Methods: Our cross-sectional study sample consisted of 214 males and 249 females (age range 18-88 yr, mean age 45.4 yr) from the Fels Longitudinal Study. Total VAT and SAT mass (kg) were assessed using a multi-slice magnetic resonance imaging (MRI) protocol. Dual energy X-ray absorptiometry was used to estimate BMD of the femoral neck (NFBMD), lumbar spine L14 (LSBMD) and total body (TBBMD). Body mass index (BMI, kg/m²) was calculated from weight and height. Covariates included age, current smoking, physical activity levels, menopausal status for women, and diabetes status. Sex-stratified general linear regression models were used for statistical analysis adjusting for significant covariates of BMD.

Results: There were significant ($p < 0.05$) sex differences in VAT (men vs women, 3.92.6 vs 1.81.4 kg) and SAT (4.82.8 vs 5.63.4 kg). In men, VAT was negatively related to NFBMD and TBBMD in multiple regression models ($p < 0.001$); for example, a one SD increase in VAT was related to decreases of 0.39 g/cm² in NFBMD, and 0.54 g/cm² in TBBMD. Higher SAT levels were associated with lower NFBMD ($p = 0.005$) and TBBMD ($p = 0.025$). There were no significant relationships between either VAT or SAT with LSBMD. In women, higher VAT was significantly related to lower TBBMD ($p = 0.025$); a one SD increase in VAT was associated with a 0.22g/cm² decrease in TBBMD. VAT was not related to NFBMD or LSBMD. Higher SAT levels were related to lower NFBMD ($p = 0.001$) and TBBMD ($p = 0.003$).

Conclusion: Our results suggest that MRI-assessed abdominal adipose tissue mass (VAT and SAT) is inversely related to BMD at specific skeletal sites. These results reveal complexities of the relationship between fat and bone in white adults.

Prevalence of Higher Fracture Risk Using FRAX® in Community-Dwelling Japanese People. Yasuyo Abe^{*1}, Eugene McCloskey², Makoto Osaki¹, Kiyoshi Aoyagi¹. ¹Nagasaki University, Japan, ²University of Sheffield, United Kingdom

Diagnosis of osteoporosis has been based on bone mineral density (BMD). However, many fractures occur in individuals with BMD above the threshold for osteoporosis. Against this background, in 2008, a WHO Working Group developed FRAX® (<http://www.sheffield.ac.uk/FRAX>), a tool to evaluate 10-year fracture probability of individual patients based on clinical risk factors with or without femoral neck BMD. Using the FRAX® model for Japan, the Japan Osteoporosis Society is considering implementing an intervention threshold at or above a 10-year major osteoporosis fracture probability of 15% into a new version of the national guideline this year. The purpose of this study was to describe the potential burden of disease by assessing the prevalence of fracture risk above certain thresholds among community dwelling men and women, and the values of heel stiffness index in those identified at risk.

Study subjects included 128 men and 194 women aged 40 years and over participating in a community health checkup program in 2010. Major osteoporotic fracture risk was calculated from clinical risk factors alone using the Japan calculator in FRAX®. Heel stiffness index (SI) was also measured using a Lunar Achilles device. The prevalence of high fracture risk was calculated according to age group and gender for cut-off points of 5%, 10%, 15%, and 20%.

Major fracture probability was significantly higher in women than men (median; 11.4% vs. 6.1%, $p < 0.001$). Fracture probability increased with age in both genders, but at all ages and thresholds, the prevalence of high risk was substantially lower in men than women. For example, in men the prevalence at risk at or above the 15% threshold was only 1.9% at age 60-69 years whereas it was 20.0% in women of the same age. Among women, stiffness index was negatively correlated with age, but there was no significant correlation among men (women; $r = -0.53$, $p < 0.001$, men; $r = -0.09$, $p = 0.3$). In women the mean values of SI decreased with increasing stringency of the threshold used to define high risk (71.512.1 at 5-10% risk to 67.011.5 at 15-20% risk, $p < 0.001$). Similar association was observed in men (90.416.8 at 5-10% risk to 67.916.5 at 15-20% risk, $p = 0.01$).

Our results confirm that, when using FRAX® for screening high fracture risk individuals, the choice of cut-off points or thresholds will have a major impact on the apparent burden of disease. At any proposed threshold, treatment will be advocated in more women than men.

PTH Is a Predictor of Osteoporotic Fracture in older individuals: the Age, Gene/Environment Susceptibility (AGES)-Reykjavik Study. Vilundur Gudnason^{*1}, Kristin Siggeirsdottir¹, Thor Aspelund², Brynjolfur Jonsson³, Gunnar Sigurdsson⁴, Tamara Harris⁵. ¹Icelandic Heart Association Research Institute, Iceland, ²Icelandic Heart Association, Iceland, ³Malmo University Hospital, Sweden, ⁴Landspítali, Iceland, ⁵Intramural Research Program, National Institute on Aging, USA

Purpose

To investigate whether serum parathyroid hormone (PTH) improves risk calculator for major osteoporotic fractures in older persons.

Methods

In the AGES-Reykjavik Study, 1,897 participants (mean age 766) had serum PTH measured (Roche Diagnostics). The cohort was enrolled between September 2002 and February 2004 with 5 years of follow-up. Risk factors based on the FRAX® risk calculator included age, sex, weight, height, history of hip fracture in parent, smoking history, medication affecting BMD, alcohol use (g per week), and BMD of the hip. All previous and prospective fractures were identified from hospital and X-ray records. Risk of fracture was estimated using survival analysis and interactions between PTH and previous fracture history were considered. Hazard ratio for fracture per 1 SD change in PTH was estimated, the difference in area under the receiver operating curve, the Integrated Discrimination Improvement (IDI) and Net Reclassification Improvement (NRI) after adding PTH to a risk model with basic risk factors.

Results

There were 437 participants with previous fractures and 208 prospective fractures. Alcohol use was low in this population, on average less than 2 drinks per week, and had no effect on the results for risk of fracture. Interaction between PTH and previous of fracture was found to be statistically significant ($p = 0.013$). The hazard ratio of sustaining an incident fracture for 1 SD change in PTH for persons without previous fracture was 1.28 (95% CI 1.11 to 1.47). The hazard ratio for 1 SD change in PTH for persons with history of fracture (N=437) was non-significant 0.87 (95% CI 0.62 to 1.21). Use of PTH serum level did not lead to improvement in fracture risk prediction for subjects with previous fracture. For subjects without previous fracture (N=1460) the area under the curve changed from 0.705 to 0.712 ($p = 0.01$), the IDI was 0.012 ($p = 0.0007$), the relative IDI was 38%, and the NRI was 10% ($p = 0.0025$) applying cutoff thresholds of 5% and 10%.

Conclusion

Circulating PTH moderately improves risk prediction for major osteoporotic fracture in older free living individuals with no previous history of fracture compared to conventional risk factors. This suggests that PTH may have some clinical utility in short term fracture risk prediction.

The Association Between S-25-Hydroxyvitamin D and Total Femur BMD May Depend on Serum Concentrations of Retinol in Men. The Hordaland Health Study and The Oslo Health Study. Norwegian Epidemiologic Osteoporosis Studies (NOREPOS). Kristin Holvik^{*1}, Haakon E. Meyer², Glara G. Gjesdal³, Rune Blomhoff⁴, Grethe S. Tell¹. ¹Department of Public Health & Primary Health Care, University of Bergen, Norway, ²Department of Community Medicine, Institute of Health & Society, University of Oslo, & Division of Epidemiology, Norwegian Institute of Public Health, Norway, ³Department of Rheumatology, Haukeland University Hospital, & Institute of Medicine, University of Bergen, Norway, ⁴Department of Nutrition, Institute of Basic Medical Sciences, Medical Faculty, University of Oslo, Norway

A positive association between serum 25-hydroxyvitamin D (s-25(OH)D) levels and BMD is commonly seen in observational studies. It has been suggested that a positive effect of vitamin D on BMD may be counteracted by high concentrations of retinol.

In a sample of elderly men and women born 1924-27 who participated in two population-based osteoporosis health studies in Bergen (59N) and Oslo (60N), and who were randomly selected to the subcohort of a case-cohort study, 170 participants (72 men and 98 women) had BMD measurements performed by DXA in 1998-2001 (age at examination 71-77 years). DXA measurements of total femur were performed on two different densitometers (Lunar Expert and Lunar DPX-L) that were cross-calibrated for this purpose. Serum analyses of 25-hydroxyvitamin D and retinol were performed by respectively HPLC-APCI-MS and HPLC-UV, simultaneously in the same laboratory. Linear regression analyses were stratified by gender. Age, body mass index, and season of blood sampling were included as covariates.

Mean (SD) total femur BMD was 0.94 (0.15) g/cm² in men and 0.81 (0.11) g/cm² in women ($p < 0.001$). Mean (SD) s-25(OH)D and s-retinol was 58.1 (23.1) nmol/l and 2.49 (0.73) µmol/l, respectively, and not significantly different in women than men.

The association between s-25(OH)D and BMD was not significant. The interaction term between s-retinol and s-25(OH)D on BMD was statistically significant for men ($p = 0.016$) but not women ($p = 0.23$). In men, the coefficient for ΔBMD per 20 nmol/l increase in s-25(OH)D was reduced by 0.036 g/cm² (corresponding to 1/4 SD) for each µmol/l higher s-retinol.

The notion that a positive association between vitamin D status and BMD may be dependent on serum retinol levels was supported by these preliminary data in men, but not women.

The Effect of Clinical Risk Factors (CRF) on Fracture Risk Decreases with Age. Diantha Howard, Edward Leib, Lynda Tilluckdharry*. University of Vermont, USA

Introduction: BMD combined with clinical risk factors (CRFs) such as in FRAX provide a better prediction of fracture risk. It is not clear however if the impact of CRFs on fracture risk varies with age.

Methods: We performed a retrospective analysis of a database of 15,033 PM women combining CRFs and BMD results utilizing a GELunar densitometer. Logistic regressions were performed at 10 year intervals, age 45-75, and individual CRFs and the odds ratio of risk of fracture were calculated.

Results: Of the total population studied, fractures occurred in 14.7%. CRFs including, smoking, current steroid use, steroid use for more than three months, rheumatoid arthritis (RA) and secondary causes of osteoporosis correlated with an increased risk of fracture. We did not find any correlation between fracture risk and parental history of a hip fracture; we did not survey for alcohol use and as fractures were historical, impact of previous fractures could not be ascertained. For every 5 year increase in age, there was a significant increase in fracture risk which was more apparent in women who did not have a clinical risk factor than for those that had the risk demonstrating that the presence of a clinical risk factor decreased the odds ratio of the impact of 5 year increments of age. However glucocorticoid use was sufficiently powerful to negate any significant effect of age. We looked at the risk of aging on the impact of a clinical risk factor at age 45, 55, 65, and 75. For the CRFs of smoking, RA, secondary osteoporosis and number of CRFs, the effect of the clinical risk factor declined with increasing age and by age 75 had no impact on risk of fracturing for any of the clinical risks.

Conclusion: Our findings from this large database of PM women demonstrate that the presence of clinical risk factors has a greater impact in younger individuals but in the elderly that effect disappears. The effect of age on fracture risk appears to be entirely negated in women on glucocorticoids. In elderly patients with CRFs, the calculated fracture risk would be increased by the presence of such factors and the impact in younger individuals may be greater than would be indicated in models such as FRAX.

The Relationship of Bone Marrow Fat with Bone Geometry and Strength Differs By Diabetic Status. Yahtyng Sheu¹, Francesca Amati², Ann Schwartz³, Xiaojuan Li³, Christine Lee⁴, Christopher Gordon⁵, Bret Goodpaster⁶, Robert Boudreau⁶, Joseph Zmuda¹, Eric Orwoll⁷, Jane Cauley¹. ¹University of Pittsburgh Graduate School of Public Health, USA, ²University of Lausanne, Switzerland, ³University of California, San Francisco, USA, ⁴OHSU, USA, ⁵McMaster University, Canada, ⁶University of Pittsburgh, USA, ⁷Oregon Health & Science University, USA

Mechanism underlying the observation of high bone mineral density (BMD) and high fracture rate among diabetic (DM) individuals is not fully understood. Identifying new pathways for this paradoxical relationship is important. Osteoblasts and adipocytes share a common precursor cell, where its differentiation process favors adipocytes with aging. Recent studies have reported a negative association of bone marrow fat (BMF) with osteoporosis and BMD; however, its relationship with bone strength and geometry, especially among DM individuals, is unknown. Therefore, we hypothesized that higher BMF is associated with lower bone strength and geometry in 156 men aged 74-96 years old from the Osteoporotic Fracture in Men study. Spine BMF was measured using magnetic resonance spectroscopy. Peripheral quantitative computed tomography was used to obtain cortical strength and geometry measures at the radius and tibia, including cross-sectional area (CSA), thickness (THK), polar moment of inertia (PMI), cross-sectional moment of inertia (CSMI), section modulus (SM) and stress-strain index (SSI). BMF was expressed as lipid to "lipid+water" ratio (%). Pearson correlation and multivariable linear regression were used to test our hypothesis. All analyses were adjusted for age, weight and height. We found that men with DM had a significantly higher BMF than those without DM (59% vs. 55%; $p=0.04$). For the radius, modest and negative correlations were found between BMF and most, not all, of the strength indices in both DM and non-DM men (Table). However, all strength indices at the tibia were significantly correlated with BMF in the DM group only. For example, the correlation coefficient between BMF and CSMI at the tibia 33% site was -0.48 ($p<0.01$) in the DM group, compared to -0.04 ($p=0.69$) in the non-DM group. Additionally, in the DM group, one standard deviation increase in BMF was associated with a 12% reduction for CSMI at the same site. The relationship between BMF and bone strength at the radius was similar between men with and without DM. However, at the tibia, this association differed between groups. More studies are needed to further investigate the impact of bone marrow adiposity on bone strength and quality in diabetes.

Longitudinal Population-based Study Assessing Abdominal Aortic Calcification and Volumetric BMD in Postmenopausal Women. Louise Stuart¹, Elizabeth Atkinson¹, Jon Camp¹, Shreyasee Amin¹, Sundeeep Khosla², Ann Kearns¹. ¹Mayo Clinic, USA, ²College of Medicine, Mayo Clinic, USA

An association between atherosclerosis and osteoporosis has long been documented. However, few studies have longitudinally examined the progression of these disorders. To better define the relationship between these disorders, we have measured abdominal aortic calcifications (AAC) in postmenopausal women and compared the rate of AAC change to the rate of change in volumetric bone mineral density (vBMD) of the lumbar spine.

From an age-stratified random sample of community adults who had QCT scans of the lumbar spine, (which included views of the abdominal aorta), at baseline, 3 yrs, and 6 yrs, we studied 50 postmenopausal women (mean age [SD]: 66 yrs [11]) who had QCT scans at all three time points. We performed an assessment of AAC from QCT scans using Analyze (version 10) software. All three scans from each individual were registered to each other so that the same area of aorta was assessed over time. Quantification of AAC was performed using the Agatston scoring system. Lumbar spine vBMD was measured from QCT scans and rates of change calculated. The relationship between rates of change were assessed using Spearman correlations.

The median Agatston score standardized by slice increased over time from 3.8 at baseline to 15.2 at 6 yrs. The change was significantly correlated with baseline age ($r=0.42$, $p=0.003$), increasing more in older women. Lumbar spine vBMD decreased over time and also was significantly correlated with baseline age ($r=0.48$, $p<0.001$), declining more in younger women. The change in Agatston score did not correlate with the change in vBMD ($r=0.10$, $p=0.50$). Correlation adjusted for baseline age was $r=-0.13$ ($p=0.37$).

In postmenopausal women, AAC increases and vBMD of the lumbar spine decreases over time. The rates of change of both AAC and vBMD depend on baseline age. In light of previous cross-sectional data demonstrating age-independent associations between vascular calcification and bone mass, additional longitudinal studies in larger cohorts are needed to further evaluate possible relationships in the rates of change in these parameters.

The Serum Uric Acid Is Not Associated with Osteoporosis in Postmenopausal Women. Hee-Jeong Choi¹, Byung-Yeon Yu², Han Jin Oh³, ILWOO JOO⁴. ¹Department of Family Medicine, Eulji University School of Medicine, South Korea, ²Department of Family Medicine, Konyang University School of Medicine, South Korea, ³Kwandong University, College of Medicine, South Korea, ⁴Cheil General Hospital, Kwandong University, South Korea

Background: A recent study demonstrated that higher serum uric acid levels are associated with higher bone mineral density (BMD) at all skeletal sites and with a lower prevalence of vertebral and non-vertebral fractures in older men. Serum uric acid is a kind of endogenous antioxidants. Also the oxidative stress has been linked to osteoporosis. The objective of this study was to determine the relationships between the serum uric acid levels and the osteoporosis in postmenopausal women.

Methods: Subjects were healthy postmenopausal women who had visited the Health Promotion Center. Medical history and lifestyle data were collected by the questionnaire and history taking. Laboratory tests include renal function indices, serum C-telopeptide, osteocalcin, 25(OH)D, and uric acid levels. The lumbar spinal BMD (L1-4) was measured by dual-energy X-ray absorptiometry. Logistic regression analysis was used to determine the high level of uric acid affecting the lumbar spinal BMD.

Results: A total of 937 postmenopausal women were selected for this study. Mean age was 56.45.9 years old. The lumbar spinal BMD were significantly different according to tertiles of uric acid levels ($P=0.013$, P for trend=0.005): Lowest tertile (1.0090.178 mg/cm²), middle tertile (1.0160.164 g/cm²), highest tertile (1.0460.152 g/cm²). The proportion of osteoporosis (L1-4 T-score ≤ -2.5) was 25.7% in the lowest tertile of uric acid group. Otherwise, in the middle and highest tertile of uric acid group, the proportion of osteoporosis was 23.3% and 19.4%, respectively. Women with the highest tertile of uric acid were not significantly decreased the risk of osteoporosis (OR=0.78, 95% CI, 0.51-1.20) compared to those with the lowest tertile of uric acid after adjusting for age, body mass index, estimated glomerular filtration rate, alcohol drinking, current smoking, and exercise.

Conclusion: In healthy postmenopausal women with the highest tertile of uric acid levels, the lumbar spinal BMD is significantly higher than those with the lowest tertile of uric acid levels. However, the risk of osteoporosis is not significantly decreased in these women compared to those with the lowest tertile of uric acid levels.

Circulating Sclerostin Correlates to Bone Mineral Mass, Micro-Structure and Turnover in Healthy Elderly Men and Women. Claire Durosier^{*1}, Antoon Van Lierop², Serge Ferrari³, Thierry Chevalley⁴, Socrates Papapoulos², Rene Rizzoli⁵. ¹Hopitaux Universitaires De Geneve, Switzerland, ²Leiden University Medical Center, The Netherlands, ³Geneva University Hospital & Faculty of Medicine, Switzerland, ⁴University Hospitals of Geneva Division of Bone Diseases, Switzerland, ⁵University Hospital, Switzerland

Sclerostin is an osteocyte product which decreases bone formation and appears to be involved in the bone response to mechanical loading. However, the role and significance of circulating sclerostin (circ-SCL) is still poorly understood. We investigated circ-SCL using 2 immunological assays recognizing different epitopes in 190 healthy subjects (100 women and 90 men) aged 651 (xSD) years. Such a well homogenous group in terms of age allowed us to minimize the influence of age in the analysis. The relation between circ-SCL and whole body, spine and proximal femur bone mineral content/areal density (DXA), micro-structure (HR-pQCT, Scanco XtremCT) at weight-bearing and non weight-bearing sites, and turnover markers was assessed. Circ-SCL was positively correlated to whole body bone mineral content (WB-BMC) ($r=0.223-0.334$, $p=0.0001-0.002$) in men and in women, in both assays. A positive correlation of circ-SCL was also found with distal radius and tibia cortical area ($r=0.206-0.319$, $p=0.005-0.001$), cortical thickness ($r=0.148-0.285$, $p=0.0445-0.001$), relative cancellous bone volume (BV/TV) ($r=0.187-0.447$, $p=0.011-0.0001$), and trabecular number ($r=0.220-0.379$, $p=0.003-0.0001$). Circ-SCL was positively correlated to lumbar spine areal BMD ($r=0.370$, $p=0.0001$) in men and in women ($r=0.316$ and 0.389 , respectively, $p<0.002$). The relation between circ-SCL and cortical thickness lost significance after adjustment for WB-BMC, at the distal radius in both assays, but not at distal tibia in one assay, suggesting that mass rather than structure may primarily account for the association. The bone turnover markers PINP and CTX were negatively correlated to circ-SCL, even after adjustment for WB-BMC, in one assay. These results indicate that circ-SCL positively correlates to bone mass, as assessed by mineral content and/or micro-structure measurements. They thus suggest that circ-SCL may primarily reflect osteocyte cell number. Furthermore, the relation of turnover markers with circ-SCL, as determined in one of 2 assays, even after adjustment for bone mineral mass, suggests that circ-SCL may also be associated with bone remodeling. However, the detection of such an association seems to rely on the epitopes recognized by the immunological assays.

SA0395

Long-term Treatment with Raloxifene, but not Bisphosphonates, Reduces Circulating Sclerostin Levels in Postmenopausal Women. Hong-Hee Kim¹, Yun Ey Chung², Sun-Kyeong Lee³, Sun-Young Lee⁴, Seung Hun Lee^{*5}, Ghi Su Kim⁵, Shin-Yoon Kim⁶, Farval S. Mirza³, Jung-Min Koh⁷, Joseph A. Lorenzo³. ¹Seoul National University, South Korea, ²Department of Internal Medicine, Seoul Veterans Hospital, South Korea, ³Division of Endocrinology, University of Connecticut Health Center, USA, ⁴Asan Institute for Life Sciences, South Korea, ⁵Asan Medical Center, University of Ulsan College of Medicine, South Korea, ⁶Kyungpook National University Hospital, South Korea, ⁷Asan Medical Center, South Korea

Purpose: Circulating sclerostin concentrations are higher in postmenopausal than in premenopausal women, and estrogen treatment suppresses sclerostin levels in both men and women. We determined whether anti-resorptives may suppress the circulating sclerostin levels.

Methods: We conducted a retrospective observational study. Eighty postmenopausal women were treated with raloxifene for 19.4 7.7 months ($n = 16$), bisphosphonates for 19.2 6.7 months ($n = 32$), or were untreated ($n = 32$) for 17.1 4.6 months. Plasma sclerostin concentrations were measured before and after treatment.

Results: Plasma sclerostin levels after treatment were significantly lower in the raloxifene than in the control group (55.8 23.4 pmol/l vs. 92.1 50.4 pmol/l, $p = 0.046$), but were similar between the bisphosphonate and control groups. Relative to baseline,

raloxifene treatment markedly reduced plasma sclerostin concentration (-40.7 22.8%, $p < 0.001$), with respect to both control (-7.5 29.1%) and bisphosphonate (-3.1 35.2%) groups. Changes in bone-specific alkaline phosphatase and osteocalcin levels showed reverse associations with sclerostin concentration changes in the raloxifene ($\gamma = -0.505$, $p = 0.017$) and control ($\gamma = -0.410$, $p = 0.020$) groups.

Conclusions: Raloxifene, but not bisphosphonates, significantly suppressed circulating sclerostin concentration, suggesting that sclerostin may mediate the action of estrogen on bone metabolism, independently of their anti-resorptive effects.

Histomorphometric Evaluation of Transiliac Bone Biopsies after Bariatric Surgery. Noortje Rabelink^{*1}, Nathalie Bravenboer¹, Dave Schweitzer², Coen Netelenbos³, Paul Lips¹. ¹VU University Medical Center, The Netherlands, ²Reinier de Graaf Gasthuis, Netherlands, ³VU Medical Center, The Netherlands

Purpose:

Patients who have undergone bariatric surgery (BS) are at increased risk for bone loss. This process of bone loss is not completely understood. We used bone histomorphometry to investigate changes at tissue level in these patients.

Methods:

In 8 patients (7 women) with an average age of 44 years (range 32-62) a transiliac bone biopsy was obtained while they were under general anaesthesia for plastic surgery. Patients were labeled with tetracycline prior to biopsy. Bone biopsies were embedded in methylmethacrylate without prior decalcification. Sections were stained with Goldner and tartrate-resitant acid phosphatase. Histomorphometry was performed with NIS-Elements AR 3.1 (Nikon GmbH, Dusseldorf, Germany) at 40 and 100 \times magnification. Dynamic parameters were measured only in 5 patients due to lack of double labelling in the other patients.

Results:

In patients after BS we found the following results; (Median [Interquartile range])

Bone volume 15.5% [9.2-19.8]
Bone surface 2.2 mm²/mm³ [1.8-3.1]
Osteoid thickness 10.9 μ m [9.0-14.8]
Osteoid volume 1.2% [0.8-1.6]
Osteoid surface 14.3% [8.4-24.0]
Trabecular thickness 127.4 μ m [116-166]
Trabecular number 1.0 mm [0.73-1.19]
Cortical thickness 1457 μ m [874-1757]
Cortical porosity 8.6 % [4.0-12.2]
Osteoclast number 0.3/mm² [0.2-1.0]
Mineral apposition rate 0.62 μ m/day [0.60-0.69]
Mineralisation surface 5.1% [3.3-7.1]
Bone formation rate (BFR) 0.033 μ m³/ μ m²/day [0.027-0.055]

Conclusion:

In our patients after BS, bone volume and trabecular number were low. This probably results from a low bone formation rate, while bone resorption continues.

Disclosures: Noortje Rabelink, None.

Erythrocyte Fatty Acid Composition of Postmenopausal Women with and without Osteoporosis: Case-Control Study in Korea. Hyoun-Jung Moon¹, Yongsoon Park¹, Hae-Hyeog Lee², Kyo Il Suh³, Jin-Yong Yoo³, Hyeongkyu Park³, Tae-Hee Kim², Dongwon Byun^{*4}, Myung Hi Yoo³. ¹Hanyang University, South Korea, ²Soon Chun Hyang University Bucheon Hospital, South Korea, ³Soon Chun Hyang University Hospital, South Korea, ⁴Soon Chun Hyang University Hospital, South Korea

The purpose of the present study was to compare erythrocyte fatty acid composition between postmenopausal women with and without osteoporosis in Korea. Fifty cases and fifty control were participated in this study and osteoporosis was defined according to International Society for Clinical Densitometry guideline as <-2.5 standard deviation below the T-score for lumbar spine 1-4, femoral neck, or femoral total. The fatty acid composition of erythrocyte was analyzed by gas chromatography. Age, height, weight, and T-scores for lumbar spine 1-4, femoral neck and femoral total were significantly greater in controls than in osteoporosis cases, who also were significantly less likely to use calcium supplementation. However, age at menopause, exercise, smoking, drinking, and case of menopause did not differ significantly between cases and controls. In erythrocytes, plant source of omega-3 fatty acid, alpha-linolenic acid was significantly lower in case than control ($0.44 \pm 0.05\%$ vs $0.61 \pm 0.07\%$), while animal source of omega-3 fatty acid, docosapentaenoic acid was significantly higher in case than control ($2.53 \pm 0.07\%$ vs $2.26 \pm 0.09\%$). Other fatty acids, saturated fatty acids, monounsaturated fatty acids, polyunsaturated fatty acids,

trans fatty acid, and omega-3/omega-6 fatty acid ratio were not significantly different between case and control. Our results suggest that plant source of omega-3 fatty acids may decrease the risk for osteoporosis, but animal source of omega-3 fatty acids may increase the risk in the Korean menopausal women.

Implications of Compromised Zinc Status on Bone Loss Associated with Low Grade Chronic Inflammation in C57BL/6 Mice. Elizabeth Rendina*, Yan Wang, Kelsey Hembree, MCKALE DAVIS, Barbara Stoecker, Stephen Clarke, Edralin Lucas, Brenda Smith, Oklahoma State University, USA

The trace element zinc is well-known for a broad range of physiological functions, including regulation of anabolic and catabolic activity of bone cells and various aspects of immunity. Compromised zinc status is common in older adults and has been associated with low bone mineral density (BMD) and increased risk of osteoporosis. Alterations in immune function in response to suboptimal zinc status parallel some of the immunological changes associated with aging. To begin to understand the relationship between zinc-induced immune changes and bone loss in a model of low grade chronic inflammation, 8 week old C57BL/6 male mice (n=32) were used in a 2 x 2 factorial design with dietary zinc (adequate = 35 ppm or inadequate = 5 ppm) and inflammation (0 or 0.1 mg LPS/kg bw). Diets were fed for 6 weeks prior to the 4 wk exposure to LPS by subcutaneously implanted slow release pellets. At the end of the study, complete blood counts were performed, tissue weights were recorded and bone specimens were collected. No differences in body weight due to treatments were observed during the course of the 10 week study. Thymus weight was increased in the cohort on the zinc adequate diet plus LPS, but the LPS-induced thymus hypertrophy was not observed in the zinc inadequate group. Spleen weight was unaltered by dietary and LPS treatments. Differential counts on whole blood smears revealed an increase in monocytes and a decrease in lymphocytes due to LPS in the zinc adequate cohort indicative of a chronic inflammatory response; however, these LPS-induced changes were ameliorated in the zinc deficient mice. Bone zinc content assessed using inductively coupled plasma (ICP) mass spectrometry was reduced ($p<0.05$) in the cohort receiving the 5 ppm zinc diet. This decrease in bone zinc was further exacerbated (11.1%) in the LPS treated mice on the zinc inadequate diet. BMD and microstructural analysis showed that LPS reduced ($p<0.05$) BMD and trabecular bone volume of the spine compared to the placebo in both diet groups, but the effect was not exacerbated by zinc status at the end of the 10 week study. Trabecular separation increased and trabecular thickness decreased in the LPS-treated cohorts irrespective of zinc status. No differences in cortical bone were observed between groups. Ongoing studies will evaluate the effects of zinc status and LPS on bone marrow lymphoid and myeloid populations, and future studies are needed to address the effects of age on this response.

Rosiglitazone Decreased Muscle Cross-sectional Area and Increased %Fat While Maintaining Glycemic Control in Women with Type 2 Diabetes (T2D). Timothy Streeper^{*1}, Isra Saeed¹, Thomas Lang¹, John Kornak¹, Chengshi Jin¹, Allison R. Northcutt², Barbara Kravitz², Gitanjali Paul², Alexander R. Cobitz², Lorraine Fitzpatrick², Antonio J. Nino², ¹UC San Francisco, USA, ²GlaxoSmithKline Pharmaceuticals, USA

Rosiglitazone (RSG) stimulates stem cells to differentiate into fat cells and improves resistance to glucose, resulting in changes in muscle metabolism and body fat content. This study evaluated the effect on muscle mass and adiposity. This double blind study randomized postmenopausal women with T2D to RSG or metformin (MET) for 1 year followed by 6-month open-label MET. Markers of glycemic control and serum hormones were determined in all subjects; hip muscle lean cross-sectional area (CSA), percentage intermuscular fat in the muscle bed (%FAT), mean Hounsfield Unit of muscle tissue (LHU, a measure of intramuscular fat) and pelvic total lean body area (LBA) were assessed using hip QCT scans in a subset of subjects. In RSG, a 4.9% decrease (185.05 vs. 176.06 cm²) in CSA, and a 13.3% increase (0.15 vs. 0.17 %) in %FAT, were observed at 1y ($p<0.001$). LHU did not change. After discontinuation of RSG, CSA and %FAT showed partial recovery but still differed from baseline ($p=0.0009$ and $p=0.03$ respectively). In MET, 7.9% loss (43.09 vs. 39.68 HU) of LHU at 18 months ($p<0.01$) and a decrease of 2.6% LBA (212.06 vs. 206.46 cm²) ($p=0.03$) at 18 months were observed. Decreases from baseline (BL) to Week 52 in HbA1c were similar between treatment groups, fasting plasma glucose decreased from BL more in RSG compared to MET over time. HOMA-S increased from BL in RSG over time and decreased in MET. Serum estradiol decreased from BL to Wk52 and increased from Wk52 to Wk 76 in both treatment groups. Total testosterone increased from BL to Wk52 and decreased from Wk52 to Wk76 in both treatment groups but the change was greater in RSG. In this study, one year RSG treatment results in loss of lean hip muscle tissue and an increase of intermuscular fat, with no change in intramuscular fat. Changes trended to BL levels after discontinuation of RSG. RSG improved glycemic control and insulin sensitivity. These data highlight the relationship between metabolic and structural effects of RSG. These data support the hypothesis that RSG

promotes differentiation of stem cells to adipocytes in this population.

β -Cryptoxanthin, A Citrus Xanthophyll Carotenoid Prevents Inflammatory Bone Loss of Alveolar Bone in the Model for Periodontal Disease. Michiko Hirata*, Chiho Matsumoto, Tsukasa Tominari, Masaki Inada, Chisato Miyaura, Tokyo University of Agriculture & Technology, Japan

Periodontal disease is accompanied by inflammatory destruction of alveolar bone. Lipopolysaccharide (LPS) induces prostaglandin E2 (PGE2) synthesis and RANKL expression in osteoblasts, and leads osteoclastic bone resorption. Xanthophyll carotenoids were thought to be anti-inflammatory substance through anti-oxidization in tissues that is against various inflammatory diseases. β -Cryptoxanthin is a member of xanthophyll carotenoids included specifically in citrus fruits such as mandarin orange in Japan. Epidemiological studies have shown that the food intake of β -cryptoxanthin from citrus oranges is closely related to the level of serum β -cryptoxanthin and the markers for bone resorption in serum. In addition, bone loss was protected by the intake of citrus β -cryptoxanthin in Japanese women, and the effects were depending on serum levels of β -cryptoxanthin. In the previous study, bone loss in ovariectomized animal was partially recovered by the treatment with β -cryptoxanthin, however, effects of β -cryptoxanthin in inflammatory bone resorption is still unknown. In the present study, we investigated the effects of β -cryptoxanthin in the disease model of periodontitis. In the model, LPS from gram-negative bacteria induces inflammatory bone resorption of alveolar bone. We examined the effects of β -cryptoxanthin on PGE2 production by gingival fibroblasts, and bone resorption of mouse mandibular alveolar bone. In co-culture of mouse osteoblasts and bone marrow cells, β -cryptoxanthin suppressed the number of osteoclasts formed by inflammatory cytokines. The PGE2 production by gingival fibroblasts was markedly elevated by the treatment with LPS, and the PGE2 production was suppressed by adding β -cryptoxanthin. In organ cultures of mouse mandibular alveolar bone, β -cryptoxanthin clearly suppressed the LPS-induced bone resorption. In vivo model for periodontitis, we measured BMD of alveolar bone by DEXA and examined three-dimensional (3D) structure of mandible by micro-CT. LPS clearly decreased the BMD of alveolar bone, and the administration of β -cryptoxanthin recovered the bone loss and 3D structure of alveolar bone. Here we show that citrus β -cryptoxanthin is a possible candidate of natural components, which prevents alveolar bone loss associated with inflammation in periodontal disease.

Fractures Are Associated with Cortical Porosity at the Tibia: A Case-Control Study of Micro-Architectural Bone Parameters in Men with Idiopathic Osteoporosis. Agnes Ostertag¹, Martine Cohen-Solal², Sylvie Fernandez³, Eric Vicaut⁴, Marie-Christine De Vernejoul^{*5}, ¹U606 INSERM, France, ²Centre Viggo Petersen, France, ³Hopital Lariboisiere, France, ⁴Unite de Recherche Clinique Lariboisiere-St Louis Hospital Fernand Widal, France, ⁵Federation De Rhumatologie Et INSERM U606, France

Purpose: Idiopathic osteoporosis (OP) in men is a rare disorder that can induce fractures. The diagnosis is reached after exclusion of secondary OP in men aged 40 to 70 year-old with low bone mineral density (BMD) (Z-score < -2). Our objective was to determine biochemical, radiological and micro-architectural bone factors related to fragility fractures in these patients through a case-control study.

Methods: 40 to 70 yrs old men with a Z-score < -2 at one site (hip, lumbar or radius) were included. Men with secondary OP, treatment or any chronic inflammatory diseases were excluded. Cases were men with at least one fragility fracture (22 vertebrae, 5 hip, 8 rib, 3 wrist, 2 humerus) that occurred after the age of 40 (F+, n=32). Controls were men with OP without fracture (F-, n=36).

Data of previous fractures were collected using an interviewer-administered questionnaire, vertebral fractures were assessed on spine X-rays. Volumetric (v)BMD and bone micro-architectural indices at distal radius and tibia sites were measured with a HR-pQCT scan (X-treme, Scanco). Dual-energy X-ray absorptiometry measures were done at spine, hip and radius (Lunar). Urine and blood samples were collected in order to determine levels of bone-turnover markers, SHBG, bioavailable estradiol and testosterone, IGF-1 and homocysteine.

Student t-tests for independent groups were used to compare F+ and F-. Multiple linear regression models included age, height and weight as adjustment factors were conducted to compare the groups.

Results: F+ were significantly older than F- (58.8 vs. 53.9 yrs, $p=0.02$), but comparable in weight and height. BMD Z-score was identical at any site except at the total-hip where Z-score was significantly lower in F+ (-1.3 vs. -0.9, $p=0.02$). After adjustment on age, height and weight, micro-architectural parameters were not different at the radius. At distal tibia, cortical vBMD was significantly lower in F+ patients (801.74 vs. 857.61 mg HA/cm³, $p=0.02$) while cortical thickness was unchanged, suggesting that the decreased vBMD was related to increased porosity. Trabecular parameters, biochemical or hormonal parameters were not different in the 2 groups.

Conclusion: Our results confirm the role of cortical bone that differs according to the occurrence of fractures in men with idiopathic osteoporosis. This suggests that, in these particular patients, cortical porosity is associated with fractures in line with our previous histomorphometric data.

