of cells, fibrous and bone tissue in histology and microCT, these hyper-intense regions were likely fluid-filled and may be suggestive of subchondral bone cysts. In humans, subchondral cysts form nearly exclusively in regions previously associated with BMLs. The cyst-like finding may reflect the late-stage degeneration in 24-month old guinea pig knees, as other OA-like features begin to develop at less than 12-months of age. Further comparison of these hyper-intense regions with younger guinea pigs will establish a model to investigate the role of BMLs in idiopathic knee OA.

SAT-0509

Accelerated Osteoarthritic-like Symptoms in a Novel Dual Injury Model Combining Destabilisation of the Medial Meniscus and Cartilage Damage Kendal Mcculloch*[1], Carmen Huesa[2], Lynette Dunning[1], Rob Van 'T Hof[3], John Lockhart[1], Carl Goodyear[4]. [1]University of the West of Scotland, United Kingdom, [2]University of Edinburgh, United Kingdom, [3]University of Liverpool, United Kingdom, [4]University of Glasgow, United Kingdom

Osteoarthritis (OA) is associated with articular cartilage damage. It is assumed OA pathogenesis can be initiated via an isolated injury, or an accumulation of joint damage over time. OA represents a major clinical challenge due to the poor regenerative capability of cartilage. Several murine models are used to study OA (e.g. destabilisation of the medial meniscus (DMM)), however, they do not combine simultaneous joint destabilisation with cartilage damage. The principle aim of this study was to investigate if combining DMM and cartilage damage could accelerate the onset of OA-like symptoms.OA was induced in C57BL/6 mice via (a) transection of the medial meniscotibial ligament (DMM), (b) micro-blade scratches of articular cartilage (cartilage damage) or (c) combined DMM and cartilage scratch (DCS). Seven and 14 days post-surgery, inflammation, cartilage degradation and bone changes were monitored using histology and microcomputed tomography. Dynamic weight bearing was assessed as an indirect measurement of pain at 14 days.Osteophytes were observed in all groups at days 7 and 14 post-surgery. When compared with DMM and cartilage damage models, osteophytes were visually larger and more numerous in the DCS model. Osteophyte total bone volume (BV) was greater at day 14 in both cartilage damage and DCS models; these osteophytes also encompassed a larger surface area of subchondral bone (14.12±0.31 versus 12.4±0.62, 12.68±0.54, p<0.01 respectively). With regard to other bone changes, at day 7 there was no detectable increase in BV and osteosclerosis was absent, but by day 14 osteosclerosis was detectable in both DMM and DCS models. Assessment of cartilage at day 14, revealed that there was a significant increase in damage in the DCS model when compared with DMM and cartilage damage models (p<0.01). Furthermore, there was a significant increase in synovitis in the DCS model compared with the cartilage scratch model (p<0.05). In mice that underwent DCS surgery there was significant increase in front paw load compared with the other models. At day 14 a positive correlation was observed between osteophyte number and front paw load (r=0.69, p=0.003).Combining DMM and cartilage damage provides a robust and reproducible model for OA-associated joint changes, suggesting this novel dual injury model not only accelerates osteophytogenesis, but also includes features of OA-related pain; arguably one of the most problematic and physically limiting symptoms of OA.

SAT-0510

LPS Induced Inflammation Pre-Injury Increases the Severity of Post-Traumatic Osteoarthritis in MRL/MpJ Superhealer Mice Melanie Mendez*[1], Deepa Murugesh[2], Allison Hsia[3], Blaine Christiansen[3], Gabriela Loots[3]. [1]University of California-Merced, Lawrence Livermore National Laboratory, United States, [2]Lawrence Livermore National Laboratory, United States, [3]University of California-Davis, United States

Post-traumatic osteoarthritis (PTOA) develops in ~50% of people who suffered a severe joint injury such as an anterior cruciate ligament (ACL) rupture. Inflammation could be one of the key contributing factors to the development of PTOA, therefore a state of heightened inflammation prior to injury could cause a more rapid progression of PTOA. Lipopolysaccharides (LPS) are microbial associated molecular patterns expressed in gram-negative bacteria which activate an inflammation cascade through toll-like receptor 4 (TLR4). To determine whether LPS-induced inflammation modulates PTOA after ACL rupture, we compared 3 strains of mice: 2 sensitive to LPS (C57Bl/6 and MRL/MpJ) and 1 resistant to LPS (C3H/HeJ, which carry a TLR4 mutation). In C57Bl/6 mice, a single non-invasive tibial compression overload that ruptures the ACL will result in severe PTOA within 6 weeks. MRL/MpJs subjected to the same type of injury did not display significant cartilage degradation 6-weeks post injury, but C3H/HeJ injured joints did display a more severe PTOA phenotype than C57Bl/6 at this time point. To determine if an acute state of inflammation prior to injury would increase the severity of PTOA, we induced systemic inflammation by administering a single LPS injection (1mg/kg) intraperitoneally 5 days prior to injury. As expected, LPS did not cause any changes in the PTOA phenotype of C3H/HeJ mice. Micro-computed tomography analysis of the femoral epiphysis revealed that LPS treated C57Bl/6 mice displayed a significant loss of epiphyseal trabecular bone in both the tibia and the femur in both injured and uninjured joints. Histological analysis revealed that there was a loss of mineralized surface area and a higher marrow content. The synovium was also thicker and more cellular in these mice. The LPS treated group showed a reduction in Safranin O staining and thinning of the articular cartilage suggesting loss of proteoglycan content and chondrocyte apoptosis, due to cartilage degradation. MRL/MpJ mice treated with LPS also showed a significant loss of subchondral bone, thinning of the cartilage, and loss of Safranin O staining. The PTOA phenotypes were less severe in MRL/MpJ than C57Bl/6, but significantly more severe than injured MRL/MpJs that received a PBS injection. These data suggests that LPS-induced inflammation prior to ACL rupture exacerbates the PTOA phenotype in both C57Bl/6 mice and MRL/MpJ mice and that MRL/MpJ mice are not protected from inflammation-induced PTOA.

Bone and Muscle Quality in Postmenopausal Women with Both Osteoarthritis and Osteoporosis – the AMBERS study Andy Kin On Wong*[1], Shannon Reitsma[2], Hana Gillick[2], Abinaa Chandrakumar[3], Eva Szabo[3], Justin Chee[3], Angela M Cheung[3], Jonathan D Adachi[2]. [1]Joint Department of Medical Imaging, University Health Network, Canada, [2]Department of Medicine, McMaster University, Canada, [3]CESHA, University Health Network, Canada

Our previous study showed that knee pain in women with both osteoarthritis (OA) and osteoporosis (OP) was associated with differences in bone but not cartilage properties. However, little is known about bone and muscle properties in this overlapping subgroup versus those with only OA.Objectives: 1) To determine differences in muscle and bone quality among postmenopausal women with OP, OA, and those with both; 2) To evaluate the impact of muscle properties in knee OA (KOA)and falls.312 women 60-85 yrs old from the Appendicular Muscle and Bone Extension Research Study (AMBERS)completed baseline imaging and annual follow-up on fractures, falls, and frailty for 3 years. This study is a cross-sectional analysis of the baseline data for women 76-85 yrs old (N=170). Peripheral QCT (pQCT) and MRI (pMRI) scans of the mid-leg (66% site) measured muscle density and % inter- and intra-muscular fat (%IMF). 4% distal tibia pQCT scans quantified bone density and micro-architecture. Total hip and lumbar spine DXA-derived BMDs were converted to T-scores for diagnosing osteoporosis. OA and KOA were self-reported. Falls over the last 2 years were captured.General linear models compared muscle and bone properties among groups, exploring interactions between disease groups. Binary logistic regression examined the effect of muscle properties on OA and falls.Among 170 women (age:80±3yrs, BMI:29.1±5.5kg/m2), 37.1% had OA (58.7% knee), 18.8% had OP, and 61.8% had osteopenia. Among those with OA, 19.0% also had OP and 63.5% also had osteopenia. Muscle density was 2.44 mg/cm3 lower in those with KOA versus without (p=0.011) but not all OA (p=0.130). In those with OA, concurrently having OP was associated with 48.51 mg/cm3 lower distal tibia volumetric BMD (p<0.001, interaction p<0.001), and 4.19% higher %IMF (p=0.023, interaction p=0.025). In those with OP, each standard deviation (SD) larger %IMF was associated with 4.85(1.18,19.91)-fold odds for KOA (interaction p=0.028). This effect was not significant in those without OP. Having KOA (OR: 2.94(1.03,8.40) or any OA (OR: 2.30(1.06,5.00) but not OP alone was significantly associated with falls.The effect on bone and muscle properties for those with both OA and OP is significantly greater than for those with either disease alone. Having higher muscle adiposity is a risk factor for KOA among those who already have OP. While this measure is not directly a risk factor for falls, KOA itself was a prominent correlate of falls.

Intermittent PTH exerts an anabolic effect on the osteochondral tissue of the TMJ Sumit Yadav*[1], Po-Jung Chen[2], Mara H O'Brien[2], Eliane Dutra[2]. [1]Associate Professor, United States, [2]University of Connecticut Health Center, United States

Introduction: Intermittent Parathyroid Hormone (I-PTH) is the only anabolic FDA-approved drug for the treatment of bone loss due to conditions such as osteoporosis. The mechanisms of the effects of I-PTH in bone are known, however, the effects of I-PTH on the mandibular condylar cartilage (MCC) remains to be understood. In addition, it is unknown whether I-PTH could be used as an anabolic drug to treat degenerative disorders of the temporomandibular joint (TMJ). Objective: The purpose of this study was to characterize the long-term effects of I-PTH on the MCC and subchondral bone of the TMJ, in vivo and in vitro. In addition, we attempted to identity the mechanisms by which I-PTH promotes its effects in the chondrogenic lineage of the MCC. Material and Methods: For the in vivo experiments, 24 10-week-old mice (C57BL/6J) were divided into two groups: (1) I-PTH (n=12): subcutaneous daily injection of PTH; (2) Control Group (n=12): subcutaneous daily injection of saline solution. Experiments were carried out for four weeks. Mice were injected with calcein, alizarin complexone and EdU before euthanasia. The mandibular condyle of I-PTH treated and control mice were examined by microCT and histology. For the in vitro

experiments, primary chondrocyte cultures from the MCC of 6-week-old mice (C57BL/6J) were treated with I-PTH for 14 days. Gene expression from experimental and control chondrocyte cultures were analyzed by QPCR. Results: There was an anabolic response in the mandibular condyle of the I-PTH treated mice when compared to control group characterized by an increase in cartilage thickness, subchondral bone volume, mineral deposition, TRAP activity and cellular proliferation. In addition, immunohistochemistry revealed that I-PTH administration led to a significant decreased expression of SOST (negative regulator of mineralization), MMP13 and ADAMST4 . QPCR analysis of the I-PTH treated chondrocytes revealed significantly increased PRG4 (lubricant and anti-inflammatory agent for the articular joints) and significantly decreased SOST, BMP2 (promoter of chondrocyte differentiation), IHH (promoter of chondrocyte hypertrophy and osteoarthritis) and Col10 (marker for chondrocyte hypertrophy and osteoarthritis). Conclusion: I-PTH exerts an anabolic effect at the MCC that may be correlated with decreased chondrocyte hypertrophy. In addition, I-PTH treatment may promote a prevent TMJ degeneration by increasing the expression of cartilage protective agents at the MCC.

Possible involvement of regulation of intracellular RANKL by a RANKL binding peptide WP9QY in osteogenesis. Yuriko Furuya*. Nagahama Institute for Biochemical Science, Oriental Yeast Co., Ltd., Japan

WP9QY (W9) peptide consisting of 9 amino acids is known to abrogate osteoclastogenesis in vitro and in vivo via blocking receptor activator of NF-kB (RANK) ligand/RANK signaling as a RANKL antagonist. We reported that W9 exerted osteoblastic differentiative activity in mouse preosteoblastic cells and human mesenchymal stem cells (MSCs), and accelerated bone formation in vivo. We reported that RNA interference (RNAi)-mediated RANKL gene knockdown using lentivirus suppressed W9-induced calcification in mouse MSCs C3H10T1/2 cells, suggesting an important role of RANKL in osteoblastogenesis by W9. Although we have hypothesized that reverse signaling through membrane-bound RANKL regulates osteogenesis, direct evidence of participation of RANKL in osteoblasts differentiation has not been clarified.In this study we established a method detecting intracellular RANKL using human and mouse RANKL antibodies. We failed to detect membrane-bound RANKL on MSCs and preosteoblastic cells. In contrast we found strong signals of intracellular RANKL in MSCs and preosteoblastic cells. Addition of W9 decreased the signal of intracellular RANKL in MSCs, suggesting the involvement of intracellular RANKL in W9-induced osteogenesis.On the other hand W9 also enhanced chondrogenesis in mouse prechondrogenic cells, human MSCs and rabbit model of full-thickness articular cartilage defects.To clarify participation of RANKL in W9-induced chondrogenesis, we conducted RNAi-mediated RANKL gene knockdown in mouse C3H10T1/2 cells using lentivirus, followed by induction of chondrocyte differentiation. As opposed to osteogenesis, W9 stimulated chondrocyte differentiation even in the RANKL knockdown cells. The results showed that RANKL had little effect on W9-induced chondrocytes differentiation. The mechanism of W9-induced osteogenesis through intracellular RANKL and the difference of mechanism between chondrogenesis and osteogenesis by W9 should be clarified in the near future.

SAT-0553

Remarkable early bone-forming efficacy of bisphosphonate (alendronate, zoledronate or risedronate)-conjugated collagen sponges as a rhBMP-2 delivery carrier Soon Jung Hwang*[1], In Sook Kim[2]. [1]Department of Oral and Maxillofacial Surgery, School of Dentistry, Seoul National University, Republic of Korea, [2]Dental Research Institute, Seoul National University, Republic of Korea

Our previous study demonstrated the manufactured collagen sponge (CS) composite combined with a bisphosphonate (BP), alendronate (ALN) led to excellent outcome with less adverse effects and higher bone-forming efficacy in the treatment of high dose rhBMP-2. This study aimed to compare the early bone-forming efficacy of CS composites conjugated with various BPs including ALN, zoledronate (ZOL) or risedronate (RIS) as rhBMP-2 carrier. Alkaline phosphatase activities of rat osteoblasts in vitro showed a synergistic effect of rhBMP-2 with BPs, while proliferation was inhibited, dependently of BP-doses. Osteoclast differentiation was also inhibited by ALN, Zol and RIS, dose dependently. ALN-, ZOL-, or RIS-CS were loaded with low and high doses (5 and 40 μg) of rhBMP-2 and analyzed for new bone formation using 8 mm-critical sized calvarial defect model of rats, compared with normal CS. Bone mass and bone density calculated from micro computertomography reconstructions at 4 weeks were significantly greater in all BP-CS-BMP groups. Ossification at defect exterior was significantly decreased in all BP-CS-BMP groups over CS-BMP group. Notable findings are that BP-CSs at low dose BMP (5 mg) resulted in approximately 2 fold greater bone volume (BV), and only a reduction rate of less than 10 % BV at the central defect area, compared to CS and BP-CSs at high dose BMP (40 mg), respectively. Histology corroborated these findings and revealed dense spatial pattern of bone formation in all BP-CS-BMP groups. Net osteogenic efficacy for rhBMP-2 delivery was evaluated as the order of ALN-CS, ZOL-CS and RIN-CS. These results demonstrate that BP-CS composites has remarkable advantages in the rhBMP-2 delivery over CS with early dense ossification minimizing heterotopic ossification, and great efficiency at low dose, suggesting a remarkably effective carrier of rhBMP-2.

SAT-0554

Gene activated-matrix (GAM) comprised of atelocollagen and plasmid DNA encoding microRNA promotes rat cranial bone augmentation Rena Shido*[1], Yoshinori Sumita[2], Masashi Hara[1], Shun Narahara[1], Izumi Asahina[1]. [1]Department of Regenerative Oral Surgery, Unit of Translational Medicine, Graduate School of Biomedical Science, Nagasaki University, Japan, [2]Basic and Translational Research Center for Hard Tissue Disease, Nagasaki University Graduate School of Biomedical Sciences, Japan

Therapeutic method for in vivo gene delivery has not been established on bone engineering though its potential usefulness has been suggested so far. To facilitate the clinical setting of this strategy, an effective condition should be developed to transfer the genes in vivo without any of transfection-reagents or virus-vectors. On this account, we have made a try at developing an atelocollagen-based GAM containing naked-plasmid (p) DNAs encoding osteogenic-proteins such as BMP-4 and have demonstrated the potential of such simple and probably safe strategy for bone engineering. However, a certain dose (more than 6μg/μl) of pDNA was still required for inducing the sufficient bone regeneration when pBMP4 was incorporated. Therefore, the efficient methods for generating non-viral GAM with high transgene efficacy and low toxicity should be developed further. In this study, we examined whether GAM containing pDNAs encoding microRNA (miR) 20a, which regulates the BMP2/4 expression on mesenchymal stem/progenitor cells (MSCs) during their osteoblastic differentiation via multiple pathways, facilitates the rat cranial bone regeneration. As experiments, first, to determine the biological activity of generated pDNA encoding miR20a (pmiR20a), we confirmed its functions of osteoblastic differentiation on rat bone marrow MSCs via gene transfection in culture. Then, GAMs were manufactured by mixing 0.5mg (3.3μg/μl) of AcGFP plasmid-vectors encoding miR20a with 100μl of 2% bovine atelocollagen and 20mg β-TCP granules. After that, GAM was lyophilized and transplanted to the rat cranial bone surface. After 1 to 8weeks of transplantation, new bone formation and its specific gene and protein expressions in specimens were analyzed. As results, transfection of miR20a could regulate the expression of its target genes multiply in rat BM-MSCs and induce the up-regulation of bmp4 mRNA expression. Then, when transplanted the GAMs containing pmiR20a, the newly formed bone tissues surrounded by Osteocalcin-stained area were markedly observed via up-regulation of bmp4, vegf-a and -b mRNA expressions, compared to GAMs containing pGFP without encoding osteogenic protein. We are currently carrying out the additional experiments, such as developing an appropriate matrix and verifying the safe concentration of pDNAs, for clarifying the actual usefulness of GAM encoding miR20a.

SAT-0555

Synergistic Effects of Adiponectin and Irisin on Bone Cells Tong Chen*[1], Weina Zhou[2,3], Qisheng Tu[2], Jinkun Chen [2,4]. [1]2nd Dental Center, Peking University School and Hospital of Stomatology, Beijing, China. Central Laboratory, Peking University School and Hospital of Stomatology, Beijing, China., China, [2]Division of Oral Biology, Tufts University School of Dental Medicine, Boston, Massachusetts, United States, [3]Jiangsu Key Laboratory of Oral Disease, Nanjing Medical University.Nanjing.China, [4]Department of Developmental, Molecular and Chemical Biology Sackler School of Graduate Biomedical Sciences Tufts University School of Medicine, United States

Objectives:Adiponectin (APN) plays a pivotal role in glucose metabolism and energy homeostasis. Evidences suggest a positive association between APN and bone formation. Irisin is a newly discovered myokine and could increase adipocyte browning and bone formation. APN and irisin are protagonists of the muscle-fat-bone axis. This study was to investigate the synergistic effects and regulatory mechanisms of APN and irisin in bone metabolism.Materials and Methods:MC3T3-E1 and RAW264.7 cells were cultured in corresponding induced media with APN or irisin or both, respectively. The ALP, Alizarin Red S and TRAP staining were performed to visualize the cell differentiation. RT-PCR was performed to detect the expression of osteoblast/osteoclast differentiation markers. Signaling transduction pathways were investigated to elucidate the mechanism by western blotting. Results:The ALP staining and ARS staining at 7- and 14-day showed that the APN plus irisin enhanced ALP activity and increased mineralization deposition, in contrast to APN or irisin treatment alone. At 1-day osteogenic induction, the level of RUNX2 and ALP expression more significantly increased in the APN plus irisin group than in control groups. At 3 and 7-day, the levels of RUNX2, ALP, collagen type 1, BSP, OSX and OCN were significantly increased in the APN plus irisin group. Western blots revealed that the expression of BSP protein could be upregulated by APN plus irisin and this effect could be inhibited by knockdown of APPL1 with siRNA. Also, a significantly increased amount of phosphorylated Akt was detected by western blot after treatment with APN and irisin, which could be impaired by PI3K inhibitor LY294002. In osteoclasts induction of RAW264.7 cells, the cell number detected by TRAP staining decreased more significantly in the APN plus irisin group than the APN or irisin, and control groups. At 1- and 3-day after osteoclasts induction, the level of CK and TRAP mRNA significantly decreased in the APN plus irisin group compared with that the APN or irisin, and control groups.Conclusions:Adiponectin and irisin could synergistically enhance the osteogenic induction of preosteoblasts via upregulating of APPL1, an adaptor protein of adiponectin signaling, and subsequently mediating PI3K/Akt pathways. Additionally APN and irisin could coactively inhibit osteoclastogenesis. This

synergistic effect can be used pharmaceutically for treating bone disorders particularly in diabetic patients.

SAT-0556

The stimulation of osteogenesis by delivery of recombinant protein of osteogenic molecular switches Woo-Jin Kim*, Youngdan Cho, Hyunmo Ryoo. Seoul National University, Republic of Korea

Protein therapy, which delivers proteins into the cell to replace the dysfunctional protein, is considered the most direct and safe approach for treating bone disease. However, there are limitations include inefficient cellular uptake, degradation of protein in serum environment and damage to cells in the delivery process. Recently, researchers have introduced silk fibroin based spherical nano-particle system. Silk Fibroin protein as a natural polymer, provides useful properties including biocompatibility, biodegradability, tunable drug loading capacity and release. Using this system, we can fabricated nano-particles which loaded verified multiple recombinant proteins and introduced functional proteins directly into the cells to control bone disease. In this study, we use recombinant Pin 1 and GFP proteins to confirm cytosolic delivery of proteins and regulatory effect of osteogenesis. Pin 1 is a cis-trans isomerase which recently reported playing critical role in osteogenesis via regulation of Runx2 protein stability. Fabrication of silk Fibroin nano-particles containing recombinant Pin 1 and GFP proteins shows high loading efficacy without any assistant conjugation and control-able particle size and stability. GFP loaded fibroin nano-particle shows significantly enhanced cellular uptake compare with naive-protein treatment and maintained long-term protein activity in serum condition. In low level BMP2 stimulating C2C12 cells, Alp activity relatively increased in Alp staining by Direct-delivery of recombinant Pin 1 proteins. However, their cellular toxicity level while protein delivery was significantly lower than commercially using transfection reagent. Multiple recombinant proteins can be delivered to cells with high efficiency while maintaining protein activity and low toxicity, suggesting potential application in bone-related disease therapy.

Osteoclastogenic cues induce both priming and assembly signals for the NLRP3 inflammasome Yael Alippe*[1], Chun Wang[1], Biancamaria Ricci[2], Jianqiu Xiao[1], Dustin Kress[1], Guillermo Blanco[3], Yousef Abu-Amer[2], Roberto Civitelli[1], Gabriel Mbalaviele[1]. [1]Division of Bone and Mineral Diseases, Washington University School of Medicine, United States, [2]Department of Orthopaedic Surgery, Washington University School of Medicine, United States, [3]IDEHU, University of Buenos Aires, Argentina

Events that promote the abundance of NLRP3 are referred to as NLRP3 priming signals. Upon recognition of ligands, NLRP3 recruits other proteins, such as caspase-1 to form a protein complex called the NLRP3 inflammasome. This inflammasome plays an important role in bone resorption associated with high bone turnover as Nlrp3 deficiency attenuates bone loss induced by ovariectomy or sustained exposure to PTH or RANKL in mice. However, the mechanisms through which the NLRP3 inflammasome regulates bone resorption remain unknown. Since crystalline materials activate this inflammasome, we tested the hypothesis that bone matrix degradation products, which are released during bone resorption, activate the NLRP3 inflammasome and regulate osteoclast differentiation. We found that bone particulates produced from shredded cortical bones synergized with RANKL to cause exuberant osteoclastogenesis from mouse bone marrow macrophages (BMM; approximately 10-fold from baseline), a response that was attenuated in cells lacking NLRP3. Mechanistically, treatment of BMM with RANKL resulted in a rapid rise in NLRP3 protein levels (approximately 50% over baseline levels), a response that peaked at 3 hours before returning to baseline levels 24 hours post RANKL exposure. Bone particles also increased NLRP3 protein abundance. Thus,osteoclastogenic factors are inducers of NLRP3 inflammasome priming signals. Given that RANKL-driven osteoclast differentiation is associated with the generation of reactive oxygen species (ROS), also potent activators of NLRP3 inflammasome assembly, we tested the role of RANKL and bone particles in NLRP3 inflammasome formation. RANKL stimulated ROS production by 43±7.3% in osteoclast precursors as detected by flow cytometry, as did bone particles. This response correlated with NLRP3 recruitment and activation of other of the components of the inflammasome, caspase-1, and was abolished upon NLRP3 ablation. Thus, the NLRP3 inflammasome is not only assembled in responses to osteoclastogenic cues, but it is also implicated in the maintenance of oxidative stress that is needed for efficient osteoclast differentiation. Collectively, we uncovered novel mechanisms in bone resorption whereby RANKL synergizes with signals originating from bone matrix to promote osteoclast differentiation by regulating multiple steps in the NLRP3 inflammasome pathway.

SAT-0607

Regulation of Membrane Localization of CD44 and Migration of Osteoclasts by ERM proteins Meenakshi Chellaiah*. School of Dentistry, University of Maryland, United States

Osteopontin is a ligand for several cell surface receptors, such as $\alpha v\beta 3$, $\alpha v\beta 1$, $\alpha v\beta 5$, $\alpha 4\beta 1$, $\alpha 8\beta 1$, and $\alpha 9\beta 1$ and CD44. Both CD44 and integrin $\alpha v\beta 3$ have been implicated in osteoclast motility and bone resorption. We have previously demonstrated that a cooperativity exists between $\alpha v\beta 3$ and CD44 receptors for osteoclast motility and bone resorption. Still, the details of how CD44 is responsible for osteoclast motility and molecular mechanism

involved in CD44 trafficking remain unclear. The goal of this study was to determine the mechanism by which PtdIns4, 5 P2 (PIP2) synthesis and its binding to ERM proteins coordinate CD44 surface expression and osteoclast (OC) motility. Transduction of TAT-fused constitutively active RhoVal14 into OCs increased phosphatidylinositol 4-phosphate (PI4P) 5-kinase activity and enhanced cellular levels of PIP2. The effects of RhoVal14 transduction simulate the effects of osteopontin (OPN) in OCs. The Rho inhibitor C3 transferase and Rho kinase inhibitor Y27632 reversed OPN or RhoVal14 effect. An increase in the phosphorylation and PIP2 binding of ERM proteins augment ERM/CD44/actin interaction and surface expression of CD44. siRNA to ezrin not only blocked CD44/ ERM/actin complex formation but also the surface expression of CD44. OPN or RhoVal14-induced migration and bone resorption is blocked in OCs treated with C3 transferase, Y27632, or siRNA to ezrin. The increased levels of PIP2 in OCs subjected to above-mentioned treatments can be attributed to increased activity of PI4P 5-kinase which is located downstream of the Rho/Rho-kinase-dependent pathway. ERM protein is dynamically regulated under these conditions and it may partake in CD44 surface expression. Bone resorption involves active motility of osteoclasts on bone surfaces to be resorbed. Activation of PI4P- 5 kinase and interaction of PIP2 with ERM may represent a key molecular switch that aides CD44 surface expression and motility of osteoclasts. We believe ERM and signaling protein(s) that regulates the activation of ERM proteins may represent rational therapeutic targets. Although our understanding of the role of ERM proteins in the mechanisms of CD44 surface expression and osteoclast motility is limited, we believe our studies outlined above will provide new insights on these cellular processes. (Work is supported by funding from NIH-NIAMS R01-AR46292 and R01AR066044).

SAT-0608

Protective effect of a novel benzamide derivative on alveolar bone erosion through suppression of NFATc1-mediated osteoclastogenesis Hye Jung Ihn*[1], Soomin Lim[2], Hong-In Shin[2], Eui Kyun Park[2]. [1]Institute for Hard Tissue and Biotooth Regeneration, Kyungpook National University, Republic of Korea, [2]Department of Oral Pathology and Regenerative Medicine, Kyungpook National University, Republic of Korea

Enhanced osteoclast formation and/or activity have been attributed to pathogenesis of diverse osteolytic bone diseases including periodontitis and osteoporosis. In this study, we investigate the therapeutic potential of a novel benzamide-linked molecule, KDS-070, for preventing alveolar bone loss in mice with ligature-induced experimental periodontitis. KDS-070 inhibited osteoclast formation in a dose-dependent manner, and attenuated the induction of nuclear factor of activated T-cells, cytoplasmic 1 (NFATc1) and the expression of osteoclast-specific genes. In addition, KDS-070 significantly suppressed the formation of actin rings and resorption pits. Analysis of the inhibitory action of KDS-070 showed that it markedly suppressed receptor activator of nuclear factor-κB ligand (RANKL)-induced extracellular signal-regulated kinase (ERK) and NF-κB signaling cascades. Moreover, KDS-070 prevented ligature-induced alveolar bone erosion in mice by suppressing osteoclast formation. These findings demonstrate that KDS-070 attenuated osteoclast differentiation and function as well as ligature-induced bone erosion by inhibiting RANKL-mediated ERK and NF-κB signaling pathways.

Fas/S1P1 crosstalk via NF-κB activation in osteoclasts controls subchondral bone remodeling in murine TMJ arthritis Islamy Rahma Hutami*, Eiji Tanaka, Takashi Izawa. Tokushima University Graduate School, Japan

Enhanced turnover of subchondral trabecular bone is a hallmark of rheumatoid arthritis (RA) and it results from an imbalance between bone resorption and bone formation activities. To investigate the formation and activation of osteoclasts which mediate bone resorption, a Fas-deficient MRL/lpr mouse model which spontaneously develops autoimmune arthritis and exhibits decreased bone mass was studied. Various assays were performed on subchondral trabecular bone of the temporomandibular joint (TMJ) from MRL/lpr mice and MRL+/+ mice. Initially, greater osteoclast production was observed in vitro from bone marrow macrophages obtained from MRL/lpr mice due to enhanced phosphorylation of NF-kB, as well as Akt and MAPK, to receptor activator of nuclear factor-kB ligand (RANKL). Expression of sphingosine 1-phosphate receptor 1 (S1P1) was also significantly upregulated in the condylar cartilage. S1P1 was found to be required for S1P-induced migration of osteoclast precursor cells and downstream signaling via Rac1. When SN50, a synthetic NF-kB-inhibitory peptide, was applied to the MRL/lpr mice, subchondral trabecular bone loss was reduced and both production of osteoclastogenesis markers and sphingosine kinase (Sphk) 1/S1P1 signaling were reduced. Thus, the present results suggest that Fas/S1P1 signaling via activation of NF-kB in osteoclast precursor cell is a key factor in the pathogenesis of RA in the TMJ.

SAT-0610

Downregulation of receptor activator NF-κB (RANK) expression by methylation of its gene promoter Riko Kitazawa*[1], Yuki Murata[2], Ryuma Haraguchi[2], Sohei Kitazawa[2]. [1]Division of Diagnostic Pathology, Ehime University Hospital, Japan, [2]Department of Molecular Pathology, Ehime University Graduate School of Medicine, Japan

Receptor activator of NF-κB (RANK) is a member of the tumor necrosis factor receptor (TNFR) family expressed in osteoclast precursors, and RANK-RANK ligand (RANKL) signaling plays a central role in differentiation, activation and survival of osteoclasts. The 5'-flanking region of the mouse RANK gene we had previously analyzed lacked canonical TATA-box but contained four continuous Sp-1 binding sites and CpG-islands around the transcription and translation start sites. In this study, the passage-dependent change in osteoclastogenesis and RANK expression in relation to the status of CpG methylation of its gene promoter was investigated with the use of RAW 264 pre-osteoclastic cells.Quantitative RT-PCR disclosed that the steady-state expression of RANK mRNA of the RAW cells was lower at passage 40 (P40) than at P18; also, RANKL-induced osteoclastogenesis as well as the expression of TRACP and CTSK mRNA was significantly lower at P40 than at P18. To clarify the epigenetic regulation of the RANK gene, the genomic DNA of the two subpopulations of RAW cells was analyzed. Methylation-specific PCR of CpG island region -150 /+110, adjacent to transcription and translation start sites, showed a methylated pattern at P40, but not at P18; bisulfite mapping detected a higher frequency of CpG methylation of region -150/+110 at P40 than at P18. Furthermore, pre-treatment with demethylating agent 5-Aza-dC, restored significantly the expression of RANK gene and RANKL-induced osteoclastogenesis at P40. Next, examination of the CpG methylation of region -150/+110 in mono-nucleated cells of mouse spleen disclosed higher methylation in 12-month-old mice than in 10.5-week-old ones, mirroring the passage-dependent CpG methylation of the cultured RAW cells. These data suggest that the epigenetical regulation of the RANK gene promoter by DNA methylation may be one of the age-dependent regulatory mechanisms of osteoclastogenesis.

SAT-0611

CCR5 is required for osteoclast function through regulating lysosomal vesicle trafficking Jiwon Lee*, Yuuki Imai, Tadahiro Iimura. Ehime University, Japan

Osteoclasts resorb bone matrix through the cellular polarization event, in which the cells directionally deliver vesicles containing specific cargo carrying bone-resorptive enzymes and protons along cytoskeleton to the bone-apposed plasma membrane. However, this critical cellular event by osteoclasts remains largely undescribed. We previously reported that the deficiency of C-C chemokine receptor 5 (CCR5), a co-receptor of HIV, impaired the cellular locomotion and bone-resorptive activity, which was associated with the disarrangement of podosomes and adhesion-mediated signaling complex including integrins and Pyk2. Our current study demonstrated that Ccr5-deficient osteoclasts dampened lysosome-related pathways and vesicle trafficking. Analysis by RNA-sequencing and subsequent data mining found that Ccr5-deficient osteoclasts impaired the expression levels of lysosomal and cargo molecules as well as H+ transporters. We observed unique and distinct subcellular distribution of a lysosomal membrane protein expression, Lamp1 in Ccr5-deficient osteoclasts compared to that in wild-type cells using immunocytochemistry. In wild-type osteoclasts, clusters of Lamp1-positive vesicles were preferentially distributed around nuclei indicating a converged distribution of lysosomal vesicles, whereas these vesicles were found to be predominantly localized in periphery of Ccr5-deficient osteoclasts when cultured either on glass-bottomed dishes and dentin slices. Further analyses demonstrated that the expression of Dynein, an important minus-end-directed cargo transporter along microtubules was attenuated in Ccr5-deficient osteoclasts, thus causing the failure of the polarized vesicle trafficking. We further observed that the interaction between centrosphere (plural of centrosome) and cytoskeletal structure were crucial for maintaining the cellular polarity and directional vesicle trafficking of osteoclasts as revealed by super-resolution microscopy-based three-dimensional fluorescence morphometry. These findings together with our previous report support an idea that CCR5-mediated signal plays an important role in osteoclast function through regulating the cell polarity and directional vesicle trafficking as well as cell adhesion, thus leading to a novel insight into the functional association between cellular architecture and lysosomal organelles.

SAT-0612

Inhibition of osteoclast differentiation and P. gingivalis lipopolysaccharide-induced alveolar bone resorption by novel Bruton's tyrosine kinase inhibitor acalabrutinib Youngkyun Lee*, Yong-Gun Kim, Jung-Hong Ha. Kyungpook National University Scholl of Dentistry, Republic of Korea

Background: Periodontitis is not only one of the most prevalent inflammatory diseases among adults, but also commonly linked to numerous systemic conditions including cardiovascular diseases, stroke, and diabetes. Although osteoclasts are responsible for the alveolar bone resorption during periodontitis pathogenesis, the development of treatment strategies targeting these cells has not been fruitful. In the present report, the effect of a novel Bruton's

kinase inhibitor acalabrutinib on osteoclast differentiation and alveolar bone resorption was studied. For in vitro experiments, mouse bone marrow macrophages were cultured in the presence of macrophage-colony stimulating factor (M-CSF) and nuclear factor of activated T cells cytoplasmic 1 (NFATc1) to induce osteoclast differentiation. The effect of acalabrutinib was tested by tartrate-resistant acid phosphatase (TRAP) staining as well as real-time PCR detection of marker genes and western blot analyses of typical osteoclast proteins. The calcium oscillation characteristics of osteoclast precursors were also tested. Finally, the protective effect of acalabrutinib on alveolar bone erosion was analyzed in mice challenged with Porphyromonas gingivalis lipopolysaccharide. The inhibition of Bruton's kinase inhibitor by acalabrutinib significantly reduced the formation and function of osteoclasts, concomitant with decreased expression of osteoclast marker genes and proteins. Acalabrutinib conspicuously diminished the phosphorylation of mitogen-activated protein kinases, calcium oscillation responses, and NFTAc1 nuclear localization, all of which are critical for osteoclastogenesis. Administration of acalabrutinib resulted in significantly reduced lipopolysaccharide-induced osteoclastogenesis and alveolar bone erosion in mice.

SAT-0613

Regulation of osteoclastogenesis by protein kinase D2 and protein kinase D3 Carina M G Meyers*, Kim Mansky, Eric Jensen. University of Minnesota, United States

Excessive bone resorption by osteoclasts contributes to bone destructive pathologies of osteoporosis, arthritis and bone malignancies. Despite having important identified functions in diverse cell types, the role of Protein Kinase D (Prkd) family of serine/threonine kinases in osteoclasts is largely unknown. The Prkdfamily consists of three related kinases: PRKD1, PRKD2 and PRKD3. Characterization of Prkdexpression in osteoclasts demonstrated predominantly Prkd2and Prkd3. We previously found that PRKD chemical inhibitors compromise fusion of mononuclear preosteoclasts into multinucleated osteoclasts. In our current work, we describe functions for PRKD2 and PRKD3 in multiple cellular processes including precursor cell migration, osteoclast fusion and maintenance of the podosome belt and resorptive function in mature osteoclasts. Toward understanding how PRKDs regulate osteoclastogenesis we are performing mass-spectrometry-based proteomic identification of PRKD phosphorylation targets and describing the skeletal phenotype of conditional knockout of Prkd2and Prkd3in osteoclast lineage cells. Together our observations suggest that antagonizing PRKD activity might represent a novel therapy in pathologies involving excessive osteoclast bone resorption.

Lipoteichoic acid, a membrane component of gram-positive bacteria, induces PGE2-mediated inflammatory bone resorption in periodontitis. Tsukasa Tominari*, Ryota Ichimaru, Keita Taniguchi, Kenta Watanabe, Chiho Matsumoto, Michiko Hirata, Masaki Inada, Chisato Miyaura. Tokyo University of Agriculture and Technology, Japan

Toll-like receptors (TLRs) are the mold receptors play a critical role in innate immunity. Several reports indicated that TLRs regulate the host defense with inflammation against the pathogens. Lipopolysaccharide (LPS), an outer membrane component of gram-negative bacteria, induced inflammatory bone resorption with TLR4 signaling in periodontitis. We also have reported that the roles of the synthetic ligand of TLR1/2 or TLR2/6 induced prostaglandin (PG) E2-mediated osteoclast differentiation via NFkB signaling pathway that induced alveolar bone destruction in in vivo mouse experimental model of periodontitis. In this study, we examined lipoteichoic acid (LTA) from gram-positive bacteria, a natural ligand of TLR2/6, induced bone destruction in the mouse model of periodontitis. In cocultures of mouse primary osteoblast (POB) and bone marrow cell, LTA dose-dependently induced osteoclast differentiation. Further treatment of LTA to purified mature osteoclast, LTA also prolonged its life span. LTA increased the bone resorbing activity in the mouse calvarial organ cultures. In osteoblasts, LTA stimulated PGE2 production and upregulated the mRNA expression of membrane bound PGE synthase (mPGES)-1, COX-2 and RANKL. When the treatment of indomethacin, a COX inhibitor, significantly blocked LTA-induced these effects. To examine LTA induced NFkB activity, the degradation of IkB alpha was analyzed using western blot based detection analysis. LTA promoted degradation of IkB alpha, suggesting RANKL expression was increased by NFkB translocation into nuclear in osteoblasts. In ex vivo organ cultures of mouse alveolar bone, LTA induced bone resorbing activity, and treatment of indomethacin abrogated its bone resorbing activity. In in vivo experiment as the mouse model of periodontitis, the local injection of LTA to mouse lower gingiva, alveolar bone destruction was clearly observed using dual energy X-ray absorptiometry (DXA) and micro-CT. These results suggested that LTA induced inflammatory bone resorption promoted RANKL expression through the pathway of COX-2 and mPGES-1 mediated PGE2 production. Recent reports indicated that LTA derived from gram-positive bacteria such as Streptococcus mutans thought to be involved augment of inflammation. LTA may prolong

inflammation in the initial stage of periodontitis, and also contribute severe bone resorption with the crosstalk between LPS in mature stage of periodontitis.

Defective Perilacunar/Canalicular Remodeling in Subchondral Bone Exacerbates Osteoarthritis Karsyn Bailey*, Jonathon Woo, Cristal Yee, Claire Acevedo, Aaron Fields, Jeffrey Lotz, Alexis Dang, Alfred Kuo, Thomas Vail, Tamara Alliston. University of California San Francisco, United States

Osteoarthritis (OA) is a debilitating joint disease characterized by articular cartilage degeneration and subchondral bone sclerosis. Although the precise contributions of articular cartilage and subchondral bone in the etiology of OA are yet to be established, mounting evidence suggests that bone-cartilage crosstalk is critical to maintain joint health. Our previous work demonstrated a role for osteocytes in osteonecrosis through perilacunar/canalicular remodeling (PLR), a process by which osteocytes maintain bone quality by dynamically acidifying their microenvironment and secreting matrix metalloproteinases (MMPs), cathepsin K, and other enzymes. Models of PLR suppression demonstrate a coordinated repression of PLR enzyme expression (MMP2, MMP13, MMP14, and cathepsin K), bone matrix hypermineralization, collagen disorganization, and disruption of canalicular networks. Similar hallmarks of hypermineralization and increased subchondral trabecular bone volume occur in OA, but the contribution of osteocytes to cartilage degeneration is unknown. We therefore hypothesize that osteocyte-mediated PLR is critical for healthy joint homeostasis and participates directly in OA development.To determine the role of osteocytic PLR in OA, we evaluated key PLR outcomes in human OA tibial plateaus and assessed arthritic changes in a mouse model of PLR deficiency. Relative to healthy cadaveric controls, tibial plateaus from patients with end-stage OA (n=5/group) exhibit hallmarks of suppressed PLR within the subchondral bone, including significantly blunted canalicular networks, disrupted collagen alignment, and decreased expression of the PLR enzyme MMP13. While these data suggest a correlation between deregulation of PLR and joint disease, in order to determine if osteocyte-mediated PLR participates causally, we evaluated cartilage in mice with osteocyte-intrinsic PLR defects. In mice with disrupted PLR due to an osteocyte-specific ablation of TGFβ receptor II (TβRIIocy-/-), OA was induced using a meniscal-ligamentous injury (MLI) model. Histological analysis of MLI-injured TβRIIocy-/- cartilage shows more severe cartilage degeneration with a trend toward increased OARSI score (WT+MLI = 5.4 vs. TβRIIocy-/-+MLI = 7.8, n=10/group, p=0.06). This work provides further evidence for the importance of healthy bone-cartilage crosstalk and suggests that osteocyte-intrinsic defects in PLR can contribute to OA progression.

SAT-0661

Effects of in vivo Induction of Diffuse Damage in Osteocyte Network Rinaldo Florencio-Silva*, Leila Mehraban Alvandi, Dorra Frikha, Erica Teixeira, Robert Majeska, Mitchell Schaffler. The City College Of New York, United States

Linear microcracks in bone induce osteocyte apoptosis. In contrast, diffuse damage regions (Dif-Dx) do not similarly impair osteocyte viability(1). However, given the extensive array of submicron-sized crack comprising Dif-Dx regions and intimate association these small cracks with canaliculi in particular, it seems reason to posit that osteocytes perceive and react to diffuse matrix damage in bone. Diffuse damage was selectively induced into rat ulnar diaphysis in order to evaluate the effects of Dif-Dx in osteocyte network in vivo (F, SD, 17w, n=8)(2). After loading, rats were either sacrificed immediately Dif.Dx or 14 survival and control. The current study focus was on how osteocyte processes are affected by Dif.Dx

and its repair in vivo. At sacrifice, ulnae were harvested and cryosections through Dif.Dx regions were stained with Alexafluor488-Phalloidin to show F-actin in osteocyte processes; imaging was performed using SIM type super-resolution microscopy. Number of osteocyte processes were measured in the perilacunar region and between adjacent osteocytes. RESULTS Osteocyte processes declined acutely (~25%) after damage loading both immediately surrounding the cell and in bone matrix between osteocytes. Number of processes in the perilacunar zone recovered by 14 days. However, number of osteocyte processes in bone between cells did not recover. DISCUSSION: Osteocytes in Dif-Dx areas lose processes acutely after induction of diffuse damage in vivo. Acute in vivo loading during in these studies lasted less than 60 minutes, thus these data indicate that osteocytes can rapidly remodel cell process cytoskeletons in response to local mechanical stresses caused by Dif-Dx. Osteocytes processes in the perilacunar zone recovered by 14 days after loading. In contrast, processes remained diminished in between osteocytes. These data suggest that osteocytes attempt to restore connectivity to other osteocytes after the acute stress of Dif-Dx induction, but this action is ineffective. Whether the cells inability to regrow their processes is due to a cellular defect or canalicular obstruction caused by damage or infilling is not known. The latter might be similar to loss of odontoblast processes and dentinal tubule infilling during dentin repair. We speculate that this process may be important for repair of diffuse damage in bone and more globally for maintaining overall bone health. SAT-0662

A potential role for the NLRP3 inflammasome in osteocyte-mediated triggering of osteoclast differentiation Dorra Frikha-Benayed*, Maria Lapshina, Robert Majeska , Mitchell Schaffler. The City College Of New York, United States

Osteocyte apoptosis activates bone remodeling by inducing neighboring surviving bystander osteocytes produce RANKL, but how apoptotic cells signal bystander cells to express RANKL is not understood. Intriguingly, mice lacking the ATP membrane channel Pannexin1 do not produce RANKL in response to osteocyte apoptosis, pointing to extracellular (e) release of ATP as a potential key signal in this process [1,2]. High levels of eATP can signal a broad range of biological responses, including activation of the NLRP3 inflammasome [3,4]. In these studies, we tested whether (1) eATP stimulates NLRP3 and RANKL expression in osteocytes and (2) if NLRP3 activation is required to trigger osteocyte RANKL expression.Methods: MLO-Y4 osteocyte cultures maintained on collagen coated plates in α-MEM with 5% FBS and 5% calf serum were treated at confluency for 1 hr with 10 μM ATP in order to mimic a bolus-type extracellular exposure associated with nearby apoptotic cells. Cell were examined either acutely (after 1 hr ATP) or after an additional 5 hr in standard medium (no ATP). NLRP3, RANKL and OPG expression (normalized to GAPDH) were assessed by qPCR. To test whether NLRP3 triggers osteocyte RANKL expression, cells were cultured wth the NLRP3-inflammasome inhibitor MCC950 (300 nM, Invivogen, [5]) prior to ATP challenge; gene expression assessed at 6 hr. Statistical test was assessed by 2-way ANOVA.Results: ATP exposure increased osteocyte NLRP3 gene expression ~3 fold after 1 hr and maintained this increase at 6 hrs. ATP also stimulated RANKL (7-fold) and OPG (2-fold) expression, but only at 6 hrs. Inhibiting NLRP3 inflammasome formation markedly suppressed the ATP-induced increase in RANKL expression. Discussion: These studies demonstrate that acute exposure of osteocytes to ATP stimulates RANKL expression, mimicking Panx1-mediated release of bolus ATP by apoptotic osteocytes [1, 2] and consistent with a driving role for ATP release in upregulation of RANKL by bystander osteocytes. Moreover, our studies reveal that this ATP-induced RANKL expression depends on the activation of the NLRP3 inflammasome, indicating a novel link between osteocyte inflammasome activation and RANKL signaling as part of the triggering mechanism for normal bone resorption.References:1) Cheung WY et al, J Bone Miner Res, 2016; 2) Ravichandran KS et al, Nature,2009; 3) Iyer S et al, Proc Natl Acad Sci, 2009; 4) Dongli Yang et al, Austin J Clin Ophthalmol. 2014; 5) Coll RC et al, Nature Med, 2015.

Scriptaid Induces Osteocyte Respiration through an HDAC5 Independent Mechanism Ningyuan Sun*[1], Ehab Azab[1], Yuhei Uda[1], Chao Shi[2], Paola Divieti Pajevic[1]. [1]Boston University Henry M. Goldman School of Dental Medicine, United States, [2]The Second Affiliated Hospital of Xi'an Jiaotong University, China

Bone undergoes continuous remodeling to maintain its structural integrity. During development, bones rely on glucose uptake for proper skeletal development. Osteoblasts take up one fifth of the glucose consumed by muscles through a Glut1/AMPK-dependent pathway independent of insulin signaling. Glucose uptake in osteoblasts is necessary for osteoblast differentiation, bone formation and glucose homeostasis. However, the role of glucose in osteocytes is still unknown. Previous studies have shown that parathyroid hormone (PTH) promotes bone anabolism, in part, by stimulating osteoblasts anaerobic glycolysis while suppressing glucose oxidation through the TCA cycle. In osteocytes, PTH suppresses Sost expression by inducing HDAC4/5 nuclear translocation and Mef2C suppression. Recently, scriptaid, an HDAC inhibitor, has been shown to induce Mef2 activation and exercise-like adaptation in skeletal muscle. In muscle cells, scriptaid disrupts the class IIa HDAC co-repressor complex comprising HDAC3, SMRT and Ncor and induces nuclear export of HDAC4/5 with increase in Mef2, Glut4, Pdk4 and ATP-5d expression. This suggested that scriptaid might upregulate Mef2 and Sost expression in osteocytes. To test this hypothesis, a clonal osteocytic cell line, Ocy454-12H was treated with scriptaid and/or PTH and gene expression was analyzed by semi-quantitative PCR. Unexpectedly, scriptaid potently suppressed Sost, whereas induced Glut4, Pdk4 and ATP-5d expression. Both scriptaid and PTH stimulated mitochondrial respiration and glucose uptake in these cells. Western blot analysis demonstrated that, in osteocytes, scriptaid induced nuclear translocation of HDAC5 whereas had no effect on HDAC4. Downregulation of HDAC5 by shRNA, increased basal Sost expression and prevented scriptaid-induced Sost suppression. However, Glut4 up-regulation by scriptaid was still present, even in the absence of HDAC5. These studies demonstrated that scriptaid induced osteocyte metabolism and glucose uptake through an HDAC5 independent mechanism. Furthermore, calvariae and long bone explants from C57/Bl6 animals treated with scriptaid showed significant increase in the expression of Glut4, Pdk4 and ATP-5d. Taken together these results suggest that scriptaid might enhance metabolism and glucose uptake in osteocytes.

Clinical Applicability of TBS in Women with Short Stature Pedro Alvarenga*[1], Mariana Diniz[2], Milena Leite[3], Caroline Silva[4], Jessica Eleuterio[2], Maria Marta Soares[5], Bruno Muzzi[6], Barbara Silva[7]. [1]Alberto Cavalcanti Hospital, Brazil, [2]Santa Casa de Belo Horizonte, Brazil, [3]Mario Pena Hospital, Brazil, [4]CEMA, Brazil, [5]Felicio Rocho Hospital, Brazil, [6]Mater Dei Hospital, Densimater, Brazil, [7]Felicio Rocho Hospital, Santa Casa de Belo Horizonte, Brazil

Introduction:Areal bone mineral density (aBMD) as measured by dual X-ray absorptiometry (DXA) is influenced by bone size such that true BMD is underestimated in those with smaller bones and overestimated in those with larger bones.This could overestimate the risk of fracture,leading to excessive treatment of small individuals,who have a lower fracture risk than taller subjects, particularly at the femoral neck.Trabecular bone score (TBS),a textural index evaluated by pixel gray-level variations in the lumbar spine (LS) DXA image,appears to be independent of bone size Objective:We aimed to assess TBS in a group of women >50 years with short stature, compared to a control group Material and methods:We retrospectively analyzed LS and femoral DXA scans of all women aged 50 to 90 years old with short stature (161cm in height, matched for age and LS BMD with cases, selected from the same database.Site-matched LS TBS was extracted from the DXA image using the TBS iNsight software Results:The study population included 171 women per group. Cases and controls were well matched in age (69.7±8.6 vs. 69.7±8.5 yrs; p=0.91), LS BMD (0.970 (0.880-1.090) vs. 0.970 (0.880-1.090) g/cm2; p=0.9), and LS BMD T-score (-1.7(-2.5; -0.7) vs. -1.7(-2.5; -0.8);p=0.9). Cases had a lower height (p1.350), despite being considered osteoporotic by BMD T-score. In contrast, none of the women with osteoporosis in the control group had a TBS >1.350 Conclusion:TBS is greater in women with short stature than in their taller counterparts. These findings suggest that TBS may offer advantages over aBMD alone to assist in treatment decisions in individuals with small bones

SAT-0691

BRIDGING THE GAP WITH FRAX: FRAX UTILITY IN PREVENTING HIP FRACTURES IN MEN Eduardo Dusty Luna*[1,2], Donna Davenport[2], John W Hinchey[2], Jan M Bruder[1,2]. [1]UTHSCSA, United States, [2]ALMVAH, United States

INTRODUCTION: Osteoporosis is an under-recognized issue that goes untreated in the majority of men with fractures. The National Osteoporosis Foundation (NOF) estimates that currently 1:4 men over the age of 50 years will have a fracture related to osteoporosis in their remaining lifetime. Although dual energy x-ray absorptiometry (DXA) classifies osteoporosis with a T-score < -2.5, the FRAX calculation can help provide an estimated ten-year likelihood of fracture based on clinical risk factors in a multivariable analysis without the use of DXA. To better understand the clinical utility of the FRAX tool, we reviewed the clinical risk factors in men admitted for hip fracture. METHODS: A retrospective chart review was conducted from January 2016 through December 2017. Seventy-seven patients

were admitted to the Veterans Administration Audie L Murphy Hospital (ALMVAH) in San Antonio, Texas with a hip fracture. Forty-four patients were seen by endocrine in consultation for osteoporosis evaluation; four female patients were excluded. Demographic data was reviewed from the medical record during hospital stay. The FRAX® tool (version 4.0) by the University of Sheffield was individualized based on ethnicity and calculated without the use of DXA for each patient. RESULTS: The average age of the men admitted for hip fracture was 74 +/- 9 years; 75% were Caucasian and 25% Hispanic. Social risk factors including alcohol and tobacco use were most prevalent at 45% and 53% of patients, respectively. Previous osteoporotic fractures were noted in 18% of patients. Only 8% of veterans had a significant family history. Fracture risk calculation without DXA upon admission, demonstrated that 60% of the veterans had a major osteoporotic fracture (MOF) or hip fracture (HF) risk warranting therapy for osteoporosis. The average MOF risk was 10.4% while HF risk was 4.9%. Treatment for osteoporosis therapy prior to hip fracture was warranted in 90% of men over age 72 years. CONCLUSION: The awareness of preventing fractures in men is crucial as patients who suffer hip fracture develop significant disability and morbidity. Prolonged hospitalizations, multiple physician visits, chronic pain and loss of independence are only some of the most common problems that translate into a significant health care cost. The FRAX tool is a quick, inexpensive and effective resource to close the gap in treating men over age 72 years at risk for osteoporotic fracture.

SAT-0692

Trabecular Bone Score (TBS) Integrating a New Correction for Soft Tissue Effects Based on Estimated Tissue Thickness François De Guio*[1], Enisa Shevroja[2], Franck Michelet[1], Doris Tran[1], Christophe Lelong[1], Didier Hans[2]. [1]Medimaps, France, [2]Center of Bone diseases, Bone and Joint Department, Lausanne University Hospital, Switzerland

Purpose: TBS is a textural parameter based on DXA spine scans that provides an indirect estimation of trabecular microarchitecture status, a valuable clinical information in osteoporosis. To account for soft tissue variability between individuals, current TBS iNsight (v3.0 and older) integrates a TBS correction based on BMI. We aimed at improving this correction by considering the tissue thickness estimated by the DXA device, which should be a better estimate of patient morphology than BMI. We evaluated the impact of this new correction in terms of in-vivo reproducibility and correlations with BMI for both GE-Lunar (GE) & Hologic (HLX) DXA manufacturers.Methods: We acquired scans of dried ex-vivo human vertebrae with several thicknesses of tissue-equivalent material and estimated the relationship between TBS and soft tissue thickness. From there, a derived specific model was defined and applied retrospectively on several datasets: one reproducibility study including 37 individuals having 2 or 3 scans each (Cohort A, GE); one reproducibility study including 27 individuals scanned 2 times each with repositioning (Cohort B, HLX); 2 population-based cohorts of women (Cohort C, HLX, N=6742, age=61±9; Cohort D, GE, N=6361, age=63±9), one population-based cohort of men (Cohort E, HLX, N=1343, age=56±11). For both current and new TBS, were computed 1) root mean square standard deviation (rms-SD) as an estimate of the reproducibility, 2) correlation coefficients with BMI.Results (see table): Overall, the new correction based on tissue thickness yield to a better in vivo reproducibility. The current TBS were negatively correlated with BMI for both manufacturers (r values ranged from -0.17 to -0.27) while the new TBS were now positively correlated which is consistent with expectations. Positive correlations between BMD and BMI were also reported (Cohort C: 0.23, Cohort D: 0.19, Cohort E: 0.26).Conclusions: With the new corrective and optimized model based on soft tissue thickness, we have a method that no longer depends on manual inputs (weight, height) and a better estimate of patient morphology enabling an improved in-vivo reproducibility. This is a promising approach to follow-up patients in longitudinal studies and to assess inter-individual variability hardly captured by BMI (for example, different morphotypes related to age). Whether clinical performance is improved with this new correction requires further studies.

Outcome	Cohort	Device	Sample size	Current TBS based on BMI	New TBS based on tissue thickness
rms-SD	A	GE	37	0.030	0.018
	B	HLX	27	0.025	0.023
TBS – BMI correlation coefficient	C	HLX	6742	-0.24	0.08
	D	GE	6361	-0.17	0.07
	E	HLX	1343	-0.27	0.08

SAT-0693

Accounting for Confounding Factors Affecting Dual-Energy X-ray Absorptiometry in a Large Clinical Trial Catherine Donlon*[1], Cindy Yu[1], Sharon Chou[1,2], Meryl Leboff[1,2]. [1]Division of Endocrinology, Diabetes and Hypertension, Brigham and Women's Hospital, United States, [2]Harvard Medical School, United States

Dual-energy X-ray absorptiometry (DXA) is considered the gold standard for measuring bone mineral density (BMD) and body composition (fat and lean tissue). As the prevalence of joint replacements, osteoarthritis (OA), and degenerative disc disease rises with the aging U.S. population, it is necessary to account for these factors, which affect the accuracy and precision of DXA measures. In the VITamin D and OmegA-3 TriaL (VITAL): Effects

on Bone Structure and Architecture study, 771 participants including 411 men ≥50 years and 360 women ≥55 years completed spine, hip, and whole body DXA scans (Discovery W; APEX Version 4.2, Hologic, Bedford, MA) at baseline and 2-years post-randomization to determine whether supplemental vitamin D and/or omega-3 fatty acids have beneficial effects on bone health. To detect small changes in BMD, it was necessary to account for internal metal, OA, degenerative disc disease, and breast implants.About 12.8% of participants had internal metal artifacts at baseline including joint replacements, spinal fusions, insulin pumps, and other screws and plates. According to the International Society for Clinical Densitometry,1 the bone measures from the unaffected, contralateral side were used to replace the metal artifact when possible, thus preventing falsely elevated BMD results (n=62; Fig. 1A). By using the equation in Kelly et al., 2009,2 T-scores and Z-scores were recalculated using the default sex and ethnicity-matched databases. However, if the metal adjustment was within the least significant change, no change was made to the bone data (n=11). Additionally, when there was not an unaffected contralateral side to copy (ie. spinal metal, bilateral hip/knee replacements), bone measures were excluded at the site as well as at the whole body (n=27).OA is also known to increase BMD.3 Femoral neck measures were excluded in 11 participants with severe OA at the hip (Fig. 1B), and 51 participants who had severe degenerative disc disease and/or scoliosis whose spine measures were excluded (Fig. 1C). Lastly, the bone density and body composition analyses of 2 participants with bilateral breast implants (Fig. 1D) were excluded due to uncertain effects on bone density, fat and lean mass.Metal artifacts, OA, advanced degenerative disease and breast implants may confound DXA results. It is therefore important in clinical studies to account for these factors to detect physiologically relevant differences in bone and soft tissue measures.References:1. Can DXA-derived 3D measurements at the lumbar spine predict thoracic spine fractures? Mirella López Picazo*[1], Ludovic Humbert[1], Silvana Di Gregorio[3], Miguel Angel Gonzalez Ballester[2], Luis Del Rio[3]. [1]Galgo Medical, Spain, [2]BCN MedTech, Universitat Pompeu Fabra, Spain, [3]CETIR Grup Mèdic, Spain

Objective: Evaluate the association of DXA-derived 3D measurements at the lumbar spine with thoracic spine fractures.Method: We retrospectively analyzed a cohort of 32 postmenopausal Caucasian women collected at CETIR Grup Mèdic: 16 subjects with thoracic spine fractures (fracture group) and 16 age-matched subjects without any type of fracture (control group). Inclusion criteria for the fracture group were no prior osteoporotic fractures at baseline, and thoracic spine fracture event between one year to ten years from baseline visit. Inclusion criteria for the control group were no prior fractures at baseline and during at least 7 years from baseline visit. Spine AP DXA scans were acquired at baseline using a Prodigy scanner (GE Healthcare). Areal BMD (aBMD) at L1-L4 segment was measured using enCORE software (v14.10, GE Healthcare). DXA-derived 3D measurements at L1-L4 segment were assessed using the software 3D-SHAPER (v2.3, Galgo Medical). The software computes the 3D shape and density distribution of the lumbar spine by registering a statistical model onto the AP DXA scan. Volumetric BMD (vBMD) is computed at trabecular, cortical and integral (cortical plus trabecular) compartments. Differences in aBMD and DXA-derived 3D measurements between fracture and control groups were evaluated using unpaired t-test. Individual odds ratio (OR) and area under the receiver operating curve (AUC) were computed.Results: No significant difference between groups was found in terms of age ($\rho = 0.74$), weight ($\rho = 0.44$), height ($\rho = 0.25$), T-score ($\rho = 0.10$), aBMD ($\rho = 0.11$) and integral vBMD at the total vertebra (vertebral body plus posterior arch) ($\rho = 0.05$). However, when computed at the vertebral body, integral, trabecular and cortical vBMD showed significant differences (Table I). Higher AUC were found for vBMD measurements at the vertebral body, compared to aBMD and integral vBMD at total vertebra.

Each incremental decrease of one standard deviation of the aBMD was associated with 1.86 the odds of presenting a fracture at dorsal vertebrae. OR for trabecular vBMD at the vertebral body was 5.42.Conclusion: This study shows that DXA-derived 3D measurements at the vertebral body could potentially be used to predict thoracic spine fracture using standard L1-L4 AP DXA scans.

Table I. Differences between measurements for fracture and control group.

L1-L4 segment		Control Mean ± SD	Fracture Mean ± SD	ρ	AUC	OR [95% CI]
Total Vertebra	aBMD (g/cm²)	0.93 ± 0.13	0.86 ± 0.13	0.11	0.66	1.86 [0.86 – 4.02]
	Integral vBMD (mg/cm³)	220.03 ± 32.95	197.12 ± 29.83	0.05	0.69	2.26 [0.96 – 5.30]
Vertebral Body	Integral vBMD (mg/cm³)	166.16 ± 20.21	144.03 ± 17.04	<0.01	0.79	4.43 [1.40 – 14.00]
	Trabecular vBMD (mg/cm³)	135.40 ± 20.92	113.08 ± 16.27	<0.01	0.81	5.42 [1.47 – 20.02]
	Cortical vBMD (mg/cm³)	213.33 ± 22.18	190.47 ± 19.90	<0.01	0.80	3.46 [1.29 – 9.24]
Figure 1. Differences between average vBMD of each group showed at the mid sagittal plane of the vertebral body.

Are They Really a Different Population? Comparing Fracture Risk Factors Between Home Care Recipients and Long-Term Care Residents Caitlin Mcarthur*[1], George Ioannidis[1], Micaela Jantzi[2], Jonathan Adachi[3], Lora Giangregorio[2], John Hirdes[2], Alexandra Papaioannou[1]. [1]McMaster University, GERAS Centre for Aging Research, Canada, [2]University of Waterloo, Canada, [3]McMaster University, Canada

Home care (HC) recipients have unique fracture risk factors compared to community dwelling individuals. Existing fracture risk assessment tools may not be feasible or valid. Our Fracture Risk Scale (FRS) leverages routinely collected RAI-MDS data and has been validated in the long-term care (LTC) setting but may not applicable to the HC setting. We hypothesize that fracture rates and risk factors in HC and LTC are not the same, and that a HC-specific scale is needed. The purpose of this study is to explore the prevalence of FRS risk factors, and number of new fractures in one year among HC recipients, as compared to LTC residents. Methods: Clinical data were obtained through the Resident Assessment Instrument-HC and Minimum Data Set 2.0, and incident fractures in the Discharge Abstract Database and National Ambulatory Care Reporting System. We included Ontario HC recipients who had an admission assessment and another assessment within one year between April 1st, 2011 and March 31st, 2015 and LTC residents between April 1st, 2006 and March 31st, 2010. We excluded people who had end-stage disease, received hospice or respite care, or expected a short stay. Descriptive statistics (n, %) were used to describe clinical characteristics and proportion of individuals sustaining fracture(s) within one year. Chi-squared tests were used to evaluate if there were statistically significant differences in the proportions of people in HC and LTC with fractures and risk factors. Results: 136868 HC recipients and 29848 LTC residents were included. The proportions of HC recipients and LTC residents with each risk factor were significantly different (p<0.001). A slightly higher proportion of HC recipients experienced fractures within one year (5.6 %HC, 5.2% LTC). Of those fractures, LTC residents experienced more hip (61.8% LTC, 43.7% HC) while HC recipients had more other fractures (56.3% HC, 38.2% LTC). HC recipients were younger, more mobile, and had less cognitive impairment (p<0.001). A higher proportion of HC recipients fell in the last 180 days (47.2% HC, 33.8% LTC) and experienced unintentional weight loss (HC 10.7%, LTC 5.3%). Conclusions: The proportion of people experiencing incident fractures and fracture risk factors differ between HC and LTC. HC recipients were younger, more mobile, and less cognitively impaired, but they experienced more falls, unintentional weight loss, and other fractures. The FRS may need to be tailored to the unique HC population.

Common mistakes in the clinical use of bone mineral density testing Radamés Leal Freitas*[1], José Seabra Alves-Neto[2], Amanda Raquel Costa Cruz[2], Francisco De Assis Pereira[1], Fábio De Souza Santos[1], Lúcio Moraes Lanzieri-Filho[1], Patricia Monique Vila Nova Pereira[1]. [1]Universidade Federal de Sergipe, Brazil, [2]Universidade Tiradentes, Brazil

Introduction: The World Health Organization considers bone densitometry (DXA) as the best technique for assessing Bone Mineral Density (BMD). DXA is used in clinical practice as the main diagnostic tool for osteoporosis and fracture risk, however, its perfomance may present errors that compromise not only its analysis and interpretation, but also decisions regarding the treatment of osteoporosis.Objective: Evaluate the frequency and types of erros present in the DXA.Materials and methods: It is a descriptive, observational and cross-sectional study with as quantitative approach and convenience sampling. In the analysis of the DXA exams, the demographic and antropometric data of the patients and the evaluation of the technical quality of the exams in lumbar spine and proximal femur were evaluated. DXA was categorized as adequate and inadequate due to poor patient positioning, poor image analysis and demographic errors.Results: Of the 246 DXA, 144 (62,6%) were adequate and 92 (37,4%) were iandequate. The lumbar spine presented inadequacies in 82 (33,4%) of the exams and the proximal femur in 72 (30,9%); inadequacies in the lumbar spine or in the proximal femur were found in 16 (6,5%) and 10 (4,0%), respectively. The most common inadequacies for lombar spine were non-centered and rectified lumbar spine and absence of vertebrae when necessary. Regarding the inadequacies found in the proximal femur densitometries, the patient`s poor positioning, poor overall hip delimitation and positioning of the region of interest in the femoral neck were observed as being more frequent. Conclusion: Of the 246 DXA, 37,4% present at least one error of poor patient positioning or poor analysis of the acquired image, this demonstrates that the orientations determined by the guidelines are not widely adopted, which may contribute to the implications for monitoring of bone mass and dignosis of osteoporosis.

SAT-0697

QCT of the femur: Comparison between QCTPro and MIAF Femur Ling Wang*[1], Oleg Museyko[2], Klaus Engelke[2], Keenan Brown[3], Xiaoguang Cheng[1]. [1]Department of Radiology, Beijing Jishuitan Hospital, China, [2]Institute of Medical Physics, University of Erlangen, Germany, [3]Mindways Software Inc., United States

Introduction QCT is commonly employed in research studies and clinical trials to measure BMD and structural parameters at the proximal femur. In this study we compared two analysis software options, CTXA and MIAF-Femur, using a semi-anthropometric femur phantom and in vivo data from Chinese elderly men and women.Methods CT scans of the European Proximal Femur Phantom (EPFP) and of the hip from 130 subjects aged 60-80 years were analyzed with QCTPro CTXA Hip and MIAF-Femur. Integral(Inte), cortical(Cort) and trabecular(Trab) vBMD, volume, and BMC of the femur neck (FN), trochanter (TR), inter-trochanter (IT), and total hip (TH) VOIs were compared. Accuracy was determined in the 5mm central portion of the femoral neck of the EPFP. Nominal values were: cross-sectional area (CSA) 4.9mm2, cortical thickness (C.Th) 2mm, CortBMD 723 mg/cm3 and TrabBMD 100 mg/cm3. In MIAF the so-called peeled trabecular VOI was analyzed which excludes subcortical bone to avoid partial volume artefacts at the endocortical border that artificially increase TrabBMD. For CTXA corrected and uncorrected (so called raw cortical values unaffected by corrections of cortical volume) data were analyzed.Results For QCTPro and MIAF phantom results were: CSA 5.9 mm2 versus 5.1 mm2; C.Th 1.68 mm versus 1.92 mm; CortBMD 578 mg/cm3 versus 569 mg/cm3; and TrabBMD 154 mg/cm3 versus 104 mg/cm3. In the human data correlations (R2) of integral and trabecular bone parameters ranged from 0.63 to 0.96. Bland–Altman analysis for TH and FN TrabBMD showed that lower mean values were associated with higher differences, which means that TrabBMD differences between MIAF and CTXA are larger for osteoporosis than for normal patients, which can be largely explained by the inclusion of subcortical BMD in the trabecular VOI with CTXA analysis. Correlations between QCTPro corrected CortBMD and MIAF were negative, whereas raw data correlated positively with MIAF measurements for all VOIs questioning the validity of the corrections.Conclusion The EPFP results demon-

strated higher MIAF accuracy of cortical thickness and TrabBMD. Integral and trabecular bone parameters were highly correlated between CTXA and MIAF. Partial volume artefacts at the endocortical border artificially increase trabecular BMD by CTXA, especially for osteoporosis patients. With respect to volumetric cortical measurements with QCTPro, it is recommended to use raw data, because corrected data cause a negative correlation with MIAF CortBMD.

SAT-0698

Comparison between laser scanning confocal microscopy and traditional light miocroscopy in forensic histo-osteology Lelia Watamaniuk*[1], Ashley Smith[2], Natalie Dion[3], Louis Georges Ste Marie[3]. [1]Department of Anthropology, McMaster University, Canada, [2]Department of Anthropology, University of Toronto, Canada, [3]CHUM- Centre Hospitalier de l'Universite de Montreal, Canada

Traditionally, in forensic histo-osteological analysis, light microscopy is utilized as the primary mode of study. Recent advances in other modalities such as scanning electron microscopy, back scatter electron microscopy, microcomputer tomography (micro CT), and synchrotron have allowed for addition avenues of histo-osteological research. The purpose of this presentation is to demonstrate the comparison between laser scanning confocal microscopy (LSCM) and traditional light microscopy, both polarized and non-polarized. This project examined variations in bone mineral visualization, and age estimation in three populations of human individuals: clinical patients (trans iliac biopsy sections; n=16), ancient remains (rib sections from 3-5th C A.D. Apollonia; n=20), and anatomical collection donors (femoral sections; n=5). The analyses were performed using two staining protocols for undecalcified bone specimens (basic fuchsin, and toluidine blue), and 5 microscopes: Carl Zeiss® LSM800 laser scanning confocal microscope, a Carl Zeiss® LSM880 laser scanning multi-photon microscope, and an LSM880 laser scanning spinning disk microscope, Keyence® VHX1000 Digital Light Microscope and an Nikon® Eclipse E200 Light Microscope with a Nikon® DSLR7000 camera. The results of this study found that the LSCMs all provided a better three-dimensional visualization of the bone microstructure using the basic fuchsin stain versus light microscopy, and provided better visualization of osteonal mineralization variance; the LSCM modality was not as practical in the age calculations. Results of this project demonstrate that laser scanning confocal microscopy is a good tool in bone mineral visualization and research.

SAT-0699

Machine Learned Features and Classifier for Automatic HR-pQCT Cortical and Trabecular Compartment Segmentation Bryce A Besler*[1], Nils D Forkert[2], Lauren A Burt[3], Steven K Boyd[3]. [1]Biomedical Engineering Graduate Program, Canada, [2]Hotchkiss Brain Institute, Canada, [3]McCaig Institute for Bone and Joint Health, Canada

Segmentation of the periosteal and endosteal surfaces are important for measuring clinical outcomes of bone health. Currently, a standardized algorithm is used for segmentation of the cortical and cancellous compartments in high resolution peripheral quantitative computed tomography (HR-pQCT). However, for poor quality bone, up to 50% of the segmentations need manual correction (internal data). This introduces rater variability and increases processing time. Using machine learning, a mathematical function can be trained to replace manual segmentation. Deep learning can be used to determine image features for classification. It is hypothesized that a machine can learn both the features and a classifier for periosteal and endosteal segmentation of HR-pQCT data.The radius and tibia of 155 healthy subjects were imaged using HR-pQCT (XtremeCT II, SCANCO Medical AG, Switzerland). Average age was 62.6 years and 45.8% were female. Age- and sex-matched Tt.BMD percentiles ranged from 0.1% to 99.9% with a mean of 53.5%. The manufacturer's standard algorithm was used to generate periosteal and endosteal segmentations. All 310 segmentations were reviewed and corrected by a human rater.A deep learning model was constructed to learn both features and a classifier for cortical and trabecular segmentation. The mathematical function maps from a 1.98 mm by 1.98 mm patch to a label of either background, cortical bone, or trabecular bone. 16 learned image features are extracted from each patch. A classifier maps from the 16 image features to a label for each voxel. The model was trained end-to-end using the corrected segmentations as ground truth. Post-processing was performed to remove the ulna/fibula.Qualitatively, the machine learned model was accurate at the periosteal surface but shrunk the endosteal surface (Figure). Average cortical and trabecular bone mineral density (Ct.BMD, Tb.BMD) were measured as outcomes. For the ground truth segmentation, Ct.BMD and Tb.BMD is 876.9 mg HA/ccm and 163.3 mg HA/ccm, respectively. For the machine learned segmentation, Ct.BMD and Tb.BMD is 856.7 mg HA/ccm and 150.5 mg HA/ccm, respectively. Average time to segment one HR-pQCT dataset was 62.1 seconds.A machine learned model for HR-pQCT segmentation is presented. The learned model shrinks the trabecular segmentation compared to the ground truth. The segmentations are rapid and comparable to manual segmentations.

Serum Estradiol, Follicle Stimulating Hormone and Sex Hormone Binding Globulin and the Risk of Fracture across the Menopausal Transition: Study of Women's Health Across the Nation (SWAN) Kristine Ruppert*[1], Jane Cauley[1], Yinjuan Lian[1], Joel Finkelstein[2], Carrie Karvonen-Gutierrez[3], Sioban Harlow[3], Joan Lo[4], Sherri Burnett-Bowie[2], Arun Karlamangla[5], Gail Greendale[5]. [1]University of Pittsburgh, United States, [2]Massachusetts General Hospital, United States, [3]University of Michigan, United States, [4]Kaiser Permanente Northern California Division of Research, United States, [5]University of California, United States

Sex steroid hormones have been linked to fractures in older women. It is unknown if hormones measured over the menopausal transition predict fractures. In SWAN, we studied 2960 women who had at least two repeat hormone measures and prospective information on fractures. Fasting serum was collected approximately annually for hormone assays on day 2-5 of the menstrual cycle when possible. Hormones were assayed at the SWAN Central Laboratory at the University of Michigan. Estradiol (E2) was measured with a modified immunoassay (Bayer Diagnostics Corp, Norwood MA) (inter- and intraassay Coefficient of variation(CV), 12% and 6%, respectively). Serum follicle stimulating hormone (FSH) (inter- and intraassay CV%, 10.6% and 6.4%, respectively) and sex hormone binding globulin (SHBG) (inter- and intraassay CV%, 9.9% and 6.1%, respectively) were measured with 2 site chemiluminometric immunoassays. Hormones were lagged (visit year -1) and transformed using log base 2 because they were not normally distributed. Incident fractures were ascertained at each annual visit and include high and low trauma fractures. Digit and facial fractures were excluded. The accuracy of self-report of fracture was determined by review of radiology reports. False positive rate was 4.6%. All medications including hormone therapy (HT) were time varying covariates. Discrete survival methods were used because information on incident fractures were identified only at annual interview. Data were censored after the first fracture. At baseline all women were pre- or early perimenopause with an average age of 46.4 (SD, 2.7) years. A total of 508 women experienced an incident fracture over an average follow-up of 8.8 (SD, 4.4). years. Women who experienced an incident fracture were more likely to be White, report high alcohol intake and diabetes and less likely to report premenopausal status at baseline. Each doubling of log E2 was associated with an 10% reduced risk of fracture independent of covariates and SHGB, (Table). The interaction between E2 and HT was not significant, p=0.45. In contrast, neither FSH or SHBG was associated with incident fractures. Serum E2 levels may help to identify women at higher risk of fractures over the menopausal transition. However, hormone assays must be standardized across laboratories for clinical implementation and further work is needed to define E2 thresholds.

Table: Relative Risk(RR) and 95%Confidence (CI) of Incident Fracture by doubling (Log base 2) of Estradiol, Follicle Stimulating Hormone(FSH) and Sex Hormone Binding Globulin(SHBG): SWAN

	Base Model[1]	MV Model[2]
Estradiol	0.92 (0.85, 0.996)	0.90 (0.82, 0.98)
FSH	0.99 (0.92, 1.10)	1.06 (0.95, 1.17)
SHBG	1.02 (0.92, 1.11)	1.04 (0.92, 1.18)

[1] Base Model adjusted for cycle day and time of blood draw, age, race and site.
[2]. Multivariable (MV) model adjusted for Base + corticosteroids, postmenopausal hormone therapy, selective estrogen receptor modulators, other osteoporosis medications e.g., bisphosphonates, smoking, alcohol, body mass index, vitamin D intake, physical activity and diabetes status. Estradiol and FSH models were also adjusted for SHBG.

Vertebral fractures cascade: potential etiologies and risk factors Helene Che*[1], Veronique Breuil[2], Bernard Cortet[3], Julien Paccou[3], Thierry Thomas[4], Laure Chapuis[5], Francoise Debiais[6], Nadia Mehsen Cetre[7], Rose Marie Javier[8], Sylvie Loiseau Peres[9], Christian Roux[10], Karine Briot[10]. [1]CHU Lapeyronie Montpellier, Rheumatology department, France, [2]CHU L'Archet Nice, Rheumatology department, France, [3]CHU Roger Salengro Lille, Rheumatology department, France, [4]CHU Nord Saint Etienne, Rheumatology department, France, [5]CH Simone Veil du Vitre, Rheumatology department, France, [6]CHU La Miletrie Poitiers, Rheumatology department, France, [7]CHU Pellegrin Bordeaux, Rheumatology department, France, [8]CHU Hautepierre Strasbourg, Rheumatology department, France, [9]CHR Orléans, Rheumatology department, France, [10]CHU Paris Cochin, Rheumatology department, France

Background Vertebral fracture (VF) is the most common osteoporotic fracture, and a strong risk factor of subsequent vertebral fracture. Prospective studies have shown that a recent VF increases an imminent risk of a subsequent one, and attention has been paid recently to a possible cascade phenomenon i.e. the occurrence of multiples VFs in less than one year. This cascade could have severe consequences, and we prompted a study to identify potential causes of osteoporosis and risk factors. Methods Vertebral fractures cascade (VFC) observations were collected retrospectively between January 2016 and April 2017. VFC was defined as the occurrence of at least 3 vertebral fractures within one year. Patients with other etiologies than osteoporosis (i.e. malignant or traumatic VFs) were excluded. The cause of osteoporosis associated with VFC was the one retained by the physician at the time of diagnosis. Results We collected in 10 centers, a total of 113 observations of VFC (79.6% of women, median age of 73). The median number of incident VF was 5. 40.5% and 30.9% patients had a previous major fracture and a previous VF respectively and 68.6% had densitometric osteoporosis (T-Score ≤ -2.5SD either at lumbar or femoral site). 18.9% patients currently received oral glucocorticoids at the time of VFC and 37.1% in the past. The main comorbidities were history of cancer (18.7%), chronic inflammatory diseases (29.7%) and diabete mellitus (7.2%). A secondary osteoporosis associated with the VFC was diagnosed in 52 patients: glucocorticoid-induced osteoporosis (25.7%), benign hemopathies (6.2%), alcoholism (4.4%), use of aromatase inhibitors (3.6%), primary hyperparathyroidism (2.7%) and hypercorticism (2.7%), anorexia nervosa (2.7%), pregnancy and lactation-associated osteoporosis (1.8%). Thirteen cases were reported following a vertebroplasty procedure. 31.5% patients previously received an anti-osteoporotic treatment. In 6 patients, VFC occurred early (in the year) following discontinuation of an anti-osteoporotic treatment: 5 after denosumab and one after an infusion of zoledronic acid. Conclusion The results of this retrospective study show that almost half of VFC occurred in patients with secondary osteoporosis. While they suggest that a careful management has to be given to these patients in order to prevent VFC in these circumstances, prospective studies are needed to further explore the determinants of such a severe complication of osteoporosis.

SAT-0751

Trabecular Bone Score in Healthy Adult Population of India: Chandigarh Urban Bone Epidemiological Study (CUBES) Abhilasha Garg*[1], Ruban Dhaliwal[2], Anshita Aggarwal[1], Rimesh Pal[1], Priyanka Singh[1], Niranjan Khandelwal[3], Naresh Sachdeva[1], Anil Bhansali[1], Sanjay Kumar Bhadada[1]. [1]Department of Endocrinology, Post Graduate Institute of Medical Education and Research, India, [2]Endocrinology, Diabetes and Metabolism, Department of Medicine, State University of New York Upstate Medical University, United States, [3]Department of Radiodiagnosis, Post Graduate Institute of Medical Education and Research, India

Purpose: Trabecular bone score (TBS), a textural analysis of the lumbar spine image, utilized complementary to dual energy x-ray absorptiometry (DXA) has been shown to assess bone quality and capture fracture risk. As bone mineral density (BMD) varies with ethnicity, TBS is also expected to vary. Indians have lower BMD than their Western counterparts. The aim of this study was to generate normative data on TBS in healthy Indian population. Methods: Study population included 764 healthy volunteers, ages 20-80 years, recruited from Chandigarh, India. Following comprehensive biochemical evaluation, BMD was assessed in all participants by DXA. TBS (L1-L4) was calculated utilizing TBS iNsight software in 310 participants.Results: Mean age of the study population (n=310) was 43.8 ± 12.5 years with 40.6% males and 59.3% females. Highest TBS was noted in both male and female subjects in the youngest decade (20-29 years), 1.297 ± 0.14 and 1.265 ± 0.15 respectively. TBS was higher in males compared to females at each decade. TBS decreased with age by 2-3 % per decade. Mean TBS in males aged >50 years (n= 39) was 1.159 ± 0.123 and in postmenopausal females (n=85) was 1.142 ± 0.015. Modest negative correlation was found between TBS and age (r = -0.375) and very weak negative correlation between TBS and vitamin D (r = -0.136). Significant positive correlation was found between BMD and TBS. Per TBS cut-offs proposed for western population, normal, partially degraded, and degraded micro-architecture was noted in 18.8%, 15.3% and 65.8% of postmenopausal females.Conclusion: Age and gender specific reference curves generated from this cohort can be used for osteoporosis management in India. Applying the western thresholds may lead to overestimation of fracture risk.

SAT-0752

Association between locomotive syndrome and bone mass, vertebral fractures and sarcopenia in the elderly aged 80 years and over. Jane Erika Frazao Okazaki*, Fernanda Martins Gazoni, Daniela Regina Brandao Tavares, Maria Carolyna Fonseca Batista Arbex, Lais Abreu Bastos, Flavia Kurebayashi Fonte, Maysa Seabra Cendoroglo, Fania Cristina Santos. UNIFESP, Brazil

Introduction: Musculoskeletal diseases, such as osteoarthritis and chronic pain, have been cited as causes of mobility loss and disabilities in the elderly. The Japanese Orthopedic Association (JOA) introduced the term Locomotive Syndrome (Slo) to refers to individuals who are at high risk of dependence due to disorders of the osteoarticular system. The evaluation of locomotor function can be performed using the GLFS-25 (25-Geriatric Locomotor Function Scale) developed by Seichi et al. This instrument was validated for portuguese language in Brazil by Tavares and named GLFS 25-P. Some japanese studies have shown association with osteoporosis, fractures and sarcopenia, but the relationship between bone health is not clear in the Brazilian population. Objective: Evaluate the association between Slo and bone density, sarcopenia, vertebral fractures and vitamin D levels. METHODS: This is an observational, analytical, cross-sectional study of locomotor syndrome in individuals aged 80 years or older, functional, and living at São Paulo. The data were collected from May 2016 to February 2017. We applied questionnaires related to Slo (GLFS 25-p), as well as anthropometric measurements. We accessed bone density and Baugartner index (IB) by densitometry of total body, and also vertebral fractures by thoracolumbar spine radiography and serum vitamin D values in the last year. The diagnosis of locomotive syndrome was defined as a score of 19 or more at the GLFS 25-P instrument. Results: Sample made by 102 elderly people with a mean age of 87.29 years, with a female majority (73.5%). Slo had a high prevalence in the study population (55%). It was observed that 18.3% of the participants have fracture; 47.9% were classified as osteoporotic; 51.7%, with sarcopenia and 5.3% VIT D 25OH below 20. There was no association between GLFS25-P and fracture (p = 0.272), Osteoporosis (p = 0.662) or Sarcopenia (p = 0.239). In addition, no differences in mean VITD 25OH (0.853) and IB (p = 0.805) were found comparing to the GLFS25-P. Conclusion: No associations were found between locomotor syndrome and osteoporosis, sarcopenia, vertebral fractures and vitamin D deficiency at this population.

SAT-0753

Involvement of lifestyle-related diseases in the development of fragility fracture of the proximal femur Takashi Iwakura*, Atsushi Sakurai, Satoru Sawamura. Awaji Medical Center, Japan

Purpose:Recently, the association between lifestyle-related diseases and osteoporosis/ fragility fracture has been investigated (1-3). The purpose of this study was to examine the involvement of lifestyle-related diseases in fracture of the proximal femur.Materials & methods:The subjects were 1,027 patients with fragility fracture of the proximal femur (229 males, 798 females) admitted to our hospital between 2013 and 2016. We retrospectively examined the patient background and incidences of lifestyle-related diseases using medical records. Hypertension (HT), dyslipidemia (DL), diabetes mellitus (DM), chronic kidney disease (CKD), and chronic obstructive pulmonary disease (COPD) were investigated as lifestyle-related diseases.Results:The mean age of the subjects was 85 years (male: 83 years, female: 86 years). Patients with lifestyle-related diseases accounted for 82% (male: 80%, female: 82%). The incidences of HT, DL, DM, CKD, and COPD were 63, 17, 18, 43, and 3%, respectively (male: 54, 11, 19, 36, and 8%, respectively, female: 65, 18, 17, 44, and 1%, respectively). The incidences of HT, DL, and CKD were significantly higher in the females. That of COPD was significantly higher in the males. We also examined the presence or absence of lifestyle-related diseases and age at the time of injury. In the DM group, the age was younger than in the non-DM group (82 years vs. 86 years). This tendency was more marked in the males (male: 78 years vs. 84 years, female: 83 years vs 86 years). Among both the males and females, the age at the time of fracture was even younger in DM patients receiving insulin (male: 71 years, female: 80 years).Discussions:Lifestyle-related diseases are associated with bone-quality reduction, and may increase the risk of non-bone-mineral-density-dependent fracture. In this study, most patients with fracture of the proximal femur had lifestyle-related diseases, and there were sex-related differences in their incidences. As an etiological factor for fragility fracture, the presence of lifestyle-related-disease-associated osteoporosis must be considered. Furthermore, the results showed that fracture of the proximal femur developed at a younger age in DM patients. It may be necessary to develop a more positive therapeutic intervention for osteoporosis in DM patients.Conclusion:Among patients with lifestyle-related diseases, fracture of the proximal femur develops at a younger age in those with DM.

Longitudinal change of bone quality according to serum adipokine levels in Korean adults: The KoGES- ARIRANG study Jung Soo Lim*[1], Tae-Hwa Go[2], Dae Ryong Kang[3], Sang Baek Koh[4]. [1]Department of Internal Medicine, Yonsei University Wonju College of Medicine, Republic of Korea, [2]Center of Biomedical Data Science, Yonsei University Wonju College of Medicine, Republic of Korea, [3]Institute of Genomic Cohort, Yonsei University Wonju College of Medicine, Republic of Korea, [4]Department of Preventive Medicine, Yonsei University Wonju College of Medicine, Republic of Korea

Fat is the biggest endocrine organ that releases various adipokines. Previous studies have shown that adipokines are involved in bone metabolism through direct or indirect effects. However, there is a paucity of data on prospective studies regarding the association between bone health and serum adipokines. The aim of the study was to investigate the effects of serum adipokine levels on longitudinal change of bone quality in Korean adults. A total of 1,874 adults aged 40–70 years assessed in the Korean Genomic Rural Cohort Study from 2005 to 2007 were examined and followed. We divided them into four groups based on sex, age, or menopausal status. The serum concentrations of leptin and adiponectin were measured by radioimmunoassay. In addition, bone status was assessed using the calcaneal quantitative ultrasound method; longitudinal change in bone parameters was evaluated using the values of baseline and follow-up. The average follow-up period was about 2.2 years. In women, logistic regression analysis showed that the change in bone stiffness index (BSI) was not significantly associated with both adiponectin and leptin levels. However, only in men aged over 50, there was a negative correlation between the change in BSI and serum adiponectin level, but not leptin, even after adjusting for confounding factors (coefficient = -0.27, p = 0.012). Our results suggest that adipokines may affect bone quality differently in Korean adults depending on their characteristics. Long-term clinical research would be needed to clarify the role of various adipokines in the development of osteoporosis.

Pain at Multiple Sites Is Associated with Prevalent and Incident Fractures in Older Adults: a 5.1-year Follow-up Study Feng Pan*[1], Jing Tian[1], Dawn Aitken[1], Flavia Cicuttini[2], Graeme Jones[1]. [1]Menzies Institute for Medical Research, University of Tasmania, Australia, [2]Department of Epidemiology and Preventive Medicine, Monash University Medical School, Australia

Purpose: Pain is common in older adults typically involving multiple sites. Pain at multiple sites has been shown to be associated with a number of adverse health outcomes; however, whether pain at multiple sites is associated with fractures, and whether this association is dependent on falls risk and/or bone mineral density (BMD) is unknown. This study aimed to describe the association between number of painful sites and fractures, and to explore whether pain at multiple sites is an independent marker for fractures.Methods: Data from a longitudinal population-based study of older adults (mean age 63 years, 51% female) were utilized with measurements at baseline (n=1086), 2.6 (n=875) and 5.1 years (n=768). Presence/absence of pain at the neck, back, hands, shoulders, hips, knees and feet was assessed by questionnaire at baseline. Fractures were self-reported at each time-point. BMD was measured by Dual-energy X-ray absorptiometry (DXA). Baseline demographic, lifestyle, and falls risk assessment were also obtained.Results: A total of 385 fractures were reported at the three time-points and 86 incident fractures were observed over 5.1 years. Greater number of painful sites was associated with higher fracture prevalence at any site, and fractures occurring at the vertebral, non-vertebral and major sites (including the femur, radius, ulnar, vertebrae, rib and humerus) in univariate and multivariable analyses with adjustment for age, sex, body mass index, smoking history, physical activity, pain medication, BMD and falls risk. There was a dose-response relationship between number of painful sites and fracture prevalence at these sites (all P for trend <0.05). In addition, there was a dose-response relationship between number of painful sites and the risk of incident fractures occurring at any sites (relative risk (RR) 1.4, 95% CI 1.1-1.8) and major sites (RR 1.9, 95% CI 1.2-2.9) over 5.1 years after adjustment for confounders. No significant association between number of painful sites and prevalent and incident hip fractures was observed possibly due to the small sample size (7 prevalent and 3 incident hip fractures).Conclusions: Pain at multiple sites is associated with a higher risk of prevalent and incident fractures, which is independent of falls risk and BMD, suggesting that widespread pain may be an independent marker of higher fracture risk.

SAT-0757

Vitamin D Insufficiency and Elevated Vitamin D Metabolite Ratios (VMR) are Associated with Increased Risk of Injuries: Results from the British Army Lower Limb Injury Prevention (ALLIP) Study Jonathan Tang*[1], Sarah Jackson[2], Rachel Izard[3], Samuel Oliver[4], Isabelle Piec[1], Christopher Washbourne[1], Neil Walsh[5], Julie Greeves[2], William Fraser[1]. [1]University of East Anglia, United Kingdom, [2]Army Personnel and Research Capability, United Kingdom, [3]Army Recruiting and Training Division, United Kingdom, [4]University of Bangor, United Kingdom, [5]Bangor University, United Kingdom

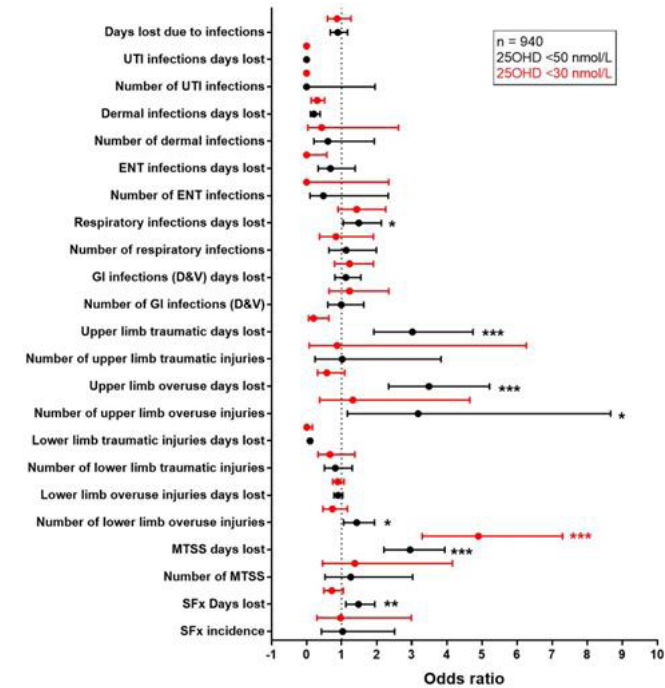
IntroductionUp to 20.4% of British Army recruits suffer from musculoskeletal injuries (MSI) during initial training. Up to 10% suffer skeletal stress fracture (SFx) resulting in lost training days and medical attrition, which is a significant financial cost to the Army. There is evidence to suggest that vitamin D deficiency is prevalent in the army. Our aim was to determine baseline vitamin D status in recruits upon starting training and the relationships between vitamin D metabolites (VDM) and health outcomes after a 14-week training programme.Methods2252 healthy new army recruits, mean (range) age 21.7(18-32)yrs participated in this prospective, observational study (ClinicalTrials.gov ID: NCT02416895). After exclusion of those who took calcium/vitamin D supplements, and those with prior injuries, 940 individuals were included in the analysis. Serum concentrations of 25OHD and 24,25(OH)2D(LC-MS/MS), 1,25(OH)2D(DiaSorin) and PTH(Roche) were among a panel of analytes tested across all seasons. The co-primary endpoints were subject incidence of SFx, MSI, infections and days lost in rehabilitation (DLR) in relation to VDM. Secondary outcomes were BMD and seasonal variations in analytes.Results38% of participants identified as vitamin D insufficient (25OHD<50nmol/L) at baseline had an increased risk (OR) of SFx (1.03), medial tibial stress syndrome (MTSS) (1.26), upper limb trauma (1.02) and respiratory infections (1.13), and highly significant risk of upper limb overuse injuries (3.18) and subsequent DLR (3.49). Mean 24,25(OH)2D was 9.5-fold lower than 25OHD, and 25OHD:24,25(OH)2D VMR was significantly increased at 25OHD<50nmol/L (p<0.001). There was no significant relationship between 1,25(OH)2D and 25OHD, whereas the distribution of 1,25(OH)2D:24,25(OH)2D VMR showed an exponential negative correlation with 25OHD (y = 1525.8x-0.983, r2Exp = 0.582, p<0.001). Using this model, we found that subjects with high 1,25(OH)2D:24,25(OH)2D VMR and low 25OHD have significantly higher PTH mean(SEM) 4.9(0.5) pmol/L, p>0.001 than those at the opposite end of the spectrum (PTH 3.0(0.3) pmol/L). Cosinor-fit curves revealed circannual rhythm on all VDM and VMR except for 1,25(OH)2D. PTH exhibited a low amplitude, circasemiannual rhythm. Baseline BMD was not associated with any health outcomes.ConclusionVitamin D insufficiency is strongly associated with training-related injuries and lengthened rehabilitation. By using VMR model we demonstrated possible underlying mechanisms preceding the accelerated injury.


Figure showing the risk of vitamin D insufficiency and deficiency with training-related injuries and health outcomes. *Denotes *(p<0.05),**(p<0.01),***(p<0.001)

SAT-0758

Greater Bone Marrow Adiposity Predicts Loss of Spine Compressive Strength and Trabecular Bone in Postmenopausal Women from the AGES-Reykjavik Study Gina Woods*[1], Susan Ewing[2], Deborah Kado[1], Trisha Hue[3], Sigurdur Sigurdsson[4], Gudny Eiriksdottir[4], Vilmundur Gudnason[4], Eric Vittinghoff[2], Thomas Lang[2], Tamara Harris[5], Clifford Rosen[6], Kaipin Xu[7], Xiaojuan Li[7], Ann Schwartz[2]. [1]Department of Medicine, UCSD, United States, [2]Department of Epidemiology, UCSF, United States, [3]Department of Epidemiology and Biostatistics, UCSF, United States, [4]Icelandic Heart Association, Iceland, [5]National Institute on Aging, United States, [6]Maine Medical Center Research Institute, United States, [7]Program of Advanced Musculoskeletal Imaging, Cleveland Clinic, United States

Greater bone marrow adipose tissue (BMAT) is associated with lower bone mineral density (BMD) and prevalent vertebral fractures in older adults, but it is uncertain whether or not greater BMAT predicts bone loss over time. If greater BMAT leads to bone loss, then targeting BMAT to prevent osteoporosis may have therapeutic potential. One previous study in 120 postmenopausal women reported that those with greater femoral neck BMAT had a non-significant trend toward femoral neck BMD loss, measured by DXA, at 4 years (r = -0.23, p= 0.14). The purpose of this study is to evaluate the associations between baseline vertebral BMAT and change in measures of bone density and strength in older adults from the Age, Gene/Environment Susceptibility (AGES) - Reykjavik study. A total of 364 participants had concurrent baseline measurements of BMAT and BMD/bone strength, and repeat BMD/bone strength measurements after a mean follow-up of 3.1 (SD 1.5) years. Those with missing BMAT measurements (n=1) and those using medications known to affect BMAT and BMD (n=65) were excluded, leaving 150 men and 148 women in the analytic sample. Mean (L1-4) BMAT (ratio of fat to water + fat, %) was measured by 1.5-T 1H magnetic resonance spectroscopy. BMD was measured by QCT and DXA of the hip and spine, and bone strength by QCT of the spine. Participants were a mean age of 81.8 (SD 4.3) years, had a mean BMI of 27.2 (SD 4.0) kg/m2, a mean (L1-4) BMAT of 54.7 (SD 8.1)%, 9.7% had diabetes, and 19.5% had prevalent vertebral fractures. During an average of 3.0 years of follow-up, participants experienced statistically significant loss of trabecular bone at the spine (-7.3%, p<0.0001) and total hip (-9.5%, p<0.0001), but not cortical bone. Greater baseline BMAT was associated with loss of spine compressive strength (r= -0.26; p=0.001) and trabecular bone loss at the spine (r= -0.18, p= 0.03) and femoral neck (r= -0.19, p= 0.03), in women but not men (Table). The reason for this gender difference is unclear. No associations between baseline BMAT and cortical bone loss were observed. Further studies are needed to investigate whether BMAT predicts incident fractures in older adults.

Table: Pearson Correlation between baseline BMAT and change in BMD/bone strength, by gender	Men (n=150)		Women (n=148)	
	r	p	r	p

Meta-analysis of Lithium use on the Risk of Fracture in Epidemiological Studies Qing Wu*[1], Bowen Liu[1], Shu Zhang[1]. [1]University of Nevada, Las Vegas, United States

Research findings regarding the association between lithium medication and risk of fracture are inconsistent. No related meta-analysis has been reported in the literature. Therefore, we conducted the first meta-analysis to examine the effect of lithium treatment on the risk of fracture. We performed an electronic search of Medline, Web of Science and Embase through February 1, 2018, and manual search of related references and review articles. Two researchers independently conducted study selection, study appraisal, and data abstraction via Research Electronic Data Capture tool. The disagreement was resolved by consensus. Confounder-adjusted risk ratios were pooled using a random-effects model. Each study was weighted by the reciprocal of its variance. Cochrane's Q and Higgins index I2 were used to examine heterogeneity. Study quality was appraised by using the Newcastle-Ottawa Scale. We also performed several pre-specified sensitivity analysis and subgroup analyses to determine if fracture risk associated with lithium use was influenced by duration of follow-up, sex, demographic region, the sample size of the study, and controlling important confounders. Five studies including 1,130,689 subjects were eligible for the meta-analysis. The Newcastle-Ottawa study quality scores ranged from 7 to 9. The overall pooled estimate

suggests that the use of lithium is associated with 20% decrease in fracture risk (RR = 0.80, 95% CI, 0.73-0.87, p<0.01). Cochrane's Q test (p = 0.61) and Higgin index (I2 = 0) indicated that no heterogeneity was observed among the included original reports. The funnel plot and Egger's test (p=0.63) indicated that no published bias was observed. The reduced fracture risk associated with lithium medication was consistent in sensitivity analyses with different inclusion criteria, and in the subgroup analyses. Therefore, our meta-analysis results suggested that lithium use is associated with a significantly decreased risk of fracture.

HIP Mobile: A community-based Monitoring, Rehabilitation and Learning e-system for patients following a Hip Fracture Ahmed Abou-Sharkh*[1], Nancy E. Mayo[1], Michelle Wall[1], Anthony Albers[2], Stephane Bergeron[3], Sonia Jean[4], Pierre Berube[5], Edward J. Harvey[1], Suzanne N. Morin[1]. [1]Research Institute of McGill University Health Center, Canada, [2]St-Mary's Hospital, Canada, [3]Jewish General hospital, Canada, [4]Institut national de sante publique du Quebec, Canada, [5]Greybox Solutions, Canada

PURPOSE: Following a hip fracture, most patients do not return to pre-fracture autonomy level. e-Health solutions incorporated within homecare rehabilitation may lead to better clinical outcomes and health-related quality of life (HRQoL). Our objective is to enable recovery and improve HRQoL following a hip fracture through the implementation of the HIP Mobile e-Monitoring and Coaching system.METHODS: HIP Mobile comprises a wearable smart insole with a tablet based app interface including an exercise program and a secure cloud based remote monitoring dashboard. Expert educational content, exercise-tracking algorithms and patient-oriented interface have been validated. A pragmatic randomized trial to determine the effectiveness of a 4-month HIP Mobile program compared to printed educational material on mobility and patient reported outcomes in men and women ≥60 y, introduced 6 weeks after hip fracture repair was initiated. The primary outcome is functional mobility measured by gait speed and 30 second sit-to-stand measured at 6-months post-fracture. Baseline results from the recruited participants are presented.RESULTS: We have recruited 12 participants with average age 78 (SD 11) y, 50% women, within an average of 75 (SD 27) days post fracture repair. One third of participants had experienced a prior fracture; yet only 2 participants were on anti-osteoporosis medication. Median gait speed (0.9; IQR 0.69- 0.95 m/sec), median 30 second sit-to-stand (10; IQR 5-12) and mean grip strength (24; SD 9 kg) and were similar normative values for community dwelling older adults. Despite this, participants voiced serious concerns in 8 areas of HRQoL affected by their hip fracture, using the Patient Generated Index, an individualized measure of HRQoL. The most frequently mentioned areas of concern were walking and mobility (26%), endurance (16%) and fatigue (16%). The top-ranking concern at baseline was walking and mobility. (Table) Of interest, no participants mentioned pain as a concern.CONCLUSIONS: Despite gait speed and sit-stand metrics being similar to normative values 10-weeks post-fracture, the top-ranking concerns identified by these elderly participants were related to functional mobility, suggesting they had not yet returned to their pre-fracture autonomy and mobility levels. Our interactive HIP Mobile encourages active engagement in the rehabilitation process and has potential to improve functional mobility over an extended period.

Table: Baseline Patient Generated Index (PGI) Results

PGI areas reported by participants*	Participants Reported areas of concern+ N=12	Top ranking areas of concern N=12
Mobility/walking	10	4
Endurance/strength	5	2
Fatigue	4	2
Social Activities	4	3
Independence	3	1

Time trends among new users of osteoporosis drugs over 20 years: considerations for pharmacoepidemiologic study design Kaleen Hayes*[1], Joann Ban[1], Grace Athanasiadis[1], Andrea Burden[2], Suzanne Cadarette[1]. [1]University of Toronto, Canada, [2]ETH Zurich, Switzerland

Background: Oral bisphosphonates entered the market in 1996 and are the main osteoporosis drugs prescribed in Canada. Introduction of new therapeutic options, updates to practice guidelines, and healthcare policy changes may make studies examining new-users of bisphosphonates susceptible to time-varying biases.Objective: To compare characteristics of first-time bisphosphonate users in Ontario, Canada over time.Methods: The Ontario Drug Benefit (ODB) program covers prescription drugs listed on the ODB formulary for residents aged 65 or more years. We identified first dispensation of an oral bisphosphonate (alendronate [10 and 70 mg], etidronate [400 mg and 500 mg calcium], and risedronate [5, 35, and 150 mg]) among residents of Ontario, from 1996/04 to 2015/03. We excluded patients taking other osteoporosis drugs, with health conditions known to impact bone, and residents of long-term care facilities. We also excluded patients aged younger than 66 years to ensure at least one year of drug plan eligibility. Medical and pharmacy claims within the year prior to first bisphosphonate dispensation were used to characterize patients. Descriptive statistics were used to summarize and compare patient characteristics by fiscal year.Results: We identified 523,210 eligible seniors starting bisphosphonate therapy in Ontario from 1996 to 2015 (mean age 75 years; 5.0% rural). A larger proportion of men (6.2% to 29.0%) and diabetics (8.7% to 17.8%) initiated therapy over time. History of benzodiazepines decreased (26.6% to 11.5%), while prior statin use (9.5% to 42.8%), oral corticosteroid use (10.6% to 14.7%), and prior bone mineral density testing (46.7% to 68.0%) increased. A shift in prescriptions from etidronate to alendronate and risedronate was documented, consistent with drug policy changes.Conclusions: Characteristics of new initiators of oral bisphosphonates among Ontario seniors changed over time, reflecting changes in healthcare delivery and osteoporosis management. Consideration must be given to time-trends when designing pharmacoepidemiologic studies in this population, including those using interrupted time series analysis, matching, propensity scores, or self-controlled designs.

SAT-0809

Reasons for not-attending the FLS: a survey among non-attenders based on home visits and questionnaires Peter Van Den Berg*[1], Dave Schweitzer[1], Paul Van Haard[1], Joop Van Den Bergh[2], Piet Geusens[3]. [1]Reinier de Graaf Gasthuis, Netherlands, [2]Maastricht University Medical Center, VieCuri Medical Centre Noord-Limburg, Netherlands, [3]Maastricht University Medical Center, Hasselt University, Netherlands

IntroductionDeveloping an effective strategy to improve Fracture Liaison Service (FLS) attendance is a challenge. To elicit reasons for non-attendance, we visited non-attenders at home and conducted structured interviews.Patients and MethodsWe analyzed 357 patients >50 yr. with a clinical fracture that had visited the Emergency Department between August 1 and December 1 2017. After exclusion of 5 patients (1%) who had died and 83 patients (24%) because of permanent institutionalization or osteoporotic treatments already given by other hospital specialists, 269 patients were invited to the FLS. In case of no response within 12 weeks, patients were requested by telephone to consent to a home visit and/or to complete a single questionnaire. Questions concerned demographics, such as age, gender and a composite score of frailty-related issues, as well as patients` perceptions regarding instructions to attend the FLS (extrinsic motivation) and patients' ideas and opinions about fracture prevention (intrinsic motivation).ResultsOf the 269 patients invited to the FLS, 133 (49%) actually attended the FLS. Of the remaining patients, 136 (51%) did not reply to our FLS invitation (non-responders). Of these 136 non-responders, 99 could be reached by telephone. Of these, 42 patients (43%) consented to be visited at home (HV), while 24 patients (24%) agreed to complete a questionnaire but did not give permission for a home visit (Q), and 33 patients (33%) did not want any contact. Outcome results of the whole group (HV and Q) were analyzed. In the perception of the majority of HV and Q patients, no information had been provided about the necessity to attend the FLS, neither from the physician (86%) nor from the plaster nurse (94%). In 100% of patients, lack of intrinsic motivation was due to the conviction that the fracture was mainly caused by trauma and/or fall and to a lack of awareness of potential fragile bones. Moreover, 39 patients (59%) explicitly reported not to be interested in their bone health. We found 2 associations between non-attenders (HV+Q) and medical reasons hearing loss (OR 0.12; p<0.01) and vertigo (OR 0.13; p<0.01). ConclusionThis is the first FLS-initiated survey with home visits focusing on patients who did not respond to our invitation to attend the FLS. Perceived lack of patient information is an important focus of concern (lack of extrinsic motivation). Notably, all non-responders reported lack of intrinsic motivations to attend, and hearing loss and vertigo was associated with non-attendance.

Saturday Posters

Non-attenders	Total (HV+Q)	HV	Q	No consent
N=136	66 (100%)	42 (100%)	24 (100%)	33 (100%)
Male	19 (29%)	6 (14%)	13 (54%)	9 (27%)
Female	47 (71%)	36 (86%)	11 (46%)	24 (73%)

Improvement in the primary and secondary prevention of osteoporosis by a Fracture Liaison Service: feedback from a single French center care pathway Arthur Vrignaud*, Simon Pelletier, Emmanuelle Dernis, Yvon Moui, Bénédicte Haettich. Le Mans General Hospital, France

Background: Osteoporosis is a major public health concern, causing significant morbidity and mortality. Care pathways, called Fracture Liaison Services, have demonstrated their utility in preventing osteoporosis-associated morbidity and mortality. The aim of this study was to analyze the activity of one such care pathway.Methods: This was a retrospective, observational, cohort study, in which 272 patients who had fragility fractures between January 2012 and December 2016 were included. Screening of the medical records and data analyses were performed to characterize the population and the medical care received related to osteoporosis, and to compare these data with those of another study carried out from January 2010 to January 2011 on 54 patients in the same Fracture Liaison Service. Results: There was no statistically significant difference between the two cohorts concerning their demographic characteristics, with 92.3% women and a mean age of 68.7 in our cohort. Secondary prevention was improved, as shown by a reduction in the number of vertebral fractures detected by systematic assessment and fewer low-energy fractures. This study also demonstrated a decline in the percentage of patients with a first-degree parental history of hip fracture and a trend towards a decline in the rate of those having vitamin D insufficiency. Conclusion: Communication with patients and healthcare professionals through the Fracture Liaison Service was beneficial for patients in terms of fracture prevention. This study supports the development of similar care pathways in other healthcare institutions.

Response of Common Genetic variants of Vitamin D Binding Protein (DBP) to vitamin D supplementation in Saudi adults Nasser Al-Daghri*. King Saud University, Saudi Arabia

Background: Genetic variations in vitamin D binding protein (DBP) gene are known to affect 25(OH)D levels in various population. However, the influence of these genetic variants on 25(OH)D levels in Saudi population is never been studied. The study aimed to determine the influence of DBP gene polymorphisms in vitamin D metabolites before and after

vitamin D supplementation. Methodology: A total of 235 Saudi adults were recruited, out of which 146 participants with vitamin D deficiency (25(OH)D <50nmol/l) were given 2000IU daily dose of vitamin D supplement for 12 months. Serum 25(OH)D, DBP levels were measured after year of supplementation. Two common single nucleotide polymorphisms (rs4588 and rs7041) DBP were assessed using TaqMan genotyping system. Results: Serum 25(OH)D (nmol/l) levels increased significantly post-supplementation [34.1 (24.0-46.8) to 55.3 (40.4-73.8); p<0.001] along with free 25(OH)D (nmol/l) [21.5 (11.7-33.2) to 31.6 (13.7-50.9); p<0.001] and bio available 25(OH)D (nmol/l) [17.0 (9.2-28.5) to 26.6 (11.7-42.1); p<0.001]. No significant change was observed in vitamin D binding protein, as well as in other factors including lipid profile after supplementation. Post supplementation median 25(OH)D was significantly higher [61.2 (46.3-76.8) and 66.6 (53.2-83.7)] in patients with CC genotype of rs4588 and GG genotype of rs7041 respectively than other genotypes. The increase in DBP was found in 94.4% from baseline only patients carrying TT genotype than other genotypes of both SNPs but this change was not statistically significant (p=0.069).Conclusion: The rs7041 and rs4588 variants in DBP are associated with baseline 25(OH)D levels and modifies 25(OH)D response after vitamin D supplementation Saudi adults.

SAT-0831

Female recruits with the lowest baseline bone strength have the greatest increases in bone strength following 8 weeks of U.S. Army Basic Combat Training Katelyn Guerriere*[1], Julie Hughes[1], Erin Gaffney-Stomberg[1], Kathryn Taylor[1], Kristin Popp[2], Chun Xu[3], Ginu Unninkrishnan[3], Mary Bouxsein[2], Jaques Reifman[3]. [1]USARIEM, United States, [2]MGH, United States, [3]BHSAI, United States

Mechanical loading has been demonstrated in animal studies to induce bone adaptations that result in increased bone strength. U.S. Army Basic Combat Training (BCT) is a period of unaccustomed physical activity at the beginning of military service when recruits are at high risk of skeletal stress fractures. Prior studies report variability in bone strength among Army recruits, with some recruits entering BCT with relatively weak bones and others with more robust bones. We hypothesized that recruits with the weakest bones at the beginning of BCT would experience relatively greater mechanical stimuli compared to recruits with stronger bones, and therefore, mount the greatest adaptive response as defined by change in bone strength. Accordingly, the purpose of this study was to determine if estimates of baseline bone strength influenced changes in bone strength following 8 weeks of BCT. Ninety one female BCT recruits (age = 21.5±3.3 yrs) completed the study. Failure load (F.ult), an index of bone strength, was estimated with finite element analysis (Scanco Medical FE software version 1.13) derived from high-resolution pQCT (XtremeCT II, Scanco Medical) scans of the distal tibia (4% of tibial length) obtained at the beginning and end of BCT. To evaluate the effects of baseline F.ult, we used a generalized additive model with naturalized spline with 3 degrees of freedom applied to baseline values of F.ult. We adjusted for age, race, and BMI prior to BCT. The relationship between baseline F.ult and change in F.ult was significantly nonlinear (p = 0.017; Figure 1). Individuals in the bottom 10% of baseline F.ult had the greatest change in F.ult (~+7%), whereas no significant changes in F.ult were detected in recruits with the highest F.ult at baseline. These results suggest that female recruits with the weakest bones at entrance to BCT will mount the greatest increases in bone anabolism during initial military training.