A Comparative Randomized Trial of Levetiracetam and Older Antiepileptic Drugs: Bone Health and Related Outcomes. Tahir Hakami¹, Terence O'Brien¹, Sandra Petty², Jemma Christie¹, Susan Kantor¹, Marian Todaro³, John Wark³. ¹University of Melbourne, Australia, ²The University of Melbourne, Australia, ³Royal Melbourne Hospital, Australia

Antiepileptic drug (AED) therapy is associated with increased fracture risk but it is uncertain whether newer AEDs carry a similar risk to older AEDs. We compared bone mineral measures, body composition and hormones in patients who had substitution monotherapy with either levetiracetam (LEV) or an "older" generation drug, carbamazepine (CBZ) or sodium valproate (VPA). Patients with partial epilepsy on monotherapy with an older AED who had lack of efficacy or adverse effects were invited into a randomised open-label study with blinded endpoints. Those taking phenytoin (PHT) or CBZ were randomised to either LEV or VPA; those taking VPA were randomised to LEV or CBZ. Visits at 3 and 15 months included: areal bone mineral density (aBMD) at the lumbar spine, total hip, femoral neck, forearm and total body bone mineral content, soft tissue composition (Hologic 4500A, software version 5.73) including abdominal fat; peripheral quantitative computed tomography (pQCT: Stratec XCT 3000) of the radius and tibia, polar strength strain index (SSI_p); serum biochemistry and hormones; validated health and lifestyle surveys; blood pressure and anthropometry. Univariate and multiple regression analyses (SAS and SPSS) examined associations between change in bone measures and treatment group, age, sex, baseline height and weight, and follow-up interval. 84 patients [51 male (median age 40.1y, IQR 27.6-61.4), 33 female (36.8y, 23.8-51.8)] were enrolled. In most, AED substitution was within 3 months prior to baseline bone measures. 70 patients were reviewed at 12 months (40 LEV, 30 older AED group). Baseline anthropometry, bone mineral measures, fat distribution, serum biochemistry and hormones did not differ between treatment groups. At 12 months, there were increases in the older AED group in weight ($p=0.039$), BMI ($p=0.035$), % abdominal fat ($p=0.013$) and leptin ($p=0.032$) and a decrease in cortisol ($p=0.043$) with no difference in the LEV group, or between groups. There was no bone loss at any site by DXA or pQCT in either treatment group or between treatment groups. Substitution with older AED, but not with LEV, in patients previously treated for epilepsy caused significant increases in body weight and abdominal fat. There was no rapid bone change, nor any difference in the early bone response between groups when treated with LEV compared with CBZ or VPA. While this study provides reassurance, long-term follow-up may better characterize any AED effects on bone health.

Aromatase Inhibitor Significantly Increased Circulating Sclerostin Level in Patients with Endocrine-responsive Breast Cancer. Yumie Rhee^{*1}, Yoon Jung Chung², Se Hwa Kim³, Sung-Kil Lim¹, Byeong Woo Park⁴.

¹Department of Internal Medicine, College of Medicine, Yonsei University, South Korea, ²Brain Korea 21 Project for Medical Science, Yonsei University, South Korea, ³Kwandong University College of Medicine, Myongji Hospital, South Korea, ⁴Department of Surgery, College of Medicine, Yonsei University, South Korea

BACKGROUND: Sclerostin, a Wnt inhibitor, product of osteocytes is known to decrease within 4 weeks of estrogen treatment in postmenopausal women. However, the level of sclerostin in endocrine-responsive breast cancer patients treated with aromatase inhibitor (AI) is still yet unknown. **OBJECTIVE:** The aim of the study was to analyze the changes in serum sclerostin levels in Korean women with endocrine-responsive breast cancer newly treated with AI assessing its relationship to estradiol, calcitropic hormones, bone turnover markers and bone mineral density (BMD). **DESIGN AND PARTICIPANTS:** We conducted a longitudinal prospective study of postmenopausal women with endocrine-responsive breast cancer ($n=45$) comparing with healthy premenopausal women ($n=36$). Patients with breast cancer were randomly assigned to either 5 mg of alendronate with 0.5 µg of calcitriol ($n=25$) or placebo ($n=20$) for 6 months to prevent bone loss associated with AI. **METHODS:** We analyzed serum sclerostin levels by ELISA (Biomedica Co., Austria) along with routine chemistry, bone markers including osteocalcin and C-telopeptide, and BMD by DXA. **RESULTS:** Premenopausal women were 27.9 years old in average, and postmenopausal women were 54.5 years old. Postmenopausal women showed significantly higher serum sclerostin levels (34.01.8 vs. 23.10.8 pmol/L, $p<0.05$). Interestingly, baseline sclerostin was positively correlated with either lumbar spine or total hip BMD ($r=0.498$, $p<0.001$ and $r=0.435$, $p<0.05$, respectively with age and Cr adjustment). There were no significant correlations between sclerostin level with bone markers but negative trend with PTH before starting AI ($r=-0.252$, $p=0.09$). Sclerostin levels after starting AI significantly increased by 31.1% in placebo group ($p<0.001$, paired t-test). It was only moderately increased in patients treated with alendronate by 16.7 % ($p=0.08$ vs placebo group). However, % changes of bone markers did not correlate with degree of sclerostin changes in either group. **CONCLUSIONS:** Our findings suggest that serum sclerostin level is indeed increased according to the level of estrogen deficiency in women either by menopause or AI use and somehow positively correlated with BMD at all sites. These findings need to be explored further in larger number of subjects.

Loss of Caspase-2 Alters Skeletal Stem Cell Properties and Results in Osteoporosis In Old C57BL/6 Mice. Ramaswamy Sharma^{*1}, Difernando Vanegas¹, Danielle Victor¹, Kathleen Woodruff¹, Marisa Lopez-Cruzan¹, Roberto Fajardo², Stephen Harris¹, Sherry Abboud Werner¹, Brian Herman¹. ¹University of Texas Health Sciences Center At San Antonio, USA, ²UT Health Science Center, San Antonio, USA

Caspase-2 is a cysteine protease involved in mitochondrial oxidative stress-induced apoptosis. Loss of caspase-2 results in premature aging, including a shortened maximum lifespan, impaired hair growth, reduced body fat content and, importantly, age-related osteoporosis. Dual energy X-ray absorptiometry (DXA) analysis of 24-26 month old *Casp2^{-/-}* mice indicated a significantly lower total body and femoral bone mineral density (BMD) as compared to wild type (WT) mice. Micro-computed tomography (µCT) analysis of *Casp2^{-/-}* femur indicated an abnormal growth plate and a lower number of secondary ossification centers that were less organized and had thinner inter-lacing trabecular bone. Reconstructed 3D-images of *Casp2^{-/-}* femur showed higher porosity, decreased bone mass and volume, wider metaphyseal compartment, significantly decreased trabecular numbers as well as decreased thickness of the bone cortex. Total indentation distance, average energy dissipated, and stiffness measurements also demonstrated decreased mechanical strength of *Casp2^{-/-}* bone. Collectively, these data demonstrate that *Casp2^{-/-}* mice become osteoporotic as they age.

Immunohistochemistry of bone sections from WT mice showed caspase-2 expression in bone marrow cells, osteoblasts, and lining cells in femur and tibia, at all ages tested. Specifically, caspase-2 is constitutively expressed in mesenchymal progenitor cells (also called skeletal stem cells) that differentiate into osteoblasts. Loss of caspase-2 in these cells resulted in decreased mineralization capacity as well as decreased sensitivity to oxidative stress-inducing agents. Interestingly, ELISA analysis of mesenchymal progenitor lysates from *Casp2^{-/-}* mice indicated a significant increase in CSF-1, which enhances differentiation of hematopoietic stem cells into osteoclasts. Taken together, we posit that loss of caspase-2 may result in altered skeletal stem cell differentiation and osteoblast function leading to decreased bone formation and increased bone resorption. Our data highlight a critical functional role for caspase-2 in male age-dependent osteoporosis. Because mortality following fracture is higher in older men as compared to women, our study suggests the use of caspase-2 as a diagnostic marker for osteoporosis as well as a putative target for treating osteoporotic disorders.

Changes in Bone Turnover Markers After Weekly Teriparatide Administration in Postmenopausal Women with Osteoporosis. Toshitsugu Sugimoto^{*1}, Toshitaka Nakamura², Hideki Yoshikawa³, Masataka Shiraki⁴. ¹Shimane University School of Medicine, Japan, ²University of Occupational & Environmental Health, Japan, ³Osaka University Graduate School of Medicine, Japan, ⁴Research Institute & Practice for Involuntal Diseases, Japan

Background and Objective: Daily administration of teriparatide is known to result in increases in markers of both bone formation and bone resorption. In our research, a single injection of teriparatide (56.5 µg) was followed by a transient decrease in bone formation markers and then an increase over baseline levels up to 72 hr later, and lasting >7 days after administration, whereas bone resorption markers showed a transient increase after administration and then decreased to below baseline from 24 hr later and beyond. This study investigated the profile of changes in bone turnover markers over 24 weeks with weekly teriparatide administration and in the 24 hr after each dose, in order to assess effects on bone metabolism of teriparatide.

Methods: Postmenopausal women with osteoporosis between 65 and 79 years old were given subcutaneous injections of teriparatide (human PTH 1-34) at 56.5 µg once a week for 24 weeks. Measurements of bone turnover markers were taken before and within 24 hr after each dose at the start of administration and after 4, 12, and 24 weeks. BMD in L2 to L4 was also measured by DXA at the start of administration and 24 weeks later.

Results: Twenty-eight postmenopausal women with osteoporosis were enrolled. Analysis of the percent changes in bone turnover markers over the course of administration (Fig. 1) revealed that serum osteocalcin was higher throughout the 24-week period compared to baseline. Urine DPD, on the other hand, was lower throughout the 24-week period compared to baseline. Analysis of percent changes in bone turnover markers up to 24 hr post-dose relative to each pre-dose level (Fig. 2) revealed a transient decrease in serum PINP after teriparatide administration, returning to baseline levels within 24 hr post-dose. Urine NTX, on the other hand, underwent a transient increase after teriparatide administration and then returned to baseline within 24 hr post-dose. These responses were the same at every observation time point. BMD increased by approximately 2.6% after 24 weeks of administration. Weekly administration of teriparatide appeared to transiently decrease bone formation and transiently increase bone resorption, followed by a sustained increase in bone formation without increased bone resorption.

Conclusion: These results suggest that, unlike daily administration, weekly teriparatide administration enhances bone formation without enhancing bone resorption.

Once Weekly Teriparatide on Hip Structure and Biomechanical Properties. Masako Ito^{*1}, Masao Fukunaga², Teruki Sone², Toshitsugu Sugimoto³, Masataka Shiraki⁴, Yoshiki Nishizawa⁵, Toshitaka Nakamura⁶. ¹Nagasaki University Hospital, Japan, ²Kawasaki Medical School, Japan, ³Shimane University School of Medicine, Japan, ⁴Research Institute & Practice for Involuntal Diseases, Japan, ⁵Osaka City University, Japan, ⁶University of Occupational & Environmental Health, Japan

[INTRODUCTION] The effects of weekly administration of teriparatide (human PTH(1-34)) on volumetric bone mineral density (vBMD), bone geometry, and parameters of bone strength at the proximal femur were longitudinally investigated using clinical CT. This investigation was done in a subgroup of the participants in the randomized double-blind multicenter placebo-controlled clinical trial of once weekly teriparatide to evaluate the efficacy to prevent incident vertebral fracture. **[METHOD]** Sixty-six ambulatory patients with osteoporosis enrolled at 15 medical centers in Japan were randomly assigned to receive either weekly subcutaneous injection of 56.5 µg teriparatide (n=29, 74.25.1 years old) or placebo (n=37, 74.85.3 years old). **[RESULTS]** 1) teriparatide increased cortical thickness/area and total vBMD in femoral neck, inter-trochanter and shaft, 2) Cortical perimeter tended to decrease in teriparatide group, while it remained unchanged or increased in placebo group, 3) teriparatide decreased cortical vBMD in inter-trochanter, but not in femoral neck or shaft, 4) teriparatide improved biomechanical properties, i.e. increasing section modulus (SM) and decreasing buckling ratio (BR), 5) according to the distribution of percentage changes in SM or BR as a function of percentage changes in cortical thickness, teriparatide improved all three parameters while maintaining the relationship between changes in cortical thickness and other parameters as in placebo group. **[CONCLUSION]** Our longitudinal analysis of hip geometry by clinical CT revealed that once weekly administration of teriparatide exerts a similar effect to daily teriparatide injections; however, once weekly treatment for 72 weeks did not decrease cortical vBMD in femoral neck. Compared with the changes in placebo group, it is suggested that weekly teriparatide reverses age-related deteriorations in bone structure and strength, i.e. increasing cortical thickness/area and total vBMD, decreasing cortical perimeter, and improving biomechanical parameters.

Safety, Tolerability, Pharmacokinetics and Pharmacodynamics of Teriparatide Administered Transdermally in Japanese Postmenopausal Women. Masako Nakano^{*1}, Efrat Kochba², John Stock³, Leijui Hu³, Kazunori Uenaka⁴, Mika Tsujimoto⁴, Yael Kenan², Corina Lohrin³. ¹Eli Lilly Japan, Japan, ²TransPharma Medical Ltd., Israel, ³Eli Lilly & Company, USA, ⁴Eli Lilly Japan K.K., Japan

A system for transdermal (TD) delivery of teriparatide (TPTD) has been developed to alleviate the discomfort of subcutaneous (SC) injections and to improve acceptance and compliance. This study was the first clinical evaluation of TD TPTD application via the ViaDerm system in Japanese. The study purpose was to evaluate the safety, tolerability, pharmacokinetics (PK), and pharmacodynamics (PD) of TD TPTD in healthy Japanese postmenopausal females, and to compare PK and PD profiles with SC. Daily doses of 30-, 50-, or 80-ug TD TPTD, applied to the upper arm either by subjects or site personnel and kept on for 12 hr, or a daily dose of 20-ug SC TPTD were given for 28 days (single dose and 27 consecutive once-daily doses) in a subject/investigator blind, placebo-controlled, parallel group, dose-escalation study. Safety evaluations were performed and blood samples were collected to measure concentrations of TPTD and markers of bone formation (PINP) and resorption (CTX). A total of 61 subjects, median age 63 years, participated. The most common drug-related adverse events were increased serum ionized calcium (similar to SC) and application site reactions (pruritus, edema, erythema, and contact dermatitis), but they were not clinically significant. Application site evaluations (Draize scores) for most subjects showed no reactions or very slight erythema or edema. The visual analog scale (0 to 100 scale) for pain scored lower for TD compared to SC, with a maximum TD mean score of 3.0 (15.5 for SC). After TD application, TPTD was rapidly absorbed and absorption was essentially complete by 6 hr, with a median tmax of 2.0 hr (0.38 hr for SC). With TD, TPTD was eliminated rapidly, with a mean t1/2 of 1.65 hr (0.72 hr for SC). There was no apparent accumulation by 27 once-daily doses of TPTD. The AUC (0-6h) and Cmax after TD application increased generally in a dose-proportional manner over the 30- to 80-ug dose range. AUC was similar for 50- and 80-ug TD and 20-ug SC, though Cmax of TPTD was lower for TD compared to SC. Serum PINP increased approximately 2-fold from baseline for 50- and 80-ug TD after single and 27 once-daily doses (comparable to SC). Serum CTX showed a trend to increase after an initial decrease. In conclusion, once-daily TD applications of TPTD at dose levels of 30 to 80 ug were well tolerated by Japanese women. The results suggest that the TD TPTD system could be an alternative to SC injections and support further development of TD TPTD in Japan.

Use of Teriparatide in Patients with Atypical Femur Fractures. Angela Cheung^{*1}, Lianne Tile², Neal Austin¹, Savannah Cardew², Heather McDonald-Blumer³, Rowena Ridout⁴, Robert Josse⁵, Judite Scher⁶, Jonathan Adachi⁷. ¹University Health Network, Canada, ²University of Toronto, Canada, ³Mount Sinai Hospital, Canada, ⁴Toronto Western Hospital, Canada, ⁵St. Michael's Hospital, University of Toronto, Canada, ⁶University Health Network, Canada, Canada, ⁷St. Joseph's Hospital, Canada

Purpose: The ASBMR task force on atypical femur fractures recently recommended the use of teriparatide for patients who have been on long term bisphosphonate therapy with atypical femur fractures. However, there is little empirical evidence that teriparatide use will help the healing of these fractures or prevent surgical intervention of incomplete fractures.

Methods: We prospectively examined 14 patients who were on long term bisphosphonate therapy and sustained atypical femur fractures. All subjects had to satisfy the major criteria as set forth by ASBMR. We measured their areal BMD at the total hip, femoral neck, lumbar spine and forearm by DXA (Hologic Discovery A, Hologic Inc.), as well as their volumetric BMD (total, cortical, trabecular) and geometric parameters by HRpQCT (Xtreme CT, Scanco Inc.) at baseline, 6, 12, 18 and 24 months. Plain radiographs were performed at regular intervals to assess fracture healing of the surgically repaired femur until healing was complete. Computed tomography scans were used to assess extent of incomplete fracture every 6 months. Outcomes, such as pain, mobility, and progression or regression of incomplete fracture as well as instability requiring surgical intervention, were noted.

Results: All 14 patients were postmenopausal women (79% Caucasians, 21% Asians) with mean age of 68.8 years, mean BMI of 25.9kg/cm² and a mean 25-hydroxyvitamin D level of 106.8nmol/L. All had normal ionized calcium and intact PTH. Average duration of bisphosphonate use was 10.5 years (range 3.0-21.0 years). Mean baseline BMD for lumbar spine, total hip and femoral neck were 0.82g/cm², 0.77g/cm², 0.62g/cm². Eleven had bilateral fractures. As of April 1, 2011, follow-up duration was 0.6 years (range: 1.4 to 22.0 months). Out of 14 patients, one discontinued therapy because of side effects, one died and 3 had to have surgical repair for their incomplete fracture despite teriparatide therapy. Patients reported variable effects with regard to pain and mobility after start of teriparatide.

Conclusions: Based on limited observational data, it is unclear whether teriparatide helps fracture healing in patients with atypical femur fractures. A randomized controlled trial examining the use of teriparatide in this population is urgently needed.

Atypical Subtrochanteric Fracture : An Easy to Find Situation in a Particular Patient with Compromised Bone Structure Treated for Osteoporosis. Carmen Barbu¹, Laura Chivu¹, Cristina Stefan², Suzana Florea³, Dariana Ionita³, Cristian Burnei¹, Dan Barbu¹, CATALINA POIANA^{*4}, Simona Fica¹. ¹Carol Davila University, Romania, ²Elias Hospital Endocrinology, Romania, ³Elias Hospital, Romania, ⁴AMGEN ROMANIA, Romania

Aim of the case report: underline the importance of the bone structure abnormalities in the etiology of the atypical subtrochanteric fracture (ATF) in a 38 yrs woman after 2 years of continuously antiresorptive treatment.

Medical history: at age of 20 yrs. had bone and joint generalized pain treated for short term with NSAIDs and prednisone 15mg daily (2 months). No clear etiology of the pain was revealed by investigations at that moment; at age of 28 yrs. was admitted in the hospital for went limp, pelvic pain. Radiographic findings: bilateral consolidated symphysis fractures, wedge-shaped vertebral body T5. L2-L4 DXA Zscore = -2.14SD. Bone scintigraphy - multiple areas of uptake in the ribs and vertebral bodies. Measurement of serum calcium and PTH ruled out the diagnosis of primary hyperparathyroidism (Ca=10 mg/dl, PTH=15pg/ml). No other endocrine disfunction was revealed by further investigations. An additional diagnosis of bilateral

spontaneous osteonecrosis of the femoral neck was made and bilateral prosthesis was recommended (postponed by the patient).

Oral bisphosphonate was started at age 29. In the next 5 years bilateral forearm fractures and 18 cm decreased in height occurred due to multiple vertebral fractures. At age 34 -histopathology showed generalized fibrous cystic osteitis.

Next 2 years treatment was stopped (pregnancy and nursing).

2009 first admitted in our department: reevaluation for endocrine diseases without abnormal results, skin biopsy - no histopathological changes of connective tissue, celiac disease test was negative, HIV test negative. Serum vitamin D, calcium, phosphate, PTH and IGF1 were normal. Bone resorption markers levels were near the upper normal limit.

2009-2010 - 5 mg intravenous zoledronic acid per year associated with strontium ranelate, and parenteral vitamin D3. During this period height and BMD measured by DXA were constant, no vertebral new fractures were revealed; the patient experienced a right forearm fracture in 2009 and a right ATF in february 2011.

Conclusion. In spite of not very typical features, all the data leads to the diagnosis of fibrous dysplasia. Intravenous 5 mg yearly zoledronic acid improved the clinical aspect and lowered significantly the fracture incidence. In our opinion, the background of the patient (progressive FD and osteonecrosis of the hips) claims a bigger impact on the ATF etiology comparing to a relative short period of continuous bisphosphonate (last 2 yrs) treatment.

Combination Therapy with Ibandronate and Calcitriol Is Effective in Patients Following Liver Transplantation (LTX): A Three Year Prospective Controlled Study. Doris Wagner^{*1}, Karl Fenal², Hans Dimai¹, Harald Dobnig³, Karin Amrein¹, Daniela Kniepeiss¹, Philipp Stiegler¹, Astrid Fahrleitner-Pammer¹. ¹Medical University of Graz, Austria, ²Roche Austria GMBH, Austria, ³Diagnostikinstitut Univ.Prof.Dr.H.Dobnig GmbH, Aut

Transplantation bone disease is a well-known complication in patients after organ transplantation. Aim of this three year study was to investigate the influence of a combination therapy of iv. ibandronate and calcitriol on bone metabolism, bone mineral density and fracture status in patients following liver transplantation (LTX).

Thirty osteoporosis patients at least one year after LTX were assigned to the treatment group (IBN), 24 patients served as a control cohort (CTR). IBN patients received quarterly 2 mg ibandronate and daily 0.25 - 1.5 µg calcitriol. Control patients received daily 1200 mg calcium and 800 IU vitamin D. Laboratory analysis and dual energy absorptiometry (DXA) of the left hip were performed at baseline and every year. All participants underwent an X-ray of the spine at baseline and at study end.

The IBN group showed favourable changes in bone metabolism, a significant increase in BMD and a lower fracture incidence than the CTR group.

At baseline, 57% in the IBN group had vertebral fractures and at study end 7% had sustained new vertebral fractures. However at study end, in the control group, 23% had radiological evidence of new vertebral fractures, even though, none had had one at study start.

These results clearly indicate that osteoporosis remains an important issue in transplantation aftercare beyond the first 12 months. Antiresorptive treatment following LTX should be considered following transplantation. Because TX patients even with normal BMD are at high fracture risk, they might benefit from antiresorptive treatment.

Effect of Ibandronate for the Treatment of Osteonecrosis of the Knee: A Randomized, Double-Blind, Placebo-Controlled Trial. Christian Meier^{*1}, Claude Kraenzlin², Niklaus Friederich³, Thorsten Wischer⁴, Leticia Grize⁵, Christoph Meier⁶, Marius Kraenzlin¹. ¹Div. of Endocrinology, Diabetes & Metabolism, University Hospital Basel, Switzerland, ²Endocrine Clinic & Laboratory, Basel, Switzerland, ³Dept. of Orthopedic Surgery, Bruderholz, Switzerland, ⁴Dept. of Radiology, Merian Iselin Hospital, Basel, Switzerland, ⁵Biostatistics & Computational Sciences Unit, Dept. of Epidemiology, Swiss Tropical & Public Health Institute; University of Basel, Switzerland, ⁶Div. of Clinical Pharmacology & Toxicology, University Hospital Basel, Switzerland

Observational studies suggest beneficial effects of bisphosphonates in spontaneous osteonecrosis (ON) of the knee. We investigated whether ibandronate would improve clinical and radiological outcome in newly diagnosed ON.

In this randomized, double-blind, placebo-controlled trial, 30 patients (mean age, 57.310.7 yrs) with ON were assigned to receive either 12 mg of ibandronate or placebo

intravenously (divided into four doses within first 2 weeks). All subjects received additional treatment with oral diclofenac (70 mg) and supplementation with calcium carbonate (500 mg) and vitamin D (400 IU) to be taken daily for 12 weeks. Patients were followed for 48 weeks. The primary outcome was the change in pain score (visual analog scale, VAS) after 12 weeks. Secondary endpoints included changes in VAS, mobility (WOMAC and IKDC questionnaires), biochemical markers of bone turnover, and radiological outcome (MRI) after 24 and 48 weeks.

At baseline, both treatment groups (IBN, n=14; placebo, n=16) were comparable in relation to age, BMI, comorbidities, pain score, bone markers, and radiological grading (bone marrow edema, ON). Mean pain score was reduced in both ibandronate (mean change, -3.4; 95%CI, -4.7 to -2.2) and placebo (-3.2; 95%CI, -4.7 to -1.18) treated subjects after 12 weeks (between group comparison, p=ns). Except for significant decrease in bone resorption markers in ibandronate treated subjects (p<0.01), mean changes in all other outcome measures were comparable between treatment groups (after 24 and 48 weeks).

We conclude that in patients with spontaneous osteonecrosis of the knee bisphosphonate treatment (i.e. IV ibandronate) has no beneficial effect.

Disclosures: Christian Meier, None.

Effects of Bisphosphonate on Bone Metabolic Markers, Bone Mineral Density and Vertebral Fractures in Young-Old or Old-Old Osteoporotic Patients. Yuji Kasukawa^{*1}, Naohisa Miyakoshi¹, Toshihito Ebina², Toshiaki Aizawa², Yoichi Shimada³. ¹Akita University Graduate School of Medicine, Japan, ²Kakunodate General Hospital, Japan, ³Akita University Graduate School of Medicine, Department of Orthopedic Surgery, Japan

Bisphosphonates improve bone mineral density (BMD) in osteoporotic patients and have preventive effects on osteoporotic fractures. Most of their effects have been demonstrated in postmenopausal osteoporotic women, but not in older osteoporotic patients, who have a high risk of fractures. The purpose of the present study was to evaluate the effects of bisphosphonates on bone metabolic markers, BMD, and incidence of vertebral fractures in young-old or old-old osteoporotic patients. Sixty-five osteoporotic women (mean age 77 years) were enrolled in this study. They were stratified into two groups: a young-old group (65–74 years old, n = 27); and an old-old group (≥75 years old, n = 38). Before and after 1-year treatment with a bisphosphonate, the following parameters were evaluated: serum markers of bone resorption (cross-linked N-telopeptide of type I collagen (NTX)) and bone formation (bone alkaline phosphatase (BAP)); and BMD, measured by dual-energy X-ray absorptiometry at the distal third of the forearm. Vertebral fractures of the thoracic and lumbar spine were detected by plain X-ray film. There were no significant differences in mean serum NTX and BAP between the two groups at baseline. The mean serum NTX and BAP were significantly decreased in the young-old group (p<.05 and p<.0001, respectively) and in the old-old group (p<.001 and p<.001, respectively) after 1-year treatment. Mean BMD (0.29 g/cm²; 59.4% young adult mean (YAM)) in the young-old group before treatment was lower than the BMD (0.25 g/cm², 52.8% YAM) in the old-old group (p=.06). BMD did not change significantly after treatment in either group. Only one new vertebral fracture occurred in the young-old group, but five occurred in the old-old group. Thus, bisphosphonates suppressed serum bone metabolic markers and maintained the BMD in both young-old and old-old groups. However, new vertebral fractures occurred more frequently in old-old patients than in young-old patients.

SA0427

Incidence of Fragility Fractures of the Femur, Including Subtrochanteric, up to 8 Years Since Initiation of Alendronate or Risedronate Treatment. Michael Pazianas^{*1}, Bo Abrahamsen², Yiting Wang³, Graham Russell¹. ¹University of Oxford, United Kingdom, ²Copenhagen University Hospital Gentofte, Denmark, ³Warner Chilcott Pharmaceuticals (former employee), USA

ABSTRACT

Few studies have acquired adequate data with prolonged follow-up on bisphosphonate users in the general population to evaluate their long-term effects on the risk of hip fractures including those in the subtrochanteric region. We explored this issue using a large USA medical claims database (Marketscan) to study the incidence of osteoporotic fractures of the femur according to therapy compliance and persistence of bisphosphonate use in the real-world setting.

Methods We compared patients with higher versus lower degrees of compliance. Radiographic adjudication of fracture site and features were not performed. Therefore the definition of atypical fractures proposed by the ASBMR was not used in this study. Hazard ratios (HR) for fracture were estimated using time-dependent Cox models. Restricted cubic splines (RCS) were used to plot fracture HRs against duration of therapy.

Results 3,655 incident cases of femoral fracture (764 subtrochanteric/shaft, 2,769 hip, 122 lower femur) were identified during 917,741 person-years of follow-up (median = 3 years) on 287,099 patients from the date when they initiated oral bisphosphonate therapy. The corresponding HRs (95% CI) for overall femoral fractures associated with each additional year of therapy were 0.93 (0.86-1.01) within

5 years, and 0.89 (0.77-1.03) beyond 5 years for risedronate and 0.86 (0.81-0.91) and 0.95 (0.84-1.07) for alendronate respectively. The corresponding estimates for subtrochanteric/shaft fractures were 1.05 (0.87-1.26) and 0.89 (0.60-1.33) for risedronate and 0.99 (0.92-1.05) and 1.05 (0.92-1.20) for alendronate respectively. The HRs (95% confidence interval) for overall femoral fractures associated with each additional year of alendronate or risedronate therapy within 5 and beyond 5 years were not significantly different.

Conclusion Our study showed evidence for a persistence of overall hip fracture protection with long-term use of alendronate or risedronate. Gaps in therapy of more than 90 days were associated with greater risk for all femur fractures (> 5 fold in all models).

Long Term Follow up of Patients on Drug Holiday from Bisphosphonates: Real World Setting. Jim Sinacore¹, Pauline Camacho², Lauren Myers^{*3}. ¹Loyola University Medical Center, USA, ²Loyola University of Chicago, USA, ³Loyola University Medical Center, Maywood, Illinois, USA

The ASBMR Task Force on Atypical Fractures recognized atypical femoral fractures to be a risk with prolonged bisphosphonate (BP) use. AACE recommends a drug holiday after 5 years of stability, but little data exists on the optimal duration. The FLEX study showed higher fracture risk at 5 years in patients who discontinued alendronate versus those who stayed on the drug. A follow up study (ASBMR 2010) showed that BMD changes did not predict who would fracture. Our aim was to describe the BMD and bone turnover marker (BTM) changes in a cohort of real world patients on BP holiday. This is a retrospective study of patients with low bone mass and osteoporosis at Loyola University Osteoporosis and Metabolic Bone Disease Center who were advised a holiday from 2005-2010. The demographic data, BP history, reports of fracture, DXA results, 25-hydroxy-vitamin D (25-OHD) and BSAP values were obtained from EMR data at the beginning of the holiday and yearly for 3 years. BSAP was chosen as the BTM due to reimbursement issues in Illinois with NTX and CTX. Comparative statistical analyses were used to compare DXA and BSAP results. Our cohort consisted of 139 patients; 123 females and 16 males, with a mean age of 6811 years and mean pretreatment length of 6.82.9 years. 70% of patients were on alendronate, 21% on risedronate and 9% on ibandronate. Baseline mean T scores were -1.81.0, and -1.31.4 in the lumbar spine BMD (LSBMD) and femoral neck (FBMD) and 25-OHD was 4516.4 ng/ml. 5 fractures occurred during the holiday. Over 3 years, there was no significant change in the mean LSBMD (1.070.25g/cm² baseline, 0.970.51g/cm² year 1, 1.030.23g/cm² year 2, 1.130.37g/cm² year 3) and femoral neck BMD (0.800.10g/cm² baseline, 0.780.09g/cm² year 1, 0.770.11g/cm² year 2, 0.850.13g/cm² year 3) There was a significant rise in BSAP starting at 6 months, (9.01.75 ug/L baseline, 10.92.78 ug/L year at 6 months). Neither the type of BP nor the duration of holiday significantly affected BMD and BTM. Vitamin D and calcium deficiency and other secondary cause of bone loss were corrected. In conclusion, this cohort of patients on BP holiday experienced stable bone density for 3 years. BSAP started to increase at 6 months but the number remained in the lower end of premenopausal range. Fractures do occur during the holiday; however, our study was not powered to assess fracture risk. Larger prospective studies are needed to adequately assess the optimal duration of holiday.

Multiple Studies with Risedronate Demonstrate Consistent Bone Turnover Regardless of Dose. Robert Recker^{*1}, Louis-Georges Ste-Marie², Pascale Chavassieux³. ¹Creighton University Osteoporosis Research Center, USA, ²Hospital Saint-LucCHUM, Canada, ³INSERM UMR1033, Universite De Lyon, France

The purpose of this analysis was to study the validity and consistency of histomorphometric data from biopsies of post-menopausal women with osteoporosis (PMO) treated with risedronate at different dose levels and dosing frequency.

In a pivotal phase III randomized, placebo-controlled clinical study, patients were treated with either 5 mg of risedronate daily or placebo for 3 years. Analysis in paired biopsies showed that risedronate reduced mineralizing surface by 58% and activation frequency by 47%, which is consistent with its anti-resorptive activity¹. Of the 70 evaluable biopsies (33 placebo; 37 risedronate), double tetracycline labels, a reflection of on-going remodeling, were seen in all biopsies. In a subsequent 2-year extension study, double labels were identified in all paired biopsies indicating continuous bone remodeling² in patients treated with 5 mg/day for up to 5 years. Subsequently, three different regimens of risedronate were developed: 35 mg once-a-week (OAW) ³, one 75 mg dose on two-consecutive-days-a-month (2CDM)⁵, and 150 mg once-a-month (OAM)⁴. Non-inferiority of these new regimens compared to the daily 5 mg dose was demonstrated, based on a prospectively defined primary endpoint (Table). The 35 mg OAW study also included a 50 mg weekly dose. In all three studies, biopsies were taken at 24 months.

Double tetracycline labels were found in 97–100% biopsies (Table). Key histomorphometric variables were comparable across these studies. These data indicate that risedronate preserved bone structure and quality with continuous remodeling in all group regardless of dose and exposure.

The presence of double labels in 99% of all biopsies does not suggest compromise of bone remodeling during treatment with these established regimens, up to 5 years with 5 mg/day dose.

Risedronate Improves Proximal Femur Bone Mineral Density and Geometry Parameters Over 3 Years in Patients with Osteoporosis or Osteopenia and Clinical Risk Factors of Fractures: A Practice-Based Observational Study. Masayuki Takakuwa^{*1}, Jun Iwamoto². ¹Takakuwa Orthopedic Nagayama Clinic, Japan, ²Keio University School of Medicine, Japan

Advanced Hip Assessment (AHA) software installed in a dual-energy X-ray absorptiometry (DXA, GE-Lunar) can be used to evaluate bone strength indices as well as bone mineral density (BMD) of the proximal femur. In particular, Femur Strength Index (FSI) is calculated using structural geometric properties, neck shaft angle, height, and body weight. The purpose of this study was to investigate the 3-year effects of risedronate treatment on AHA parameters of the proximal femur and BMD of the lumbar spine and proximal femur in patients with increased risk of fractures. In total, 174 patients (mean age: 67.8 yrs; 165 females and 9 males) with osteoporosis or osteopenia and clinical risk factors of fractures were treated with risedronate for 3 years in our outpatients clinic. AHA parameters of the proximal femur and BMD of the proximal femur and lumbar spine (L1-L4) were evaluated every 4 months over 3 years. The mean percentage changes from baseline in FSI after 4 months of risedronate treatment were 7.5% ($p < 0.001$) for the right femur and 4.3% ($p < 0.01$) for the left femur. The respective values for the right femur after 8, 12, 16, 20, 24, 28, 32, and 36 months of treatment were 5.8%, 10.0%, 12.6%, 13.6%, 15.2%, 15.7%, 13.4%, and 17.5% ($p < 0.001$) and those for the left femur were 7.7%, 8.2%, 11.5%, 10.2%, 12.9%, 16.9%, 16.7%, and 16.2% ($p < 0.001$). Cross-sectional moment of inertia (CSMI), cross-sectional area (CSA), mean neck width in the femoral neck, and BMD of the right and left proximal femur and BMD of the lumbar spine also continued to increase during 3 years of treatment. The increases in FSI and CSMI in the proximal femur at each time point were apparently greater than those in the proximal femur and lumbar spine BMD. These results suggest that risedronate treatment may more significantly improve femoral strength parameters than BMD of the proximal femur and lumbar spine over 3 years. Thus, it has been demonstrated that risedronate dose not only increase lumbar spine and proximal femur BMD, but also more significantly improves bone strength indices of the proximal femur in patient with increased risk of fractures.

ZOOM-NIS: Zoledronic acid - Osteoporosis Monitoring (a non-interventional study). Ruediger Moericke^{*1}, Christian Kasperk², Christine Kleinmond³. ¹Germany, ²University of Heidelberg, Germany, ³Novartis Pharma GmbH, Germany

Background: Annual iv infusion of zoledronic acid 5mg (ZOL) is an effective and welltolerated therapy for patients with osteoporosis; in patients with a recent low-trauma hip fracture and glucocorticoid-induced osteoporosis. Methods: The aim of the ZOOM-NIS is to evaluate the patient criteria that lead to the decision for the first-time treatment with ZOL 5mg, the characteristics of patients who are treated with ZOL 5mg, and the tolerability of the infusion in normal clinical setting. Further questions during the one-year observational period are pain reduction, change of general clinical presentation,

effects of therapy, adherence, and changes of quality of life assessed by questionnaire. Data are collected at baseline, at an optional follow up after 6 months, and at a final visit after 12 to 15 months. Results: Here we describe the results of an interim analysis of the first 1593 baseline visits with the ZOL 5 mg infusion. Population: female: 1347 (84.6), male: 212 (3.3%), not specified: 34 (2.1%). The mean age was 72.8 years (SD: 9.4; Median: 74.0; Min: 22.0; Max 96.0). In all, 818 (51.3%) of the patients had experienced at least one osteoporotic fracture (no fracture: 725, not specified: 50), and 1072 (67.3%) patients had received some treatment of osteoporosis (none: 427 [27.4%], not specified: 84 [5.3%]). The mean duration of the ZOL-infusion was 35.6 min (SD 18.0; Median 30.0 min, Min: 10, Max: 360). 91.7% of patients received adequate hydration (according to local SmPC), while 28.9% received prophylactic medical treatment of post-infusion syndrome, 63.7% with paracetamol. 84.2% of the patients received osteoporosis-related concomitant therapy: vitamin D 79.2%, calcium 73.2%, 14.6 % analgesics. Information on practicability was gathered by asking about the ease of preparation and safety of the infusion. More than 98% of the responses rated both categories as "very good" or "good". Regarding tolerability, there were no physician reports of AEs for 1460 (91.7%) of the patients. In total, 130 AEs were reported in 67 patients, of whom 14 patients experienced 44 serious AEs (30 assessed by the physician to be related 1 not related, and 13 were not specified). Summary: This non-interventional study is the first to collect information on the use of ZOL 5mg in the normal clinical setting. The interim analysis presented here describes the population and attests to the good tolerability of the infusion.

Factors Related to Permanent Discontinuation of Osteoporosis Treatment. Ryan Outman¹, Jeffrey Curtis¹, Julie Locher¹, Meredith Kilgore², Kenneth Saag¹, Cornelis Van Den Bogert^{*1}, Amy Mudano¹, Elizabeth Kitchin¹, Lang Chen³.

¹University of Alabama at Birmingham, USA, ²University of Alabama At Birmingham School of Public Health, USA, ³UAB CERTs, USA

Purpose – To identify factors associated with non-persistence with osteoporosis treatment among community-dwelling individuals with osteoporosis or a prior fracture receiving home health services agency.

Methods – Eligible patients were contacted by phone; those agreeing to participate completed a computer-assisted telephone interview. We collected demographics, medical and fracture history, fall risk, osteoporosis treatment (current and past) and osteoporosis-related attitudes and beliefs using validated instruments informed by the Health Belief Model (osteoporosis knowledge, self-efficacy, perceived benefits and barriers to treatment and perceived severity of and susceptibility to osteoporosis). The primary outcome was past use of any prescription osteoporosis medication referent to current use of any medication. Stepwise logistic regression was used to identify factors associated with past vs. current use of osteoporosis treatment.

Results – Among 558 surveyed home health patients, we identified 88 past users (34.2%) and 169 current users (65.8%). Most common reasons for stop were 'took it as long as needed' (65.4%); 50% reported 'doctor told to stop', 'didn't feel it was helping/working' and 'don't like to take medications'. The most common medications among the persistent patients were Fosamax, Actonel and Reclast. Current users were more likely to have an osteoporosis diagnosis ($p = 0.02$) and to have higher perceived treatment benefits ($p = 0.01$), while past users were more likely to have higher perceived treatment barriers ($p = 0.02$). The individual items, "Would you still take your medication if the drug is expensive" ($p = 0.10$) and "Would you still take your medication if the drug upsets the stomach or causes other side effects" ($p = 0.01$) of the Self-Efficacy Scale, were positively associated with current use. In the multivariable model, osteoporosis and fracture diagnosis, treatment benefits and barriers and the individual efficacy subscale regarding side effects were significant (Table).

Conclusion – Patients with higher perceived prescription medication benefits, self-efficacy regarding side-effects and osteoporosis diagnosis are more likely to be persistent with osteoporosis medication, while perceived treatment barriers showed negative correlation with persistence. Opportunities exist to increase use of osteoporosis medication in this vulnerable population through interventions that incorporate these identified motivations and barriers.

Feasibility and Efficacy of computer-assisted quantitative Morphometry (MorphoXpress®) of vertebral fractures in patients before, after and at 12 month follow up of kyphoplasty treatment

J. Banzer, S. Radmer, G. Moeller, HC. Schober, R. Andresen

Introduction:

Balloon kyphoplasty (BKP) for treating fresh osteoporotic vertebral fractures (VF) has been established as a method of choice over the past years. Next to pain reduction it aims at height restoration (augmentation) VF.

Computer assisted quantitative vertebral morphometry using MorphoXpress® (cqVM) offers a validated objective method to assess the percentage of vertebral height reduction.

Goal of this study is to test the feasibility of cqVM in VF treated with BKP and to assess a possible augmentation immediately after the treatment and at 12 month follow-up in order to estimate and document the sustainability.

Patients and methods:

321 patients (230 f., 91 m., 48-91 years of age, mean age 70 y.) were examined: Vertebral heights were assessed by cqVM from lateral x-rays. Bone mineral density was measured using spinal quantitative CT. Fresh VF were identified by MRI.

VF were categorised using the AO classification system. Fracture types A.1.1., A.1.2. and A.1.3. were considered for BKP treatment.

Vertebral height was again assessed and documented post-interventionally and at 12 month follow-up.

Results:

In 120 of 321 patients BKP was performed in a total of 161 vertebral bodies. 85 patients presented single VF, 30 patients had two VF, and five patients suffered from more than two VF. QCT measurement identified a low BMD in all 120 patients (mean 46 mgHA/ml, range 3-112 mgHA/ml).

CqVM showed a mean vertebral height reduction of 43 % (range 12-82%) before BKP.

Mean augmentation of vertebral height was 9 % immediately after BKP (mean height reduction: 34 %, range 8-85%). At 12 month follow-up mean height reduction was 36 % (range 8-80%).

Discussion:

Computer assisted quantitative vertebral morphometry is a feasible tool for assessing vertebral height reduction and augmentation after balloon kyphoplasty.

Using cqVM we also show that BKP leads to a significant augmentation of VF. At 12 month follow up this augmentation remains fairly stable showing no significant height loss over time.

Computer assisted vertebral morphometry using MorphoXpress® seems to be an adequate tool for documentation of treatment success after BKP and for assessment of possible subsequent VF.

Patients Reject the Concept of Fragility Fracture - A New Understanding Based on Fracture Patients' Communication of their Fracture. Joanna Sale^{*1}, Monique Gignac², Lucy Frankel¹, Gillian Hawker³, Dorcas Beaton¹, Victoria Elliot-Gibson¹, Earl Bogoch¹. ¹St. Michael's Hospital, Canada, ²University Health Network, Canada, ³Women's College Hospital, Canada

Introduction and purpose: The reasons why fracture patients often do not associate their fragility fracture with low bone mass is important to the management of bone health. We examined patients' communication about fragility fractures to gain insight into the reason why some patients fail to perceive the connection between their fracture and low bone mass.

Methods: We conducted a descriptive phenomenological (qualitative) study. English-speaking male and female patients aged 65+ years who were high risk for future fracture based on their age, fracture status, and T-score were eligible for the study and screened for osteoporosis through an established screening program at an urban teaching hospital. During face-to-face interviews, participants described the experience of their fracture in detail, what they were doing when they sustained the injury, and the circumstances surrounding the fracture. Data analysis was guided by Giorgi's methodology.

Results: Participants were 21 females and 9 males, aged 65-88, who presented with a hip (n=11), wrist (n=11), shoulder (n=6), or other (n=2) fracture. Ten of the 30 fractures occurred inside the home and the remaining fractures occurred outside the home. Based on the interviews, sustaining a fragility fracture was perceived as a traumatic event, both physically and emotionally, for many older fracture patients. In general, participants used forceful, action-oriented words and referred to hard surfaces to describe the experience. Explanations for the fracture, other than bone quality, were often reported, especially that falls were "freak" or "fluke" events. Patients who fractured under more mundane circumstances (e.g. standing from a chair) seemed more likely to perceive a connection between the fracture and their bone health.

Conclusion: The term "fragility" or "low trauma" fracture was a misnomer for many older adults. This term, combined with participant perceptions that their fall was an isolated incident, seemed to result in many older fracture patients at high risk for future fracture not connecting their fracture with bone health and taking appropriate steps to reduce fracture risk.

Persistence and Compliance with Osteoporosis Medical Treatment - Analysis of a Large Scale, Representative, Longitudinal, German Database. Volker Ziller^{*1}, Karel Kostev², Ioannis Kyvernitis³, Jelena Boeckhof³, Peyman Hadji¹. ¹Philipps-University of Marburg, Germany, ²IMS HEALTH GmbH & Co. OHG, Germany, ³Philipps-University, Germany

Background

Osteoporosis can be effectively treated with a number of medications. However high persistence and compliance is required to assure efficacy.

Objective:

This study analysis persistence and compliance with a variety of medical interventions including oral, i.v. and s.c. administrations in Germany.

Methods:

This retrospective cohort study used a representative longitudinal database (IMS® LRX) comprising longitudinal prescription data for Germany from almost 80% of all German prescriptions of members of the German statutory health insurance.

Persistence is defined as the proportion of patients who remained on their initially prescribed therapy at 1 year. Compliance is measured indirectly based on the medication possession ratio (MPR).

Results: 1.107.482 patients were identified between 06/2006-05/2009 in the database with a prescription of a bisphosphonate, strontium or PTH. 268.568 of those fulfilled further inclusion criteria and had been included in the persistence analysis and 164.985 could be analysed concerning compliance. At 12 months rates of patients that remained on treatment were for Zoledronate 5mg 65.6%; Ibandronate iv 3mg 56.6%; PTH (Teriparatide and 1-84 PTH) 54.7 %, Ibandronate 150mg p.o. 51.0 %; Alendronate 70 mg 44.8 %; Etidronate 43.4%; Risedronate plus Calcium 42.3 %; Alendronate plus Vitamin D 37.8 %; Risedronate 35mg 35.2 %; Risedronate 5mg 30.6 %; Strontium ranelate 31.4 %; Alendronate 10mg 17.3 %.

Conclusion:

Persistence and Compliance in osteoporosis treatment is insufficient. I.v. treatments and PTH showed the highest persistence and compliance rates and daily oral bisphosphonates the lowest. More effort to improve treatment compliance and persistence is needed to assure clinical efficacy.

The effect of enhanced Dual-energy Xray Absorptiometry (DXA) reports on osteoporosis care. Karen Barnard^{*1}, Cathleen Colon-Emeric². ¹Duke University Medical Center, Durham VAMC, USA, ²Duke University & Durham VAMC, USA

Purpose: To assess whether providers randomized to receive enhanced DXA reports that include an estimation of a patient's fracture risk and treatment recommendations plus an electronic order entry set for osteoporosis order more guideline-recommended osteoporosis therapy than those providers who receive usual DXA reports. **Methods:** An exploratory randomized controlled trial was conducted at the Durham VAMC from January 2010 to January 2011. Providers were randomized in a stratified fashion according to their DXA ordering frequency to either intervention or control groups. Subjects in the control group received the usual DXA reports and a handout on the indications for DXA. Subjects in the intervention group received the usual DXA report plus an assessment of their patient's fracture risk using the FRAX risk calculator, and guideline-based recommendations for laboratory evaluation non-pharmacologic and pharmacologic therapy. In addition, the intervention group had access to an electronic order entry screen which provided "point and click" ordering of recommended care. **Results:** Informed consent was obtained from 37 providers. A total of 161 DXA scans were ordered by the participating providers during the twelve month study period. The mean age of the patients was 62.5 years. There were 103 (64%) males and 58 (36%) females, 59 (37%) African Americans and 101 (63%) whites. Thirty seven patients (23%) had osteoporosis by T score, or osteopenia plus a FRAX score meeting recommended treatment thresholds (>20% for major osteoporotic fractures or >3% for hip fracture). Of these, 18 were in the control group and 19 were in the intervention group; representing 27% and 20% of total scans in each group respectively. **Results** are shown in table 1. **Conclusion:** In this small, exploratory study, enhanced bone density reports containing an assessment of the patient's fracture risk and recommendations for treatment did not result in improved osteoporosis care.

Therapy	Intervention (n=19)	Control (n=18)
Calcium and vitamin D	12 (63%)	10 (55%)
Bisphosphonate	10 (53%)	15 (83%)

Table 1. Proportion of patients meeting treatment criteria who received recommended therapy

Use of Pharmacologic Agents for the Prevention of Osteoporosis among Older Women with Low Bone Mass is Discordant with NOF Guidance. Jie Zhang^{*}, Jeffrey Curtis, Elizabeth Delzell, Kenneth Saag. University of Alabama at Birmingham, USA

Objective: To determine if treatment with pharmacologic agents among postmenopausal women with low bone mass (T score between -1.0 and -2.5) was in concordance with the current and recent National Osteoporosis Foundation (NOF) clinical guidelines.

Methods: Cross-sectional analysis from 2007 to 2009 among participants of the Global Longitudinal Study of Osteoporosis in Women (GLOW) recruited from the Birmingham, Alabama, site. Eligible subjects had a bone density test within 2 years prior to a GLOW survey and had their lowest T score (of either total hip, femoral neck, lumbar spine, or 1/3 radius) between -1.0 and -2.5. Those who reported a history of hip or spine fracture were excluded. Fracture risk factors and the use of anti-osteoporosis medications were self-reported. We examined the proportions of women managed in concordance with the NOF 2003 and 2008 guidelines, with concordance

defined as ever (current or past) received treatment among those recommended for treatment and never received treatment among those not recommended for treatment. Univariate odds ratios (ORs) and 95% confidence intervals (CIs) were calculated.

Results: Mean age among 770 eligible women was 70.7 years. When NOF 2003 guidelines were applied, 463 (61%) women were managed in concordance with the guidelines. Those who met NOF 2003 criteria were more likely to have ever received treatment (OR, 2.5; 95% CI, 1.9-3.4). Women with lower T scores were more likely to be treated (Table 1). Among those not recommended for treatment, women with T scores between -2.0 and -1.5 and absent of major risk factors were more likely to be treated than women with T scores between -1.5 and -1.0. Three hundred and nine (52%) women were managed in concordance with NOF 2008 guidelines. Those who met NOF 2008 criteria were not more likely to have ever received treatment (OR, 1.1; 95% CI, 0.8-1.6). Compared to women not recommended for treatment, those satisfying both NOF FRAX criteria were more likely to be treated (OR, 1.7; 95% CI, 1.1-2.6), while those satisfying only one of the criteria were not more likely to be treated (OR, 0.8; 95% CI, 0.5-1.4).

Conclusion: Up to 50% of the women with osteopenia were not treated in concordance with NOF guidelines. Those having one but not both of the NOF FRAX criteria for intervention were not more likely to be treated than those having neither. These results may reflect a lack of awareness of and insufficient dissemination of the guidelines among physicians.

Table 1. Univariate associations between meeting and not meeting National Osteoporosis Foundation criteria and having ever received anti-osteoporosis treatment

	N (%) Treated	Odds Ratio (95% Confidence Interval)
NOF 2003 Guidelines¹		
Overall		
Treatment recommended	262 (60.4)	2.5 (1.9-3.4)
Treatment not recommended	122 (37.8)	Reference
By BMD category and presence of major risk factors²		
Treatment recommended		
T score = -2.0	168 (63.9)	3.8 (2.6-5.7)
-2.0 < T score = -1.5 and presence of at least one of the following risk factors ³	94 (55.0)	2.7 (1.7-4.1)
Treatment not recommended		
-2.0 < T score = -1.5 and absent of the following risk factors ³	64 (46.0)	1.9 (1.2-2.9)
-1.5 < T score < -1.0	58 (31.5)	Reference
NOF 2008 Guidelines¹		
Overall		
Treatment recommended	168 (54.2)	1.1 (0.8-1.6)
Treatment not recommended	147 (51.0)	Reference
By FRAX risk score		
Treatment recommended		
10 year probability of hip fracture = 3% and 10 year probability of major osteoporotic fracture = 20%	98 (64.1)	1.7 (1.1-2.6)
Either 10 year probability of hip fracture = 3% or 10 year probability of major osteoporotic fracture = 20%, but not both	70 (44.6)	0.8 (0.5-1.4)
Treatment not recommended		
10 year probability of hip fracture < 3% and 10 year probability of major osteoporotic fracture < 20%	147 (51.0)	Reference

¹The NOF 2003 and 2008 criteria could not be evaluated in 13 and 172 women respectively due to missing values on key fracture risk factors.

²Risk factors include fracture since turning 45, parental hip fracture, body weight < 127 lbs, current smoking, and current glucocorticoid use

Evaluation of Effect of Raloxifene Hydrochloride on the Quality of Life of Patients with Postmenopausal Osteoporosis. Kousei Yoh¹, Etsuro Hamaya², Noriko Iikuni³, Noriko Takagaki², Takanori Yamamoto², Masanori Taketsuna², Akimitsu Miyauchi⁴, Hideaki Sowa⁵, Hisashi Urushihara², Kiyoshi Tanaka^{*6}. ¹Department of Orthopedic Surgery, Sasayama Hospital, Japan, ²Eli Lilly Japan KK, Japan, ³Eli Lilly & Company, USA, ⁴Miyauchi Medical Center, Japan, ⁵Lilly Research Laboratories Japan, Eli Lilly Japan K.K., Japan, ⁶Kyoto Women's University, Japan

[Aim] To evaluate the effects of treatment with raloxifene (RLX) on the quality of life (QOL) of patients with postmenopausal osteoporosis in daily practice. **[Subjects/Methods]** In patients with postmenopausal osteoporosis [based on Diagnostic Criteria for Primary Osteoporosis (rev. 2000)] treated with RLX in accordance with the package insert, a battery of QOL questionnaires [SF-8, EQ-5D and Japanese Osteoporosis Quality of Life Questionnaire (JOQOL) 2000] and the 10.0 cm-scale Visual Analogue Scale (VAS) for pain were administered at baseline and Weeks 8 and Week 24 of treatment. The changes in these scales from baseline were tested with paired t-test or Wilcoxon's signed rank test. Adverse reactions were also assessed. **[Results]** Of 536 patients enrolled in the study, 507 (mean age: 70.7 years) were included in the analyses. In comparison with baseline, all the SF-8, and physical and mental summary scores were significantly improved at Weeks 8 and 24 (p<0.001, t-test). The EQ-5D index score also significantly improved from baseline at both Weeks 8 and 24 (p<0.001, t-test). Furthermore, the total JOQOL 2000 score significantly improved at Week 24 (mean changeSD: 4.811.8, p<0.001, t-test). The VAS for pain

was significantly reduced at Weeks 8 (mean SD: -1.052.33 cm, $p<0.001$, t-test) and 24 (mean SD: -1.3 2.67 cm, $p<0.001$, t-test), with 2.0 cm or more reduction in over 30% of patients. In addition, a survey for pain frequency in the past four weeks revealed significant improvement ($p<0.001$, t-test). Adverse drug reactions were reported in 34 patients (6.71%) with the most commonly reported System Organ Class of gastrointestinal disorders in 10 patients. [Conclusion] In Japanese clinical setting, significant improvements in the QOL and pain were observed at Week 8 of treatment with RLX and maintained throughout the observation period. These results can provide the first evidence of effectiveness of RLX for osteoporosis patients in Japan.

Cost Effectiveness Of A Targeted Intervention To Reduce Refracture Rates: Analysis Of A Four Year Prospective Controlled Study. Mark Cooper^{*1}, Kirtan Ganda², Andrew Palmer³, Markus J Seibel⁴. ¹University of Birmingham, United Kingdom, ²Australia, ³University of Tasmania, Australia, ⁴Bone Research Program, ANZAC Research Institute, University of Sydney, Australia

We recently reported the clinical effectiveness of a Minimal Trauma Fracture (MTF) service. The MTF intervention is offered on an outpatient basis to patients presenting with a minimal trauma fracture to Concord Repatriation General Hospital (CRGH) in New South Wales, Australia. In a 4-year prospective observational study, that was unique in having a control group treated in primary care, it was demonstrated that the MTF service significantly reduced the risk of refracture by 80%. The MTF service involves input from a specialist clinic and greater use of bone density assessment, laboratory tests and medications. It was thus unclear whether the benefits seen would be cost-effective. Our aim was therefore to determine the costs and improvements in quality-adjusted life years (QALYs) associated with the MTF service, allowing a comparison of value for money versus standard practice. We developed a Markov, 2nd-order Monte Carlo simulation model to project the 4-year clinical and cost outcomes to 10 years. The model accounted for hip, forearm and humerus fractures; their associated direct costs; changes in health utility; and in the case of hip fracture, increases in mortality. Fracture probabilities were calculated directly from the recently published clinical trial. Direct medical costs (expressed in 2010 Australian Dollars) for the MTF intervention and the control arm were derived from reported health resource consumption. Outcomes were discounted at 5% annually. Total 10-year costs (C), quality-adjusted life years (QALY) and incremental C/QALY-gained were calculated for MTF versus control. Extensive sensitivity analyses were performed e.g. varying anti-fracture effectiveness, intervention costs, number of patients treated and level of compliance with therapy.

Reducing recurrent fracture rates with the MTF service versus control led to an improvement of 0.08 QALYs per patient over 10 years. Despite higher treatment costs, total costs in the MTF treatment arm were only increased by \$1,480 per patient over the 10-year period, due to reduced costs from fractures avoided. The incremental cost-effectiveness ratio for the MTF service versus control was \$19,102/QALY gained, indicating that the MTF intervention represents excellent value for money. Sensitivity analysis demonstrated that the results were robust under all plausible assumptions.

The MTF service is thus a cost-effective intervention to reduce recurrent osteoporosis fractures in a high risk population.

SA0444

Global Health Care Utilization Following a Fracture: The Global Longitudinal Study of Osteoporosis in Women. George Ioannidis^{*1}, Julie Flahive², Laura Pickard¹, Alexandra Papaioannou³, Roland Chapurlat⁴, Kenneth Saag⁵, Stuart Silverman⁶, Stephen Gehlbach⁷, Jonathan Adachi⁸. ¹McMaster University, Canada, ²University of Massachusetts Medical School, USA, ³Hamilton Health Sciences, Canada, ⁴E. Herriot Hospital, France, ⁵University of Alabama at Birmingham, USA, ⁶Cedars-Sinai/UCLA, USA, ⁷University of Massachusetts, USA, ⁸St. Joseph's Hospital, Canada

Purpose: Using the Global Longitudinal study of Osteoporosis in Women (GLOW) – an observational longitudinal study of non-institutionalized women aged ≥ 55 years recruited from 723 primary physician practices in 10 countries – we evaluated the direct medical health utilization associated with treating several types of fractures in different regions around the world.

Methods: Information was collected from GLOW via self-administered patient questionnaires at baseline and year 1 (N=51,491). From these tools, clinically recognized low trauma fractures at year 1 were classified into incident hip, spine, wrist/hand, arm/shoulder, and other fractures (included ankle, foot, knee, clavicle, elbow, coccyx, sternum, or neck.). Health care utilization data included whether the fractured patient was treated at a doctor's office/clinic, or at a hospital. Patients were also asked if they had undergone surgery and if they had been treated at a rehabilitation center or nursing home.

Results: The table shows the use of health care service for individual fracture types. In addition, patients with wrist/hand, arm/shoulder and other fractures were more

likely to be treated at a hospital in Southern (88.2%, 93.5%, 84.2%) and Northern European regions (92.3%, 86.7%, 84.3%) as compared with the USA (67.9, 71.0, 53.3%), respectively.

Conclusions: Patients who experience hip fractures use significant health care services. However, given the higher incident rates of the additional fracture types examined, all fracture types have an important impact on health care services. The resource utilization patterns identified in this study may assist health planners in developing future health care services.

Health care service used	New fracture at specific location, n/n (%)				
	Spine (n=195)	Hip (n=134)	Wrist/hand (n=419)	Arm/Shoulder (n=197)	Other ^a (n=658)
Office/clinic	121/165 (73)	76/124 (61)	270/379 (71)	130/181 (72)	456/596 (77)
Hospital	101/165 (61)	117/127 (92)	313/389 (80)	149/184 (81)	371/579 (64)
Overnight at hospital	57/95 (60)	102/111 (92)	85/281 (30)	66/138 (48)	115/339 (34)
Surgery	29/99 (29)	103/116 (89)	114/296 (39)	49/141 (35)	107/355 (30)
Rehabilitation center	24/161 (15)	69/122 (57)	47/357 (13)	43/176 (24)	64/563 (11)
Nursing home	8/153 (5.2)	19/116 (16)	8/349 (2.3)	12/168 (7.1)	13/534 (2.4)

Rates of Diagnosis and Treatment of Osteoporosis in Males Before and After Hip, Vertebral, and Non-Hip/Non-Vertebral (NHNV) Fractures. Susan Brennenman¹, Laura Christensen¹, Nicole Yurgin^{*2}. ¹Innovus, USA, ²Amgen Inc, USA

Purpose: To determine the proportion of male patients with closed fractures who were diagnosed (dx) or treated (tx) for osteoporosis before or after a closed fracture.

Method: Descriptive analysis was conducted on administrative claims from a large, national health plan. Subjects were males 45 or older with at least one medical claim for a new closed fracture at a single site (e.g., hip, vertebral) between January 1, 2005 and December 31, 2008, were continuously enrolled for 12 months before and after the fracture, and had at least two fracture-related outpatient visits in the follow-up. A closed fracture was considered 'new' if there were no health care claims for the fracture in the 12 month pre-fracture baseline period. For hip, femur, tibia and humerus fractures, individuals were excluded if they did not receive inpatient care. Commercially insured (COM) and Medicare Advantage Plan (MAP) members were analyzed separately. Osteoporosis treatment was defined as having at least one filled prescription for alendronate, risedronate, teriparatide, ibandronate, pamidronate, or zoledronate. Diagnosis of osteoporosis was defined as the presence of an ICD-9 diagnosis code of 733.0x on a medical claim.

Results: The sample mean age was 58 yrs and 74 yrs for COM and MAP, respectively. The study identified 18,917 (COM 16,191, MAP 2,726) new closed fractures during the study period. In the COM group, the pre-fracture dx and tx rates were 2.5% and 2.1%, respectively. After the men experienced a fracture, the mean dx and tx rates were 6.8% and 4.0%, respectively. The post-fracture dx rates by fracture type were: 14.4% for hip, 20.1% for vertebral, and 2.5% for NHNV. The post-fracture tx rates by fracture type were: 7.5% for hip, 11.8% for vertebral, and 1.5% for NHNV.

In the older MAP population, the pre-fracture dx and tx rates were 5.6%, and 2.4%, respectively. After the men experienced a fracture, the mean dx and tx rates were 17% and 6.8%, respectively. The post-fracture dx rates by fracture type were: 13.4% for hip, 31.3% for vertebral, and 7.1% for NHNV. The post-fracture tx rates by fracture type were: 3.2% for hip, 13.2% for vertebral, and 2.7% for NHNV.

Conclusion: Amongst males 45 and older, the rates of diagnosis and treatment for osteoporosis were higher after fracture. Nevertheless, the highest post-fracture diagnosis rate was still less than one-third of the fracture patients.

Do our People Meet the IOM Recommendations on Calcium Dietary Intake?

Cristina Carbonell^{*1}, Daniel Prieto-Alhambra², Carmen Olmos³, Isabel Aymar⁴, Adolfo D  ez-Perez⁵, Xavier Nogues⁵. ¹Healthy Primary Care Via Roma Barcelona.Facultat de Medicina Universitat de Barcelona, Spain, ²Department of Internal Medicine, URFOA IMIM-Hospital del Mar, Parc de Salut Mar, Autonomous University of Barcelona, IDIAP Jordi Gol, Barcelona, Spain, Spain, ³Healthy Primary Care Via Roma Barcelona, Spain, ⁴Densitometry Unit. URFOA Hospital del Mar. Barcelona, Spain, ⁵Department of Internal Medicine, URFOA IMIM-Hospital, RETICEF (Red Tematica de Investigacion Cooperativa en Envejecimiento y Fragilidad), Instituto Carlos III, Barcelona, Spain del Mar, Parc de Salut Mar, Autonomous University of Barcelona,, Spain,, Spain

AIMS

Calcium is an important mineral for bone formation and cellular activity as second messenger with specific roles. We aimed to determine the percentage of people who meet an adequate intake of calcium in their diet according to the last IOM (Institute of Medicine) recommendations. Secondly, we determined predictors of calcium intake amongst the following: gender, age, education level and co-morbid conditions.

METHODS

Design: Observational, cross-sectional.

Subjects: consecutive sample of patients aged over 15 attending participant primary care consults in Barcelona (Spain) for any reason during the recruitment period (one week in January/2011). We excluded patients with osteoporosis or other bone metabolism conditions, those receiving antiresorptive drug/s or Calcium supplements, pregnant women and those with a history of renal stones.

Measurements: Validated weekly food frequency questionnaire of calcium intake. We collected age, sex, co-morbid conditions, educational level and nationality. Participants were considered to have sufficient calcium dietary intake if they reported ≥ 1100 mg daily in 15-19 years; ≥ 1000 in women 19 – 50 and in men aged 19 to 70; and ≥ 1200 mg/d in women older than 50 and men over 70.

Statistics: binomial test was used to calculate 95% Confidence Interval (95CI) for the proportion of patients meeting IOM recommendations. Multivariate linear regression models were fitted to study determinants of dietary calcium intake.

RESULTS

545 patients were eligible, 25 excluded and 520 included.186 were males (35.8%). Calcium intake was inadequate (low) in 276(53.1% (IC 95% 48.7- 57.4%)) patients. None were over the upper level intake. Significant predictors of dietary calcium intake were: age (adjusted beta per year 13.6 [95CI 0.76 to 26.5;p=0.038]), and educational level (adjusted beta 320.6 [95CI 42.0 to 599.2;p for linear trend=0.024]). We observed a borderline-significant trend to lower calcium intake for foreign nationality (adjusted beta -525.5;p=0.08) and for a history of COPD (adjusted beta -1270.8;p=0.057).

CONCLUSION

Only half of patients attending a primary care health center for any reason, excluding those with osteoporosis and/or bone metabolism diseases meet IOM recommendations for adequate dietary calcium intake. Patients with higher educational levels, and older participants, had a higher calcium intake. Immigrants and COPD patients might be at risk for insufficient calcium intake.

Effect of two years Dietary Hesperidin Supplementation on Bone Metabolism in Postmenopausal Women. Veronique Habauzit¹, Elizabeth Offord², Winnie Chee³, Lydia Jafrelo¹, Laurent Ameze², Gary Williamson⁴, Marie-noelle Horcajada^{*2}. ¹INRA, France, ²Nestle, Switzerland, ³National University of Malaysia, Malaysia, ⁴Nestle, France

Hesperidin (Hp), a major citrus flavonoid, has anti-inflammatory properties and prevents ovariectomized-induced bone loss in rodents. Here we report the results of the first clinical study to be conducted on the ability of Hp to protect against postmenopausal bone loss. The study was a parallel, placebo-controlled, double blind, 24-month randomized intervention trial assessing the effect of Hp on validated biomarkers of bone turnover and bone mineral density (BMD).

110 healthy Caucasian postmenopausal women, 50-65y, were randomized on their Ca intake and hip BMD and assigned to the Hp (500 mg Hp/day in 2 biscuits) or placebo (P) group (same biscuits without Hp). Subjects kept dietary records and minimized their citrus-rich food intake during the study period.

Both groups completed the study to a similar extent (87.5 % in P group, 91 % in Hp group). Demographics and baseline characteristics such as daily calcium intake (P: 884.7 276.2; Hp: 887.7 246.9 mg/day) or 25(OH)D (P: 82.0 38.3 ; Hp: 79.5 34.1 nmol/l) were not significantly different between the two groups. Evolution from baseline to 24 months of anthropometry, standard laboratory parameters was similar in the two groups. Concerning BMD, whatever bone site (total hip, femoral neck or lumbar spine), no statistically significant difference was found between groups based on mixed models with or without covariates in an ITT analysis. In the P group, from baseline to 24 months, the mean % change in BMD was between 2.48% and -1.15% depending on the bone site, and in the Hp group, changes ranged from 2.85% to 1.43%.

For serum b-ALP, serum CTX-1, serum PINP and calciuria, no statistically significant difference was seen between groups. However, a significant interaction group x time (p<0.05) was detected for bone turnover index: computed ratio b-ALP / CTX-1 and PINP / CTX-1. This significant effect could mainly be attributable to a higher value of the ratio at 18 and 21 months in the Hp group.

In conclusion, the yearly rates of bone loss (1-2%) were equivalent in the two groups. Evolution in BMD was not statistically different between the two groups. However, the hesperidin supplementation resulted in a significant modulation of biomarkers of bone remodeling after at least 18 months of exposure. As reflected by bone turnover index, the subjects consuming hesperidin daily presented a better balance in bone metabolism during the 2nd year of follow-up at the 18 and/or 21 month time-points.

Effects of Strontium on the Quality of Bone Apatite Crystals.

Audrey Doublier^{*1}, Delphine Farlay¹, Xavier Jaurand², Ruben Vera³, Georges Boivin¹. ¹INSERM UMR1033; Universite De Lyon, France, ²Universite de Lyon, Centre technologique des microstructures, F-69622, France, ³Universite de Lyon, Centre de diffractometrie Henri Longchambon, F-69622, France

Interactions between strontium and bone mineral have been investigated at the tissue level in animals (1,2) and in women after 3 years of treatment with strontium ranelate (3-5). In treated women, strontium was exclusively present in bone formed during treatment, and degree of mineralization was maintained. The goal of this study was to assess the effect of strontium on the characteristics of apatite crystals. Ten paired iliac bone biopsies were taken from osteoporotic women before and after 3 years of treatment with either 2g per day of strontium ranelate (SrRan, n=7) or placebo (PLA, n=3), and then embedded in methyl methacrylate. By X-ray diffraction (XRD), position and full width at half-maximum of the apatite peaks (i.e., crystallinity) were measured on cortical and cancellous bone. Crystals' size was calculated by Scherrer's formula, as well as interplanar distances d002 and d310. d002 was also measured by selected area electron diffraction (SAED) in new and old bone (age of tissue). After treatment, the presence of strontium in new bone was verified by X-ray microanalysis in SrRan patients. The effects of treatment were assessed by a Wilcoxon test and difference between groups by a Kruskal-Wallis test (significant if p \leq 0.05). All spectra (PLA and SrRan) were characteristic of a biological apatite, and crystals were preferentially oriented along the organic matrix. Globally, in cortical and cancellous tissues, crystallinity (size and perfection of crystals), d002 (XRD and SEAD) and d310 (XRD) were not significantly modified neither by the duration (3 years versus before treatment) nor by the type of treatment (SrRan versus PLA). Moreover, d002 was similar in cortical and cancellous bone whatever the treatment group. To conclude, the quality of bone apatite crystals is maintained in a normal range in osteoporotic patients after 3 years of treatment with strontium ranelate. 1. Farlay et al. Therapy With Strontium Ranelate Improves Bone Mineral Mass,Volumetric Bone Mineral Density and Geometrical Parameters of Bone in Postmenopausal Osteoporotic Women- 2Years Results. A Peripheral Quantitative Computed Tomography (PQCT) of the Tibia Study. Konstantinos Stathopoulos^{*1}, Erato Atsali¹, Ilias Bournazos², Aristidis B. Zoubos¹, Grigoris Skarantavos³. ¹"Attikon" Athens University Hospital, Greece, ²"Attikon" Athens University Hospital, Greece, ³Attikon University Hospital, Greece

Objective: We assessed the effects of strontium ranelate on bone mineral mass, volumetric bone mineral densities, geometrical properties of the bone and strength indexes in postmenopausal osteoporotic women using tibia pQCT.

Material and methods: We reviewed medical records of 32 women with postmenopausal osteoporosis who received strontium ranelate 2g sachets per os daily for 2 consecutive years. Inclusion criteria: 1) age \geq 50y 2) postmenopausal status \geq 2y, 3) DXA measurement (Spine/Hip) with Tscore \leq -2.5 SD 4) Tibia pQCT before, 1 y and 2 y

after treatment. Exclusion criteria: 1) Secondary osteoporosis' conditions 2) Other bone metabolic diseases 3) Previous use of bone anabolic agents 4) malignancies. Patients had tibia pQCT (Stratec Medizintechnik, Pforzheim, Germany), 3 slices were obtained at the 4% (trabecular), 14% (subcortical and cortical) and 38% (cortical bone) of tibia length sites. We studied 15 variables per slice, mainly total bone content (TOT_CNT), total density (TOT_DEN), trabecular content (TRB_CNT), trabecular density (TRB_DEN), cortical content (CRT_CNT), cortical density (CRT_DEN), subcortical content (CRTSUB_CNT), subcortical density (CRTSUB_DEN), cortical area (CRT_A), subcortical area (CRTSUB_A), mean cortical thickness (CRT_THK), and Stress Strength Indexes (SSIs) at the 14% and 38% sites. Results were corrected for strontium ranelate atomic weight. We performed statistical analysis (t-test, ANCOVA)-data expressed as meanstandard deviation (S.D.)

Results: Patients' mean age was 64.3 12.6y and mean tibia length 352.14 65.03mm. After 2 years treatment, we report increases at the 14% site in _CNT (181,0421,51 vs 183,0521,34, $p=0,006$), SUBCRT_CNT (168,6419,58 vs 170,4819,11, $p=0,005$), and CRT_CNT (62,9118,58 vs 66,6320,63, $p=0,021$). At the 38% site we report increases in TOT_CNT (276,4636,24 vs 278,9435,71, $p=0,09$), SUBCRT_CNT (205,8625,60 vs 208,5925,47, $p<0,000$), CRT_CNT (160,0931,19 vs 168,8432,62, $p<0,000$) and CRT_DEN (1192,4614,50 vs 1203,1517,05, $p<0,000$). We also report increases in CRT_A (134,1825,73 vs 140,1326,57, $p<0,000$) and mean CRT_THK (2,180,44 vs 2,280,46, $p=0,001$).

Conclusions: Our results indicate that 2 years of therapy with strontium ranelate increase significantly bone mineral mass, volumetric cortical densities, cortical area and mean cortical thickness in post menopausal osteoporotic women.

Effects of Calcitonin Treatment in Patients with Osteoporosis Who Developed Acute Low Back Pain Due to a New Vertebral Fracture. Keiji Fujino¹, Naoto Endo², Shinya Tanaka³. ¹Fujino Orthopaedic Clinic, Japan, ²Niigata University, Japan, ³Saitama Medical University, Japan

Objectives Many elderly subjects have become bedridden or self-confined due to a vertebral fracture associated with osteoporosis. This study was performed to determine whether calcitonin treatment is effective for achieving early ambulation and preventing confinement to bed, in comparison with oral treatment with non-steroidal anti-inflammatory drugs (NSAIDs), in patients with osteoporosis who developed acute low back pain after suffering a new vertebral fracture.

Methods This was a multicenter, open-label, randomized study including female patients aged 65 years and over with primary osteoporosis who developed low back pain after suffering a new fragile fracture of the vertebrae. They were randomized either to receive intramuscular injection of calcitonin at 20 IU once weekly or oral treatment with NSAIDs. The study endpoints comprised the degree of low back pain assessed using the visual analog scale (VAS) and patients' quality of life (QOL) rated using the Roland Morris Questionnaire (RDQ) and the Japan Questionnaire for Osteoporotic Pain (JQ22).

Results The low back pain according to VAS assessment and QOL assessed using RDQ and JQ22 improved in both patients treated with calcitonin and those receiving oral NSAIDs at the end of Week 4 of study treatment. The assessment results were superior in these variables for the calcitonin group in comparison with the NSAIDs group, suggesting greater efficacy of calcitonin therapy as compared to oral treatment with NSAIDs.

Discussion Calcitonin has an analgesic effect via the central-nervous serotonergic system, which lasts a relatively long period, while lacking in a fast onset of effect like NSAIDs. Calcitonin injected once weekly is thus considered to be sufficient to provide pain control and improving patients' QOL. Calcitonin is considered to be essential in an early-stage treatment of pain due to a new vertebral fracture.