SAT-0832

Effect of high impact exercise on femoral neck bone mineral density and T2 relaxation times of articular cartilage in postmenopausal women Chris Hartley*[1], Robert Kerslake[2], Jonathan Folland[1], Katherine Brooke-Wavell[1]. [1]NCSEM, School of Sports and Exercise Science, Loughborough University, United Kingdom, [2]Nottingham University Hospital NHS Trust, United Kingdom

Unilateral, high impact exercise has been found to increase femoral neck bone mineral density (BMD) in older men and premenopausal women. Postmenopausal women are at increased risk of osteoporotic fracture and could benefit from an intervention to increase BMD but may be reluctant to participate in high impact exercise due to concern about knee joint damage. The aim of the current study was to evaluate the effects of high-impact exercise on femoral neck BMD and knee articular cartilage properties in postmenopausal women. Postmenopausal women were recruited into a six-month, unilateral exercise intervention. This progressed to 50 multidirectional hops each day, using a randomly assigned exercise leg for comparison with the contralateral control leg. Dual energy X-ray absorptiometry provided information on the BMD of both femurs. Coronal T2 maps using a 3.0T MRI scanner provided T2 relaxation times of knee articular cartilage in 12 regions of interest (ROIs) from a single slice in the weight bearing region. Scans were taken of both legs, pre and post intervention. Repeated measures ANOVA were carried out to analyse effects of leg, time and interaction.To date, 29 of the 43 participants have completed the study (age 61.1 ± 4.4 years; BMI 24. ± 3.7 kg/m2). Of these, 4 participants withdrew due to exercise related injury or discomfort (knee pain that resolved upon cessation of exercise [n=3], Achilles tendonitis [n=1]), 2 due to other injury or illness and 2 were lost to follow up. Femoral neck BMD increased by 0.73% in the exercise leg and decreased by 0.74% in the control leg, but this difference between legs did not reach statistical significance (P=0.067). There were no significant exercise effects on T2 relaxation times of knee cartilage (0.97>P>0.18): across the 12 ROIs changes ranged from -3.2 to 2.7% in the exercise leg and -6.1 to 4.6% in the control leg.The intervention was feasible but the incidence of withdrawal due to exercise related injury or discomfort suggests that modification may be desirable for postmenopausal women. That there were no significant changes in T2 relaxation times in healthy women agrees with previous research, in women with mild osteoarthritis, that high impact exercise does not adversely affect knee articular cartilage. Although not statistically significant, this brief, high impact exercise had similar net effects on femoral neck BMD in postmenopausal women (1.5%) as reported in a group of 35 older men (1.6%).

SAT-0833

Association of trabecular bone score and bone density with actigraphy-measured physical activity in NHANES 2005-2006 Rajesh Jain*[1], Meltem Zeytinoglu[2], Tamara Vokes[2]. [1]Lewis Katz School of Medicine at Temple University, United States, [2]University of Chicago Medicine, United States

Background: Physical activity is generally associated with good bone health and lower fracture rates. It is not clear whether this beneficial effect is due to higher bone mass or better bone structure. Recently, the trabecular bone score (TBS), a textural analysis of the lumbar spine DXA image that correlates with measures of bone microarchitecture, has been developed. In this study we examined the association between objectively measured physical activity with BMD (as a measure of bone mass) and with TBS (as a measure of bone structure). We also investigated whether the association depends on the type or intensity of activity. Methods: This is a study of NHANES 2005-2006 data. Subjects over age 20 and with BMI 15-37 were analyzed, as that is the working BMI range for TBS. Women were stratified by menopausal status. Individual physical activities were obtained by questionnaire and grouped by the 2011 Compendium of Physical Activities. Included subjects were asked to wear physical activity monitors (Actigraph 7164) for 7 days. Only subjects with at least 4 days of at least ≥10 hours of wear time were included. All analyses were done using survey weights and controlled for age, BMI, and race.Results: Among 493 postmenopausal women, those in the top half of actigraphy-measured moderate to vigorous physical activity (MVPA) had higher TBS (0.029 ± 0.011, 0.19 standard deviations (SD), p=0.02), and total hip T-score (0.30 ± 0.12, p=0.02), but not femoral neck or spine T-score. No specific activity was associated with TBS or T-score when controlling for MVPA. Among 388 pre-menopausal women, neither MVPA, nor specific activities were associated with TBS or T-scores. Among 1,126 men, men in the top half of MVPA had higher TBS (0.021 ± 0.006, 0.14 SDs, p=0.006), total hip T-score (0.28 ± 0.09, p=0.009), and femoral neck T-score (0.25 ± 0.10, p=0.03), but not spine T-score. Walking was associated with greater TBS (0.014 ± 0.006, 0.09 SDs, p=0.04), while running/jogging and sports activities were associated with higher T-scores at all sites (range 0.28-0.52, p<0.05) even when controlling for MVPA. Conclusion: Actigraphy-measured physical activity was associated with higher TBS and BMD at hip sites. While intensity of activity had a clear association with bone outcomes, the association with activity types was less striking when controlling for intensity. This suggests that activity intensity may be more important than the type of activity.

SAT-0834

Dairy Intake and Its Associations with Bone Mineral Density and Trabecular Bone Score in the VITamin D and OmegA-3 TriaL (VITAL) Meryl Leboff*[1,2], Catherine Donlon[1], Nancy Cook[2,3,4], Sharon Chou[1,2], Julie Buring[2,3,4], Joann Manson[2,3,4]. [1]Division of Endocrinology, Diabetes and Hypertension, Brigham and Women's Hospital, United States, [2]Harvard Medical School, United States, [3]Department of Epidemiology, Harvard T.H. Chan School of Public Health, United States, [4]Division of Preventive Medicine, Brigham and Women's Hospital

Higher intakes of dairy products have been associated with greater lumbar spine bone mineral density (BMD) in adults taking vitamin D supplements.1 Therefore, dairy intakes may have beneficial effects on bone. In this study, we investigated whether there were similar associations in the VITamin D and OmegA-3 TriaL (VITAL) between dairy intake (servings/week of milk, cream, cheese, or yogurt, individually and combined) and BMD at the spine, femoral neck, total hip, and whole body. Additionally, we assessed whether dairy intake was associated with Trabecular Bone Score (TBS), a structural measure of bone.VITAL is a 2X2 factorial randomized controlled trial (RCT) investigating whether a median of 5-years of supplemental cholecalciferol (2000 IU/day) and/or omega (ω)-3 fatty acids (1 g/d) in 25,874 US men ≥50 years and women ≥55 years is of benefit in the primary prevention of cancer and cardiovascular disease. In-person assessments were completed at baseline and 2-years post-randomization in a subcohort of 771 participants (46.8% women, 53.2% men) in the VITAL: Effects on Bone Structure and Architecture ancillary study.2,3 A detailed food frequency questionnaire was used to collect dairy and vitamin/mineral supplement intakes at baseline, and BMD was determined by dual-energy X-ray absorptiometry (Discovery W; APEX Version 4.2, Hologic, Bedford, MA). TBS was derived from the lumbar spine DXA images (Medimaps Version 2.1, Geneva, Switzerland). The statistical analyses below were adjusted for age, race, sex, and BMI.At baseline, participants had a mean age of 63.79 ± 6.13 years and a mean of 11.17±0.57 servings of milk, yogurt and cheese per week (Table 1). There were no significant associations at baseline between combined or separate dairy intakes and BMD at the spine, femoral neck, total hip or whole body or TBS. Analyses on the effects of dairy intakes on two-year changes in bone health outcomes are in progress and will be assessed. The RCT design of VITAL will evaluate, without bias, whether baseline intakes of dairy products modify effects of supplemental vitamin D on bone density and other structural measures.References: 1. SAT-0835

Vitamin D status and its associated factors in Taiwanese healthy adults Yi-Chin Lin*, Yi-Wen Cheng. Deparement of Nutrition, Chung Shan Medical University, Taiwan

Vitamin D plays critical roles in maintaining serum calcium and phosphorus balance. According to the results of the Nutrition and Health Survey in Taiwan (NAHSIT) 2005-2008, there is more than 66% of the Taiwanese adults are deficient in vitamin D. The purposes of the current study were to explore the vitamin D status and its associated factors in Taiwanese adults. The current cross-sectional study was conducted between February and August in 2017, and a total of 60 healthy subjects aged 20-50 years were recruited in Taichung, which is the metropolis of central Taiwan. Structural questionnaires were administered to obtain data of lifestyle information and dietary intake, and a sun exposure score was generated according to the frequency and body parts exposing to sun. Skin melanins at inner and outer forearm as well as forehead were measured by a multiprobe mexameter. Body composition, including bone measurements were measured by a dual-energy x-ray absorptiometry. The venous blood samples were collected and the serum levels of 25(OH)D and PTH were measured by RIA method. The prevalence rates of vitamin D deficiency

and insufficiency were 30.33% and 34.88%, respectively. Age was significantly correlated with serum level of 25(OH)D in both genders. In men, weight, waist-circumference, waist-hip ratio were each significantly correlated with serum level of 25(OH)D. The average skin melanin index at outer forearm was significantly correlated with serum level of 25(OH)D in females. Male's serum level of phosphorus and female's serum level of calcium were significantly correlated with serum level of 25(OH)D, respectively. Positive correlations were also observed between the intake of codfish, mushroom, and golden mushroom and the level of serum 25(OH)D in females.. There was also a positive correlation between the amount of diary products consumption and serum level of 25(OH)D in males. In addition, comparing to the group of vitamin D deficiency [25(OH)D < 20 ng/mL], those who were sufficient in vitamin D had higher serum level of calcium, and higher intake of salmon as well. In conclusion, there is positive correlation between women's average skin melanin index at outer forearm and serum level of 25(OH)D . For young female adults, exposure to sunlight before 10 am and after 2 pm at least twice weekly should be encouraged to improve and/or maintain optimal vitamin D status.

Bilirubin promotes down-regulation of RUNX2 and up-regulation of RANKL gene expression in bone explants and in osteoblastic and osteocytic cell lines Silvia Ruiz-Gaspà*, Albert Parés, Andrés Combalia, Pilar Peris, Ana Monegal, Núria Guañabens. Metabolic Bone Diseases and Liver Units, Hospital Clínic, IDIBAPS, CIBERehd, University of Barcelona, Barcelona, Spain

In vitro studies have shown that the retained substances of cholestasis have deleterious effects in human osteoblasts and osteocytic cells. Bilirubin (BIL) and lithocholic acid (LCA) induce alterations in the proliferation, differentiation and apoptosis of osteoblastic and osteocytic cells. However, their effects in human bone tissue and in bone cell lines have not been deeply analysed.Aim: To investigate the effects of BIL, LCA and ursodeoxycholic acid (UDCA) in gene expression of human trabecular bone explants as well as in osteoblastic (SAOS2) and osteocytic cells (MLO-Y4/ MLO-A5).Methods: Bone tissue harvested from trabecular bone fragments, SAOS2 and MLO-Y4/ MLO-A5 cells were cultured and treated with BIL (50μM), LCA (10μM) and UDCA (10/100μM) for 24h. Gene expression of osteocalcin (BGLAP), Cbfa1 (RUNX2)/Osterix (OSX) and RANKL (TNFRSF11)/osteoprotegerin (TNFRSF11B) were quantified by real time PCR.Results: BIL diminishes RUNX2 gene expression in bone tissue (-37%), SAOS2 (-75%), MLO-Y4 (-56%) and MLO-A5 (-77%), and increases RANKL expression in 60%, 27%, 72% and 60%, respectively (p≤0.02). In bone tissue and in osteoblastic and osteocytic cells, LCA increases gene expression of BGLAP (NS) and RANKL (p≤0.03). UDCA 100μM increases RUNX2 and OSX expression in bone tissue (78% and 82%), MLO-Y4 (72% and 80%) and SAOS2 (75% and 70%) (p≤0.03). In addition, UDCA 100μM significantly increases expression of BGLAP, OPG and RANKL in bone tissue and in osteocytic lines. UDCA 10/100μM counteracts the decrease in RUNX2 induced by BIL in bone tissue, SAOS2, MLO-A5 and MLO-Y4 cells. Conclusion: The retained substances of cholestasis, particularly bilirubin, cause noxious effects on transcription factors of osteoblast differentiation and on osteoclastic activators in bone tissue and in osteoblastic and osteocytic cells. Ursodeoxycholic acid reverses the harmful effects of bilirubin. These results provide new insights into the low bone formation and at some stages, high resorption, associated with chronic cholestasis.

SAT-0864

Effects of hydroxyapatite/collagen complex on bone formation at osteotomy site of proximal tibia after povidone-iodine or ethanol exposure in ovariectomized rats Itsuki Nagahata*, Naohisa Miyakoshi, Yuji Kasukawa, Yuichi Ono, Manabu Akagawa, Yusuke Yuasa, Chiaki Sato, Yoichi Shimada. Akita University graduate school of medicine, Japan

Introduction: Hydroxyapatite/collagen complex (HAp/Col) is widely used in reconstruction of bone defects after severe trauma or resection surgery for bone tumor. Povidone-iodine or ethanol is sometimes used for sterilization at trauma sites or for prevention of tumor recurrence. These agents have the possibility of impairing bone formation. However, whether HAp/Col exerts similar effects on local bone formation after povidone-iodine or ethanol exposure remains unclear. This study examined the effects of HAp/Col or hydroxyapatite (HA) on osteogenesis and chondrogenesis at osteotomy sites on the proximal tibia after povidone-iodine or ethanol exposure in ovariectomized (OVX) rats.Method: OVX was administered to 16-week-old female Sprague-Dawley rats. After 4 weeks, cancellous osteotomy was performed at the proximal tibia and soaked with 10% povidone-iodine (I), 90% ethanol (E), or vehicle for 6 min. Rats were divided into the following four groups (n = 4-6 each): 1) HAp/Col group, HAp/Col placed into the osteotomy following vehicle soaking; 2) I+HAp/Col group, HAp/Col placed following I soaking; 3) E+HAp/Col group, HAp/Col placed following E soaking; and 4) HA group, HA placed in the osteotomy site following vehicle soaking. After 2 or 4 weeks, sections of proximal tibia were decalcified, stained with hematoxylin and eosin and prepared for subsequent evaluations. Cancellous bone volume (BV/TV) was measured at the osteotomy boundary (Border) and center of artificial bone (Center). Cartilage volume (CV/TV) was measured at the same sites of proximal tibia using Safranin O-stained sections.Results: BV/TV at Border and Center did not differ significantly among groups at 2 weeks. At 4 weeks, BV/TV at Border were significantly higher in the HAp/Col and E+HAp/Col groups than in the HA group (p < 0.05). BV/TV at Center was significantly higher in the HAp/Col group than in the HA group (p < 0.05). No significant difference in BV/TV was seen in the I+HAp/Col or E+HAp/Col groups compared with the HAp/Col group. CV/TV was significantly higher in the HAp/Col group than in the HA group at 2 weeks (p < 0.05). At 4 weeks, no significant difference was evident between groups. Conclusion: With bone formation at cancellous bone osteotomy sites in OVX rat, HAp/Col promoted osteogenesis even after exposure to povidone-iodine or ethanol at the proximal tibia. Povidone-iodine and ethanol treatment delayed cartilage formation.

Absence of Alpha-Synuclein (Snca) Protects Against Ovariectomy-Induced Weight Gain and Bone Loss by Independent Mechanisms. Carolina Figueroa*[1], Clifford Rosen[1], Charles Farber[2], Gina Calabrese[2], Victoria Demambro[1]. [1]Maine Medical Center Research Institute, United States, [2]University of Virginia, United States

Alpha-Synuclein (Snca) intracytoplasmic aggregation known as Lewy bodies are the major hallmark of most patients with Parkinson's disease (PD). PD has been associated with high incidence of osteoporosis. Recently, we have shown that Snca is one of the majorly connected "hub" genes and its global deletion in mice leads to a 40% reduction in Ovariectomy(Ovx)-induced bone loss. These observations lead us to hypothesize that deletion of Snca may protect against bone loss caused by estrogen-deficiency in a cell-autonomous manner. Therefore, we generated a conditional knock out for Snca; Prrx1-Cre+/- Snca-/- female mice that were randomly assigned to Sham or Ovx surgical groups (n=3-8 per group) and euthanized at 16 weeks after surgery. Analysis of body composition of the femur by Dual-energy X-ray absorptiometry showed that +/+ Snca-/- mice weighed significantly more (p=.0319) after Ovx, however, this change was not significant in Prrx1Cre/+ Snca-/- mice. Ovx increased %body fat in both genotypes, although, Prrx1Cre/+ Snca-/- mice showed a tendency to acquire less body fat (23.3%+/- 3.3, mean ± SE) compared to +/+ Snca-/- mice (31.1% ± 9.5) after Ovx. There were no differences in lean mass, whole body aBMD or aBMC. Contrary to our expectations, μCT of femoral trabecular (Tb.) bone after OVX

revealed that both genotypes showed loss of femoral BV/TV, but showed no differences in Tb.BV/TV, Tb.TMD, Tb.N and Conn.D between genotypes. Similarly, no significant difference was observed in respect to the cortical parameters. On the other hand, Inguinal white adipose depots (iWAT) from Prrx1-Cre/+Snca-/- were 53.8% smaller (0.2095g ± 0.059) than in +/+ Snca-/- (0.3889g ± 0.038). Analysis of H&E staining in iWAT sections from Sham and Ovx Prrx1-Cre/+Snca-/- mice showed presence of small and multilocular adipocytes, meanwhile, +/+ Snca-/- showed enlarged and unilocular adipocytes. iWAT gene expression showed significant increase in Pcg1a (p= 0.0267) mRNA levels in Prrx1Cre/+Snca-/- after Ovx compared to +/+ Snca -/-. Pparg, aP2, Prdm16 and DiO2 followed similar trends. In sum, deletion of Snca under the Prrx1 Cre promotor seems to affect iWAT capacity to store lipids, switching adipocytes phenotype from white to beige-like and protecting mice from Ovx-induced weight gain. This study provides evidence that Snca may be regulating systemically bone homeostasis and estrogen-deficiency induced bone loss, but cell-autonomous peripheral lipid accumulation.

Low Bone Density and Fragility Fractures as the Initial Presentation of Hemochromatosis: Two Case Reports Yi Liu*[1], Joseph Lane[1], Raymond Pastore[2], Dorothy Fink[1]. [1]Hospital for Special Surgery, United States, [2]New York Presbyterian Hospital, Weill Cornell Medical College, United States

Hereditary hemochromatosis (HH) is a genetic disorder of iron metabolism. The clinical manifestations of HH are related to tissue damage from iron deposition, including liver disease, skin pigmentation, diabetes mellitus, hypopituitarism and heart disease. Patients with HH are at high risk of bone loss and low energy fractures due to underlying hypogonadism or liver disease. Here we presented two HH cases presenting with osteoporosis and fragility fractures as the initial presentation of HH in the absence of cirrhosis. A 68 year-old female presented with buttock pain after knee replacement. MRI confirmed sacral insufficiency fracture and bone density showed mild osteopenia (lowest T-score of -1.4 at right total hip). She underwent bone biopsy that revealed hemochromatosis. Abdominal ultrasound showed increased echogenicity of the liver. Genetic test revealed she carries HFE H63D genetic mutation. Patient was treated with denosumab for her fragility fracture and monthly phlebotomy. Her ferritin went down to normal after three months of treatment. A 52 year-old man presented with multiple spontaneous vertebral compression fractures. DXA showed osteopenia with lowest Z-score of -2.4 at lumbar spine. Secondary work up for osteopenia showed hypogonadotrophic hypogonadism. He underwent bone biopsy and was found to have hemochromatosis. Lab tests were summarized in the table. He is managed with testosterone replacement and teriparatide for his compression fractures. With these two cases, we aim to enhance the awareness of osteoporosis and fragility fracture in patients with HH and suggest bone biopsy might be a useful diagnosis for HH.

Lab Tests	Reference Range for Case 1	Case 1	Reference Range for Case 2	Case 2
Ferritin	15-150 ng/ml	175	22-320 ng/ml	223.9
Iron	27-139 ug/dl	63	65-175 ug/dl	95
TIBC	250-450 ug/dl	313	250-425 ug/dl	429
Iron Saturation	15-55%	20	13-15%	22.1
ESR	0-40 mm/hr	59	0-20 mm/hr	<1
CRP	0.0-4.9 mg/L	4.1	<1 mg/L	<0.4

SAT-0883

Effect of Parathyroidectomy versus Antiresorptive Treatment on Bone Mineral Density in Osteoporotic Postmenopausal Women with Primary Hyperparathyroidism Tomaz Kocjan*[1], Gaj Vidmar [2], Andrej Janez[1], Soncka Jazbinsek[3], Katarina Remec[3], Mojca Jensterle Sever[1]. [1]University Medical Centre Ljubljana, Slovenia, [2]University Rehabilitation Institute Republic of Slovenia, Slovenia, [3]Medical Faculty Ljubljana, Slovenia

Limited data suggest that surgical treatment and antiresorptive therapies increase BMD in primary hyperparathyroidism (PHPT) to a similar degree, and thus medical treatment represents a reasonable option for patients who are unwilling or unfit for the parathyroidectomy (PTX). We compared BMD changes in osteoporotic patients with PHPT after 12 – 18 months post operation versus after 12 – 18 months of antiresorptive treatment.We retrospectively analyzed 55 women (age 69 years, 20 years from menopause, BMI 28 kg/m2 on average) with PHPT and osteoporosis who had been treated at our clinic from 2004 to 2016. 17 of them sustained at least one osteoporotic fracture before the study onset. They were prescribed with vitamin D3 800-1400 IU daily and instructed to ingest 1000 mg of calcium daily. PTX was performed on 23 patients, while 33 patients opted for medical treatment,

either with a bisphosphonate (alendronate (8), risedronate (7), ibandronate (3) or zoledronic acid (5 patients)) or with denosumab (9 patients) per physician's and/or patient's preference. BMD was measured at lumbar spine (LS), total hip (TH), femoral neck (FN) and distal radius (RAD) by DXA at the time of diagnosis and 12 – 18 months after intervention.No significant difference in any difference score was found between the denosumab and the bisphosphonate group, so they were pooled into one medically treated (MED) group and compared with the PTX group. As expected, serum calcium decreased significantly more in the PTX group than in the MED group (median decrease by 0.50 vs. 0.04 mmol/L, p<0.001). PTH also decreased markedly in the PTX group (median decrease by 144 ng/L) and remained unchanged (median increase by 6 ng/L) in the MED group (p<0.001 for comparison of change scores). The increase in TH BMD was higher in the PTX group than in the MED group (median 0.037 vs. 0.001 g/cm2, p=0.008) and marginally so for the LS BMD (median 0.051 g/cm2 vs. 0.018 g/cm2, p=0.065). No difference between the PTX and the MED group was observed regarding change in FN BMD, whereby FN BMD increased significantly in the whole sample (median increase by 0.019 g/cm2, p=0.046). RAD BMD did not change significantly, and its change did not differ between the groups. No new fractures occurred in either group during the observation period.In osteoporotic postmenopausal women with PHPT, PTX is superior to antiresorptive treatment with bisphosphonate or denosumab in terms of improvement of BMD, in particular of TH BMD.

Glucocorticoid-induced osteoporosis induced poor bone quality, low bone mineral density, low muscle mass and high low back pain Tomohisa Koyama*[1], Masayuki Miyagi[1], Sho Inoue[1], Shuichiro Tajima[1], Kosuke Murata[1], Ayumu Kawakubo[1], Yui Uekusa[1], Yuji Yokozeki[1], Hisako Fujimaki[1], Daisuke Ishi[1], Koji Ishikawa[2], Seiji Ohtori[3], Kazuhide Inage[3], Kentaro Uchida[1], Gen Inoue[1], Masashi Takaso[1]. [1]Department of Orthopedic Surgery, Kitasato University, School of Medicine, Japan, [2]Department of Orthopedic Surgery, Showa University, School of Medicine, Japan, [3]Department of Orthopedic Surgery, Chiba University, Graduate School of Medicine, Japan

BACKGROUND: Glucocorticoid-induced osteoporosis (GIO) patients have been reported at high risk for fragility fractures as compared with primary osteoporosis patients. To better understand the characteristics of GIO and to improve treatment of GIO patients, we focused on low back pain (LBP), muscle mass, and bone quality. The aim of the current study was to compare GIO patients and primary osteoporosis patients for LBP, muscle mass, bone mineral density (BMD), and bone turnover markers.METHODS: Two hundreds and four osteoporosis over 60 years patients (35 men and 169 women) without evidence of new vertebral body fractures were included in the study. Forty two subjects with a mean age of 73.6 years were in the GIO group (G group); 162 patients with a mean age of 73.9 years composed the primary osteoporosis group (P group). We reviewed BMD of the lumbar spine (LS) and total hip (TH), and also reviewed the number of vertebral fractures. We calculated lean muscle mass and limb muscle mass (corrected by the square of height: lean mass index (LMI) and skeletal muscle mass index (SMI)) using the bio-impedance method (TANITA MC - 780A). Bone turnover markers were used to assess bone formation (BAP) and bone resorption (TRACP5b). Bone quality was assessed by evaluating pentosidine, and homocysteine. LBP was evaluated using the Oswestry disability index (ODI). These factors were compared between the two patient groups. Group comparisons for muscle mass were made in men and women separately.RESULTS: BMD of TH in the G group (0.58) was significantly lower than that in the P group (0.63). There were more vertebral fractures in the Group (2.4) than that in the P group (1.0). Homocysteine in the G group (14.7) was significantly higher than that in the P group (10.3). LMI in women in the G group (14.3) were significantly lower than those in women of the P group (14.6). ODI score in the G group (34.5) was significantly higher than that in the P group (25.2).DISCUSSION: GIO patients had lower BMD of TH, more vertebral fractures, and poorer bone quality than patients in the primary osteoporosis group. Poor bone quality might be one risk factor for osteoporotic fragility fractures in GIO patients. In addition, GIO patients had low muscle mass and high LBP. Although we could not still identify the mechanisms of these findings, exercise therapy and intervention for LBP might help to improve treatment efficacy in GIO patients.

BONE STATUS OF PATIENTS WITH CHRONIC KIDNEY DISEASE STAGE 5 (CKD5) WAIT-LISTED FOR KIDNEY TRANSPLANTATION IS POORLY EVALUATED BY DXA Vanessa Lapierre*[1], Martin Jannot[1], Myriam Normand[1], Pawel Szulc[2], Elisabeth Sornay-Rendu[2], Thierry Thomas[1], Christophe Mariat[3], Roland Chapurlat[2], Marie-Hélène Lafage-Proust[1]. [1]INSERM 1059, Université de Lyon, France, [2]INSERM 1033, Université de Lyon, France, [3]NEPHROLOGY DPT, CHU ST-ETIENNE, France

Kidney transplantation (KT) increases fracture (Fx) risk. Thus, we need to assess bone status in patients with CKD5 when they are wait-listed for KT (WKT) in order to detect patients at risk and develop preventive strategies. Our aim here, was to compare bone status evaluated by DXA and High Resolution μCT (HR-pQCT) in this population. METHODS:We included 102 CKD5 patients, 64? and 38? at the time of KT list registration. We evaluated

clinical risk factors for Fx, hip and vertebral areal (a) Bone Mineral Density (BMD) by DXA, FRAX score for Major Osteoporotic (MOF) and Hip (HF) Fx, radius and tibia structural parameters and volumetric (v) BMD by μCT (Scanco).Patients were compared to age and sex-matched non uremic subjects (CT) from two cohorts,OFELY and STRAMBO, with 1 WKT/2 CT ratio.Statistics included Student t or Bivariate Wilcoxon tests.HR-pQCT data were adjusted for the FRAX-MOF without BMD score.Results are mean±SD or median [1st-3rd IQ]. RESULTS: In males, median age was 65 [54-69].WKT included more patients with diabetes (28 vs 13%), hypertension (81 vs 30%) and more smokers (21 vs 8%) than CT. In WKT, hip aBMD was higher than in CT (0.85 [0.79-0.94] vs 0.81 [0.74-0.89]g/cm²) while the FRAX-MOF or HF scores were higher (4 [3-5] vs 3% [2-5]) than in CT (p<0.01). In contrast, cortical (Crt) and trabecular (Tb) vBMD were lower in WKT (Radius Total vBMD: 297±84 vs 328±57 mg/cm3 p<0.01).Tb bone was less dense and connected (p<0.01) in WKT at the radius only. In females, median age was 58 [53-63].WKT had more prevalent osteoporotic Fx than CT (32 vs 4% p<0.01), lower BMI [24 (21-27) vs 27 (24-29), p<0.02], higher FRAX-MOF (4.8 [3.4-6.7] vs 3.6% [2.6-4.6], p=0.03) than CT. aBMD was similar in the 2 groups at both the spine and the hip.In contrast, Crt and Tb vBMD were lower in WKT than in CT (radius Total vBMD 245±81 vs 306±62 mg/cm3, p<0.03).Crt thickness at both sites was similar in the 2 groups while tibia Crt porosity was lower in WKT than in CT (6.2 [3.7-10.5] vs 8.8% [4.5-13.7] p<0.01).Tb bone Volume and Thickness were lower at both sites in WKT (Tibia BV/TV: 10±3 vs 13±3%, p<0.01). 29 % WKT had a DXA Hip T-score <-2.5. Fractured WKT were older than patients with no Fx (p<0.01).Patients with KT history had worse bone status.Neither aBMD nor HR-pQCT parameters were discriminantCON-CLUSIONS:Osteoporosis in CKD5, is gender specific and combines structural trabecular bone degradation and hypomineralization of both bone compartments, not detected by DXA

Skeletal Consequences of Nephropathic Cystinosis Pablo Florenzano*[1,2], Carlos Ferreira[3], Galina Nesterova[3], Mary Scott Roberts[4], Sri Harsha Tella[4], Luis Fernandez De Castro[4], Sydney M. Brown[4], Adom Whitaker[4], Renata C. Pereira[5], Dorothy Bulas[6], Rachel I. Gafni[4], Isidro B. Salusky[5], William A. Gahl[3], Michael T. Collins[4]. [1]Skeletal Diseases and Mineral Homeostasis Section, National Institute of Dental and Craniofacial Research,NIH, United States, [2]Department of Endocrinology, School of Medicine. Pontificia Universidad Catolica de Chile., United States, [3]Medical Genetics Branch, National Human Genome Research Institute. NIH, United States, [4]Skeletal Disorders and Mineral Homeostasis Section, National Institutes of Dental and Craniofacial Research, NIH, United States, [5]Division of Nephrology, Department of Pediatrics, David Geffen School of Medicine at University of California, Los Angeles, United States, [6]Division of Radiology, Children's National Health System, United States

Nephropathic cystinosis is a rare lysosomal storage disorder. Patients present in the first year of life with renal Fanconi syndrome that evolves to progressive chronic kidney disease (CKD).Goal: Despite the multiple risk factors for bone disease, the frequency and severity of skeletal disorders in nephropathic cystinosis have not been described. Methods: We performed systematic bone and mineral evaluations of subjects with cystinosis seen at the NIH (N=30), including history and physical examination, serum and urine biochemistries, DXA, vertebral fracture assessment, skeletal radiographs, and renal ultrasound. Additionally, histomorphometric analyses are reported on six subjects seen at the UCLA-Bone and Mineral Metabolism Clinic. Results: In NIH subjects, mean age (range) was 20 (5-44), 60% were CKD stage 1 to 4, and 40% had a renal transplant. Mean bone mineral density (BMD) Z-scores were decreased in the femoral neck, total hip and 1/3 radius (p<0.05). Low bone mass at one or more site was present in 46% of subjects. Thirteen percent of subjects reported one or more long bone fractures. Thirty-two percent of subjects had incidental vertebral fractures, which were unrelated to transplant status. Long bone deformity/bowing was present in 64%; 50% had scoliosis.Diffuse osteosclerosis was present in 22% of evaluated subjects. Risk factors included CKD, phosphate wasting, hypercalciuria, secondary hyperparathyroidism, vitamin D insufficiency, male hypogonadism, metabolic acidosis and glucocorticoid/immunosuppressive therapy. Over half of the non-transplanted subjects had ultrasonographic evidence of nephrocalcinosis or nephrolithiasis. Histomorphometric analyses showed impaired mineralization in 4 of 6 studied subjects.Conclusions: We conclude that skeletal deformities, decreased bone mass, and vertebral fractures are common and relevant complications of nephropathic cystinosis, even before renal transplantation. Efforts to minimize risk factors for skeletal disease include optimizing mineral metabolism and hormonal status, combined with monitoring for nephrocalcinosis/nephrolithiasis.Fig 1. BMD Z-scores in NIH subjects with nephropathic cystinosis.*Z-score mean values in total hip, femoral neck, and 1/3 radius are significantly lower than age-, sex-, and ethnicity- matched population (p<0.05). No statistical differences between Z-score mean values from subjects with and without a renal transplant (p=ns).BMD Z-scores have been corrected for height (HAZ) in subjects <20 years of age.

Persistence with Buffered Solution of Alendronate 70mg: Prospective Observational Study Andrea Giusti*[1], Dennis M Black[2], Antonella Barone[3], Josef Hruska[4], Gerolamo Bianchi[1]. [1]La Colletta Hospital, Italy, [2]University of California San Francisco, United States, [3]Galliera Hospital, Italy, [4]EffRx Pharmaceuticals, Switzerland

Keywords: osteoporosis, persistence, buffered alendronate Introduction: Alendronate 70mg effervescent (ALN-EX) was developed to improve upper gastrointestinal (GI) tolerability of alendronate tablets (ALN-T)1. It is associated with a lower frequency of GI adverse

reactions (AR) than ALN-T2, potentially leading to increased persistence with ALN-EX. Objective: To evaluate persistence and reasons for discontinuation in patients treated with ALN-EX, and to compare the outcomes with a historical cohort of patients on ALN-T. Materials and Methods: Postmenopausal women (PMW) from a standardized Clinical Database with BMD T-score <-2.5, or between -2 and -2.5 and at least one vertebral fracture, starting ALN-EX between July 2015 and June 2016 were included. A historical cohort comprised of randomly selected and age-matched PMW on ALN-T was used as a control. Persistence at 6- and 12-month and reasons for discontinuation were compared between the ALN-EX and ALN-T groups. Reasons for discontinuation including occurrence of AR were recorded prospectively (ALN-EX) or retrieved from the database (ALN-T). Efficacy data (BMD and bone ALP) are reported separately. Results: 144 PMW on ALN-EX and 216 PMW on ALN-T (144 ALN, 72 ALN plus cholecalciferol) were analyzed. The two groups were comparable with respect to baseline characteristics (previous fractures, baseline BMD and use of PPIs). Persistence at 6- and 12-months was 91% and 81% in ALN-EX group vs 75% and 69% in ALN-T. The difference was significant at both time points: 6-month P<.001 and 12-month P=.009. Significantly higher % of PMW receiving ALN-T discontinued treatment due to GI AR or patient preference: GI AR, 4% ALN-EX versus 11% ALN-T (P=.027); patient preference, 6% ALN-EX versus 13% ALN-T (P=.016). Conclusion: This is the first report indicating that ALN-EX is associated with higher persistence than ALN-T. ALN-EX is a well tolerated oral bisphosphonate and a viable alternative option in the management of osteoporosis, being able to improve persistence.

Effect of Prevalent Vertebral Fractures on Incidental Vertebral Fractures and Low Back Pain During Bisphosphonate Treatment for Osteoporosis
Yuji Kasukawa*[1], Naohisa Miyakoshi [1], Toshihito Ebina[2], Michio Hongo[1], Koji Nozaka[1], Yoshinori Ishikawa[1], Hiroyuki Tsuchie[1], Daisuke Kudo[1], Yoichi Shimada[1]. [1]Department of Orthopedic Surgery, Akita University Graduate School of Medicine, Japan, [2]Department of Orthopedic Surgery, Kakunodate General Hospital, Japan

Introduction: Osteoporotic vertebral fractures (VFs) comprise one cause of low back pain. We prospectively determined the incidence of low back pain (LBP) and VFs during treatment with risedronate alone or risedronate and vitamin K2 in osteoporotic women over 60 years of age with and without already present VFs.Methods: Altogether, 101 osteoporotic women were randomly stratified into two groups: Ris-group (n = 51) treated with risedronate alone (17.5 mg/week) and the Ris+K2 group (n = 50) treated with risedronate and menatetranone (45 mg/day). In all, 29 women in the Ris group and 26 in the Ris+K2 group continued treatment and were included in this study. They were divided into two subgroups—with or without VF—and underwent evaluation for incidental VFs by plain radiography, bone metabolic markers including serum cross-linked N-telopeptide of type 1 collagen (NTX) and bone alkaline phosphatase, and LBP by interview before and after treatment.Results: VFs were present pretreatment in 12 patients (41%) in the Ris group and 13 (50%) in the Ris+K2 group. LBP was present pretreatment in 15 (52%) in the Ris group and 15 (58%) in the Ris+K2 group. After 1 year of treatment, incidences of VF and LBP had decreased to 4 (14%) and 8 (28%), respectively, in the Ris group and 7 (27%) and 7 (27%), respectively, in the Ris+K2 group. Among the patients who developed VF or LBP during treatment, pretreatment VFs had been present in all 4 (100%, p = 0.01) and in 7 of 8 patients (88%, p = 0.002), respectively, in the Ris group and in 6 of 7 (86%, p = 0.02) and in 4 of 7 (57%, NS) patients, respectively, in the Ris+K2 group. The serum NTX level in participants with pretreatment VFs was significantly higher than that in those who did not already have VFs in both the Ris (p = 0.01) and Ris+K2 (p = 0.03) groups.Conclusion: VF incidences were significantly high in participants with pretreatment VFs independent of the type of treatment for osteoporosis. Incidence of LBP was significantly high only in participants who had pretreatment VFs and who were treated with Ris monotherapy.

SAT-0915

The impact of switching once-weekly teriparatide to denosumab in severe osteoporosis patients
Masayuki Miyagi*, Kosuke Murata, Tomohisa Koyama, Hisako Fujimaki, Koji Naruse, Gen Inoue, Masashi Takaso. Department of Orthopedic Surgery, Kitasato University School of Medicine, Japan

INTRODUCTION: Switching from daily (d) teriparatide (TPTD) to denosumab (DMAb) had been reported effective for severe osteoporosis patients. However, there have been no reports about switching from weekly (w) TPTD to DMAb in patients with osteoporosis. Once-weekly 56.5-μg TPTD treatment increases bone mineral density (BMD) and reduces fracture events. The objective of the current retrospective study was to elucidate the impact of switching w-TPTD to DMAb in patients with severe osteoporosis. METHODS: In this study, 40 patients were treated with w-TPTD for 18 months and then switched to DMAb for 18 months. The sample included 2 men and 38 women with a mean age of 74.5 (60-85) years. Twenty-five subjects had primary osteoporosis, and 15 had secondary osteoporosis. The mean number of osteoporotic vertebral fractures was 4.1. Serum bone turnover markers and BMD were evaluated every 6 months. And we also reviewed incident vertebral fractures by X-ray every 6 months.RESULTS: Bone alkaline phosphatase (BAP) and tartrate resistant acid phosphatase 5b (TRACP5b), markers of bone formation and resorption respectively, were not significantly different in w-TPTD subjects at 18 months compared with those at baseline (p>0.05), but BAP and TRACP5b in subjects treated with DMAb were significantly lower at 36 months compared with those at baseline (p<0.05). BMD of the lumbar spine (LS), femoral neck (FN), and total hip (TH) increased by 12.3%, 2.5%, and 2.2% by 36 months with DMAb treatment, significantly higher than at baseline (p<0.05). Changes in BMD of LS, FN, and TH in primary osteoporosis patients were significantly higher than in secondary osteoporosis patients at 18 months (w-TPTD) and 36 months (DMAb, p<0.05). Incident vertebral fractures were observed in 5 cases (12.5%), four (26.7%) of which were in patients with secondary osteoporosis, one (4%) case was in patients with primary osteoporosis. DISCUSSION: This is the first study to evaluate the impact of switching from w-TPTD to DMAb in severe osteoporosis patients, including those with secondary osteoporosis. BMD significantly increased in severe osteoporosis patients switched from w-TPTD to DMAb. However, the impact of switching from w-TPTD to DMAb in secondary osteoporosis patients was not as great as in primary osteoporosis patients.

Effects of Intravenous Ibandronate among Patients with Insufficient Changes to Bone Resorption Markers after Oral Bisphosphonate Monotherapy
Naohisa Miyakoshi*[1], Yuji Kasukawa[1], Michio Hongo[1], Akira Horikawa[2], Yoichi Shimada[1]. [1]Department of Orthopedic Surgery, Akita University Graduate School of Medicine, Japan, [2]Igarashi Memorial Hospital, Japan

Introduction: Among multiple therapeutic options available for pharmacotherapy against osteoporosis, bisphosphonates (BPs) are the first-line drugs and act strongly to reduce osteoclast-mediated bone resorption. However, some individuals do not adequately respond to these drugs. This study first investigated the prevalence of non-responders to oral BP monotherapy among patients with postmenopausal osteoporosis using serum N-terminal telopeptide of type I collagen (NTX) as a marker. Second, we tested the effects of intravenous ibandronate among patients with insufficient changes to NTX after oral BP monotherapy to identify true non-responders to BPs.Methods: Among 146 consecutive patients with postmenopausal osteoporosis who received oral BP monotherapy for more than 12 months, insufficient responders to oral BP monotherapy were switched to intravenous ibandronate injection. The decision on whether to switch to intravenous ibandronate was made by each patient. Patients who agreed to switch intravenous ibandronate were followed-up for more than 12 months and bone turnover markers at 6 and 12 months after switching to intravenous ibandronate were evaluated. Serum NTX and bone alkaline phosphatase (BAP) concentrations were measured. Patients who also showed insufficient response to intravenous ibandronate were defined as true BP non-responders. Insufficient response to BP therapy was evaluated based on the serum NTX reduction cut-off for minimum significant change.Results: Sixty-one patients (41.8%) were diagnosed as oral BP non-responders. Among these non-responders, 22 patients (36.1%) agreed to switch to intravenous ibandronate treatment. Fourteen patients who switched to intravenous ibandronate and had complete data available were used for final analysis. After switching to intravenous ibandronate, both NTX and BAP decreased significantly (p<0.05). However, at 6-12 months after switching, 57.1-64.3% of patients still showed insufficient response of NTX as compared to baseline (before oral BP monotherapy), and 21.4-35.7% of patients still showed insufficient response of NTX when compared to data immediately before switching.Conclusions: These results estimated that as few as 9-15% (i.e., 21.4-35.7% of 41.8%) or as many as 24-27% (i.e., 57.1-64.3% of 41.8%) of patents might be true BP non-responders.

The Impact of Prior Bisphosphonate Treatment on Weekly Teriparatide for Severe Osteoporosis Kosuke Murata*, Tomohisa Koyama, Sho Inoue, Masayuki Miyagi, Eiki Shirasawa, Shuichiro Tajima, Ayumu Kawakubo, Yui Uekusa, Hiroki Saito, Maho Tsuchiya, Yusuke Mimura, Masahiro Yoneda, Koji Naruse, Kentaro Uchida, Gen Inoue, Masashi Takaso. Department of Orthopedic Surgery, Kitasato University, School of Medicine, Japan

Introduction: Bisphosphonate (BP) use prior to daily teriparatide (d-TPTD) treatment may reduce the increase in bone mineral density (BMD). The impact of prior BP treatment on weekly (w) TPTD has not been reported. This study aimed to determine the effect of BP prior to w-TPTD on the efficacy of osteoporosis treatment.Methods: This study included 58 patients with severe osteoporosis (3 men and 55 women, mean age: 77.4 years). Of these, 32 had primary osteoporosis and 26 had secondary osteoporosis, including glucocorticoid-induced osteoporosis. The mean number of fractures was 3.3, indicating severe osteoporosis. We reviewed bone turnover markers (BAP, TRACP 5b) and BMD (lumbar spine [LS] and femoral neck [FN] using DEXA) every 6 months and calculated the ratio of change from baseline. We also reviewed medical records for new osteoporotic fragility fractures. We divided subjects into a prior BP treatment group (prior BP(+): n=18) and others (prior BP(-): n=40), and compared all reviewed factors.Results: BAPchanges from baseline at 6, 12, and 18 months were -8.5%, -2.8%, and -4.7%, respectively. TRACP 5b changes at 6, 12, and 18 months were -8.5%, -12.9%, and -15.9%, respectively. BMD changes in the LS and FN at 6, 12, and 18 months were 2.6%, 3.7%, and 5.2%, and 0.6%, 0.5%, and 0.3%, respectively. There were 12 secondary osteoporosis patients (66.7%) in the prior BP(+) group and 14 secondary osteoporosis patients (35%) in the prior BP(-) group. BAP and TRACP 5b changes in the prior BP(+) group and prior BP(-) group at 18 months were 3.6% and -11.4%, and -8.7% and -18.1%, respectively. Changes in bone turnover markers tended to be high in the prior BP(+) group, although there was no significant difference between groups (p>0.05). BMD changes in the LS and FN at 18 months were 5.0% and -1.5%, respectively in the prior BP(+) group, and 5.3% and 0.7%, respectively in the prior BP(-) group. There were no significant differences between groups (p>0.05). However, BMD changes in the FN tended to be low in the prior BP(+) group. Of 7 cases with 9 new osteoporotic fragility fractures, the prior BP(+) group had 4 cases (22%) and 6 fractures, and the prior BP(-) group had 3 cases (7.5%) and 3 fractures.Discussion: The prior BP(+) group had more secondary osteoporosis cases, indicating less effect on BMD of the FN and more new osteoporotic fragile fractures. Thus, BP prior to w-TPTD treatment, especially for secondary osteoporosis, might reduce treatment efficacy.

SAT-0918

Denosumab was superior to teriparatide to improve bone mineral density in patients with rheumatoid arthritis; 18 months of follow-up Tokutaro Okawa*[1], Motomi Okawa[1], Shuhei Ueno[2], Eri Narita[2], Tatsuya Koike[2]. [1]Okawa Orthopaedic Surgery Hospital, Japan, [2]Search Institute for Bone and Arthritis Disease, Shirahama Foundation for Health and Welfare, Japan

Background: Both denosumab (DMB) and teriparatide (TPTD) are well known as a great useful treatment option for OP. RA and medications for RA have been considered risk factors for fractures and bone loss, especially in the elderly. Head to head comparison between these medications for OP in RA patients in elderly has not been well addressed previously. Object: In this retrospective study, we compared BMD changes with DMB and TPTD treatment for OP in elderly Japanese RA patients for 18 months of follow-up. Methods: Subjects were patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria. All patients were postmenopausal women with OP who were OP treatment naïve. The DMB dose was 60 mg every 6 months with daily native vitamin D. The treatment with TPTD included 20 μg daily or 56.5 μg weekly by subcutaneous injection. BMD was measured with DXA for lumbar spine (LS), femoral neck (FN) and total hip (TH) at baseline and months 6, 12, 18 during treatment. The statistical significance in mean values between two groups in time with Mann-Whitney U-tests. To identify difference in one group between time points, Wilcoxon signed rank test was used. Result: DMB (n=21) and TPTD (n=15) were enrolled. Baseline characteristics of DMB and TPTD were the mean age 72.1 and 72.8 years old, the body mass index 19.6 and 19.9, LS-BMD 0.658 and 0.662, FN-BMD 0.437 and 0.448, TH-BMD 0.573 and 0.539, respectively. There was no significant difference between two groups at baseline. The percent change of LS-BMD from baseline to 6, 12 and 18 months were each 4.59% vs -1.85% (p<0.01) at 6 months, 6.77% vs -2.89% (p<0.01) at 12 month and 8.35% vs -1.78% (p<0.01) at 18 months. The percent change of FN-BMD from baseline to 6, 12 and 18 months were each 2.22% vs -6.02% (p<0.01) at 6 months, 2.85% vs -5.46% (p<0.01) at 12 months and 2.75% vs -7.02% (p<0.01) at 18 months. The percent change of TH-BMD from baseline to 6, 12 and 18 months were each 2.93% vs -2.78% (p<0.05) at 6 months, 4.35% vs -3.82% (p<0.01) at 12 months and 3.78% vs -4.71% (p<0.01) at 18 months. Conclusion: This study shows that DMB was more effective to increase BMD than TPTD in elderly RA patients with osteoporosis.

*p<0.05 and **p<0.01 vs. baseline with Wilcoxon signed rank test
#p<0.05 and ##p<0.01 vs. DMB with Mann-Whitney test

SAT-0919

Comparative Analysis of new adjacent and remote fracture after vertebroplasty: survivorship analysis of 205 patients Ye Soo Park*[1], Jaedong Kim[1], Jin-Sung Park[2], Woong Hwan Choi[3]. [1]Hanyang University Guri Hospital, Republic of Korea, [2]Korea University Ansan Hospital, Republic of Korea, [3]Hanyang University Hospital, Republic of Korea

Background: We don't know the risk factors of adjacent and remote vertebral fracture after vertebroplasty.Objective: The purpose of this study was to investigate the natural history of new fracture following vertebropalsty for osteoporotic vertebral compression fracture (OVCF) and to evaluate the risk factors for adjacent vertebral fracture (AVF) and remote vertebral fracture (RVF) separately.Design: A retrospective study of 205 consecutive patients who underwent a vertebroplasty for OVCF with a minimum follow-up of 1 year was conducted. A separate survivorship analysis of AVF and RVF was performed using the Cox proportional hazards model.Results: Of the 47 patients (22.9%) with new vertebral fracture, AVF developed in 21 patients (10.2%) and RVF in 26 patients (12.7%). The median survival time was 4.0 months for AVF and 14.0 months for RVF. Multivariate analyses revealed that sagittal alignment imbalance and initial vertebroplasty at the thoracolumbar junction were independent risk factors for AVF (hazard ratio=9.6 and 4.7, respectively), whereas the significant risk factor for RVF was a sagittal alignment imbalance (hazard ratio=11.5). A low bone mineral density of the spine (T-score ≤-3) was shown to be a risk factor for AVF and RVF on univariate analyses, but not on multivariate analyses.Conclusion: AVF developed at a median of 4 months and RVF at a median of 14 months. An initial vertebroplasty at the thoracolumbar junction was an independent risk factor for AVF, and patients with sagittal alignment imbalance had a high risk of AVF and RVF after vertebroplasty for OVCF.

SAT-0920

The mechanical properties of human trabecular bone accompanying one to twenty years of bisphosphonate treatment. David Pienkowski*, Constance Wood, Hartrmut Malluche. University of Kentucky, United States

Bisphosphonates are widely used for treating osteoporosis, but the relationship between treatment duration and bone quality is unclear. Material properties determine bone quality, thus the present study quantifies the relationship between modulus and hardness of human bone with bisphosphonate treatmentt duration.Patients and Methods: iliac crest bone samples from a consecutive series of 86 osteoporotic Caucasian women continuously treated with oral bisphosphonates for 1.1 to 20 years were analyzed using nanoindentation. Youngs modulus and hardness were measured and related to bisphosphonate treatment duration by statistical modeling.Results: the statistical models showed that modulus and hardness increased, peaked, and plateaued with increasing bisphosphonate treatment duration. Both quadratic and linear terms were needed to model modulus increases from 1 to 6 years of bisphosphonate treatment and plateaus from 6 to 20 years of treatment. Models also indicated that the quadratic-linear transition point in bisphosphonate treatment duration depends upon trabecular location. Hardness increased and peaked at 12.4 years of treatment; it remained constant from 12.4 to 20 years and was less sensitive to trabecular location. Conclusions: bone modulus increases with bisphosphonate treatment duration up to 6 years and no addi-

tional modulus gains can be expected from treatment durations exceeding 6 years. Hardness increased, peaked at 12.4 years, and remained constant up to 20 years of bisphosphonate treatment. The clinical relevance of hardness awaits further study.

Effectiveness of Monthly Intravenous Ibandronate Injections in a Real-World Setting: Subgroup Analysis of a Post-Marketing Observational Study Yasuhiro Takeuchi*[1], Junko Hashimoto[2], Hiroyuki Kakihaya[2], Yosuke Nishida[2], Michiko Kumagai[2], Chiemi Yamagiwa[2]. [1]Endocrine Center, Toranomon Hospital, Japan, [2]Chugai Pharmaceutical Co. Ltd., Japan

Purpose: The favorable safety and consistent effectiveness of monthly intravenous (IV) ibandronate (IBN) injections was reported recently in a prospective, post-marketing, observational study in Japanese patients (pts) with osteoporosis (BON1301) [Takeuchi Y et al. Osteoporosis and Sarcopenia, 2018. In press]. Here we present subgroup analyses from the study. Methods: The effectiveness parameters evaluated in this large-scale, real-world study included bone mineral density (BMD) gains and the cumulative incidence of vertebral fractures. BMD gains were assessed in the following subgroups: previous bisphosphonate (BP) treatment, concomitant vs naïve osteoporosis drug treatment, younger vs older age (<75 or ≥75 years), and absence vs presence of vertebral fractures.Results: 1,062 pts were enrolled and 1,025 pts received monthly IV IBN 1mg for 1 year. Overall, significant increases in BMD relative to baseline were observed at the lumbar spine (LS; 4.84%, 95% CI 3.47, 6.21) at 12 months. In total, 515 pts (50.2%) had previously been treated with osteoporosis drugs; of these, 166 pts (16.1%) were treated with other BPs. The mean BMD changes at the LS were 4.15% (95% CI, 1.43, 6.87) in pts previously treated with other BPs and 6.12% (95% CI, 3.13, 9.11) in pts receiving other prior osteoporosis treatments at 12 months from baseline, compared with 4.04% (95% CI, 2.61, 5.47) in pts who had not received prior osteoporosis treatment. Among the 510 pts (49.7%) concomitantly prescribed activated vitamin D drugs, mean LS BMD changes were 5.75% (95% CI, 3.65, 7.86) at 12 months from baseline vs 3.54% (95% CI, 1.98, 5.10) in pts receiving IBN alone.In pts aged <75 or ≥75 years, LS BMD gains were 4.30% (95% CI 2.82, 5.77) and 5.24% (95% CI 3.12, 7.36), respectively. LS BMD gains were 5.75% (95% CI 3.95, 7.56) and 5.21% (95% CI 2.42, 8.00), respectively, in pts with vs without vertebral fractures. No renal-related adverse drug reactions were observed. Estimated glomerular filtration rate (eGFR) levels did not change throughout the study (mean eGFR: 67.64mL/min/1.73m2 at baseline; 67.60mL/min/1.73m2 at 12 months). No notable renal impairment was seen in 24 pts with eGFR levels <35mL/min/1.73m2. Conclusions: Monthly IV IBN demonstrated comparable BMD gains in subgroups defined by prior or concomitant osteoporosis treatment, age, and presence or absence of vertebral fractures. These data suggest that IBN shows high utility and a positive benefit-risk profile in these pts.

SAT-0922

Pharmacogenomics study of denosumab Victoria Ho-Yee Wong*, Vincent Ka-Fai Cheng, Grace Koon-Yee Lee, Ching-Lung Cheung. The University of Hong Kong, Hong Kong

BackgroundDenosumab (Dmab) is a fully human monoclonal antibody that targets the key bone resorption mediator RANKL. RANKL is expressed in osteoblasts and stromal cells and binds to its receptor RANK that regulates bone resorption. Contrary to this, OPG is secreted endogenously to bind RANKL, thus inhibiting bone resorption. As Dmab functions by blocking the binding between RANKL and RANK, understanding the function and expression of members of RANKL–RANK–OPG axis is essential to pharmacodynamic study of Dmab. However, the genetic variation or expression of these genes remain unexplored. We aimed to study the association between serum levels of RANK/RANKL/OPG, mRNA expression levels of RANK/RANKL/OPG, and bone mineral density (BMD).MethodsWe recruited cases (N=50) who are osteoporotic patients treated with Dmab monotherapy, while controls (N=217) being participants from the Hong Kong Osteoporosis Study who had never received anti-osteoporotic treatment. BMD was measured by DEXA with 6-month period prior to Dmab monotherapy, at 12 months (+/-3 months) after 1-year Dmab monotherapy. Peripheral blood mononuclear cells (PBMC) from the cases and controls were collected and used for mRNA expression study. Circulating RANK/RANKL/OPG in serum was quantified using ELISA. Association studies were performed using linear regression.ResultsAfter 1-year treatment efficacy of Dmab, 20.6% of cases did not have lumbar spine BMD increased, while 27.5% of them did not have femoral neck BMD increased. We observed that circulating RANKL (R=-0.505, P=0.002) and OPG/RANKL ratio (R=0.364, P=0.029) were significantly correlated with 1-year BMD change at the lumbar spine after Dmab monotherapy, but not with bone loss in controls. No significant association between circulating OPG/RANK/RANKL and BMD change at the hip was observed. On the other hand, mRNA expression of RANKL in PBMC was positively correlated with the circulating RANKL levels (R=0.497; P<0.001) and showed trend toward significant association with BMD change at the lumbar spine after 1-year Dmab treatment (R=-0.298, P=0.10). No significant association between mRNA expression levels of OPG/RANK/RANKL and BMD change at the hip was observed.ConclusionThe circulating RANKL is likely to be an important determinant of Dmab treatment outcome; whereas RANKL mRNA expression in PBMC is highly cor-

related with circulating RANKL. This pharmacogenomic study provided useful insight to the evaluation of efficacy of Dmab.