Patient Education in the Digital Age. Jay Ginther*. Cedar Valley Bone Health Institute, USA

Communicating full information about osteoporosis prevention and treatment to patients and their families during the limited time of an office visit is virtually impossible. They will seek further information outside the office setting. The abundance of information aimed at the lay public available on the internet is impressive. Its accuracy is not. Our challenge is to supply abundant, scientifically accurate information, written for the lay public, to our patients. This poster presentation will detail the mix of paper handouts, office video, website, blog, CD, u-tube, and magazine articles used by Cedar Valley Bone Health Institute of Iowa.

Relative Importance of Attributes that Influence Osteoporosis Decision-Making in Postmenopausal Women. Stuart Silverman¹, Andrew Calderon², Amy Mofield³, Wendy Brynildsen⁴, Michael Koenig², Kristina Kaw², Deborah Gold³. ¹Cedars-Sinai/UCLA, USA, ²OMC Research, USA, ³Duke University Medical Center, USA, ⁴Duke University, USA

Purpose: Patient preferences about medication attributes significantly influence osteoporosis (OP) medication decision making. Patients may decide to initiate, change, or stop therapies based on ranking of perceived attributes of the therapy and their personal rankings. Max-Diff is a form of conjoint analysis which allows participants to rank attributes by randomly presenting statements about these attributes. **Objective:** We examined the rank order of OP medication attributes using MaxDiff in a convenience sample of Caucasian postmenopausal (PM) women at risk of OP fracture. **Methods:** After conducting qualitative interviews with 13 postmenopausal women, we identified six major attributes that influence OP medication decision making: efficacy, short-term safety, long-term safety, cost, delivery system, and dosing interval. A sample of PM Caucasian women who were at risk of fracture based on FRAX (FRAX scores 3% risk hip fx or 20% major OP fx) were recruited to complete a laptop-based questionnaire to provide demographic data and to rank 39 statements about these attributes using Max-Diff. **Results:** We recruited a convenience sample of 82 PM Caucasian women (mean age=76.6 yrs, SD=5.83, range=65-89) at two US sites. Over half (53.7%) were not married (e.g. widowed, divorced or never married) and 54% had some post high school education. The majority of respondents considered their income at least enough to meet their needs (89.02%) and 93% reported to have a co-pay. 30% were currently taking an osteoporosis medication. Although interindividual variability was seen, these women rated efficacy (6 statements, mean importance score 6.63, range 5.88-7.16) twice as important as safety (14 statements, mean importance score 3.35, range 1.37-4.97). Safety (short- and long-term) was rated approximately threefold higher than cost (4 statements, mean 1.02, range 1.37-0.61). Cost was rated approximately 50% higher than either dosing interval (6 statements, mean importance 0.66, range 0.38-0.93) or delivery method (5 statements, mean importance score 0.54, range 0.08-0.65). **Conclusions:** A convenience sample of postmenopausal Caucasian women with risk of OP fractures rated efficacy and safety higher than cost, delivery system or dosing interval. This information may be helpful in structuring communication about osteoporosis medications to PM women. Ranking of attributes on an individual basis may allow the development of targeted communication to individual patients.

SA0457

Annual Bone Loss in Postmenopausal Women is Attenuated with 1000 IU but not 400 IU Daily Vitamin D3: A 1 Year Double Blind RCT Designed to Include Seasonal Effects at High Latitude. Adrian Wood¹, Lorna Aucott¹, Alexandra Mavroei², Karen Secombes¹, Alison Black³, William Fraser⁴, David Reid¹, Helen Macdonald⁵. ¹University of Aberdeen, United Kingdom, ²University of Aberdeen School of Medical Sciences College of Life Sciences, United Kingdom, ³Woolmanhill Hospital Aberdeen Osteoporosis Research Unit, United Kingdom, ⁴Royal Liverpool University Hospital, United Kingdom, ⁵University of Aberdeen Bone & Musculoskeletal Research Programme, United Kingdom

A number of trials have investigated the effect of vitamin D on bone health with mixed results. Subsequent meta-analyses have concluded that for beneficial effects either adequate calcium intake is also required or the daily vitamin D dose needs to be >800 IU. There may be confounding from the underlying effects of season, and the relationship between change in vitamin D status and bone status is unclear. The aim of this 1-year double blind placebo controlled RCT, designed to directly compare the seasonal changes in vitamin D status, was to determine whether vitamin D3 at daily doses of 400 IU or 1000 IU affected bone loss in postmenopausal women.

Three hundred and five women aged 60-70 y were randomised to receive either vitamin D or placebo in January-March 2009 and were seen at two-monthly intervals until January-March 2010 (87% attending the final visit). 25-hydroxyvitamin D [25(OH)D] was measured by dual tandem mass spectrometry using NIST aligned standard (Chromsystems UK). Bone mineral density (BMD) was measured at the hip and spine by Lunar iDXA.

The mean 25(OH)D change SD for the placebo, 400 IU and 1000 IU vitamin D groups was: -412 nmol/L, +3120 nmol/L and +4319 nmol/L, respectively. Figure 1 highlights a non-linear response showing that (i) the incremental increase in 25(OH)D for 1000 IU over 400 IU was small and (ii) the seasonal pattern for the placebo group was not followed for the vitamin D treatment groups. In contrast mean BMD loss at the hip was significantly less for the 1000 IU vitamin D group (-0.051.46%) compared to the 400 IU vitamin D and placebo groups (-0.571.33% and -0.601.67%, respectively) (P=0.02). There was no effect of treatment on BMD at the spine.

The discordance between the incremental increase in 25(OH)D when comparing the two doses of vitamin D and the effect on hip BMD suggests that serum 25(OH)D may not accurately reflect clinical outcome. It is not known whether the additional vitamin D was not converted to 25(OH)D because it was stored or degraded or whether it was not fully absorbed. Further research is required to explain whether the bone anabolic effect is confined to cortical bone or to particular sites, and whether the

increase in BMD is a result of transient increases in serum calcium after ingestion of the higher dose vitamin D, or if there are other explanations.

Effect of treatment on vitamin D status

Fermented Milk Enriched with Calcium and Vitamin D and Anthocyanins Improves Bone Metabolism in Postmenopausal Women. caroline puel¹, Veronique Coxam^{*2}, MJ Davicco³, patrice lebecque³, Yohann Wittrant⁴. ¹ELVIR, France, ²INRA Theix, France, ³INRA, France, ⁴Institut National de la Recherche Agronomique, France

Research in the field of nutrition allows considering the establishment of a real prevention of osteoporosis. The value of fruit and vegetables is discussed. A major reason is the recognition of their likely involvement in the prevention of various diseases associated with oxidative stress, such as osteoporosis. Red fruits are particularly interesting for their high anthocyanins content, endowed with anti-oxidant and anti-inflammatory properties.

The present clinical, controlled, randomized, double-blind placebo, prospective study, conducted over 3 months, aims to evaluate the possible osteoprotective effects of anthocyanins on bone metabolism, in postmenopausal women (less than 6 years).

In that purpose, fermented based blueberry extract milk, providing respectively 25% and 20% RDA of calcium and vitamin D, rich in anthocyanins, has been given to volunteers. Fifty six women aged 50 to 65 years, without HRT, were included in the study after a medical examination and a blood test. Throughout the study period, they kept their eating habits, limiting however the red fruits. They were randomized into 2 groups of 28 subjects receiving either 0 or 120 mg of anthocyanins per day. The intake of anthocyanins was conducted in the form of fermented milk containing 0 or 60 mg of active molecule / 100ml, with 2 bottles of 100 ml per day.

Consumption of a milk enriched in polyphenols significantly improved the serum bPAL activity, (an osteoblastic marker), without significant modification of CTX, a marker for bone resorption. This favorable orientation of bone metabolism could be explained by the contribution of anthocyanins from bilberry extract, the only noticeable difference between the 2 test foods. This finding is independent of the initial calcium and vitamin D consumption.

In conclusion, consumption of fermented milk containing blueberry, enriched with calcium and vitamin D for 3 months, has corrected the vitamin status of postmenopausal women for less than 5 years. In addition, it resulted in a favorable orientation of bone metabolism, as indicated by the rise of a biomarker of osteoblastic activity. This benefit is most likely related to the presence of blueberries (rich in polyphenols and phenolic acids).

Vitamin D Serum Levels Influence Adequate Response To Bisphosphonate Treatment In Postmenopausal Osteoporosis. Angels Martinez-Ferrer^{*1}, Pilar Peris², Ana Monegal³, M. Jesus Martinez de Osaba⁴, Africa Mux⁵, Nuria Guanabens⁷. ¹Hospital Clinic Barcelona, Spain, ²Rheumatology. Hospital Clinic, Spain, ³Metabolic Bone Diseases Unit. Hospital Cl  nic. University of Barcelona., Spain, ⁴Hormonal Laboratory. Hospital Clinic., Spain, ⁵Universitat De Barcelona, Spain

It is not clear whether vitamin D sufficiency may optimize the response to bisphosphonates (BP) treatment in postmenopausal osteoporosis. Therefore, the aim of this study was to evaluate the role and possible mechanisms of vitamin D in adequate response to standard treatment with BP for postmenopausal osteoporosis.

Methods: We included 120 postmenopausal osteoporotic women (aged 688 years) treated with BP (alendronate or risedronate) at their annual follow-up visit. All patients underwent complete anamnesis, including treatment adherence, use of vitamin D supplements, and previous falls and fractures during the last year. Bone mineral density (BMD) evolution during this period was analyzed in all patients as was the bone mineral profile evaluating serum PTH and 25-OH vitamin D (25-OHD) and urinary NTx. In addition, muscular strength in lower limbs was measured in all patients. Patients were classified as inadequate responders to the antiosteoporotic treatment based on a BMD loss > 2% and/or the presence of fragility fractures during the last year.

Results: Thirty percent of patients showed inadequate response to BP treatment, with significantly lower levels of 25 OHD (22.41.3 vs. 26.60.3 ng/ml, p=0.01), a higher frequency of 25OHD levels < 30 ng/ml (91% vs. 69%, p=0.019) and higher urinary NTx (42.23.9 vs. 30.92.3 nM/mM, p=0.01). Inadequate responders also had an increase in lumbar (-3.70.7 vs. 3.50.4 %, p<0.001) and total femoral bone loss (-1.70.4 vs. 1.030.3 %, p<0.001) and in fragility fractures (p=0.007) when compared with adequate responders. No other significant differences were observed on comparing the two groups of patients. Patients with values of 25-OHD >30 ng/ml had a greater significant increase in lumbar BMD at the annual control than women with values <30 ng/ml (3.6 % vs. 0.8%, p<0.05). The probability of inadequate response was 4-fold higher in patients with 25-OHD levels < 30 (OR, 4.42; 95% CI, 1.22-15.97, p=0.02). Conclusions: Inadequate response to BP treatment is frequent in postmenopausal women with osteoporosis as is vitamin D insufficiency, despite vitamin D supplementation. Maintenance of vitamin D levels over 30 mg/ml is especially indicated for adequate response to BP treatment.

Determination of Intermittent PTH(1-34) Regimens Sufficient to Restore Trabecular Bone Mass in Adult Ovariectomized Osteopenic Rats. Jukka Morko^{*1}, ZhiQi Peng¹, Jukka Vaaranen¹, Mari Suominen¹, Katja Fagerlund¹, Tiina A. Suutari¹, Jukka P. Rissanen¹, Harrie C.M. Boonen², Trine S.R. Neerup³, Hanne H. Bak³, Jussi Halleen¹. ¹Pharmatest Services Ltd, Finland, ²Department of Pharmacology & Pharmacotherapy, University of Copenhagen, Denmark, ³Zealand Pharma A/S, Denmark

Recombinant human parathyroid hormone analog PTH(1-34) is the major bone anabolic agent in clinical practice. In preclinical studies, PTH(1-34) regimens have varied substantially and induced strong effects including osteosclerotic and hypercalcemic conditions. The purpose of this study was to identify intermittent PTH(1-34) regimens sufficient to restore trabecular bone mass in long bone and vertebra and to determine their effects on circulating calcium levels in adult osteopenic rats. Female Sprague-Dawley rats were ovariectomized (OVX) at the age of 6 months. After 6 weeks without treatment, a reduction in trabecular bone mineral density (Tb. BMD) was confirmed in their tibial metaphysis. Treatment was started at 7 weeks after the operations and continued once daily for 6 weeks. The osteopenic rats were treated subcutaneously with PTH(1-34) at 1.2, 4, 12, 40 and 120 µg/kg/d. During the treatment period, the reduction in Tb.BMD exacerbated in OVX rats treated with vehicle. At the end of the treatment period, their Tb.BMD and trabecular bone volume (BV/TV) were decreased by 70% in tibial metaphysis and by 35% in lumbar vertebra. Treatment with PTH(1-34) reversed these OVX-induced reductions at all doses in a dose-dependent manner. The doses 12 and 4 µg/kg/d were sufficient to restore Tb.BMD and BV/TV in tibial metaphysis and lumbar vertebra, respectively. These effects were associated with 100% increase in bone formation rate (BFR/BS) and 50% reduction in osteoclast number (N.Oc/B.Pm) in tibial metaphysis and with 60% increase in BFR/BS and 30% reduction in N.Oc/B.Pm in lumbar vertebra when compared with OVX rats treated with vehicle. Serum levels of total calcium (Ca) decreased and blood levels of ionized free calcium (Ca²⁺) remained unchanged in OVX rats treated with vehicle at 80 minutes after dosing at 5 weeks after the start of treatment. Treatment with PTH(1-34) reversed the OVX-induced reduction in serum Ca levels at 4-120 µg/kg/d and increased blood Ca²⁺ levels at all doses in a dose-dependent manner. The dose 4 µg/kg/d was sufficient to restore serum Ca levels and to increase blood Ca²⁺ levels transiently, whereas the dose 12 µg/kg/d induced a transient increase in both of these levels. This study demonstrated that intermittent subcutaneous treatments with PTH(1-34) at 12 and 4 µg/kg/d are sufficient to restore trabecular bone mass in long bone and vertebra, respectively, and that these doses induce a mild transient hypercalcemia in adult OVX rats.

Effect of Estrogen Deficiency in Sclerostin Knockout Mice. Min Liu*, Pam Kurimoto, Qing-Tian Niu, Hua Zhu Ke, Amgen Inc., USA

Estrogen deficiency is an important risk factor for postmenopausal osteoporosis, where bone resorption exceeds bone formation. Sclerostin (Scl) is a potent inhibitor of bone formation and sclerostin knockout (SOST KO) mice have a high bone mass phenotype. Here, we examined the effects of estrogen deficiency induced by ovariectomy (OVX) in SOST KO mice.

Eight-month old female mice underwent sham or OVX surgery and were sacrificed 4 months later. At baseline, SOST KO mice had a higher femoral (+36%) and spine (+44%) DXA BMD than wildtype (WT) mice. Following OVX, there was a decrease in bone mass in both WT and KO mice compared with their respective sham controls. Histomorphometry analysis of the femoral diaphyseal cortical bone and the 5th lumbar vertebral body trabecular bone demonstrated a significantly higher cross-sectional area, periosteal perimeter, cortical porosity area, and a significantly lower marrow cavity area in 12-month-old KO mice compared with WT mice. These changes led to a 122% increase in cortical bone area in KO mice. OVX induced a similar decrease in cortical bone mass independent of genotype. As for vertebral cancellous bone, KO mice had significantly higher trabecular bone volume and trabecular thickness than WT mice. OVX reduced both trabecular thickness (-16%) and trabecular number (-29%) in WT mice, and induced a greater decrease in trabecular thickness (-34%) than trabecular number (-15%) in SOST KO mice. However, at 4-months post OVX, femoral and vertebral bone mass were still significantly higher in OVX SOST KO mice than sham WT mice (Figure).

We also examined the vertebral bone dynamic change induced by 2 weeks of OVX in SOST KO mice compared with WT mice (4-month-old mice). In this short-term study, increased bone formation and bone resorption post-OVX were observed in both WT and KO mice.

These results demonstrated that SOST KO mice maintained higher cortical and trabecular bone mass at an older age. However, KO mice were not resistant to the systemic bone loss induced by estrogen deprivation. SOST depletion during skeletogenesis did not interfere with bone resorption mediated by estrogen deficiency. Additionally, although OVX induced bone loss in SOST KO mice, the bone mass in these mice was still significantly higher than that in WT sham controls after long-term OVX. This suggests that the higher bone mass in SOST KO mice present at the time of OVX provided protection against the deterioration of skeletal mass and structure induced by OVX.

Figure

*p<0.05 compared with WT Sham-OVX, **p<0.001 compared with WT Sham-OVX. N=11/group.

Effect of Vitamin K₂ on Cortical and Cancellous Bone Mass and Hepatic Lipids in Rats with Combined Methionine-Choline Deficiency. Jun Iwamoto*¹, Azusa Seki², Hideo Matsumoto¹. ¹Keio University School of Medicine, Japan, ²Hamri Co., Ltd., Japan

The present study examined changes of cancellous and cortical bone in rats with combined methionine-choline deficiency (MCD). In addition, the effects of vitamin K₂ on cortical and cancellous bone mass and hepatic lipids were investigated in rats with MCD. Six-week-old male Sprague-Dawley rats were randomized into three groups of 10, including an age-matched control (standard diet) group, MCD diet group, and MCD diet + vitamin K₂ (menatetrenone at 30 mg/kg/day orally, five times a week) group. After the 1-month experimental period, histomorphometric analysis was performed on cortical and cancellous bone from the tibial diaphysis and proximal metaphysis, respectively, while histological examination of the liver was performed

after staining with hematoxylin & eosin and Oil Red O. MCD rats displayed weight loss, diffuse and centrilobular fatty changes of the liver, and a decrease of the cancellous bone volume per tissue volume (BV/TV) and percent cortical area (Ct Ar) as a result of decreased trabecular, periosteal, and endocortical bone formation along with increased trabecular and endocortical bone resorption. Administration of vitamin K₂ to rats with MCD attenuated weight loss, accelerated the decrease of cancellous BV/TV due to an increase of bone remodeling, and ameliorated the decrease of percent Ct Ar by increasing periosteal and endocortical bone formation. Vitamin K₂ administration also prevented MCD-induced diffuse fatty change of the liver. These findings suggest a beneficial effect of vitamin K₂ on cortical bone mass and hepatic lipid metabolism in rats with MCD. The loss of cancellous bone mass could possibly have been due to re-distribution of minerals to cortical bone.

Exported 18kDa Isoform of Fibroblast Growth Factor-2 Improved Bone Regeneration in Critical Size Mice Calvarial Defects. Daisuke Ueno*¹, Liping Xiao², Liisa Kuhn², Marja Marie Hurley³. ¹Tsurumi University, Japan, ²University of Connecticut Health Center, USA, ³University of Connecticut Health Center School of Medicine, USA

In this study we utilized Col3.6-18kDa FGF2-IRES-GFP sapphire transgenic (18kDa TgFGF2) mice in which a 3.6-kb fragment of the type 1 collagen 5' - regulatory region (Col3.6) is associated with green fluorescent protein-sapphire (GFP saph) expression combined with an induced over-expression of only the 18kDa isoform of FGF2. Vector only transgenic mice (Col3.6-IRES-GFPsaph, VTg) were utilized as controls. The purpose of this study was to analyze the bone regenerative capacity of the 18kDa TgFGF2 mice relative to vector only controls in a calvarial defect model. Bilateral calvarial defects (3.5 mm) were created in parietal bones of 18kDa TgFGF2 transgenic mice (n=5) and vector mice (n=4). A scaffold made of 70% type 1 collagen and 30% hydroxyapatite that was 3.5 mm in diameter and 1.5 mm thickness was placed into the defects. All mice were labeled with calcein and xylene orange on day 7 and day 2, respectively, before euthanasia. New bone was assessed by micro-CT of live animals (VIVA-CT) at 4, 6, 10, 16, 24 and 27 weeks post-surgery (Fig. 1). The experiment was terminated at 29 weeks post surgery and digital x-rays of the skulls were taken. The non-filled defect area was quantified from the x-ray images. There was a 47% significant decrease of the original defect area from 18kDa TgFGF2 mice compared with vector mice (3.020.31 cm² vs 5.710.73 cm² P< 0.008). Histologic analysis of the excised calvaria was performed. Samples were frozen, embedded and 7µm sections were taken through the middle of the defect to assess bone healing. Sections were scanned at 100x for GFPsaph, calcein, xylene orange and bright field using a Zeiss Axioplan 200 inverted microscope with a Zeiss AxioCam color digital camera. At all time points, the defect size was smaller in 18-kDa TgFGF2 mice compared with vector only mice indicating that the 18-kDa over-expression enhances bone defect repair. The majority of new bone formed at the defect edges with a few small islands of bone in the center of the defect. The double label distance of the new bone in the defect area was increased in 18kDa TgFGF2 mice compared with VTg (8.380.66µm vs 4.860.50µm) consistent with the observed increased bone formation (Fig. 2). The results of the present study demonstrate that FGF-2 over-expression can enhance bone healing and provides a rationale for the clinical application of a local gene therapy strategy to augment bone fracture healing.

Figure 1. Representative VIVA-CT images of calvarial defect. Scans were taken at 4, 6, 10, 16, 24, 27 weeks post surgery on living mice.

Figure 2. Representative frozen section scanning images of calvarial defect. Calvaria were collected at 29 weeks post surgery. Mice were labeled with calcein and xylene orange on day 7 and day 2 before euthanasia. 7µm frozen sections were scanned at 100x for GFPsaph, calcein, xylene orange and bright field. Double labeled distance was measured by OsteoMeasure.

Correlations Between Serum Levels of TGF- β 1 and Bone Mineralization or Bone Strength Following Prolonged Bisphosphonate Treatments. Junjing Jia^{*1}, Wei Yao¹, Mohammad Shahnazari², Zhiqiang Cheng³, Sarah Amugongo⁴, Min Guan¹, Nancy Lane¹. ¹University of California, Davis Medical Center, USA, ²UCSF VA Medical Center, USA, ³University of California, San Francisco, USA, ⁴Department of Medicine, University of California Davis Medical Center, USA

Bisphosphonates (BPs) are the most common agents prescribed for the treatment for osteoporosis. While the anti-resorptive effects of the Bis are well documented, some investigators have reported that Bis may also have direct effects in regulating osteoblast differentiation through the involvement of TGF- β 1 signaling, and the reduction in TGF- β 1 signaling was shown to improve bone quality (Wu et al. Cell Stem cell 2010; Balooch et al. PNAS 2005). We hypothesize that Bis may alter TGF- β 1 serum levels, and this may be associated with overall bone quality and strength.

Serum levels of total serum TGF- β 1 levels, bone turnover, bone mineral density by microCT and biomechanical properties from bone cortical (tibiae) and trabecular bone (lumbar vertebral bodies) were obtained from three studies (Cheng & Shahnazari et al., JBMR 2008; 2011; Bone 2010): 1, Eighteen-month-old OVX rats received one iv injection of risendronate (500 μ g/kg) or zoledronic acid (100 μ g/kg). Rats were sacrificed on days 30, 60, 120 and 180. 2, Eighteen-month old OVX rats were treated with either risendronate (30 or 90 μ g/kg/month, sc. x3) or ibandronate (30 or 90 μ g/kg/month, sc x3) and were sacrificed at 24 months of age. 3, Six-month old OVX rats were either treated with continuous alendronate (OVX+Ale-Ale, 0.5 μ g/kg/3x/ week, sc) or alendronate for 3 months and then followed by vehicle (OVX+Ale-Veh). Rats were sacrificed on days 60, 150, 210 and 270. Correlation analyses were performed using Spearman Correlation test. We found 1, Single iv. BPs did not alter while continuous BP treatments dose-dependently increased total serum TGF- β 1 levels, which remained elevated even when BP treatment was withdrawn. 2, Total serum TGF- β 1 correlated with bone resorption (DPD/Cr). 3, No correlation was found between total serum TGF- β 1 levels with the degree of bone mineral density (DBM) of the trabecular bone or trabecular bone strength. 4, Total serum TGF- β 1 levels negatively correlated with DBM of the cortical bone and cortical bone strength; and every unit increase in TGF- β 1 accounted for a 4% decrease in the cortical DBM and a 10% decrease in cortical bone strength measured by 3-point bending of the tibiae.

In conclusion, prolonged BP treatments increased total serum TGF- β 1 levels and this appears to have negative effects on cortical bone mineralization and strength. Further studies are now warranted to elucidate how TGF- β 1 alters bone quality.

Effects of Endurance Running and Zoledronic Acid Treatment on Ovariectomy-induced Osteopenia in rats. Tsang-hai Huang^{*1}, Hsin-Shih Lin², Shen-Yu S Hsieh², Ming-Shi Chang³, Rong-Sen Yang⁴. ¹National Cheng-Kung University, Taiwan, ²National Taiwan Normal University, Taiwan, ³National Cheng Kung University, Taiwan, ⁴National Taiwan University Hospital, Taiwan

PURPOSE: To determine the effects of endurance running (EXE) and zoledronic acid (ZOL) treatment on bone histomorphometry and related serum markers. **METHODS:** Eight-four female Wistar rats (35 weeks old) were assigned to one sham operated group (SHAM) and six ovariectomized groups with different doses of zoledronic acid treatment and endurance running training, which were the OVX, EXE, LOW, HIGH, EXE+LOW, EXE+HIGH groups (n=12 for each group). A single injection of zoledronic acid (20 or 100 μ g/kg body weight) was done on the LOW and HIGH groups (with or without exercise training), respectively. Animals of exercise groups were subjected to treadmill running training by a protocol of 16m/min, 60min/day and 5 days/week for 10 weeks. Statistical analysis was preceded using one-way ANOVA. Fisher's LSD method was adopted for post hoc comparisons when statistical significance (p<0.05) was shown. **RESULTS:** In static histomorphometric analysis, four ZOL treated groups show significant higher bone volume ratio (BV/TV, %) and thicker trabeculae. Moreover, the EXE group showed significantly higher BV/TV as compared to the OVX. Osteoclast numbers were significantly higher in the OVX group as compared to other groups. Dynamic histomorphometric parameter of MS/BS (%) was significantly higher in the OVX and EXE groups as compared to the other groups. In serum marker assays, the EXE group and LOW+EXE groups revealed significantly higher serum phosphorus. C-terminal telopeptides of Type I collagen (CTX-I) showed no difference among groups. However, after normalized CTX-I by values of BV/TV, the OVX group showed a

significant higher modified CTX-I as compared to the EXE group, and, both them were significantly higher than all the other groups. In bone formation marker, the SHAM, OVX and EXE groups showed significantly higher serum osteocalcin as compared to the four ZOL treated groups. In addition, IGF-1 and IGFBP-3, were significant or marginally lower and higher, respectively, in the three exercise-trained groups as compared to the other four groups. Ratio between IGF-1 and IGFBP-3, which could served as another index of aging, showed significantly lower values in three exercise groups while the OVX group revealed the highest values in this index.

CONCLUSION: Exercise and zoledronic acid treatment seemed to protect ovariectomized induced bone degradation via different pathways. No synergistic effects were shown between exercise training and zoledronic acid treatment.

Flaxseed Along with Low-Dose Estrogen Therapy Protects Bone Tissue by Favorably Influencing Bone Turnover in Ovariectomized Rats. Sandra Sacco^{*1}, Jianmin Chen², Bernhard Ganss², Lilian U. Thompson², Wendy Ward². ¹University of Toronto, Switzerland, ²University of Toronto, Canada

Background: Using the ovariectomized (OVX) rat model of postmenopausal osteoporosis, we previously demonstrated that flaxseed (FS), rich in phytoestrogens and n-3 polyunsaturated fatty acids, provides the greatest protection to bone mineral density (BMD), bone microarchitecture and strength at the lumbar vertebrae when combined with low-dose estrogen therapy (LD) compared to either treatment alone. We also showed that FS feeding results in the incorporation of phytoestrogen lignan and n-3 polyunsaturated fatty acids in skeletal tissue. These results suggest a potential role for FS to increase the effectiveness of LD during postmenopausal bone-loss.

Objective: To determine the effects of FS combined with LD on bone turnover in OVX rats to explain our previous findings.

Study Design: 3-month-old female Sprague-Dawley rats (OVX, n=56; SHAM, n=14) were randomized 3 weeks following ovariectomy or sham surgery to: 1) SHAM, 2) OVX, 3) OVX+FS, 4) OVX+LD or 5) OVX+FS+LD. Ground FS was added to the AIN-93M diet (100g/kg diet), and LD (0.42 μ g 17 β -estradiol/kg body weight per day) was delivered by a subcutaneous implant. After 2 weeks, rats were killed and the fifth lumbar vertebra and serum were collected. Histological analyses of vertebra were performed to determine bone volume fraction, osterix, osteocalcin, tartrate-resistant-acid-phosphatase-5 β (TRAP-5 β), osteoprotegerin (OPG) and receptor activator of NF- κ B ligand (RANKL). The following serum markers of bone metabolism were also measured: osteocalcin, TRAP-5 β , C-terminal peptides of type I collagen (CTX), OPG, RANKL and the ratio of OPG to RANKL.

Results: FS+LD resulted in higher bone volume fraction (p<0.05), OPG (p<0.001) and lower osteocalcin (p<0.01) at the lumbar vertebra compared to the OVX control. Serum analyses complemented these findings; FS+LD induced lower TRAP-5 β (p<0.05), CTX (p<0.001), osteocalcin (p<0.01), RANKL (p<0.05) and higher OPG (p<0.05) and OPG/RANKL ratio (p<0.05) compared to OVX control. FS resulted in higher osterix (p<0.05) and serum OPG (p<0.05) while the effects of LD in lumbar vertebra and serum were intermediate to both the SHAM and OVX control groups and did not differ significantly from FS+LD.

Conclusion: These findings suggest that LD and FS+LD, and less so with FS, protect against the deterioration of bone tissue due to a reduction in bone turnover but the specific mechanisms of action require further investigation.

Green Tea Polyphenols Supplementation Improves Bone Microstructure and Quality on Long-term High-fat-diet-induced Obese Rats. Chwan-Li Shen^{*1}, Jay Cao², Raul Dagda¹, Samuel Chanjaplammootti³, Ming-Chien Chyu³, James Yeh⁴. ¹Texas Tech University Health Sciences Center, USA, ²USDA ARS, USA, ³Texas Tech University, USA, ⁴Winthrop-University Hospital, USA

We have demonstrated that green tea polyphenols (GTP) attenuate trabecular bone loss in various bone loss models. This study investigated the efficacy of GTP at bone microstructure and quality in high-fat-diet-induced obese rats. Thirty-six 3-month-old CD female rats were fed either a low-fat (LF, 10% energy as fat) diet (n=12) or a high-fat (HF, 45% energy as fat) diet (n= 24) at libitum for 4 months. Animals in the LF diet group continued in a LF diet for additional 4 months, while those in the HF diet group were divided into two groups: with or without GTP (0.5% wt/vol) in drinking water, in addition to a HF diet for another 4 months. Efficacy was evaluated in femur and tibia by dual-energy absorptiometry and histomorphometric analysis, respectively. In addition, bone strength using a 3-point bending test, body composition using a bioimpedance spectroscopy device, and serum leptin and insulin-like growth factor-I (IGF-I) concentrations using ELISA were also determined. Data were analyzed by one-way ANOVA followed by Fisher's LSD test. After 8 months of feeding study, compared to the rats in the LF diet (LF group), the rats in the HF diet (HF group) (i) had no impact on bone mineral density and strength at femur; (ii) increased trabecular separation, formation rate, and resorption rate, serum leptin and IGF-I levels, body weight, and fat mass; and (iii) decreased trabecular volume and thickness, femoral strength, and fat-free mass. Supplementation of GTP into the

drinking water for 4 months increased bone mineral density and strength, trabecular bone volume, thickness, and number, and fat-free mass, but decreased trabecular separation, formation rate, and resorption rate, fat mass, serum leptin and IGF-I in HF diet-induced obese rats. This study demonstrates that GTP supplementation in drinking water increased bone mineral density, strength, and microstructure through suppressing bone turnover rate. In addition, GTP supplementation also favored body composition through inhibiting leptin and IGF-I. The results from this animal model merit investigation of a potentially significant prophylactic role of green tea in bone health of obese humans.

Icaritin Exerts Beneficial Effect on Skeletal Muscle Independent of Estrogen Receptor Pathway in Rats with Established Osteoporosis Induced By Ovariectomy. Baoting Zhang^{*1}, Baosheng GUO², Yixin HE³, Ling Qin⁴, Ge Zhang⁵. ¹Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, ²Prince of Wales Hospital, Hong Kong, ³The Chinese University of Hong Kong, Hong Kong, ⁴Musculoskeletal Research Laboratory, Department Of Orthopaedics & Traumatology, The Chinese University of Hong Kong, Hong Kong, China, Hong Kong, ⁵Prince of Wales Hospital, Hong Kong

We have reported that Icaritin prevents both bone loss and muscle dysfunction during osteoporosis development in ovariectomized rodents via estrogen-receptor (ER) -dependent and -independent pathways, respectively. This study aimed to examine the treatment effects of Icaritin on muscle and bone in rats with established osteoporosis induced by ovariectomy and its association with ER pathway. One hundred and ten 9-month-old female Wistar rats were either sham-operated (n=20) or ovariectomized (OVX) (n=90) and left untreated for 90 days. Before initial treatment, ten sham-operated and ten ovariectomized rats were sacrificed for verifying established osteoporosis. The remaining OVX rats were orally administered with vehicle (OVX-180) or Icaritin at low dose (Low-ICT) or Icaritin at middle dose (Middle-ICT) or Icaritin at high dose (High-ICT) or Icaritin combined with ER antagonist ICI 182780 (Low-ICT+ICI, Middle-ICT+ICI, High-ICT+ICI) or ICI 182780 only (ICI) for 90 days until sacrifice. The remaining sham-operated rats were served as control (Sham-180). After sacrifice, the femoral shaft was collected for microCT analysis (periosteal area, CSPA; endosteal area, CSEA; bone area, CSBA; cross-sectional moment of inertia, CSMI; volumetric bone mineral density, BMD) and for subsequent mechanical test (ultimate load and stiffness). The extensor digitorum longus (EDL) muscle was dissected for muscle contractile properties test (contraction time and peak tetanic force). For microCT analysis (Figure 1), OVX decreased CSBA, CSMI and BMD, and increased CSPA and CSEA. For mechanical test (Figure 2), OVX reduced the ultimate load and stiffness of the femoral shaft. For muscle functional test (Figure 3), OVX lowered peak tetanic force and prolonged contraction time and half-relaxation time. OVX-induced abnormalities in femoral shaft microstructure and mechanical properties were not changed by Icaritin at any dosage combined without or with ICI 182780. Interestingly, the peak tetanic force of EDL muscle was dose-dependently higher and the contraction and half-relaxation time was dose-dependently lower in the Icaritin-treated groups than that in the OVX-180 group. ER antagonist ICI 182780 didn't abolish the beneficial effect of icaritin on muscle contractile properties. It was concluded that Icaritin exerted beneficial effect on muscle independent of ER pathway in rats with established osteoporosis induced by ovariectomy.

Anti Osteoporotic Effects of 1,4-dihydroxy-2-naphthoic acid. Eiki Yamachika^{*1}, Masakazu Matsubara², Ken-ichiro Kita², Kiyofumi Takabatake², Yuki Fujita², Nobuyoshi Mizukawa², Tatsushi Matsumura², Hidetsugu Tsujigiwa³, Hitoshi Nagatsuka³, Seiji Iida².

Introduction

Homeostasis of bone remodeling is regulated by the endocrine, nervous, and immune systems, and various bone diseases occur when this balance is disrupted. One such disease is osteoporosis. Several medications have been attempted to redress that unbalanced condition and vitamin K2 is often used for the treatment of steroid induced or postmenopausal osteoporosis. Since vitamin K2 facilitates bone formation and has a naphthoquinone skeleton, we focused on 1,4-dihydroxy-2-naphthoic acid (DHNA), a bacterial substance with a naphthoquinone skeleton. DHNA is the main component of the metabolic by-products of fermentation by *Propionibacterium freudenreichii* ET-3 (PC). In addition, DHNA has been reported as a bifidogenic growth stimulator that specifically facilitates the growth of *Lactobacillus bifidus*, part of the normal intestinal flora. We had reported the anti osteoporotic effects of DHNA from the experiments with using steroid induced osteoporosis mice. In the present study, DHNA was administered to ovariectomized (OVX) mice to confirm the anti osteoporotic effect of DHNA for postmenopausal osteoporosis.

Materials and methods

This study used 30 female ICR OVX mice and 5 female ICR sham operated mice. OVX mice were randomized into 6 groups: DHNA group, Vitamin K2(VK) group, Risedronate(Ris) group, Ris+VK group, Ris+DHNA group and control group. In each group, drugs were administered daily for 5 weeks. In each group, the right femur was collected and fixed in 4% paraformaldehyde. Fixed tissues were demineralized using 10% ethylenediaminetetraacetic acid for 30 days, and embedded in paraffin. Paraffinized tissue was stained using hematoxylin and eosin (HE).

In addition, in each group, the left femur was collected for radiological analysis. Micro-CT machine (Scan X mate-A80; Scancom, Tokyo, Japan) was used to obtain 10- μ m sections of the distal epiphyseal femur. The resulting images were subjected to analysis using software (TRI/3D-BON; RATOC, Tokyo, Japan) to reconstruct 3D images for bone morphological analysis.

Results

Histological and radiological analysis showed that in the OVX group, the trabecular bone was narrow and the bone marrow cavity was wide. But these osteoporotic changes were improved in DHNA group, Ris group, Ris+VK group and especially in Ris+DHNA group.

Conclusions and discussion

DHNA was effective for improving osteoporotic bone changes in not only steroid induced osteoporosis model mice but also postmenopausal osteoporosis model mice.

Effect of SBM on the Degree of Mineralization of Bone of OVX rats. Racquel LeGeros, Ning Jiang*. New York University College of Dentistry, USA

It is now accepted that bone quality (including degree of mineralization, DOM) is a better determinant of susceptibility to fracture associated with osteoporosis. A novel compound, described as MZF-CaP or synthetic bone mineral (SBM) with composition and crystallinity similar to that of bone mineral was recently developed [LeGeros 2004]. Our long-term goal was to demonstrate that this novel compound will be effective, safe and affordable for osteoporosis therapy and bone loss prevention. Objective: This study aimed to determine the effect of SBM on the degree of mineralization (DOM) of tibia bone in an ovariectomized (OVX) rat model. Methods: 40 Sprague Dawley rats were randomly divided into 4 groups (n=10/group): sham-operated on low mineral diet (LMD), OVX on LMD, OVX on LMD + SBM (126) and OVX on LMD + commercial calcium supplement (Caltrate). The rats were sacrificed after 2 months; tibia bones were separated, cleaned, and stored in alcohol. Bone sections were analyzed using backscattered electron (BSE) microscopy (SEM, Hitachi S3500N, Japan) operated at 20 kV. The image histograms were rescaled such that value 0 was the darkest and 255 was the brightest then further divided into eight equal intervals. For image display purposes, we designed a pseudo-color look-up table featuring the same eight classes (1-32 dark blue, 33-64 blue, 65-96 green, 97-128 yellow, 129-160 orange, 161-192 red, 193-224 pink and =>225 grey) [Boyde et al 1999]. Results: BSE images demonstrated that OVX rats had the lowest DOM and the SBM treated group had the highest average DOM in the tibia bone compared to sham-operated, OVX OVX on Caltrate. Conclusions: SBM (126) administered orally as a supplement, was effective in preventing bone loss induced by ovariectomy in a rat model, and may have a potential as a therapeutic compound.

PTH 1-34 Rescues Impaired Fracture Healing in COX-2 Deficient Mice. Kiminori Yukata^{*1}, Chao Xie¹, Tian-Fang Li¹, Jennifer Jonason¹, Xinping Zhang², Edward Schwarz¹, Regis O'Keefe¹. ¹University of Rochester, USA, ²University of Rochester Medical Center, USA

Genetic ablation of cyclooxygenase-2 (COX-2) and its inhibition by non-steroidal anti-inflammatory drugs is known to impair fracture healing in mice. COX activity is essential for prostaglandin production, which activates PKA signaling through EP receptors. The parathyroid hormone receptor (PTH1R), similar to the EP receptors, is a G-coupled 7-transmembrane receptor that activates PKA signaling. PTH1R mediates the anabolic effect of Forteo (PTH 1-34) in osteoporosis patients via PKA signaling. Based on the similar signal transduction cascades induced by PGE2/EP4 and PTH/PTH1R, we hypothesized that PTH 1-34 rescues the defective fracture healing observed in COX-2 deficient (*Cox2*^{-/-}) mice. Here we tested this using a tibial fracture model. X-rays demonstrated that *Cox2*^{-/-} mice had decreased fracture callus formation and delayed healing. Micro-CT showed that *Cox2*^{-/-} mice treated with PTH 1-34 for 14 and 21 days had increased callus volume (2.22 and 4.02-fold, respectively;

$p < 0.05$) vs. untreated WT control. Quantitative histomorphometry showed that PTH 1-34 significantly increased both cartilage (day 7 and 10) and bone area (day 7, 10, 14 and 21) in *Cox2*^{-/-} mice ($p < 0.05$). Both chondrocyte (*coll10a1*) and osteoblast (*osteocalcin*) marker genes were increased in PTH 1-34 treated *Cox2*^{-/-} mice. PTH 1-34 treatment resulted in persistence of cartilage, consistent with a delay in endochondral bone formation in both genotypes. PTH 1-34 also increased both cell number (1.82 fold) and percentage of PCNA positive cells (11.7% vs. 0%) in the periosteum of *Cox2*^{-/-} mice on day 7 vs. untreated control. Consistent with these observations, *cyclin-D1* and β -catenin gene expression increased in *Cox2*^{-/-} fracture callus and in cell cultures of periosteal progenitor cells isolated from WT and *Cox2*^{-/-} callus. Finally, biomechanical testing showed that the maximum torque of fractured tibiae in treated *Cox2*^{-/-} mice was significantly increased vs. untreated control (166%, $p < 0.05$). Collectively, these results demonstrate that PTH 1-34 treatment rescues both structural and biomechanical fracture healing defects in *Cox2*^{-/-} mice, and suggest that PTH acts by increasing stem cell proliferation, chondrogenesis, and osteoblast differentiation. A more complete understanding of the effects of PTH 1-34 and its target cell populations will enhance the translation of this important anabolic agent into new treatments for bone repair.

Daily Administration of Eldecalcitol (ED-71), an Active Vitamin D Analog, Increases Bone Mineral Density by Suppressing RANKL Expression in Mouse Trabecular Bone. Suguru Harada^{*1}, Toshihide Mizoguchi², Yuko Nakamichi², Yasuhiro Kobayashi², Satoshi Takeda¹, Sadaoki Sakai¹, Fumiaki Takahashi¹, Hitoshi Saito¹, Hisataka Yasuda³, Nobuyuki Udagawa², Tatsuo Suda⁴, Naoyuki Takahashi². ¹Chugai Pharmaceutical Co., LTD., Japan, ²Matsumoto Dental University, Japan, ³Oriental Yeast Company, Limited, Japan, ⁴Research Center for Genomic Medicine Saitama Medical School, Japan

Eldecalcitol (ED-71) is a new vitamin D₃ derivative recently approved for the treatment of osteoporosis in Japan. Previous studies have shown that the daily administration of ED-71 increases bone mineral density (BMD) by suppressing bone resorption in various animal models. However, the mechanism of inhibition of in vivo bone resorption by ED-71 remains unknown. In this study, we examined how ED-71 suppresses bone resorption in vivo, using in vivo analyses of bone histomorphometry and osteoclastogenesis. Daily administration of ED-71 (50 ng/kg body weight) into mice for 2 and 4 weeks increased BMD in femoral metaphysis without causing hypercalcaemia. Bone and serum analyses revealed that the ED-71 administration inhibited both bone resorption and formation, indicating that the increase in BMD by ED-71 is due to the suppression of bone resorption. This suppression was associated with the decrease in the number of osteoclasts in trabecular bone. We previously identified cell cycle-arrested receptor activator of NF- κ B (RANK)-positive bone marrow cells as quiescent osteoclast precursors (QOPs) in vivo. Daily administration of ED-71 affected neither the number of RANK-positive cells in vivo, nor the number of osteoclasts formed from QOPs in ex vivo culture. In contrast, the ED-71 administration suppressed the expression of RANK ligand (RANKL) mRNA in tibiae. Immunohistochemical experiments also showed that the perimeter of RANKL-positive cell surface around the trabecular bone was significantly reduced in ED-71-treated mice than in the control mice. These results suggest that the daily administration of ED-71 increases BMD by suppressing RANKL expression in trabecular bone in vivo.

Activating Mutation of the Calcium Sensing Receptor: A Single Centre Experience. Shaila Sukthankar^{*}, Sarah Ehtisham, Zulf Mughal. Royal Manchester Children's Hospital, United Kingdom

Introduction: Activating mutation of the calcium sensing receptor (CaSR), with gain in function in the renal tubule and the parathyroid gland, is associated with hypocalcaemic hypercalcaemia. Aggressive treatment to 'normalise' serum calcium level can lead to progressive hypercalcaemia and eventual nephrocalcinosis in the long term. It is important to recognise and distinguish this condition from other well-established aetiologies of primary hypoparathyroidism.

Aims and methods: We describe our single centre experience of symptoms, investigations and management of 6 children with activating mutation of the CaSR.

Results: Six children (3 boys) presenting with hypocalcaemia were found to have activating mutation of the CaSR. Four were asymptomatic. One had sensory neural deafness, autism and seizures for several years, with cerebral dysplasia. One had palpitations with flushing episodes, and incidental hypocalcaemia. Initial renal ultrasonography was normal in all. Five were started on oral 1- α hydroxycholecalciferol. Shortly after starting treatment, while serum calcium levels were still subnormal (1.8 - 2.1 mmol/L), there were sharp rises in the urinary calcium: creatinine (Ca:Cr) ratio (up to 1.4) - confirming hypocalcaemic hypercalcaemia. Genetic studies confirmed an activating mutation of the CaSR in all five tested. All children are currently asymptomatic (follow-up period 10 months - 9 years). Four have now developed nephrocalcinosis.

Conclusions: Activating mutation of the CaSR is an important cause of apparent primary hypoparathyroidism with hypocalcaemia. Our experience highlights that

contrary to literature reports, these children can have profoundly low/unrecordable parathyroid hormone (PTH) levels. The key to diagnosis is the close monitoring of urinary Ca:Cr ratio which starts increasing at relatively 'subnormal' serum calcium levels. Cautious treatment with active vitamin D analogues, and close monitoring for 'optimal' serum calcium levels to minimise hypercalcaemia will help delay the onset of nephrocalcinosis and consequent long term renal impairment.

Case	Sex/Age Years	Age at diagnosis Years	Family History	Ca mmol/L (2.2 - 2.4)	PTH pg/ml (10 - 60)	Urine Ca:Cr (< 0.56)	Nephrocalcinosis
1	M/16	15	Yes	1.99	11	0.58	Yes
2	M/3.5	1.5	Yes	1.68	<3	0.3	No
3	F/6	0.1	Yes	1.8	15	0.5	No
4	F/9	0.02	Yes	1.74	15	0.5	Yes
5	F/8	7	Yes	1.6	<3	0.5	No

Glucocorticoids Downregulate Gap Junction Function and Connexin Expression through Autophagy Dependent and Independent Pathways. Rekha Kar^{*1}, Manuel Riquelme², Wei Yao³, Nancy Lane⁴, Jean Jiang⁵. ¹The University of Texas Health Science Center, USA, ²University of Texas Health Science Center, USA, ³University of California, Davis Medical Center, USA, ⁴University of California at Davis, USA, ⁵University of Texas Health Science Center at San Antonio, USA

Glucocorticoid (GC) therapy is the most frequent cause of secondary osteoporosis and osteocytes are a major bone cell type affected by GCs. Gap junction channels formed by connexins play important roles in bone development and function. Connexin 43 (Cx43) is the major connexin expressed in osteocytes. We observed that treatment with GCs, dexamethasone (Dex) significantly decreased gap junction intercellular coupling in MLO-Y4 osteocyte cells determined by both scrape loading and microinjection dye transfer assays. In addition, Dex treatment decreased expression of Cx43 protein in a dose dependent manner. Interestingly, a similar decrease in Cx43 protein was also observed in osteocytes of bones from GC treated mice as opposed to the placebo (PL) controls. To determine the possible involvement of the glucocorticoid receptor pathway, we treated MLO-Y4 cells with the steroid receptor antagonist RU486. Dex-induced downregulation of Cx43 protein level was completely abolished by this antagonist. Dex treatment not only decreased Cx43 protein, but also caused a reduction in Cx43 mRNA expression. However, GCs did not have any effect on luciferase gene expression driven by a 2kb Cx43 promoter, suggesting lack of regulation at the gene transcriptional level. To explore the possibility of post-transcriptional regulation of Cx43 by Dex, we performed real time quantitative PCR to determine the quantity of Cx43 mRNA at different time points in the presence of actinomycin D, an inhibitor of gene transcription. Coincubation with Dex greatly reduced Cx43 mRNA level, suggesting that Dex decreases Cx43 mRNA stability. We reported previously that Dex induces the development of autophagy in MLO-Y4 cells. The autophagy inhibitor, Bafilomycin A, partially rescued Dex-induced decrease expression of Cx43 and also restored the gap junctional coupling between the osteocyte cells. Thus, apart from decreased mRNA stability, autophagy-dependent protein degradation also contributes to decreased Cx43 by Dex. Furthermore, the bone anabolic reagents PGE2, parathyroid hormone, conditioned media collected from fluid flow-treated osteocytes and alendronate failed to rescue Dex-induced decreased Cx43 expression. Taken together, our study, for the first time, demonstrates the regulation of gap junction mediated intercellular communication and Cx43 expression by GCs, which sheds new insight into mechanisms of bone loss by excess GC therapy.

Regulation Of Osteoblastic 11 β -Hydroxysteroid Dehydrogenase Type 1 Expression By NF- κ B and p38 MAPK: Towards Osteoblast Specific Enzyme Inhibition. Rowan Hardy^{*}, Mohammad Ahasan, Chris Jones, Elizabeth Rabbitt, Karim Raza, Paul Stewart, Mark Cooper. University of Birmingham, United Kingdom

The 11 β -hydroxysteroid dehydrogenase type 1 (11 β -HSD1) enzyme is a tissue specific regulator of glucocorticoid (GC) action linked to the development of inflammation- and age-related osteoporosis. Systemic inhibition of 11 β -HSD1 activity has been proposed as a therapeutic option in these conditions. However, 11 β -HSD1 activity is also important in regulation of immune responses and the HPA axis. We previously demonstrated that proinflammatory cytokines, GCs and their combination dramatically increase 11 β -HSD1 expression and activity in osteoblasts. Expression in osteoblasts also increases with age.

We have now examined the mechanisms underlying regulation of 11 β -HSD1 activity in osteoblasts. Regulation was not due to any previously described

mechanism. The increase in activity induced by TNF α /IL-1 β was independent of new protein synthesis. 5' RACE and luciferase gene reporter studies showed that this effect was mediated via the classical HSD11B1 promoter. Chemical inhibitor studies showed that this increase in activity, along with basal enzyme activity, was mediated via NF- κ B. The involvement of classical NF- κ B signalling was confirmed using mouse embryonic fibroblasts (MEFs) where targeted deletion of p65/RelA, but not RelB, reduced basal expression and blocked cytokine induction of 11 β -HSD1. NF- κ B inhibitors had no effect on 11 β -HSD1 expression by other cell types e.g. hepatocytes. In lymphocytes GCs repress NF- κ B signalling by preventing nuclear translocation. However, translocation assays showed that GCs had no inhibitory effect on NF- κ B nuclear translocation in osteoblasts.

RelA KO studies also unmasked an inhibitory effect of TNF α /IL-1 β on 11 β -HSD1 expression. Chemical inhibitor studies showed that this effect was mediated through the p38 MAPK pathway. p38 MAPK inhibitors had the same synergistic effect on TNF α /IL-1 β induced 11 β -HSD1 expression as GCs. Cycloheximide studies showed the effect of GCs on p38 MAPK depended on new protein synthesis. Inhibitor and transgenic deletion studies confirmed the essential role of dual specificity MAPK phosphatase (DUSP1) in mediating the effect of GCs on p38 MAPK.

The mechanism by which expression of 11 β -HSD1 is regulated in osteoblasts is distinct from that in cells such as hepatocytes or lymphocytes. The finding that osteoblastic 11 β -HSD1 activity is regulated by NF- κ B and p38 MAPK pathways opens up new opportunities to inhibit or stimulate 11 β -HSD1 activity in an osteoblast restricted manner.

Endogenous Parathyroid Hormone Is Associated with Reduced Cartilage Volume in Vivo in a Population-Based Sample of Adult Women. Sharon Brennan¹, Flavia Cicuttini², Geoff Nicholson³, Julie Pasco⁴, Mark Kotowicz⁵, Margaret Henry⁶, Anita Wluka^{*7}. ¹Department of Epidemiology & Preventive Medicine, Monash University 2. Northwest Academic Centre, Western Section, Department of Medicine, The University of Melbourne, Australia, ²Department of Epidemiology & Preventive Medicine, Monash University, Australia, ³Rural Clinical School, The University of Queensland, Australia, ⁴Deakin University, Australia, ⁵Barwon Health, Australia, ⁶School of Medicine, Deakin University, Australia, ⁷Monash University & Alfred Hospital, Australia

Purpose: Osteoarthritis (OA) affects the whole joint, including bone and cartilage. Parathyroid hormone (PTH) has complex actions on bone. Recent animal and in vitro studies also suggest that PTH may affect articular cartilage. However, little is known of the relationship between PTH and joint structure in vivo. Thus, the aim of this study was to examine the association between endogenous PTH and cartilage volume in vivo a healthy adult population with no symptoms of knee OA.

Methods: Magnetic resonance imaging of the dominant knee was performed on 101 asymptomatic females aged 35-49 years (2007-9), from which knee cartilage volume was determined. Blood samples were obtained 10 years prior (1994-7), and stored at -80C for random batch analyses. Serum intact PTH was quantified by chemiluminescent enzyme assay. Serum 25-hydroxyvitamin D (25(OH)D) was assayed using an equilibrium radioimmunoassay after extraction with acetonitrile.

Results: A 1-unit (pmol/L) increase in PTH was associated with reduced medial cartilage volume [regression coefficient (standard deviation, p value) (-0.70.3, p=0.03), after adjustment for age, BMI and bone area. Further adjustment for seasonal variation (-0.80.3, p=0.01), and 25(OH)D (-0.080.4, p=0.03), did not affect the results. All results remained significant (p<0.01) after excluding subjects with osteophytes to account for the possibility of pre-clinical osteoarthritis. No significant associations were observed with lateral cartilage volume (0.2 \leq p \leq 0.5).

Conclusions: This study suggests increased levels of PTH might be detrimental to cartilage in humans in vivo. Animal studies suggest that increased PTH may reduce the ability of cartilage to heal following minor injury. This may explain our results, particularly given the effect we observed in the medial compartment which is exposed to higher loads during weight bearing compared to the lateral compartment.

Estrogen Receptor-Related Receptor Gamma (ERR γ) Is a Regulator of Bone Turnover. Marco Cardelli^{*1}, Ruolin Guo², Jonathan Boetto¹, Ralph Zirngibl¹, Jane Aubin³. ¹University of Toronto, Canada, ²University of Rochester, USA, ³University of Toronto Faculty of Medicine, Canada

Sex steroids, such as estrogen, play a role in the onset and severity of symptoms in arthritis and osteoporosis. Estrogen exerts its activity via its receptors, estrogen receptor α and β , which are members of the nuclear receptor family. There are also members of the family for which ligands have not been identified, the so-called orphan receptors. Amongst these are the estrogen receptor-related receptors (ERRs), ERR α , ERR β , and ERR γ . Previously, we showed that ERR α is highly expressed in bone and cartilage and that it plays a functional role in osteogenesis and chondrogenesis in vitro (Bonnelye et al., 2001; Bonnelye et al., 2007). We have also found that ERR γ is expressed in skeletal cells and tissues, albeit at levels significantly lower than ERR α . Consistent with recent evidence from *in vitro* and ectopic bone formation experiments, suggesting that ERR γ is a negative regulator of osteogenesis, impinging on the BMP-Runx2 pathway (Jeong et al., 2009), we also found that knockdown of ERR γ in calvarial cell cultures increases osteoblast differentiation and bone nodule formation. To extend our *in vitro* findings to the whole animal level, we have utilized an ERR γ knockout line (Deltagen). Whole mount skeletal preparations of late embryonic/early postnatal stages revealed an increase in intramembraneous bone formation, but no significant difference in long bone length. By μ CT, we determined that several trabecular bone parameters are increased in 14 week and 6 month-old heterozygous male mice, and at 6 months there is also a significant decrease in SMI (indicative of a more plate-like trabecular structure) and a decrease in trabecular number. qPCR on mRNA isolated from trabecular bone of heterozygous 2 month-old male mice revealed an increase in osteoblast markers *Osx*, *Alp* and *Bsp*, as well as RankL and cathepsin K (*Ctsk*), markers of osteoclast differentiation and activity, respectively, suggesting an increase in bone turnover in ERR γ +/- compared to WT mice. To investigate the underlying cellular mechanisms, femoral bone marrow cells were isolated from 2 month-old male mice and cultured under osteoblast differentiation conditions. ALP- and von Kossa-positive colonies (number and area) were increased in ERR γ +/- compared to WT cultures. In silico analysis for ERRE consensus sequences identified *Alp*, *Bsp*, and *Ctsk* as putative ERR γ target genes. Collectively, our data indicate that ERR γ is a negative regulator of osteoblasts and osteoclasts, and further experiments are in progress to define how ERR γ impinges on the osteoblast-osteoclast signaling axis.

Loss of ER α DNA Binding Suppresses Bone Gain In Vivo and In vitro Osteoblast Differentiation in the Context of a Wild-type or Null ER Alpha Allele. Orhan Oz^{*}, Asghar Hajibeigi. University of Texas Southwestern Medical Center, Dallas, USA

Estrogens regulate bone mass and metabolism through genomic and non-genomic pathways involving ER α . Mice have been created that harbor an ER α allele with a mutation in the DNA binding domain, the NERKI allele (N). We have previously reported that 129SvEv male mice with genotype +/-N have decreased bone mass and mechanical strength. To further understand the impact of the NERKI allele on bone metabolism we studied the prevention of bone loss and stimulation of bone gain in castrated male mice. WT and +/-N mice (n=5 or more/group) were castrated then immediately treated with estradiol pellets (0.1mg 21 day release) or after a 3 week washout. Bone mass was assessed by DEXA. The +/-N mice showed significantly less prevention of bone loss and lower bone gain compared to WT mice. Congenic B6 mice carrying the N allele were created by backcrossing 13 generations on the B6 JAX background. Male B6 -/N mice were created by mating with female ER α +/- mice. To study the impact of the N allele on in vitro osteoblastogenesis, bone marrow cells from +/-N and -/N male mice, grown in osteogenic medium, were tested for the ability to form alkaline phosphatase positive colonies and mineralized nodules versus WT or -/N marrow derived cells, respectively. The presence of the NERKI allele was associated with significantly fewer colonies and nodules. These data suggest that non-DNA binding activity of ER α may be involved in a pathway that suppresses osteoblastogenesis and bone formation.

A Cross talk between Prohibitin and Importin α 3 in Vitamin D signaling pathway- A novel implication in allergic airway inflammation. Tanupriya Agrawal^{*1}, Gaurav Gupta¹, Devendra Agrawal². ¹Creighton University, USA, ²Creighton University School of Medicine, USA

Purpose: Prohibitin is a ubiquitously expressed protein localized to the cell and mitochondrial membranes as well as the nucleus. Vitamin D has potent immunomodulatory properties including inhibition of proinflammatory cytokine production and induction of antimicrobial peptide synthesis in the cells of the innate immune system. NF- τ B is a transcriptional factor that activates many genes involved in inflammatory response. The nuclear import of p65 and p50 subunits of activated NF- τ B is

dependent on importin $\alpha 3$ (KPNA4) and importin $\alpha 4$ (KPNA3). We previously reported that calcitriol decreases the expression of importin $\alpha 3$ and nuclear translocation of NF- κ B in human bronchial smooth muscle cells (HBSMCs). TNF- α is a potent pro-inflammatory cytokine that plays a central role in systemic inflammation and airway hyperresponsiveness in asthma. In this study, we characterized the role of prohibitin in vitamin D receptor (VDR) function and identified prohibitin as a novel Vitamin D target gene which regulates the expression of importin $\alpha 3$. We also examined the effect of TNF- α on the expression of prohibitin with and without calcitriol.

Methods: HBSMCs were cultured in smooth muscle cell media containing 10% FBS. Cells in the passages 3-7 were stimulated with calcitriol (0.1-100nM) for different times (2- 36 hrs) and TNF- α (10ng/ml) for 12 hrs. Protein and mRNA expression of prohibitin were analyzed using Western Blot and qPCR, respectively.

Results: There was significant expression of mRNA and protein of prohibitin in HBSMCs. Treatment with increasing doses of calcitriol significantly increased mRNA and protein expression of prohibitin at 12hrs. There was a significant decrease in the mRNA and protein expression of prohibitin after stimulation with TNF- α for 12hrs and this effect was attenuated by calcitriol.

Conclusions: These data suggest that calcitriol increases the expression of prohibitin and this inhibits translocation of NF- κ B to nucleus by a novel mechanism of decreasing importin $\alpha 3$ expression. These results suggest a possible mechanism by which vitamin D may have a therapeutic effect in the treatment of allergic airway inflammation.

A Role of Calcium in the Control of Hair Cycling. Leila J. Mady*¹, Dare V. Ajibade¹, Arnaud Teichert², Daniel Bikle³, Sylvia Christakos¹. ¹University of Medicine & Dentistry & New Jersey - New Jersey Medical School, USA, ²Department of Medicine, UCSF, USA, ³Endocrine Research Unit, Division of Endocrinology UCSF, USA

The skin has long been known as a target organ for vitamin D action. Although 1,25(OH)₂D₃ and calcium promote differentiation of keratinocytes, current literature does not suggest a role for 1,25(OH)₂D₃ and/or calcium in hair follicle development. Vitamin D receptor (VDR) deficient mice have been shown to develop alopecia and a role for unliganded VDR in hair follicle development has been reported. Whether 1,25(OH)₂D₃ and/or calcium have a direct effect on hair follicle development is, as yet, unresolved. Recent findings from our lab indicate that calbindin-D_{9k} nullmutant (KO) pups generated from calbindin-D_{9k} KO parents fed a vitamin D deficient, low calcium (0.4%) diet have alopecia. The pups appear phenotypically normal until 13 days of age, after which the coat begins to look ruffled and progressively sheds in a caudocephalic direction. This telogenic effluvium results in a truncal alopecia totalis at 20 - 23 days of age, sparing only the head and a tuft around the base of the tail. The alopecia is complete by 23 days with a spontaneous recovery completed by the end of the 4th wk. Histological and immunohistochemistry (IHC) examination of whole skin thickness were examined. During the late stages of catagen and early telogen (days 17 - 23) the hair follicles became markedly dystrophic and the hair shafts were lost. Histological studies indicate increased number of keratinocytes in the epidermis and hair follicle transformation toward utricle. IHC shows increased expression of Loricrin in the epidermis and atypical expression, suggesting altered differentiation. Unlike the VDR KO mice, there is permanent recovery of alopecia. Feeding the mothers a vitamin D deficient/high Ca²⁺ (2%), high lactose (20%) diet during lactation (from birth to post natal day 28) results in a delayed and less severe phenotype in the pups. The hair follicle defect was rescued when the pups were fostered to mothers on vitamin D (2,000 IU/D2/kg diet) and calcium (1%) in the diet. When wild type C57BL6 parents were fed a vitamin D deficient low calcium diet, a similar alopecia was observed but it was not consistent (it was observed in approx. 40% of the litters). Taken together our results show that vitamin D and calcium directly affect postmorphogenic hair follicle development and that deficiency of vitamin D and calcium leads to non-cicatricial alopecia, indicating for the first time a role of calcium in hair cycling.

A Vitamin D₃ Analog, ED-71 Facilitates Vitamin D Receptor Degradation. Ken-ichi Takeyama^{*1}, Yumi Shiozaki¹, Yoko Yamamoto¹, Takeshi Kondo¹, Yuko Fukuda¹, Yuuki Imai¹, Suguru Harada², Naoki Tsuji², Fumiaki Takahashi², Hitoshi Saito² and Shigeaki Kato¹. ¹IMCB, Univ. of Tokyo, ²Chugai-pharm. Co., Japan

The active vitamin D₃ has a pivotal role in a many biological processes such as maintenance of calcium and phosphorous homeostasis, that are mediated by transcriptional regulation of target genes through nuclear vitamin D receptor (VDR). One of the vitamin D₃ analog, ED-71 has shown anabolic effect in bone, through the attenuation of bone resorption. Along with active vitamin D₃, ED-71 binds to VDR and induces the transactivation in the target genes. However, we never completely understood how ED-71 appears the attenuation of bone resorption through the VDR function, and its molecular mechanisms.

We have generated VDR deficient mice and analyzed its phenotype in bone. Intriguingly, heterozygous mutant mice of VDR (VDR+/-) only affect high bone mass phenotype, indicating that VDR function in bone negatively maintains, and rather, decreasing of VDR protein may facilitates bone volume and strength. Therefore, to test ED-71-mediated VDR function, we focused on the aspect of VDR protein in cells.

VDR protein levels in MG63 osteoblast like cell were significantly attenuated in the presence of ED-71. This attenuation of VDR protein was regulated by calpain which is calcium-dependent cysteine protease. Indeed, when a regulatory subunit of calpain, Capn1 was knocked down in the cells, the degradation of VDR protein was reduced, and ED-71-dependent VDR transactivation was significantly enhanced. Moreover, we could find that VDR protein levels in the ED-71-treated mouse bone were decreased, but not in other tissues. These findings indicate that ED-71 facilitates VDR degradation through the calpain protease, suggesting that ED-71-dependent anabolic effect in bone is mediated, at least in part, by VDR protein stability.

Automated Measurement of Total 25 Vitamin D on the IDS-iSYS System. Etienne Cavalier*, Anne-Catherine Bekaert, Agnes Carlisi, Jean-Paul Chapelle. University of Liege, CHU Sart-Tilman, Belgium

Introduction: Most health professionals know vitamin D for its critical role in increasing the efficiency of dietary calcium absorption and preventing rickets in children. In the past decade, emerging research has also uncovered other important relationships between vitamin D and bone health as well as new information indicating it could potentially play a significant role in strengthening the body's defenses against chronic and autoimmune diseases and in controlling the growth of cells (both normal and cancerous). These new evidences have fuelled the global demand for 25-OH D testing. Clinical laboratories are under pressured to seek automated reliable platforms for 25-OH D analysis to keep up with the demanded volume.

Objective: Immunodiagnosics System (IDS, Boldon, UK) has commercialized a direct, fully automated, co-specific immunoassay for 25-OH D for use on the IDS-iSYS system. We seek to assess the analytical performance of the IDS-iSYS 25-OH D assay, and to compare this method to LC-MS/MS, DiaSorin Liaison, and DiaSorin RIA methods.

Methods: We determined the repeatability and reproducibility on 6 pools, ranging from 6.2 ng/mL to 71.2 ng/mL, the limit of quantification (LoQ) and the accuracy profile of the IDS-iSYS 25-OH D method. A total of 88 samples, selected to represent a wide range of 25-OH D concentrations [5.6-85.6 ng/mL], was assayed by each method.

Results: Intra and inter-assay coefficients of variation (CV) were <11% at 6.2 ng/mL and <8% at 71.25 ng/mL. The LoQ was established at 6.2 ng/mL. The accuracy profile between 6.2 and 71.2 ng/mL showed that the risk that one result falls out of the 30% acceptance limit is <5%, indicating that the method is completely validated in this range. The actual assay working range is 5 to 140 ng/mL. A comparison of IDS-iSYS 25-OH D with LC-MS/MS yielded the Passing Bablok fit equation: IDS-iSYS = 1.03 x (LC-MS/MS) + 1.50. The corresponding equation with Liaison was: IDS-iSYS = 0.94 x (Liaison) + 2.41, and with RIA: IDS-iSYS = 1.00 x (RIA) - 0.62.

Conclusions: The IDS-iSYS 25-OH D is a robust method, presenting analytical performances in accordance with the clinical expectations. The IDS-iSYS 25-OH D values were in excellent agreement with those determined with LC-MS/MS, DiaSorin Liaison and DiaSorin RIA. This method demonstrated suitable characteristics as a high throughput, fully automated, co-specific 25-OH D assay for clinical laboratories.

Disclosures: Etienne Cavalier, None.

D Vitamin Levels in Children Born by Mothers with Vitamin D Deficiency. Ingrid Bergstrom^{*1}, Agneta Blanck², Lars Savendahl³. ¹Division of Endocrinology, Metabolism & Diabetes, Karolinska University Hospital, Huddinge, CLINTEC, Karolinska Institutet, Stockholm, Sweden, ²Unit for Obstetrics & Gynecology, Karolinska University Hospital, Huddinge, CLINTEC, Karolinska Institutet, Stockholm, Sweden, ³Division of Pediatric Endocrinology, Karolinska University Hospital, Solna, Department of Women's & Children's Health, Karolinska Institutet, Stockholm, Sweden, Sweden

It is important that the mother is vitamin D-sufficient enabling her to coop with the increased need of calcium during pregnancy when the fetus accretes large amounts of calcium. During pregnancy, vitamin D is transferred through the placenta to the fetus where it is stored. Consequently, the mother must increase her vitamin D intake to avoid deficiency. In the newborn, vitamin D stores are depleted by 8 weeks of age, if not supplemented. Breast fed infants are at risk of becoming deficient, as the amount of vitamin D taken up from the breast milk is low. In Sweden, it is recommended to supplement all infants with 10 micrograms of vitamin D3 daily starting from 2 weeks of age. We aimed to study if this recommendation is sufficient in infants of vitamin D deficient immigrant mothers. We characterized a cohort of 68 pregnant immigrant women living in Stockholm and compared their vitamin D levels with 51 controls born in Sweden of non-immigrant parents. The levels of 25 (OH) VitD3 was measured with a competitive RIA (Dia Sorin, Stillwater, MN). Intra-assay and inter-assay variations were 5% and 9%, respectively. Of the immigrant pregnant women, 77.9% had 25 (OH) VitD3 levels < 25 nmol/L and 29.4 % had levels <12 nmol/L. In contrast control subjects only 3.9% had vitamin D levels < 25 nmol/L and none had a level <12 nmol/L. We also made an attempt to monitor the infants of immigrant mothers and were able to follow 25 of the 64 infants up to the age of 6-12 months. Their mothers originated from Middle Asia (16), Africa (7) and South America (2). The table details 25 (OH) VitD3 levels in the pregnant mothers, in the umbilical cord at delivery, and in the infants at 6-12 months of age. Calcium levels in cord blood could only be measured in 11 out of 25 newborns, ranging between 2.3-3.0 mmol/L, which is normal. All newborns were normal and healthy. Their birth weight and Apgar score was normal. None of the children were reported to have a history of hypocalcemic seizures or any other condition leading to hospitalization. As shown in the table, most children had normal levels of vitamin D when assessed at 6-12 months of age (range 38-142 nmol/L) and none of them were severely deficient. We therefore conclude that the daily-recommended supplementation dose of 10 micrograms vitamin D3 is sufficient for children of vitamin D deficient immigrant women. Furthermore, our data suggest that compliance is good with the recommended vitamin D supplementation.

Table

	Mother; week 12 (n=25)	Mother; at delivery (n=12)	Umbilicus cord (n=12)	Infant; 6-12 mth (n=25)
25 OH vit D3 nmol/L (range)	14.8 (4.6) (10-28)	15.4 (8.7) (10-39)	23.3 (11.1) (20-54)	82.8 (29.7) (38-142)

Hypercalcemia In The Elderly: Malignancy?. ALVARO PUIG^{*1}, Daisy Acevedo², Sanford Baim¹. ¹Miller School of Medicine, University of Miami, USA, ²University of Miami, USA

INTRODUCTION:

The majority of hypercalcemia cases are caused by hyperparathyroidism or malignancy. Less frequent etiologies for hypercalcemia include granulomatous diseases and drug-induced. The clinical history should also focus on the use of vitamins and over the counter preparations that the general population worldwide often consumes and are believed to be harmless. We describe a case of severe hypercalcemia in an elderly man caused by vitamin D supplementation prescribed by his physician.

CASE PRESENTATION:

An 86 year old Ecuadorian male presented with a two week history of lower extremity pain, polyuria, lethargy, abdominal pain, and 10 pound weight loss.

Initial laboratory testing revealed: serum total calcium 14.9 mg/dL (8.5-10.5), albumin 3.2mg/dL (3.9-5), PTH intact 7.81pg/mL (10-65). His evaluation to determine the underlying cause of hypercalcemia included the following negative tests: SPEP, UPEP, Skeletal survey and CT of Chest, abdomen and pelvis.

Additional laboratory testing revealed: 25-hydroxyvitamin D level >316 ng/mL (30-100), 1,25-dihydroxyvitamin D 74 pg/mL (18-72), PTHrP 11pg/mL (14-27).

Initial treatment of hypercalcemia consisted of IV normal saline and pamidronate 60 mg IV x1. Due to cardiac comorbidities, IV fluids were held with worsening serum calcium and development of metabolic acidosis.

Endocrinology was consulted and after extensive questioning it became evident the patient had taken one 600,000 IU ampoule of vitamin D each week PO (Raquiferol by Spedro Caillon Laboratories), that had been recommended by his physician in Ecuador for the past 6 weeks (total dose 3,600,000 IU).

The patient was restarted on IV hydration, furosemide, and a second dose of pamidronate 90 mg x1. Volume status was carefully monitored. His mental and physical condition gradually improved and he was able to ambulate with minimal assistance. The patient had been admitted to the hospital for a total of 1 month.

Upon discharge, he was encouraged to continue aggressive oral fluid intake. Calcium levels were closely observed with twice per week outpatient follow up.

CONCLUSION:

Patients commonly take over-the-counter medications as well as those prescribed by their clinician that may be unknown to the admitting physician, emphasizing the importance of a thorough historical evaluation. Hypercalcemia due to vitamin D intoxication may be an underlying cause for life-threatening complications.

The Effect of Mechanical Loading on the Regulation of 1 α -hydroxylase in Primary Human Bone Cells. Karen Van Der Meijden^{*1}, Astrid Bakker², Nathalie Bravenboer¹, Paul Lips¹. ¹VU University Medical Center, The Netherlands, ²ACTA - UVA & VU, RESEARCH INSTITUTE MOVE, Netherlands

1,25-dihydroxyvitamin D (1,25(OH)₂D) can change the response of bone cells to mechanical stimuli, which has important consequences for the maintenance of bone mass by mechanical loading. Bone cells express the 1 α -hydroxylase gene CYP27B1, and they can likely convert 25(OH)D into its' active metabolite 1,25(OH)₂D. However the regulation of 1 α -hydroxylase in bone cells is largely unknown. The aim of this study was to investigate whether 25(OH)D affects the response of primary human bone cells to mechanical loading, similar to 1,25(OH)₂D. Furthermore, we examined whether mechanical loading affects the conversion of 25(OH)D to 1,25(OH)₂D by human bone cells.

Primary human bone cells were incubated with 25(OH)D (0 or 400 nM) or 1,25(OH)₂D (0 or 100 nM) for 24h. Thereafter the cells were subjected to pulsating fluid flow (PFF; 0.7 0.3 Pa, 5 Hz) or kept under static conditions for 1h, and postincubated (0 or 3h) without PFF. The response to PFF was quantified by measuring nitric oxide (NO) using Griess reagent and ATP production using the bioluminescence (Roche). mRNA expression of mechano-regulated genes with a vitamin D response element, as well as CYP27B1 and CYP24 expression were quantified using RT-qPCR.

The stimulation of NO and ATP release by PFF was not influenced by incubation with 25(OH)D and 1,25(OH)₂D in human bone cells. PFF increased RANKL, FGF23 and MEPE mRNA expression 3 hours after PFF. Both 25(OH)D and 1,25(OH)₂D decreased the stimulating effect of PFF on RANKL, MEPE and FGF23. CYP27B1 mRNA was increased after PFF in the presence or absence of 25(OH)D or 1,25(OH)₂D, but CYP24 mRNA was not affected by PFF.