Racially determined, serum-mediated resistance to 25-hydroxyvitamin D induced innate immune responsivity in human macrophages Rene Chun*[1], Carter Gottlieb[1], Kathryn Zavala[1], Albert Shieh[1], Andrea Salinas[1], Vahe Yacoubian[1], Samya Konda[1], Jefferey Wang[1], Martin Hewison[2], Philip Liu[1], John Adams[3]. [1]Department of Orthopaedic Surgery, UCLA, United States, [2]Institute of Metabolism and Systems Research, University of Birmingham, United Kingdom, [3]Departments of Orthopaedic Surgery and Molecular, Cell and Developmental Biology, UCLA, United States

Low serum concentrations of 25-hydroxyvitamin D (25D), not low levels of intra-cellularly-active hormone, 1,25-dihydroxyvitamin D (1,25D), are correlated to increased mortality and poor disease outcomes in humans. This observation indicates the importance of the linkage between substrate levels of inactive 25D and bioactivity in target cells through the functionality of CYP27B1- and CYP24A1-hydroxylases and vitamin D receptor (VDR) and the influence of factors that impinge upon their activity. An example of intracrine regulation is that of antimicrobial cathelicidin (CAMP) gene expression in human macrophages. Paired serum samples, obtained before and after vitamin D supplementation and restoration of 25D>30ng/ml, from age and sex-matched White (n=11), Black (n=11) or Hispanic (n=11) donors were used to culture non-autologous primary human adherent monocyte-macrophages. Total and free 25D-normalized serum from White, but not Black or Hispanic, subjects was associated with increased expression of CAMP (p<0.001). Thus, some 25D-independent factor(s) in serum may impose resistance to intracrine induction of CAMP in the face of normalized 25D levels. Considering that cells and platelets are absent in serum, we speculated resistance may reside in the exosome fraction of serum; exosomes are extracellular vesicles that contain non-organelle intracellular and membrane contents of its source cell. To explore this possibility, we employed chemical precipitation or ultracentrifugation to isolate exosomes from pooled human serum. The resultant exosome-containing pelleted material was re-suspended, cultured with adherent monocytes, and CAMP expression measured. Expression of CAMP was reduced while CYP27B1, VDR and TREM1 were increased. Given that increased CYP27B1 and VDR should increase CAMP expression, the observed CAMP reduction suggests the presence of a potent inhibitory component. After boiling, the bioactivity was lost revealing it to be either heat-labile protein(s) or intact exosomes. Because exosomes frequently co-purify with protein aggregates, we used sucrose density gradient to separate exosome-enriched (lower density) and protein-enriched (higher density) fractions. We found that the CAMP suppressive activity segregated with the protein-enriched fraction. These findings point to protein(s) co-migrating with isolated human serum exosomes that can inhibit 25D-dependent CAMP innate immune responses in human macrophages.

Allosteric or ectosteric inhibition of cathepsin K by an exosite inhibitor Simon Law*, Dieter Bromme. University of British Columbia, Canada

Cathepsin K (CatK) is the predominant mammalian bone-degrading protease and thus an ideal target for anti-osteoporotic drug development. NSC-13345 was previously characterized as an allosteric inhibitor of CatK binding at a site remote from the active site. However, crystallization was performed using a non-fully processed enzyme where the binding site was influenced by a remaining propeptide piece. Here we crystallyzed the fully processed and active protease with NSC-13345 and identified three simultaneous binding sites different from the putative allosteric site. In particular, one binding site was located in the S2-3' region of the enzyme without blocking the catalytic Cys-His diad. This binding site may explain the substrate selective inhibition of the hydrolysis of peptides and proteins by hindering the proper binding of a peptide chain C-terminally from the scissile bond. Larger substrates that occupy this region were selectively inhibited whereas substrates occupying only the Sx-S1' site were not affected. In addition, a second binding site of the inhibitor corresponded to a chondroitin sulfate-binding site that has been associated with the collagenase activity of CatK. This may contribute to the observed anticollagenase activity of the inhibitor. A third site appears to have no effect. The binding of NSC-13345 at all three sites does neither influence the geometry of the catalytic diad nor traditional substrate binding sites and thus excludes an allosteric mechanism. The previously described allosteric site was not observed and mutations of this site had no effect on any of the substrate hydrolyses. These findings suggest that NSC-13345 may function as a substrate selective ectosteric inhibitor for CatK.

SAT-0982

Pharmacokinetic Models for Bisphosphonate-Conjugated Drugs Jayesh Shah*[1], Frank H. Ebetino[2], Lianping Xing[3], Robert Boeckman[3], Shuting Sun[2], Parish Sedghizadeh[4], Michael T Yin[1], Suzanne Lentzsch[1], Graham Russell[5], Serge Cremers[1]. [1]Columbia University Medical Center, United States, [2]Biovinc, United States, [3]University of Rochester, United States, [4]University of Southern California, United States, [5]University of Oxford, United Kingdom

Introduction: Bisphosphonates (BPs) can be used to target other compounds to bone. New chemical linker strategies have enabled BP-conjugated agents that deliver the drug specifically to the skeleton, and not release the active compounds until the bone has been reached (Wang 2017, Sedghizadeh 2017). BP-conjugates are in development for various therapeutic classes which include antibiotics and anti-cancer drugs. For BPs, identification of an optimal dose regimen has been challenging. The optimal dose regimens for BP-conjugated drugs will also be a challenge, especially because of the difficulties in assessing the active compound at the bone. In a first effort to help find the right dose regimen for these compounds we developed PK models for BP-Ciprofloxacin(BP-Cipro)- and BP-Bortezomib(BP-Btz)-conjugated drugs which are able to simulate the active drugs at the bone, and might be useful for drug development.Methods: Compartmental PK models for BPs, Cipro and Btz in humans were derived from the literature (Cremers 2002, Forrest 1993, Hanley 2017). These models were merged to multi-compartmental PK-models for the BP-conjugates with SAAM-II PK software. Using these models serum, urine and bone concentrations (concs) of the BP conjugate, the free BP and the free Cipro and Btz were simulated during various dose regimens. Simulations were also performed using PK models for free Cipro and Btz.Results: Our simulations suggest that the PK of free Cipro and Btz is different when the drug is administered as conjugate. Serum and bone concs of the free drugs reach Cmax a few days rather than a few hrs after IV administration with tmax and Cmax determined by the hydrolysis rate of the free drug from the conjugate. Concs of free drug at the bone are projected higher than in serum. Importantly, the serum conc of the free drug over time parallels the bone conc over time as free drug seems to be released with depot like characteristics. The model also suggests that studies into the PK of BP-conjugated drugs need to be of sufficient length to fully characterize the long term release of the drugs from bone.Conclusion: We developed mechanism-based PK models for BP-conjugated drugs. These models which remain to be validated and further optimized can ultimately be used to estimate free drug at bone

surfaces over time. Expanding these models with bactericidal and anti-tumor effects will be useful to determine the optimal dose regimens for these most interesting new class of drugs.

SAT-0983

Calcilytic, the calcium-sensing receptor antagonist, enhances bone remodeling and increases bone mineral density without increasing urinary calcium excretion Bingzi Dong*[1], Itsuro Endo[2], Yukiyo Ohnishi[2], Zhengju Fu[1], Toshio Matsumoto[3], Yangang Wang[1]. [1]Department of Endocrinology and Metabolism, the Affiliated Hospital of Qingdao University, Qingdao, China, [2]Department of Hematology, Endocrinology and Metabolism, Tokushima University Graduate School of Medical Sciences, Japan, [3]Fujii Memorial Institute of Medical Sciences, Tokushima University, Japan

Calcium-sensing receptor (CaSR) belongs to the G-protein coupled receptor superfamily, locating on parathyroid gland, gastrointestinal tract, and kidney, and plays an important role in maintaining calcium hemostasis. CaSR is also expressed in cartilage, osteoblast and osteoclast in the bone, to regulate skeletal development and bone metabolism. Calcilytic is the antagonist of CaSR. It binds to the transmembrane domain, blocks downstream signaling, and disturbs the sensitivity of CaSR to extracellular calcium. Calcilytic mimicks hypocalcaemic environment, leading to the stimulation of endogenous parathyroid hormone (PTH) release. Thus, calcilytic may promote bone anabolic effect. In this study, we examined the effects of calcilytic (JTT-305) on bone metabolism, and compared them with calcium-vitamin D supplement and PTH(1-34) (teriparatide) administration. Calcilytic rapidly stimulated endogenous PTH release. Daily administration of calcilytic significantly increased cancellous and cortical bone mineral density (BMD) to the comparable level to teriparatide treatment. Bone histomorphometric analysis revealed that bone volume, trabecular thickness, and trabecular number was increased. Calcilytic also improved bone formation markers, serum bone-specific ALP and osteocalcin, and bone resorption markers, serum TRAP and urinary NTX. Both calcilytic and teriparatide accelerated bone turnover. Calcilytic administration slightly increased serum calcium level. However, compared with calcium-vitamin D supplement or teriparatide treatment, calcilytic did not increase urinary calcium excretion, which did not increase the risk of kidney stone formation. For the treatment and prevention of osteoporosis, calcium-vitamin D supplement is essential but not enough. Calcilytic increases BMD by stimulating endogenous PTH secretion, and shows comparable bone anabolic effect to teriparatide injection. Thus, calcilytic may become a promising anti-osteoporosis candidate.

Influence of Vitamin D Restriction on Bone Strength, Body Composition, and Muscle in Ovariectomized Rats Fed a High-fat Diet Kanae Nakaoka*, Asako Yamada, Seiko Noda, Masae Goseki-Sone. Japan Women's University, Japan

Vitamin D insufficiency is associated with a greater risk of osteoporosis and also influences skeletal muscle functions. Obesity is associated with metabolic syndrome, and low levels of serum 25-hydroxyvitamin D3 have been frequently observed in patients with obesity. Both obesity and vitamin D insufficiency have been recognized as major public health issues worldwide. The present study investigated the influences of vitamin D restriction on bone strength and body composition in ovariectomized (OVX) rats fed a high-fat diet.Twenty-four 13-week-old female rats were ovariectomized, and another six rats were sham-operated (Sham). The OVX rats were divided into four groups and fed experimental diets: a basic control diet (OVX-Cont.), a basic control diet with vitamin D restriction (OVX-DR), a high-fat diet (OVX-F), and a high-fat diet with vitamin D restriction (OVX-FDR). At 28 days after starting the experimental diets, the food intake, final body weight, and fat mass were significantly increased by OVX (p<0.001, p<0.01, and p<0.01, respectively) and the cancellous bone mineral contents (BMC) of the vertebrae and femur were significantly decreased by OVX (p<0.05 and p<0.01, respectively). The fat mass was significantly increased in the OVX-F and OVX-FDR groups compared with OVX-Cont. group (p<0.001 and p<0.01, respectively), while the muscle mass was significantly decreased in the OVX-F and OVX-FDR groups compared with OVX-Cont. group (p<0.05 and p<0.001, respectively). The BMC of the vertebrae and femur were significantly lower in the OVX-DR and OVX-FDR groups compared with OVX-Cont. group [OVX-DR (p<0.01 and p<0.05, respectively) and OVX-FDR (p<0.001 and p<0.05, respectively)]. In addition, the cortical bone of the vertebrae was significantly thinner in the OVX-FDR group compared with OVX-F group (p<0.05). Myogenin is one of the muscle-specific transcription factors. The levels of mRNA expression of myogenin of the soleus and gastrocnemius from the OVX-DR and OVX-FDR groups were reduced markedly compared with those from the OVX-Cont. group [OVX-DR (p<0.01 and p<0.05, respectively) and OVX-FDR (p<0.01, respectively)].In conclusion, we provide evidence that a high-fat diet with vitamin D deficiency markedly impairs bone and muscle metabolism using OVX rats. Further studies on vitamin D insufficiency in the regulation of muscle as well as bone metabolism would provide valuable data for the prevention of lifestyle-related disorders, including osteoporosis and sarcopenia.

Propranolol administration has a non-statistically significant positive effect on the osseointegration procedure of stainless steel implants. An experimental study in rats Marinos Karanassos*[1], Kyriakos Papavasiliou[2], Ioannis Mirisidis[3], Ioannis Margaritis[4], Ioannis Sarris[2], Pericles Papadopoulos[5], Dimosthenis Tsitouras[2], Dimitrios Tsatsalis[2], Fares Sayegh[2]. [1]2nd Dept. of Orthopaedics and Trauma Surgery, 424 General Military Hospital, Thessaloniki, Greece, [2]3rd Orthopaedic dept., Aristotle University of Thessaloniki, Papageorgiou General Hospital, Thessaloniki, Greece, [3]Dept. of Mechanical Engineering, University of Western Macedonia, Kozani, Greece, [4]Laboratory of Physiology, Faculty of Veterinary Medicine, School of Health Sciences, Aristotle University of Thessaloniki, Greece, [5]1st Orthopaedic dept., Aristotle University of Thessaloniki, Papanikolaou General Hospital, Thessaloniki, Greece

Purpose. Orthopaedic implants are widely used in everyday practice (especially in elderly patients), either in elective surgery or in trauma (osteoporotic or not).??-Blockers, apart from their current well-established indications, are considered as potential candidates of therapeutic drugs under investigation for enhancing fracture healing and treating osteoporosis. Fracture healing and orthopaedic implants' osseointegration procedure share common pathways, hence ??-Blockers administration may enhance the latter as well. Aim of this study was to assess the potentially positive effect of the administration of ??-Blocker on the osseointegration procedure of stainless steel orthopaedic implants.Methods. This experimental study (approved by our Institution's Ethical Committee) was performed in two groups (study, control), consisting of 15 adult (12-weeks old) male Wistar rats each. Their average weight was 340±20 gr and there was no difference as far as the weight was concerned between groups (t-test, p=0.989). In the proximal metaphysis of each tibia of all animals, a specially designed stainless steel screw was implanted under sedation on day 0. All animals followed the same pharmaceutical perioperative protocol, had unrestricted access to food and water and were exposed to the same period of light (12h) on a daily basis. Starting on the first postoperative day, study group animals received 2.5mg/kgr of propranolol daily intraperitoneally (Dociton Injektionslösung® 1mg/ml). Control group received saline. On day 29, all animals were euthanized, tibias were harvested and the implants' pullout strength and removal torque were assessed.Results. All animals completed the study period and all harvested tibias were suitable for evaluation. The weight of the animals of both groups increased in a statistically significant manner (study: p=0.002 Wilcoxon test, control: p=0.000 t-test). However, the difference in weight increase between groups was statistically non-significant (p=0.299, Mann-Whitney test). (See Table of Results for data concerning pullout strength and removal torque).Conclusions. Propranolol enhances the osseointegration of stainless steel orthopaedic implants, albeit in a non-statistically significant manner. Blocking of ??-adrenergic receptors in osteoblasts and stromal cells, leading to increased bone formation and decrease of bone resorption may be its mechanism of action.

Parameter	Units	Study Group	Control Group	P (student t-test, 95% CI)
Pullout strength	Newton	104.23 ± 21.28	90.76 ± 18.19	0,103
Torque	N/cm	5.398 ± 0.778	4.89 ± 0.715	0.091

SAT-0986

Intra-Articular Monosodium Iodoacetate Induced Knee Osteoarthritis: Effects on Bone as Measured by Micro-Computed Tomography in Rats Jukka Vaaraniemi*, Jukka Morko, Jaakko Lehtimaki, Zhiqi Peng, Jussi M Halleen. Pharmatest Services Ltd, Finland

Several experimental animal models have been developed for human osteoarthritis (OA) and used to study the preclinical efficacy of disease and symptom modifying OA drug candidates. One of these models is induced chemically by an intra-articular injection of monosodium iodoacetate (MIA) into rat knee. Intra-articular MIA disrupts chondrocyte glycolysis through the inhibition of glyceraldehyde-3-phosphate dehydrogenase resulting in chondrocyte death, joint damage, and OA symptoms. In this study, we characterized the effects of intra-articular MIA injection on bone by high-resolution micro-computed tomography (micro-CT) in the tibiofemoral and patellofemoral joints of young rats. Unilateral OA was induced by the injection of MIA at 2 mg into the knee joint of male Sprague-Dawley rats at the age of 6 weeks. Rats were terminated at 4 weeks after the MIA injection and their knee joints were fixed in 10% neutral buffered formalin. After the fixation, knee joints were scanned by high-resolution micro-CT using 8 μm image pixel size. After the scanning, the epiphyses of femur and tibia, the weight-bearing regions of femoral condyles and tibial plateau in medial and lateral compartments, and patella were segmented using a free-hand tool, and analyzed separately. The intra-articular MIA injection decreased bone volume (BV) slightly more in the entire epiphysis of femur than in the entire epiphysis of tibia, namely by 47% in femur and 44% in tibia. In the weight-bearing region, the amount of epiphyseal bone was decreased slightly more in the medial compartment than in the lateral compartment of MIA-injected knee. Namely, BV was decreased by 34% in the medial compartment and 29% in the lateral compartment of femoral condyles, and by 44% in the medial compartment and 40% in the lateral compartment of tibial plateau. These reductions in epiphyseal BV were associated with decreased number and thickness of individual trabeculae in epiphyseal marrow cavity. In patellofemoral joint, clear erosion was observed on articular surface without significant changes in the BV of entire patella. This study demonstrated that micro-CT is a

useful tool to measure MIA-induced changes in bone when testing the preclinical efficacy of disease modifying OA drug candidates in the rat MIA model of knee OA. The follow-up of treatment effects by in vivo micro-CT both on articular cartilage and bone would improve the analysis of preclinical efficacy in the rodent models of human OA.

SAT-0987

Effect of Age and Dietary Phosphorus Intake on Phosphorus Regulatory Hormones and Intestinal Phosphate Transporter Gene Expression Colby Vorland*[1], Loretta Aromeh[2], Pamela Lachcik[1], Sharon Moe[2], Neal Chen[2], Kathleen Hill Gallant[1]. [1]Department of Nutrition Science, Purdue University, United States, [2]Division of Nephrology, Department of Medicine, Indiana University School of Medicine, United States

We previously reported higher phosphorus (P) absorption efficiency in 10wk SD rats vs older rats and no effect of low P diet on net P absorption using an in situ ligated loop method (Vorland JBMR 31(S1)). To understand the mechanisms involved in these age-related changes, we evaluated the effects of age and dietary phosphorus (P) on P-regulating hormones and intestinal P transporter gene expression. N=72 male SD rats studied at 3 ages (10wk, 20wk, and 30wk of age) were fed diets of 0.6% Ca and 0.1% (LP), 0.6% (NP), or 1.2% (HP) P (n=8/group) for 14d before sacrifice. Intestinal P absorption was measured by jejunal ligated loop (5 μCi 33P in 0.5 mL of 0.1 mmol/L P transport buffer) over 30min prior to sacrifice. Jejunal and duodenal mucosal tissue and blood were collected. Gene expression of intestinal P transporters NaPi2b and Pit1 were measured by RT-PCR, plasma 1,25-dihydroxyvitamin D3 (1,25D) by EIA, and intact parathyroid hormone (iPTH), intact and c-terminal fibroblast growth factor 23 (iFGF23, cFGF23) by ELISA. Data were analyzed by 2-way ANOVA for age, diet and interaction effects, with Tukey's post-hoc tests.1,25D levels were significantly lower, and iFGF23 and iPTH levels were higher at 20 or 30wk compared with 10wk in all animals (all p<0.05). LP increased 1,25D, decreased both iFGF23 and cFGF23 (all p<0.01). There was an age x diet interaction only for iPTH (p<0.0001) where LP had lower iPTH vs NP and HP, but the magnitude was greatest in 10wk.10wk rats had higher jejunal NaPi2b mRNA than 20wk and 30wk rats (p=0.002 & p=0.02), but there was no effect of diet (p=0.14), consistent with our previously reported increased P absorption at 10wk versus 20wk and 30wk of age. LP diet increased duodenal NaPi2b mRNA expression, but only in 10wk (p=0.001). There were no significant effects for age or diet in Pit1 mRNA in the duodenum (p=0.50). In contrast to the NaPi2b with age, there was an increase in jejunal Pit1 mRNA expression at 30 weeks compared to 10wk and 20wk (p=0.002).These results show that higher P absorption observed in younger normal SD rats is due to higher 1,25D and lower PTH and FGF23, resulting in upregulation of NaPi2b. Overall, LP diet caused expected changes in P-regulating hormones, but only upregulated NaPi2b at 10wk and only in the duodenum, and had no effect on Pit1. This corresponds with the lack of effect of diet P level on intestinal P absorption assessed in the jejunum in these rats.

SAT-0988

Effects of selective estrogen receptor modulator and low-intensity aerobic exercise on bone and fat parameters in ovariectomized rats Yusuke Yuasa*, Naohisa Miyakoshi, Yuji Kasukawa, Itsuki Nagahata, Manabu Akagawa, Yuichi Ono, Chiaki Sato, Yoichi Shimada. Department of Orthopedic Surgery, Akita University Graduate School of Medicine, Japan

IntroductionEstrogen deficiency decreased bone mineral density (BMD) and dyslipidemia. The selective estrogen receptor modulator bazedoxifene (BZA) may inhibit both diseases. However, the effects of treatment with a combination of BZA and exercise are unclear. In this study, we examined the effects of BZA and exercise on bone and fat parameters in ovariectomized (OVX) rats.MethodsSixteen-week-old Sprague Dawleyfemale rats were OVX and randomized into the following 4 groups (n=6-9) after 8 weeks: (1) BZA group, 0.3 mg/kg/day BZA orally; (2) Ex group, exercised by treadmill at 12-15 m/min, 60 min/day, 5 days/week; (3) Combined (COMB)group, treated with BZA and exercised by treadmill; and (4) Control (CNT)group, treated with vehicle of BZA and no exercise. BZA administration and/or exercise were continued for 4 or 8 weeks. After sacrifice, BMD of the total femurand lumbar spine (L2-4, LS) as well as body fat percentage were measured by dual-energy x-ray absorptiometry (DXA). Bone histomorphometry was performed at the proximal tibia. Adipocyte volume per total bone marrow volume (AV/MV), number of adipocytes per unit area of marrow (N.A/MV), and volume of each adipocyte per number of adipocytes (AV/N.A) were evaluated in the bone marrow of the proximal tibia. Mechanical strength of the femoral shaft were measured using the three-point bending test.ResultsBMDof the LS was significantly higher in the BZA and COMB groups than in the Ex and CNT groups (p < 0.05) at 4 weeks. After 8 weeks of treatment, only the BMD of the LS in the COMB group was significantly higher than that in the Ex and CNT groups (p < 0.05). Body fat percentages were significantly lower in the BZA and COMB groups than in the CNT group (p < 0.05) at 4 and 8 weeks. AV/MV ratios were significantly lower in the Ex and COMB groups than in the CNT group (p < 0.05), and AV/N.A ratios were significantly lower in the Ex and COMB groups than in the BZA and CNT groups (p < 0.05) at 4 weeks. AV/MV and AV/N.A were significantly lower in the Ex, BZA, and COMB groups than in the CNT group (p < 0.01) at 8 weeks. Breaking times were significantly longer in the COMB groups than in the CNT group

(p < 0.05) at 4 and 8 weeks.ConclusionA combination of BZA and exercise improved BMD of the LS, body fat percentage, bone marrow adipocytes, and breaking time. Combination therapy with BZA and exercise has positive effects on BMD and fat metabolism in OVX rats.

Clinical features of Sternocostoclavicular Hyperostosis: a large Single Center Dutch Cohort Ashna Ramautar*, Natasha Appelman-Dijkstra, Shannon Lakerveld, Pieter Valkema, Marieke Snel, Marielle Schroijen, Liesbeth Winter, Neveen Hamdy. LUMC, Netherlands

Sternocostoclavicular hyperostosis (SCCH) is a rare inflammatory bone disorder due to a chronic sterile osteomyelitis of unknown origin, leading to hyperostosis and sclerosis of sternum, medial end of clavicles and first ribs. Other areas of the axial skeleton such as mandible and vertebrae may also be affected. We report the clinical characteristics of a large single centre Dutch cohort of 189 patients with an established diagnosis of SCCH on the basis of characteristic clinical, scintigraphic and radiological features.Data on gender, age at first symptoms and at diagnosis, clinical manifestations, shoulder girdle function, and disease-related incapacity for work, were retrieved from medical records.The cohort consisted of 189 patients, predominantly female (88%), with a median age of 37 years (range 17-70) at first symptom. Most common first symptoms were pain in 159 patients (85%), local inflammatory changes in 77 (41%), impairment of shoulder girdle function in 63 (34%), and bone swelling in the SCC region in 54 (29%). At time of diagnosis, which occurred after a mean delay of 5±5 years, main clinical manifestations were chronic pain of variable severity in the SCC region in 183(95%), bony swelling of affected areas of the anterior chest wall in 124(66%) and restricted shoulder girdle function in 81 patients(43%). 64 patients (35%) had palmoplantar pustulosis, and 47 (25%) had an autoimmune disease, mainly psoriasis (n=15, 8%). The most commonly affected sites were the medial end of the clavicles in 76% of patients, followed by medial end of first ribs in 64%. Mandible and vertebrae were less commonly affected. SCCH is a rare inflammatory bone disorder associated with variable degrees of disability leading to potential disease-related incapacity to work due to chronic pain

and impairment in shoulder girdle function. Initial symptoms may be elusive, and delayed diagnosis is common because of inability to identify the clinical features of the disorder. This may result in irreversible structural changes in the SCC region and potentially debilitating chronic symptoms. Early diagnosis and early institution of therapy may positively influence prognosis by preventing disease progression, although this remains to be established by long-term follow-up studies.

Joint Replacement Procedures in Individuals with Skeletal Dysplasias Kate Citron*, Sobiah Khan, Erin Carter, Mathias Bostrom, Mark Figgie, Cathleen Raggio. Hospital for Special Surgery, United States

INTRODUCTION: Skeletal dysplasias are a heterogeneous group of more than 400 genetic disorders characterized by abnormal growth and remodeling of cartilage and bone. Many individuals experience joint pain and limitation. Epiphyseal development is affected in many of these disorders,resulting in hindered endochondral ossification. Joint replacements are usually required much earlier and survival rate of the prosthesis is shorter than in individuals without these disorders. Underlying medical conditions, including cardiovascular and pulmonary issues, are common, as are other orthopaedic issues such as atlantoaxial instability, spinal deformity, and spinal stenosis. Use of BMI to predict failure is not reliable in this short-statured population.METHODS: This is an IRB–approved, retrospective chart review of 19 individuals (14 women and 5 men) with a confirmed diagnosis of a skeletal dysplasia who underwent joint replacement surgery. RESULTS: 19 individuals enrolled had 41 surgeries: 33 hip replacements, 4 knee replacements, and 4 shoulder replacements. The average age, height, weight, and BMI were 41.5 years, 126.0 cm, 56.6 kg, and 35.1, respectively. Average follow up was 5.9 years. 43.9% of surgeries were done on individuals with an underlying cardiovascular or pulmonary condition. All individuals had decreased pain and mobility after surgery. 14.6% of surgeries required revision. 19.5% of surgeries performed on 6 individuals had serious post-operative complications, including hematoma, pulmonary embolism, effusion secondary to staph infection, deep vein thrombosis, myocardial infarction and pneumonia. 7/8 of the surgeries with a serious complication were done on individuals with an underlying cardiovascular/pulmonary condition. No individuals died in surgery. DISCUSSION: Our study supports existing literature that have concluded that individuals with skeletal dysplasias have decreased pain and increased function after joint replacement. Short stature skews BMI. Based on our results BMI does not seem predictive of complication risk in this population. Pre-existing cardiovascular or pulmonary disorder as a better indication of complication risk, as 7/8 surgeries (88%) that resulted in serious complication were done on individuals with a pre-existing cardiovascular and/or pulmonary condition.
Figure 1. BMI of study participants with those with major complications in red.

SAT-1031

Iatrogenic Osteosclerosis in Osteogenesis Imperfecta Vandana Dhiman*[1], Anshita Aggarwal[2], Nirmal G Raj[3], Ruban Dhaliwal[4], Sanjay Kumar Bhadada[5], Naresh Sachdeva[3], Sudhaker D Rao[6]. [1]PhD student, India, [2]DM Resident, India, [3]Additional Professor, India, [4]Assistant Professor, United States, [5]Professor, India, [6]Professor, United States

Purpose: Bisphosphonates (BPs) are widely used fortreatment of osteogenesis imperfecta (OI).However, prolonged use may be associated with suppression of bone turnover, the exact molecular mechanism of which is poorly understood.Caspase-3 activity is necessary for osteoclast differentiation.The objective of this study was to evaluate the effect ofzoledronic acid (ZOL) on precursor osteoclasts by studying the caspase-3 activity.Methods: Total 15 children were enrolled in the study (n = 10 with OI,n=5 controls). Out of the 10 children with OI, six had OI type IV, two had type III and two had types I & II each. Five children with OI had received a cumulative dose of ZOL<30mgand the other five had received ≥30 mg. Serum bone turnover markers (P1NP,CTX) were measured in theserum

of all participants.Peripheral blood mononuclear cells were isolated from all participants andstudied for caspase-3 activity.Results:The mean age of study participants was 7 ±1.5 years. Radiographsshowed "zebra stripe sign" and densemetaphyses, suggestive of acquired osteosclerosis. Bone turnover markers (BTM)were suppressed in all OI patients compared to controls. Caspase-3 activity increasedin osteoclastsat higher doses of BPs (>30 mg).Conclusions: Overzealous use of ZOL in OI suppresses bone turnover markers (P1NP, CTX), causes osteosclerosis and increases expression of caspase-3 activity in osteoclasts which results in adynamicbones.

SAT-1032

Childhood Hypophosphatasia: Painful Bone Marrow Edema Mimicking Chronic Recurrent Multifocal Osteomyelitis Improved After Three Months of Asfotase Alfa Enzyme Replacement Therapy Gary S Gottesman*[1], Deborah Wenkert[1], William H Mcalister[2], Geetika Khanna[2], Karen Mack[1], Steven Mumm[2], Michael P Whyte[1]. [1]Shriners Hospital for Children - St. Louis, United States, [2]Washington University School of Medicine, United States

Hypophosphatasia (HPP) is the inborn-error-of-metabolism that features hypophosphatasemia, tooth loss, and impaired skeletal mineralization with varying expressivity. In 2009, we reported an unrelated boy and girl with childhood HPP and recurrent periarticular soft tissue swelling and pain, primarily at the distal forearms and ankles. Radiographic, histopathologic, and MRI findings, including bone marrow edema, mimicked chronic recurrent multifocal osteomyelitis (CRMO). The pathogenesis remained unknown. Herein, we report a teenage boy with childhood HPP and 7 episodes of recurrent wrist swelling and pain (5 episodes within the preceding 3 years). At age 9 years, he reported brief morning stiffness and intermittent leg pain treated with non-steroidal medications (NSAIDS). He had no fever or mucocutaneous or gastrointestinal symptoms. Each episode occurred with minor trauma causing rapid localized swelling and was associated with point tenderness. Conservative treatment with casting, for presumed Salter-Harris I growth plate fractures, improved the pain and swelling. The NSAIDS were usually taken twice weekly for pain. At 13 years of age, our review of his interval radiographs revealed slight worsening of the changes typical of HPP at his wrists and knees. We then explored the most recent episode with an MRI of his forearms and hands, which showed metadiaphyseal signal increases consistent with CRMO. Additionally, functional testing confirmed new gross motor deficits consistent with childhood HPP. Mutational analysis of ALPL identified a novel heterozygous ~65 base pair deletion 5' of exon 4 that removed the splice site. With a worsening clinical status during his pubertal growth spurt, we started asfotase alfa enzyme replacement therapy (ERT). Three months later, pain had resolved (off NSAIDs), and follow-up MRI showed significant improvement of the metadiaphyseal bone edema (Figure). C-reactive protein and erythrocyte sedimentation rate were normal at baseline and the follow-up. Procollagen type I amino-terminal peptide, elevated at baseline, fell 3.6-fold but was still increased; collagen carboxy-terminal telopeptide also elevated at baseline, had normalized. Autoinflammatory mechanisms are considered an etiology for CRMO. Our patient's response to ERT alone suggests that CRMO-like lesions in HPP reflect a metabolic consequence of the alkaline phosphatase deficiency.

Forearm MRI: Panel A: Baseline - increased metadiaphyseal signal in marrow cavities of the distal radius and ulna together with evidence of an inflammatory response in the surrounding tissue mimics CRMO.   Panel B: After 3 months of asfotase alfa therapy, there is markedly decreased signal intensity consistent with resolving CRMO-like abnormalities.

SAT-1033

A case report of the novel use of asfotase alfa to improve outcomes after spinal surgery for dystrophic scoliosis related to neurofibromatosis type 1 Tasma Harindhanavudhi*[1], Takashi Takahashi[1], Anna Petryk[2], David Polly[1]. [1]University of Minnesota, United States, [2]Alexion Pharmaceuticals, United States

Dystrophic scoliosis is a rare and serious skeletal manifestation in neurofibromatosis type 1 (NF1) patients. Dystrophic curves progress rapidly and require early fusion, often complicated by poor bone healing and lack of fusion (pseudoarthrosis). Due to poor bone quality, patients may experience loosening of the spinal instrumentation with rods displacement into the surrounding soft tissue leading to serious neurological complications. Poor bone quality in NF1 is multifactorial and caused by a reduction of bone formation, increased bone resorption, and poor bone mineralization due to accumulation of a mineralization inhibitor, inorganic pyrophosphate (PPi), and impaired osteoblast differentiation with reduced alkaline phosphatase expression. There is a need to develop effective medical approaches to improve surgical outcomes.Asfotase alfa (AA, STRENSIQ®) is a recombinant human alkaline phosphatase approved for the treatment of pediatric-onset hypophosphatasia (HPP). Subcutaneous administration of AA in HPP reduces serum PPi concentration and improves bone mineralization. In a mouse model of NF1, AA also improved bone mineralization and strength. Its use in humans with NF1 has not been previously reported.We describe a case of a 54-year-old woman with NF1 who underwent 3 spinal surgeries for advanced dystrophic scoliosis over the past 7 years, complicated by advanced dural ectasia and pseudoarthrosis. She continued to have progressive loosening of the spinal instrumentation, paresthesia of the thighs, and intractable back pain. A CT scan revealed a fracture of the left vertical rod at the L4 pedicle screw connection, left posterior iliac screw loosening and a periscrew fracture, necessitating the 4th spinal surgery.Given a high probability of failing, she received all available treatments, including intrasurgical bone morphogenetic proteins (BMPs) to enhance bone formation, zoledronic acid to inhibit bone resorption (5 mg IV at 3 months after surgery x1), and off-label AA to improve bone mineralization (2 mg/kg 3x/week s.c. injection from 7 to 13 months after surgery) without adverse events. A CT showed stable instrumented spinal fusion and healed fracture at the tip of the left posterior iliac screw without evidence of loosening 13 months after surgery.In conclusion, AA in combination with BMPs and a bisphosphonate resulted in solid arthrodesis and enhanced bone healing after spinal surgery in a patient with NF1-related dystrophic scoliosis.

SAT-1034

A novel TRPS1 mutation in a patient with tricho-rhino-phalangeal syndrome provides further support for the importance of this zinc-finger transcription factor in skeletal development Anara Karaca*[1], Lauren Toyomi Shumate[1], Monica Reyes[1], Isilay Taskaldiran[2], Tulay Omma[2], Nese Ersoz Gulcelik[3], Murat Bastepe[1]. [1]Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, United States, [2]Ankara Training and Research Hospital, Endocrinology, Turkey, [3]University of Health Sciences, Gulhane Training Hospital, Turkey

Brachydactyly type E (BDE), inherited as an autosomal dominant trait with variable expressivity, is shortening of one or more metacarpals or metatarsals and can often involve digits. Genetic aberrations in genes that are important during maturation of growth plate chondrocytes typically lead to BDE, including PTHLH, PRKAR1A, PDE4D, HOXD13, HDAC4, and TRPS1. Depending on the mutated gene, the patient may display additional features, such as hormone resistance, facial dysmorphism, and cognitive impairment.Herein we report two unrelated Turkish females with an autosomal dominant pattern of BDE. The first patient had severe BDE and short stature, while the second had relatively milder BDE with normal height. Neither patient showed evidence of hormone resistance or cognitive impairment. We screened the patients for PTHLH, PDE4D, and TRPS1 mutations by Sanger sequencing of exons and flanking intronic regions. In the first patient, we identified a novel heterozygous missense mutation in exon 6 (c.2783A>G, p. Tyr928Cys) of TRPS1. The second patient was found to have a previously described heterozygous nonsense mutation in exon 4 (c. 1870C>T, p. Arg624Ter) of the same gene.Mutations in TRPS1 cause a tricho-rhino-phalangeal syndrome (TRPS). Along with BDE, the hallmarks of the syndrome include sparse hair, a pear-shaped nose with bulbous tip, an underdeveloped alae nasi, and a long flat philtrum. These phenotypic features were largely present in our patients. While the nonsense mutation identified in the second patient is predicted to lead to nonsense-mediated decay and loss of protein, the novel Tyr928Cys variant is located in the GATA DNA-binding domain, which is critical for the function of TRPS1, a zinc-finger transcriptional repressor. Multiple other mutations have been previously identified in nearby residues of this domain. The Tyr928Cys variant is absent from the Genome Aggregation Database of control populations, and in silico tools (SIFT, MutationTaster, Polyphen-2) predict it to impact protein function. Therefore, this variant is likely pathogenic.Missense mutations, particularly within the GATA DNA-binding region, are associated with significantly more severe BDE and short stature than nonsense mutations. Thus, the novel mutation in our first patient explains her severe phenotype.Our findings emphasize the role of TRPS1 in skeletal development and highlight the GATA DNA-binding region with respect to phenotype-genotype correlation in patients with TRPS.

SAT-1035

Bruck Syndrome Variant Lacking Congenital Contractures Due To Novel Compound Heterozygous PLOD2 Mutations Steven Mumm*[1], Gary S. Gottesman[2], Philippe M. Campeau[3], Angela Nenninger[2], Margaret Huskey[1], Vinieth N. Bijanki[2], Deborah J. Veis[1], Aileen Barnes[4], Joan C. Marini[4], Deborah Wenkert[2], William H. Mcalister[5], Michael P. Whyte[2]. [1]Division of Bone and Mineral Diseases, Department of Internal Medicine, Washington University School of Medicine, United States, [2]Center for Metabolic Bone Disease and Molecular Research, Shriners Hospital for Children, United States, [3]Department of Pediatrics, University of Montreal, Canada, [4]National Institute of Child Health and Human Development, NIH, United States, [5]Mallinckrodt Institute of Radiology, Washington University School of Medicine at St. Louis Children's Hospital, United States

A 10-year-old girl was referred for an unidentified skeletal dysplasia featuring osteopenia with poorly-healing fragility fractures, short stature, Wormian bones in her skull, cleft soft palate and uvula, congenital fusion of cervical vertebrae, bell-shaped thorax, progressive scoliosis, restrictive and reactive pulmonary disease, blue sclera, and other dysmorphic features. Previously, chromosome 22q11 deletion analysis for velocardiofacial syndrome and COL1A1 and COL1A2 sequencing were negative. Iliac crest biopsy revealed low trabecular connectivity, abundant osteoid, and active bone formation featuring widely-spaced tetracycline labels consistent with osteogenesis imperfecta (OI). Alendronate treatment improved her bone density. Copy number microarray excluded a contiguous gene syndrome. Sanger sequencing of LRP5, PPIB, FKBP10, and IFITM5 was negative. Instead, exome sequencing revealed two novel missense variants in PLOD2 (exon 8, c.797G>T, p.Gly266Val; exon 12, c.1280A>G, p.Asn427Ser) which encodes procollagen-lysine, 2-oxoglutarate 5-dioxygenase 2 (lysyl hydroxylase 2, LH2). In ExAC, absence (Asn427Ser) and low frequency (Gly-266Val, 0.0000419) implicated both as mutations. The father carried the exon 8 mutation whereas the mother and sister carried the exon 12 defect, and all were well. Autosomal recessive (AR) PLOD2 mutations cause Bruck syndrome 2 (OMIM #609220) reported in at least 20 cases/15 families as a rare OI featuring congenital contractures of large joints, typically with pterygia, a feature not seen in our patient. Defective LH2 causes under-hydroxylated type I collagen telopeptides compromising crosslinking. Most PLOD2 missense mutations causing Bruck syndrome 2 are located in exons 17-19 (of 20 total) encoding the C-terminal domain having LH activity, but others are truncating defects (frameshift, splice site mutations) found throughout the gene. AR PLOD2 mutations causing mild or moderate OI without congenital contractures have been reported in only three cases. Our patient represents the fourth such patient. Her PLOD2 missense mutations are in the central domain of unknown function, and one (Gly266Val) is the most N-terminal missense defect to date. Hence, our patient's novel PLOD2 mutations underlie a distinctive skeletal phenotype. Atypical Bruck syndrome should be considered as a possibility in COL1A1 and COL1A2-negative OI cases

Prevalence of Hypophosphatasia in a Reference Hospital in Granada (Spain) Manuel Muñoz-Torres*[1], Cristina Garcia Fontana[2], Juan Miguel Villa Suarez [3], Francisco Andújar-Vera [2], José María Gómez Vida [4], Tomás De Haro [3], Beatriz García-Fontana García-Fontana [5]. [1]Endocrinology and Nutrition Unit. University Hospital San Cecilio. Department of Medicine. University of Granada. Biomedical Research Institute of Granada. (ibs GRANADA), Spain, [2]Biomedical Research Institute of Granada. (ibs GRANADA), Spain, [3]Clinical Analyses Unit. University Hospital San Cecilio., Spain, [4]Pediatric Unit. University Hospital San Cecilio, Spain, [5]Endocrinology and Nutrition Unit. University Hospital San Cecilio. Biomedical Research Institute of Granada. (ibs GRANADA).CIBERFES. ISCIII., Spain

Hypophosphatasia (HPP) is a rare, serious and potentially mortal genetic disease caused by one or several mutations in the gene coding for the alkaline phosphatase without tissue specificity (TNSALP). A low serum total alkaline phosphatase (ALP) level is the hallmark for the diagnosis of HPP. Objective: To assess the recognition of persistent low ALP levels in a tertiary care hospital in Granada (Spain) to identify the patients affected with HPP and to provide an appropriate management of this patients. Subjects & Methods: An assessment of ALP levels was performed in 78590 patients between 1st of January and 31st of December 2016 in the Biochemistry Unit of our hospital. The database was divided into adult population and pediatric population. Ninety-eight patients (66 adults and 32 children) had several serum ALP values persistently below the reference interval. Twenty-two patients were discarded because of potential causes of secondary HPP. Twenty-four potential HPP patients were contacted to fulfill a questionnaire about clinical manifestations HPP-related. Pyridoxal-5'-phosphate (PLP) was determined by high-performance liquid chromatography (HPLC) and sequencing TNSALP gene was performed. This project was approved by Ethical Committee from Granada. Results: 0.12% of the studied patients had persistently low value of ALP (65% females). Twenty-four were contacted. Ten of them had fractures, 4 had symptomatic chondrocalcinosis and 4 had dental abnormalities. From them, 11 patients (9 adults and 2 children) presented decreased ALP and increased PLP levels, of which, 7 adults had TNSALP mutations (4 corresponding to new variants not described previously). In conclusion our study shows that there are several omitted diagnostics of HPP in a tertiary care

hospital. From 78590 patients analyzed, 7 of them presented TNSALP mutation obtaining 2 new genetic variants. These data indicate an estimated prevalence of 9/100.000 in our area.

Asfotase Alfa: Interference with ALP-detection systems in immunoassays Isabelle Piec*, Beatrice Thompkins, William D. Fraser. University of East Anglia, United Kingdom

Asfotase alfa (AA, STRENSIQ®, Alexion Pharmaceuticals, Inc.) is the first FDA-Approved treatment for patients with hypophosphatasia, the result of a mutation in the tissue-nonspecific alkaline phosphatase (ALPL) gene. ALP continues to be used as the measuring/signalling system in routine assays for proteins, hormones and other small molecules, albeit less and less commonly. Because it contains the ALP active site, AA is able to catalyse the substrate as the antibody-conjugated ALP would within an assay. Therefore, AA present in a patient's sample may generate a false positive or a false negative assay result. We investigated whether the presence of AA within a sample induces interference in sandwich and competitive assays using plate based assays and on a routine automated analyser that use ALP or alternative detection systems. AA was added to samples at concentrations from 0.08-5 µg/mL. Manual ELISAs and COBAS6000 assays were tested. We observed no significant change in the absorbance of ALP measured using the RayBiotech assay for ALKP1, Normetanephrine (IBL) in urine samples (hydrolysed or not) and nor adrenaline (IBL) at any AA concentration. However, AA significantly cross-reacted with an oxytocin assay (ENZO, p<0.001), in a concentration dependant manner in non-extracted samples (false negative results). Recommended extraction of the samples for this assay is using a C18 column. While the ALP activity showed a significant (p<0.0001) AA concentration-dependant increase, the concentration of the analytes of interest did not change by more than 2.4% from the baseline value for assays run on the COBAS analyser (TSH, LH, FSH). Assays using a different detection system than ALP were not affected by the presence of AA in the samples. Most assays tested using ALP detection systems were sufficiently specific not to show interference with AA. Oxytocin needed to be extracted to demonstrate this specificity. The effects observed depended on the method of ALP detection used. The presence of AA must be taken into consideration when analysing blood samples using certain assay technology to avoid any risk of misinterpretation of false positive/negative results

Analyte	Assay type	Format	Manufacturer	Detection system	Interference
ALP	ELISA (Manual)	Enzyme activity	RayBiotech	HRP	YES
IL6		Sandwich	R&D systems	ALP/NADPH	No
Oxytocin		Competitive	IBL/ biosupply	ALP/PNPP	YES on non extracted samples

Hypophosphatasia: Clinical Presentation Jay R Shapiro*. Unifomed Services University of the Health Sciences, United States

Hypophosphatasia (HPP) is a rare metabolic bone disorder inherited in either an autosomal recessive or dominant form. Approximately 500 cases are recognized in the US although the actual incidence may be several fold that number. HPP is notable for marked variability in clinical expression. A low serum tissue non-specific alkaline phosphatase (TNSALP) level is the hallmark of HPP. However, the clinical expression of that defect is highly variable over the lifespan ranging from life threatening or severe in infants, to varied clinical expression ranging from asymptomatic to severe in adults. This report describes the clinical findings in 6 patients with HPP ages 16-62 years. (Table). DXA scores vary from normal to osteoporotic regardless of age. There is no apparent genotype/phenotype correlation. Serum Vit B6 levels are elevated in most individuals. In certain patients, treatmemt with asfotase alpha may improve bone density and function. Conclusion: HPP is rare disorder in which the diagnosis is based on low serum TNSALP levels, This abnormal test result may frequently be overlooked or misinterperted when a patient is evaluated for osteoporosis and/or a history of fractures.

SAT-1070

Utility of Optical Coherence Tomography in the Diagnosis of Optic Neuropathy in Fibrous Dysplasia of Bone Kristen S Pan *[1], Alison M Boyce[1], Edmond J Fitzgibbon[2], Michael T Collins[1], Janice S Lee[3]. [1]Skeletal Disorders and Mineral Homeostasis Section, National Institute of Dental and Craniofacial Research, National Institutes of Health, United States, [2]Laboratory of Sensorimotor Research, National Eye Institute, National Institutes of Health, United States, [3]Office of the Clinical Director, National Institute of Dental and Craniofacial Research, National Institutes of Health, United States

Fibrous dysplasia (FD) is an expansile bone disorder that frequently affects the cranial base, resulting in encasement of the optic canal. Rarely, compression and/or traction of the optic nerve may result in optic neuropathy (ON). Optic nerve decompression can prevent blindness; however, surgery may also lead to vision loss. Optical coherence tomography (OCT), an imaging modality to measure retinal nerve fiber layer (RNFL) thickness, has emerged as a potential diagnostic and prognostic tool for compressive ON and visual recovery. Some clinicians have advocated using OCT to identify patients who may benefit from optic nerve decompression. The purpose of this study was to evaluate the utility of OCT findings in the management of ON. 159 neuro-ophthalmologic exams and concurrent OCTs were reviewed from 81 subjects with FD. The diagnosis of ON was defined by abnormal results on 2 of the following tests: 1) best corrected visual acuity, 2) visual fields (Humphry Visual Field Analyzer), 3) color vision (16 Ishihara plates), 4) contrast sensitivity vision (Pelli Robson chart), and 5) fundus examination. The performance of each test, including RNFL thickness, in diagnosing ON was determined using receiver operator characteristic (ROC) analyses. The following area under the curve (AUC) values, listed best to worst, were generated (p<0.005, compared to AUC=0.5): visual field mean deviation=0.960 (SE 0.01, 95% CI 0.934–0.987), RNFL=0.958 (0.29, 0.90–1.00), contrast vision=0.865 (0.06, 0.75–0.98), best corrected visual acuity=0.819 (0.05, 0.73–0.91), color vision=0.684 (0.07, 0.56–0.81). Based on 95% CI, the AUC for visual field mean deviation, RNFL thickness, contrast vision, and best corrected visual acuity were not different. An RNFL thickness of ≤75 μm was the cutoff that yielded the greatest sensitivity and specificity (0.92 and 0.93) for diagnosing ON. These data, demonstrate that OCT measurement of RNFL thickness is not the best single test for diagnosing ON in FD. Also, RNFL thickness used as a single test for ON carries an unacceptably high false positive rate of 7%, even when optimized. Given the high morbidity of surgical ON decompression, we advocate that RNFL thickness be used in combination with additional testing, to confirm diagnosis of ON in patients with FD.
Figure 1. Receiver operator characteristic (ROC) analysis. Diagnostic performance of single tests for the detection of optic neuropathy, demonstrated by the area under the curve (AUC).

Microarray Expression Profile Analysis and its Clinical Implication for the Treatment of Fibrogenesis Imperfecta Ossium Sanjay Kumar Bhadada*[1], Vandana Dhiman[2], Ruban Dhaliwal[3], Anil Bhansali[1], Wim Van Hul[4], Sudhaker D Rao[5]. [1]Professor, India, [2]PhD student, India, [3]Assistant Professor, United States, [4]Professor, Belgium, [5]Professor, United States

Introduction: Fibrogenesis imperfecta ossium (FIO) is a rare bone disease manifested by generalized by bone pain, fragility fractures, progressive disability, and extensive mineralization defect on bone biopsy. The molecular pathogensis and treatment stratification of FIO is not clearly known. Hence, the present study is designed to study to identify putatively invloved genes in the pathogenesis of FIO based on their expression profile.Methods: Two siblings (males, 48 and 38 years) with FIO were recruited for differential gene expression and compared with healthy controls by using global microarray (Affymetrix Genechip. Human Primview) and then analyzed by Gene Spring GX 12.1 software. We explored the topological characteristics of differentially expressed genes in the context of the human interactome and furthurmore analyzed for pathway annotations using reactome and NCBI gene database.Results: We observed downregulation of Secreted protein and acidic rich in cystine (SPARC) and Bone gamma carboxyglutamic acid containing protein (BGLAP), the proteins encoding osteonectin and osteocalcin repectively. The mineralization defect and clinical finding of psuedo fractures can be explained by down regulation of genes involved in mineralization, namely Secreted phosphpprotein (SPP1) and BGLAP. We found upregulation of Osteoporosis associated transmembrane protein 1 (OSTM1) involved in osteoclastogenesis. Similarly, we also observed increase in collagen expression but a decrease in expression of signalling molecules such as Matrix metalloproteinases and Intercellular adhesion molecules (MMP1 and ICAM) involved in the assembly of these collagen fibrils leading to defective collagen synthesis.Conclusion: Altered gene expression profile in FIO suggests the molecular mechanisms underlying the defect in mineralization and collagen synthesis in this rare bone disorder. The effect on potential therapies on these genes can be studied to identify an effective treatment for FIO.

Whole-cell proteomic profiling of osteoclasts from a mouse model for craniometaphyseal dysplasia Jitendra Kanaujiya*[1], Jeremy Balsbaugh[2], Ernst Reichenberger[1], I-Ping Chen[1]. [1]University of Connecticut Health, United States, [2]University of Connecticut, United States

Craniometaphyseal dysplasia, a rare genetic disorder characterized by hyperostotic craniofacial bones and flaring metaphyses of long bones, can be inherited by autosomal dominant (AD) or autosomal recessive (AR) forms. We have previously reported a knock-in (KI) mouse model expressing a F377del mutation in ANK, one of the most common mutations for AD CMD. AnkKI/KI mice replicate many features of CMD. AnkKI/KI osteoclasts are smaller in size with disrupted actin rings and resorb less bone when cultured on bone chips. Here we examine via liquid chromatography-mass spectrometry (LCMS) and bioinformatics data mining whether proteomic profiles of AnkKI/KI and Ank+/+ osteoclasts differ, and whether the differentially expressed proteins in AnkKI/KI osteoclasts can be clustered in the context of cell regulatory pathways. Bone marrow-derived macrophage (BMM) cultures were derived from 8-week-old Ank+/+ and AnkKI/KI male mice. Cell lysates were prepared from BMMs treated with MCSF and RANKL for 2.5 days using a previously published Filter-Aided Sample Preparation (FASP) protocol. After proteolysis, peptides were labeled using a Duplex Tandem Mass Tag (TMT) kit (Thermo Fisher Scientific). Equimolar amounts of samples were pooled and analyzed on a Thermo Q Exactive HF mass spectrometer. All raw data were analyzed using Proteome Discoverer 2.2 software for peptide/protein identifications and TMT reporter ion-based abundance ratios. Further classification of these proteins was analyzed by gene ontology. LCMS data of Ank+/+ and Anknull/null BMMs were compared to Ank+/+ and AnkKI/KI data. Each LCMS biological replicate identified and quantified over 3000 proteins. Approximately 100 proteins were differentially expressed between Ank+/+ and AnkKI/KI osteoclasts (p<0.05) with about 90% targets down-regulated in Ank-KI/KI osteoclasts. These targets were mainly involved in cellular processes and metabolic processes with binding or catalytic activity. Three major clusters of these proteins emerged: 1) signaling pathways (Wnt, FGF, Toll-like receptors); 2) cytoskeleton regulation; 3) inflammation. While ANK is undetectable in Anknull/null BMMs, ANK was found significantly decreased in AnkKI/KI osteoclasts. Targets only being affected in AnkKI/KI but not

Anknull/null BMMs suggested unique effects of CMD-mutant ANK. These results will help us to understand CMD pathogenesis and to potentially develop therapeutic targets for CMD.

Lack of mature collagen-links is associated with osteomalacia in patients with X-linked hypophosphatemia Nadja Fratzl-Zelman*[1], Stamatia Rokidi[1], Stéphane Blouin[1], Pia Plasenzotti[2], Kamilla Nawrot-Wawrzyniak[1], Katharina Roetzer[3], Goekhan Uyanik[3], Gabriele Haeusler[4], Klaus Klaushofer[1], Peter Fratzl[5], Eleftherios Paschalis[1], Paul Roschger[1], Elisabeth Zwettler[1,6]. [1]Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK and AUVA Trauma Centre Meidling, 1st Medical Department Hanusch Hospital, Austria, [2]1st Medical Department, Hanusch-Hospital, Austria, [3]Center for Medical Genetics, Hanusch-Hospital, Austria, [4]Department of Pediatrics, Medical University of Vienna, Austria, [5]Max Planck Institute of Colloids and Interfaces, Department of Biomaterials, Germany, [6]Medical Directorate, Hanusch-Hospital, Austria

X-linked hypophosphatemia (XLH) is caused by inactivating mutations in the PHEX gene, resulting in decreased circulating phosphate, low 1,25-dihydroxyvitamin D levels and osteomalacia. Osteopontin, a potent inhibitor of mineralization normally degraded by PHEX, was reported to accumulate within the unmineralized XLH osteoid. However, it is not clear whether bone matrix is generally modified or less mineralized.We present four adult patients (33-41 years old) with short stature and elevated FGF23 serum levels. They were prescribed oral phosphate and calcitriol supplementation but according clinical records two of them had a discontinuous treatment adherence (DTA). Transiliac bone biopsies were obtained and evaluated by histomorphometry, Fourier-transform infrared imaging (FTIRI) and quantitative backscattered electron imaging (qBEI) to assess matrix composition and material properties.DTA patients had increased ALP and PTH levels, severe osteomalacia and twice the amount of mineralized trabecular bone volume as the compliant ones. In contrast, the latter had very low indices of bone formation and osteoid thickness mostly within normal range.FTIRI analysis of XLH osteoid showed that while divalent collagen cross-links were evident in all patients, the mature trivalent cross-link pyridinoline (Pyd) was present only in the compliant ones. Interestingly, also in the compliant patients, the few osteoid seams that were broader than 5µm did not have any measurable Pyd. However, Pyd was evident in the mineralized tissue in all patients. Unexpectedly, all osteoid independently of compliance exhibited considerable acidic lipid content.qBEI revealed that the average calcium content of the mineralized bone matrix was within normal range in all patients but the percentage of lowly and highly mineralized matrix were both increased, resulting in a broad heterogeneity in mineralizationIn summary, the increased trabecular bone volume in DTA along with the finding that bone mineralization was not decreased in any patient is consistent with densitometric reports of elevated trabecular BMD in XLH. Differentiation of osteoid based on width and therapy compliance indicate altered collagen maturation while the abundant acidic lipids may be contributing to the delayed mineralization. The data of this study highlight additionally to the already published osteopontin accumulation, further organic matrix alterations that may contribute to the delayed mineralization in XLH.

SAT-1087

Patient with resistant poliostotic Paget relapsed after discontinuing long time olpadronate oral treatment. A case-report of protracted drug exposition Claudia Gomez Acotto*[1], Susana Moggia[1], Emilio Roldán[2]. [1]Maimonides Univ., Argentina, [2]Scientific Direction Gador S.A., Argentina

Paget´s disease of bone, or osteitis deformans, is a focal disorder of bone metabolism that is characterized by an accelerated rate of bone remodeling, resulting in bone overgrowth. It is a rare skeletal disease that remais asymptomatic for many patients most of the time. The response to bisphosphonates is usually satisfactory, but some patients become resistant and request further therapies. In Argentina, sodium olpadronate, a di-methylated amino-bisphosphonate, is available for com passionate use, therefore it is accessible to patients not responding to any other approved compound. We describe a case of an 80-year-old patient diagnosed with poliostotic Paget 20 years before having high serum bone alkaline phosphate (bone ALP) 4,258 UI/mL. He was initially medicated with disodium pamidronate orally, referring mild pain at the sacrum area. Skeletal 99mTec scintigraphy bone scan of the total skeleton showed a hyper-uptake of the pelvis and lumbar vertebrae 2, 3 and 4. In the radiography, an osteo-dense image with an osteolytic lesion in the right iliac wing was observed. At the beginning of the treatment he received 90mg of intravenous pamidronate, after which serum ALP was reduced to 3,828 UI/mL. Then with a second infusion bone ALP decayed to 1,842 UI/mL, with an elevation of PTH. No further response was achieved. Afterwards, he received 200 mg oral olpadronate per day during 12 days (Under Ministry of Health compassionate use authorization). The subsequent month bone ALP was 1,848 UI/mL, but 4 months later it was 1,379 UI/mL. After 7 months bone ALP increased again, and he repeated the 200 mg/day oral olpadronate, but this time during 4 consecutive months, until bone ALP was reduced to 488 UI/mL. During the following years up to present, the patient repeated several schedules of oral olpadronate having bone ALP remained normal with borderline values. Finally, the intervention was halted 3 years ago, after being longterm asymptomatic. But, at present he has returned to our service with a scintigraphy study

informing a similar state to the original one, bone ALP relapse to 1,248 UI/mL. According to our knowledge, this patient is the person most protractedly treated with olpadronate, at least with several schedules from 12 to 120 days each, during 17 years. The therapy was satisfactory as well as the tolerability of oral olpadronate. It is important to highlight that unlike other bisphosphonates, olpadronate solubility is much greater and so its gastrointestinal tolerability, as well as its dosing regimens, can be more flexible. Olpadronate is currently under development for different indications and this case suggests efficacy and safety in a condition not responding well to other compounds. After approximately three years, the condition relapsed, and the patient requires medical intervention again, which shows severe nature of Paget's bone disease in some subjects.