These data show that 25(OH)D affects the response of bone cells to mechanical loading in a similar manner to 1,25(OH)₂D, which suggests that 25(OH)D is hydroxylated into 1,25(OH)₂D in primary human bone cells. Interestingly, PFF increased mRNA expression of CYP27B1, suggesting that physical activity may enhance the availability of 1,25(OH)₂D to bone cells, thereby contributing to bone mass regulation.

A Muscle Derived Soluble Factor Activates PI3K/ β -catenin Signaling in Osteocytes. Nuria Lara*¹, Katharina Jaehn¹, Sandra Romero-Suarez¹, Chenlin Mo¹, Lynda Bonewald¹, Marco Brotto¹, Mark Johnson².
¹University of Missouri - Kansas City, USA, ²University of Missouri, Kansas City Dental School, USA

Osteoporosis and sarcopenia are major clinical problems in the aging population and in many patients these two conditions occur concurrently suggesting a molecular coupling of these diseases. Current dogma states that muscle applies load to bone and bone serves as an attachment site for muscle. We hypothesize that muscle releases myokines that condition osteocyte responsiveness to mechanical loading.

Osteocytes are considered the principle cell type in bone for sensing and responding mechanical loading. We have shown that mechanical loading stimulates the release of PGE2 from osteocytes leading to a 3-4 fold activation of PI3K/Akt pathway which ultimately leads to activation of β -catenin signaling, a key enhancer of bone formation. In the presence of muscle cell (C2C12 myotubes) conditioned media (CM) the load induced activation of the PI3K/Akt pathway was 7-8 fold increased. In this current study we examined the effect of muscle cell CM on the activation of the PI3K/Akt and β -catenin pathways in osteocytes under static conditions.

CM was collected from C2C12 cells induced to differentiate into myotubes (MTCM) or non-differentiated myoblasts (MBCM). HeLa cell CM was used as a control. MLO-Y4 osteocyte like cells and long bone primary osteocyte enriched cells were exposed to blank, control or CM for 15, 30, 60 and 120 minutes, the cells collected, and western blotting performed using antibodies against phospho-Akt, and the endogenous control, GAPDH. Translocation of β -catenin to the nucleus was studied using immunofluorescence with an antibody to the active form of β -catenin.

In the presence of 1% or 10% MTCM, the PI3K/Akt pathway was stimulated by 2-3 fold over control, in a transient manner peaking at 30min and returning to basal levels after 2h. HeLa cell CM had no effect. The addition of MTCM also resulted in β -catenin nuclear translocation at 1h post-addition. We did not observe this effect when cells were exposed to 10% MBCM. These data suggest that factors released by fully differentiated, mature muscle cells condition and/or regulate the response of osteocytes to loading. The identification of this factor could result in a new paradigm for enhancing the anabolic effects of loading on the aged or diseased skeleton.

Age-related Decreases in Anti-oxidative response, Autophagy and Osteogenesis -Gene Profiles Studies. Min Guan*, Wei Yao, Junjing Jia, Nancy Lane.
University of California, Davis Medical Center, USA

Introduction. Bone loss is a normal consequence of aging and occurs in both genders after peak bone mass has been obtained. Starting in the third decade, women lose 35% of their cortical bone and 50% of their trabecular bone, whereas men lose approximately two thirds of this amount over their respective lifetimes. The accelerated bone loss during post-menopausal period is associated with increased osteoclast activity due to declining estrogen levels. The more gradual bone loss observed with aging results from lower recruitment of osteoblasts to the bone surface and reduced osteoblast activity. In addition, oxidative stress in bone tissue was increased with age, and was associated with increased osteoblast apoptosis (Jilka, Aging Cell, 2010; Manolagas Endo Reviews, 2010) Based on these data we hypothesize that mesenchymal osteogenic activity and lifespan with aging is influenced by oxidation (Almeida, JBC, 2009) and cell autophagy, (Chen, Cell Death Differ. 2009),

Methods. We evaluated the age-dependent changes in gene-profiles of the oxidative stress responsive, autophagic and osteogenesis pathways (SABioscience) in three models: 1, Primary bone marrow cells culture from 3-, 12- and 28-week-old C57BL/6 female mice. 2, Distal femur cortical bone of 10-, 16 and 56-week-old C57BL/6 female mice. 3, Cortical bones of 6-, 12-, 18- and 24-month-old female Fisher rats. The gene-profiles obtained from the three studies were used to perform correlation analyses using Spearman Correlation test (SPSS 12.0). Correlations between gene expressions of anti-oxidation and autophagy were considered significant at the 0.05 level (2-tailed).

Results. 1, Aging is associated with decreased activation of gene expressions associated with anti-oxidative defense (1-5-fold decreases), autophagy (1-5-fold decreases) and osteogenesis(1-10-fold decreases) in bone marrow cells in vitro and cortical bone in vivo. 2, Anti-oxidative responses were positively correlated with increase osteogenesis ($R^2=0.02$, $p=0.04$) but were not correlated to activation of autophagy with aging.

Conclusion. Aging is associated with decreases in anti-oxidation and autophagy in the bone tissues in rodents. An intervention that augments the anti-oxidant defense potential represents a potential strategy to maintain osteogenesis and ameliorate age-related decrease in osteogenesis.

Analysis of Lipid and Lipoprotein Metabolism of the Skeleton Using Nanocrystals. Alexander Bartelt*¹, Barbara Freund¹, Harald Ittrich¹, Joerg Heeren¹, Andreas Niemeier¹, Oliver T. Bruns².
¹University Medical Center Hamburg-Eppendorf, Germany, ²Heinrich-Pette-Institute for Experimental Virology & Immunology, Germany

Objective

Lipids are transported via plasma lipoproteins, which can be either processed to release lipid constituents or can be taken up as whole particles. Next to triglycerides and cholesterol, also lipophilic vitamin K is delivered by lipoproteins. However, the contribution of the skeleton as a lipid storage organ to lipoprotein metabolism is poorly understood. Recently, we followed the fate of lipids using lipoproteins engineered with radioactive superparamagnetic iron oxide (SPIO) nanocrystals embedded within the hydrophobic lipoprotein core^{1,2}. Here we analyze lipoprotein uptake into bone with magnetic resonance imaging (MRI) in vivo in real-time and quantify the contribution of the skeleton to systemic lipoprotein metabolism.

Methods

Fasted FVB mice were injected with lipoproteins labeled with SPIOs and uptake was visualized by MRI at 3T. ⁵⁹Fe-SPIO and ³H-triolein labeled lipoproteins were injected to follow lipoprotein particle and fatty acid uptake simultaneously. Uptake was determined in organ extracts by scintillation counting. Animal models of defective lipoprotein function were used to elucidate molecular pathways responsible for lipid entry into bone.

Results

The liver and brown adipose tissue, two major organs in lipoprotein clearance, show greatly enhanced T2* contrast after SPIO lipoprotein injection which is indicative for lipoprotein uptake. Compared to liver and brown adipose tissue, the contrast increase in femur is low. However, femur displays a strong specific fatty acid uptake for ³H-triolein which is independent of lipoprotein receptor ligand apolipoprotein E and neither is blocked by pre-treatment with natural lipoproteins. In contrast to fatty acids, uptake of ⁵⁹Fe-SPIO core label into femur is low, and notably is blocked by pre-treatment with lipoproteins.

Conclusion

The majority of lipids are taken-up by 1. initial binding of lipoproteins, 2. hydrolysis of triglycerides and uptake of fatty acids and 3. clearance of remnant particles by liver and brown adipose tissue. Of note, when calculated for total organs, the skeleton plays a major quantitative role in triglyceride clearance. As the close relationship between glucose metabolism and the skeleton has been demonstrated recently, the uptake of fatty acids adds another piece of evidence that there is a complex interaction between systemic energy metabolism and the skeleton.

SU0004

Beta-ecdysone has Bone, Cartilage and Muscle Protective but no Estrogenic Effects in Ovariectomized Rats. Dana Seidlova-Wuttke¹, Wolfgang Wuttke*².
¹Robert-Koch-Str. 40, Germany, ²University of Goettingen, Germany

Purpose: Estrogens exert beneficial effects in the bone, joint cartilage and striated muscles. Their use however bears several risks. Therefore, intensive search for non-estrogenic alternatives is going on. By quantitative computer tomography we demonstrated that β -ecdysone can partially prevent osteoporosis following ovariectomy (ovx) of rats. Whether the bone protective effects can be confirmed by histomorphometric structure (STRUT) analysis and whether β -Ecd can also exert protective effects on joint cartilage and striated muscles is currently unknown and was therefore tested. **Methods:** Ovx rats were treated orally over a 3 months with no Ecd (control) or with 18 and 57mg Ecd/day/animal. Estradiol-17 β benzoate (E2) (159 μ g/day/animal) fed animals served as positive controls. STRUT analysis was performed in the upper metaphysis of tibia; cartilage thickness in the knee joint and thickness of muscle fibers in the M. gastrocnemius were determined histomorphometrically. **Results:** STRUT analysis demonstrated significantly better trabecular architecture: number of free ends (termini) were lower, number of nodes (cross sections of trabecles) were higher in E2 and Ecd treated animals in comparison to the ovx controls. Thickness of the knee joint cartilage was lowest in ovx, highest in E2 and at intermediate values in the Ecd treated animals. The muscle fiber diameter was lowest in ovx and significantly higher in Ecd and E2 treated animals. **Conclusions:** It is concluded that Ecd has similar osteo- and chondro-protective effects as E2 and that it stimulates muscle fiber diameter which, taken together, are beneficial effects in the musculo-skeletal unit.

Role of SKI-1 Protease in Osteoblast/Osteocyte Formation and Maintenance of Bone and Body Mass. Jeffrey Gorski^{*1}, Nichole T. Huffman¹, Annita Achilleos², Paul A. Trainor², Nabil G. Seidah³, Clifford Rosen⁴, Lynda Bonewald¹. ¹University of Missouri - Kansas City, USA, ²Stowers Institute for Medical Research, USA, ³Institut de Recherches Cliniques de Montreal, Canada, ⁴Maine Medical Center, USA

SKI-1 (subtilisin kexin-like or site-1) is an auto-catalytically activatable cis-Golgi serine protease required for activation of membrane embedded transcription factors and secreted proteins such as bone sialoprotein and BMP1 enhancer PCOLCE1. Germ-line disruption of SKI-1 is embryonically lethal whereas cartilage-specific knockout of SKI-1 displays a lack of endochondral ossification. Recently we showed in UMR106-01 cells that SKI-1 regulates transcription of 140 genes (including DMP1, Phex, COL11A1, fibronectin, and fibrillin-2) encoding key extracellular matrix proteins required for normal bone mineralization via release of endoplasmic reticulum bound transcription factors SREBP-1, SREBP-2, and OASIS. To clarify the role of SKI-1 in bone, we produced three separate bone knockouts using 3.6kb COL1 Cre, 2.3kb COL1 Cre, and 10kb DMP1 Cre. These three Cre transgenes cover distinct stages of osteoblast to osteocyte differentiation or ontogeny. SKI-1 cKO produced with 3.6kb COL1 [SKI-1 (flx/flx) x Cre (+/-)] exhibited hindlimb paralysis and spinal fusions at birth and diminished BMD at 10 days, while with 2.3kb COL1 Cre, SKI-1 cKO were dramatically smaller than controls. 3.6kb COL1 SKI-1 cKO embryos at E12 were deficient in fibrillin-2 in the posterior region, a gene regulated by SKI-1 in vitro. In contrast, DMP1 Cre SKI-1 cKO mice and control littermates showed no difference in BMD or in body weight at 5-11 weeks of age and expected ratios of the various genotypes were obtained. However, at 6-8 months of age, DMP1 SKI-1 cKO mice displayed an apparent decrease in BMD [cKO (males, n=6): 0.0616 g/cc +/- 0.0034 STD vs. controls (males, n=5): 0.0646 g/cc +/- 0.0030 STD; p=0.1666] and an apparent increase in body mass. Specifically, three out of six of the male SKI-1 cKO mice weighed 43-50 g vs. an average of 36 g for male controls. While total fat content as assessed by DEXA also increased in DMP1 SKI-1 cKO, the proportion of fat to body mass remained relatively constant. Our results indicate that deletion of SKI-1 early during bone development (3.6kb and 2.3kb COL1 Cre) can lead to dramatic changes in skeletal development while deletion later in osteocytes (DMP1 Cre) leads to a decrease in postnatal bone formation and an increase in body mass, the opposite of that predicted by Wolff's law. Our new hypothesis is that SKI-1 is required for bone formation during embryonic growth and for maintenance of not only bone mass but also body mass in adults.

Approaches to Enhancing Sarco-osteoporosis Identification in Older Adults. Bjoern Buehring^{*1}, Diane Krueger¹, Neil Binkley². ¹University of Wisconsin, Madison, USA, ²University of Wisconsin, USA

Purpose: Chronologic age is a poor predictor of functional status. Nonetheless, age is currently included in the FRAX[®] fracture risk calculator but functional status and falls are not. Sarcopenia (SP) likely contributes to the increasing fracture risk currently attributed to age. Individuals with both osteoporosis (OP) and SP, so-called "sarco-osteoporosis" (SOP), may be at higher fracture risk than those with OP or SP alone. This study examined the overlap of OP and SP in older adults and the effect of advancing age on prevalence of SOP. Additionally, approaches to facilitate SOP identification, i.e., radius bone mineral density (BMD) measurement, and use of tallest historical, rather than current, height for SP diagnosis were explored.

Methods: BMD and total body composition data were acquired in community dwelling adults age 60+ by DXA using a GE Lunar iDXA densitometer. OP and SP were defined using standard criteria: T-score \leq -2.5 at the lumbar spine or hip and appendicular lean mass (ALM)/current height² $<$ 5.45 kg/m² (female) and 7.26 kg/m² (male). "Sensitive" OP criteria added the 1/3rd radius T-score, while "sensitive" SP criteria used historical tallest height instead of current height. The primary outcome was SOP prevalence by decade (60-69, 70-79, 80+). Fisher's Exact test was used to compare "sensitive" with standard criteria.

Results: 235 individuals (132 F/103 M) were included in this analysis. OP, SP and SOP prevalence was higher (p < 0.05) with the "sensitive" criteria and increased with advancing age. Prevalence of SOP was lower than OP or SP. Values for the SOP (standard/sensitive) criteria increased from 1.4%/3% in the 60-69 age group to 10.1%/25.6% in the 80+ age group. Prevalence of SP and OP increased from ~5%~10% to ~27%~47.5% in the same age groups.

Conclusions: Sarco-osteoporosis becomes more common with advancing age. The concept of sarco-osteoporosis might more accurately predict fracture risk than simple use of age. Similarly, use of 1/3rd radius BMD might improve fracture risk prediction in older adults. Use of historical tallest height and 1/3rd radius BMD may more appropriately identify those with sarco-osteoporosis. Future studies need to document whether those with SOP are at truly at higher fracture risk and explore the utility of 1/3rd radius BMD measurement and use of tallest height. Ultimately, sarco-osteoporosis might be integrated in fracture risk prediction models.

Are the Institute of Medicine Vitamin D Guidelines "Sufficient" for Frail Long Term Care Residents? MaryAnn Ferchak^{*1}, Megan Miller¹, Carroll Lee¹, Kimberly Zukowski¹, Subashan Perera², David Nace², Neil Resnick², Susan Greenspan³. ¹University of Pittsburgh, Division of Endocrinology, USA, ²University of Pittsburgh, Division of Geriatrics, USA, ³University of Pittsburgh, USA

Background: New Institute of Medicine (IOM) vitamin D guidelines suggest that levels of vitamin D above 20 ng/mL are sufficient for skeletal and muscle health.

Methods: To examine the impact of vitamin D deficiency and insufficiency for skeletal health and physical performance measures in frail elderly women, we measured 25 hydroxyvitamin D (liquid chromatography mass spectrophotometry) in 233 residents from long term care facilities, mean age 85 years. Vitamin D classification included: deficiency <20 ng/mL, insufficiency 20 \leq vitamin D <30 ng/mL, sufficiency \geq 30 ng/mL. Outcome measures included age, height, weight, body mass index (BMI), daily vitamin D and calcium intake, bone mineral density of the spine and hip (g/cm² and T-scores), Physical Activities of Daily Living (PADL), Instrumental Activities of Daily Living (IADL), Physical Performance Test (PPT includes timed 6 meter walk and sit to stand test), Duke Comorbidity Index (DCI), Short Verbal Mental Status Questionnaire (MSQ) and number of residents who fell in the past year.

Results: 19% of patients had vitamin D deficiency, 29% had insufficiency. By analysis of variance residents with vitamin D deficiency had lower serum calcium, higher serum PTH, longer sit to stand time and lower hip and femoral neck bone mineral density (Table). Vitamin D level was associated with the sit to stand time (p=0.024) with an estimated 0.4 second decrease for every 10 ng/mL increase in vitamin D. There were no significant differences in age, BMI, calcium or vitamin D intake, albumin, IADL, PADL, DCI, MSQ or history of falls. PTH levels were elevated (\geq 65 pg/mL) in 43%, 30% and 18%, respectively, among those with deficient, insufficient and sufficient serum vitamin D.

Conclusion: Higher levels of vitamin D are associated with greater BMD, walking and sit to stand performance measurements in frail residents of long term care. IOM guidelines may be "insufficient" for this cohort.

Variable	Vitamin D Deficiency	Vitamin Insufficiency	Vitamin D Sufficiency

Association of Spinal Muscle Composition and Prevalence of Hyperkyphosis in Healthy Community-Dwelling Older Men and Women. Wendy Katzman^{*1}, Peggy Cawthon², Greg Hicks³, Eric Vittinghoff⁴, John Shepherd⁴, Jane Cauley⁵, Tamara Harris⁶, Eleanor Simonsick⁷, Elsa Strotmeyer⁸, Catherine Womack⁹, Deborah Kado¹⁰. ¹University of California San Francisco, USA, ²California Pacific Medical Center Research Institute, USA, ³University of Delaware, USA, ⁴University of California, San Francisco, USA, ⁵University of Pittsburgh Graduate School of Public Health, USA, ⁶Intramural Research Program, National Institute on Aging, USA, ⁷Clinical Research Branch, National Institute on Aging, USA, ⁸University of Pittsburgh, USA, ⁹University of Tennessee, USA, ¹⁰University of California, Los Angeles, USA

Background: Older adults with hyperkyphosis are at increased risk of falls, fractures, and functional decline. Modifiable risk factors for hyperkyphosis have not been well studied. Our objective was to determine whether spinal muscle area and density are associated with hyperkyphosis, independent of age, race, sex, bone mineral density (BMD) and trunk fat. Methods: Using data from the Pittsburgh site of the Health, Aging and Body Composition study, we performed a baseline cross-sectional analysis. Participants were black and white men and women 70-79 years old (N=1172), independent in activities of daily living and able to walk 1/4 mile and up 10 steps without resting. We measured Cobb's angle of kyphosis from supine lateral scout computed tomography (CT) scans, and categorized hyperkyphosis as Cobb's angle $>$ 40 degrees. Axial images from lateral scout CT scans assessed spinal extensor muscle cross-sectional area and density (proxy for fat infiltration). Results: In our sample, 21% had hyperkyphosis. Prevalence of hyperkyphosis in black men was 11%; in white men, 17%; in black women, 26%; and in white women, 30%. In multivariate analysis, each standard deviation increase in muscle density was associated with a 29% reduction in the odds of hyperkyphosis, independent of covariates. Muscle area was

not significantly associated with hyperkyphosis. Conclusions: Lower spinal muscle density is associated with hyperkyphosis in healthy community-dwelling older men and women. This potentially modifiable risk factor could be targeted in exercise interventions. Randomized trials are needed to determine whether an exercise program targeting spinal muscle density reduces hyperkyphosis and in turn improves health outcomes.

Effect of Vitamin D Supplementation on Cognitive Function in Older Adults with Mild Cognitive Impairment - A Randomized Trial. Leon Flicker^{*1}, Kathryn Greenop², Osvaldo Almeida³, Helman Alfonso³, Christopher Beer³, Keith Hill⁴, Caryl Nowson⁵, Samuel Vasikaran⁶, Nicola Lautenschlager⁷. ¹University of Western Australia, Australia, ²Telethon Institute for Child Health Research, Australia, ³Western Australian Centre for Health & Ageing, Australia, ⁴Latrobe University, Australia, ⁵Deakin University, Australia, ⁶Department of Core Clinical Pathology & Biochemistry, PathWest Laboratory Medicine, Royal Perth Hospital, Australia, ⁷Department of Psychiatry, University of Melbourne, Australia

Aims: Vitamin D insufficiency has been associated with reduced cognitive function in older people. The effect of vitamin D supplementation on cognitive function is currently unknown. The aim of this study was to determine whether vitamin D supplementation would improve cognitive function in older people with mild cognitive impairment.

Methods: Participants fulfilled criteria for mild cognitive impairment (MCI) but did not have dementia. All subjects scored 1.0 SD below age and sex matched norms on any of the tests of the CERAD test battery including verbal fluency, Boston Naming Test, word list (learning, delayed recall and recognition) and constructional praxis (including recall task). All subjects had a MMSE score of 24 or greater at study entry. In addition, participants had vitamin D insufficiency as determined by serum 25-hydroxyvitamin D (25-OHD) levels between 12.5 and 70 nmol/l. Participants were randomly assigned a daily tablet of 1000IU of cholecalciferol or placebo. Participants with calcium intake < 800 mg per day were treated with 600 mg of calcium carbonate. The primary outcome measure was the Cambridge Cognitive Score (CAMCOG). The Clinical Dementia Rating Scale (CDR) was scored with additional information from an informant.

Results: Mean age of subjects who entered the study was 73.2 years for the 59 subjects in the vitamin group and 73.5 for the 58 in the placebo group. Mean baseline 25-OHD levels were 49.1 and 53.2 nmol/l, respectively. The two groups were balanced for baseline age, 25-OHD levels, CAMCOG and MMSE scores. 52 subjects in the vitamin group and 51 in the placebo group completed the 18 month intervention. The difference between groups in 25-OHD levels at the 18 month timepoint was 25.4 nmol/l (95% CI: 17.3, 33.4). There was an apparent difference in the changes in CAMCOG score between groups at the 12 and 18 month time points with worse performance in the vitamin group (see Table 1 and Figure 1). Subjects in the vitamin group were 2.85 (95%CI 1.12-7.28) more likely than the placebo group to develop a worse CDR score at the 18 month timepoint.

Conclusion: Contrary to our hypothesis, vitamin D supplementation did not improve the cognitive outcomes of older people with MCI. In fact, our results suggest that treatment with vitamin D may be deleterious.

Figure 1

Table 1 Change in CAMCOG Scores
Follow-up score minus baseline score (SD)

	6 months	12 months	18 months

Osteoporosis and Spinal Cord Injury in Patient with Ankylosing Spondylitis. Hyun-Sook Kim^{*}. Chosun University Hospital, South Korea

Objectives: Ankylosing spondylitis (AS) is an inflammatory disease involving the axial spine. Relating osteoporosis (OSP) is pathologic process of osteoclast activation and abnormal ankylosis. The spine is frequently kyphotic and has lost its flexibility. This is caused by a paravertebral benign ossification and sacroiliac joint. In the most severe form, these disease finally affects the entire spine including of cervical spine. We assess the OSP and related spinal injury sequelae in AS patients

Method: We present the atypical case of the severe OSP and related spinal traumatic neurological injury in AS patients

Result:

case1) Bilateral pedicle fracture in AS: A 63 year old man with 4 year history of AS was suddenly exacerbated low back pain. CT scan revealed bilateral L4 pedicle fracture accompanying spondylitis.

case2) Adjacent posterior element fracture in AS: A 54-year old man, with 10-year history of AS, had sudden onset back pain. CT scan confirm the transverse fracture through ossified posterior element below prior vertebroplasty.

case3) Epidural hematoma in AS: A 63-year old man, with 15-year history of AS suffered slip-down resulting paraplegia. lateral CT scanning revealed C7 interspinous fracture and intervertebral fracture. MRI confirmed the large epidural hematoma

Conclusion: Diffuse OSP responsible for bone fragility of AS is another feature established by recent data. The risk of vertebral fractures may be 7-fold increased compared with healthy individuals. The cervical spine in patient with long term AS has alteration in vertebral biomechanics that even minor trauma can cause fracture and serious neurological lesion

Disclosures: Hyun-Sook Kim, None.

Prevalence of Sarcopenia and Osteopenia among 70-80-year Old Finnish Women. Kirsti Uusi-Rasi^{*}, Pekka Kannus, Saija Karinkanta, Matti Pasanen, Radhika Patil, Harri Sievanen. UKK Institute for Health Promotion Research, Finland

Aging is associated with decline in muscle mass and bone mass. The European Working Group on Sarcopenia in Older People recently devised a consensus algorithm to define sarcopenia on the basis of specific cut-off points for gait speed, handgrip strength and muscle mass index. The WHO definition of osteopenia rests on DXA-measured femur T-score. This study assessed the prevalence of sarcopenia and osteopenia among a population-based sample of 408 independently living 70 to 80-year-old Finnish women. They had normal or somewhat declined functional ability (Short Physical Performance Battery, SPPB ranging from 1 to 12).

Femoral BMD and body composition were measured with DXA. Skeletal muscle mass index was defined as ASM (appendicular skeletal muscle mass/height²). Four-meter gait speed and handgrip strength were used to assess physical performance and muscle strength. Gait speed provides a predictive value for the onset of disability, and low handgrip strength is a quick, simple clinical indicator of frailty and impaired mobility.

Of 408 women, 351 had no indication of sarcopenia (gait speed >0.8 m/s and grip strength >20 kg). Among the remaining 57 women, ASM was assessed in relation to the proposed cut-off point of 5.5 kg/m². In only 4 women (1% of the total sample) the ASM fell below the threshold of sarcopenia. Eight women had bilateral hip prosthesis leaving 400 women for femoral BMD analyses, 36% (n=144) of these women had femur T-score <-1. Three of the four sarcopenic women also had osteopenia.

Our study suggests that when using the above described definition, sarcopenia is very rare among older home-dwelling women while every third had osteopenia. Those with sarcopenia tend to have low bone mass.

Disclosures: Kirsti Uusi-Rasi, None.

SU0012

Prevalence of Sarcopenia in Older Men: The Geelong Osteoporosis Study. Julie Pasco^{*1}, Margaret J Henry¹, Mark Kotowicz², Geoff C Nicholson³.¹Deakin University, Australia, ²Barwon Health, Australia, ³The University of Queensland, Australia

Purpose: While sarcopenia develops in all individuals with advancing age, the extent varies on a continuum that progressively impacts on mobility, independence and frailty. We aimed to determine the prevalence of sarcopenia in older men living in south-eastern Australia. As recommended by the European Working Group on Sarcopenia in Older People (EWG-SOP), we defined sarcopenia in terms of both low muscle mass and low muscle function.

Methods: A random sample of 1540 men aged 20-97yr was selected from the population and enrolled in the Geelong Osteoporosis Study (GOS), 2001-6 (67% participation). Muscle mass was measured as total lean mass by DXA (Lunar) and expressed as a percentage of body mass; low lean mass was defined as more than 1SD below the mean for young adult men. The cut-off point derived from GOS men aged 20-39yr was 66.9%. Low muscle function was based on performance and identified using the timed up-&-go (TUG) test (distance 3m, cut-off point 10s). Dietary energy intakes and dietary protein intakes (adjusted for energy intake), were assessed using a food frequency questionnaire. Physical activity scores were determined using a questionnaire for the elderly. BMD at the femoral neck was measured using DXA (Lunar). Associations between sarcopenia and dietary intakes, physical activity and BMD were determined using multivariate linear regression.

Results: Among 624 men aged 60-97yr, 233 had low lean mass, 169 had TUG>10s and 81 had both, thus meeting criteria for sarcopenia. Age-specific prevalence for sarcopenia was 60-64yr 3.8%, 65-69yr 7.7%, 70-74yr 12.2%, 75-79yr 13.5%, 80-84yr 16.7% and 85+ 31.2%. Sarcopenia was associated with lower adjusted mean dietary energy intakes (by 10.8%), protein intakes (4.9%), physical activity scores (40.4%) and BMD (4.1%); all $p < 0.03$.

Conclusions: The prevalence of sarcopenia increased with age, affecting one-third of elderly men, aged 85+. Prevalence data age-standardised to national levels (2001) suggest that sarcopenia affects 10.6% of Australian men aged 60+. Cross-sectional analyses reveal that sarcopenia is associated with reduced caloric intakes that are relatively low in protein, and that men with sarcopenia are habitually less active and have lower BMD at the femoral neck. Prospective data are now being sought to identify risk factors for sarcopenia.

The Association of Sarco-Osteopenia With Health Related Quality Of Life: A Population-Based Study In Estonia. Mart Kull^{*}, Riina Kallikorm, Margus Lember. University of Tartu, Estonia

Purpose. The aim of the study was to assess the association of a new sarco-osteopenia (SOP) phenotype, which was defined by decrements in both muscle functional and quantitative parameters with health related quality of life (HRQoL).

Methods: A population sample of 304 subjects aged 25-70 years was analysed with a Lunar DPX-IQ DXA machine and their HRQoL was assessed with the SF-36 questionnaire. SOP was defined as bone mineral density 1 standard deviation (SD) and height adjusted appendicular muscle mass 2SD and/or grip strength 2SD below the mean of 77 young individuals in the population sample (age 25-39). The impact of SOP on HRQoL was evaluated in the remainder (n=228) of the population sample with US norm based scoring. The study has Tartu University Ethics Committee approval and all patients signed a written informed consent. All study procedures were performed in accordance with the Declaration of Helsinki.

Results: The new SOP definition identifies 3-9% of middle aged (age 40-70 years) individuals as sarco-osteopenic. The prevalence of osteopenia/osteoporosis in the population group was considerably higher at 35-43%. Individuals who were sarco-osteopenic showed markedly lower scores in role-physical ($p=0.01$), vitality ($p=0.03$) and role-emotional ($p=0.02$) sub-scales of the SF-36 questionnaire (Figure). No difference in HRQoL was observed between osteopenic/osteoporotic and individuals with normal bone mineral density.

Conclusion: The new SOP definition identifies a population with significant decrements in both physical and mental health domains of HRQoL when compared with isolated osteopenia or osteoporosis subjects. We conclude that combining muscle as well as bone parameters under an umbrella diagnosis of sarco-osteopenia helps to isolate a more frail subpopulation than can be achieved utilising only bone density indices.

The Association of Sarcopenia and Sarcopenic-Obesity with Mobility Limitations in Older Men and Women: The Framingham Study. Alyssa Dufour^{*1}, Marian Hannan², Joanne Murabito³, Douglas Kiel¹, Robert McLean⁴. ¹Hebrew SeniorLife, USA, ²HSL Institute for Aging Research & Harvard Medical School, USA, ³Boston University School of Medicine & NHLBI's Framingham Heart Study, USA, ⁴Hebrew SeniorLife, Harvard Medical School, USA

Age-related loss of muscle mass and strength, termed sarcopenia, is common among older adults and associated with reduced mobility, functional disability and increased mortality. Our previous work suggested high % body fat was associated with mobility limitations (ML) in older adults, yet unexpectedly, low absolute lean mass and grip strength were not. New definitions of sarcopenia that account for body size and fat mass have since been proposed, as have measures of sarcopenic-obesity that assess the potential synergistic effects of combined low lean and high fat mass. We thus examined alternative definitions of sarcopenia and sarcopenic-obesity in relation to ML among 291 men and 513 women, who had information on ML and DXA, from the population-based Framingham Study Original Cohort. Whole body DXA (Lunar DPX-L) measured appendicular lean mass (ALM) and total fat mass in 1992-95.

Sarcopenia was defined using 2 published definitions: 1) $ALM/ht^2 > 2SD$ below young reference population; 2) lowest sex-specific quartile of residuals from regression of ALM on height and total fat mass. Obesity was defined as % body fat > 30 for men and > 40 for women, and combined with ALM/ht^2 to classify subjects into 4 sarcopenia-obesity groups: referent, obese, sarcopenic, sarcopenic-obese. Subjects reporting inability to walk 0.5 mi, walk up and down stairs, or perform heavy housework were defined as having ML. Sex-specific logistic regression calculated the odds of ML for sarcopenia and sarcopenia-obesity categories, adjusting for age (yrs), estrogen use (y/n), CVD (y/n), diabetes (y/n) and depression (CES-D). Mean age was 79 y (range 72-92). 18% of men and 30% of women had ML. In men, though CIs were wide, ALM/ht^2 and residuals sarcopenia were associated with 4-5 times the odds of ML (Table). Compared to referent men, the odds of ML for obese men was not significantly different, yet was 8-fold higher among sarcopenic men. Sarcopenic-obese men had only 4 times the odds of ML, suggesting no synergistic effect. In women, residuals sarcopenia, but not ALM/ht^2 , was associated with a 2-fold increase in the odds of ML, while there were no significant associations for sarcopenic-obesity. Our results support previous reports that lean mass sarcopenia definitions should consider body size and fat mass, and that lean and fat mass have different individual and combined effects on mobility in elders. Studies are needed to explore potential sex differences in these associations.

Table: Multivariable adjusted* odds ratios (OR) and 95% confidence intervals (CI) for association of sarcopenia and sarcopenia-obesity with mobility disability in 291 men and 313 women in the Framingham Study						
	Men			Women		
Sarcopenia	N	% limited	OR (95% CI)	N	% limited	OR (95% CI)
ALM/ht ²	60	36.67%	4.2 (2.06, 8.78)	65	33.85%	1.3 (0.72, 2.33)
Residuals	37	36.84%	4.5 (2.06, 9.81)	120	36.67%	1.7 (1.06, 2.69)
Sarcopenia-obesity						
Referent	108	9.26%	1.0	198	25.76%	1.0
Obese	123	15.45%	1.9 (0.81, 4.43)	250	32.80%	1.5 (0.94, 2.37)
Sarcopenic	35	42.86%	7.5 (2.80, 20.13)	44	34.09%	1.6 (0.75, 3.29)
Sarcopenic-obese	25	28.00%	4.2 (1.29, 13.32)	21	33.33%	1.7 (0.62, 4.74)

Higher Premenarcheal Bone Mass in Elite Gymnasts is Maintained into Young Adulthood After Long-Term Retirement From Sport: A 14-year Follow-Up. Marta Erlandson¹, Saija Kontulainen², Phil Chilibeck², Cathy Arnold², Bob Faulkner², Adam Baxter-Jones². ¹University of Toronto, Canada, ²University of Saskatchewan, Canada

Purpose: Sports that impact load the skeleton during childhood and adolescence increase determinants of bone strength such as bone mineral content and density; however, it is unclear if these benefits are maintained after retirement from the sport. The purpose of this study was to assess whether the skeletal benefits of gymnastics training previously reported in premenarcheal girls were still apparent 10 years after the cessation of gymnastics participation.

Methods: In 1995, 22 elite premenarcheal gymnasts 8-15 years of age were measured and compared to 22 age-matched non-gymnasts. The same former gymnasts and non-gymnasts were measured again 14 years later (2009-2010). Gymnasts had been retired from gymnastics training and competition for an average of 10 years. Total body (TB), lumbar spine (LS), and femoral neck (FN) bone mineral content (BMC) was assessed at both measurement occasions by dual energy X-ray absorptiometry (DXA). MANCOVA was used to compare gymnasts' and non-gymnasts' BMC while controlling for differences in body size and maturation (covariates: age, height, weight, and years from menarche (1995) or age at menarche (2009/10)).

Results: Premenarcheal gymnasts had significantly ($p < 0.05$) greater size adjusted TB, LS, and FN BMC (15, 17, and 12%, respectively). After retirement, gymnasts maintained similar size adjusted TB, LS, and FN BMC significant differences ($p < 0.05$) (13, 19 and 13%, respectively) compared to non-gymnasts.

Conclusion: Higher bone mass related to gymnastics training before menarche was still apparent even after long-term removal of the gymnastics-loading stimulus.

Disclosures: Marta Erlandson, None.

The Development of Neuromuscular Function in Pre-school Aged Children. Tom Hazel¹, Sarah Finch¹, Thu Trang Pham¹, Sonia Jean-Philippe¹, Catherine A. Vanstone¹, Sandra Dell'Elce¹, Atul K. Sharma², Hope Weiler¹, Celia Rodd¹. ¹McGill University, Canada, ²Montreal Children's Hospital, Canada

Childhood is a critical period for growth and development of the musculoskeletal system. However, the development of neuromuscular function in young children is not well established, as there are currently no data on children under the age of 6-7y. The objective of the current study was to measure neuromuscular function in pre-school children (3-5y of age) to provide data on their neuromuscular development. Using a

force plate (Kistler Instrument Corp., NY, USA), forty-nine children (26 boys, 23 girls; 3.71.1y) performed several neuromuscular function tests, including jumping (JMP), sit-to-stand (STS), and body sway tests. Children were grouped based on age, with $n=23$ at 3y, $n=11$ at 4y, and $n=15$ at 5y. One-way ANOVAs were used to compare age categories (3 vs 4 vs 5y) for indices of neuromuscular function (GraphPad Prism 5.00 for Windows, GraphPad Software, CA, USA). Mean (sd) height for age z-scores (3y: -0.10.8; 4y: -0.60.9; 5y: 0.41.5), and mean (sd) weight for age z-scores (3y: 0.50.7; 4y: -0.20.7; 5y: 0.51.1) were not different by age. Tables 1 and 2 summarize neuromuscular performance by age: JMP peak power ($P=0.01$) and normalized peak power (normalized for body weight, $P=0.05$), STS peak force ($P < 0.001$) and slope at 20-90% force (a proxy for muscle power; $P < 0.001$), and body sway amplitude ($P=0.03$) were all greater in 5y olds than in 3y olds. There were no age differences for JMP peak force, normalized peak force, or body sway velocity. These novel data demonstrate the progression of neuromuscular function in preschool aged children (3-5y of age), with significant differences observed in 5y old compared to 3y old children. Although originally developed for older children and adults, force-plate assessment of neuromuscular function is applicable in children as young as three years of age.

Table 1 Jumping (JMP) Performance				
Age (y)	Peak Force (N)	Normalized Peak Force (N/kg)	Peak Power (W)	Normalized Peak Power (W/kg)

Use of the Safe Functional Motion-Short Form Test to Classify Risk in Individuals Following a Distal Radius Fracture. Norma MacIntyre¹, Joy C. MacDermid¹, Ruby Grewal², Julie Richardson¹. ¹McMaster University, Canada, ²Hand & Upper Limb Centre, St Joseph's Health Centre, Canada

Purpose: Long and short forms of the Safe Functional Motion test (SFM) have been used to measure body mechanics and functional motion during performance of everyday tasks in individuals at risk for osteoporotic fracture. The predicted probability of a prevalent vertebral or hip fracture for 1257 individuals seen in an osteoporosis specialty clinic increased by 18 to 21% for each 10% decrease in SFM score regardless of bone mineral density (aBMD, g/cm^2). For some individuals, distal radius fracture (DRF) may be the first clinical manifestation of osteoporosis. The purpose of this study was to determine the feasibility of using the short form of the SFM (SFM-short) to assess movement patterns in individuals with a recent DRF which may predict an increased risk for subsequent fracture.