SAT-1088

Exome sequencing identifies novel variants in GATA3 and MAFA genes associated with isolated hypoparathyroidism in Korean population Ji Hyun Lee*[1,2], Taekyeong Yoo[3], Jung Hee Kim[1], Hyung Jin Choi[4], Kyung Sil Chae[1], A Ram Hong[5], Sang Wan Kim[5], Murim Choi[3], Chan Soo Shin[1]. [1]Department of Internal Medicine, Seoul National University College of Medicine, Republic of Korea, [2]Department of Internal Medicine, VHS Medical Center, Republic of Korea, [3]Department of Biomedical Sciences, Seoul National University College of Medicine, Republic of Korea, [4]Department of Anatomy, Seoul National University College of Medicine, Republic of Korea, [5]Department of Internal Medicine, Seoul National University College of Medicine, Boramae Medical Center, Republic of Korea

INTRODUCTION Isolated hypoparathyroidism is a very rare disease and has been linked to several loci including CASR, GCM2, PTH and GATA3. Here, we report four rare novel variants in GATA3 and three in a novel candidate gene, MAFA (MAF bZIP transcription factor A) in isolated hypoparathyroidism. METHODS We enrolled 18 hypoparathyroidism patients without 22q11.2 deletion. Whole-exome sequencing was performed for all of them. We compared them with 1,055 healthy Korean individuals (Korean Variant Archive) using gene burden test. RESULTS The median age of onset was 33.5 years. Seizures were the most common symptom of onset, although there was one patient without symptom. Four of 7 patients presented with seizure and/or deafness had GATA3 variants. We identified three novel missense variants (p. Arg276Trp, p.Cys288Tyr, and p.Cys318Tyr), and a nonsense variant (p.Glu180*) in the GATA3 (novel variant burden P = 6.7 x 10-6). We also discovered a rare missense variant in the N-terminal region of MAFA (p.Glu114Lys). Two frameshift variants (p.His200fs and p.His201fs) were found in MAFA (novel variant burden P = 4.3 x 10-8) CONCLUSIONS Using whole exome sequencing, we identified four genetic variants in GATA3 and discovered three novel MAFA variants in patients with isolated hypoparathyroidism in Korean population. Identification of these novel types of GATA3 and MAFA variants has potential implications for better understanding of molecular pathogenesis of isolated hypoparathyroidism.

SAT-1089

Molecular Characterization of a Complex Mosaicism in Supernumerary Ring Chromosome 6 Involving Bone–Related Factors in a Proband Yang Lou*[1], Lauren Hurd[2], John A. Wixted[3], Jonathan A.R. Gordon[4], Katrina A. Conard[5], Micheal B. Bober[2], Jane B. Lian[6]. [1]University of Massachusetts Medical School, United States, [2]Department of Biomedical Research, Alfred I. duPont Hospital for Children, United States, [3]University of Massachusetts Medical Center School, United States, [4]Department of Biochemistry, University of Vermont, United States, [5]Department of Pathology, Alfred I. duPot Hospital for Children, United States, [6]Department of Biochemistry, University of Vermont Medical School, United States

Certain chromosomal translocations, t(16;17)(q22;p13) and rearrangement of 17p13 have been associated with primary recurrent aneurysmal bone cysts. Two unrelated patients were recently reported with a small supernumerary ring chromosome 6 [sSRC (6)], a rare chromosomal abnormality characterized by a broad clinical phenotype, including normal to severe developmental delay and congenital anomalies. We characterized the phenotype of a proband (designated sSMC6) with sSRC (6) and a unique skeletal phenotype associated with decreased bone mineral density and cortical thinning, severe osteopenia, pathologic fractures and multiple aneurysmal cysts appeared with woven dysplastic bone. The duplicated region encompasses a pure 18.2 Mb gain from 6p12.3-6q12. of chromosome 6 and contained several osteogenic regulatory factors including genes promoting faced and limb development (TRAP2B, 2D) endochondral, bone formation (BMP5), and cytokines (TNFRSF21, IL-17) related to bone resorption. Nearly contiguous to the chromosomal duplication is the bone essential transcription factor Runx2 transcription factor gene. that is implicated in the skeletal abnormalities of the proband. We find that isolated skin fibroblasts from an unaffected region of the patient express very high levels of the entire family of human Runx factors (Runx1 and Runx3) and these cells undergoes ex vivo osteoblast differentiation in normal MEM media (!0% FCS without osteogenic supplements) compared to biopsied fibroblasts from a control subject. Microarray analyses revealed high levels of Runx2 and Runx2 target

genes, ITGA1, ITGA3, TGFβ1, TGFβ3, VEGFA, EGF and the hypertrophic cartilage marker, COL10A compared to control cells. Our data suggest that genes expressed in the duplicated region of Chromosome 6 and including Runx2 can drive promiscuous osteogenic potency behavior in non-osteoblastic cells and that high RUNX 2 levels Runx2 may the signaling molecule for induction of the bone cyst formation as well as contributing to osteopenia in this novel pathological fracture syndrome.

Lithium-mediated effects on vertebral bone formation in mucopolysaccharidosis I dogs during postnatal growth Sun Peck*, Yian Khai Lau, Justin Bendigo, Megan Lin, Toren Arginteanu, Jessica Bagel, Patricia O'Donnell, Neil Malhotra, Peter Klein, Eileen Shore, Margret Casal, Lachlan Smith. University of Pennsylvania, United States

Mucopolysaccharidosis (MPS) I is a lysosomal storage disease characterized by deficient alpha-L-iduronidase activity that leads to abnormal accumulation of glycosaminoglycans (GAGs). MPS I patients present with severe spinal deformity, due in part to impaired vertebral bone formation during postnatal growth, which decreases quality of life and increases mortality. Current treatments fail to normalize bone formation in MPS I patients. Our previous work in other MPS subtypes with similar bone manifestations showed that impaired bone formation is associated with decreased Wnt signaling, an important regulator of endochondral ossification during postnatal growth. Thus, the objective of this study was to investigate whether treatment with lithium, a Wnt pathway agonist, could enhance bone formation during postnatal growth in MPS I using the naturally-occurring canine model.MPS I dogs (n=3) were treated orally with lithium carbonate daily from 14 days to 6 months-of-age. The lithium dose was adjusted twice a week based on animal weight and serum analyses in order to maintain serum lithium levels in the putative therapeutic range (0.5-1.5 mmol/L). At 6 months-of-age, serum bone alkaline phosphatase (BAP) was measured in lithium-treated dogs along with age-matched normal (control, n=4) and untreated MPS I (n=5) dogs. Thoracic vertebrae were excised postmortem and analyzed using μCT.While control dogs had significantly higher serum BAP than either the untreated or treated MPS I dogs, BAP levels were significantly higher in lithium-treated than untreated MPS I dogs (Fig A) suggesting increased osteoblast activity with treatment. While bone volume fraction, bone mineral density, and trabecular thickness were not significantly different in lithium-treated MPS I dogs compared to untreated MPS I dogs, connectivity density and trabecular number were significantly higher, and trabecular spacing was significantly lower, suggesting improvements in bone microarchitecture (Fig B, C). Importantly, these findings demonstrate that bone cells in MPS I are still able to respond to activating stimuli despite significant GAG storage and that Wnt pathway agonists may represent a potential therapeutic strategy for stimulating bone formation in MPS I. Ongoing work will establish the underlying cellular basis of improved bone formation with lithium treatment in MPS I dogs and if these alterations in trabecular bone architecture are associated with improved mechanical properties.
A. Serum bone-specific alkaline phosphatase (BAP) levels in control (n=4), MPS I (n=5), and MPS I lithium-treated (n=3) animals. *p<0.05; one-way ANOVA with Bonferroni post-hoc test. **B.** Micro-computed tomography (μCT) measurements of T12 vertebrae from control (representative image), MPS I (n=3), and MPS I lithium-treated animals (n=3). Associations between Educational Attainment and Operational Definitions of Sarcopenia: Data Spanning Six Years from the Tasmanian Older Adult Cohort Sharon Brennan-Olsen*[1,2], Sara Vogrin[1,2], Saliu Balogun[3], David Scott[4], Graeme Jones[3], Alan Hayes[5], Steven Phu[1], Gustavo Duque[1], Tania Winzenberg[3]. [1]University of Melbourne, Australia, [2]Australian Institute for Musculoskeletal Science, Australia, [3]University of Tasmania, Australia, [4]Monash University, Australia, [5]Victoria University, Australia

Introduction: A social gradient has been observed for osteoporosis and osteoporotic fracture. Such a gradient is also possible for sarcopenia; however, to date this is under-investigated. Thus, we aimed to examine the relationship of education with two operational definitions of sarcopenia, handgrip strength and appendicular lean mass (ALM), in community-dwelling older adults.Methods: ALM was measured by dual-energy X-ray absorptiometry (Hologic Corp., Massachusetts, USA) and handgrip strength measured by pneumatic dynamometer in 1,099 randomly recruited community-dwelling adults (51 % female; aged 50-80 years at baseline), and followed up twice: approximately 3 years, and 5 years after baseline. The highest level of education was self-reported at baseline and categorised according to having a tertiary education, completed secondary/high school, or not completed secondary/high school. Lifestyle variables were self-reported. Potential confounders of age, sex, smoking (ever, or current at baseline), protein intake (achieving the recommended dietary intake of 1.2g/kg/day), and history of stroke/diabetes were tested for inclusion in the final models. General estimating equations were performed separately for handgrip strength and ALM divided by body mass index (kg/m2) (ALMBMI).Results: Mean ALMBMI at baseline was 0.89±0.20 units. A decrease in ALMBMI was observed at first follow up (0.85±0.19) and an increase at second follow up (0.90±20). Similar trends were observed for handgrip strength (12±3 psi at baseline, 10±3 at 1st follow up and 11±4 at 2nd follow up). Those with a tertiary degree had ~0.03 units higher ALMBMI (95%CI 0.01-0.05) than those that did not complete secondary schooling (p=0.019); no other differences were observed between education groups. Similar associations were observed for handgrip strength, whereby those with a tertiary degree had ~0.5 psi greater handgrip strength compared to those with the lowest level of education (95%CI 0.1-0.9, p=0.017). Changes in ALMBMI and/or handgrip strength over time were not affected by education.Conclusions: Having a greater educational attainment were associated with small but potentially clinically significant differences in anthropometric and performance-based operational measures of sarcopenia across education groups. Further work is required to investigate change over time in these operational measures of sarcopenia, particularly in terms of other social factors such as occupation-related exposures.

SAT-1124

Sex- and age-related changes in body composition among population-based healthy Chinese in Taiwan Yi-Chien Lu*[1], Wing P. Chan[1], Ying Chin Lin[2], Ing-Jy Tseng[3]. [1]Department of Radiology, Wan Fang Hospital, Taipei Medical University, Taiwan, [2]Shuang Ho Hospital, Taipei Medical University, Taiwan., Taiwan, [3]School of Gerontology Health Management, College of Nursing, Taipei Medical University, Taiwan

Background: We aimed to evaluate sex- and age-related changes in BMD, lean mass (LM), and fat mass (FM) using population-based health examinations of healthy Chinese, which have not been previously described. Methods:A cross-sectional study was conducted using 2256 consecutive healthy Chinese in Taiwan (1169 women) who were aged 20-89 years. Lumbar spine and bilateral femoral neck BMDs and body composition were measured using DXA. Osteoporosis was diagnosed based on WHO classification criteria using the lowest T-score from these BMD measurements. The Asian Working Group for Sarcopenia (AWGS) recommends that the cutoff for DXA-derived low muscle mass (sarcopenia) is 5.4 kg/m2 and 7.0 kg/m2 in women and men, respectively. This value and the reference cutoff from our data were compared in determining the prevalence of sarcopenia. Obesity cutoffs of 38% and 25% body fat were used for women and men, respectively. Participants were

grouped by sex and age using 10-year intervals except for the oldest group aged 70 years or more. For comparison, 20 participants (16 women) from community-dwelling elderly were recruited for body composition examinations. Results: In women, peak BMD (1.18 g/cm2) was reached by age 30-39 years in the lumbar spine, but it was reached by age 20-29 years in the right and left femoral necks (0.93 g/cm2 and 0.92 g/cm2, respectively). In men, it was reached by age 20-29 in all three areas (1.17 g/cm2, 0.97 g/cm2, and 0.97 g/cm2, respectively). Peak mean LM was reached by age 20-29 years in both women (35.21 kg) and men (52.37 kg), whereas mean peak FM was reached in women by age 60-69 years (21.32 kg), but in men by age 20-29 years (22.04 kg). Distribution of the FM varied in the reverse way by sex and age. In men, both LM and FM declined with aging, but in women, less LM was lost than in men (-0.8% vs. -2.4% per 10-yr increment) and more fat, almost twice as much, was gained than in men (+4.7% vs. -4.4% per 10-yr increment). The prevalence of osteoporosis in individuals aged more than 50 years was 24% among women and 6% among men. The cutoffs for sarcopenia from our data in women and men were 4.25 kg/m2 and 6.10 kg/m2, respectively. In those considered to be elderly (age 65 or more), when the AWGS cutoff was compared to our cutoff, the prevalence of sarcopenia was greater in both sexes (23.5% vs. 0% in women and 33.0% vs. 7.0% in men), as was the prevalence of osteosarcopenia (10.6% vs. 0% in women and 10.0% vs. 2.0% in men). In comparison, using our reference value, the prevalence of sarcopenia in community-dwelling elderly people was 6% in women and 25% in men, respectively. Additionally, obesity occurred in 33.7% of the women and 59.9% of the men aged more than 60 years. Conclusion: This study provides the first data describing the body compositions of healthy adult Chinese in Taiwan. Further studies with larger sample size are needed to obtain valid cut-off points for our populations to improve diagnosis of sarcopenia.

SAT-1125

Association of bone mineral density and appendicular lean mass with fracture risk assessed by FRAX for postmenopausal women in the north part of China. Dr Dongmei*. The Second Affiliated hospital of Inner Mongolia Medical University, China

Objective: In order to prevent osteoporotic fractures, numerous studies have shown the positive effects of bone mineral density and appendicular lean mass among the middle-aged and elderly women in the community. However, the effect of osteoporotic fracture risk on the postmenopausal women with bone mineral density and appendicular lean mass has not yet been addressed. Methods: A cross-sectional study was conducted with 369 postmenopausal women at the Second Affiliated Hospital of Inner Mongolia Medical University living in the community of Hohhot, north part of China. Subjects were included for no drug treatment for osteopenia or osteoporosis. The whole body, spine and hip bone mineral density and body composition were measured by dual-energy x-ray absorptiometry, and the fracture risk assessment was calculated using WHO FRAX risk assessment for the risk of major fractures and the hip fracture. Results: There were 369 women with a mean age of 60.7 years (range, 50 to 86 years). The fracture risk calculated in 10 years by using the FRAX for hip fracture and major fracture was 0%~ 27% and 1.1%~28.8%, respectively. Appendicular lean mass was significantly and positively associated with hip fracture and major fracture rates at all site even after adjustment for aBMD. Conclusions: The results of this study suggest that the implementation of the risk of major fracture or of the hip for the prevention of osteoporosis has a significant association with muscle mass in postmenopausal Chinese women.

SAT-1126

Osteosarcopenia phenotype and frailty status by CHS and SOF Criteria
Alberto Frisoli*, Angela Paes, Sheila Inghan, Antonio Carlos De Camargo Carvalho. Federal University of Sao Paulo, Brazil

There is a robust physiological interaction between muscle and bone. Sarcopenia and osteoporosis are risk factors for fracture and frailty. Different concepts of frailty have sub-

stantial heterogeneity in the physical phenotype. We hypothesized that Osteosarcopenia is musculoskeletal manifestations of Frailty. To test our hypothesis we evaluate the association among Osteosarcopenia (OSP), Osteoporosis only (OPON) and Sarcopenia only (SARCON) with frailty by Fried criteria and SOF criteria. Method: Cross sectional analyzes of 386 patients from SARCOS study, an observational study of the epidemiology of Sarcopenia and Osteoporosis in older outpatients from Federal University of Sao Paulo-Brazil. All patients were underwent DXA of total body and bone sites. Frailty was defined by the SOF criterion (2-3 frailty, 1 pre frailty and 0 robust): Weight loss, Chair stand test; low energy; and by CHS criterion (≥3 frailty, 1-2 pre frailty and 0 robust): Weight loss, low walking speed, weakness, Low energy (adapted), exhaustion. Osteoporosis was diagnosed if BMD ≤ -2.5SD at any bone site. Sarcopenia was diagnosed only by low muscle mass according to FNIH criterion (appendicular muscle mass/ BMI < 0.567 women,; <0.723 men). Osteosarcopenia (OSP) was diagnosed if Osteoporosis and Sarcopenia were present.Results: The mean age was 78.22(7.16) yo, and 56.2% were women. OSP occurred in 14.8%, SARCON in 39.8% and OPON in 19.2% (p<0.001). Subjects with OSP were older (p<0.001), with lower fat index (p<0.001), muscle mass (p<0.001) and BMD at all bone sites (p<0.001) compared to others phenotypes. Frailty by CHS was diagnosed in 17.8%of the sample, and by SOF criterion, in 20.2%. Among subjects classified by CHS criterion, OSP occurred in 25.8% of frailty, 7.3% of pre frailty and 3.4% of robust; SARCON occurred in 41.9% of frailty, 40.6% of pre frailty and 34.5% of robust and OPON in 22.6% in frailty, 20.8% pre frailty and in 22.4% of robust (p=0.005). In the SOF Frailty phenotype, OSP occurred in 16.7% of frailty, 16.1% of pre frailty, and 12.7% of robust; SARCON in 38.5% of frailty, 39.9% of pre frailty and 40.0% of robust; OPON only in 21.8% of frailty, 17.5% of pre frailty and 19.4% of robust (p=0.937). In the adjusted (age/female) regression analysis for Frailty by CHS, OSP OR: 19.01 (CI 95%: 3.84-93.95; p<0.001), SARCON OR: 4.78 (CI 95%:1.25-18.20;p=0.022), and OPON OR: 3.35 (CI 95%:0.79-14.21; p=0.10). For Frailty by SOF criterion, OSP presented OR: 1.22 (CI 95%:0.54-2.79; p=0.624), SARCON OR: 1.19 (CI 95%:0.61-2.30; p=0.597) and OPON: 1.25 (CI 95%:0.59-2.67, p=0.552).Conclusion: There are significantly differences in the musculoskeletal manifestations of the frailty phenotypes according to the criterion chosen. Osteosarcopenia and sarcopenia only are associated with frailty by CHS, however, Osteosarcopenia seems to be more specific of the frailty status than other musculoskeletal phenotypes.

SAT-1127

Integrated Women's Health Programme (IWHP): A cross-sectional study of prevalence & correlates for sarcopenia in midlife Singaporean women
Win Pa Pa Thu*[1], Susan Jane Sinclair Logan[1], E.L Yong[1], Jane A. Cauley[2]. [1]Department of Obstetrics & Gynaecology, National University of Singapore, Singapore, [2]Department of Epidemiology, Graduate School of Public Health, University of Pittsburgh, United States

Purpose: Singapore is one of the countries in Asia facing a rapid demographic transition towards ageing. By 2030, one in five people will be 65 years and older. Sarcopenia, prevalent in older women, poses major healthcare and dependence costs due to associated disability. No previous studies on midlife Singaporean women exist. This study aimed to determine the prevalence of sarcopenia and evaluate its correlates.Method: Cross-sectional study enrolling 45-69 year old women attending gynaecology for "well women" checks & symptoms, excluding cancer. Assessments included standardised questionnaires- socio-demographics, menopausal, incontinence/prolapse, health/function, depression, anxiety, sleep, physical activity & sex; biophysical measures; short physical performance battery/grip strength & Dual-Energy X-ray Absorptiometry (DXA) scan. Sarcopenia was diagnosed using the Asian Working Group for Sarcopenia (AWGS) definition- handgrip strength <18 kg, gait speed ≤0.8 m/sec and skeletal muscle mass ≤ 5.4 kg/m2 using DXA. Analysis used SPSS Version 20.Results: Of 1201 women, the mean (SD) age was 56.3(6.2) years. Majority were Chinese (84%) followed by Malay (6%) & Indian (10%). Postmenopausal, peri-menopausal and pre-menopausal women constituted 72%, 16% and 12%, respectively. Diabetes and hypertension were the most commonly reported medical conditions affecting 10% and 29%, respectively. Mean (SD) body mass index was 24.1(4.4) kg/m2 with 5 % in underweight category (BMI < 18.5 kg/m2). Only 3% were alcohol consumers.A high prevalence of Sarcopenia (39%) was observed. Among these, 6% were also osteoporotic at either hip or spine. Chinese ethnicity (p<.001), menopausal status (p<.05), diabetes (p<.01), hypertension and BMI less than 18.5 (p<.001) were positively associated with sarcopenia. Adjusted multivariate logistic regression model reported that only women with BMI < 18.5 kg/m2 were more likely to have sarcopenia (Odd Ratio=4.16, 95% Confidence Interval = 1.99-8.71). The risk of sarcopenia attributable to this BMI category was 43%. Age, physical activity, number of falls in the last 12 months and consumption of alcohol did not influence the likelihood of sarcopenia.Conclusion: The 39% prevalence rate reported is higher than previously described and needs urgent confirmation in a community-based sample. Our findings suggest that a BMI cut-off (<18.5 kg/m2) could be used to screen sarcopenia in midlife Singaporean women attending gynaecology outpatients.

Exploration of an epidemiological association between air pollutant exposure and the development of T2DM. A systematic review. Marilena Marzia*. Freelance Professional Nutritionist, Italy

Background: Type 2 diabetes (T2DM) and obesity are known to be associated with high bone mass and increased fracture risk. Environmental and life-style factors are risk factors explaining the 80% of adverse effects for communicable and not communicable diseases, including osteoporosis, Paget's disease of bone, osteoarthritis, cancer, and T2DM. The exposure to climate and high level of air, water, food, and food packaging contamination can convey infective and not infective agents. Air pollution is hypothesized to be a risk factor for diabetes and obesity.Objective: This review is exploring the existence of an epidemiological association between air pollutant and the development of T2DM.Methods: Electronic literature databases have been systematically searched (through 2017) for studies reporting the association between air pollution exposure and the T2DM. Selected studies have been synthesized.Results: 39 articles have been included; those studies have been conducted in Europe, UK, Switzerland,USA, Canada, South Israel, Latin America Asia. 20 studies were longitudinal, 7 cross-sectional, 6 cross-over, 6 time-series.Conclusions: Existing evidence indicates positive association between air pollutant exposure (PM2.5, PM10, NO2, SO2, CO, O3) and the T2DM prevalence and incidence, the T2DM-related mortality and morbidity; research has been expanded in those countries with high level of air pollution and where obesity and diabetes prevalence are increasing; to better understand this association further high quality studies assessing dose-response are needed.

Distribution of Stress on the Distal Femur in Advanced Osteoarthritis Kwangkyoun Kim*. Konyang University, Republic of Korea

Purpose: The aim of this study is to analyse regional differences of the stress distribution on the distal femur in the advanced osteoarthritis.Design:Distal femur specimens with primary OA were obtained from ten donors composed of 10 women cadaver with OA (mean age of 65 years, ranging from 53 to 79). As controls, distal femur without OA was obtained from age and gender matched cadavers consisting of 10 women (mean age of 67 years, ranging from 58 to 81). Articular surface of distal femur was divided with anterior, middle, posterior regions on each condyle. Mechanical property and microstructure of regions were assessed with micro-CT and finite element model analysis.Results: Table 1 shows the summary of the mechanical and microstructural measures (median, interquartile range) on the 6 regions of OA and control groups. In the control group, there was regional difference of stress distribution among 6 regions on the distal femur(p=0.037), but there was no regional difference of stress distribution among 6 regions on the distal femur in the advanced osteoarthritis group (p=0.179). There was significant regional difference in BV/TV, SMI, Tb.Th, Tb.Sp, Tb.N and DOA in the control group. In the advanced OA group, BV/TV, SMI and Tb.Th showed no regional difference (p=0.132, p=0.136, 0.712), but there was significant regional difference in Tb.Sp, Tb.N and DOA (p=0.003, p=0.009, p=0.000).Conclusion: Microstructural and mechanical properties of the distal femur were changed according to the progression of osteoarthritis. No regional differences in stress distribution were detected in advanced OA. Altered loading patterns, bone remodeling and chemical composition affect changes in stress distribution.

Table 1. Summary of the mechanical and microstructural measures (median, interquartile range) on the 6 regions of OA and control groups.

Atypical Femur Fractures: Influence of the Femoral Neck Shaft Angle and Lateral Bowing on Maximum Principal Strains within the Femur Michael Reimeringer*[1], Natalia Nuno[1], Suzanne Morin[2]. [1]Laboratoire de recherche en imagerie et orthopédie, École de technologie superieure, Canada, [2]Department of Medicine, McGill University, Canada

Purpose: The etiology of atypical femur fractures (AFF) is still incompletely understood. In addition to prolonged bisphosphonates use, specific femur geometry parameters such as lateral bowing (LB) and neck shaft angle (FNSA) have been associated with increased risk of AFF. Using finite element analysis (FEA), we aimed to determine the influence of the FNSA and LB on femur peak maximum principal strain (MPS) to better understand the impact of these parameters in the pathogenesis of AFF.Methods: A composite femur, Sawbones® medium size geometry, was chosen as a reference model with LB (-0.7°) and FNSA (126.5°). Based on this geometry, a parametric 3D model was developed on which we modified LB from -20.7° (curve outward in the coronal plane) to +9.7° (curve inward) and FNSA from 106.5° (varus) to 146.5° (valgus). With increments of 10° for each parameter, we obtained a total of 20 different configurations. All 3D models were transferred into Ansys Workbench to generate a mesh with a size of 3mm using second order tetrahedral elements. All material properties were defined as isotropic elastic homogeneous. FEA was carried out for the static loading conditions simulating walking. Peak MPS were extracted from the regions immediately under the lesser trochanter to just proximal of the supracondylar flare on the lateral cortex.Results: Figure 1 demonstrates the peak MPS as a function of FNSA and of LB. For the reference model (FNSA=126.5° and LB=-0.7°), the peak MPS is 4004με. The peak MPS increased to 4175με (+4%) and 4272με (+7%) as the FNSA was varied to 116.5° and to 106.5°, respectively. The peak MPS decreased to 3696με (-8%) and 3327με (-17%) as the FNSA was increased to 136.5° and to 146.5°, respectively. On the other hand, the peak MPS increased to 4982με (+24%) and 5822με (+45%) when the LB was varied to -10.7° and -20.7°, respectively. The peak MPS decreased to 3085με (-23%) when the LB was increased to 9.7°. Overall, for each FNSA variation, peak MPS follows the same trends when LB was modified. Peak MPS were always located on the lateral cortex in the middle of the diaphysis.Conclusion: Peak MPS are highest in the lateral diaphysis of femurs that exhibit a FNSA lower than 126.5° (in varus) and lateral bowing (10° or more). These configurations could favor the formation of microcracks and increase the risk of AFF. Among the 2 parameters evaluated, LB appears to have the most impact on peak MPS within the femoral diaphysis.

Strength of Vertebral Bodies with Metastatic Lesions Can be Assessed by Finite Element Analysis Marc Stadelmann*[1], Christopher Lenherr[1], Benjamin Voumard[1], Ghislain Maquer[1], Jasmin Wandel[2], Ron Alkalay[3], Philippe Zysset[1]. [1]University of Bern, Switzerland, [2]Bern University of Applied Sciences, Switzerland, [3]Harvard Medical School, United States

Introduction: Vertebral fractures become a clinical concern in the management of cancer patients with metastatic spine disease. Little is known about the material properties of bone tissue in the vicinity of metastatic lesions. In addition, clinical grading scales were shown to have limited sensitivity in estimating fracture risk of metastatic vertebrae. The aim of this study is to assess the mechanical competence of metastatic bone tissue by nanoindentation and establish if the finite element (FE) method used for healthy bones can be applied to estimate the strength of metastatic vertebrae.Materials and methods: Fifty-nine vertebral bodies including lytic, blastic or mixed metastatic lesions due to various primary tumors were obtained from 11 donor spines. Parallel sections from fourteen vertebrae were infiltrated with PMMA and tested by nanoindentation. Forty-five metastatic vertebral sections were scanned with uCT and compressed axially to failure with an established protocol [1]. After conversion of uCT into QCT images, non-linear, homogenized FE analysis simulated the axial compressive test and computed vertebral strength (maximal force).Results: Blastic lesions showed significantly lower indentation moduli (-5.1%, p<0.001) compared to normal

trabecular tissue. No significant differences in any indentation properties between lytic and normal trabecular tissue were found (p>0.05). As shown in the figure, vertebral strength computed by FE analysis correlated linearly with the experimental values (r=0.883). The linear regression parameters obtained for metastatic vertebrae were not significantly different from those reported in [2] for healthy vertebrae (p>0.05) and the adjusted coefficients of determination were comparable (r2=0.779 vs r2=0.768).Discussions: The small indentation modulus difference observed between blastic and normal bone may be attributed to the woven nature of the blastic tissue in comparison to the lamellar organization of normal tissue. The bone tissue surrounding lytic lesions does not seem to be altered. Despite the lack of patient history in this ex vivo study, the results suggest that the FE method developed in osteoporosis research may also be used in the estimation of fracture risk in vertebrae with metastatic lesions. However, the influence of radiotherapy on vertebral biomechanics needs to be further investigated.We acknowledge funding from grant #165510, SNF and grant #R21AR066916, NIAMS/NIH.[1] Dall'Ara et al., J Biomech, 2010. Sleep Duration and Timing Predicts Bone Mineral Density Among Adolescents Jonathan Mitchell*[1], David Dinges[2], Knashawn Morales[2], Nicholas Huffnagle[1], Struan Grant[1], Babette Zemel[1]. [1]Children's Hospital of Philadelphia, United States, [2]University of Pennsylvania, United States

In adults, inverted U-shaped associations between sleep duration and areal bone mineral density (aBMD) have been observed and this may be a consequence of circadian misalignment. It is not known if this association replicates in the pediatric setting when bone is being accrued. We aimed to determine if sleep duration and sleep timing are associated with aBMD among 8thgraders. Our sample comprised 102 adolescents enrolled in the Sleep and Growth Study (13-14y, 54% female, 72% white). From dual energy X-ray absorptiometry scans, sex and age-specific aBMD Z-scores were calculated for total hip, femoral neck, and spine. We also calculated total body less head (TBLH) bone mineral content (BMC) Z-scores. Sleep patterns were objectively estimated over a 14-day period using wrist actigraphy. Multiple linear regression was used to test for the associations between the sleep exposures with each bone Z-score, with quadratic sleep variables included to assess for inverted U-shaped associations. All models were adjusted for sex, race, body mass index Z-score, dietary calcium, physical activity and pubertal stage.Nighttime sleep duration averaged 7.85 (SD: 0.66) hours. Sleep onset timing averaged -0.64 (SD:0.86) hours from midnight (i.e., 23:22). The average bone Z-scores for TBLH, total hip, femoral neck and spine were 0.62 (SD:0.84), 0.18 (SD:1.18), -0.10 (SD:1.12) and 0.18 (SD:1.04). We observed inverted U-shaped associations between nighttime TST and each bone Z-score (Figure 1: panel 1A-D). For example, 8 hours of nighttime sleep predicted TBLH Z-score to be 0.71 (95%CI: 0.57, 0.85). This was 0.79 (95%CI: 0.14, 1.43) Z-score units higher than the 6-hour prediction, and 0.66 (95%CI: -0.03, 1.36) Z-score units higher than the 9.5-hour prediction. We also observed inverted U-shaped associations between sleep onset timing and each bone Z-score (Figure 1; panel 2A-D). For example, 23:00 sleep onset predicted TBLH-BMC Z-score to be 0.76 (95%CI: 0.61, 0.91). This was 0.61 (95%CI: 0.18, 1.04) Z-score units higher than the 1:00 sleep onset prediction. Shorter and longer sleep durations predicted lower bone Z-scores compared to moderate sleep duration among adolescents. Whereas, earlier-to-moderate timing of sleep onset predicted higher bone Z-scores, compared to later timing of onset. Follow-up investigation is needed to fully understand sleep patterns in early life and their contribution to bone accretion and risk of later life osteoporosis.

Rescuing age-associated decline in muscle mass by inhibition of the receptor for advanced glycosylation end products, RAGE Alyson Essex*[1,2], Hannah Davis [1,2], Fabrizio Pin[2,3], Lilian Plotkin[1,2,4], Andrea Bonetto[1,2,3]. [1]Department of Anatomy & Cell Biology, Indiana University School of Medicine, [2]Indiana Center for Musculoskeletal Health, United States, [3]Department of Surgery, Indiana University School of Medicine, [4]Roudebush Veterans Administration Medical Center, United States

RAGE inhibition by treatment with Azeliragon (Az), a small molecule RAGE inhibitor developed as a therapeutic for Alzheimer's Disease, suppresses bone turnover with no net effect on architecture or mechanical properties in young 5-month old (mo) and aged 16mo C57BL/6 mice. Interestingly, these studies found that treatment with 110 μg/d Az for 28 days increases lean body mass and skeletal muscle weight in aged mice. Consistent with the previously reported Az-induced decreased mRNA expression of the E3-ubiquitin ligase atrogin-1, our studies now show that, when compared to 5mo vehicle-treated young mice, Az also prevented the age-associated increase in total protein ubiquitination. In addition to restoring the expression of the myogenesis marker myoD in aged mice to the young-vehicle treated values, as previously described. Az reversed several age-induced metabolic changes in skeletal muscle including reduced levels of the glucose transporters (GLUT1-4) and glycolysis-associated enzymes (PGK1 and LDHA). Additionally, Az increased protein levels of OPA1 and PGC1α, associated with mitochondrial inner membrane cisternae fusion and biogenesis respectively. Concurrently, Az also rescued the age-associated decrease in the levels of mitofusin-2, implicated in the fusion of mitochondrial outer membranes, and of SOD-1, an enzyme endowed with antioxidant properties. Furthermore, in studies aiming to clarify whether Az treatment rescues the decrease in muscle mass with aging through a systemic effect rather than a direct action on muscle cells, differentiated murine C2C12 myotubes exposed to 5% serum from aged mice displayed fiber atrophy when compared to cells treated with serum from young vehicle-treated counterparts, whereas serum from Az-treated aged mice did not promote atrophic effects on the myotubes. Interestingly, we found no discernable changes in diameter in C2C12 myotube cultures treated with 1nM Az for 48 hours. Altogether, our observations suggest that Az rescues aging-associated muscle wasting by counteracting skeletal muscle hypercatabolism and by restoring mitochondrial homeostasis and metabolism, thereby highlighting a novel potential therapeutic use for this drug. Future studies will aim to elucidate the Az-target cell(s) and the molecular mediators of the skeletal muscle protective effect of the drug in aging.

Bone metastatic growth was not inhibited by anti-PD-1 blockage in a humanized mouse model of triple-negative breast cancer – difference in responses between primary and bone metastatic tumors Tiina E Kähkönen*[1], Mari I Suominen[1], Jenni Mäki-Jouppila[1], Jussi M Halleen[1], Teppo Haapaniemi[2], Azusa Tanaka[3], Michael Seiler[3], Jenni Bernoulli[1]. [1]Pharmatest Services, Finland, [2]BioSiteHisto Ltd, Finland, [3]Taconic Biosciences, United States

Immuno-oncology (IO) has provided promising results in cancer treatment. Triple-negative breast cancer (TNBC) tumors attract immune cells, including programmed cell death 1 (PD-1) positive tumor-infiltrating lymphocytes (TILs), and high number of TILs is linked to improved survival in patients. High frequency of bone metastases is typical in TNBC. As immune regulation is different in bone than in other organs it is essential to study the efficacy of IO therapies in the metastatic bone microenvironment. The aim of this study was to assess

the efficacy of anti-PD-1 therapy (pembrolizumab, Keytruda®) in TNBC cells growing in bone of humanized mice.MDA-MB-231(SA)-luc human TNBC cells were inoculated into tibia bone marrow of female huNOG mice (Taconic Biosciences). Treatment with pembrolizumab or human IgG4 isotype control (5 mg/kg, i.p., Q5D, n=8) was started 3 days after the inoculations and continued for 18 days. Tumor-induced bone changes were monitored by X-ray imaging. At sacrifice, tumor–bearing and healthy tibias were collected for ex vivo analysis by micro-computed tomography (μCT) and histological and immunohistochemical characterization of tumors, TILs and PD-1 expression in tumors. A group of mice inoculated orthotopically with the same cells served as a positive control for pembrolizumab treatment. Pembrolizumab had no effect in regulation of bone metastatic growth in humanized mice. No changes were observed in tumor area at endpoint, in the development of osteolytic lesions, or in any of the bone parameters studied. Also, no changes were observed in bone parameters of the healthy tibias of pembrolizumab treated mice. CD4+ cells were dominant in tumors growing in bone, and CD8 and PD-1 positive cells were rarely observed. On the contrary, orthotopic tumors responded to pembrolizumab treatment, as expected. In these tumors, CD8 and PD-1 positive TILs were observed in moderate to high quantity.Bone metastatic growth was not inhibited by the PD-1 blockage in this study, which could be explained by low infiltration of cytotoxic cells. Bone marrow has a unique microenvironment and immune cell compartment compared to any other organ, and the immune cells in bone are involved in immune surveillance and favor tumor cells to become immune evasive. Demonstration of efficacy of IO compounds in preclinical metastasis models would be important before entering clinical phases in IO drug development.

Exosomal release of L-plastin by breast cancer cells facilitates metastatic bone osteolysis Kerstin Tiedemann*[1], Gulzhakhan Sadvakassova[1], Nicolas Mikolajewicz[1], Michal Juhas[1], Zarina Sabirova[1], Sebastien Tabaries[1], Jan Gettemans[2], Peter M. Siegel[1], Svetlana V. Komarova[1]. [1]McGill University, Canada, [2]Gent University, Belgium

Breast and prostate carcinoma often metastasize to bone, where excessive bone degradation is mediated by bone resorbing osteoclasts. Previously we demonstrated that breast and prostate cancer cells secrete soluble factors that promote osteoclastogenesis and using proteomics identified peroxiredoxin-4 as a mediator of these effects. Here we report identification and validation of L-plastin as an osteoclastogenic factor secreted by breast cancer. Using immunoblotting and mass spectrometry, L-plastin was detected in MDA-MB-231 conditioned medium (CM). When L-plastin in MDA-MB-231 cells was silenced using siRNA, the CM ability to induce osteoclast formation was significantly reduced. L-plastin, but not PRDX4, was detected in cancer-derived exosomes, and inhibition of exosomal release significantly decreased osteoclastogenic capacity of MDA-MB-231 CM. When added to osteoclast precursors primed with RANKL for 2 days, recombinant L-plastin induced calcium oscillations, NFATc1 nuclear translocation, and osteoclastogenesis to the levels similar to continuous treatment with RANKL. Using shRNA, we generated MDA-MB-231 cells lacking L-plastin, PRDX4 or both; injected the parental and clonal cancer cells intra-tibial in CD-1 immunodeficient mice; and examined bone osteolysis two weeks after the injection. Micro-CT and histomorphometric analysis of the mouse tibial metaphyseal area demonstrated the trend for reduction in osteolysis when MDA-MB-231 cells lacking L-plastin or PRDX4 were injected, and prevention of the osteolysis when MDA-MB-231 cells lacking both L-plastin and PRDX4 were injected. A meta-analysis demonstrated an increase in L-plastin mRNA expression in carcinoma and metastatic breast tissues. This study demonstrates that secreted L-plastin and PRDX4 mediate osteoclast activation by human breast cancer cells, and may represent viable targets for the development of novel therapies for prevention of osteolytic bone metastasis.

1,25(OH)D3 abrogates palmitic acid-induced lipotoxicity in normal human osteoblasts in vitro Ahmed Al Saedi*, Damian Myers, Steven Phu, Gustavo Duque. Australian Institute for Musculoskeletal Science (AIMSS), The University of Melbourne and Western Health, St. Albans, VIC, Australia

Introduction: Bone loss begins in the third decade of life and involves decreased bone formation associated with a progressive reduction in osteoblast (Ob) survival, function and number. With ageing, MSC number and differentiation potential decrease due to reduced capacity to transform into Ob, leading instead to increased adipogenesis and lipid accumulation in the bone marrow of osteoporotic bones. Adipocytes produce palmitic acid (PA), a fatty acid (FA) known to be toxic to Ob in vitro. Potential mechanisms include induction of dysfunctional autophagy and reduced differentiation. Vitamin D (1,25(OH)2D3) induces osteoblastogenesis and has an anti-apoptotic effect on Obs. We therefore hypothesised that 1,25(OH)2D3might rescue Obs from PA-induced lipotoxicity in vitro.Methods: Initially we compared the capacity of human Obs (Lonza, CC2538) to differentiate and mineralize in the presence of PA or 1,25(OH)2D3 or in combination. Cell survival was assessed using a 3-(-2,5-diphenylterazolium bromide (MTT) assay. Autophagy was assessed via LC3-II expression, confocal microscopy, and monitoring of live autophagosomes at different time points. RT-PCR was performed to test the palmitoylation process in the presence of PA and 1,25(OH)2D3.Results: As expected, PA decreased mineralisation, differentiation and

affected autophagy in human Obs. In contrast, cells treated with a combination of PA and 1,25(OH)2D3recovered their capacity to differentiate and mineralise. 1,25(OH)2D3 increases Ob survival (P<0.01) in the presence of PA. Furthermore, 1,25(OH)2D3 inhibited the autophagy process which was induced by PA at 24 and 48 hrsConclusion: This study has identified potential mechanisms to explain how 1,25(OH)2D3might abrogate PA-induced lipotoxicity, including normalization of mineralization, survival and autophagy in Obs exposed to a strong lipotoxic milieu that mimics the human bone marrow environment. Future work should characterise the mechanisms of this effect as a step towards development of novel therapies to overcome lipotoxicity in the bone setting.

Changes In Bone Marrow Adipose Tissue Composition Are Associated With Metabolic Improvements After Gastric Bypass-Induced Weight Loss Tiffany Kim*[1], Ann Schwartz[1], Xiaojuan Li[2], Kaipin Xu[2], Galateia Kazakia[1], Carl Grunfeld[1], Robert Nissenson[1], Dolores Shoback[1], Anne Schafer[1]. [1]University of California, San Francisco, United States, [2]Cleveland Clinic, United States

Bone marrow adipose tissue (MAT) may interact with bone and energy metabolism. Both the quantity and composition are altered in metabolic bone disease, with higher levels of total MAT but lower levels of the unsaturated MAT fraction in those with osteoporosis and diabetes (DM). While longitudinal changes in total MAT have been studied, changes in MAT composition have not been described. Roux-en-Y gastric bypass (RYGB) surgery presents a unique opportunity for insights in MAT, given dramatic postoperative changes in bone, fat and glucose metabolism. We hypothesized the effect of RYGB-induced weight loss on MAT varies with DM status and glycemic control.We enrolled 30 morbidly obese women (14 with DM, 16 without DM) and measured vertebral MAT before and 6 months after RYGB with 3T magnetic resonance spectroscopy. Other measures included BMD by DXA and quantitative CT.Baseline characteristics were similar between those with and without DM, aside from hemoglobin A1c (HbA1c). There were no differences in baseline vertebral total MAT and the unsaturated MAT fraction (mean 66.3% and 4.9%, respectively). Six months after RYGB, women lost a mean 27 kg. BMD significantly declined at the spine and hip. Mean HbA1c decreased from 7.6% to 5.7% in women with DM. For total MAT, mean changes were -6.1% ±11.7% in those with DM (p=0.08) and +5.3% ±9.5% in those without DM (p=0.08; p=0.01 for difference between groups). For the unsaturated MAT fraction, mean changes were +25.8% ±37.9% in those with DM (p=0.03) and -14.4% ±22.3% in those without DM (p=0.05; p<0.01 for difference between groups).In the overall cohort, changes in total MAT and the unsaturated MAT fraction correlated with HbA1c improvements (r=0.41, p=0.04; r=-0.51, p=0.01, respectively). Changes in total MAT correlated with spinal volumetric BMD decline (r=-0.41, p=0.04) and femoral neck areal BMD decline (r=-0.39, p=0.06). In contrast, changes in MAT composition did not correlate with BMD declines or weight loss.Changes in MAT composition after RYGB correlated with metabolic improvements and varied by DM status. There was no relationship between changes in the unsaturated MAT fraction and declines in BMD, as was observed for changes in total MAT. Distinct MAT composition profiles are associated with marrow adipocyte subpopulation profiles. Thus, shifts in MAT composition may reflect changes in marrow adipocyte function, although how these changes affect skeletal health requires further study.

KDM6B Regulates Estrogen-Mediated Osteogenic Differentiation of Human DMSCs Zhenqing Liu*[1], Chang-Ryul Lee[1], Zhongkai Cui[1], Michael Zhou[2], Hye-Lim Lee[3], Min Lee[1], Cun-Yu Wang[1], Christine Hong[1], Tara Aghaloo[1]. [1]University of California, Los Angeles, United States, [2]University of California, Berkeley, United States, [3]University of California, Irvine, United States

Objectives: KDM6B is a histone demethylase that removes the repressive epigenetic mark, H3K27me3 and has been previously shown to regulate the osteogenic commitment of human mesenchymal stem cells. The role of estrogen as an important medical component to preventative and therapeutic post-menopausal osteoporosis is well studied, but the epigenetic regulation of estrogen-mediated osteogenesis remains elusive. Estrogen is known to induce osteogenesis by activating the estrogen signaling pathway and upregulating osteogenic genes such as bone morphogenic proteins (BMP). This study assessed the epigenetic controls over these processes by looking at the effects of KDM6B in dental mesenchymal stem cells (DMSCs) in order to gain mechanistic insight into their potential clinical use in tissue regeneration and repair.Methods: Using the overexpression and knockdown of KDM6B in DMSCs, we induced cells to undergo osteogenic differentiation following estrogen treatment and investigated further mechanisms with ChIP. In vivo, the calvarial defect model was used and DMSC/Scrsh-Control, DMSC/Scrsh-E2, DMSC/shKDM6B-Control, DMSC/shKDM6B-E2 cells were loaded onto apatite-coated poly (lactic-co-glycolic acid) (Ap-PLGA) scaffolds (3 mm in diameter and 0.5 mm in height) and were transplanted. After 10 weeks, we compared new bone formation between the 4 groups.Results: Estrogen dramatically induced the expression of histone demethylase, KDM6B in DMSCs. When KDM6B was overexpressed, osteogenic differentiation was significantly enhanced. In contrast, KDM6B depletion by shRNA led to a significant reduction in osteogenic potential of DMSCs. Mechanistically, upon estrogen stimulation, ERα was recruited to the KDM6B promoter and enhanced KDM6B expression. Subsequently, KDM6B removed a silencing epigenetic mark, H3K27me3, from the BMP2 and HOXC6 promoters and activated the transcription of BMP2 and HOXC6, master genes of osteogenic differentiation. In vivo, micro-CT analysis demonstrated that BV/TV was increased in DMSC/Scrsh cells upon E2 treatment, however this increase was not seen in DMSC/shKDM6B even with E2 treatment. In addition, quantification of H&E staining showed the consistent results. In brief, KDM6B depletion inhibited estrogen-mediated bone formation in vivo.Conclusion: Our results demonstrated the critical role of KDM6B in the epigenetic regulation of estrogen-mediated osteogenic differentiation of DMSCs.

Effects of bone marrow regeneration on mechanoadaptation in aged bone Judith Piet*[1], Roland Baron[2], Sandra Shefelbine[1]. [1]Northeastern University, United States, [2]Harvard School of Dental Medicine, United States

Bone marrow in long bones become fatty with age, with mesenchymal stem cells differentiating into adipocytes rather than the osteoblast lineage. Previous studies have found an inverse relationship between marrow adiposity and bone volume [Justesen et al. 2001, Shen et al. 2012, Scheller et al. 2015]. This shift in marrow composition is suspected to be one of the causes for the age-related decrease in mechanoadaptation.In young mice, ablated bone marrow regenerates within 4 weeks but, to our knowledge, no study has investigated bone marrow regeneration in aged mice. We hypothesize that (1) bone marrow regeneration decreases the adipocyte composition in aged bone; (2) the response to mechanical loading in aged bone increases after bone marrow regeneration.Material and methods:In aged female C57BL6 mice (22 months), we aspirated bone marrow in the right tibia with a saline-filled needle, inserted through the tibial plateau. Left legs were kept intact as internal controls. We sacrificed mice after 1, 2 and 4 weeks (Figure 1A). We imaged tibiae with micro-computed tomography to test changes in bone geometry, between the tibio-fibular junctions (from 0% at proximal junction to 100% at distal junction, see Figure 1B). We then performed Osmium staining and imaging in order to quantify marrow adipose tissue.Additionally, we examined 3 groups of aged mice: (1) axial loading at 9N for 2 weeks (100 cycles a day, 3 days a week); (2) bone marrow aspiration followed by 4 weeks recovery and 2 weeks axial loading at 9N; (3) bone marrow aspiration followed by 6 weeks recovery (Figure 1A). Left legs were kept intact as internal controls. After sacrifice, we imaged samples with micro-computed tomography. Samples were then embedded for histomorphometry.Results:2 weeks following aspiration, bone cross section increased the proximal end, due to trabecular bone (p<0.05). After 4 weeks, trabeculae were resorbed and the amount of bone was no different from the contralateral leg, but the adipocyte volume was increased locally (volume between 35-40%, p<0.05). The location of adaptation was different in the groups that received loading only (adaptation at 50% and 70%, p<0.05), or combined marrow regeneration and loading (adaptation in a more proximal site, between 30% and 50%, p<0.05).Conclusion:Bone marrow aspiration changes the cellular environment of bone in response to loading, which alters the mechano-adaptive response in aged bone.

Dietary Inflammatory Index and Cortical Bone Outcomes in Healthy Adolescent Children Lauren Coheley*[1], Emma Laing[1], Nitin Shivappa[2], James Hebert[3], Richard Lewis[4]. [1]Department of Foods and Nutrition, University of Georgia, United States, [2]Cancer Prevention and Control Program, University of South Carolina, United States, [3]Cancer Prevention and Control Program, Epidemiology and Biostatistics, University of South Carolina, United States, [4]Department of Foods and Nutrition, University of Georgia, United States

Chronic, low-grade inflammation is theorized to negatively affect bone strength. Dietary factors are thought to influence inflammation through pro- and anti-inflammatory processes. The Dietary Inflammatory Index (DII®) was developed to assess the inflammatory potential of the diet on a continuum from maximally pro-inflammatory to maximally anti-inflammatory. The primary aim of this study was to determine the relationships between DII® score and cortical bone in 290 healthy black and white adolescents, ages 9-13 years. The secondary aim was to assess the associations between DII® score and biomarkers of inflammation. The DII® score was calculated based on 3-day diet records and categorized into tertiles defined as low (<-1.34), medium (-1.34 to 1.41), and high (>1.41) levels of inflammation. Radius and tibia cortical bone were assessed via peripheral quantitative computed tomography (Stratec XCT 2000) at the 66% site relative to the distal growth plate. Fasting sera was measured for tumor necrosis factor-alpha (TNF-a), interleukin-6 (IL-6), vascular endothelial growth factor (VEGF), and monocyte chemoattractant protein-1 (MCP-1) using Luminex XMap system (TNF-a, VEGF, MCP-1) and Meso Scale Discovery assay (IL-6). The relationships between DII® score and cortical bone outcomes and biomarkers of inflammation were assessed using bivariate and multiple partial correlations adjusting for BMI-for-age-percentile, sexual maturation rating stage, and sex. ANOVA and ANCOVA models were used to compare DII® tertiles with cortical bone outcomes and biomarkers of inflammation. DII® score was negatively associated with tibia trabecular area (r=-.141, P=.019), periosteal circumference (Peri.Circ; r=-.145; P=.016); endosteal circumference (r=-.145, P=.016), strength strain index (SSI; r=-.129, P=.032), and radius Peri.Circ (r=-.138, P=.027) and SSI (r=-.131, P=.036). All relationships were nullified when adjusting for covariates. Mean tibia Peri.Circ was higher in the lower DII® score group compared to medium (P=.050) and high (P=.046) DII® score groups, but nullified when controlling for covariates. DII®score was not associated with TNF-a, VEGF, or IL-6, but was positively associated with MCP-1 in the unadjusted (r=.125, P=.042) and adjusted (r=.021, P=.038) models. It appears that DII® score is not related to bone strength in adolescents. The relationship between MCP-I and DII® score should be further explored.

Prickle1 is Required for Chondrocyte Polarity and Terminal Differentiation during Endochondral Ossification Yong Wan*, Heather Szabo-Rogers. University of Pittsburgh, United States

The organized, polarized maturation of chondrocytes in the growth plate is necessary for the expansion and growth of the limb and cranial base. Decreased expansion of the

growth plates can result in shorter stature and midfacial hypoplasia. The molecular pathology of decreased growth plate expansion is not well described. We observed that the Prickle1Bj/Bj mutant mice develop a shorter cranial base and limbs. The Prickle1Bj mouse line has a missense mutation that results in compromised protein structure. Prickle1 is a core component of the Wnt/Planar cell polarity pathway. We hypothesized that the midfacial hypoplasia and short stature observed in Prickle1Bj/Bj mutants, resulted from loss of cell polarity and signaling during endochondral ossification. The Prickle1Bj/Bj midfacial hypoplasia results from loss of growth and expansion in the cranial base. We observed completely randomized polarity of the Prickle1Bj/Bj resting and proliferating chondrocytes. In addition, we observed prolonged and increased Wnt/β-catenin and HH signaling resulting in the precocious maturation of chondrocytes and the stalling of terminal differentiation in the Prickle1Bj/Bj synchondroses and growth plates. Our data support the conclusion that Prickle1 acts as a rheostat in endochondral ossification by regulating chondrocyte polarity and coordinating HH and Wnt/β-catenin signaling to control chondrocyte maturation during endochondral ossification.

Circulating cells of the osteoblast lineage are increased in breast cancer patients with bone metastasis and could represent a novel biomarker for diagnosis and monitoring of tumor progression Jiarong Li*, Karine Sellin, Louis Dore Savard , Richard Kremer. Research Institute of MUHC, Canada

Circulating cells of the osteoblast lineage(cOB) have previously been identified using flow cytometry by positive selection with osteocalcin(OCN) and alkaline phosphatase(AP) antibodies. Although OCN is predominantly an intracellular protein, when secreted, it can be anchored to the cell membrane through Gla residue and bind to cell surface OCN receptors thus permitting its characterization in live cells. cOB may play a role in bone remodelling and are found in higher concentrations in peripheral blood during the pubertal growth spurt and in patients with recent bone fractures.However, the role of cOB has not yet been studied in patients with cancer and bone metastasis.We posit that cOB could be used as markers of skeletal metastases in breast cancer patients.Peripheral blood mononuclear cells (PBMC) of healthy volunteers and patients with breast cancer with and without bone metastasis were collected by apheresis and underwent further purification by Ficoll-Paque density gradients. We next examined the proportion of circulating tumor cells and cOB in 5 healthy volunteers, 5 patients without bone metastasis and 8 patients with bone metastasis. PMBC were then subjected to flow cytometry using an antibody directed at the white blood cells surface marker CD45 and fixable viability dye negative selections to eliminate white blood cells and dead cells.CD 45 negative fractions were further fractioned by positive selection using monoclonal antibodies against human OCN, ALP and Cytokeratin 8/18(for CTCs) molecular markers. Our results (Table 1) indicated that CTCs were significantly increased above baseline values (from healthy volunteers) (p<0.001) in breast cancer patients with or without bone metastasis. In contrast both OCN and AP expressing cOB were found to be significantly higher than healthy volunteers only in breast cancer with bone metastasis(p<0.001) but not in patients without bone metastasis.Our results suggest that cOB may represent novel biomarkers of skeletal metastasis.

Table 1

PERK activity in osteoblast lineage does not contribute to skeletal homeostasis in mice Srividhya Iyer*, Alexander Harb, Christian Melendez-Suchi, Aaron Warren, Ha-Neui Kim, Maria Almeida. University of Arkansas for Medical Sciences, United States

The bone matrix synthesizing osteoblasts secrete large amounts of collagen and have extensive endoplasmic reticulum (ER). The ER orchestrates protein folding and secretion and the unfolded protein response (UPR) maintains ER homeostasis. The UPR is mediated by three signal transduction pathways, controlled by the proteins PERK, IRE1α, and ATF6, that act to clear unfolded proteins from the ER. Sustained elevation of the UPR, or

its insufficient activation, contributes to the pathology of diseases such as diabetes, obesity, atherosclerosis, and cancer. Notably, humans and mice lacking functional PERK protein exhibit several metabolic defects, have low bone mass and abnormal collagen matrix. In mice, these skeletal defects are associated with a reduction in osteoblast number and bone formation. However, it remains unknown whether the skeletal defects in PERK null mice are due to a decrease in the UPR in osteoblasts or in other cell types. We found that PERK phosphorylation increases during osteoblast differentiation of bone marrow derived stromal cell cultures. To determine if Perk activity in osteoblasts contributes to skeletal homeostasis, we deleted the Perk gene from the entire osteoblast lineage using Osx1-Cre transgene. The body weight, lumbar and femoral BMD of CKO mice was indistinguishable from the Osx1-Cre littermate control males and females mice at 3 and 5 months of age. Bone marrow-derived osteoblast cultures from 6 month-old CKO mice had reduced mRNA expression of PERK, however, their ability to mineralize was comparable to similar cultures obtained from Osx1-Cre mice, as determined by Alizarin staining. MicroCT analysis revealed that the vertebral cancellous bone volume and femoral cortical thickness was indistinguishable between CKO and Osx1-Cre mice at 6 months of age. Moreover, Perk deletion did not affect vertebral compression strength. Collectively these results indicate that Perk signaling in osteoblasts is not essential for skeletal homeostasis. It is therefore likely that either the Ire1 or ATF6 axes mediate osteoblast differentiation in vivo or that there is functional redundancy between the three arms of UPR.