Methods: The SFM-short, a performance-based assessment tool for quantifying habitual movement patterns during 6 typical daily tasks - removing/putting on footwear, picking up a newspaper from the ground, placing a container on an overhead shelf, getting down/up off the floor, carrying groceries up/down stairs and an emergency task that simulates getting up in the night (assessing vestibular components of the balance system), was administered to individuals seen in a tertiary care centre between March 2009 and March 2011 following DRF. Total SFM-short score is reported as a percentage of the maximum points associated with 6 domains. T-scores for lumbar spine and hip aBMD were recorded if available. Participants were asked about osteoporosis risk factors fracture and completed the SF-12 to determine physical health status.

Results: Of 83 patients with a recent DRF enrolled in a concurrent study, 67 (5 men) consented to complete the SFM-short. Only 61 patients (4 men; mean(SD) age = 61.2(7.5) y; mean(SD) weeks post DRF = 2.9(1.8); 13 treated surgically) completed all 6 tasks. Testing took approximately 15 minutes. Table 1 summarizes patient characteristics with respect to each outcome measure. The association between SFM-short and SF-13 was $r = 0.013$.

Conclusions: SFM-short scores, aBMD, and risk factor profiles concur in indicating that not everyone in the DRF population has an elevated risk for osteoporotic fracture but a substantial proportion do. SFM-short scores provide information that is distinct from self-reported physical health status. These findings suggest that further study of the predictive ability of this tool for future fracture in this population is warranted.

SU0019

The Effect of Obesity on Pediatric Fractures. Rushyuan J. Lee^{*1}, Colleen Cullen¹, Josephina Baca-Asher¹, Meredith Lazar-Antman¹, Arabella Leet².
¹Johns Hopkins University, USA, ²Johns Hopkins University School of Medicine, USA

Purpose: Increasing obesity among children is a major health care concern. The purpose of this study is to examine children with fractures, comparing those who are normal weight with obese/overweight children.

Methods: 185 consecutive pediatric fracture patients were enrolled into an IRB approved registry. Information collected at the time of injury included: sex, age, height, weight, fracture location and pattern. Patients 2-16 years old were divided into two groups for comparison: (1) normal weight (2) obese/overweight (defined as > 85 %ile BMI for age). Statistical analysis was performed using Graph pad Prism 4 for Chi2 or Mann Whitney tests.

Results: The total population of 185 patients consisted of < 2 years of age (14), normal weight (112), and obese/overweight (59). Obese patients made up 22% of the entire population; obese/overweight combined were 34% of the study group. There was no difference between the mean ages in the normal weight group (9.4 yrs) compared with the overweight/obese group (9.0 yrs). There was a slight increase in numbers of girls in the obese group (16/59, 27%), compared with the normal weight children (27/112, 24%), but this was not statistically significant. The distribution of upper and lower extremity fractures was also comparable between groups. The normal weight group had a significantly higher rate of operative interventions compared to the overweight/obese group (33% vs 15%, $p < 0.05$). However, the overweight/obese group had a significantly higher rate of growth plate injuries (25% vs 10%, $p = 0.02$).

Conclusions: Twenty-two percent of children with fractures were obese which is higher than the expected prevalence of obesity in the general population. In contrast to the study by Rana, we report a lower number of operative cases in the heavier children(1). While Rana studied children from trauma registries, our patient population included both low and high energy mechanisms of injury. The growth plate is the weakest part of the bone, so the finding that obese/overweight children had a greater number of growth plate injuries is not surprising. Future studies include continued expansion of this database with the hope that understanding fracture patterns based on weight will lead to better injury protection strategies for obese children in the future.

Assessment of Bone Mineral Status in Children with Noonan Syndrome: Another Consequence of Dysregulated RAS-MAPK Signaling? Monica Grover^{*1}, Kiran Choudhry¹, Alyssa Tran¹, Susan Carter¹, E. O' Brian Smith¹, Kenneth Ellis¹, Brendan Lee². ¹Baylor College of Medicine, USA, ²Baylor College of Medicine & Howard Hughes Medical Institute, USA

BACKGROUND: The RAS/mitogen activated protein kinase (MAPK) pathway is essential for regulation of cell differentiation and growth. However, its role in skeletal tissue development is unclear. Various skeletal abnormalities including low bone density in Neurofibromatosis (NF) 1, a disorder of dysregulated MAPK signaling, has given insight into its role in skeletal homeostasis. Noonan Syndrome (NS) is also a disorder of RAS-MAPK pathway, with clinical features of a skeletal dysplasia, but little information about the mineralization of bone.

OBJECTIVE: We evaluated bone mineral status in children with NS.

DESIGN/METHODS: Using dual energy X-ray absorptiometry (DXA) bone status in 12 (9 males; 3 females) subjects (mean age 8.7 years) with NS was analyzed. The subjects were diagnosed with NS clinically and underwent genetic testing. 9 had mutation in PTPN11 gene, 1 in SOS1, and 2 patients had no mutations. As femur and lumbar BMD is unreliable at younger age, only total body measurements of bone were done. In subjects with low bone mass, indices of calcium-phosphate metabolism and bone turnover were obtained.

RESULTS: The mean height was low at 6.9 %ile. None of the subjects were on medications affecting bone metabolism or had history of fractures. BMC (bone mineral content) z-score calculations were based on age, gender, height, and ethnicity. Mean BMC z-scores were reduced at -0.89 gm (SEM +/-0.51) [95% CI -2.01; 0.23], P value 0.109. Whole body BMD (bone mineral density) z-scores were low. Mean total body BMD was -1.87g/cm2 (SEM +/-0.393), [95% CI -2.73; -1.0], P value 0.001. Most of our patients' height was < 2 SD for general population, we calculated total body BMD z-score based on height age. The mean adjusted total body BMD was -0.82g/cm2 (SEM +/-0.258), [95% CI -1.39; -0.25], P value 0.009. All biochemical parameters were within normal range. Serum IGF-1 and IGFBP3 were low normal.

CONCLUSIONS: We report low bone mineral density as compared to age and height matched controls and trend towards low bone mineral content as compared to age matched controls in NS. This is similar to the findings in the NF and indicates poor bone quality. The bone metabolism markers in our study indicated an absence of overt metabolic bone disease. Histomorphometric analysis of bone tissue from NS patients and mouse model of NS could further elucidate correlations between genetic defects in the RAS MAP kinase pathway and alterations in skeletal homeostasis.

Youth School Physical Education Grades and Tibial Bone Traits in Adulthood. Vera Mikkilä¹, Marika Laaksonen¹, Olli Raitakari², Sanna Tolonen^{*1}, Harri Sievanen³, Terho Lehtimäki⁴, Mika Kahonen⁵, Jorma Viikari⁶. ¹University of Helsinki, Finland, ²Turku University Hospital & Research Centre of Applied & Preventive Cardiovascular Medicine, Finland, ³UKK Institute, Finland, ⁴Medical School & Tampere University Hospital, Finland, ⁵Tampere University Hospital, Finland, ⁶Turku University Central Hospital, Finland

Bone mass in adulthood is determined by peak bone mass attained in early life and the rate of bone loss during lifespan. High bone mass achieved in childhood may decrease the risk of osteoporosis later in life. We studied whether in 9-18 years old children (girls, n=655; boys, n=496) physical education grades at school (grades from 4 to 10; 10 being the highest) are associated with the structural peripheral quantitative computed tomography (pQCT) bone traits measured from tibia in adulthood approximately 25 years later. Results were adjusted with adult height and weight.

In girls, higher school physical education grades were associated with higher trabecular bone density, bone mineral content (BMC) and bone strength index (BSI) at the distal tibia (linear, P-values≤0.02), and total area, BMC, cortical strength index (CSI) and stress-strain index (SSI) at the tibial shaft (linear, P-values≤0.02). In boys, higher school physical education grades were associated with higher total area, BMC and BSI at the distal tibia (linear, P-values≤0.007), and total area, BMC, CSI and SSI at the tibial shaft (linear, P-values<0.001). These findings suggest that youth physical activity has a great influence on bone health later in life and may, therefore, reduce the risk of osteoporosis.

Disclosures: Sanna Tolonen, None.

SU0021

A Comparison of Trabecular Bone Microstructure at the Distal Radius Between Postpubertal Asian and Caucasian Adolescents: An HR-pQCT Study. SoJung Kim^{*1}, Lindsay Nettlefold¹, Christa Hoy¹, Sarah Moore¹, Meghan Donaldson², Heather Macdonald¹, Heather McKay¹. ¹University of British Columbia, Canada, ²San Francisco Coordinating Center, USA

Fracture incidence is lower among Asians compared with Caucasians; however, areal bone mineral density (BMD) is also lower in Asians than Caucasians. With these incongruities, it is important to investigate ethnic differences in three-dimensional properties of bone microstructure that contribute to bone strength during growth. Therefore, we used high-resolution peripheral QCT (HR-pQCT; isotropic voxel size 80µm) to directly assess bone trabecular microstructure at the non-dominant distal radius (7% site) in Asian (n=66) and Caucasian (n=78) boys and girls (17.6 ± 1.8 yrs). We used cross-sectional HR-pQCT data from the longitudinal Healthy Bones Study to compare trabecular bone volume fraction (BV/TV, %), trabecular thickness (Tb.Th, µm), trabecular number (Tb.N, 1/mm), and trabecular separation (Tb.Sp, µm) between Asian and Caucasian adolescents. Asian participants were those with either

both parents or all four grandparents born in Hong Kong or China, India, Philippines, Vietnam, Korea or Taiwan and Caucasian participants were those with parents born in North America or Europe. We assessed height and weight using standard protocols. We assessed physical activity (PA) and calcium intake (mg/day) by questionnaires. We conducted a separate analysis for boys and girls when comparing ethnic groups. We performed multiple regression analysis to evaluate the variance in trabecular bone microstructure explained by ethnicity, after adjusting for age (yrs), weight (kg), calcium (mg/day), PA (min/day), and radial length (mm). The magnitude of the difference for trabecular variables between ethnicities (Asian-Caucasian) adolescents was similar for both sexes (Boys: Tb.Sp ~ 8.7 %; Tb.N ~ -6.8%; Girls: Tb.Sp ~ 8%; Tb.N ~ -6.5%). However, ethnicity was only a significant predictor of trabecular bone variables for boys (Tb.N (p<0.05) and Tb.Sp (p<0.01)). The small sample size for girls may explain the sex difference in outcome. Differences in dietary calcium (both), PA (boys) and age (girls) may also contribute to these findings. Longitudinal data are needed to further clarify these differences and their implications.

Table 1. Descriptive characteristics of post-pubertal Asian and Caucasian boys and girls.

Negligible Influence Of Vitamin D Status On Cortical Bone Development In Childhood: Findings From A Large Prospective Cohort Study. Adrian Sayers^{*1}, Debbie Lawlor¹, William Fraser², J.H. Tobias³. ¹University of Bristol, United Kingdom, ²Royal Liverpool University Hospital, United Kingdom, ³Avon Orthopaedic Centre, United Kingdom

Background and aims: How vitamin D status affects bone development is unclear. In a prospective cohort study, we investigated relationships between vitamin D status in childhood (reflected by plasma levels of 25(OH)D2 and 25(OH)D3 at age 9.9) and subsequent development of cortical bone (measured by tibial pQCT at age 15.5).

Methods: 3260 children from the Avon Longitudinal Study of Parents and Children were included. The proportion of variation in pQCT parameters explained by 25(OH)D2 and 25(OH)D3 was estimated from r² derived from crude regressions with/without seasonal adjustment of 25(OH)D3. Further analyses were by bootstrap linear regression with additional adjustment for age, sex, body composition, social economic position and physical activity.

Results: 25(OH)D3 was positively skewed and seasonally patterned, mean(sd) 23.5 (8.4) ng.mL⁻¹, whereas 25(OH)D2 was positively skewed with no discernable seasonal patterning, mean(sd) 1.8(1.8) ng.mL⁻¹.

In crude analyses, 25(OH)D2 and 25(OH)D3 together explained only 0.4% of the variability in cortical bone mineral density (BMD_C), 0.7% in cortical thickness, 0.02% in periosteal circumference (PC), and 0.2% in cortical bone mineral content. Most of this explained variability represented seasonal variation; 25(OH)D3 explained 0.4% of the variability in cortical thickness in unadjusted models and after seasonal adjustment it only explained 0.04% of the variability.

25(OH)D2 and 25(OH)D3 differed in their associations with cortical bone outcomes in fully adjusted models: 25(OH)D2 was inversely related to BMD_C [-0.041 (-0.073,-0.008), P=0.01], whereas no association was observed with 25(OH)D3 [0.005 (-0.016,0.026), P=0.65, beta (with 95%CI) represents SD changes per doubling of vitamin D], P=0.02 for difference in associations with 25(OH)D2 and 25(OH)D3. 25(OH)D2 was unrelated to cortical thickness (calculated as inverse of endosteal circumference adjusted for PC) [-0.019(-0.046,0.009), P=0.18], whereas 25(OH)D3 was positively related to this parameter [0.024(0.008,0.04), p=0.0035], P = 0.007 for difference in associations.

Conclusions: Vitamin D status in children showed negligible association with subsequent cortical bone development, particularly after adjusting for confounders. These results suggest that population-based vitamin D supplementation is unlikely to improve bone development in childhood, even if based on D3, which unlike D2 showed, albeit weak, evidence of a protective effect.

Non-Elite Gymnastics Induces Musculoskeletal Benefits in the Upper Limbs of Early Pubertal Girls: A 6-Month Study Using pQCT. Lauren Burt^{*1}, David Greene², Geraldine Naughton², Daniel Courteix³, Gaele Ducher⁴.

¹Centre of Physical Activity Across the Lifespan, Australian Catholic University, Australia, ²Centre of Physical Activity Across the Lifespan, School of Exercise Science, Australian Catholic University, Australia, ³Universite Clermont Ferrand Laboratoire De Biologie Des APS, France, ⁴Noll Laboratory, Department of Kinesiology, Penn State University, USA

Purpose

Little is known about the longitudinal musculoskeletal development of weight-bearing loading to the upper limbs of non-elite gymnasts during early pubertal growth. The purpose of this longitudinal study was to examine the effects of non-elite female gymnastics participation on upper body musculoskeletal parameters.

Methods

Eighty-four girls, (6-12 years, Tanner stages I to III) were divided into three groups based on their participation in gymnastics: high training (HGYM), 6-16 hr.wk⁻¹, low training (LGYM), 1-5 hr.wk⁻¹ and non-gymnasts (NONGYM). At baseline and 6 months, total density (ToD), bone mineral content (BMC), total and cortical area (ToA, CoA), bone strength (BSI and SSI) were assessed by pQCT at the 4% and 66% radius and ulna. DXA-derived BMC and lean mass in the arms, as well as pQCT-derived forearm muscle cross sectional area (MCSA) were also obtained. Upper body muscle function was assessed with generic assessments for explosive power, strength, and endurance.

Results

Growth rate (in height) over 6 months was not significantly different between groups. Arm lean mass, grip strength and muscle endurance, 66% BMC and ToA at radius 66% were the only bone parameters to increase over 6 months in NONGYM ($p<0.05$). Following body weight-adjustment, arm lean mass, SSI at the 66% forearm, ToA (66% radius), BMC and CoA (66% ulna), explosive power and muscle endurance, which were initially higher in gymnasts than NONGYM, remained higher at follow up. MCSA increased more in HGYM than both NONGYM and LGYM. At the 4% radius, HGYM had greater BMC, ToD and BSI than NONGYM at baseline, whereas LGYM had greater ToD ($p<0.05$). At 6 months, both groups of gymnasts had a greater increase in ToD at the 4% radius than NONGYM (LGYM +8% greater, HGYM +15% greater, $p<0.05$). HGYM had a greater increase in BMC and BSI at the 4% radius than both NONGYM (+25-45% greater, $p<0.01$) and LGYM (+20-28% greater, $p<0.05$).

Conclusion

At baseline, gymnasts had upper limb musculoskeletal benefits, potentially resulting from an average training history of three years. Benefits were maintained, and in some instances, increased over the duration of the study. Muscle function tests consistently showed superior skills among gymnasts, independent of hours of training. Although favorable skeletal gains were seen in LGYM, HGYM had the greatest gains. Musculoskeletal benefits beyond growth-induced effects exist following non-elite gymnastics participation during early puberty.

Optimizing Low-Magnitude, High-Frequency Vibration Parameters to Stimulate an Osteogenic Response in The mdx Mouse Model of Duchenne Muscular Dystrophy. Susan Novotny^{*1}, David J. Nuckley¹, Moiria Petit¹, Kristen A. Baltgalvis¹, Gordon L. Warren², Dawn A Lowe¹.

¹UNIVERSITY OF MINNESOTA, USA, ²Georgia State University, USA

Low-magnitude, high-frequency vibration prevents bone loss and stimulates bone formation in various populations. This modality of mechanical loading is particularly attractive to preserve skeletal health in Duchenne muscular dystrophy (DMD) because patients are advised to avoid traditional exercise. Prior to clinical usage, it is important to establish parameters for vibration (acceleration and frequency) that maximize osteogenic responses. Therefore, the purpose of this research was to use the mdx mouse model of DMD to determine the acceleration and frequency of vibration resulting in the greatest improvements in osteogenic gene expression and plasma osteocalcin (OC). Mdx mice were exposed to 14 days of vibration (15min/d) at an acceleration of either 0.3 or 0.6g at 30, 45, or 90Hz (n=6-8) and were compared amongst each other as well as to non-vibrated (control) mdx mice (n=8). RNA was extracted from tibiae for RT-PCR analysis of gene expression along the osteoblastic lineage (alkaline phosphatase (ALP), Runx2, bone morphogenetic protein 2, and collagen type-1 (COL1A1)) as well as genes known to inhibit and activate osteoclasts (osteoprotegerin (OPG) and RANKL). Osteoblast activity was assessed by plasma OC levels on day 14. RT-PCR and OC data were analyzed by two-way ANOVAs and post-hoc tests were used to compare against control mice; significance was set at $P<0.05$. Comparisons amongst the varying accelerations and frequencies showed that gene expression was not affected by the acceleration or frequency of vibration; there was however a trend for OPG to increase with higher frequencies (i.e., main effect of frequency $P=0.052$). Relative to control mice, the 45Hz at 0.6g mice had 31% upregulation in COL1A1 along with a trend toward greater ALP mRNA ($P=0.09$). Mice vibrated at 90Hz and 0.3g also had 40% upregulation of ALP compared to control mice ($P<0.05$). OC levels were similar across vibration conditions ($P>0.64$) and between vibrated and control mice ($P>0.28$). These results, similar to those found

in wildtype mice, indicate that acute vibration at 45Hz at 0.6g or 90Hz at 0.3g have a modest potential to elevate genes associated with osteoprogenitor cell proliferation and extracellular matrix mineralization in the mdx mouse. Despite these modest effects, improvements in bone strength have previously been realized with long-term vibration thus establishing the need of long-term studies in mdx mice to ensure improvements in skeletal health.

Racial Differences in Cortical Bone Mass, Size and Estimated Strength at the Tibial Diaphysis in Early Pubertal Children. Stuart Warden^{*1}, Ashley Ferira², Emma Laing², Kathleen Hill³, Berdine Martin⁴, Connie Weaver⁴, Munro Peacock⁵, Richard Lewis². ¹Indiana University, USA, ²The University of Georgia, USA, ³Indiana University School of Medicine, USA, ⁴Purdue University, USA, ⁵Indiana University Medical Center, USA

Osteoporotic fracture rates differ according to race, with blacks having up to half the rate of whites. The reduced fracture rate in blacks has been suggested to be due to their superior bone mass; however, mass is not the sole determinant of bone strength. Bone strength, and consequent fracture risk, is also influenced by how bone material is distributed or structured. It is likely bone structure also contributes to the lower incidence of fractures in blacks and that racial differences in bone structure have roots in childhood. The aim of this study was to assess the influence of race on pQCT-derived cortical bone mass, size and estimated strength at the tibial diaphysis in early pubertal children. 160 children were recruited, with equal subjects according to race (black, n=80; white, n=80) and sex (female, n=80; male, n=80). Subjects were at sexual maturation stages 2 or 3. Tomographic slices of the tibial diaphysis at 66% proximal from the medial malleolus were acquired using pQCT. Slices were assessed for cortical volumetric BMD (Ct.vBMD), cortical BMC (Ct.BMC), total (Tt.Ar) and cortical (Ct.Ar) area, density weighted maximum (I_{MAX}) and minimum (I_{MIN}) second moments of area, density-weighted polar strength-strain index (SSI_p), and muscle cross-sectional area (mCSA). Group differences were assessed by two-way analysis of covariance, with race (black vs. white) and sex (female vs. male) as independent variables. Covariates included predicted years from peak height velocity (maturity offset), tibial length and mCSA. There were no interactions between race and sex (all $P=0.50-0.98$) or main effect for sex (all $P=0.08-0.45$). Blacks had 15.7% more Ct.BMC, and 10.8-11.8% larger Tt.Ar and Ct.Ar than whites (all $P<0.001$). The greater enhancement of Ct.BMC relative to Ct.Ar resulted in blacks having 3.6% greater Ct.vBMD than whites ($P<0.001$). The combination of increased cortical bone mass, size and density in blacks contributed to enhanced estimated bone strength, with I_{MAX} , I_{MIN} and SSI_p being 20.0%, 34.5% and 25.2% greater in blacks than whites, respectively (all $P<0.001$). These data indicate that early pubertal black children have enhanced bone mass, size and estimated bone strength at the tibial diaphysis versus whites, independent of tibial length and mCSA. They suggest bone structural differences may contribute to observed racial differences in fracture rates and that structural divergence between races develops during childhood.

Sex Specific Effects of Physical Activity on Proximal Femur BMD in 8-9 Years Children. Graça Cardadeiro¹, Fatima Baptista^{*1}, Rui Ornelas², Luís B. Sardinha¹. ¹Exercise & Health Laboratory, Faculty of Human Movement, TU Lisbon, Portugal, ²Madeira University, Portugal

Mechanical loading by impact or via muscle forces is critical for skeletal growth and development in children and physical activity interventions are one way to target this important health-related outcome. The increase in femoral bone mass and strength in pre and pubertal children has been reported as a response to physical activity intervention programs, with the majority of studies showing that femoral neck sensitivity (as a surrogate of proximal femur sensitivity) to mechanical loading is higher in boys than in girls. Purpose: To investigate sex specific associations between everyday physical activity and mineralization of three regions of proximal femur in pre and early pubertal boys and girls aged 8-9 years. Methods: BMD in femoral neck, trochanter and intertrochanter regions, and lean mass of whole body were assessed using dual-energy x-ray absorptiometry in 161 girls (age: 9.70.3 yrs; body mass: 34.29.0 kg; body height: 137.20.1 cm) and 164 boys (age: 9.70.3 yrs; body mass: 34.17.1 kg; body height: 137.00.1 cm). Physical activity was assessed by accelerometry. Multiple linear regression analyses were used to investigate the ability of physical activity to explain the variance in BMD in the three regions of the proximal femur, after adjustment for body height, total lean mass, and pubertal status. Results: Physical activity explained 2-6% ($p<0.05$) in BMD variance in the three regions in both girls and boys, with differences between boys and girls for variance in bone regions BMD. An additional 10 minutes per day of vigorous physical activity (the best single predictor of BMD within physical activity variables) was associated with a ~2% higher trochanteric and intertrochanteric BMD in girls, while in boys it was related to a ~1% higher femoral neck, trochanter, and intertrochanteric BMD ($p<0.05$). Conclusions: Proximal femur response to weight-bearing physical activity may differ between boys and girls aged 8-9 years old, particularly in the femoral neck. Boys showed a more homogeneous response among the three regions of proximal femur, while a significant greater bone density in the trochanteric and intertrochanteric

regions was observed in the more active girls, compared with less active female participants.

Vitamin D Insufficiency and Bone Mineral Status in Newcomer Immigrant and Refugee Children to Canada, an Emerging Public Health Problem. Hassanali Vatanparast^{*1}, Christine Nisbet². ¹University of Saskatchewan, Canada, ²University of Saskatchewan, Canada

Nutrition and physical activity are two important factors influencing bone mineral mass accumulation during childhood and adolescence. Newcomer immigrant/refugee children are at a high risk of poor nutritional status and low level of physical activity. Vitamin D deficiency, in particular, and its related diseases is a major concern due to minimal sun exposure and limited dietary sources. No study is available in Canada to evaluate the relationship between nutrition, physical activity and bone mineral status on newcomer immigrant and refugee children. Objective: to evaluate the association between nutrition, physical activity and bone mineral status in immigrant and refugee newcomer children to Canada. Methods: In a cross-sectional design, we recruited 72 immigrant (n=33) and refugee (n=39) children aged 7-11 years who had been living in Saskatchewan, Canada for no more than five years. Measurements included serum 25OHD using LC-MS/MS method, total body bone mineral content (TBBMC) using DXA, dietary assessment using three 24-h recalls, physical activity questionnaire and food security using USDA questionnaire. Results: The mean age of children was 8.91.6 y. The rate of food insecurity was 38.5% and 57.1% in immigrants and refugees respectively. Most children (87.5%) were meeting the recommended level of physical activity (≥ 60 minutes/day). Fourteen percent of children had the TBBMC lower than the predicted values for their age, sex and ethnicity. We found 29% of participants were vitamin D deficient and another 44% had inadequate levels of serum vitamin D for bone health. Prevalence of inadequacy in vitamin D intake was 89%. In the regression model, after controlling for possible confounders including immigration status, food security, age, sex, ethnicity, physical activity level, total caloric intake, calcium intake, magnesium intake, phosphorus intake, sodium intake, and caffeine intake; height and serum vitamin D status were found to be determinants of TBBMC ($R^2=0.82$, $p<0.05$). Children who were taller and had greater serum vitamin D also had greater TBBMC with $\beta=0.95$ for height and $\beta=0.13$ for serum vitamin D. A considerably high rate of vitamin D deficiency and insufficiency in newcomer immigrant and refugee children and its association with bone mineral mass during this important stage of life requires immediate preventive interventions to minimize the risk of serious vitamin D related diseases.

Zinc Supplementation Improves Bone Formation in Early Pubertal Females. Richard Lewis^{*1}, Norman Pollock², Emma Laing¹, Paul Bernard³, Arthur Grider¹, Sue Shapses⁴, Kehong Ding², Carlos Isaacs³. ¹The University of Georgia, USA, ²Georgia Health Sciences University, USA, ³Medical College of Georgia, USA, ⁴Rutgers University, USA

Both animal and human studies show that beyond correcting skeletal and growth impairments under deficiency conditions, supplementation with zinc may have a bone health-promoting role. The purpose of this study was to determine if zinc supplementation (23 mg/d zinc sulfate) over 4 weeks altered serum zinc, markers of bone turnover [bone formation: osteocalcin (OC), procollagen type 1 amino propeptide (PINP); bone resorption: carboxyterminal telopeptide region of type 1 collagen (ICTP), pyridinoline (PYR), deoxypyridinoline (DPD)], and insulin-like growth factor-I (IGF-I) in early pubertal white and black females (9 to 11 years of age). A secondary aim was to determine if there was a race x treatment interaction among these variables. Early pubertal females of similar maturational status were randomized into a zinc supplementation group (ZN; n=75) or placebo group (CON; n=72), in a double-blind, placebo-controlled trial. Serum zinc was determined using atomic absorption spectrophotometry. OC, PINP and ICTP were assessed using RIA. PYR and DPD were determined using HPLC and IGF-I was determined by ELISA. Over 4 weeks, plasma zinc and PINP increased significantly more in the ZN vs CON group ($P<0.05$). There were no group differences in the other biomarkers (all $P>0.05$, see figure). No differences were observed by race. Findings from this study provide preliminary evidence that zinc may be a viable nutritional strategy for improving bone strength in young females. A long-term clinical bone trial is warranted to more definitively assess the potential for supplemental zinc to improve bone strength and to explore potential mechanisms involved.

Bioavailability of Vitamin D in Adolescents with Anorexia Nervosa. Amy DiVasta^{*1}, Michael Holick², Catherine Gordon³. ¹Children's Hospital Boston, USA, ²Boston University School of Medicine, USA, ³Children's Hospital Boston & Harvard Medical School, USA

Purpose: Young women with anorexia nervosa (AN) have a normal vitamin D status. Whether the bioavailability of vitamin D is different in states of malnutrition is not known. We sought to examine whether the serum response to oral vitamin D₂ is altered in young women with AN compared to normal-weight teens.

Methods: Twelve adolescents with AN (age 19.62.0 yr, BMI 16.51.4 kg/m² and 12 healthy controls matched by age and skin pigmentation (20.02.4 yr, 22.7 1.0 kg/m²) received a single oral capsule of vitamin D₂ 50,000 IU. Serum samples were collected pre-ingestion, 6h, 24h, and 1, 2, 3, and 4 wk following ingestion. Samples were analyzed for D₂, D₃, 25(OH)D, and 1,25(OH)₂D. Body composition was measured at baseline by dual-energy X-ray absorptiometry (DXA). The course of serum vitamin D concentrations over time was compared by repeated-measures ANOVA.

Results: The AN group was severely malnourished (77.26.3% median body weight), while controls were normal-weighted (106.26.2%). From a common baseline D₂ level (1.51.6 nmol/L, $p=0.34$) the groups diverged (time x group interaction $p=0.04$), reaching a peak of 7034 nmol/L at 6h in controls compared to 4328 nmol/L in AN subjects ($p=0.008$). The D₂ trajectories converged at 24 hr (57 nmol/L, $p=0.98$) and returned to near-baseline at 1 wk (3.11.6 nmol/L, $p=0.34$). D₃ was 3-4-fold higher in AN subjects at baseline (12.19.6 vs 3.12.3 nmol/L, $p<0.001$) and remained so throughout the study, despite a significant rise among controls at 1 wk (+1.41.7 nmol/L, $p=0.01$). 25(OH)D followed a common trajectory in AN and control subjects over the 4-wk study (time x group interaction $p=0.15$), rising from 3911 nmol/L pre-ingestion to a peak level of 4510 nmol/L at 24 hr and returning to baseline by wk 3 ($p=0.36$). 1,25(OH)₂D was lower in AN subjects at baseline (316 vs 548 pmol/L, $p=0.006$) and did not change at 4 wk in either group ($p>0.40$). Correlating the vitamin D levels with fat measures (BMI, body fat) in place of the AN-control comparison produced similar findings.

Conclusions: Despite severe malnutrition, young women with AN had a similar response to a single dose of oral ergocalciferol compared to healthy-weighted control subjects. These findings have implications for defining the baseline vitamin D requirements in AN. Based on our data, it appears that vitamin D dosing for patients suffering from malnutrition, irrespective of etiology, may not differ from that for normal-weighted adolescents.

Leptin-directed Osteocalcin Regulation is Influenced by Health and Gender in Adolescents with Type 1 Diabetes. Shannon Haley¹, Mary Murray², Laurie Moyer-Mileur^{*2}, Kenny Helmandollar², Hillarie Slater², Kristine Jordan². ¹University of Utah School of Medicine, USA, ²University of Utah, USA

Background: Low bone density in adolescents with Type 1 diabetes (T1DM) has been established by our group and others. Leptin, produced by adipocytes, regulates carboxylation of osteocalcin (OC), a bone derived hormone that promotes bone formation. Undercarboxylated OC (ucOC) has low bone affinity, is the predominant

form in circulation with a positive effect on insulin sensitivity. Both serum leptin and OC levels are decreased in young adults with T1DM. The effect of T1DM on leptin-driven uOC, metabolic control, and bone mass is unclear. We tested relationships between serum leptin, OC, uOC, fasting glucose and insulin, body fat, and bone mass in adolescents with T1DM.

Methods: Adolescents age 12-15y with T1DM (n=14; 6M/8F) were compared to matched controls (CTL, n=12; 5M/7F). Subjects were admitted overnight and given a standardized diet. Height (cm), weight (g) as well as whole body minus head fat (%), bone area (BA, cm²), bone mineral content (BMC, g), and areal bone density (aBMD, g/cm²) by DXA (Hologic 4500A) were measured. Fasting blood samples were obtained with leptin, OC, and uOC determined by ELISA. Serum uOC was corrected for total serum OC. ANCOVA tested differences between groups controlling for gender and pubertal maturation; Pearson's R tested the relationships between serum, fat mass, and bone parameters (p<0.10).

Results: Age, maturation by Tanner stage, and body size were similar between groups and genders. Body fat (%) was lowest in T1DM males (group x gender interaction, p<0.10). T1DM subjects had higher serum leptin (16,915.7ng/ml T1DM vs. 11,510.0ng/ml CTL; p<0.05). In males, serum OC was higher in T1DM (60,413.2ng/ml T1DM vs. 42,320.2ng/ml CTL, p<0.10). Serum uOC values were greatest in CTL males compared T1DM males or CTL and T1DM females (p<0.10). Serum leptin was positively related to body fat% (R=0.60, p<0.01). In contrast serum leptin was negatively related to serum uOC (R=-0.46, p<0.10) as was serum OC to whole body BA and BMC (R=-0.33, p=0.10). Serum OC was positively related to fasting glucose (R=0.42, p<0.05).

Conclusions: In contrast to young adults, serum leptin and OC levels were elevated in adolescents with T1DM. Surprisingly, serum uOC did not reflect higher serum leptin. We speculate that the lower uOC in the presence of greater serum leptin may be due to health- and gender-divergent responses to leptin-driven osteocalcin regulation in adolescents with Type 1 diabetes.

The Interaction of Maternal Obesity and Neonatal Vitamin D Deficiency on Neonatal Anthropometrics. Jami Josefson^{*1}, Heather Price², Alfred Rademaker¹, Dinah Zeiss¹, Craig Langman². ¹Northwestern University, USA, ²Children's Memorial Hospital, USA

Maternal vitamin D deficiency (D-) is associated with low birth weight, while maternal obesity is associated with high birth weight. One study demonstrated that with increasing maternal obesity, mothers and newborns were more likely to be D-. In this study, we asked the question as to whether obese versus non-obese women, both without D-, would have newborns with similar vitamin D levels and differences in birth weight and anthropometry predicted by obesity alone. Obese [OB, pre-pregnancy BMI \geq 30 kg/m²] and healthy weight [HW, 18-25 kg/m²] pregnant women with a normal diabetes screening test were studied. All women had singleton, term pregnancies and were not hypertensive. Maternal fasting blood was collected at 36-38 weeks gestation and cord blood was collected at birth. Neonatal measurements, including length and body composition analysis by air displacement plethysmography to provide weight, fat mass, and % body fat were performed within 48 hours of birth. 23 OB and 38 HW mothers and their newborns completed the study. Maternal total 25(OH)D levels did not differ between the OB and HW groups (50 (mean) 23 (sd) vs. 46 17 ng/mL). The OB women had higher levels of fasting glucose (86.7 8.6 vs. 80.9 6.5 mg/dL, p=0.03), C-peptide (4.4 2.0 vs. 2.4 1.0 ng/mL, p<0.01), and leptin (54.1 14.5 vs. 25.0 12.7 ng/mL, p<0.001) compared to the HW women. Cord blood 25(OH)D levels were lower in neonates of OB women compared to HW women (20.8 10.3 vs. 27.5 10.0 ng/mL, p=0.02), and cord blood C-peptide levels were higher in OB newborns (1.2 0.7 vs. 0.9 0.3 ng/mL, p=0.04). In HW newborns, cord blood 25(OH)D levels were positively correlated to neonatal anthropometric measures of weight (r=0.45, p<0.01), length (r=0.43, p<0.01), fat mass (r=0.52, p<0.01), and % fat mass (r=0.46, p<0.01) but these correlations were not found in OB newborns. No differences were seen in any of the anthropometric measures of the OB vs. HW newborns or in their cord blood glucose, leptin, adiponectin or osteocalcin levels. Herein, we demonstrate that obese women without D- have neonates with lower cord blood 25(OH)D levels but not higher birth weight or other anthropometric evidence of obesity when compared to HW newborns. We suggest that maternal obesity may reduce the impact of vitamin D deficiency on low birth weight. The mechanism of vitamin D metabolism whereby OB offspring have lower vitamin D remains under investigation.

Hypophosphatasia (HPP): Iliac Crest Histomorphometry of Affected Children Given Subcutaneous Enzyme Replacement Therapy, ENB-0040. Michael P. Whyte^{*1}, Katherine L. Madson², Amy L. Reeves², Deborah Wenkert², Cheryl R. Greenberg³, Nerissa Kreher⁴, Hal Landy⁴, Frank Rauch⁵, Francis Glorieux⁶. ¹Shriners Hospital for Children & Washington University School of Medicine, St. Louis, USA, ²Shriners Hospital for Children, St. Louis, USA, ³University of Manitoba, Canada, ⁴Enobia Pharma, Inc, USA, ⁵Shriners Hospital for Children, St. Louis, Canada, ⁶Shriners Hospital for Children & McGill University, Canada

Background:

HPP is the heritable metabolic bone disease caused by inactivating mutation(s) in the gene that encodes the tissue-nonspecific isoenzyme of alkaline phosphatase (TNSALP). Impaired skeletal mineralization develops from extracellular accumulation of inorganic pyrophosphate (PPi), an inhibitor of hydroxyapatite crystal growth. ENB-0040 is a bone-targeted, recombinant TNSALP protein, delivered subcutaneously (SC), that has been reported in clinical trials to improve radiographic and functional outcomes in infants and children with HPP (Greenberg et al, ASHG 2010, abs. 13 & Whyte et al, ASBMR 2010, abs. 1016)

Objective:

Evaluate by iliac crest histomorphometry the effects of 6 months of treatment (Rx) with ENB-0040 on the skeletal findings of HPP in children.

Methods:

A 6-month, multi-center, open-label, historical control study of 13 children receiving ENB-0040 (2 or 3 mg/kg SC 3X weekly). Twelve of the 13 patients completed the study (one withdrew for elective scoliosis surgery). Iliac crest specimens were obtained, after tetracycline labeling, using a 5 mm diameter trephine at baseline and study completion. Specimens were analyzed "blindly" for osteoid indices, structural parameters, and dynamic parameters of bone formation. Wilcoxon testing was used for statistical comparisons.