Deletion of menin early in the osteoblast lineage reduces mineralization of dense collagen gels by primary osteoblasts Ildi Troka*[1], Gabriele Griffanti[2], Showan N. Nazhat[2], Geoffrey N. Hendy[1]. [1]Division of Experimental Medicine, McGill University, Canada, [2]Department of Mining and Materials Engineering, McGill University, Canada

Background: Menin, the product of the Multiple Endocrine Neoplasia Type 1 (MEN1) gene, is a widely expressed, predominantly nuclear protein that facilitates cell proliferation and differentiation control. In vivo studies have shown the importance of menin for proper functioning of the mature osteoblast and maintenance of bone mass.Aims of the study: To use three-dimensional (3D) dense collagen hydrogel scaffolds, which mimic the physiological bone microenvironment, as a cell-culture model to investigate the differentiation and mineralization capabilities of primary osteoblasts of conditional knockout mice in which the Men1 gene is deleted early in the osteoblast lineage.Methods: Primary calvarial osteoblasts were isolated from control, Men1f/f, and Prx1-Cre;Men1f/f mice which represent knockout of the Men1 gene at the level of the pluripotent mesenchymal stem cell that gives rise to osteoblasts. The cells were seeded into plastic compressed dense collagen gels and cultured for 21 days in an osteogenic medium to induce differentiation.Results: The viability and metabolic activity of primary calvarial osteoblasts within the dense collagen scaffolds of knockout mice were identical to that of control. Scanning electron microscopy of day 21 samples revealed that in contrast to collagen gels seeded with control primary osteoblasts, collagen fibres of Prx1-Cre;Men1f/f cell-seeded gels were covered by smaller quantities of calcium phosphate based mineral, suggesting a difference in the cell mediated mineralization process carried out by knockout cells. By Fourier Transform Infrared Spectroscopy analysis, the absorption band intensities attributable to phosphate and carbonate groups were lower in collagen gels seeded with knockout primary osteoblasts. The mineral to matrix and carbonate to phosphate ratios in knockout samples were significantly lower (p<0.01) and higher (p<0.05), respectively, indicating impairment in the mineralization process and in the mineral crystal purity. Diffractograms obtained by X-Ray Diffraction at day 21 from knockout cell-seeded gels were characterized by the presence of lower intensity peaks attributable to hydroxyapatite, the main mineral component of bone. Conclusions: By the use of 3D dense collagen hydrogel scaffolds–a better alternative to the conventional two-dimensional system of primary cell culture–we show that expression of menin early in the osteoblast lineage is important for osteoblast mineralization

Adiponectin Receptor Agonist AdipoRon Increases Mitochondrial Fusion and Biogenesis in Diabetic Bone Cells Xiaoxuan Wang*[1,2], Xingwen Wu[1], Qisheng Tu[1], Jake Chen[1,3]. [1]Division of Oral Biology, Tufts University School of Dental Medicine, Boston, Massachusetts, United States, [2]Department of Periodontology, Peking University School of Stomatology, United States, [3]Department of Developmental, Molecular and Chemical Biology Sackler School of Graduate Biomedical Sciences, Tufts University School of Medicine, Boston, Massachusetts, United States

Objective: AdipoRon is an orally active synthetic adiponectin agonist. It binds to both adiponectin receptors1 and 2, and ameliorates diabetic complications. The dynamics and biogenesis of mitochondria were reported to be disrupted in diabetes. Mitofusin 2 (Mfn2), plays critical roles in mitochondrial fusion. Nrf2 and PGC-1β are related to mitochondrial biogenesis. We for the first time investigated the role of AdipoRon in mitochondrial fusion and biogenesis genes expression in type 2 diabetic (T2D) bone cells.Materials and methods: Twenty-week-old diet-induced obesity (DIO, a model for T2D) mice were divided into 2

groups: diabetes mellitus group (DIO), AdipoRon treatment group (DIO + AdipoRon). Bone marrow derived stem cells (BMSCs) were isolated from femur and tibia of mice. In each group, cells were treated respectively with low glucose (5.5mM glucose, glucose control), high glucose (25 mM glucose) for 5 days and 7days. Expression of Mfn2, Nrf2 and PGC-1β genes in mouse BMSCs were detected by real time PCR assays.Results: Expression of Nrf2 was increased in AdipoRon treatment group compared to the diabetes group (p<0.05) when treated with high glucose for 5 days. Interestingly, expression of PGC-1β was increased only on day 7 (p<0.05). When the cells were treated with low glucose for 7 days, expressions of Mfn2 and PGC-1β were higher in cells from AdipoRon treatment group than that from diabetic mice group (p<0.05). Furthermore, in the diabetes group, the expressions of Mfn2 and Nrf2 were significantly downregulated when cells were treated with high glucose for 5 days (p<0.05). The expression of PGC-1β was also downregulated, but there was no statistical significance. In contrary, expressions of Mfn2, Nrf2 and PGC-1β genes were similar between cells treated with low glucose and high glucose in the AdipoRon treatment group. Conclusion: We have previously shown that AdipoRon promotes osteoblast differentiation and bone formation. The findings of current study provide the first evidence of the mitochondrial protective effects of AdipoRon in DIO mice model suggesting that AdipoRon exerts its anabolic effect probably through increasing the critical gene expressions of mitochondrial biogenesis. It also opens new revenue to develop pharmaceutical molecules to manipulate mitochondrial biogenesis aiming to target the bone disorders particularly in the diabetic patients.

A. Expression of Nrf2 was increased in AdipoRon treatment group compared to the diabetes group when treated with high glucose for 5 days.
B. Expression of PGC-1βwas increased only on day 7 when treated with high glucose. When the cells were treated with low glucose for 7 days, expressions of Mfn2 and PGC-1βwere higher in AdipoRon treatment group than that in diabetic mouse group.
C. In the diabetes group, the expressions of Mfn2 and Nrf2 were significantly downregulated when cells were treated with high glucose for 5 days.
D. In the AdipoRon treatment group, expressions of Mfn2, Nrf2 and PGC-1βgenes were similar between cells treated with low glucose and high glucose.
* Represents statistical significance. PGC-1β/A and PGC-1β/D in Figures C and D represent AdipoRon group and diabetes group, respectively.

Osteoclasts serve as an intracellular niche for replicating Staphylococcus aureus Anna Ballard*[1], Jennifer L. Krauss[1], Pei Ying Ng[2], Linda Cox[1], Emily Goering[1], Nathan J. Pavlos[2], Deborah J. Veis[1]. [1]Division of Bone and Mineral Diseases, Washington University School of Medicine, United States, [2]School of Biomedical Sciences, University of Western Australia, Australia

Osteomyelitis (OM) is a severe bacterial infection of bone associated with an inflammatory reaction and disruption of skeletal integrity, and Staphylococcus aureus (S. aureus) is the primary causative agent. Although S. aureus is considered to be an extracellular pathogen, recent evidence indicates it can persist intracellularly in many cell types, including osteoblasts (OB). Infected OBs produce RANKL and recruit osteoclasts (OCs) to the site of bone infection, but the role of OCs in OM, and in particular their ability to become infected, is not well understood. We hypothesized that S. aureus could infect OCs to contribute to OM pathogenesis. Confocal imaging of decalcified calvaria sections from TRAP-red reporter mice injected with GFP-labeled S. aureus over the periosteum shows that S. aureus is present within OCs following infection, in vivo. We next utilized an in vitro infection protocol to assay the ability of S. aureus to reside in differentiating OCs. Primary expanded bone marrow macrophages (BMMs), cultured +/- RANKL, are infected with S. aureus for 30 min, extracellular bacteria killed with 1 hr gentamycin treatment, and cells cultured 16.5 hrs more prior to lysis; intracellular S. aureus growth is assessed by colony forming assay, comparing numbers immediately following gentamycin treatment with endpoint. We find that while BMMs cultured in M-CSF alone reduce S. aureus, the same cells stimulated with M-CSF + RANKL experience increases of ~50-fold (2 d RANKL) to ~500-fold (3 d RANKL) in intracellular bacteria. Further supporting the requirement for OC lineage differentiation, intracellular S. aureus levels are diminished to BMM levels in RANKL-treated cells lacking NFATc1 or NIK, which fail to form OC. To determine whether increased bacterial recovery in mature OCs represents intracellular S. aureus proliferation, we used a microscopy approach and observe replicating bacteria in infected OCs in vitro by transmission EM. Further, in vitro confocal imaging on both glass and bone demonstrates that S. aureus division events occur inside OC cells. While most bacteria co-localize with lysosomes 2 hrs post-infection, this occurrence decreases by 18 hrs post-infection in OCs, suggesting a possible mechanism for

lack of killing. In sum, our data indicate that OCs represent a unique niche for intracellular S. aureus proliferation, and further study of host-pathogen interactions in OCs may inform our understanding of disease progression in OM.

Ciliogenesis is inherent to osteoclastogenesis and IFT proteins drive osteoclast formation Vishwa Deepak*, Shuying Yang. University of Pennsylvania School of Dental Medicine, United States

Purpose: Osteoclasts are multinucleated bone resorbing cells. Primary cilia are microtubule-based organelles present on almost all vertebrate cells. IFT proteins regulate protein transport and cilia formation and their loss causes ciliopathies. Even though presence of cilia is essential for other cell types, it remains enigmatic that cilia are absent on osteoclasts and play no role in osteoclastogenesis. Hence, we performed this study to identify and delineate the exact roles of cilia and IFT proteins in osteoclasts.Methods: Myeloid-specific IFT80 or IFT20 knockout LysM-Cre transgenic mice were generated. Cilia were identified through a cilia-GFP mouse model and cilium-specific antibody staining. A detailed view of cilia was observed using electron microscopy. TRAP staining for osteoclasts was done in differentiation assays and bone histology sections. Bone mineral density was analyzed through μCT. Inhibitors of cilia formation and PI3K, AKT, GSK3β were used to identify molecular pathways. Gene expression, and phosphorylation of these pathways were analyzed through qPCR, western blotting and immunofluorescence.Results: Here, we report for the first time the presence of cilia on osteoclasts. The shape and physical structure represented characteristic properties of cilia. Cilium with well-defined axoneme, ciliary pocket and a 9+0 microtubule arrangement were seen through SEM and TEM respectively. Cilia number and length increased within 1 day of RANKL addition whereas they decreased at day 3 and further increased again at day 5 of osteoclastogenesis. IFT80 and 20 mRNA and protein expression modulated in same manner along with the differentiation. IFT 20 or 80 deletion caused cilia loss and growth retardation in mice. Increased osteoclast size and numbers were seen both in ex vivo assays as well as in histological sections of long bone. μCT analysis revealed massive bone erosion in trabecular region of 1 and 3-month-old mice. Mechanistically, inhibition of cilia formation through cilia inhibitor also increased osteoclast formation. Inhibition of PI3K/AKT pathways decreased osteoclast numbers in mutant cells. Increased activation of NFATc1 and phosphorylation of Akt, GSK3β, ERK1/2 proteins was observed in mutant cells.Conclusions: Primary cilia are present on osteoclasts and are inherent to osteoclast differentiation and bone resorption. These findings may pave the way for designing novel therapeutics against bone overgrowth or destructive disorders.

Bone Cell Effects of Mono-unsaturated Palmitoleic Acid Jian-Ming Lin*, Karen E Callon, Jillian Cornish. Department of Medicine, University of Auckland, New Zealand

We have previously demonstrated that saturated palmitic acid (C16:0) potently inhibited osteoclast formation and function at low concentrations while some reports show that it is cytotoxic and has detrimental effect on health at higher concentrations. In the current study, we have investigated the bone cell effects of palmitoleic acid (C16:1), an omega-7 mono-unsaturated fatty acid, which is biosynthesized from palmitic acid in cells including adipocytes and is a common component in the diet. Comparing to saturated palmitic acid, mono-unsaturated palmitoleic acid has demonstrated a wide array of positive effects on health, being anti-inflammatory, cytoprotective in beta-cells and down-regulating lipogenesis.Osteoclastogenesis assays were conducted using both RAW264.7 cells and primary mouse bone marrow cells. Palmitoleic acid inhibited osteoclast formation with significant effect seen at 10 and 20 μg/mL in RAW264.7 cells (by 29 and 52%, respectively; P < 0.0001, ANOVA) and in bone marrow cultures (by 27% and 33%, respectively; P <0.002). The inhibition was not due to non-specific cytotoxicity, since the AlamarBlue® assay showed that the fatty acid stimulated the viability in both of the models. In addition, palmitoleic acid significantly stimulated the viability (by 33 % at 20 μg/mL; P < 0.002) and 3H-thymidine incorporation (by 12 and 14%, at 1 and 10 μg/mL respectively; P < 0.001) in primary osteoblasts. Further study using real-time PCR found that palmitoleic acid reduced the expression of osteoclastic genes M-CSF, DC-STAMP, NFATc1, TNF-α and TRAP. It is likely that the inhibition of osteoclastogenesis is independent of RANKL/OPG pathway since the molecule reduced RANKL and OPG expression at the similar rates.In conclusion, palmitoleic acid is a promising factor in increasing bone health, stimulating osteoblasts and inhibiting osteoclasts.

Fracture Risk Assessment in Patients on a Drug Holiday Michael Morkos*[1,2], Paul Mahrous[1], Alessandra Casagrande[1], Muriel Tania Go[2], Hasan Husni[2], Mirette Hanna[1], Sara Bedrose[2], Dingfeng Li[2], Monica Tawfic[1], Yu-Chien Cheng[1,2], Sanford Baim[1]. [1]Rush University Medical Center, United States, [2]John H. Stroger, Jr. Hospital of Cook County, United States

We aimed to describe fracture risk assessment practices among providers prescribing osteoporosis medications in a real-life setting. This is a retrospective cohort study in a tertiary academic center in Chicago, IL. Inclusion criteria involved adults (aged ≥18 years) who received minimum adequate therapy (bisphosphates, raloxifene, or denosumab ≥ 3 years, or Teriparatide ≥ 18 months), otherwise patients were excluded. Of 1,814 charts randomly selected and reviewed, 274 patients met the inclusion criteria.Risk stratification tools included: fragility fractures, Dual-energy X-ray Absorptiometry (DXA), and the FRAX risk assessment tool. Fracture risk assessment for the patients was assessed at the time of therapy initiation (N= 274 patients) and at the time of drug holiday (N=119 patients). High risk patients were defined as: prevalent fragility fracture, T-score ≤-2.5 on DXA at the lumbar spine, femur neck, total hip, or distal 1/3 radius, or high risk score by FRAX defined as 10-year major osteoporotic fracture risk ≥20% and/or hip fracture risk ≥3%; otherwise, patients were considered as low risk. Data was collected by chart review and FRAX scores were independently calculated by the research team for comparison and assessment purposes. Prior to initiation of therapy, 29.9% of patients had a baseline fragility fracture. DXA scan was performed at least once in 58.8% of the patients and 10.5% of the providers performed a FRAX risk assessment. At baseline, 71.5% of all patients would be considered at high risk for fragility fractures and as such eligible for therapy based on the aforementioned high risk categorization of patients.Drug holiday (DH) was started in 119 patients (43.4%) and 3.4% of the patients sustained a fragility fracture during therapy. At the time of initiation of a DH, 67.2% of patients had DXA performed within the previous 2 years and 10.9% of the providers preformed a FRAX risk assessment. At the time of initiation of a DH, 66.4% of patients would be considered at high risk and eligible for continuation of therapy. A DXA scan was performed at least once in 95.3% of the total cohort that included the continued therapy and drug holiday groups.In conclusion, there was an under-utilization of FRAX risk stratification at the time of DH with two thirds of patients considered at high risk for future osteoporosis fractures placed on drug holiday. We recommend comprehensive fracture risk assessment utilizing history of fractures, DXA, and FRAX at therapy initiation and when considering a DH.

Fracture Risk Assessment – A Real Life Experience

	At Therapy Initiation (N=274 patients)	At Drug Holiday (N=119 patients)
DXA Scan performed	58.8%	67.2%
FRAX Score Performed	10.5%	10.9%
Fragility Fractures	29.9%	3.4%
High Risk Patients (candidates for therapy)	71.5%	66.4%

Lower total hip BMD and 25OHD levels are associated with the presence of abdominal aortic calcification in the Canadian Multicentre Osteoporosis Study (CaMos) Claudie Berger*[1], Alexandre Semionov[2], Brian C. Lentle[3], Christopher S Kovacs[4], David A Hanley[5], Stephanie M Kaiser[6], Robert G Josse[7], Jerilynn C Prior[3], Jonathan D Adachi[8], Wojciech Olszynski[9], K Shawn Davison[10], Nancy Kreiger[11], Suzanne N Morin[12], David Goltzman[12]. [1]Research Institute of the McGill University Health Centre, Canada, [2]McGill University Health Centre, Canada, [3]University of British Columbia, Canada, [4]Memorial University, Canada, [5]University of calgary, Canada, [6]Dalhousie University, Canada, [7]St. Michael's Hospital, Canada, [8]McMaster University, Canada, [9]University of Saskatchewan, Canada, [10]CaMos, Canada, [11]University of Toronto, Canada, [12]McGill University, Canada

Purpose: We examined the association between risk factors (including total hip BMD and serum 25-hydroxyvitamin D (25OHD)) with cross-sectional and longitudinal 10-year measures of abdominal aortic calcification (AAC) in older CaMos participants.Methods: We scored AAC on lateral lumbar spine (L1-L4) x-rays using the Framingham method (scores 0-24) on 1930 participants aged 60+ at Year 10 follow-up (949 with 25OHD levels). We used a zero-inflated negative binomial (ZINB) model to determine cross-sectionally risk factors for presence and severity of AAC, and linear regression, for longitudinal change

in AAC from baseline to Year 10 (n=1196 with total hip BMD and n=243 with 25OHD). Additional risk factors studied: sex, age, BMI, race, education, smoking status (current, past, never), self-reported hypertension, heart attack, TIA, diabetes and kidney disease, use of calcium or vitamin D supplements and total calcium intake.Results: Presence and severity of AAC in women and men at Year 10 increased with age: 49% of those 60-69 years had AAC with mean (SD) score of 5.4 (4.6), while 87% of those 80+ years had AAC with mean score of 8.4 (5.6). Participants with AAC had mean (SD) total hip BMD and median (IQR) 25OHD levels of 0.868g/cm2 (0.15) and 67nmol/L (53-82) compared to 0.904g/cm2 (0.15) and 70nmol/L (58-84) in those without AAC. Being older and Caucasian, smoking, self-reported hypertension, heart attack and diabetes were associated with the presence of AAC (Table 1) in ZINB adjusted models. Lower total hip BMD was associated with higher odds of having AAC: OR=1.25 (95% C.I.:1.04; 1.51) per SD. Age, smoking, self-reported hypertension, heart attack, TIA and diabetes were all associated with higher AAC severity while total hip BMD was not. Participants with 25OHD levels < 50nmol/L had higher odds of having AAC (OR of 1.95 (1.01; 3.76)), compared to those with levels > 50nmol/L, but lower 25OHD levels were not associated with severity of AAC. Finally, a model assessing change in AAC score from baseline to Year 10 showed self-reported heart attack and diabetes, current smoking, older age and higher baseline AAC score were associated with increasing AAC score over 10 years; but baseline total hip BMD and 25OHD levels were not.Conclusion: Lower total hip BMD and 25OHD levels are associated with the presence of AAC independently of self-reported cardiovascular disease and other risk factors, but not with severity or longitudinal change in AAC.

Table 1: Cross-sectional associations between risk factors and presence and severity of abdominal aortic calcification at CaMos Year 10 follow-up.

	PRESENCE vs. absence (ZINB, non-zero count)		SEVERITY (ZINB, count)	
	OR	95% C.I.	RR	95% C.I.

Determinants of Bone Microarchitecture Assessed by HR-pQCT in Adults with Long-Term HIV Infection Sarah Foreman*[1], Po Hung Wu[1], Ruby Kuang[1], Malcolm John[2], Phyllis Tien[2], Thomas Link[1], Roland Krug[1], Galateia Kazakia[1]. [1]Department of Radiology and Biomedical Imaging, UCSF, United States, [2]Department of Medicine, UCSF, United States

Purpose: In adults with long-term HIV infection, low bone density and increased fracture risk have emerged as significant comorbidities. Our aim was to assess influences of exercise, nutrition, and medications on bone microarchitecture using high-resolution peripheral QCT (HR-pQCT) in adults with long-term HIV infection.Methods: Thirty subjects with HIV (3 postmenopausal women, 27 men) were prospectively enrolled (BMI 26±4 kg/m2, age 57±6 years, HIV duration 21±9 years). Questionnaires included the revised Community Healthy Activities Model Program for Seniors (CHAMPS), the Mini Nutritional Assessment (MNA), and medication assessments. Participants underwent radius and tibia HR-pQCT and dual-energy x-ray absorptiometry (DXA) of spine and hip. Multivariable linear regression models were used to evaluate effects of exercise, nutritional status, tenofovir disoproxil fumarate (TDF) and protease inhibitor (PI) use on bone macro- and microstructure, adjusting for demographic risk factors.Results: In regression models, higher nutrition scores were associated with higher radius and tibial cortical thickness (radius: R2=0.47; β=0.04; p=0.026; tibia: R2=0.46; β=0.07; p=0.005) and tibial cortical BMD (R2=0.56; β=12.77; p=0.026). Higher weekly frequency of all activities predicted higher radius and tibial trabecular number (radius: R2=0.36; β=0.01; p=0.020; tibia: R2=0.55; β=0.02; p=0.002) and less heterogeneity of tibial trabecular distribution (R2=0.46; β=-0.01; p=0.002) while higher caloric expenditure of all activities was associated with increased moment of inertia (resistance to bending and torsion) (radius: R2=0.51; β=28.91; p=0.023). TDF used in combination with a PI predicted decreased trabecular number (R2=0.35; β=-0.49; p=0.024) and increased heterogeneity of radius trabecular distribution (R2=0.35; β=0.17; p=0.006), while TDF use without a PI did not. A secondary analysis of extent of HIV disease control, showed no significant influence of HIV viral load and CD4 count on bone microarchitecture. DXA

BMD values were not significantly associated with any evaluated determinants (p>0.05). Conclusions: Cortical bone in adults with HIV is detrimentally affected by poor nutrition status, while trabecular bone is detrimentally affected by reduced physical activity. TDF use in combination with a PI is associated with deleterious effects on trabecular bone structure. DXA may be less useful for evaluating osseous changes in adults with HIV infection.
Figure 1: Ultradistal tibial HR-pQCT images of two HIV-infected subjects with high nutritional scores (A, B) and two HIV-infected subjects with low nutritional scores (C, D). Those with low nutritional scores show reduced cortical BMD with visibly increased porosity (C, white arrows) and reduced cortical thickness (D, white arrowheads).

Definition of Vitamin D Deficiency based on Free 25OH Vitamin D Concentrations Nicolas Heureux*. DIAsource Immunoassays, Belgium

25-hydroxy Vitamin D (25OHD) is today the best marker of Vitamin D status. Since decades, the measurement of total 25OHD has been considered as the most reliable method to evaluate individual's Vitamin D deficiency and insufficiency. Recently, several publications have identified free 25OHD as a potentially better marker of Vitamin D status in multiple conditions (B. Hocher J. Steroid Biochem. Mol. Biol. 2018 181:80-87, S. Pilz J. Clin. Endocrinol. Metab. 2018 103(6):2385-2391). In this communication, we define probationary cut-off points of Vitamin D deficiency and insufficiency, based on the concentration of free 25OHD.Although the measurement of total 25OHD exists since more than 30 years, there is still no clear consensus on the cut-off points of Vitamin D deficiency and insufficiency. Severe deficiency is defined by concentrations below 10 ng/mL (25 nmol/L) and insufficiency is considered at levels between 10 and 20 or 30 ng/mL (50 or 75 nmol/L), depending on experts. One of the reason could be that the measurement of total 25OHD is not pertinent in multiple conditions. Therefore, we have established cut-off points for free 25OHD, based on a large multi-center study correlation between total 25OHD and free 25OHD.Two methods are applied: using the mean percentage of free 25OHD compared to total 25OHD, or based on the correlation parameters between both metabolites. The first method results in cut-offs of 2.0, 4.0 and 6.0 pg/mL for 25OHD severe deficiency and insufficiency. Using the correlation between free and total 25OHD leads to 1.5, 4.2 and 5.5 pg/mL.Both methods deliver similar probationary cut-off points of Vitamin D deficiency and insufficiency, based on the concentration of free 25OHD, and can be used by researchers and clinical laboratories.

Mechanisms of Bone Loss Associated with Inflammatory Bowel Disease Christopher Peek*[1], Caleb Ford[1], Nicole Putnam[1], Jacob Curry[2], Blanca Piazuelo[1], Keith Wilson[1,2], Jim Cassat[1,2]. [1]Vanderbilt University, United States, [2]Vanderbilt University Medical Center, United States

Inflammatory bowel disease (IBD) is characterized by severe gastrointestinal inflammation and changes in the intestinal microbiota. Patients with IBD often experience extra-intestinal disease manifestations. Skeletal abnormalities are a frequent extra-intestinal manifestation of IBD, and patients exhibit a 40% increased fracture risk compared to that of the general population. Many factors, including malabsorptive malnutrition and glucocorticoid use, contribute to IBD-associated bone loss. Yet, nutritionally replete and glucocorticoid naive patients remain susceptible to bone loss. We used complementary mouse models of colitis-driven bone loss to test the hypothesis that IBD-associated bone loss is triggered in part by inflammatory cytokines and microbial constituents. We observed significant reductions in trabecular bone volume over total volume (BV/TV), up to 36%, and trabecular thickness in mice subjected to a chemically induced colitis with dextran sodium sulfate (DSS). Furthermore, trabecular bone loss occurs 7 days after DSS treatment and is sustained after DSS withdrawal. Using multiplexed cytokine analysis, we defined the abundance and kinetics of 32 cytokines within the skeletal microenvironment during DSS-colitis. We discovered increased abundance of several cytokines which have been implicated in multiple models of inflammatory bone loss, including TNF-a, CXCL5, and CXCL10, in the skeletal microenvironment of DSS-treated mice. Additionally, IL-12/23p40, the common subunit of IL-12 and IL-23, was found to be significantly increased. Intriguingly, IL-12 and IL-23 cytokines share a common subunit, IL-12/23p40 (p40), yet exert opposing effects on bone remodeling. IL-12 largely inhibits osteoclast differentiation, while IL-23 leads to bone

resorption through enhanced osteoclastogenesis. Co-housing experiments indicate that dysbiosis may contribute to these cytokine changes, as femur homogenates of DSS-treated mice cohoused with control mice exhibited reductions in p40 and TNF-a. We are utilizing fecal microbiome transplants, gnotobiotic mice, and skeletal specific pattern recognition receptor genetic knockout mice to test the hypothesis that the microbiome impacts skeletal homeostasis during colitis. This work will elucidate fundamental mechanisms by which systemic cytokines and circulating microbiota components impact bone biology during colitis and provide a platform to test the role of colitis-associated cytokines in pathologic bone loss.

Long-term risk of bone loss and fracture in rheumatoid arthritis and inflammatory bowel disease in the population-based Canadian Multicentre Osteoporosis Study (CaMos) Dana Bliuc*[1], Thach Tran[1], Tineke Van Geel[2], Jonathan Adachi[3], Claudie Berger[4], Joop Van Den Bergh[5], John Eisman[1], Piet Geusens[2], David Goltzman[3], David Hanley[6], Robert Josse[7], Stephanie Kaiser[8], Christopher Kovacs[9], Lisa Langsetmo[10], Jerilynn Prior[11], Tuan Nguyen[1], Jacqueline Center[1]. [1]Bone Biology Garvan Institute of Medical Research, Australia, [2]University of Maastricht, Netherlands, [3]Department of Medicine, McMaster University, Canada, [4]McGill University, Canada, [5]Maastricht University, Netherlands, [6]University of Calgary, Canada, [7]University of Toronto, Canada, [8]Dalhousie University, Canada, [9]Memorial University, Canada, [10]University of Minnesota, United States, [11]University of British Columbia, Canada

Background: This study sought to assess long-term risk of bone loss, and fracture in people with chronic inflammation such as rheumatoid arthritis (RA) and inflammatory bowel disease (IBD).Design and setting: Canadian Multicentre Osteoporosis Study, population based prospective study with 9 centres in Canada.Participants: 5527 women and 2164 men aged 50+ at baseline (1995/1997) who had been followed for an average of 10 (±5) years until 2013.Exposure: Self-reported RA (n=483, 78% women) and IBD (n=434, 85% women) at baseline. Linear regression models were used to estimate the rate of bone loss at the site of femoral neck. Cox's proportional hazards model was used to assess the association with fracture and post-fracture mortality, after adjustment for age, physical activity, smoking, co-morbidities, education, weight and glucocorticoids use.Main outcome measure: Annual rate of bone loss (between baseline, year 3, 5 and 10), low trauma fracture (except head and digits), and all-cause mortality.Results: Participants with RA and IBD had similar baseline characteristics and both were older, had lower BMD, and a greater prevalence of cardio-vascular and respiratory diseases compared to controls. The use of glucocorticoid therapy throughout the study was low (9%, 3%, and 3% for RA, IBD and controls, respectively). Compared to controls, RA had a higher rate of bone loss [mean difference, %/year, 0.2 (95% CI, 0.8-0.31); p<0.0001], and an increased risk of hip [HR 1.64 (95% CI, 1.01-2.65)], vertebral [HR 1.59 (95% CI, 0.92-2.74)] and non-hip non-vertebral fracture [HR 1.57 1.27-1.94)] after adjusting for all confounders. Compared to controls, IBD had a similar rate of bone loss, but increased risk of hip [1.62 (95% CI, 1.00-2.63)], vertebral [2.06 (95% CI, 1.25-3.39)] and non hip non vertebral fracture [HR 1.30 (95% CI, 1.04-1.64)]. Exclusion of glucocorticoid users did not change fracture risk magnitude. Following fracture, mortality risk was increased by 2-fold in RA [HR, 2.05 (1.15-3.65)] and IBD [2.18 (95% CI, 1.09-4.37)] and by 43% in controls [1.45 (95% CI, 1.29-1.64)].Conclusion: Patients with RA and IBD have increased risk of long-term bone loss, fractures, and increased post-fracture mortality which are not explained by glucocorticoid therapy. Further studies are needed to determine the role of inflammatory factors on bone metabolism and fracture outcomes in these conditions.

AFFs with Bisphosphonate Therapy (BP): Real Rare Side-Effect or Bad Medicine? David B. Karpf*[1], Frederick Singer[2], Kathleen Cody[3]. [1]Stanford University, United States, [2]John Wayne Cancer Institute, United States, [3]American Bone Health, United States

Introduction:Hypophosphatasia (HPP) is a rare disease affecting the development of bones and teeth, caused by the absence/reduced level of tissue-nonspecific alkaline phosphatase. Its severe, potentially fatal congenital form occurs in 1/100,000 births. HPP leads to increased circulating levels of inorganic pyrophosphate (iPyrP), which inhibits bone mineralization. The milder adult form usually presents in early middle age with low T-scores and sometimes metatarsal or femoral stress fractures, often with no history of premature loss of deciduous teeth. These patients usually have total alkaline phosphatase (TAP) levels ≤40, and an elevated vitamin B6 level. TAP may be >40 in some adults with HPP (JCEM 103(6):2234-2243). However, physicians unfamiliar with HPP may not note a low TAP, and these patients are often misdiagnosed with osteoporosis and inappropriately treated with a bisphosphonate (BP). As BPs are hydrolysis-resistant analogs of iPyrP, they should not be used in patients with HPPMethods and Results:Atypical femur fractures (AFFs) have been associated with long term BP use in several case-control studies, yet no signal for AFFs was observed in the FDA review of 100,000 patient-years of data from the RCTs including 2-10 years of treatment with all 4 BPs. It is possible that this discordance results from patients with HPP being excluded from the BP trials, but occasionally, perhaps frequently, being

treated with BPs in clinical practice. One of the authors has been referred patients on BP therapy who he subsequently diagnosed as having HPP.Discussion and conclusion:Many clinical labs still lack a lower limit of normal for TAP, further hindering the proper diagnosis of milder forms of HPP in adults. Given the rarity of HPP, many practicing physicians are unaware that all adults with a TAP ≤40 should be screened for HPP by assessing for an elevated B6 level, even absent a stress fracture or history of premature tooth loss. It is possible that at least a portion of the patients who develop AFFs while on BP therapy may be non-diagnosed HPP patients inappropriately treated with BPs. This could explain the association of BP therapy with the rare event of AFFs in case-control studies but not in RCTs. This hypothesis could be tested by screening large hospital or HMO (eg, Kaiser) databases for adults with TAP values ≤40, their association with diagnostic codes for osteoporosis, followed by chart reviews to screen for BP therapy and codes for AFFs.

Hydroxyapatite Nanoparticles Doped with Silver and Gold for Enhanced Bone Regeneration Deepak Kumar Khajuria*, David Karasik. The Musculoskeletal Genetics Laboratory, The Azrieli Faculty of Medicine, Bar-Ilan University, Safed-1311502, Israel

The repair of bone defects is one of the most challenging tasks in the orthopedic and maxillofacial surgery. Recapitulating embryological development is an attractive approach for engineering new bone at the defect site. We have investigated the osteogenic potential of hydroxyapatite (HA), silver doped HA (Ag-HA), gold doped HA (Au-HA), or silver-gold doped HA (Ag-Au-HA) nanoparticles in a zebrafish jaw bone regeneration (JBR) model1. The HA, Ag-HA, Au-HA, and Ag-Au-HA nanoparticles were fabricated by the co-precipitation technique. The surface structures of HA, Ag-HA, Au-HA, and Ag-Au-HA nanoparticles were characterized by X-ray diffraction (XRD), Fourier-transform infrared spectroscopy, scanning and transmission-electron microscopy (TEM), Energy Dispersive X-Ray Spectroscopy (EDS) and elemental mapping analysis. Zebrafish JBR model was used to confirm the effect of HA, Ag-HA, Au-HA, and Ag-Au-HA nanoparticles on bone regeneration. After jaw resection surgery, ZF were divided into 9 groups of 20 fish each. Two experimental diets were designed with adding each of HA, Ag-HA, Au-HA, and Ag-Au-HA nanoparticles in concentrations of 40, and 80 mg/kg to the fish feed TetraMin, and control group without any nanoparticles, for the whole duration of the experiment. The ZF jaw bone volume after 14, 28 and 35 days post-resection (dpr) was statistically superior in the Ag-Au-HA 40 and 80 mg/kg ($p < 0.001$), HA 40 and 80 mg/kg ($p < 0.05$), Ag-HA 40 and 80 mg/kg ($p < 0.05$), and Au-HA 40 and 80 mg/kg ($p < 0.05$) treated groups as compared to the control group. Strikingly, the whole-body bone mineral density (BMD) of ZF after 14, 28 and 35 dpr was statistically superior in the Ag-Au-HA 40 and 80 mg/kg ($p < 0.001$), HA 40 and 80 mg/kg ($p < 0.05$), Ag-HA 40 and 80 mg/kg ($p < 0.05$), Au-HA 40 and 80 mg/kg ($p < 0.05$) groups as compared to the control group. Besides that, it is noteworthy to mention that both the ZF lower jaw bone volume and whole-body BMD in Ag-Au-HA (80 mg/kg) group was statistically superior to HA (40 and 80 mg/kg), Ag-HA (40 and 80 mg/kg) and Au-HA (40 and 80 mg/kg) treated groups ($p < 0.05$) after 14, 28 and 35 dpr. These observations indicate the intriguing therapeutic potential of Ag-Au-HA nanoparticles for bone repair; these nanoparticles seem especially important for bone regeneration. Finally, we showed that in-vivo Ag-Au-HA nanoparticles have the capacity to enhance BMD in ZF, suggesting their potential application as anti-osteoporotic agents.1 Khajuria et al. ACS Appl Mater Interfaces 2018; 13;10(23):19373-19385.

Activation of guanylyl cyclase-B increases long bone mass, density and strength Jerid Robinson*[1], Nicholas Blixt[1], Gordon Warren[2], Andrew Benton[2], Zhou Ye[1], Conrado Aparicio[1], Kim Mansky[1], Lincoln Potter[1]. [1]University of Minnesota, United States, [2]Georgia State University, United States

C-type natriuretic peptide (CNP) activation of guanylyl cyclase (GC)-B, also known as NPR2 or NPR-B, increases intracellular cGMP and stimulates long bone growth. However, the possible function of GC-B in maintaining bone density is relatively unknown. CNP activation requires the phosphorylation of multiple GC-B residues and dephosphorylation inactivates the receptor (1). Knock-in GC-B7E/7E mice expressing a phosphomimetic, glutamate-substituted, form of GC-B that cannot be inactivated by dephosphorylation, have increased CNP-dependent cellular cGMP concentrations and longer bones (2). Here, we show that male nine-week old GC-B7E/7E mice have greater bone mass, density, and flexural strength. Micro-computed tomography of tibiae indicated that GC-B7E/7E tibiae have 43% greater trabecular bone volume, 40% greater trabecular number and 17% less trabecular separation than wild type tibiae. GC-B7E/7E tibiae also have 10% greater cortical cross-sectional area, 9% greater cortical thickness, 6% greater periosteal diameter and a 24% greater cortical cross-sectional moment of inertia. Trabecular, but not cortical, bone mineral density was elevated 40% in tibiae from the mutant mice. Three-point bending analysis determined that mutant tibiae and femurs had 35% and 36% greater ultimate load and 35% and 49% greater stiffness compared to wild type bones, respectively. Microhardness assays revealed no differences in bone quality. Serum P1NP levels were increased and CTx levels were not decreased in the GC-B7E/7E mice, consistent with increased osteoblast but not decreased osteoclast activity. In a translational study, 12-week-old male and female wild type mice

injected subcutaneously once daily for four weeks with a protease-resistant form of CNP (BMN-111) had 27%, 28% and 48% greater tibial trabecular bone volume fraction, trabecular number, and serum osteocalcin levels, respectively, with no changes in tibial length compared to bones from saline-injected control mice (Figure 1). We conclude that GC-B activation increases bone mass, density and strength possibly by elevating osteoblast activity. To our knowledge, these are the first data to show that GC-B activation results in anabolic effects in adult bone. We suggest that GC-B activators may be beneficial in the treatment of bone fractures and/or osteoporosis and warrant further study. References:1. Potter, L. R. The A242T Mutation in the Low-density Lipoprotein Receptor-related Protein 5 Gene in Korean Family with Osteopetrosis Eunheui Kim*, Yunkyung Jeon, Injoo Kim. Pusan National University Hospital, Republic of Korea

ObjectiveOsteopetrosis is a heterogeneous group of disorders that characterized by a generalized increase in bone density. Type I autosomal dominant osteopetrosis results from mutation of low-density lipoprotein receptor-related protein 5 (LRP5) gene.MethodsRadiographic and biochemical examinations and bone mineral density (BMD) and genetic analyses were performed in patient and her family members.ResultsA 22-year old woman went to dental clinic for orthodontics with asymptomatic malocclusion. She transferred to endocrinologist for the evaluation of acromegaly due to the jaw enlargement. She had normal height (161.6 cm), and weight (49.5kg). She had a palpable torus palatinus which the patient was not aware of. Skull, humerus, femur and hand X-ray revealed thickened calvaria especially at the frontal and occipital bone, increased gonial angle of mandible and cortical thickening of long bone, metacarpal bone and phalanges. The BMD values were significantly higher than the standard age- and sex- matched adult mean reference values. The aBMD value of the hip and lumbar spine revealed 1.745 g/cm2 in the left total hip (Z-score = +8.75), 1.612 g/cm2 in the femoral neck (FN; Z-score = +5.6) and 1.868 g/cm2 in the L1–L4 spine (Z-score = +6.1). The serum calcium level was 9.1mg/dL (8.5-10.3mg/dL), serum phosphate 3.6mg/dL (2.0-4.6mg/dL), urinary calcium 134.4mg/24hr, serum intact parathyroid hormone 22.44pg/mL (10-57pg/mL), and 25-hydroxyvitamin D3 51.56ng/mL (30-150ng/mL). The values were serum osteocalcin 10.69ng/mL (4-20ng/mL), bone specific alkaline phosphate (bone ALP) 18.51?/L (premenopausal 8.50-14.30?/L), c-telopeptide of type 1 collagen (CTX) 0.54ng/mL (premenopausal <0.573ng/mL). The heterozygous missense mutation p.Ala242Thr in exon 4 of the LRP5 gene was detected in patient. And her mother, older sister and younger brother had the same missense mutation c.724G>A, but her father did not.ConclusionAs far as we know, this is the first case report of A242T mutation in LRP5 gene with osteopetrosis in South Korea. The autosomal dominant gain-of-function missense mutations resulting in a high bone mass phenotype with an elongated mandible and torus palatinus. It is necessary to study the underlying mechanism of elevated bone mineral density including gene mutations. These studies might give us a clue to improve bone health.

Asfotase Alfa in Adults – Functional Outcome in a Real World Setting Lothar Seefried*, Silke Achtziger, Franca Genest. Wuerzburg University, Germany

BACKGROUND: Hypophosphatasia (HPP) is rare metabolic disorder due to genetically determined deficient activity of the Tissue Non-specific Alkaline Phosphatase (TNAP), causing a wide range of musculoskeletal symptoms and functional disabilities. Asfotase Alpha (AA) is approved as enzyme-replacement therapy for the treatment pediatric-onset HPP. Clinical trials with AA have mainly focused on survival and functional improvements in children. Available data on AA treatment in adults is largely limited to solitary case reports. In order to add to this knowledge, we report real-world data on functional outcomes of AA treated adult HPP patients.METHODS: Retrospective data analysis of adult patients with pediatric-onset HPP treated with AA for bone manifestation of the disease in line with the label in Europe. Analysis focused on functional outcome data over a follow-up period of the first 12 months of treatment. Statistical analysis was conducted using non-parametrical testing procedures.RESULTS: Evaluation included 12 individuals (9 female) with a mean (SD) age of 51.4 (18.1) years, an average body weight of 81.5 (22.6)kg and a height of 159.6 (12.4) cm. During the course of treatment, one patient sustained a fracture not requiring surgery while three patients were subject to elective orthopedic surgeries of their lower limbs. Along with that, 4 patients could reduce their level of dependency on walking aids and still, distance covered during 6 Minute Walking Test (MWT) increased significantly from 327.6m to 354.9m (p=0.008). However, time required to perform the Chair Rising Test (CRT) only improved insignificantly (p=0.125) and average results for handgrip strength remained unchanged. In line with that, constitutional assessment using Bioimpedance Analysis (BIA) did not show any alteration of the Skeletal Muscle Index (SMI). None of the patients cancelled treatment for side effects or subjective lack of efficacy.Discussion: On label treatment with AA was safe and essentially enhanced patients mobility while results on other parameters of physical performance showed insignificant improvements. Importantly, functional outcome data exhibited a wide range of individual variability and was affected by numerous additional health issues like pre-existing limb deformities and concomitant illnesses. Considering the time course, functional changes were not completed at 6 months and further improvements could still be observed at 6 to 12 months.

An Acvr1[R258G] "Conditional On" Mouse Model of Atypical Fibrodysplasia Ossificans Progressiva (FOP) is Activin A dependent Sarah J. Hatsell*, Lily Huang, Chris Schoenherr, Lili Wang, Xialing Wen, Joyce Mcclain, Vincent Idone, Kalyan C. Nannuru, Andrew J. Murphy, Aris N. Economides. Regeneron Pharmaceuticals Inc, United States

FOP is an autosomal dominant disorder characterized by early onset, episodic and progressive ossification of skeletal muscle and associated connective tissue. FOP is driven by mutations in the intracellular domain of ACVR1 (ALK2), the most common of which is R206H. However, rare FOP causing mutations exist throughout the GS and the kinase domain of Acvr1. Several of these mutations result what appears to be a more severe FOP phenotype that includes significant developmental abnormalities in addition to the postnatal heterotopic bone formation. Two unrelated individuals with one such mutation, R258G, in the kinase domain of Acvr1 have a severe phenotype (Kaplan et al. 2015). We have modeled this mutation to investigate whether it results in a more severe phenotype in a mouse when present in the same genetic background as the more common R206H mutation. We engineered a Cre-regulated 'conditional-ON' allele of ACVR1[R258G] in the mouse, Acvr1[R258G] FlEx/+, similar to that previously used to model the R206H mutation (Hatsell, Idone et al. 2015). Body-wide activation of the FOP allele in Acvr1[R258G]FlEx/+;Gt(ROSA26)Sor-CreERt2/+ adult mice resulted in progressive ossification, evident radiographically as early as 2 weeks after dosing with tamoxifen in a similar manner to that seen with the previously published Acvr1R206HFlex mouse. Detailed studies to determine whether this mutation has a different and more severe embryonic phenotype compared to R206H are planned. We have previously shown that HO resulting from R206H mutation is Activin A dependent and can be completely blocked with the administration of an Activin A blocking antibody. Other FOP causing mutations also render Acvr1 responsive to Activin A (Hino et al 2015) suggesting Activin A blockade would also be effective in inhibiting HO formation induced by these mutations. Here we show that HO generated by the R258G mutation is also Activin A dependent in this mouse model.

Percent total body fat is negatively associated with muscle strength and jump test performance in older men and women, independent of age, height, and muscle mass. Bethany Moore*, Harshvardhan Singh, Gary Hunter. University of Alabama at Birmingham, United States

Purpose: To assess the independent relationship between percent total body fat, muscle strength, and neuromuscular performance in older men and women.Methods: Dual X-ray absorptiometry (DXA) was used to measure percent total body fat and muscle mass in 60 older adults (men = 27, women = 33) between ages 55-85 (men = 64.8 ± 6.5 years, women = 62.5 ± 5.3 years). Appendicular skeletal muscle mass (ASM) was quantified as the sum of the lean soft-tissues of the arms and legs. An average of three maximum countermovement jumps was used to calculate jump power (JPow) and jump height (JHt). Two leg press (LP) as well as the right and left side hip abduction (HipAbd) strength were assessed by 1-repetition maximum testing. The average of the right and left HipAbd values were used for analysis. JPow, LP, and HipAbd were normalized for body weight. Data normality was checked with Shapiro-Wilk test. Stepwise sequential multi-variable regression analysis was used to examine associations of percent total body fat and ASM with jump test performance and muscle strength tests.Results: Stepwise sequential regression analysis of percent total body fat and ASM versus jump test performance and measures of muscle strength after adjusting for age and height showed that percent total body fat negatively predicted 1) JPow (n = 27, β = -0.583, 95% CI = -0.289 to -0.073, rpartial = -0.586, P = 0.002), 2) JHt (n = 27; β = -0.618, 95% CI = -0.149 to -0.538, rpartial = -0.624, P = 0.001), and 3) HipAbd (n =27, β = -0.433, 95% CI = -0.056 to -0.002, rpartial = -0.423, P = 0.035) in men. In women, percent total body fat negatively predicted 1) JHt (n = 33, β = -0.618, 95% CI = -0.258 to -0.096, rpartial = -0.639, P < 0.001), 2) LP (n = 33, β = -0.542, 95% CI = -0.128 to -0.035, rpartial = -0.556, P = 0.001), and 3) HipAbd (n = 33, β = -0.067, 95% CI = -0.067 to -0.032, rpartial = -0.720, P < 0.001). Conclusion: Our findings suggest that percent total body fat has an independent negative association with jump test performance and muscle strength in older men and women. This knowledge is important for evidence-based musculoskeletal rehabilitation in older adults with sarcopenia and increased adiposity as well as decisions about weight loss in overweight or obese older men and women.

LB SAT-1245

FGF-inhibition of NPR2-mediated Cyclic cGMP Production in Growth Plate Chondrocytes Is Reversed by the Phosphatase Inhibitor LB-100 Leia C Shuhaibar*, Giulia Vigone, Laurinda A Jaffe. Department of Cell Biology, University of Connecticut Health Center, United States

Chondrocyte proliferation and differentiation during endochondral bone growth is controlled by multiple regulatory pathways. Activating mutations in fibroblast growth factor receptor 3 (FGFR3) and inactivating mutations in the natriuretic peptide receptor 2 (NPR2) guanylyl cyclase both cause decreased production of cyclic GMP (cGMP) and severe short

stature, causing Achondroplasia and Acrosomelic Dysplasia Type Maroteaux, respectively. However, how these signaling pathways interact to regulate bone growth is poorly understood. We developed a novel ex vivo imaging system using mice expressing the cGi500 FRET sensor for cGMP and confocal microscopy to measure real-time changes in cGMP production in chondrocytes of living newborn tibias, and showed that FGF18 decreases cGMP production by NPR2 (1). Activation of NPR2 requires both C-type natriuretic peptide (CNP) binding to the extracellular domain and phosphorylation of 7 intracellular serines and threonines. Conversely, FGF-induced inactivation of NPR2 depends on the dephosphorylation of these phosphorylation sites (1, 2). These results suggested the potential use of phosphatase inhibitors to suppress the FGF-induced NPR2 dephosphorylation and inactivation, for the treatment of skeletal dysplasias such as Achondroplasia, a condition where FGFR3 is constitutively active. To investigate this possibility, we tested the effect on chondrocyte NPR2 activity of the PPP family phosphatase inhibitor LB-100, a small molecule that has been used successfully in phase one clinical trials for other diseases (3). By treating tibias from cGi500 mice with LB-100, we tested whether inhibiting PPP-family phosphatases counteracts the inhibitory effect of FGF18 on NPR2 and enhances the production of cGMP in the growth plate, thus stimulating bone growth. We show that LB-100 dose-dependently reverses the inhibition of NPR2 activity by FGF in the growth plate. Tibias treated with FGF18 for 1 hour produced 44% less cGMP when exposed CNP, as compared to control bones (Fig 1A). In contrast, when tibias were treated with 10-20μM LB-100 for 1 hour prior to treatment with FGF18, the production of cGMP was restored to normal levels (Fig 1B). Our results suggest that LB-100 or other phosphatase inhibitors could also be useful for treatment of skeletal dysplasias. References: 1. Shuhaibar et al., eLife. 6: e31343, 20172. High Frequency of Bone Mineral Density (BMD) Abnormalities in Women with Symptoms Typical of Thyroid Dysfunction and Normal Thyroid Hormones Georgia Antoniou*[1], Stelios Kasikis[2], Charis Chourpiliadis[2], Dimintra Bantouna[2], Panagiota Koukoutsidi[2], Juan Carlos Jaume[3], Rodis D Paparodis[4]. [1]Agia Sofia General Pediatric Hospital, Greece, [2]University of Patras Medical School, Greece, [3]Division of Endocrinology, Diabetes and Metabolism and Center for Diabetes and Endocrine Research (CeDER), University of Toledo, United States, [4]Division of Endocrinology Diabetes and Metabolism and Center for Diabetes and Endocrine Research (CeDER) University of Toledo, Greece

Background: Subclinical thyroid disease has significant negative impact on bone metabolism, both in the forms of bone accrual at the young age and bone loss after menopause. Our clinical observation suggested that this phenomenon is present in women with normal thyroid hormones as well, as long as thyroid abnormalities can be found by ultrasound or thyroid scan. We performed the present study to further delve into this topic.Methods: We prospectively enrolled women complaining of five or more concurrent, unexplained symptoms of potential thyroid dysfunction at our Endocrinology clinic in Patras, Greece within 3 years. Subjects with abnormal thyroid function, primary hyperparathyroidism, eGFR<60ml/min, or those on medications affecting thyroid hormones were excluded. We measured serum TSH, performed a Tc-99m thyroid scan, thyroid ultrasound and DEXA scan of the spine, hip or distal radius. We split our subjects by age (pre and post- menopausal) and BMD, [lowest T- or Z -score >-1.0 - Normal, -1.0 to -2.4 - Low Bone Mass (LBM) and <2.4 Osteoporosis (OST)]. Fracture history was recorded as well. The non-Hispanic white female population from the NHANES database was used as a control (CON). Mann-Whitney test was used to compare TSH, T/Z scores of the hip area between our subjects and CON.Results: Out of 3563 subjects, 356 consecutive women met the inclution criteria; Ultrasound findings: n=8 (2.2%) were normal; n=282(79.2%) increased vascularity; n= 91(25.6%) single thyroid nodule; n=170(47.8%) multiple nodules. Thyroid scan findings: n=273(76.7%) increased uptake; n=25(7.0%) decreased uptake; n=178(50.0%) cold nodule(s); n=40(11.4%) hot nodules; n=17(4.8%) both hot and cold nodules; n=52(14.6%) normal thyroid scan. No subjects had normal thyroid ultrasound and scan at the same time. TSH was higher in our subjects compared to the CON(p<0.001). LBM was present in 23.8% to 50.5% of our subjects, while OST prevalence increased with age. High rates of fracture were noted in all age groups and increased with age (18.2%-45.5%)Conclutions: Subjects with symptoms suggestive of thyroid dysfunction and TSH values within reference range, regardless their age group, tend to have low bone mass. Our findings imply that an unidentified thyroid dysfunction might strongly impact bone mass accrual and peak bone mass, leading to a high risk of OST in this population even before menopause.

Renal Function Change in Chronic Hypoparathyroidism Patients Treated With Recombinant Human Parathyroid Hormone (1-84) (rhPTH[1-84]) and in a Historical Control Cohort Treated With Standard Therapy Kristina Chen*[1], Mishaela Rubin[2], Fan Mu[3], Elyse Swallow[3], Jing Zhao[3], Jessie Wang[3], Alan Krasner[1], Nicole Sherry[1], James Signorovitch[3], Markus Ketteler[4], John Bilezikian[2]. [1]Shire Human Genetic Therapies, Inc., United States, [2]Columbia University College of Physicians and Surgeons, United States, [3]Analysis Group Inc., United States, [4]Division of Nephrology, Klinikum Coburg, Germany

Standard therapy (ST) for chronic hypoparathyroidism (HPT) includes calcium and active vitamin D supplementation, which can be associated with an increased risk of renal complications. This study compared renal function change, assessed by estimated glomerular filtration rate (eGFR) over 5 years, between HPT patients receiving rhPTH1-84 as an adjunct to ST and a historical control cohort without rhPTH1-84.rhPTH1-84-treated HPT patients were selected from 2 single-arm, long-term, open-label studies, RACE (NCT01297309) and NCT02910466. Control patients were selected from the MedMining database using similar inclusion criteria to the 2 studies. Patients were required to have ≥2 eGFR measures, 5 years apart, after HPT diagnosis. Index date was defined as the baseline visit in the rhPTH1-84-treated cohort and the 1st eligible eGFR measure date in the historical control cohort. eGFR change over time from baseline was compared using an adjusted multivariable model. A sensitivity analysis was conducted at 3 years for patients with ≥2 eGFR measures 3 years apart after HPT diagnosis.122 patients (n=69 with and 53 without rhPTH1-84) were included in the 5-year analyses. At baseline, rhPTH1-84-treated patients compared with control patients were younger (51.7 vs 55.8 y) and had lower eGFR (75.5 vs 82.5 mL/min/1.73mm2). Race and sex were similar between cohorts. A lower proportion of rhPTH1-84-treated patients had concomitant nephrotoxic drug use or a history of hypocalcemia, hypercalcemia, hypertension, diabetes mellitus, or cardiac disorders. Characteristics were similar in the 3-year sensitivity cohorts (n=75 with and 76 without rhPTH1-84). In the adjusted model, predicted eGFR change at year 5 was +5.80 vs –5.56 mL/min/1.73mm2 in the rhPTH-treated vs historical control cohort. Annual rate of eGFR decline over 5 years of follow-up was significantly lower in rhPTH1-84-treated patients (difference in annual eGFR change=2.13 mL/min/1.73mm2; P=0.002). The trend in eGFR change over 3 years was similar in the sensitivity analysis (difference in annual eGFR change=2.96 mL/min/1.73mm2; P<0.001).In this retrospective analysis, patients with chronic HPT without rhPTH1-84 treatment exhibited significantly greater decline in eGFR than patients receiving rhPTH1-84 over 5 years, with

and without adjusting for confounders. This difference was also observed over 3 years in similar cohorts. This analysis is hypothesis generating and further research is warranted.

Treatment of Tertiary Hyperparathyroidism After Renal Transplant Chee Kian Chew*[1], Jennifer Hill[2], Robert Wermers[2], Tricia Veglahn[2], Hatem Amer[2], Matthew Hathcock[2]. [1]Tan Tock Seng Hospital, Singapore, [2]Mayo Clinic, United States

Background: Elevated parathyroid hormone (PTH) persists in up to 70% of patients one year and 43% two years after renal transplant. Tertiary hyperparathyroidism (3HPT) occurs in an estimated 23% of patients one year after renal transplant. Although hyperparathyroidism has been identified as an independent risk factor for fractures and allograft failure, appropriate treatment remains unclear. Purpose: To evaluate if bone health and allograft function in adult patients with 3HPT is adversely affected by 3HPT and if 3HPT management provides benefit in these parameters within the first five years after renal transplant. Methods: A retrospective chart review of renal transplant patients 18 years of age or older at a Midwestern tertiary healthcare center who received a first time, solitary kidney transplant between January 1, 2010 - December 31, 2011 was completed. Results: A total of 209 patients were identified with a mean age of 53 years and of whom 128 were male (61.2%). The mean PTH at the time of transplant was 196 pg/mL. Overall, 45 patients (23%) had 3HPT during at least one time point throughout the study, and specifically was present in 32 (15%), 28 (13%), 14 (7%), and 6 patients (3%) at 4 months, 1 year, 2 years, and 5 years after renal transplant respectively. Parathyroidectomy was performed in 20 patients, 9 pre-transplant and 11 post-transplant. Those with 3HPT were noted to have longer hemodialysis duration pre-transplant (P < 0.001) and received a deceased donor transplant (P = 0.04). Resolution of 3HPT was noted in 10% of patients with 3HPT between 4 months and 12 months and 4% between 12 months and 24 months without parathyroidectomy or cinacalcet. When comparing patients with 3HPT to those without 3HPT there was no significant difference in bone mineral density at the spine or hip or fractures post-transplant. Renal function at 5 years and graft failure were also not significantly different in patients with 3HPT.Conclusions: A significant number of patients develop 3HPT after renal transplant especially in patients with dialysis prior to transplant or with deceased donor transplants. Although skeletal health and renal function were not adversely impacted by the presence of 3HPT, changes in the management of renal transplant (e.g. preemptive living donor transplants) likely impacted the results. Further study will be needed to clarify appropriate management of patients who develop 3HPT after renal transplant.

Premenopausal women with idiopathic osteoporosis (PreMenIOP) and low bone formation have decreased responsiveness to teriparatide (TPTD) and evidence of IGF-1 resistance in skeletal and non-skeletal tissues Adi Cohen*[1], Nandini Nair[1], Stephanie Shiau[1], Robert R. Recker[2], Joan M. Lappe[2], David W. Dempster[1,3], Hua Zhou[3], Binsheng Zhao[1], Xiaotao Guo[1], Mafo Kamanda-Kosseh[1], Mariana Bucovsky[1], Julie Stubby[2], Elizabeth Shane[1]. [1]Columbia University Medical Center, United States, [2]Creighton University, United States, [3]Helen Hayes Hospital, United States

PreMenIOP have marked deficits in bone microarchitecture but variable bone remodeling. We have reported that PreMenIOP with low tissue level bone formation rate (BFR) are less responsive to TPTD and have higher serum IGF-1, a hormone anabolic for osteoblasts and other tissues. The IGF-1 data were unexpected because serum IGF-1 is low in other forms of low turnover osteoporosis: male IOP, obesity, growth hormone deficiency (GHD). We thus hypothesized that PreMenIOP with low BFR have IGF-1 resistance at the osteoblast level and this IGF-1 resistance may affect nonskeletal tissues. To investigate these hypotheses, we prospectively evaluated 39 PreMenIOP who received 12M of TPTD (20 mcg/d) in an FDA-funded RCT.The mean 12M increase in lumbar spine (LS) BMD was 8.7±5.6% but varied widely:-7% to +21%. Lower LSBMD response to TPTD was again associated with lower pre-TPTD cancellous (CAN;r=0.4,p=0.03) and endocortical (ENDO;r=0.4,p=0.01) BFR. Consistent with our hypothesis, IGF-1 Zscores correlated inversely with CAN(r=-0.5,p=0.007) and ENDO(r=-0.4,p=0.04) BFR. LSBMD response was also inversely related to IGFBP3(r=-0.3,p=0.04),with a trend for an inverse association with IGF-1 Zscore (r=-0.3,p=0.1).To assess for evidence of IGF-1 resistance in nonskeletal tissues, we asked whether PreMenIOP with low BFR/high IGF-1 resemble patients with low IGF-1 due to GHD, a clinical profile characterized by visceral adiposity, low adiponectin/high leptin, insulin resistance, high LDL/low HDL, high inflammatory CV risk markers (CRP, IL-6). We compared PreMenIOP with low and high BFR based on median CANBFR on biopsy (Table). LowBFR had lower BMD response to TPTD, higher serum IGF-1 and IGF-1 Zscores. They also had higher weight, BMI, central adiposity and leptin (all p<0.05).Lower BMD response to TPTD was associated with some clinical features of GHD: higher DXA trunkfat (r=-0.4,p=0.01), subcutaneous fat at L4 level by CT (r=-0.5,p=0.01) and leptin (LS:r=-0.3,p=0.08). Also consistent with our IGF-1 resistance hypothesis, several common features of GHD were associated with higher IGF-1 Zscores in PreMenIOP: higher DXA trunk fat (r=0.3,p=0.048), triglycerides (r=0.3,p=0.03) and leptin (r=0.4,p=0.02) and lower adiponec-

tin (r=-0.4,p=0.02).In conclusion, IGF-1 resistance may underlie both the skeletal phenotype and decreased responsiveness to TPTD in PreMenIOP with low bone turnover. Such women also demonstrate metabolic consequences of IGF-1 resistance in nonskeletal tissues.

Functional outcomes of nonoperatively treated LC-1 pelvic ring fractures: a retrospective study Aidan Hadad*[1], Matthew Cohn[2], Rehan Saiyed[1], Omer Or[3], Eric Marty[1], Gülce Askin[4], Joseph Lane[1]. [1]Hospital for Special Surgery, United States, [2]Rush University Medical Center, United States, [3]Hebrew University Hadassah Medical Center, Israel, [4]Weill Cornell Medical College, United States

Lateral compression type 1 (LC-1) fractures are the most common pelvic ring injury.(1) Formally standardized treatment regimens for LC-1 fractures are lacking, with symptomatic treatment, medical management, and surgical stabilization observed.(1,2) While data on short-term pain after nonoperative treatment is available, there is limited data on long-term function.(3) No study to date has compared long-term functional outcomes to age and sex matched non-injured controls. This study evaluates the effect of nonoperative treatment on functional outcomes in a consecutive cohort of patients with LC-1 pelvic ring fractures. We identified consecutive adults treated nonoperatively from 2012-2015 for an isolated LC-1 pelvic ring fracture per Young and Burgess classification.(4) Patients with additional lower extremity fracture at presentation or treatment with osteoactive medications within 6 months of injury were excluded. Those meeting inclusion/exclusion criteria, along with age and gender matched (2:1) controls with no history of lower extremity fracture, were contacted and administered the Short Musculoskeletal Function Assessment (SMFA). Associations between continuous variables were assessed with Wilcoxon rank-sum tests or t-tests and discrete variables with chi-squared tests or Fisher's exact tests. 39 of 97 (40%) identified LC-1 fracture patients were consented a median of 3 years (range 2-4 years) after injury. 15 patients (15%) were reported deceased. Non-contacted individuals were older (84 vs 80 years, p=0.008) and demonstrated shorter length of stay (3 vs 4 days, p=0.004) than those contacted. No significant difference was observed in charlson comorbidity index at time of presentation between contacted and non-contacted individuals (p>0.05). No significant differences were observed in SMFA scores of LC-1 fracture patients versus controls (Table 1). No patient, radiographic, or injury characteristics predicted worse functional outcome. Patents with LC-1 pelvic ring fractures appear to achieve functional outcomes comparable to healthy age and sex matched controls at least two years after injury. Such findings can be viewed in the context of heightened focus towards anti-resorptive and anabolic medications in the acute post-fracture setting. Our results suggest that such treatments, which are often costly and burdensome in their administration, may ultimately be unnecessary in this subset of pelvic ring injury.

		Case N=39	Control N=78	p

Magnetic Resonance Imaging (MRI) Evidence that Trabecular Bone Structure and Marrow Adipose Tissue (MAT) Are not Affected in Type 2 Diabetes Mellitus (T2D) Iana De Araujo*[1], Carlos Salmon[2], Carlo Rondinoni[1], Marcello Nogueira-Barbosa[1], Francisco De Paula[1]. [1]Ribeirao Preto Medical School-University of Sao Paulo, Brazil, [2]Faculty of Philosophy, Sciences and Arts – University of Sao Paulo, Brazil

Introduction: The underlying mechanisms of bone fragility in T2D remain unclear. There are conflicting results using HR-pQCT to estimate bone structure (Figure 1) in T2D. MRI is a versatile technique able to measure bone structure and adipose tissue, including MAT. Objective: To evaluate bone structure and MAT by MRI in T2D, as well as the relationship between total MAT [lumbar spine (L3) and proximal tibia (pT)] and soleo intramyocellular lipids (IMCL/EMCL with BV/TV [i.e., apparent bone/total volume (appBV/TV)] in T2DM. Material and Methods: MR 1H spectroscopy was used to assess bone L3MAT, pTMAT) and soleo intramyocellular lipids (IMCL/EMCL). In addition, MRI was used to quantify BV/TV. DXA was used to measure bone mass in lumbar spine (LSBMD), total hip (THBMD) and femoral neck (FNBMD). Results: 75 volunteers were evaluated: control (C: 11F/8M), overweight (Ov: 15F/7M), obese (O:10F/6M) and type 2 diabetes (T2D: 12F/6M). The groups were matched by sex, age (C:50±11; Ov:51±13; O:47±8; T2D:52±9 years) and height (C:1.69±0.1; Ov:1.65±0.1; O:1.66±0.1; T2D:1.65±0.1m). The BMI was higher in O and T2D than in C and Ov (C:23±1.6; Ov:26.0±1.3; O:35±4.4; T2D:32±6.0Kg/m²; p<0.05). The LSBMD was similar in the groups (C:0.974±0.095; Ov:1.003±0.105; O:0.995±0.112; T2DM:1.057±0.117 g/cm², p>0.05), whereas FNBMD and THBMD was higher in T2D than the C group, respectively (C:0.750±0.139; Ov:0.801±0.116; O:0.860±0.134; T2D:0.869±0.119 g/cm²) and (C: 0.860±0.143; Ov:0.910±0.114; O:0.939±0.141 e T2D:0.991±0.117 g/cm²). The L3MAT and PTMAT were similar in the four groups, respectively (C: 40.6±9.7; Ov: 44.6±10.6. O: 46.0±16.6 and T2D:46.8±12.9%) and (C: 92±3.4; Ov: 89±7.6. O: 83±20.6 and T2D: 90±6.9%). Also, the BV/TV was similar in the 4 groups (C:0.507±0.056; Ov:0.526±0.054; O:0.516±0.047 e T2D: 0.555±0.023). There was no correlation between BV/TV and pTMAT (r=0.03, p>0.05). There was a trend of negative correlation between L3MAT and FNBMD (r=-0.25, p=0.08). Also, there was a tendency for positive correlation between IMCL/EMCL with PTMAT (r=0.31, p=0.07) and L3MAT (r=0.26, p=0.1). Conclusion: The present results indicate that there is no impairment in trabecular bone structure as determined by MRI in T2D. MAT is not increased in peripheral and axial bone in T2D, but lipids deposition in muscle and MAT seems to be related.
SUN-0025

Bone loss in hepatitis B virus-infected patients is associated with greater osteoclastic activity independently of the retroviral use Renata Dessordi*[1], Rodrigo Carvalho De Santana[2], Elen Almeida Romão[2], Anderson Marliere Navarro[2]. [1]Sao Paulo State University, Brazil, [2]University of Sao Paulo, Brazil

Hepatitis B is a major public health problem worldwide and is associated with considerably high mortality rates. Oral medications, generally nucleoside/nucleotide analogs such as tenofovir, are used as long-term therapy and have possible side effects such as the reduction in bone mineral density associated with their use. Objective: to evaluate the effects of tenofovir, compared with those of other nucleoside/nucleotide analogs (entecavir and lamivudine), on the bone mineral density of hepatitis B patients. Materials and Methods: a cross-sectional study was conducted with 81 adult patients with chronic hepatitis B who were treated at the Clinical Hospital of Ribeirão Preto (University of São Paulo [USP]). Dual-energy x-ray absorptiometry (DXA) was performed to assess bone mineral density. Biochemical analyses were performed of osteocalcin, deoxypyridinoline, parathyroid hormone and anthropometric measures of weight, height, and body mass index were taken. Participants, of both sexes, were subdivided according to the use of antiretrovirals: Group 1: 27 patients who were inactive virus carriers without medication; Group 2: 27 patients on tenofovir; Group 3: 27 patients taking lamivudine or entecavir. Results: there was no difference in the mean age, body mass index, lean and fat mass between the patients in both study groups (p > 0.05). Osteopenia was diagnosed from the DXA readings for lumbar spine in the Group 1: 7.4%; Group 2: 15%; and Group 3: 3.7%. It was observed that the bone formation markers, osteocalcin levels as well as parathyroid hormone and insulin growth factor 1 values were within normal values for all groups. In all groups, the bone resorption marker, urinary deoxypyridinoline levels, showed an increase. Conclusion: the increase in the bone resorption marker levels indicates a high resorptive activity of bone tissue. These data point to a greater osteoclastic activity resulting in the bone loss in hepatitis B virus-infected patients both treated and not treated with antiretrovirals.

SUN-0026

Bone Tissue Composition in Post-menopausal Women Varies with Glycemic Control Heather B. Hunt*[1], Nicholas A. Miller[1], Kimberly J. Hemmerling[1], Maho Koga[1], Kelsie A. Lopez[1], Kendall F. Moseley[2], Eve Donnelly[1,3]. [1]Department of Materials Science and Engineering, Cornell University, United States, [2]Division of Endocrinology, Johns Hopkins University School of Medicine, United States, [3]Research Division, Hospital for Special Surgery, United States

Type 2 diabetes mellitus (T2DM) is associated with elevated skeletal fragility, despite patients with T2DM having normal to high bone mineral density (BMD). The observation that individuals with T2DM are at higher risk for fracture suggests that sustained glycemic derangement causes changes in bone quality independent of BMD. Therefore, the objective of this study was to assess the bone tissue composition in post-menopausal women with varying degrees of glucose tolerance.Transiliac crest biopsies were collected in three groups of postmenopausal women based on an oral glucose tolerance test or an established, insulin-requiring T2DM diagnosis: normal glucose tolerance (NGT; n=35, age=64.8±6.8), impaired glucose tolerance (IGT; n=27, age=64.5±5.4), and T2DM (n=25, age=64.2±6.1). Biochemical parameters of glucose control and bone metabolism were collected. Three cortical (c) and three trabecular (t) regions (1600μm2) on 3 sections per biopsy were scanned using Fourier transform infrared imaging. The means and widths of the pixel distributions of each image were calculated for mineral:matrix ratio (M:M), collagen maturity (XLR), mineral crystallinity (XST), and carbonate:phosphate ratio.In T2DM vs NGT cortex, the mean M:M was 7% greater, the M:M distribution was 10% narrower, and the XST distribution was 16% wider (all p<0.05). In T2DM vs NGT trabeculae, the mean XLR was 5% lower and the XST distribution was 14% wider (all p<0.05). The mean c-XLR and t-XLR and c-M:M distribution width were negatively correlated with HbA1c, and the distribution widths of c-XST and t-XST were positively correlated with HbA1c (Table 2). No differences between IGT and NGT or T2DM were observed.The distributions of M:M were narrower and shifted to higher mean values in T2DM vs NDM cortex,, indicating that glycemic derangement is associated with increased mineral content that is more homogeneous. Because mineral content increases with tissue age (time since formation), these findings support prior observations of reduced turnover in T2DM. In contrast, the greater mean XLR values and wider XST distributions of both tissue types in T2DM suggests glucose intolerance yields

less-mature collagen with more heterogeneous crystals, a finding consistent with less mature tissue. In summary, this study demonstrates that T2DM, but not IGT, has complex effects on bone tissue composition, particularly its mineral properties, and that T2DM may affect cortical and trabecular tissue differently.

The Effect of TransCon PTH on Bone Markers in a Phase 1 Trial David B. Karpf*[1], Susanne Pihl[2], Aimee Shu[1], Eva Mortensen[1], Jonathan A. Leff[1]. [1]Ascendis Pharma Inc., United States, [2]Ascendis Pharma A/S, Denmark

Background:Hypoparathyroidism (HP), a condition of parathyroid hormone (PTH) deficiency, leads to abnormal calcium metabolism. Standard of care (active vitamin D and calcium) does not correct decreased osteoclast activity and diminished bone turnover associated with HP. PTH replacement therapy is evolving with PTH analogues such as Natpara [PTH(1-84)] and Forteo [PTH(1-34)]. However, due to short half-lives, they incompletely control the disease and are known to be anabolic, causing an increased risk of osteosarcoma in rats.True replacement therapy would entail PTH exposure in the normal range 24 hours per day with an infusion-like profile. Horwitz et al demonstrated that continuous PTH(1-34) infusion in healthy adults led to suppression of bone formation and increased resorption markers. NIH studies in adults with HP showed continuous PTH(1-34) infusion in the normal range via an infusion pump normalized bone turnover.TransCon PTH, a sustained-release prodrug of PTH(1-34), is in development for the treatment of HP. Through auto-cleavage at physiological temperature and pH, unmodified PTH(1-34) is sustainably released.Methods:This phase 1, randomized, placebo-controlled, single and multiple ascending dose (SAD and MAD) trial evaluated safety, tolerability, pharmacodynamics (PD), and (pharmacokinetics) PK of TransCon PTH in 130 healthy adults. Cohorts of 10 subjects (8 active, 2 placebo) received

7 SAD (3.5-124 μg) or 6 MAD (3.5-24 μg) for 10 days. The PD endpoints included serum calcium and bone turnover markers (serum P1NP, BSAP, CTx, and urine NTx). The primary PK endpoint was free PTH.Results:Completed SAD and MAD cohorts showed TransCon PTH was generally well-tolerated. Free PTH (and serum calcium) showed a dose-dependent response, with a half-life of approximately 60 hours and an infusion-life profile with daily administration. Similar to the Horwitz data, P1NP decreased in response to TransCon PTH administration, consistent with suppression of bone formation and in contrast to increases known to occur with daily PTH(1-34) and PTH(1-84) therapies, while serum CTx levels increased.Conclusion:Interim data supports an infusion-like PTH profile with TransCon PTH, which may predict improved efficacy and long-term safety in the treatment of HP. The effect of TransCon PTH on both bone formation and bone resorption markers were consistent with a continuous infusion of PTH(1-34) and lacking an anabolic effect.

The Relationship of Trabecular Bone Score (TBS) with Vitamin D in Older African–American Women John Aloia*, Mageda Mikhail. NYU Winthrop hospital, United States

BackgroundTrabecular bone score (TBS) is a software program approved by the US Food and Drug Administration for post–acquisition and processing of the lumbar spine dual–energy X-ray absorptiometry images that allows assessment of bone structure as as surrogate for bone quality. Low TBS values are associated with increased risk of major osteoporotic fractures in postmenopausal women and men aged 40 years and older independent of BMD. ObjectiveWe examined TBS in elderly African–American women, in a randomized, double–blind, placebo–controlled trial designed to examine the effect of vitamin D on bone loss and physical performance in elderly African–American women.DesignIn this 3–year intervention trial, 260 healthy African–American women older than 60 years of age, were assigned to receive either placebo or vitamin D3. Initial vitamin D3 dose was determined by the baseline serum 25OHD levels. The vitamin D3 dose was further adjusted at 3–month intervals, to maintain serum 25OHD levels between 75-172 nmol/L. Subjects with baseline 25OHD <20 nmol/L or >65 nmol/L, were excluded from the study. Trabecular bone score (TBS) was measured in 217 subjects, every 6 months. Total daily calcium intake of 1200 mg was ensured.ResultsNo significant differences in baseline characteristics (demographics, BMD, TBS, and serum total 25OHD) were noted between the active and placebo group. Baseline serum 25OHD level was 54.8+16.8 nmol/L. Spearman correlation coefficients were calculated between TBS and all demographic and clinical variables in 217 subjects. Significant negative correlation was observed between TBS and BMI. There were highly significant positive correlations with each of the BMD measurements. None of the biochemical variables including 25OHD level, BSAP and CTX were significantly correlated with TBS. Mixed effects model for repeated measures showed that TBS significantly declined over time (P<0.001) regardless of the treatment assignment. However, this decline was not different between the treatment groups (P=0.985).ConclusionThe lack of vitamin D supplementation over a 3–year period, did not differentially diminish TBS in older African–American women compared to those treated to maintain serum 25OHD above 75 nmol/L.

A Rare Case of Bilateral Maxillary Brown Tumors in a Patient with Primary Hyperparathyroidism Sapna Patel*, Uma Gunasekaran. University of Texas Southwestern Medical Center, United States

The presentation of primary hyperthyroidism is variable with brown tumors being a rare sequelae of hyperparathyroidism. Brown tumors localize in areas of intense bone resorption with bone defect becomes filling with fibroblastic tissue. We report a rare case of primary hyperthyroidism presenting as a brown tumor of the maxillary sinus.Ms. R is a 47 year old female who presented to the ED with intermittent constipation and recent imaging showing a left maxillary mass. Four months prior to onset of symptoms, patient noted a bump on the left side of her face, which she initially thought was acne, but progressed over two months to deform the left maxillary and nasal surface. Clinical evaluation and labs revealed calcium level, 16.5 mg/dL, PTH, 555 pg/mL, low Vitamin D 25-OH (value unavailable) and a soft, non-tender, immobile lesion in the left maxillary region. CT maxillofacial showed a ~3cm mass in left maxillary region with exophytic extension to adjacent soft tissues of the face. Patient was acutely reevaluated in the ED and found to have serum calcium 16.5 mg/dL, (ionized 8.7 mg/dL). Phosphorous 2.0 mg/dL, PTH level 953.5 pg/mL, Vitamin D 25-OH 14.7 ng/mL, alkaline phosphatase 186 U/L.A parathyroid technetium scintiscan showed increased uptake posterior to the right lobe of the thyroid indicating a 4.6 x 2.7 x 2.4 cm mass. The patient underwent excision of the maxillary mass, and was noted to have a bilateral, multifocal maxillary mass. Pathology of the maxillary mass was consistent with brown tumor. Subsequently, the patient underwent right superior parathyroidectomy. Intra-operatively, patient's parathyroid hormone decreased from 671.1 pg/mL to 54.9 pg/mL. The patient's calcium decreased post-procedure as expected, and she was started on calcium carbonate and ergocalciferol with stable electrolytes on discharge. While the mandible is the most frequently involved bone in brown tumors of the head and neck region, maxillary involvement is extremely rare. Very few cases in the literature describe Brown tumor localizing in the maxillary/facial regions in primary hyperparathyroidism [1]. Furthermore, as seen in our patient, it is extremely rare for a brown tumor occurring within the facial bones to be the first

manifestation of the systemic condition.1. Heath H, Hodgson SF, Kennedy MA. Primary hyperparathyroidism. Incidence, morbidity, and potential economic impact in a community. The New England Journal of Medicine. 1980;302(4):189–193

Effect of Renal Transplantation on Bone Microstructure and Strength Assessed by MRI Catherine Reilly*, Mary Leonard, Wenli Sun, Chamith Rajapakse, Felix Wehrli. University of Pennsylvania, United States

Abnormal vitamin D and mineral metabolism are a universal complication of advanced chronic kidney disease (CKD). Secondary hyperparathyroidism results in abnormal trabecular microarchitecture and cortical thinning. Renal transplantation (RTxp) corrects many of the risk factors for bone deficits; however, glucocorticoid therapy and persistently elevated PTH levels may further deteriorate bone. The objective of this study was to investigate the effects on bone microstructure and strength following RTxp.Sixty RTxp recipients (52% male, 32% preemptive), ages 20-60 years, were enrolled at transplantation. MRI of the distal tibia was performed on a 1.5 Tesla scanner (Siemens Tim Trio, Erlangen, Germany) using a 2-element surface coil at 0.137 mm x 0.137 mm x 0.410 mm voxel size.Microstructural bone parameters and whole-section stiffness were computed on the basis of these images using digital topological and finite element analysis, respectively, to test the hypothesis that bone quality assessed in terms of the derived structural and mechanical parameters improves upon treatment. Whole cross-section stiffness was computed by simulating compressive loading conditions along bone's axial direction. Cortical porosity was computed at each voxel retaining partial volume information and averaged over the entire cortical bone region. BV/TV was computed as the average fractional occupancy of bone over the total trabecular volume. Plate-to-rod ratio was computed to describe the relative plate and rod likeness of trabeculae. Longitudinal changes in bone parameters are summarized in Table 1. Briefly, bone deteriorated structurally and mechanically from baseline to 6 months, and to a lesser extent from 6 to 12 months of RTxp, but improving thereafter during the final 12 to 24-month period. Initial deterioration is likely a consequence of exposure to high doses of steroid.

Table 1: Changes in Parameters between Study Visits

	0-6 Month (%)	6-12 Month (%)	12-24 Month (%)

Total Alkaline Phosphatase is an unrealiable marker of relapse in treated Paget's Disease of the Bone Rebecca Sagar*, Stephen Orme, Afroze Abbas. Leeds Centre for Diabetes and Endocrinology, Leeds Teaching Hospitals Trust, United Kingdom

Background: Paget's disease of bone is a disorder of increased bone remodeling. Current guidelines suggest the use of imaging and biochemistry (total alkaline phosphatase) to aid diagnosis and monitoring. The use of intravenous zoledronic acid (ZOL) has been shown to induce sustained remission in most patients. However, the utility of total alkaline phosphatase (ALP) as a means of identifying disease relapse after initial treatment remains controversial. Methods: We retrospectively evaluated the management of 100 unselected patients with Paget's disease of bone treated with ZOL over the last 5 years in a UK teaching

hospital (mean follow-up 4 years 3 months, post first infusion). Data collected included demographics, presentation, sites, biochemistry and imaging findings.Results: The majority of patients were male (56%), had polyostotic disease (64%) and had radionuclide bone imaging at baseline (84%). Prior to any treatment, 84% of patients had elevated ALP (monostotic mean ALP 462iu/L vs polyostotic mean ALP 872 iu/L, range 30-300 iu/L). Most patients required a single ZOL infusion (mean 1.81 treatments). 88% of patients had normal ALP levels at 6 months post infusion. However only 39% were below the mid-point of the reference range, as recommended per guidelines. The vast majority of these patients were patients with polyostotic disease (66%). 74% of patients had normal ALP post ZOL for the duration of the follow-up (mean 4.5 years). Of the patients who had a biochemical relapse, as evidenced by elevated ALP, 74% had polyostotic disease. 26 patients received a second IV zoledronic acid infusion. Of these, 71% did not reach an ALP below the mid-point of the reference range. 26% of patients had symptomatic relapse during follow-up, but less than half of these had elevated ALP at the time. Overall, 28 patients had repeat radionuclide bone scan during follow-up, with 64% of these demonstrating active disease on imaging. However, 72% of patients with scan-confirmed relapse had normal ALP at the time of the repeat scan.Conclusions: Our study reaffirms the efficacy of single ZOL infusion in normalizing ALP, in a large cohort of patients with Paget's disease of bone, over 4-5 years. However, the majority of patients do not reach an ALP below the mid-point of the reference range, as suggested in guidelines. Additionally, our data suggests ALP is not a reliable biochemical marker of relapse in patients who have been previously treated with ZOL.

Cardiovascular Autonomic Neuropathy as a new complication of chronic hypoparathyroidism Gaia Tabacco*[1], Anda Mihaela Naciu[1], Roberto Cesareo[2], Claudio Pedone[3], Gianluigi Gaspa[2], Assunta Santonati[4], Daniela Bosco[4], Daria Maggi[1], Nicola Napoli[1], Paolo Pozzilli[1], Silvia Manfrini[1], Andrea Palermo[1]. [1]Unit of Endocrinology and Diabetes, Dept. of Medicine, University Campus Bio-Medico, Italy, [2]Thyroid Disease Center, "S. M. Goretti" Hospital, Italy, [3]Unit of Geriatrics, University Campus Bio-Medico, Italy, [4]Department of Endocrinology, San Giovanni Addolorata Hospital, Italy

Backgroud:calcium and vitaminD supplementation represent the conventional therapy for chronic Hypoparathyroidism(HP) but this treatment does not fully replace the functions of PTH. Several case reports revealed peripheral neuropathy and myopathy in HP subjects with or without hypocalcemia. Fatigue is a common compliant but not related to post-surgical hypothyroidism. In most cases, symptoms diminished or disappeared when plasma calcium levels bring back to normal but their relationship to biochemical control or other aspects of the disease have been not well described. Autonomic dysfunction has been described in a broad variety of endocrine diseases but, up to now, no studies have evaluated this complication in HP subjects.Aim:to evaluate cardiovascular autonomic neuropathy (CAN) in subject with HP.Design:Monocentric, cross-sectional study comparing 44 post-surgical HP patients treated with calcium and calcitriol to 37 control subjects underwent thyroidectomy without PTH/calcium/phosphate disorders. CAN was assessed by NeuroTester (Meteda) evaluating: 1)heart rate response to deep breathing (expiratory-to-inspiratory ratio) 2)heart rate response to lying-to-stand test (30:15 ratio) 3)heart rate response to Valsalva maneuvre (maximun heart rate during expiration- minum heart rate after exporation ratio) 4)blood pressure response to standing. One pathologic test is diagnostic for early CAN, two or more identify moderate CAN.Results:The overall prevalence of CAN was 48.8%, with a marked difference between HP and control (70.5% and 23.7%, respectively, OR 7.4, 95% CI 2.8-21.1). Of the 12 patients with 2 positive tests, 11 had hypoparathyroidism. Among people with HP, we found no association between serum calcium, PTH and phosphate concentration and CAN, and the prevalence of CAN was not significantly increased in people with hypocalcemia, PTH<10 pg/ml or hyperphosphatemia. The prevalence of moderate CAN, instead, was increased among patients with calcium< 8.5 mg/dL (n=18, 44%) compared to those with normal serum calcium concentration (n=26, 11%), with OR 5.7 (95% CI 1.3-32.3). These results were not confirmed for PTH< 10 pg/mL (N:22, prevalence of moderate CAN 31.8%vs18.2%, OR 2.03, 95% CI 0.5-9.5) and for phosphate> 4.4 mg/dL (N:22, prevalence of moderate CAN 31.8%vs18.2%, OR 2.03, 95% CI 0.5-9.5).Conclusion:HP is associated with CAN and hypocalcemia seems to affect its severity. However, larger and prospective studies are needed to confirm our findings.

Cognitive and Emotional Deficits in Hypoparathyroidism and Their Relation to Undercarboxylated Osteocalcin Mishaela Rubin*, Gaia Tabacco, Rukshana Majeed, Beatriz Omeragic, Maximo Gomez, Elzbieta Dworakowski, Christiane Hale, Adam Brickman. Columbia University, United States

Clinically, hypoparathyroid patients (HypoPT) describe poor cognitive and emotional function. SF36 tests show poor quality of life (QoL), but cognitive and emotional data do not exist. HypoPT also have low bone remodeling, with low osteocalcin (OC) levels; in mice, circulating undercarboxylated OC (uOC) binds in the hippocampus and improves learning, memory and mood. We hypothesized that HypoPT have cognitive and emotional deficits and that these are associated with uOC. 18 HypoPT (44±13 yrs, 2 men, duration 8.9±1 yrs,

median education=16 years, calcium 2.3±2 g/d, calcitriol 0.74±1 µg/d, serum calcium 8.9±1 mg/dl, PTH 5.3±5 pg/ml) were tested with the SF36 and NIH Toolbox®. The cognitive battery assesses "crystallized" (dependent upon past learning) and "fluid" (capacity for new learning and information processing) abilities and the emotional battery assesses psychological well-being. Scores are adjusted for age, sex, race/ethnicity, education and compared to census-based averages for the US population. The SF36 showed decreases in physical role, vitality, social function and general health. The Toolbox showed overall cognitive function at 42nd percentile of the US population. Crystallized abilities were at 58th percentile: general vocabulary knowledge at 52nd percentile and reading decoding skill at 66th percentile. Fluid abilities were at 27th percentile: inhibitory control and attention at 47th percentile, executive function at 68th percentile, episodic memory (acquisition and retrieval of new information) at 32nd percentile, working memory (ability to store information) at 32nd percentile and processing speed (amount of information processed within a certain time) at 7th percentile. Toolbox emotion tests showed overall psychological well-being at 30th percentile; social satisfaction at 21st percentile and negative affect at 75th percentile. SF36 measures correlated strongly with emotional measures. uOC was associated with episodic memory (r=0.50, p=0.07), psychological well-being (r=0.57, p=0.02) positive affect (r=0.52, p=0.03) and general life satisfaction (r=0.54, p=0.03). In conclusion, HypoPT have cognitive deficits primarily involving processing speed, and to a lesser extent episodic and working memory. Emotional deficits are associated with poor QoL. uOC in HypoPT relates to episodic memory and well-being, suggesting that it might cross the blood brain barrier to bind in the brain and thus provide a skeletal regulation of cognition and emotion.

SUN-0034

A Unique Longitudinal Cohort of Hypoparathyroidism Treated for 8 Continuous Years with rhPTH (1-84) Donovan Tay*[1], Gaia Tabacco[1], Natalie Cusano[2], John Williams[1], Beatriz Omeragic[1], Rukshana Majeed[1], Maximo Gomez Almonte[1], John Bilezikian[1], Mishaela Rubin[1]. [1]Columbia University Medical Center, United States, [2]Lenox Hill Hospital Department of Medicine, United States

Hypoparathyroidism (HypoPT) is characterized by hypocalcemia and undetectable or insufficient PTH levels. Conventional management consists of supplemental calcium, sometimes in high dosage, and active vitamin D. With the advent and approval of human recombinant parathyroid hormone [rh)PTH(1–84)], the missing hormone in this disorder can now be replaced. Since no limit has been placed on the duration of therapy by the Food and Drug Administration (FDA), and given the chronic nature of this disorder, the need for long term data of the efficacy and safety of rhPTH(1-84) is compelling. Twenty four HypoPT subjects (46±3 yrs, 75% women, disease duration 22.9±3 yrs) were studied. Causes were postsurgical (n=13), autoimmune (n=10) and DiGeorge (n=1). Baseline medications were calcium 3.0±0.3 g/d; calcitriol 0.76±0.1 µg/d; vitamin D 13932±3132 IU/d and HCTZ 36.6±9.0 mg/d. Serum calcium was 8.5±0.2 mg/dL, PTH 4.0±0.6 pg/mL, phosphate 4.5±0.2 mg/dL; Ca*P product 38±2 mg2/dL2 ; 24-hr urine calcium 254±29 mg/d. BMD measurements (g/cm2) were: lumbar spine (LS) 1.242±0.044; femoral neck (FN) 0.992±0.033, total hip (TH) 1.105±0.029 and distal 1/3 radius (DR) 0.735±0.011. rhPTH(1-84) was started at 100 µg every other day and changed after 3 yrs to doses ranging from 25-100 µg/d. Daily calcium supplementation fell by 57% to 1.3±0.3 g/d (p<0.01) as did calcitriol by 76% to 0.18±0.1 µg/d (p<0.001). Parent vitamin D intake decreased by 59% to 5727±3433 IU/d, p=0.02. Only 8 subjects required more than 1.5g/d of calcium supplementation and half of all subjects (n=12) eliminated calcitriol completely. Serum calcium remained stable (8.1±0.2 to 8.5±0.2 mg/dL; p=NS) while 24-hr urine calcium decreased by 38% to 157±37 mg/d (p=0.01). There were no changes in serum phosphate, Mg, creatinine, or in the Ca*P product. Total alkaline phosphatase increased (64±4 to 76±4 U/L; p=0.006). BMD increased by 2.8 ± 1.5% (p=0.06) at LS, 2.6 ± 1.1% at TH (p=0.03), unchanged at FN and fell 3.5 ±1.1% at DR (p=0.001). Adverse events consisted of hypocalcemia in 3 patients (1-2 events/patient in yr 2); 3 episodes of hypercalcemia in 3 patients at yr 1, 4 and 7; 8 fractures in 6 patients (yr 1, elbow; yr 2, toe; yr 3 metatarsal; yr 5, wrist; yr 6, wrist, leg, yr 8, metacarpal, wrist) and a single renal stone (1 patient in yr 4). These data, the longest-term clinical experience with continuous PTH treatment for HypoPT or any condition, suggest that rhPTH(1-84) is a safe and effective long-term option in HypoPT

SUN-0035

Survival in primary hyperparathyroidism over five decades (1965-2010) Robert Wermers*[1], Marcio Griebeler[2], Euijung Ryu[1], Prabin Thapa[1], Matthew Hathcock[1], Ann Kearns[1]. [1]Mayo Clinic, United States, [2]Cleveland Clinic, United States

Purpose: To update survival in primary hyperparathyroidism (PHPT) in our community and determine if there has been a decrease in survival as suggested by others.Methods: Rochester, Minnesota, residents who met criteria for PHPT from 2002 through 2010 were identified through the medical records-linkage system of the Rochester Epidemiology Project and added to the historical cohort beginning in 1965. Survival was estimated using the Kaplan Meier product-limit method. Comparison of survival experience between two or more groups was done with log-rank test. The Cox proportional hazards model was used to determine associations, as relative hazards (RR) with 95% confidence intervals (CI), of

Sunday Posters

various risk factors with time to death. Results: From 1965 through 2010, we identified 1139 PHPT patients with a median age of 57.8 years and the majority were female (75.9%). The overall age and gender-adjusted survival compared to white Minnesota residents was unchanged in patients with PHPT with a relative risk of death of 0.998 (95% CI: 0.91-1.09, P = 0.97) (Figure 1). In a multivariate model older age, male sex, maximum serum calcium level, and PHPT diagnosis after June 1974 were significantly associated with all-cause mortality. Survival declined with increasing quartiles of serum calcium elevation, with a significantly worse survival among patients with serum calcium levels above 10.8 mg/dL (RR 1.32, P = 0.002). Parathyroid surgery was performed in 350 patients (30.7%), with more patients undergoing surgery from 1965-June 1974 (35.9%) and 1998-2010 (35.2%) compared to July 1974-1997 (26.1%). Survival among PHPT patients after parathyroidectomy was no different from expected (RR = 1.07, P = 0.465). However, in patients with a maximum serum calcium $\geq$ 10.8 mg/dl, parathyroidectomy was associated with a significant reduction in mortality (HR 0.47, 95% CI: 0.36-0.61, P < 0.001).Conclusions: In a well-defined unselected U.S. community based cohort of PHPT subjects with predominantly asymptomatic disease and mild hypercalcemia mortality is not increased. However, a maximum serum calcium elevation of $\geq$ 10.8 mg/dL was associated with increased mortality and parathyroidectomy in these subjects was associated with a significant reduction in mortality, suggesting that the current recommendation for surgery in asymptomatic PHPT when serum calcium is > 1 mg/dL (0.25 mM) the upper limit of normal may warrant reconsideration.

Disuse Alters the Size of Osteocyte Lacunar Voids Mohammed Akhter*, Diane Cullen, Robert Recker. Creighton University, United States

We have shown that skeletal disuse due to the tail or hindlimb suspension caused significant decline in trabecular number and thickness for adult WT mice (Akhter et al., 2011). In this study we used MicroXCT-200 (Zeiss/Xradia) 3D imaging to quantify osteocyte lacunar void properties (void volume, surface area, density, sphericity, etc.) in mid-shaft femurs (C57BL/6Tac mice) obtained from the previous study (Akhter et al., 2011). Osteocyte lacunar void properties may influence bone mechanical properties with regards to changes in the mineralization. The aim of this study was to quantify changes in the osteocyte lacunar void properties of cortical bone with regards to disuse. Male adult (15wk-old) mice were randomized to Disuse, tail suspended (hindlimb) in individual cages for 4 weeks or Control, allowed normal ambulation. This study was approved by the Institutional Animal Care and Use Committee (IACUC). Femoral mid-shaft cortical sections (~300 micron [μm] thick, n=6/group) were scanned in the medial and lateral regions at 0.6 micron resolution (Figure-1). Avizo (v9.4, FEI) software was used to segment the lacunar voids (Figure-2). Using the one-way ANOVA (SPSS), the treatment related (Control vs Disuse, P<0.05) differences were analyzed. A Total of 22,741 segmented lacunar voids (1,895voids/specimen , 50 to 610μm3 range) were analyzed. The osteocyte lacunar void volume was lower (P<0.05) and surface area tended to be lower in Disuse than Control (Table). The lacunar void sphericity (=1 for perfect sphere) was lower (P<0.05) in Disuse than Control suggesting a less spherical shape. The density of lacunar voids was similar between the two groups. These data suggest that disuse alters the lacunar properties (size, shape) and thus may have some influence on the intrinsic properties of bone tissue with regards to greater brittleness (Vennin et al., 2017). Disuse may promote osteocyte apoptosis and therefore causing micropetrosis (Bonewald

et al., 2011; Jilka et al., 2013) and shrinking of osteocyte lacunar voids. Micropetrosis may increase mineralization of the lacunar voids and thus cause changes in the intrinsic material properties of bone tissue (Mullender et al., 2005). Future studies of determining the relationship between lacunar voids and intrinsic material properties of bone tissue are important to understand their impact on bone quality.

Figure-1 Femoral section (~300um thick)   Figure-2 Segmented lacunar voids

Table: Osteocyte LacunarVoid Properties	Volume (μm³)	Surface Area (μm²)	Density (#Voids/cm³)	Sphericity (=1 perfect sphere)
Control	184±1.3	237±1.4	40179±1524	0.661±0.0011

SUN-0073

Assessing Correlates of Fracture Toughness using Nanoindentation Faisal Almehaimid*, Chelsea M Heveran, Bhavya Senwar, Virginia L Ferguson. University of Colorado, Boulder, United States

Introduction:Measuring fracture toughness (Kc) is conventionally achieved with whole-bone notched fracture, but a critical need exists for small-volume testing techniques to evaluate fracture toughness through less destructive methods. A brittleness parameter from nanoindentation was proposed by Labonte et al1, which quantifies the degree of material brittleness using the ratio of indentation hardness to modulus (H3/E2). The purpose of this study was to evaluate whether microscale H3 /E2 predict whole-bone fracture toughness in bone.Methods:Femurs from young adult male, exercised (n = 5) and sedentary (n = 5) Wistar rats fed a low fat diet were evaluated for notched fracture toughness. Femur fragments were then dehydrated, embedded with poly(methyl)methacrylate and polished to 0.1 μm finish to expose the midshaft cortical bone near the notch. Nanoindentation arrays (Hysitron TI950, high load, berkovich tip) were placed in lamellar bone in the lateral quadrant (Figure 1). Rows of three indents each were placed at 30, 60, 100, 150, and 225 mN for each bone. At each point, H3/E2 and plastic work (hysteresis of load-unload curve) were evaluated. The average H3/E2 for each row was plotted against Kc.Results:H3/E2 was strongly linearly related to plastic work for every sample, r2 = 0.98-0.99. The relationship between Kc and H3/E2 improved with increasing load. At 30, 60, 100, 150, and 225 mN, r2 for Kc vs H3/E2 was 0.0056, 0.0544, 0.0876, 0.263, and 0.2627, respectively. A similar relationship was observed between Kc and plastic work, where r2 increased from 0.0116 at 30 mN to 0.216 at 225 mN.Conclusion:We sought to evaluate whether fracture toughness was related to microscale indentation properties of bone material measured for the same whole bones tested in notched fracture. Here, H3/E2 was a proxy for plasticity, indicating that microscale plasticity is related to whole bone fracture toughness. While correlations between fracture toughness and H3/E2 were moderate at best and may improve in hydrated tissue, no other tool has provided insight into fracture toughness for bone at this length-scale. However, some plasticity was indeed apparent for embedded samples and was related to fracture properties. These results suggest that monitoring H3/E2 or plastic work at sufficient indentation load may access information about fracture toughness at the microscale.

The effects of age and sex on viscoelastic bone properties in mice Ingo Grafe*[1], Ian Tomkinson[2], Heather Haeberle[2], Yi-Chien Lee[1], Xiaohong Bi[3], Brendan Lee[1], Catherine G. Ambrose[2]. [1]Department of Molecular and Human Genetics, Baylor College of Medicine, United States, [2]Department of Orthopaedic Surgery, UTHSC-Houston, United States, [3]Department of Precision Biomedicine, UTHSC-Houston, United States

Age and sex have been shown to have significant effects on the elastic properties of bone but less is known about the effects of these variables on bone ductility and viscoelastic properties. Mouse femora from 2 strains (FVB/N and C57BL/6), 3 age groups (6 weeks, 3 months, 9 months), and both sexes were analyzed using both dynamic mechanical analyses (DMA) and quasi-static monotonic loading to failure to determine the effect of mouse strain, age and sex on elastic, plastic, and viscoelastic bone material properties. A three-point bending configuration (anterior side in compression, posterior side in tension) was used for both dynamic and quasi-static loading and, although the spans were adjusted for each group to maximize span to diameter aspect ratio, the same spans were used for both tests. DMA tests were conducted at frequencies ranging from 0.1 to 20Hz with displacements cycling between 0.01 to 0.018mm. Quasi-static loading was conducted at a rate of 0.1mm/s until failure. All tests were performed with the bones wet and at room temperature. For both strains and sexes, bone strength and modulus increased with age (average increases of 34% and 84%, respectively), while measures of ductility (post-yield displacement and energy to failure) and viscoelasticity (phase angle, reported as tanδ) decreased with age (average decrease of 71%, 44% and 17%, respectively). More significant differences were seen between the 6 week and 3 month age groups than between the 3 and 9 month age groups. Overall, FVB/N femurs were stronger (p=0.002) but more brittle (p=0.01) than those from C57BL/6J mice. Regardless of mouse strain, femurs of male mice were more ductile (p=0.007) but the femurs from females had higher strength (p=0.01) and elastic moduli values (p=0.001). A general linear model using strain and sex as fixed factors and age as a covariate showed that strength and ductility properties depended on all 3 variables (strain, age and sex), while modulus only depended on age and sex, and viscoelastic properties varied only by age. Future work will investigate relationships between these properties and the bone composition (from Raman spectroscopy and chemical analyses) to determine the contributions of the mineral and protein components of bone to the mechanical properties.

SUN-0075

SERUM 25-HYDROXYVITAMIN D AND ITS METABOLISM IN BONE TISSUE IS ASSOCIATED WITH IMPROVED BONE QUALITY IN ELDERLY HIP FRACTURE PATIENTS Deepti Sharma*[1], Rebecca Sawyer[1], Roumen Stamenkov[2], Thomas Robertson[3], Catherine Stapledon[3], Gerald Atkins[3], Peter Clifton[1], Lucian Solomon[2], Morris Howard[1], Paul Anderson[1]. [1]University of South Australia, Australia, [2]Royal Adelaide Hospital, Australia, [3]University of Adelaide, Australia

Vitamin D and calcium supplementation significantly reduces the risk of fractures although improvement of bone mineral density (BMD) is controversial suggesting that these nutrients may act through improvement of bone quality and not by increasing BMD. We

have investigated the relationship between vitamin D status and trabecular bone quantity and quality in intertrochanteric biopsies retrieved from elderly hip fracture patients.Material and Methods: Intertrochanteric trabecular bone biopsies and serum samples were collected from hip fracture patients undergoing hip arthroplasty (65 females, 38 males, mean age 85 years) at Royal Adelaide Hospital. Trabecular bone was analysed by micro CT (SkyScan 1076), mean wall thickness was measured by histology and serum 25(OH)D, 1,25(OH)2D, and parathyroid hormone (PTH) by immunoassay (Diasorin Liaison). Bone mRNA levels for vitamin D metabolising enzymes CYP27B1 and CYP24A1 were measured by RT-PCR. Results: Serum 25(OH)D correlated negatively to the ratio of bone surface to bone volume BS/BV (r = -0.206, p<0.05) and positively (trend) with trabecular thickness (r= 0.19, p=0.06) both indicators of improved bone quality. Patients with higher vitamin D status had significantly higher mean wall thickness (p<0.001). No correlation was found between serum 25(OH)D and any variable describing bone quantity. No bone quality or quantity variables correlated with either PTH or 1,25(OH)2D levels. Serum 25(OH)D, gender and bone CYP27B1 and CYP24A1 mRNA accounted for 19% of the variability of BS/BV (P=0.001). Conclusion: Three measures of bone quality relate to serum 25(OH)D and support the concept that bone metabolism of 25(OH)D to 1,25(OH)2D improves bone quality through increasing plate-like trabeculae even in elderly patients. Plate-like structures improve bone strength (1). At the cellular level these structures arise from an increase in the bone formation period with osteoblasts forming bone for longer. These data support the need for maintaining adequate vitamin D status in the elderly to promote bone health and BMD is likely an inadequate measurement for vitamin D action on bone.

SUN-0076

Ultra-low dose MDCT allows accurate assessment of vertebral fracture risk: a finite element study D. Anitha*[1], Kai Mei[2], Felix Kopp[2], Peter Noel[2], Thomas Baum[2], Karupppasamy Subburaj[1]. [1]Singapore University of Technology and Design, Singapore, [2]Technical University of Munich, Germany

Purpose: Assessment of osteoporotic vertebral fracture risk is insufficient using BMD measurements as the current clinical standard. A non-invasive fracture prediction tool such as finite element modelling (FEM) will be useful in identifying patients at risk for osteoporotic vertebral fractures. The goal of this study was to assess if patients with and without OVFS can be differentiated using MDCT scans at virtually reduced ultra-low doses.Materials and Methods: Vertebral MDCT images were retrieved from patients undergoing routine thoracic and abdominal scans. Patients with (n=8; age=75±11 years) and without vertebral fractures (n=8; age=71±11 years) were matched for sex and age and associated with the groups, Fracture and Control respectively. MDCT dose was virtually reduced to 50%, 25%, and 10% of the standard clinical dose using a simulation algorithm. Lumbar vertebrae (L1-3) were segmented from each patient. Finite element analysis was performed on all segmented vertebrae to simulate axial loading and a numerical failure load was obtained 2. Statistical differences within each group at individual doses and between each group at each dose was performed with Kruskal-Wallis and Mann-Whitney test respectively. Pearson correlations with standard dose were reported for all reduced doses. Receiver operating characteristic (ROC) curve analysis was performed to differentiate between Fracture and Control groups. Results: In both Fracture and Control groups respectively, numerical failure load obtained at standard dose was not significantly different from half (p=0.718 and p=0.670) and quarter dose (p =0.606 and p =0.592), except the tenth dose (p =0.00198 and p=0.0354). Numerical failure loads predicted at all doses, were able to differentiate patients in fracture and control groups (standard (3254 ± 909 vs. 3794 ± 984 N; p=0.0373), half (3390 ± 890 vs. 3860 ± 1063 N; p=0.0305) and quarter (3375 ± 915 vs. 3925 ± 990 N; p=0.0233) doses, except at the tenth dose (4513 ± 1762 vs. 4766 ± 1628 N; p=0.458). ROC analysis also demonstrated that standard, half, and quarter doses can significantly differentiate both groups (p<0.05).Conclusion: With a dose reduction of up to 75%, patients can undergo regular and longitudinal MDCT examinations, which allows better monitoring of fracture risk and treatment response. Osteoporotic patients at high risk of OVFs can benefit from a non-invasive analysis on spinal stability with clinically acceptable exposure of radiation.

Alterations in Bone Matrix Composition During Estrogen-deficiency Induced Bone Loss are Influenced by Genetic Background Michael-John Beltejar*, Dana A. Godfrey, Robert D. Maynard, Cheryl L. Ackert-Bicknell. Center for Musculoskeletal Research, University of Rochester Medical Center, United States

Reduction in bone mass during osteoporosis is a well-appreciated phenomenon, however concomitant alterations in bone-matrix composition are understudied. Knowing how changes in bone-matrix composition during osteoporosis results in fragile bones is critical, given that matrix composition contributes to fracture toughening mechanisms in and above what is captured by bone mass. While estrogen is known to impact bone turnover and thereby alter parameters of bone-matrix composition, it is undetermined if this interacts with genetic factors. The goal of this work was to determine if genetic variation modifies the response to estrogen deficiency with regards to bone-matrix composition. To accomplish this, we leveraged the genetic diversity of 3 inbred mouse strains: C57BL/6J (B6), NZO/HlLtJ (NZO) and 129S1/SvImJ (129). At 12 weeks of age, female mice were ovariectomized and humeri and

uteri were collected at 20 weeks of age (n=10 per strain and per procedure). Uterine masses, normalized to individual body mass, were used to exclude mice in which there was incomplete ovariectomy. From the humeri, the following parameters of bone-matrix quality were obtained using Fourier-Transform Infrared Spectroscopy (FTIR): mineral to matrix ratio, carbonate to phosphate ratio, collagen crosslinking/maturity, non-enzymatic crosslinking, mineral maturity and splitting factor. A two-factor ANOVA was conducted for the six aspects of bone-matrix composition to compare the main effects of strain and ovariectomy, and the interaction between these main effects (so called Gene by Environment effects). All statistical analyses were conducted using R statistical computing software with the Companion to Applied Regression (car) package. The interaction between strain and ovariectomy was significant for the mineral to matrix ratio, $F(1,58) = 4.1013$, p=0.022, suggesting that genetics interacts with estrogen status to influence the amount of mineral relative to collagen in compact bone. Furthermore, interactions of main effects were significant for the non-enzymatic crosslinking of collagen, $F(2,58) = 7.8304$, p = 0.000976. This indicates that glycation of collagen helices, is also susceptible to estrogen levels. Taken together, these results indicate that estrogen-deficiency differentially affects facets of bone-matrix composition based in part on genetic background and could potentially affect intrinsic fracture resistance beyond reductions in bone mass.

SUN-0078

Damage under Anterior Bending is Associated with Vertebral Body Structural Organization, but not Donor Characteristics Travis D. Eliason*[1], Ellen E. Quillen[2], Donald E. Moravits[1], Roberto J. Fajardo[3], Karl J. Jepsen[4], Todd L. Bredbenner[5]. [1]Materials Engineering, Southwest Research Institute, United States, [2]Molecular Medicine, Wake Forest School of Medicine, United States, [3]Clinically Applied Science Education, University of the Incarnate Word School of Osteopathic Medicine, United States, [4]Orthopedic Surgery, University of Michigan, United States, [5]Mechanical and Aerospace Engineering, University of Colorado Colorado Springs, United States

The structural behavior of bone is an integrative function of a multitude of complex and interrelated characteristics, including bone morphology and the spatial distribution of bone mineral density (BMD). In earlier work, composite traits, that describe independent combinations of vertebral body geometry and BMD distribution, were determined from quantitative computed tomography data of 28 L1 vertebral bodies obtained from cadavers (15 males, 13 females, age range of 25-88 years). A subset of composite traits was found to be associated with donor sex and age [1]. The objective of this work was to investigate whether there is an association between vertebral body damage and composite traits, volumetric BMD (vBMD), donor sex, age, or BMI. We loaded the same 28 L1 vertebral bodies experimentally. A damaging pulse with peak anterior bending moment of 30.6 Nm was applied, held for 60 seconds, and specimens were unloaded. After a recovery period of 300 seconds, a second loading pulse with a peak bending moment of 2.5 Nm was applied. Bending stiffness was determined from data from each loading pulse. Vertebral body damage was determined using a continuum damage mechanics approach to determine the loss of bending stiffness due to an applied anterior bending moment [2]. An unbalanced ANOVA was used to determine whether damage was associated with vertebral body composite traits and a 4-way unbalanced ANOVA was used to determine whether damage was associated with vertebral body vBMD, sex, age, or BMI. Two composite traits were significantly associated with damage (p = 0.014 and p = 0.017). These composite traits cumulatively describe 7.5% of the total variability in structural organization within the set of vertebral bodies. Vertebral body damage was not significantly associated with vBMD, sex, age, BMI, or with interactions of these characteristics (p > 0.05 in all cases). Furthermore, there was no overlap between the composite traits associated with sex and age and those associated with vertebral body damage. Previously published studies have related structural bone traits to vertebral fracture risk [3,4], supporting the notion that vertebral body damage is related to structural bone traits, rather than characteristics of the individual.[1] Coogan, et al. ASBMR 2015. [2] Bredbenner and Davy, J Biomech Eng, 2006. [3] Ruyssen-Witrand, et al. Osteoporos Int 2007. [4] Bruno, et al. J Bone Miner Res, 2014.

Differential Effects of Zoledronic Acid and Teriparatide on Microdamage Across Bone Sites. A Study at the Femoral Diaphysis, Neck, Lumbar Vertebra and Iliac Crest in Ewes Nathalie Portero-Muzy*, Pascale Chavassieux, Roland Chapurlat. INSERM UMR 1033, Université de Lyon, France

Purpose: It has been debated whether bisphophonates (BPs) might promote bone microdamage, in contrast to teriparatide (TPTD). No association between BPs treatment and microdamage accumulation has been observed in humans (1), but a site-specific variation of microdamage has been reported (2). Thus, the purpose of this study performed in aged ewes was to compare the cortical (Ct) and cancellous (Cn) microcrack density/tissue volume (Cr. Dn) and length (Cr.Le) in Ct bone of femoral diaphysis (FD), in Ct and Cn bone of femoral neck (FN), lumbar vertebra (LV) and iliac crest (IC).Methods: Ewes (n=8/group) received either vehicle (CTRL), or one single dose of 10 mg of zoledronic acid (ZOL) or 20µg/day of TPTD. After 3 months, microdamage was sought after bulk-staining of bone samples with

5mM xylenol orange in 70% ethanol.Results: In CTRL, Ct-Cr.Dn was significantly higher at FD than at the 3 other sites (p=0.027). When compared to CTRL, ZOL treatment induced significant increases in Ct-Cr.Dn at FN, FD and IC. In all treatment groups, Ct-Cr.Dn was always markedly greater at FD than at other sites (Table). ZOL also induced a significant increase in Cn-Cr.Dn at all sites and Cr.Dn was significantly greater in Cn than Ct bone at LV (p=0.036) and IC (p=0.017) but lower at FN (p=0.018) (Table). At the FN, it was associated with increases in Ct and Cn-Cr.Le. In contrast, TPTD did not significantly change Ct and Cn-Cr.Dn vs CTRL but decreased Cr.Le in both Ct and Cn bone in FN (Table).Conclusion: In ewes, microdamage density differs across the skeletal sites and is greater at FD than at other sites. A high dose of ZOL increases microdamage density in the short term, at all sites, especially at FD.1. Chapurlat et al. J. Bone Miner. Res. 22:1502-9, 20072. Allen MR et al. Bone. 49:56-65, 2011

Peripheral neuropathy is associated with diabetes-induced bone fragility Clarissa S Craft*[1], Madison R Mcmanus[1], Madelyn R Lorenz[1], Amy Stickland[1], Kristann Magee L[1], Natalie K Wee[2], Eric D Hilker[1], Sungjae Park[1], Zhaohua Wang[1], Yusuf Bekirov[1], Aaron Diantonio[1], Jeff Milbrandt[1], Erica L Scheller[1]. [1]Washington University in St. Louis, United States, [2]University of Connecticut, United States

Patients with type-1 and type-2 diabetes mellitus are at significantly increased risk of bone fracture. Fracture risk remains unexplained by common clinical measures including body mass index, bone mineral density by DEXA, or glycemic control. The purpose of this study was to determine whether neuropathy is predictive of diabetes-induced bone fragility. Methods: Streptozotocin (STZ) injections were used to induce type-1 (insulin dependent) diabetes in 12-week old c57BL/6J (c57) control and neuropathy-resistant SARM1-knock-out mice. Diabetes was confirmed by blood glucose and insulin measurement. Peripheral neuropathy was determined by nerve conduction studies and quantitative histomorphometry of epidermis nerve fibers within foot pads. Bone mass and architecture were determined by micro-CT. Bone quality (fragility) was characterized using 3-point bend testing. Results: STZ injections caused sustained hyperglycemia (>300mg/dL) and hypoinsulinemia in both c57 and SARM1-KO mice. The development of peripheral neuropathy was evident in STZ-treated c57 mice. Specifically, electrophysiology studies performed 12-weeks post STZ treatment showed reduced nerve depolarization (amplitude), and histomorphometry revealed a reduction in the relative abundance of CGRP+ peptigergic sensory nerve fibers within the footpads of STZ-treated c57 mice. As expected, SARM1-KO mice were resistant to STZ-induced neuropathy. Interestingly, micro-CT demonstrated that c57 and SARM1-KO mice had comparable cancellous bone mass loss in response to STZ, however, STZ-treated SARM1-KO femurs did not develop cortical thinning that was evident in STZ-treated c57 mice. Importantly, STZ-treated SARM1-KO femurs were also less susceptible to mechanical failure than STZ-treated c57 femurs; suggesting neuropathy contributes to impaired bone mechanical properties in diabetes.Conclusions: In total, this work suggests that diabetic patients with diagnosed neuropathy may be at higher risk for fracture, prompting preventive intervention with anti-resorptive or osteo-anabolic therapy.

Bone Mechanical Properties (nanoindentation) and Microarchitecture (micro-CT) in Type 2 Diabetes Ruban Dhaliwal*[1], Jagadeesh Bose[2], Navin Kumar[2], Praveer Sihota[3], Ram Naresh Yadav[3], Vijay Goni[4], Sameer Agarwal[4], Sudhaker D. Rao[5], Sanjay Kumar Bhadada[2]. [1]Endocrinology, Diabetes and Metabolism, Department of Medicine, State University of New York Upstate Medical University, United States, [2]Department of Endocrinology, Postgraduate Institute of Medical Education and Research, India, [3]Department of Mechanical Engineering, Indian Institute of Technology Ropar, India, [4]Department of Orthopedics, Postgraduate Institute of Medical Education and Research, India, [5]Bone and Mineral Research Laboratory, Henry Ford Hospital, United States

Purpose: Individuals with type 2 diabetes (T2D) have a 2.8-fold greater fracture risk than non-diabetics despite normal to high BMD. Mechanisms underlying diabetic skeletal fragility are poorly understood, making it difficult for clinicians to identify those at risk for fractures. Poor bone quality has been implicated in diabetic skeletal fragility, but no data exists on biomechanical properties of bone assessed by nanoindentation in T2D.Methods: Femoral neck bone tissue specimens were collected from adults during surgery for femoral neck fractures; n=8 with T2D of duration >5 years, n=9 without diabetes. Specimens were examined using nanoindentation technique. Elastic modulus (E) and hardness (H) were calculated using the Oliver-Pharr method. Bone microarchitecture was assessed by microcomputed tomography. Linear mixed model analysis was used for comparisons and statistical significance was set to 0.05.Results: Baseline characteristics were comparable for both groups [Table 1]. Elastic modulus and hardness were significantly lower in those with T2D compared to non-diabetic controls (E= 6.76 ± 2.67 vs. 9.64 ± 2.14, p=0.026) (H=0.23 ± 0.13 vs 0.26 ± 0.10, p=0.027). No differences were observed in microarchitectural measurements between the groups. Of note, the E/H ratio was lower in T2D compared to controls (29 vs. 37), representing reduced fracture resistance.Conclusion: Our study is the first to demonstrate compromised bone mechanical strength as assessed by nanoindentation in individuals with T2D. Further studies are needed to precisely characterize the relationship between nanoindentation measures and increased fracture risk in T2D.

Table 1. Characteristics of individuals with T2D and controls

Local, but Not Global, CT-Based Texture Analysis Improves the Prediction of Femoral Strength Fjola Johannesdottir*, Mary L. Bouxsein. Beth Israel Deaconess Medical Center and Harvard Medical School, United States

It is not clear whether evaluation of spatial distribution of bone mineral density gives additional information about bone strength beyond BMD. The purpose of this study was to determine if co-occurrence textural features (Haralick 1973) from clinical resolution CT images combined with aBMD by DXA are more strongly associated with femoral failure load than aBMD alone. We obtained 64 human cadaveric proximal femurs (41 women and 24 men; age 73 ± 8 yrs), performed imaging with DXA and QCT, and mechanically tested the femurs to failure in a sideways fall configuration at a high loading rate. Textural analysis was performed on 3D region of interests (ROIs) extracted from the trochanter, femoral neck and head. For each ROI, gray level co-occurrence matrices were calculated (distance of 1 voxel in each neighboring direction). A number of different textural features were derived from the co-occurrence matrices to quantify textural patterns (e.g. smoothness, heterogeneity). We also evaluated global textural features: skewness and kurtosis of trabecular bone density at the total hip. The prediction of femoral failure load was evaluated using multiple regression analysis.The observed mean failure load was 3805 ±1839 N. We found that combining femoral neck aBMD and a textural feature from either the femoral head or the neck significantly improved the failure load prediction (Table 1). A textural feature assessed from the femoral head improved the adjusted r2 by 2% (p<0.05, Table 1) and a textural feature from the femoral neck improved the adjusted r2 by 4% (p=0.003, Table 1), whereas an assessment from the trochanter provided no additional information. The global textural features did not

improve the failure load prediction compare to FN aBMD alone (p>0.25). The localized textural feature was independent of femoral aBMD (p>0.05), whereas skewness and kurtosis were negatively correlated with FN aBMD, r = -0.84 and r = -0.49, respectively (p < 0.0001). These findings imply that increased localized heterogeneity is negatively associated with failure load. In addition, these results suggest that incorporation of localized textural features may enhance hip fracture prediction, though additional studies are needed to identify the optimal region for textural analysis.

	Adjusted r^2	p-value vs aBMD alone	RMSE (N)
aBMD	0.679	-	1039
aBMD + head texture	0.695	0.047	996
aBMD + neck texture	0.717	0.003	964
aBMD + troch texture	0.675	0.428	1049

SUN-0083

MRI-Based Assessment of Proximal Femur Compared to Direct Mechanical Testing Daniel Kargilis*[1], Gregory Chang[2], Jae Lee[1], Alexander Farid[1], Sneha Shetye[1], Michael Hast[1], Chamith Rajapakse[1]. [1]University of Pennsylvania, United States, [2]New York University, United States

Half of the women who sustain a hip fracture would not have qualified for osteoporosis treatment by the current criteria, which are based on bone mineral density measurements by DXA. Thus, a better approach is needed to determine if an individual is at risk for hip fracture from a fall. MRI provides an ionizing-radiation free approach for assessing proximal femur microstructure in human subjects. The objective of this study was to determine the association between MRI-derived strength compared to direct mechanical testing of cadaveric femurs. This study used human femurs obtained from 6 male and 7 female donors aged 36-99 years. Specimen storage occurred at a temperature of -30° C before experimentation. Imaging was conducted on a clinical whole-body 3 Tesla MRI scanner (Siemens Prisma, Erlangen, Germany) using a sequence (flip angle 25°, TR/TE 27/3.8 ms, and voxel size 0.242 x 0.242 x 1.5mm 3). Femora were dissected free of soft tissue and 4-120 ohm strain gauges (Omega Engineering, Norwalk, CT) were securely applied to the areas of interest on the bone with an adhesive (Figure 1). Strain gauges were arranged with 120 ohm resistors on a breadboard to form a Wheatstone bridge. The circuit was connected to custom software (Labview 2013, National Instruments, Austin, TX) capable of converting changes in resistance to changes in strain. The femora were securely fixed into a vise at a 10 degree angle relative to horizontal, similar to Keyak et al. (1998). The actuator of a universal test frame (Instron 8874, Norwood, MA) was equipped with a rigid, molded acetabular cup that conformed with the femoral head, and another rigid mold conformed to the greater trochanter. Bone strains (strain x 10 6) were recorded at a rate of 100Hz as the actuator pressed down upon the femoral head at a rate of 1.67mm/s until failure occurred. The acquired MR images were processed to generate FE models. Simulations included forces that mimicked loading conditions for a side fall condition that replicated falling directly on the hip. Computational bone stiffness showed strong correlation with experimental stiffness (R 2 = 0.82). The findings from this study support the use of MRI-based FE analysis of the hip to reliably predict the mechanical competence of the human femur in clinical settings. Further work is needed to determine if post yield measures such as yield strength and ultimate strength could be accurately predicted using the MRI-based computational biomechanics approach.

Exercise driven changes in subchondral bone thickness and distribution John Polk*, Munsur Rahman, Mariana Kersh. University of Illinois at Urbana-Champaign, United States

The adaptive response of bone to mechanical loading via exercise remains an opportunity to encourage bone modeling and remodeling at all stages of life[1]. However, efforts to identify specific responses that decrease bone fracture risk and influence bone stiffness have been hampered by low image resolution and small animal models that do not reflect the nature of human bone at the microstructural level. We aimed to evaluate the response of subchondral bone in an ovine exercise model. METHODS Following IACUC approval, juvenile sheep (mean age = 60 days) were divided into (i) incline treadmill (15% grade; n=5),

(ii) flat treadmill (0% grade; n=5), and (iii) control (n=4) groups. Groups (i) and (ii) were exercised twice daily at 1.12m/s for 20 min/bout for 60 days[2,3]. Joint angles were measured at mid-stance using a motion capture system (Qualisys). All subjects were euthanized humanely at day 61. Femora were microCT scanned (50μm voxel, Siemens). Images were post-processed (Amira) and binarized using a histogram-based threshold (Matlab). Thickness measurements were obtained using BoneJ (imageJ). The subchondral surface of the medial femoral condyle was analyzed and the location of maximum thickness was identified. Areas of high thickness, normalized per subject, were defined as thickness values within the highest 30%. Differences between groups were assessed using t-tests (α=0.05). RESULTS Exercised sheep experienced ~ 3600 more loading cycles per day than did non-exercised sheep. On the incline walking, sheep used more flexed knees (8% increase, p < 0.0001) at mid-stance than on flat treadmills. There was a heterogeneous distribution of subchondral bone thickness, with the highest thickness values located on the posterior portion of the joint surface (Fig 1A). Exercise increased the maximum subchondral thickness by 22.5% for flat walking and 9.7% for inclined walking. Similarly, areas of high thickness were larger in the exercised sheep (Fig 1B). Areas of increased thickness were spread out over a larger portion of the joint surface in the exercised sheep compared to the controls (Fig 1C). CONCLUSIONS Exercise increased both the maximum thickness and the spread of increased thickness throughout the joint surface. Increased flat walking more evenly spread the distribution of increased bone thickness compared to inclined walking. These spatially specific increased areas of thickness are likely modulated by the changes in flexion angle and body posture. 1. Warden + PNAS 111(14): 5337-5342, 2014 2. Lower Limb Geometry in Individuals With Atypical Femoral Fractures as Compared to Typical Fracture and Unfractured Controls Van Krueger*[1], Marjolein Van Der Meulen[2,3], Jeri Nieves[4,5], Elizabeth Foley[2], Eric Marty[3], Amelia Ni[3], Jordan Troy[2], Abigail Campbell[3], Douglas Mintz[3], Jingyan Yang[5], Joseph Lane[3]. [1]Brown University, United States, [2]Cornell University, United States, [3]Hospital for Special Surgery, United States, [4]Helen Hayes Hospital, United States, [5]Columbia University, United States

Bisphosphonates (BP) have been associated with atypical femoral fractures (AFF), but the mechanism is unknown, yet hypothesized to have a critical mechanical component. AFFs initiate on the lateral cortex, suggesting elevated stresses at this location, likely developed through geometric characteristics. We hypothesized that individuals with AFFs will have lower limb geometry differences compared to two BP control groups: hip fractures and unfractured controls. We compared 3D femoral geometry based on CT scans from AFF patients (n=21) and asymptomatic patients on long-term (>5y) BP treatment without AFF or other femoral fracture (BP-nofx, n=50); and, patients on long-term (>5y) BP treatment with femoral neck (FN) or intertrochanteric fractures without AFF (BP-hipfx, n=15). Femur structure and cortical geometry were characterized from the contralateral (nonfractured) femur by isolating contour data from thresholded CT scans and creating a 3D solid model (Materialise Mimics). We then identified relevant femoral geometric landmarks on the model (Geomagic Studio). Finally, we compared 10 anatomic measurements (MATLAB; n=2 blinded individuals): Femoral Length (FL), Femoral Head Width, Femoral Offset, Hip Axis Length, FN Axis Length, FN Shaft Angle, Cortical Thickness (at 25/50/75% FL), middiaphyseal width (at 50/75% FL), FN anteversion and FN offset. Data are presented as mean (SD). The AFF and BP-nofx were age-matched: 72y (8.1); 73y (9.2), but the BP-hipfx group was significantly older: 81y (7.7). BP use was 7.7y (4.4) in AFF, 9.2y (3.4) in BP-nofx (p=0.03 vs AFF) and 8.6y (2.5) in BP-hipfx. BMI was significantly higher in the AFF group, 26.0 (4.6) kg/m2, than in either control group (22 kg/m2 in both controls). In unadjusted analysis cortical thickness at 25%FL and 50%FL were different between AFF and BP-nofx group (p=0.04 for both). AFF and BP-hipfx differed in FN width (p=0.02), FN offset (p=0.04), cortical thickness at 25%FL and 50%FL (p<0.05) and middiaphyseal width at 75%FL (p=0.03). After adjusting for age, BMI and years of BP use, only FN width differed between AFF and BP-hipfx (p=0.03). Several geometric differences existed between AFF and other BP users, but these differences were eliminated after controlling for BMI and age (with or without BP years).Controlling for BMI eliminated the skeletal differences, raising the question as to whether higher BMI, and the associated geometric differences in the lower limb, may increase susceptibility to AFF.

Osseointegrated implants for trans femoral amputees: radiographic evaluation of bone remodeling Seamus Thomson*[1], William Lu[1], Munjed Al Muderis[2]. [1]The University of Sydney, Australia, [2]The Osseointegration Group of Australia, Australia

Background and aim(s)Osseointegration is a novel method to overcome persistent socket prosthetic issues in amputees by anchoring a transcutaneous implant directly onto the skeletal residuum. Although similar technologies have been widely applied in the area of hip and knee arthroplasty, little evidence exists in the literature reporting the bone remodeling effects of osseointegrated implants. Stress shielding results in the reduction of bone density due to the implant removing the stress that is usually exerted on the bone, which greatly reduces implant stability. This paper investigates the bone remodeling effect and quantifies it in two of the most common osseointegration implants.MethodThis is a prospective study of 50 patients with trans-femoral amputations, consisting of 35 males and 15 females, aged 20-73 (mean 48.2) years at surgery, with minimum two-year follow-up. Two implants, the Integral Leg Prosthesis (ILP) and Osseointegrated Prosthetic Limb (OPL), with differences in tapering, coating and bone ingrowth regions were examined. Radiographs were taken at 6 months, 1, 2 and 5-years post-surgery. The surrounding bone was defined using inverse Gruen zones and graded into 5 levels of bone growth or resorption.Result(s)Results obtained at 1 and 2 year follow-ups were compared to the 6-month follow-up values as a baseline. Significant bone growth near the proximal zones of the implant was observed on patients with the ILP implant. This was accompanied by significant resorption towards the distal end indicating the occurrence of stress shielding. The OPL implant demonstrated much more uniform bone density throughout the length of the implant.Conclusion(s)Overall, the patterns of bone remodeling after osseointegration showed similarities to those seen on hip stems with a press-fit design. Of the two osseointegration implants examined in this paper, the OLP implant exhibited less stress shielding effects and is expected to provide better long-term stability.

The role of MEK1/2 and MEK5 on melatonin-mediated effects on bone microarchitecture, mechanical strength, osteogenic and metabolic protein expression in intact female Balb(c) mice Fahima Munmun*[1], Van Hoang[2], Matthew Burow[2], Bruce Bunnell[3], Paula Witt-Enderby[1]. [1]Duquesne University Division of Pharmaceutical, Administrative and Social Sciences, United States, [2]Tulane University School of Medicine Department of Pharmacology, United States, [3]Tulane University School of Medicine Cancer Research Center, United States

Melatonin exposure has been shown to increase bone mineral density (BMD) in intact female mice equal in efficacy to a one-year exposure to an estrogen/progesterone hormone therapy. In the Melatonin Osteoporosis Prevention Study (MOPS; NCT01152580), melatonin (3mg, p.o. nightly for 6 mos) renormalized bone marker turnover in perimenopausal women. In the MelaOst (NCT01690000) and MOTS (NCT01870115) RCTs, melatonin (3mg for MelaOst or 5mg for MOTS, p.o. nightly for one year) alone (MelaOst) or in combination with strontium citrate, vitamin K2 and vitamin D3 (MOTS) increased BMD in postmenopausal osteopenic women. Using a human bone marrow-derived mesenchymal stem cell (hMSC) and peripheral blood monocyte (hMC) co-culture model system, we have demonstrated that MT2 melatonin receptors, MEK1/2, MEK5 and perhaps PPARγ and GLUT4 underlie melatonin's stimulating effects on osteoblast differentiation, which results in osteoprotegerin-mediated inhibition of osteoclastogenesis. We wanted to further these findings in vivo using intact female Balb(c) mice. Specifically, mice were injected with melatonin (0.166mg/kg) in the absence or presence of the selective MEK1/2 inhibitor, PD184352 (25mg/kg), MEK5 inhibitor, Bix02189 (25mg/kg), or the dual MEK1/2 and MEK5 inhibitor, SC-1-151 (25mg/kg) for 45 days. We assessed the effect of these treatments on osteogenic and metabolic protein expression in femur bone by western blot; bone microarchitecture through microCT; and bone biomechanics by the mediolateral three-point bending test. Melatonin, through MEK1/2 or MEK5, increased the expression of Runx2, Bmp-2, Fra-1 and decreased Pparγ expression. Furthermore, melatonin in combination with Bix02189 modulated bone microarchitecture by decreasing trabecular number and connectivity density and by increasing trabecular separation. Melatonin in combination with SC-1-151 decreased ultimate breaking load of the femur bone. These in vivo studies support the findings in the hMSC:hMC co-culture model system and lend further support for a role of MEK1/2 and MEK5 in melatonin effects on bone.

The Relationship of Whole Bone Strength across Cadaveric Diaphyseal and Cortical-Cancellous Sites Daniella Patton*[1], Erin Bigelow[1], Stephen Schlecht[2], Todd Bredbenner[3], Karl Jepsen[1]. [1]Department of Orthopedic Surgery, University of Michigan, United States, [2]Mechanical Engineering, University of Michigan, United States, [3]Department of Mechanical and Aerospace Engineering, University of Colorado Colorado Springs, United States

Estimating the strength of fracture-prone cortico-cancellous structures like the proximal femur would benefit from knowing how well bone strength correlates across anatomical sites and whether age-related declines in strength at another site predicts strength-declines at the hip. We conducted a biomechanical evaluation of bone strength at weight and non-weight bearing sites, determined how strength correlates across anatomical sites on an absolute basis and relative to age, and tested for sex-specific effects. Cadaveric proximal femora (M: n=45, F: n=40) and femoral (M: n=34, F: n=19) and radial diaphyses (M: n=36, F: n=19) were loaded to failure in a fall-to-side and four-point bending configuration, respectively. Whole bone strength of the proximal femur correlated significantly with the strength measured for the femoral diaphysis for both sexes (M: R2=0.30, p=0.002, F: R2=0.60, p<0.001) and only for the male radial diaphysis (M: R2=0.18, p=0.029, F: R2=0.18, p=0.145). Likewise, diaphyseal strength of the radius and femur correlated significantly only for males (M: R2=0.41, p<0.001, F: R2=0.28, p=0.093). Significant sex-specific effects were observed at the proximal femur and femur diaphysis with males being 60% (~2159 N) stronger than females at matched diaphyseal strength values (Fig. 1). Residuals from the strength-age regressions were plotted across bone sites. Strength-age residuals of the proximal femur and femur diaphysis were significant for both sexes (M: R2=0.22, p=0.011, F: R2=0.50, p<0.001) and only for the male radial diaphysis (M: R2=0.19, p=0.023, F: R2<0.01, p=0.810). Strength-age residuals of the femur and radial diaphysis were only significant for males (M: R2=0.46, p<0.001, F: R2=0.01, p=0.705). Our results indicate that bone strength correlates across anatomical sites on an absolute basis and relative to age, such that individuals who were weak (or strong) for their age at one site, were also weak (or strong) for their age at other sites. In addition, females had significantly weaker proximal femurs than would be predicted from their diaphyseal strengths compared to males. These findings are clinically important because they reveal the potential to improve estimates of bone strength at fracture-prone site like the proximal femur based on strength and age effects at more simple tubular structures of the diaphysis.

Comparative effect of deproteinized bovine bone, bioglass and synthetic hydroxyapatite on bone reparation Andrea Mattiuzzi*[1], Miguel Angel Pellegrini[1], Macarena Gonzales-Chaves[1], Ricardo Orzuza[2], Susana N Zeni[1], Gretel G Pellegrini[1]. [1]CONICET-Universidad de Buenos Aires. Instituto de Inmunología, Genética y Metabolismo (INIGEM). Facultad de Farmacia y Bioquímica-Hospital de Clínicas "José de San Martín", Buenos Aires, Argentina., Argentina, [2]Universidad de Buenos Aires, Facultad de Odontología. Cátedra de Bioquímica Gral y Bucal, Buenos Aires, Argentina., Argentina

Deproteinized bovine bone putty (BB), bioglass (BG) and synthetic hydroxyapatite (SH), (Synergy, Odontit Implant Systems, Argentina) guide bone repair because of their osteoconductive properties. The bone healing response of these bone-grafting materials was compared using a critical sized bone defect model. A bone defect of 4 mm diameter was created in rat tibiae for implantation with each biomaterial (N=30 rats). Samples for histological

and histomorphometrical analysis of new bone formation (NBF) and remaining particles of each device (RP) were collected at 2 and 4 weeks. Results: Percentage (%) of NBF (mean ± SD): 2 weeks: Control group: 6.60±3.71; BB group: 23.23±3.89*; BG group: 18.35±5.23*; SH group: 26.27±9.30*; 4 weeks: Control group: 6.69±2.38; BB group: 24.37±3.66*; BG group: 17.45±6.64*; SH group: 32.25±3.80*. Percentage (%) of RP: 2 weeks: Control group: 0±0; BB group: 5.04±1.39*; BG group: 3.03±2.31*; SH group: 4.46±2.87*; 4 weeks: Control group: 0±0; BB group: 4.45±2.35*; BG group: 2.87±1.14*; SH group: 3.78±1.68* (*p<0.05 versus control group; p= NS between BB, BG and SH groups). We did not find statistical significance among the three biomaterials, although SH exhibited a trend towards increased NBF. The three biomaterials were histologically substantially equivalent showing the expected histological stages of bone repairing: progressive inflammatory response accompanied bone healing at the implanted sites. All biomaterials were associated with trabecular bone formation. While further studies need to be done, our results indicate that BB, BG and SH exhibit similar characteristics in terms of osteoconduction.

High Resolution pQCT Micro-Architectural Parameters to Predict Bone Failure in the Case of a Forward Fall Martin Revel*, François Duboeuf, François Bermond, Jean-Paul Roux, David Mitton, Hélène Follet. Univ Lyon, INSERM, UMR1033, France

The gold standard for the diagnosis of osteoporosis is the measurement of bone mineral density by Dual X-ray absorptiometry. However, the assessment of the risk of fracture is still not sufficiently discriminant. Indeed, half of the patient considered non-osteoporotic will fracture [1]. In this context, the objective of this study is to evaluate whether bone micro-architecture of distal radius assessed by high-resolution peripheral quantitative computed tomography (HR-pQCT) manage to discriminate fractured from non-fractured bones obtained in an ex vivo experimental study reproducing a forward fall under dynamic loading conditions [2]. Thirty radii from elderly donors (79 ± 12 y.o., 15 M, 15 F) were scanned using a HR-pQCT device with an isotropic 82 µm voxel size (XtremeCT, Scanco Medical AG) before being loaded at 2 m/s to mimic impact that corresponds to a fall, leading to two groups: fractured and non-fractured. Clinical standard evaluation was performed on the images in order to assess bone micro-architecture. Statistical non-parametric Spearman's and Wilcoxon's rank-sum tests were performed using R software and p-values under 0.05 were considered as significant. On the entire population, all the parameters were significantly correlated to the maximal load. Nevertheless, important differences appeared when analyzing in two groups. Indeed, the fractured group shows high significant correlation with the trabecular parameters whereas no link was found with any parameters in the other group (Table 1). Furthermore, the two groups showed in the second test a significant difference for: all trabecular parameters, the cortical thickness and the experimental load (p < 0.05) but the cortical vBMD remain non-significant. The aim of this study was to assess whether micro-architecture assessed by HR-pQCT could discriminate bone fracture obtained experimentally. The correlations showed that trabecular parameters explained the bone strength for the fractured group and showed significant difference between the two groups. The results are in accordance with an epidemiologic study where the authors conclude that the trabecular micro-architecture in the radius is a good predictor of incident fracture in postmenopausal women [3]. Finite element analysis will be performed to enhance our understanding of bone fracture during a fall.[1] E. S. Siris et al, Arch.Intern.Med. 164:10, 2004[2] E. Zapata et al, J.Biomech., 63, 2017[3] E. Sornay-Rendu et al, JBMR, 32:6, 2017

Impact of Sex and Maturation on Trabecular and Cortical Microarchitecture in Children and Young Adults Tandy Aye*[1], Kyla Kent[1], Jin Long[1], Jessica Whalen[1], Ariana Strickland[1], Andrew Burghardt[2], Mary B. Leonard[1]. [1]Stanford University School of Medicine, United States, [2]University of California San Francisco, United States

The impact of sex and maturation on trabecular (Tb) and cortical (Ct) microarchitecture in children and young adults has not been well established. The new second-generation high-resolution peripheral quantitative CT (HR-pQCT) scanner (XCT II, Scanco Medical)

incorporates three important advances. First, the 61μm isotropic voxel provides greater spatial resolution to accurately determine the thickness of individual human trabeculae. Second, the device uses direct voxel-based measures of trabecular thickness and spacing with Gaussian thresholding. Third, the gantry of the scanner allows the limb to advance further into the field of view, providing measures in the cortical midshaft that are less subject to partial volume effects. The objective of this study was to identify sex and maturation effects on bone structure and strength, and to determine the impact of adjustment for leg muscle mass. This cross-sectional study included 208 healthy participants (98 females), ages 5 to 30 yrs recruited from the community and excluded from diseases or medications known to effect growth and bone health. The reference line was placed 2 mm proximal to the proximal margin of the growth plate (or growth plate remnant if fused) and scans were centered 3.5% and 30% of tibia length proximal to the reference line. Log linear regression models were adjusted for age, age2, sex, tibia length and Tanner stage. The results are presented as percent differences in female vs. male, and Tanner stage (Table). Female participants had significantly lower Ct thickness, greater Ct bone mineral density (BMD), and lower Ct porosity, with lower micro-finite element analysis estimates of failure load, compared with males. Greater skeletal maturity was associated with greater Ct thickness and failure load, independent of age. Cortical porosity was markedly higher in pre-pubertal participants (averaging 5.2 and 3.5% in Tanner stage 1 males and females respectively, compared with 1.5 and 1.1% in Tanner stage 5). In the tibia metaphysis, female participants had significantly, lower bone volume fraction (BV/TV) and Tb thickness compared with males; Tb number did not differ. BV/TV and Tb number were greater in progressively mature participants, compared with pre-pubertal participants. Leg muscle mass was positively associated with Ct thickness and failure load and Tb BV/TV and Tb thickness. Adjustment for muscle mass eliminated sex and Tanner differences in these outcomes.

Healing rickets: Lessons from the Vienna Studies 1921-1923 David Ayoub*. Southern Illinois University School of Medicine, United States

Purpose: Hans Wimberger's landmark study on the radiology of healing rickets was based upon the observations of infants who developed disease prior to or following admission to institutions in and around Vienna, Austria from 1919-1922 following WWI. I sought to reanalyze the original findings in greater detail for further characterization of healing patterns. Methods:High quality prints of radiographs from the original publication were reviewed from ten institutionalized infants (6-13 months, x̄ = 9.2 months) who underwent unilateral upper and lower limb (n=9) or upper limb only (n=1) imaging during various stages of disease. Radiographs were taken at 4 to 6 points in time in each infant, including 19 limbs, and yielded a dataset comprised of 264 individual long bones and 440 growth plates (GPs). Nine infants were treated with various combinations of either sun exposure (n=3), cod-liver oil (n=4), artificial light (n=3) or calcium (n=1). One was allowed to spontaneously heal. Results: Changes of active rickets was present in 9 of 10 infants while one presented in a state of healing. All infants demonstrated healing as manifested by mineralization above an original and distinct zone of provisional calcification (ZPC). This occurred in 39% of all GPs. During healing, a new line of mineralization often appeared above the original ZPC in all infants (range 2-7 GPs per infant). Other signs of healing included the appearance of perichondrial spurs in 100% of infants and 46% of GPs) and subperiosteal new bone (SPNB) (90% of infants and x% of bones). SPNB was never during pre-rachitic or healed states. Generalized osteopenia was uncommon, seen in 30% of infants during active stages, often worsened during the healing process. The changes of both active and healing rickets commonly occurred asynchronously in time. The disease never involved all bones. Conclusions: Rickets presents as a much more diverse range of radiographic changes than widely assumed. A classification scheme of healing stages is proposed.

Irisin Levels Are Positively Associated with Bone Mineral Density and Better Glycemic Control in Healthy and Type 1 Diabetes Children Graziana Colaianni*[1], Giacomina Brunetti[2], Maria Felicia Faienza[3], Lorenzo Sanesi[1], Monica Celi[4], Laura Piacente[3], Gabriele D'Amato[3], Giorgio Mori[5], Silvia Colucci[2], Maria Grano[1]. [1]Department of Emergency and Organ Transplantation, University of Bari, Italy, [2]Department of Basic Medical Sciences, Neuroscience and Sense Organs, University of Bari, Italy, [3]Department of Biomedical Science and Human Oncology, Paediatric Unit, University of Bari, Italy, [4]Tor Vergata, University of Rome, Italy, [5]Department of Clinical and Experimental Medicine, University of Foggia, Italy

Irisin is a myokine secreted by skeletal muscle during physical activity both in mice and humans. After its discovery, irisin raised great expectations as regulator of energy homeostasis able to promote the trans-differentiation of white into brown adipocytes, triggering non-shivering thermogenesis. Later, we demonstrated that its primary target organ was the skeleton given that a lower dose of irisin was able to increase cortical bone mineral density in healthy mice and to ameliorate bone and muscle losses in a mouse model of disuse-induced osteoporosis and muscular atrophy.Aiming to understand if these results could be translated to humans in future, we sought to determine if irisin levels were correlated with a bone healthy status in a population of children, given that bone mass reached during childhood is one of the most important determinants of lifelong skeletal health. More specifically, we investigated irisin correlation with bone status in both physiological and pathological conditions, by analyzing two subpopulations of children, healthy or diagnosed with childhood type 1 diabetes mellitus (T1DM), with the latter group characterized by decreased bone mass.34 controls (9.82 ± 3.2 years) and 96 T1DM subjects (12.2 ± 4 years), the latter further divided in 56 children receiving multiple insulin daily injections (MDI) and in 40 children on continuous subcutaneous insulin infusion (CSII), were included in the study. Irisin and bone metabolic markers were quantified in sera and bone mineral density (BMD) was evaluated by QUS.In healthy children, we found that irisin levels were positively correlated with BMD measured as BTT-Z-score (r= 0.375; p<0.001), and osteocalcin (r=0.37; p<0.001), and negatively correlated with Dickkopf WNT Signaling Pathway Inhibitor 1 (DKK1) (r=-0.27; p<0.001) and glucose (r=-0.14; p<0.01). Interestingly, irisin levels were higher in T1DM children respect to controls (p<0.001). In these patients, irisin negatively correlate with HbA1c% (r= -0.105; p<0.001), years of diabetes (r= -0.07; p<0.04), 25(OH)-Vitamin D (r= -0.175; p<0.0001), and positively with BTT-Z-score (r= 0.088, p=0.016) and osteocalcin (r=0.059, p<0.04). Moreover, we detected higher levels of irisin in CSII than MDI patients (p<0.001), indicating a strong positive association between irisin and the better glycaemic control given by the pump device which closely mimic the behaviour of the pancreas and improves the bone health status of these patients.

Safety and Effectiveness of Stoss Therapy in the Treatment of Vitamin D Deficiency. Paul Tannous*[1], Melissa Fiscaletti[1], Chris Cowell[1], Nicholas Wood[1], Yvonne Zurynski[2], John Coakley[1], Philip Britton[1], Hasantha Gunasekera[1], Andrew Biggin[1], Craig Munns[1]. [1]Children's hospital at Westmead, Australia, [2]Australian Pediatric Surveillance Unit, Australia

BACKGROUND AND OBJECTIVES:Pediatric vitamin D deficiency is associated with musculoskeletal disease, most notably nutritional rickets. Vitamin D treatment can correct vitamin D status (25-hydroxyvitamin D - 25OHD), prevent nutritional rickets and its extra-skeletal complications including hypocalcemic seizure, cardiomyopathy and rarely death. Compliance with daily oral therapy can be difficult to achieve, making high dose, short-term vitamin D (stoss) therapy a potentially valuable therapeutic tool to improve compliance and thus normalize 25OHD status. Consensus on optimal stoss dosing is lacking and concerns regarding its safety in children remain. Our objective was to compare the effectiveness and safety of stoss versus standard vitamin D therapy in treating 25OHD deficiency in children.METHODS:Children aged 2 to 16 years of age with vitamin D deficiency (25OHD <50nmol/L) were randomized to receive either stoss (100,000 IU/ week for 4 weeks) or standard (5,000IU/day for 80 days) therapy. Participants underwent clinical and biochemical evaluation of effectiveness and safety at baseline, 4 weeks, and 12 weeks after starting therapy. Primary outcome was 25OHD status at 12 weeks. Compliance was measured by assessment of medication taken.RESULTS: 135 children were enrolled in the study; 73 received stoss therapy and 62 received standard therapy, median age of 9 years (IQR: 6,12 years). Baseline 25OHD levels were 26 nmol/L (IQR: 19, 35 nmol/L) and 32 nmol/L (IQR: 24, 39 nmol/L) in the standard and stoss groups respectively. Change in 25OHD was 50 nmol/L (IQR: 35, 98 nmol/L) in the standard group and 35 nmol/L (IQR: 25, 46 nmol/L) in the stoss group (p = 0.0005). While the standard group achieved greater changes in the 25OHD levels over the study period, there was no significant difference in normalization of 25OHD status between the two groups. At 12 weeks, more than 80% of participants in both groups achieved sufficiency (25OHD>50nmol/L). A similar result was seen with ALP, and PTH levels. Similarly, serum calcium and urinary calcium/creatinine ratio were largely within normal limits with no significant difference seen between the two groups. Compliance was similar in the 2 treatment groups.CONCLUSIONS: We found no difference in efficacy or safety between 100,000 IU weekly for 4 weeks and standard daily therapy of 5,000 IU in the management of vitamin D deficiency in children. Although simplifying treatment regimens

has been known to improve medication compliance, this was not evident in our study. These results add to previous data supporting stoss as an effective and safe alternative for children. Long-term studies are needed to determine optimal dosing and monitoring schedules to maintain sufficient vitamin D levels throughout childhood.

SUN-0123

Larger muscle area is a positive predictor of bone strength while subcutaneous fat is a negative predictor of bone strength: A pQCT and HR-pQCT study of boys and girls Saija Kontulainen*[1], Amy Bunyamin[2], Chantal Kawalilak[2], Kelsey Bjorkman[2], Jd Johnston[2]. [1]University of Saskatchewan, UofS, Canada, [2]UofS, Canada

Muscle and fat tissues are proposed to have clinically important site- and sex-specific roles on bone strength development in children but evidence is limited. Study purposes were to A) quantify sex-differences in bone strength estimates at the distal radius and tibia in children approaching their growth spurt; and B) assess if sex-differences in bone strength were influenced by adjustment of site-specific muscle and subcutaneous fat areas. We scanned the dominant distal radius and tibia from 138 children (mean age: 10.7, SD: 1.8 yrs) using high resolution peripheral quantitative CT (HR-pQCT) and applied finite element analysis to estimate bone strength (failure load and stiffness). We scanned the dominant forearm and lower-leg with pQCT to quantify muscle and subcutaneous fat areas. We defined biological age by calculating age from the estimated age at peak height velocity (aPHV) and included 129 children (67 girls) preceding aPHV. We compared anthropometrics, physical activity (via questionnaire), dietary intakes of protein, calcium and vitamin D (questionnaire) between sexes to identify covariates. We compared bone strength estimates between boys and girls using biological age, limb length and weight as covariates. We then entered site-specific muscle and fat areas in the linear regression models. Maturity, limb length and weight adjusted failure load and stiffness were 11% greater at the distal radius and 12% and 11% greater, respectively, at the distal tibia in boys vs. girls. After adjusting for forearm or lower-leg muscle area (with or without subcutaneous fat area), failure load and stiffness no longer differed between sexes. Inclusion of muscle area improved the fit (R2 from 0.5 to 0.6, p<0.001) of all bone strength models and was a significant positive predictor of failure load and stiffness at both the distal radius and tibia (B ranged 0.50 to 0.58, p<0.05). Subcutaneus fat area was a negative predictor of failure load and stiffness at the distal tibia only (B -0.36 to -0.37, p<0.05). Findings suggest that greater bone strength at the distal radius and tibia in boys was explained by larger forearm and lower-leg muscle areas. Results also indicated a negative role of calf subcutaneous fat on distal tibia bone strength. Interventions to improve muscle size and strength development, particularly for girls, may alleviate observed sex-differences in bone strength may contribute to life-long prevention of bone fragility fractures in both sexes.

Is adiposity increased in children with achondroplasia and hypochondroplasia? Takuo Kubota*[1], Yukako Nakano[1], Kei Miyata[1], Kenichi Yamamoto[1], Shinji Takeyari[1], Hirofumi Nakayama[1,2], Takeshi Kimura[1], Yasuhisa Ohata[1,3], Taichi Kitaoka[1], Keiichi Ozono[1]. [1]Department of Pediatrics, Osaka University Graduate School of Medicine, Japan, [2]The Japan Environment and Children's Study, Osaka unit center, Japan, [3]The 1st. Department of Oral and Maxillofacial Surgery, Osaka University Graduate School of Dentistry, Japan

Achondroplasia (ACH) and hypochondroplasia (HCH) are caused by gain-of-function mutations of FGFR3. FGF18 and FGF2 bind FGFR3 and regulate the development of chondrocytes in the growth plate. However, endocrine FGF, FGF21 and FGF23, also binds FGFR3 and plays some roles in glucose and phosphate metabolism. Obesity is one of complications of ACH and HCH, but evaluation of obesity by BMI is inappropriate in these disorders due to extreme short stature. Thus, it is required to develop appropriate measurements for ACH and HCH. In this study, dual X-ray absorptiometry (DXA) was used to evaluate the degree of obesity in children with ACH and HCH. Our objective is to assess their obesity using % body fat by DXA and body index obtained from anthropometric measurement and to examine whether any body index predicts an accurate adiposity. Thirty-one participants with ACH (14 males, 10 females) and HCH (4 males, 3 females) with p.N540K at our University Hospital were recruited in this retrospective study. The mean age of male and female was 10.7 and 10.4 years, respectively. Their anthropomorphic measurements (height, weight, hip circumference and waist circumference) were obtained from their medical records. We calculated BMI, waist height ratio and waist hip ratio. Whole body DXA scans were performed to measure % body fat (%BF) on a Hologic Discovery A DXA scanner. All statistical analyses were performed using IBM SPSS Statistics software. On basis of 'Guidelines for the management of obesity disease in children and adolescents 2017', we defined obesity as the following; boys with more than 25% BF, girls under 10 years of age with more than 30% BF and girls over 11 years with more than 35% BF. One quarter (25.8%) of ACH patients met the criteria for obesity by %BF (27.8% in boy and 23.1% in girl). On the other hand, subjects with BMI percentile over 85% accounted for 83.9% (83.3% in boy, 84.6% in girl). Moreover, as much as 45.2% of all was above 95% BMI (50% in boy, 38.5% in girl). Our data showed no age dependency to fulfill obesity criteria from the point of %BF. The prev-

alence of obesity was high in children with ACH and HCH compared to general population according to the "general" obesity criteria. No apparent age-dependence was observed. High BMI percentile did not predict increased %BF in the cohort. The relationship between obesity and insulin resistance is the next issue to be examined.

Racial Differences in Bone Histomorphometry within Children and Young Adults on Dialysis. Marciana Laster*, Renata Pereira, Isidro Salusky. UCLA, United States

Introduction: In the healthy population, Black race is associated with greater bone mineral density and decreased risk of fracture when compared to White race. Comparison of iliac crest histomorphometry in healthy children reveals greater cortical thickness and decreased cortical porosity in Black vs. White children. How these differences are reflected in the bone of children and young adults on dialysis is unknown. Methods: Using tetracycline-labeled, iliac crest bone biopsies obtained in prior research protocols in pediatric and young adult dialysis patients, we compared trabecular and cortical parameters between Black subjects and non-Hispanic White subjects matched by age, gender, disease etiology, modality and PTH. Results: The cohort consisted of 25 Black subjects and 29 White subjects with a mean age of 13.9 ± 4.7. 60.4% of subjects were male and 73.6% used PD as the primary modality. There were no differences in phosphate, PTH or Alkaline Phosphatase between the racial groups and albumin-corrected serum calcium was significantly lower in Black subjects (Table 1). Turnover, mineralization and volume parameters in trabecular bone did not show significant differences between racial groups (Table 2). Analysis of cortical bone showed greater median cortical thickness in Black subjects (Figure 1) and in linear regression analysis, Black race was associated with 37.5% higher cortical thickness (95% CI 2.1% to 85.2%, p=0.04). There was no significant difference in cortical porosity. Conclusions: Similar to findings in populations of normal children, Black race in pediatric and young adults on dialysis is associated with greater cortical thickness. Contrarily, there were no significant differences in cortical porosity or trabecular bone. These findings suggest the possibility of racial variation in the response of cortical bone to the perturbations of CKD-MBD.

Multimodality Study of Glucocorticoid Induced Osteoporosis in Pediatric Crohn's Disease Jin Long*[1], Dale Lee[2], Rita Herskovitz[3], Babette Zemel[4], Mary Leonard[5]. [1]Department of Medicine, Stanford University, Stanford, United States, [2]Department of Pediatrics, Seattle Children's Hospital, Seattle, WA, United States, [3]Department of Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, United States, [4]Division of GI, Hepatology & Nutrition, The Children's Hospital of Philadelphia, Philadelphia, PA, United States, [5]Department of Pediatrics, Stanford University, Stanford, CA, United States

Childhood Crohn's disease (CD) is associated with multiple risk factors for impaired bone accrual. We reported the results of a 12 month double-blind, placebo-controlled trial of low magnitude mechanical stimuli on bone health in 138 children with CD, ages 8 to 21 year, followed by one year open-label extension (JBMR 2016). The trial showed a modest effect on spine quantitative CT (QCT) trabecular volumetric bone mineral density (BMD). In all participants combined, tibia pQCT trabecular vBMD and cortical area, DXA BMD at all sites, DXA leg lean mass, and spine QCT trabecular BMD Z-scores improved markedly (all p<0.001). Greater physical activity (by accelerometer) and lesser disease activity were associated with greater gains in leg lean mass. The objective of this secondary analysis was to identify correlates of changes in bone outcomes over 24 months. DXA and pQCT scans were obtained at baseline, 6, 12 and 24 months, and spine QCT at baseline, 12 and 24 months. Longitudinal multivariable mixed models were used to assess correlations of bone Z-scores (adjusted for height/tibia length) with demographics, pediatric Crohn Disease Activity Index (PCDAI), leg lean mass Z-score, physical activity, glucocorticoid exposure, and 25(OH) vitamin D. Younger age was associated with greater BMD across most sites (see Table). Glucocorticoid therapy was associated with significantly lower trabecular vBMD in the tibia and spine, and DXA BMD across all sites. Vitamin D was associated with greater trabecular vBMD in the tibia only, and greater physical activity was associated with greater tibia trabecular vBMD and femoral neck BMD. Leg lean mass Z-score was not associated with cortical vBMD but was highly and positively associated with all bone outcomes shown below (all p<0.0002 with the exception of spine QCT vBMD with p=0.02). Adjustment for leg lean mass attenuated the associations with age and physical activity. In summary, glucocorticoid therapy was associated with significant bone deficits across multiple axial and appendicular sites, independent of disease activity. The observation that glucocorticoids were associated with greater cortical vBMD is consistent with our prior reports in multiple pediatric conditions, and attributed to glucocorticoid effects to suppress bone formation with greater accumulation of older cortical bone of greater density. Greater muscle mass was associated with greater trabecular vBMD, cortical area and DXA Z-scores across all sites.

Measured Cortical Bone Strain during Muscle Contraction in a Mouse Model of Osteogenesis Imperfecta Alycia Berman*[1], Rachel Surridge[2], Joseph Wallace[2]. [1]Weldon School of Biomedical Engineering, Purdue University, United States, [2]Department of Biomedical Engineering, Indiana University - Purdue University Indianapolis, United States

In many bone diseases, bone wasting is accompanied by sarcopenia. Bone responds to the strains engendered on it and since muscle contraction is one contributor to bone strain, the presence of sarcopenia may reduce the ability of muscle to engender strain on bone, leading to further bone disease progression. In this study, we used a mouse model of osteogenesis imperfecta (OI) and measured bone strain during muscle contraction to assess the ability of weakened muscle to engender strain on weakened bone. Osteogenesis imperfecta murine (OI) mice and their wildtype (WT) and heterozygous (HET) littermates underwent surgery at 16 weeks to attach a single axis strain gage to the anteromedial portion of the tibial diaphysis. After surgery, the posterior muscles (predominately gastrocnemius and soleus) were stimulated in vivo (250 Hz repeated activation over a 200-ms period) to induce isometric plantar flexion. Muscle torque and bone strain were recorded simultaneously. After the stim-

ulation protocol, mice were euthanized and their tibiae harvested. Tibiae were scanned by micro-CT (10 µm resolution) and a 1-mm midshaft region of interest was analyzed to assess cortical geometry. Data were statistically analyzed using one-way ANOVA with post-hoc Tukey tests (p<0.05). All animal procedures were performed with prior approval from IUSM IACUC.Results demonstrated that OI mice had smaller bones, with a reduced cross-sectional area as compared to WT (-24%; p=0.01) and HET (-27%; p<0.01). In addition, functional muscle testing indicated weaker muscle in OI mice, with a 78% reduction (p<0.0001) and a 76% reduction (p<0.0001) in maximum contractile torque compared to WT and HET, respectively. Interestingly, although muscle force was reduced by 78% compared to WT, the strain engendered on bone during muscle contraction was only reduced by 44% (vs WT; p=0.02). As a result, although there was a reduction in both muscle force and bone strain in OI mice, the amount of strain engendered on the bone per unit torque was significantly greater in the OI group (+486% vs WT; +700% vs HET; both p<0.0001). Thus, the OI mice required far less muscle torque to engender strain on bone. In addition, the average strain engendered on OI bone during muscle contraction was 1400 µε, which is similar to levels of strain noted during other stimulation methods (e.g. axial compression) and suggests that muscle stimulation may be a viable means to induce bone formation in this OI mouse model.
Fig. 1 - A) CT scans show a smaller overall cross-section with a thin cortex in the OI group. **(B)** Representative images and **(C)** quantification of the torque and strain curves show decreased maximum torque and strain in the OI group, but significantly increased strain per unit torque.

Reactive oxygen species (ROS) accumulate in skeletal muscle with age, and ROS stimulates the release of exosomes from myoblasts that can induce senescence-like changes in bone marrow derived stem cells (BMSCs) Sadanand Fulzele*, Bharati Mendhe, Carlos Isales, William Hill, Meghan Mcgee-Lawrence, Kanglun Yu, Mark Hamrick. Augusta University, United States

The molecular mechanisms underlying loss of muscle mass and strength with age are not completely understood, but reactive oxygen species (ROS)-induced injury is thought to play a role. Elevated ROS levels can increase cellular senescence, and senescent cells may negatively impact other cells and tissues in a paracrine fashion by secreting molecules referred to as the senescence-associated secretory phenotype (SASP). Here we test the hypothesis that exosomes carry SASP-related factors induced by age-associated ROS accumulation in skeletal muscle. We first assessed ROS levels in skeletal muscles of aged (22-24 mo) and young (4-6 mo) mice using Amplex Red assay for hydrogen peroxide and 4HNE staining to examine lipid peroxidation. Amplex Red data indicate that hydrogen peroxide (H2O2) levels are significantly (2-fold) increased in muscles of aged mice. The age-associated increase in ROS is further confirmed by positive 4HNE staining in muscle tissue from aged mice but not young mice. We then performed co-culture studies to determine the effects of muscle-derived exosomes on proliferation of bone marrow stromal cells (BMSCs) using MTT assay, since exit from the cell cycle and impaired proliferation are hallmarks of cellular senescence. Exosomes isolated from mouse C2C12 myoblasts significantly increased BMSC proliferation; however, exosomes isolated from C2C12 myoblasts following myoblast exposure to hydrogen peroxide had the opposite effect. That is, exosomes from H2O2-treated myoblasts significantly decreased cell proliferation. Exosomes from H2O2-treated myoblasts were found to be enriched in senescence-associated microRNAs such as miR-183, and miR-183 was also significantly elevated in aged skeletal muscle. These findings suggest that ROS-induced senescence in skeletal muscle cells can stimulate the production of extracellular vesicles that may have detrimental effects on bone cells, ultimately contributing to age-related bone loss.

Prx1-derived muscle interstitial cells contribute to bone repair and cause fibrosis in musculoskeletal trauma Anais Julien*[1], Anuya Kanagalingam[1], Oriane Duchamp De Lageneste [1], Jerome Megret[2], Frédéric Relaix[3], Céline Colnot[1]. [1]INSERM U1163, Imagine Institute, Paris Descartes University, France, [2]INSERM US24 - CNRS UMS3633 Cytometry Platform, Paris Descartes University, France, [3]INSERM IMRB U955, Paris Est-Créteil University, France

Skeletal muscle and bone exhibit great capacities to regenerate due to tissue-specific stem cells, i.e. satellite cells and skeletal stem cells from periosteum(1,2). However, bone fails to heal properly in 10% of bone injuries and delayed healing is increased to 40% in patients with soft tissue damage. The role of muscle in bone repair is well recognized clinically but the underlying cellular and molecular mechanisms are poorly understood. Muscle regulates the inflammatory environment of fracture and muscle satellite cells are providing a source of growth factors for bone repair(3, 4). Here we characterized the impact of muscle injury on bone regeneration in a new musculoskeletal trauma model. Under ethical approval, tibial fractures were induced in adult mice with or without injury to skeletal muscles surrounding the tibia. Histomorphometric analyses show that muscle injury delays callus, cartilage and bone formation. This is accompanied by abnormal callus organization with the presence of unresorbed cartilage and fibrosis leading to non-union. Using cell lineage tracing in genetic mouse models and tissue grafting, we show that osteochondro progenitors are actively recruited from muscle during bone repair and are derived from the Prx1 mesenchymal lineage also giving rise to periosteal cells[2]. In fractures combined with muscle injury, the contribution of muscle and periosteal cells to cartilage is decreased. Moreover, in the traumatic environment, Prx1-derived muscle cells but not periosteal cells are the source of fibrosis in the fracture callus. FACS and molecular analyses indicate that the Prx1-derived muscle cells are muscle interstitial cells distinct from endothelial, hematopoietic and myogenic cells, and express CD29, Sca1 and Cxcl12. This Prx1-derived muscle cell population overlaps with the muscle fibro/adipogenic progenitor population marked by PDGFRa. In conclusion, we identified a critical cell population within muscle that participates directly in cartilage and bone formation during fracture repair, but fails to do so after traumatic injury and becomes the source of fibrosis causing fracture non-union. This study provides a cellular basis for delayed bone regeneration in severe musculoskeletal injuries.[1] Lepper C, et al, Development, 138(17): 3639–3646, 2011[2] Duchamp de Lageneste O, et al, Nature Communications, 22;9(1):773, 2018[3] Abou-Khalil R, et al, JBMR, 29(2):304-15, 2014[4] Abou-Khalil R, et al, Stem cell 33(5):1501-11, 2015

The bone anabolic effects of irisin are through preferential stimulation of aerobic glycolysis Sung Kil Lim*. College of Medicine, Yonsei Univerisity, Republic of Korea

Irisin, a recently identified hormone secreted by skeletal muscle in response to exercise, displays anabolic actions on the skeleton primarily through the stimulation of bone formation. However, the mechanism underlying the irisin-stimulated anabolic response remains largely unknown. To uncover the underlying mechanism, we biosynthesized recombinant irisin (r-irisin) using Escherichia coli expression system and used it to treat several types of osteoblast cell. Our synthesized r-irisin could promote proliferation and differentiation of osteoblasts as evidenced by enhanced expression of osteoblast-specific transcriptional factors, including Runt-related transcription factor-2 (Runx2) and Osterix (Osx), along with transcriptional activating transcription factor 4 (Atf4); and osteoblastic early differentiation markers, such as alkaline phosphatase (Alp) and collagen type I alpha 1 (Col1a1). Furthermore, we showed that the promotion of r-irisin on the proliferation and differentiation of osteoblast lineage cells are preferentially through aerobic glycolysis, as indicated by the enhancement on the abundance of its representative enzymes lactate dehydrogenase A (LDHA) and pyruvate dehydrogenase kinase 1 (PDK1), together with increased lactate levels. The favorite of the aerobic glycolysis after r-irisin treatment was then confirmed in the primary cultured calvarial cells by metabolic analysis using gas chromatography-mass spectrometry. Thus, our results suggest that the anabolic actions of r-irisin on the regulation of osteoblast lineage cells are preferentially through aerobic glycolysis, which may help us to develop new irisin based bone anabolic agents.

Risedronate could rescue podocyte injury in Pit-1 overexpressing transgenic rats Atsushi Masuda*[1], Takeshi Takayanagi[1], Yohei Asada[1], Shogo Nakayama[1], Eisuke Tomatsu[1], Yasumasa Yoshino[1], Sahoko Sekiguchi-Ueda[1], Megumi Shibata[1], Eishin Yaoita[2], Atsushi Suzuki[1]. [1]Department of Endocrinology and Metabolism, Fujita Health University, Japan, [2]Department of Structural Pathology, Institute of Nephrology, Niigata University Graduate School of Medical and Dental Sciences, Japan

Hyperphosphatemia is known to be one of prognostic factors in chronic kidney disease - mineral and bone disorder (CKD-MBD). We have previously reported type III Pi

transporter(Pit-1)-overexpressing transgenic(TG) rats increased proteinuria via podocyte injury and glomerular basement membrane (GBM) thickening. We have also revealed that risedronate could improve proteinuria and reduce GBM thickening. In the present study, we investigated the effect of risedronate on podocyte injury in Pit-1 TG rats.Methods: Pit-1TG rats and control rats are randomly divided into 4 groups; I: control rat without risedronate administration(C-C), II: control rat with risedronate administration(C-R), III: Pit-1TG rat without risedronate administration (TG-C), and IV: Pit-1TG rat with risedronate administration (TG-R). The protocol of risedronate administration was 5 µg/kg weight s.c. twice a week starting at 5 weeks old through 12 weeks old. Tissues for histological analysis were performed at 12 weeks of age. For immunofluorescence microscopy, the sections were immunostained with murine monoclonal anti-nephrin antibody as a podocyte constituent protein marker, and murine monoclonal anti-desmin antibody and rabbit anti-connexin 43 antibody as podocyte injury markers.Results: TG-C group rats showed GBM thickening, and risedrontate could keep the width of GBM and its three-layers structure in TG-R rats. Immunostaining for podocyte injury markers such as desmin and connexin 43 exhibited focally and segmentally conspicuous staining in TG-C rats. When the TG rats were treated with risedronate, podocytes showed less changes than TG-C rats. On the other hand, localization or staining intensity of nephrin were same in all groups.In conclusion, these finding suggests us that risedronate could improve injury of podocyte and keeps barrier function of the gromerulus in the kidney.

Isomeric aminobutyric acids, especially β-aminoisobutyric acid (BAIBA) and γ-aminobutyric acid (GABA), are PGC-1α-dependent myokine-like signaling molecules released from skeletal muscle during exercise. We demonstrated that BAIBA plays an important role in bone-muscle crosstalk through protecting osteocytes against oxidative stress. Quantification of BAIBA and GABA in biological samples is a huge challenge due to the nature of their ultra-low molecular weight and extreme similarity in structure. All methods to date are indirect and require long sample preparation i.e. derivatization. In this study, by developing a fast and sensitive LC-MS/MS method, we were able to quantify simultaneously five major aminobutyric acid enantiomers BAIBA (D-, L-), GABA, and α-aminobutyric acid (AABA, D-, L-) in biological fluids from humans and rodents. This newly developed LC-MS/MS methodology enables baseline separation for underivatized aminobutyric acid isomers, and is sensitive for the detection of these isomers in the minimal sample amount (10 µL) of mouse serum/plasma and human serum/cerebrospinal fluid. Accuracy (85%−115%) and precision (±15%) of the method met assay acceptance criteria as required in FDA guidance. The predominant configuration of BAIBA in human serum is the R-enantiomer (D-BAIBA), with an average concentration of 0.34 ± 0.02 µM in pooled healthy human serum. This result was confirmed in serum samples from 22 individual human subjects, with the ratio of L:D less than 1:10. In contrast, L-BAIBA is the dominating form in mouse circulation, with the D being not detected. Difference in diet (protein sources) and metabolism between mice and humans possibly accounts for these differences in D vs L levels. We measured the serum concentration of BAIBA and GABA in females 50-60 and 66-75 years old with or without osteoporotic fractures (OF). D-BAIBA was lower in the 50-60 OF group but not in the 66-75 OF group. GABA levels were significantly lower (P = 0.024) in the 66-75 OF group. Our findings reinforce the concept of muscle-bone crosstalk and indicate that BAIBA and GABA might be necessary for optimal bone function. This fast and sensitive quantification method, first developed by our group, will facilitate the study of mechanisms underlying biological activities of BAIBA, GABA, and other aminobutyric acids in bone-muscle crosstalk, which will further promote the development of new methods in the diagnosis and treatments for musculoskeletal diseases.