Results:

Osteoid indices (thickness, surface per bone surface, volume per bone volume) were markedly elevated at baseline. In general, osteoid was "patchy" and not distributed evenly as commonly seen in other forms of rickets or osteomalacia. After Rx, median osteoid thickness had decreased significantly from 13.8 to 7.7 μ M (p=0.02), and osteoid surface per bone surface had decreased by 55% (p=0.04). Mineralization lag time was markedly elevated at baseline, and the median value almost halved [82.3 (25-75% 34.3, 126.0) vs. 44.0 (35.1, 58.0)] after Rx, but the change was not statistically significant (p=0.26), likely from the high variability of individual results. Structural parameters (bone volume per tissue volume, trabecular number, trabecular thickness) were similar to age-specific averages at baseline, and did not change significantly with Rx.

Conclusions:

Children with HPP manifest "patchy" accumulation of osteoid that seems different from other forms of rickets or osteomalacia. This osteoidosis improves after 6 months of Rx with ENB-0040. This tissue benefit parallels the radiographic and functional improvements reported in infants and children with HPP receiving ENB-0040.

Accuracy of Histomorphometric Parameters to Quantify Trabecular Architecture: Comparison of 2D Thin Sections with 3D μ CT Data. Oleg Musevko¹, Robert Percy Marshall², Jing Lu¹, Georg Schett³, Michael Amling², Klaus Engelke^{*1}. ¹University of Erlangen, Germany, ²University Medical Center Hamburg-Eppendorf, Germany, ³Friedrich-Alexander University Medical School, France

Histomorphometry using 2D thin stained sections is the standard method to quantify trabecular bone architecture. However, the preparation is tedious and a single or even a few number of sections may not be representative for a 3D volume. Moreover the calculation of the structural parameters requires the assumption of a structural model such as the plate or rod model. 3D μ CT has increasingly replaced 2D stained sections as a full volume can be assessed. However, due to the lower spatial resolution compared to thin sections partial volume artifacts results that may impair the accuracy of the histomorphometric parameters.

In this study 3D μ CT datasets (Scanco μ CT40, 15 μ m isotropic voxel size) were obtained from 7 vertebrae from 4 wild type mice. Afterwards two stained sections (3 μ m; von Kossa staining) were prepared for each vertebra. In order to directly compare the histomorphometric results the 2D sections were registered into the 3D μ CT volume using an affine transformation. As some stretching occurred during the preparation of the sections a simple rigid transformation gave unsatisfactory results. In the 2D sections the trabeculae were segmented using a global threshold whereas in the 3D μ CT datasets a local adaptive threshold was used in order to account for some of the partial volume artifacts. In addition in each μ CT dataset 6 slices neighboring the one corresponding exactly to the 2D section were analyzed. Also the size of the analysis ROI was varied (s. Fig).

The results shown in the table as means SD for the 7 vertebrae confirm that there is an accuracy error in the determination of histomorphometric parameters using

μ CT, in particular for Tb.Th. However, the variation from slice to slice that is not captured in 2D stained sections and even more so the choice of the analysis ROI in the 2D sections is comparable or even larger than the accuracy error. In this study a high resolution μ CT was used and the results may not be applicable at lower μ CT resolutions. Also the accuracy errors increased when global thresholds were used for the segmentation of the trabeculae in the μ CT datasets.

Age and Gender Differences in Tibia Morphology and Estimated Bone Strength in Caucasians Using Serial pQCT Scans. Vanessa Sherk*, Debra Bembien. University of Oklahoma, USA

Variability in pQCT measurement sites limits direct result comparisons between studies. Further, it is unclear what estimates or surrogates of bone strength are most indicative of changes in fracture resistance due to aging, disease, or interventions. The purpose of this investigation was to compare pQCT-derived bone variables at multiple sites throughout the tibia in healthy men and women. Methods: Self-identifying Caucasian men (n=49) and women (n=56) ages 20-59 years had their non-dominant tibias assessed with pQCT (XCT 3000) at every 10% of the limb length from 5%-85% from distal to proximal. Participants were grouped by decade and by gender. Volumetric BMD, BMC, and area of the total, cortical and trabecular bone were determined. Also, periosteal (PeriC) and endosteal (EndoC) circumferences, cortical thickness (CTh), bone strength index (BSI), strength strain index (SSI), Imax, Imin, mass ratios, and strength to mass ratios were quantified. Results: Bone morphology and strength characteristics varied along the tibia in a nonlinear fashion. There were significant ($p < 0.01$) site effects for BMC, vBMD, area, strength (SSI, Imin, Imax, SSI:Tot.BMC ratio), PeriC and EndoC. Total vBMD peaked at the 35%, while cortical BMC peaked at 55% with minimums at 5% and 85%. Total BMC, SSI, SSI:Tot.BMC ratio, Imax all peaked at the 85% site. Gender differences (20-27.3%) in Tot. BMC were explained largely by differences in Tot.Area (19.3-23.7%), due to differences in Cort.BMC and area (20.3-25.3%) ($p < 0.01$). Gender differences ($p < 0.01$) in Imax, SSI, and SSI:Tot.BMC ratio were smallest at the 15% sites and increased through the diaphysis. Women had significantly ($p < 0.05$) greater Cort. vBMD than men. Men had significantly ($p < 0.01$) greater Tot.BMC ratios at 5%:35% and 5%:65%. Site*gender interaction effects were significant ($p < 0.05$) for area, BMC, circumference, and strength variables. CTh and total vBMD were lowest ($p < 0.05$) in 50-59 yr group, and many trends ($p < 0.10$) existed for BMC variables. EndoC was highest in the 50-59 yr group. Site*age interactions existed for Cort.vBMD, total and trabecular area, Tot.BMC, SSI, Imax, PeriC and EndoC. BMC ratios for 5:35% and 5:65% were highest ($p < 0.05$) in the 20-29 yr group. Conclusion: Gender differences were driven by bone size, whereas age differences were mostly due to density. The magnitude of age and gender differences varied by measurement site. Standardization of measurement sites is recommended.

Anatomically Confined Alterations in Collagen Cross-Links Coupled with Structural Changes Influence the Mechanical Properties of Whole Bone Independently of the Amount and Quality of Bone Mineral. Eleftherios Paschalis*¹, Dimitris Tatakis², Simon Robins³, Peter Fratzl⁴, Inderchad Manjubala⁴, Ruth Zoehrer¹, Sonja Gamsjaeger¹, Birgit Buchinger¹, Andreas Roschger¹, Roger Phipps⁵, Enrico Dall'Ara⁶, Peter Varga⁷, Philippe Zysset⁶, Klaus Klaushofer¹, Paul Roschger¹. ¹Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK & AUVA Trauma Centre Meidling, 1st Medical Department, Hanusch Hospital, Austria, ²Division of Periodontology, The Ohio State University, USA, ³Rowett Institute, United Kingdom, ⁴Max Planck Institute of Colloids & Interfaces, Department of Biomaterials, Research Campus Golm, Germany, ⁵Husson University School of Pharmacy, USA, ⁶Vienna University of Technology, Austria, ⁷Institut für Leichtbau und Struktur-Biomechanik, TU, Austria

In the present study a rat animal model of lathyrisms was employed to decipher whether anatomically confined alterations in collagen cross-links coupled with structural changes influence the mechanical properties of whole bone independently of amount and quality of mineral. Animal experiments were performed under an Ohio State University ethics committee approved protocol. Sixty-four female (47 day old) rats of equivalent weights were divided into four groups (16 per group): 2 control and 2 treatment groups. Controls were fed a semi-synthetic diet containing 0.6% calcium and 0.6% phosphorus for 2 or 4 weeks and β -APN treated animals were fed the same diet supplemented with β -aminopropionitrile (0.1% dry weight) for 2 or 4 weeks. At the end of this period the rats in the two groups were sacrificed, and L3-L6 vertebra were collected. Collagen cross-links were determined by both biochemical and spectroscopic Fourier transform infrared imaging (FTIRI) analyses. Mineral content and distribution was determined by quantitative backscattered imaging (qBEI), and mineral maturity / crystallinity by FTIRI techniques. Micro-CT was used to describe the architectural properties. Data were analyzed by two-way ANOVA with Bonferroni post-hoc tests. The results of the present study indicate a relationship between bone strength (determined by compression tests) and both bone structural properties (by micro-CT) and the amount and type of collagen cross-links (both by biochemical and FTIRI analyses), independently of the amount and quality of mineral (by qBEI and FTIRI). Microspectroscopic (FTIRI) analysis and nanoindentation mechanical tests reveal that the collagen cross-links alterations are confined in areas of primary mineralized bone exclusively. Interestingly, the collagen cross-link ratio in these areas had the same profile as seen in equivalent anatomical areas (in terms of tissue age and mineralization extent) in human iliac crest biopsies of both untreated high- and low- turnover osteoporotic patients, as well as of patients with fragility fractures unaccounted for by the classical clinical bone strength indicators such as bone mineral density and / biomarkers. Results of the present study suggest a considerable role of collagen cross-links in the determination of bone structural properties and strength, even when these changes are anatomically confined.

Association Between Prevalent Vertebral Fracture and Lumbar Vertebral Bone Density, Morphology, Geometry, and Compressive Strength in Men and Women: the Framingham QCT Study. Yoo Mee Kim*¹, Serkalem Demissie², Qiong Louie-Gao², Elizabeth Samelson³, Douglas Kiel⁴, Mary Bouxsein⁵. ¹Division of Endocrinology, MizMedi Hospital, South Korea, ²Department of Biostatistics, Boston University School of Public Health, USA, ³Hebrew SeniorLife, Harvard Medical School, USA, ⁴Hebrew SeniorLife, USA, ⁵Beth Israel Deaconess Medical Center, USA

There has been renewed interest in 3D bone measurements based on the possibility that these measures may provide additional predictive value for fracture risk. Although skeletal imaging with quantitative computed tomography (QCT) has been available for several decades, there are few studies comparing QCT measures and fracture risk using data from newer volumetric acquisitions. Thus, we aimed to determine the association between QCT-based bone density, morphology, geometry, compressive strength and prevalent vertebral fracture (VFX) in men and women in the Framingham Study. Methods: This cross-sectional study included 1,693 participants, 808 men and 885 women, age ≥ 50 years from the community-based Framingham CT Study. VFXs were identified from lateral CT scout views using Genant's SQ scale. QCT assessments at L3 included: integral (IvBMD), trabecular (TvBMD) and cortical volumetric BMD (CvBMD), cross-sectional area (CSA), and compressive strength (CStr) estimated using beam theory. We determined odds ratios for prevalent VFX, per SD decrease for each independent variable adjusted for age, height and weight. Results: We identified mild VFX in 141 (17%) men and 105 (12%) women, and moderate/severe VFX in 20 (2.5%) men and 16 (1.6%) women. Compared to persons without fracture, vBMD's were 3 to 8% lower in those with mild VFX and 8 to 30% lower in those with moderate/severe VFX ($p < 0.05$). Considering all fractures, decreased IvBMD and CvBMD were significantly associated with VFX in women and men (Table), although decreased TvBMD and CStr were only significant in men. In women, a lower CSA was protective of VFX. In those with moderate and severe

VFX, the associations with VFX were similar in men, although few reached statistical significance due to smaller sample size. However, in women with moderate and severe VFX, associations with low vBMD were stronger — for example, OR for a 1 SD decreased in integral vBMD was 7.18 (95% CI: 3.2-15.9). Conclusion: Decreased vBMD and CStr is associated with prevalent VFX in men and women. In women, but not men, lower CSA was unexpectedly associated with reduced risk of VFX. The association between vBMD of different compartments and risk of VFX differed somewhat in men and women, particularly among those with more severe VFX, suggesting that structural analysis by QCT may improve our understanding of sex-related differences in risk of VFX.

Table. Odds Ratio and 95% confidence intervals per 1 SD decrease of the independent variable for association with prevalent VFX in men and women (adjusted for age, height, and body weight)

	Men (n=151)	Women (n=114)	Men (n=151)	Women (n=114)
Int vBMD	1.50 (1.07-2.13)	1.38 (1.05-1.81)	1.54 (0.98-2.40)	1.59 (1.24-2.04)
Tr vBMD	1.29 (1.01-1.66)	1.04 (0.79-1.38)	1.48 (0.83-2.61)	1.27 (1.00-1.59)

Bone Microarchitecture and Finite Element Analysis Measured with HR-pQCT can Identify Postmenopausal Women with and Without Forearm Fragility Fractures. Kyle Nishiyama^{*1}, Heather Macdonald², David Hanley¹, Steven Boyd¹. ¹University of Calgary, Canada, ²University of British Columbia, Canada

Measures of bone microstructure and estimates of bone strength can be obtained with high-resolution pQCT (HR-pQCT); however, it is unclear if these parameters can be used to identify people with fractures. Our objective was to determine if HR-pQCT measurements and finite element (FE) estimates of bone strength could identify women with and without low-trauma forearm fracture. We studied postmenopausal women in the Calgary cohort of the Canadian Multicentre Osteoporosis Study (CaMos) for whom we had 10-year fracture data and HR-pQCT (XtremeCT, Scanco Medical AG) scans at the completion of the study (Macdonald et al. 2011). During the follow-up, 14 women reported low trauma forearm fractures and were each randomly matched by age (+/- 1 year) to 2 women without fractures (Total N = 42, 72.9 ± 8.3 yrs.). In addition to standard HR-pQCT measurements (Boutroy et al. 2005), we measured cortical thickness, porosity (Bue et al. 2007; Nishiyama et al. 2010), finite element ultimate stress, and the portion of the load carried by the cortical and trabecular regions (MacNeil and Boyd 2007) in all subjects. We used DXA to measure femoral neck (FN) and lumbar spine (LS) areal BMD. Support vector machines (SVM; WEKA, University of Waikato) were used to classify women with and without fracture. A 10-fold cross validation scheme was used to gauge the accuracy and generalizability of the model. The first model was based on all HR-pQCT and FE parameters, the second model used FE measurements alone, and the third model used DXA aBMD (LS and FN) alone. The SVM based on all parameters correctly classified 35 of the 42 subjects in the cross validation (Accuracy = 83.3%, Sensitivity = 73.3%, Specificity = 88.9%, Kappa = 0.63, ROC AUC = 0.84). Using only FE parameters, 34 subjects were correctly classified (Accuracy = 81.0%, Sensitivity = 66.7%, Specificity = 91.7%, Kappa = 0.60, ROC AUC = 0.81). Areal BMD classified all subjects as controls resulting in 28 correct (Accuracy = 66.7%, Sensitivity = 66.7%, Specificity = 0.0%, Kappa = 0.00, ROC AUC = 0.50). Combined HR-pQCT and FE measurements and FE measurements alone had good accuracy identifying women with forearm fractures vs. age-matched controls, while DXA measurements failed to identify subjects. These models may help to predict individuals at risk of forearm fracture in a prospective study and form a basis to identify which parameters from HR-pQCT and FE analysis are critical for assessing fracture risk.

Bone Tissue Quality Determination Using Novel Reference Point Indentation Technique. Oran Kennedy^{*1}, Matin Lendhe¹, Davis Brimer², Robert Majeska¹, Mitchell Schaffler¹. ¹The City College of New York, USA, ²Active Life Scientific, Inc., USA

Introduction: Deterioration of bone strength with age is associated with increased fracture risk. The toughness of bone, a parameter representing crack growth resistance, is critical in predicting fracture risk. Traditional toughness testing requires large sample size, obviating their use clinically. Recent data suggests a reference point indentation approach provides a novel toughness measurement of whole bones¹. Here, we evaluated the sensitivity of this method to discriminate small known differences in toughness between inbred mouse strains with small genetically based differences in mineralization². To do this we measured a new parameter called

Indentation Distance Increase (IDI) which is related to fracture toughness¹. We also characterized damage patterns beneath the indentation.

Methods: Femora from three genetically distinct mouse strains (A/J, C3H and B6) (n=5/group) were excised for testing. The reference point indenter (Biodent, Active Life Scientific, CA) consists of a two-probe assembly, one of which is fixed at the bone surface while the other moves cyclically to create an indent in the tissue, relative to that surface. Specifically, IDI is the distance between the indenter tip at the last cycle relative to the first. During testing femora were hydrated and clamped while two mid-diaphyseal indents were made at an interval of 500µm. Then samples were fixed and stained in basic fuchsin for damage visualization. Finally samples were embedded in PMMA and polished for SEM and fluorescence microscopy.

Results and Discussion: IDI was highest in A/J followed by C3H and then B6. These data precisely parallel reported bone phenotypes in these strains; A/J being most brittle, followed by C3H and B6 respectively². In all bones, a single or several small cracks formed under the indenter tip, suggesting that it is acting like an "opening-wedge". These cracks initiated in the transverse direction and were immediately blunted by diverting into the longitudinal direction; no differences in length were found. However, other toughening mechanisms were observed: Un-cracked ligament bridging in C3H bones, and extensive delamination in the B6 group, consistent with internal slippage in the mineralized collagen fibrils.

Conclusion: These data suggest that this is a suitable and sensitive method for detecting differences in toughness as a result of small differences in mineralization. This may have important clinical implications in the assessment of fracture risk.

Calcium Phosphate Glass/Collagen: Preparation and Properties. Yu Zhang, Ning Jiang^{*}, Racquel LeGeros. New York University College of Dentistry, USA

Introduction: The human bone is a biologic composite consisting of an inorganic (hydroxyapatite crystals) and organic (collagen fibers) phases. Several calcium phosphate/collagen composites are explored as potential bone substitute materials. Objective: This study aimed to explore the potential of a novel Calcium Phosphate Glass/Collagen (CPG/COL) composite as potential biomaterials for bone repair. Methods: The CPG compositions from the system CaO-P2O5-MgO-ZnO were prepared according to methods previously described [LeGeros/Lee 2004]. The CPG/COL composite was prepared by mixing CPG (70%) and COL (30%) in a neutral salt solution maintained at 37°C to form CPG/COL gel and then freeze-dried. The CPG/COL composites were characterized using Scanning Electron Microscopy, Fourier Transform Infrared Spectroscopy and X-ray Diffraction Analysis, and Mechanical Testing. Degradation (dissolution) properties were evaluated in acidic buffer (0.1M KAc, pH 5, 37°C). Results: The results demonstrated that the morphological and structural features (i.e., porosity) and chemical composition of CPG/COL composite were very similar to that of bone. Conclusions: The composites showed physico-chemical properties similar to bone and may be potential materials as scaffolds for bone repair or in tissue engineering for bone regeneration. Future studies include: in vitro cell response and in vivo tissue response to the new composite.

Cell Based Gene Therapy for Fracture Healing on a Rat Femoral Critical Size Defect. Corinne Sonnet^{*1}, Ronke Olabisi², Kayleigh Sullivan¹, LaShan Simpson², John Hipp¹, ZaWaunyka Lazard¹, Zbigniew Gugala³, Francis Gannon¹, Steve Stice⁴, John Peroni⁴, Michael Weh⁴, Eva Sevik², Michael Heggeness¹, Alan Davis¹, Jennifer West², Elizabeth Olmsted-Davis¹. ¹Baylor College of Medicine, USA, ²Rice University, USA, ³University of Texas Medical Branch, USA, ⁴University of Georgia, USA, ⁵University of Texas, USA

Although bone is thought to possess the capacity to repair or remodel, often this process is ineffective when large amounts of bone must be rapidly regenerated, such as following traumatic injury. Thus orthopedic intervention to induce bone repair using autologous graft materials and osteoinductive agents is often the only option. However, in cases with substantial traumatic injury to hard and soft tissues, enhancing repair while suppressing destructive processes such as infection, are a significant challenge and may lead to loss of limb. We have developed a cell-based molecular therapy which induces rapid bone formation and healing at a targeted location in a femoral traumatic injury model in wild-type rats. In our model, an external fixation device is placed on the length of the femur and a critical size defect is made in the midshaft of the bone. Microencapsulated AdBMP2-transduced cells were injected into the defect at the time of surgery. The cells are microencapsulated within poly(ethylene) glycol diacrylate (PEGDA) hydrogel microspheres. At different time points post surgery, we radiologically evaluated bone formation and either allowed the healing to progress, or isolated the tissues for microCT, biomechanical and histological analysis.

We observed consistent bone formation at the targeted site after injection of the osteoinductive microspheres. The new bone formation was extensive enough to bridge the defect and appeared in many cases to be integrated with the skeletal bone as early as 2 weeks. This integrated bone appeared to be well fused, both radiologically (micro-

CT) and histologically to the adjacent skeletal bone with contiguous cartilage and bone within the defect site. Biomechanical analysis showed that the stiffness and strength of the repair bone were even greater than the contralateral control femur as early as 3 weeks postsurgery. In some cases, the external fixator was removed to confirm that the substantial well mineralized bone, as determined by x-ray, was able to support weight bearing and normal daily activity. In these experiments, the rats were able to ambulate normally, and no apparent additional fractures occurred in the callus region.

Thus, injection of the PEGDA hydrogel containing AdBMP2-transduced cells provides a novel method for inducing rapid repair of traumatic bone injuries, without the need for additional surgical intervention, autologous bone graft or a scaffold.

Changes in Human Vertebral Bone Microstructure from Infancy to Senescence. Jesper Thomsen^{*1}, Annemarie Bruel¹, Ellen Hauge². ¹University of Aarhus, Denmark, ²Aarhus University Hospital, Denmark

Introduction: During aging, not only is bone mass is lost, the bone structure also deteriorates: The volume fraction of bone and the number of connections in the trabecular network decrease. During growth, it is well known that the areal bone mineral density increases, whereas changes in trabecular bone microstructure are less well elucidated. Therefore we aimed at quantifying the changes in vertebral trabecular bone structure from infancy to senescence.

Methods: Age-related changes were investigated using third lumbar vertebral bodies obtained during routine autopsy procedures. The study comprised 119 individuals (51 women, 68 men), aged 0.2–95 years (median 59 years). The individuals had died suddenly from accidents or acute diseases. Individuals with known malignant, renal, or metabolic bone diseases were excluded as were vertebral bodies with known fractures. The vertebral bodies were rotated around a central craniocaudal axis and sawn into quarters. One randomly chosen quarter was embedded in methylmethacrylate and μ CT-scanned with a voxel size of $18.5 \times 18.5 \times 18.5 \mu\text{m}^3$. The reconstructed images were threshold-filtered with a constant value of 436 mgHA/cm and standard microstructure measures were computed. Data were analyzed by linear regression.

Results: Until peak bone mass (0–25 years), the connectivity density (CD) (r^2 ; B; p) (0.42; 12 1/mm; $p < 0.05$) and the structural modeling index (SMI) (0.62; 2.0; $p < 0.001$) decreased markedly. The CD continued to decrease (0.10; 8.0 1/mm³; $p < 0.01$) after peak bone mass, whereas SMI increased (0.37; 0.55; $p < 0.001$). Bone volume fraction (BV/TV) showed a non-significant increase until peak bone mass (0.18; 0.12%; $p = 0.05$), but a significant decrease after (0.47; 0.17%; $p < 0.001$). Trabecular separation (Tb.Sp*) increased before (0.51; 0.63 mm; $p < 0.001$) as well as after (0.35; 0.67 mm; $p < 0.001$) peak bone mass. Trabecular thickness (Tb.Th*) did not change significantly with age.

Conclusions: During growth (0–25 years), the architecture changes dramatically from a dense, highly connected network of rods to a less dense, less well connected network of plates, whereas the change in volume fraction of the trabecular network is less pronounced. During aging (>25 years), the architecture shifts to a less dense, less well connected network of rods accompanied by a loss of trabecular bone volume fraction. Interestingly, the mean trabecular thickness remains constant with throughout life.

Changes of Mechanical Properties of Lumbar Vertebrae in Ovariectomized Rats. ZhiQi Peng*, Jukka P. Rissanen, Jukka Vaaranemi, Heikki Vuorikoski, Jussi Halleen, Jukka Morko. Pharmatest Services Ltd, Finland

Ovariectomy (OVX) induces trabecular bone loss and decreases mechanical properties of femoral neck and lumbar vertebra in rats. However, it is not clear how OVX changes material properties of bone. We have demonstrated earlier that the decreased femoral neck strength in OVX rats was mainly due to elongation of the femoral neck, and OVX did not influence the bending strength in tibial diaphysis, suggesting that OVX did not influence material properties of rat bones. In order to understand the changes of the material properties of the lumbar vertebrae in OVX rats, we studied the compressive strength of the lumbar vertebral body with micro-CT analyzed vertebral samples. Eighteen young (3 months old) and 18 adult (6 months old) Sprague-Dawley rats were either OVX or sham operated. Lumbar vertebrae 5 (L5) of the young rats and lumbar vertebrae 4 (L4) of the adult rats were collected at 8 weeks after the operation and stored at -20°C. The lumbar vertebral bodies were trimmed by cutting from the pedicle of vertebral arch and pocketed by paraffin film for micro-CT scanning. After the micro-CT measurements, 4 mm long vertebral body cylinders were prepared for compressive test. Finally, the pressed vertebral bodies were embedded in plastic for sectioning to get the bone fracture morphometry. The micro-CT measurements and mechanical tests showed that the trabecular bone volume and maximal load of vertebral body were significantly decreased by OVX. The micro-CT analysis demonstrated that the minimum 2D cross-sectional bone area was in the cranial third of the artificially vertebral cylinder in all samples, and the fractures were found in this site or with some other sites. The stress of bone was calculated by maximal load to the minimum bone area. The stress was not affected by OVX. The modulus of bone was not affected either. The maximal load and the minimum bone

area correlated strongly both in L5 of young ($r = 0.807$, $p < 0.001$) and L4 of adult ($r = 0.766$, $p < 0.001$) rats. The study indicated that OVX did not influence the material properties of rat lumbar vertebral bone. Therefore, the changes of the bone mechanical properties in OVX rats were induced by bone structural changes due to the high bone turnover and the trabecular bone loss.

Differences in Skeletal Micro-architecture in African-American and Caucasian Women. Melissa Putman^{*1}, Elaine Yu², Elizabeth Schindler², Alexander Taylor², Emily Cheston², Mary Boussein³, Robert Neer², Joel Finkelstein². ¹Massachusetts General Hospital Children's Hospital Boston, USA, ²Massachusetts General Hospital, USA, ³Beth Israel Deaconess Medical Center, USA

African-American women have a lower risk of fracture than Caucasian women, and this difference is only partially explained by differences in DXA-measured areal bone mineral density (aBMD). Little is known about possible ethnic differences in skeletal micro-architecture.

Methods: To evaluate potential factors underlying these racial differences in aBMD and fracture rates, we assessed cortical and trabecular volumetric bone mineral density (vBMD), cortical porosity, and measures of cortical and trabecular bone micro-architecture using high-resolution peripheral quantitative CT (HR-pQCT, Scanco Medical AG) in 222 peri- and post-menopausal African-American (n=79) and Caucasian (n=143) women participating in the Study of Women's Health Across the Nation (SWAN) in Boston, MA.

Results: On average, the women were 59.8 years old and experienced their final menstrual period 7.5 years earlier. 10.8% had used oral glucocorticoids, and 9.9% had been treated with anti-resorptive medications. Caucasian women had lower BMI (28.4 vs. 31.4 kg/m², $p < 0.01$), had higher vitamin D levels (27 vs. 17.9 ng/mL, $p < 0.01$), and were more likely to use hormone therapy (29.1 vs. 44.1%, $p = 0.03$). On unadjusted analysis, African-American women had greater cortical area, cortical thickness, and cortical vBMD at both the radius and tibia ($p < 0.05$ for all). These differences remained significant after adjusting for weight. Cortical porosity did not differ consistently between races. Even after multivariate adjustment, cortical area of radius and tibia, and cortical thickness of radius remained significantly higher in African-American women than in Caucasians. Similar results were obtained after excluding women with histories of glucocorticoid use, hormone therapy, or bisphosphonate use. There were no consistent differences in total vBMD, trabecular vBMD, trabecular number or trabecular thickness between groups.

Conclusions: African-American women have higher cortical volumetric density and greater cortical thickness and cortical area than Caucasian women. These differences are present in both weight-bearing and non-weight-bearing bones and persist even after adjustment for weight. Structurally advantageous differences in cortical bone may be a key factor that contributes to the higher BMD and lower fracture risk observed in African-American women.

	Radius		Tibia	
	African-American	Caucasian	African-American	Caucasian

Effect of a High-Fat Diet on Bone Strain in Adult Rat Femurs. Cheryl Druchok*, Andrew Don-Wauchope, Alison Holloway, Gregory Wohl. McMaster University, Canada

A diet high in fat adversely affects bone mechanical and material properties but it is unknown how these changes affect bone adaptation. Bone adaptation is thought to occur in response to strain-related mechanisms, and strain in the bone is affected by both structural and material properties. The purpose of this study was to compare the mechanical strain during loading in femurs from rats fed a high-fat (HF) or normal control (NC) diet. The Animal Research Ethics Board at McMaster University approved all animal experiments. At weaning (3 weeks of age), male and female Wistar rats were randomly assigned to receive a normal control diet (NC-5% fat; N=8 per gender) or high-fat diet (HF-41% fat; N=8 per gender) until termination (39 weeks of age). Post-mortem, right femurs were harvested and scanned by microCT (GE

Medical Systems, Toronto). Rosette strain gauges were then attached to the posterior aspect of the femoral mid diaphysis. Strains were recorded as femurs were loaded in 3-point bending to physiologic levels in the anterior-posterior direction. Femoral cross-sectional properties (bone area (XSA), moment of inertia) determined from microCT scans, were significantly greater in HF femurs vs. NC for males and females ($p<0.05$) (Fig 1a). At the applied loads there were no significant differences in measured principal longitudinal strains between HF and NC femurs for either the male or female rats (Fig 1b). Elastic modulus was calculated from the load and measured strain data and no difference was found between NC and HF femurs for either gender. Despite the significantly larger cross-sectional area properties between HF and NC male and female femurs, there was no significant difference in measured bone strain. However, when the HF femur strain was predicted using the average NC elastic modulus and the HF femur cross-sectional properties, there was a significant difference between the predicted HF strain (HF-Pred E=NC) and the measured NC strain (NC-Actual) ($p<0.05$) (Fig 1c). These findings suggest that the significantly greater femoral cross-sectional properties are a compensatory mechanism for deficient material properties in the HF bone, and is consistent with the notion that adaptive modeling is targeted to strain or a strain related phenomenon to preserve bone structural integrity.

Effects of Cyclical Treatments with PTH and Alendronate on Trabecular Bone Mass and Strength. Sarah Amugongo¹, Wei Yao², Junjing Jia³, Daniel Walsh⁴, Mohammad Shahnazari⁵, Brian Panganiban⁶, Robert Ritchie⁶, Min Guan², Chin-Shang Li⁷, Nancy Lane². ¹University of California, Davis, USA, ²University of California, Davis Medical Center, USA, ³UCDavis, USA, ⁴UC Davis Medical Center, USA, ⁵UCSF VA Medical Center, USA, ⁶University of California Berkeley, USA, ⁷UC Davis, USA

Osteoporosis is currently treated with effective therapies that reduce fracture risk. While, the benefits of the individual agents are well known, the changes that occur following long-term sequential therapies in bone quantity and quality are not well understood. We evaluated these changes in an ovariectomized (OVX) rat model.

Methods: Six-month old female Sprague Dawley rats were either sham operated or OVX. The OVX rats were left untreated for two months to develop osteopenia then treated with subcutaneous injections of either vehicle (saline) 0.1ug/kg, 3x/wk; hPTH (1-34) 20ug/kg/d, 3x/wk; or alendronate (Ale) 0.5ug/kg/2x/wk. We studied three sequential treatment regimens in three 90 day cycles (Veh-Veh-Veh, PTH-Ale-Veh, Ale-PTH-Ale). Serum samples were collected for evaluation of biochemical markers of bone turnover, the 5th lumbar vertebrae were used for μ CT scans (microarchitecture and bone mineral density, BMD) and the 6th lumbar vertebrae were used for compression testing to determine bone strength (maximum (Max) load and stress).

Results: In OVX control group, bone turnover increased accompanied with decreases in BMD and strength from day 0-270 ($p<0.05$). In PTH-Ale-Veh group, PTH treatment day 0-90 increased Max load 81%, Max stress 70%, ($p<0.0001$); BMD 5% and Tb.Th 65% ($p<0.0001$) compared to OVX control. PTH-Ale treatment day 91-180 reduced bone strength parameters by an average of 9% ($p<0.005$) but maintained the increase in BMD and Tb.Th. PTH-Ale-Veh treatment day 181-270 further reduced strength by an average of 30%. However, at the end of treatment period Max load was 36% and BMD was 7% higher ($p<0.0001$) compared to baseline healthy rats. In Ale-PTH-Ale group, Ale treatment day 0-90 reduced DPD/Cr 67% ($p=0.0007$); increased Max load & stress ~40% ($p<0.05$) and did not change BMD compared to OVX control. Ale-PTH treatment day 91-180 increased DPD/Cr 47%, Max load & stress ~100%; BMD 8% and Tb.Th 100% ($p<0.000$). Ale-PTH-Ale treatment day 181-270 maintained the changes induced by PTH for all measured

parameters, which were higher compared to baseline healthy rats (Max load 88%, Max stress 53%, and BMD 8%, Tb.Th 53%).

Summary: Sequential treatment with PTH and Ale or Ale and PTH improve trabecular bone mass and strength. Additional studies are now being done to further evaluate the influence of cyclical therapies on cortical bone quality and quantity.

Evaluation of QCT Cortical Hip Parameters in a Clinical Trial with Rosiglitazone: The Potential for a New Study Endpoint? Colin G. Miller¹, Antonio J. Nino², John P. Bilezikian³, Barbara Kravitz², Gitanjali Paul², Alexander R. Cobitz², Allison R. Northcutt², Lorraine A. Fitzpatrick². ¹Bioclinica, USA, ²GlaxoSmithKline Pharmaceuticals, USA, ³Columbia University, College of Physicians & Surgeons, USA

Quantitative Computerized Tomography (QCT) measurements have been used extensively for ascertaining information about bone quality and density due to the 3D information it provides and its ability to segment out trabecular and cortical bone. This is particularly important for the evaluation of new therapeutic agents that affect bone metabolism and for the understanding of the role that each bone compartment plays in the pathogenesis and prognosis of fracture. However, precise assessments of the cortical bone remain elusive. This study was conducted to explore the effect of edge definition at different thresholds at the femoral neck (FN) in vBMD assessment.

We previously presented the Mechanism-of-Action Study1, assessing the effect of rosiglitazone (RSG) on bone mass and structure of the lumbar spine (LS) and FN DXA for areal Bone Mineral Density (aBMD) and with QCT1 for volumetric BMD (vBMD). We also presented an analysis of the cortical bone vBMD in FN quadrants (FNQ's). Here we present further evaluation of the FNQ's as measured by QCT.

This was a double-blind, randomized study in postmenopausal women with Type 2 Diabetes mellitus; BMD T-score >-2.5 at FN, LS, and total hip (TH). Subjects were randomized to RSG or metformin (MET) for 52 Weeks (Wk) followed by 24Wk of open-label MET. DXA T-scores: FN=-0.960.91; TH=-0.020.97; LS=-0.551.25

Using spiral multi-detector scanners with a standard acquisition technique, a subset of 79 subjects underwent QCT scans of the hip at baseline, after 52Wk of double blind treatment and after 24Wk of treatment with MET. All scans were evaluated centrally and analyzed using Mindways Software Inc. The % change in cortical vBMD and cortical thickness (mm) FNQ's is presented at 3 different thresholds: 350mg/cm³, 375mg/cm³, 400mg/cm³.

The results using different thresholds yielded changes in similar direction in cortical vBMD and cortical thickness at the superior-posterior quadrant. Cortical vBMD at the FN can be precisely segmented from trabecular bone and used to demonstrate therapeutic effect on this bone compartment. FNQ may provide utility as an endpoint in clinical trials for the elucidation of the therapeutic effect of new entities.

Fibula Osteotomy Model in the Sprague-Dawley Rat: Radiology, Densitometry, Biomechanics and histological characterization. Aurore Varela^{*1}, Luc Chouinard², Yannick Trudel³, CAROLINE RUH³, Iryna Primakova³, Gabrielle Boyd³, Katherine Escott⁴, Susan Y. Smith¹. ¹Charles River Laboratories, Canada, ²Charles River Laboratories, PCS Montreal, Canada, ³Charles River, Canada, ⁴Astrazeneca R&D, United Kingdom

The objective was to characterize the rat fibula osteotomy model using positive (PTH1-34 (PTH) and Alendronate (ALN)) and negative controls (Diclofenac (Dicl)). Male rats (18/group) were assigned to 4 groups and terminated 15 or 29 days after surgery. Five females were assigned as controls to assess gender effects (euthanized on Day 29). Animals received 0.5% methylcellulose and 0.025% Tween 20 orally daily or PTH (60 µg/kg/dose SC, 3/week) or ALN (0.03 mg/kg/dose SC 2/week) or Dicl (5 mg/kg/day orally daily). In addition, 45 females were assigned to control, PTH and ALN groups for histology. Osteotomy was performed at midshaft using a bone cutter. Clinical signs, body weights (BW) and food consumption (FC) were evaluated. X rays were taken after surgery at Weeks 1, 2, 3, 4 and Faxitron images obtained ex vivo. Callus area and BMC were measured by pQCT and Micro-CT ex vivo. Fibulae (osteotomized and intact) were tested in 4 point bending. Histologically, callus was scored for fibrous, cartilaginous or bone tissue relative percentages.

Animals recovered quickly, without signs of pain or effect on BW or FC. At Day 28, a similar radiological healing was observed between controls, PTH and ALN groups. In Dicl group, bone healing was lower with less cortical remodeling and bridging. Callus size measured by pQCT increased on PTH and ALN and decreased on Dicl at Day 14. Callus BMC showed a marked increase on ALN and a marked decrease on Dicl. At Day 28, similar differences between treatment groups were noted. Micro-CT changes in callus size and mineralization were similar. At Day 14, Peak load was increased 41% on ALN and decreased 35% on Dicl. At Day 28, peak load was decreased 25% on Dicl. At Day 28, peak load recovered to 50% relative to contralateral intact side in controls, PTH and ALN groups, and to 40% in Dicl group. No difference was noted between males and females. Histologically, callus was undergoing endochondral ossification with no meaningful effect of PTH. ALN treatment resulted in a slightly higher histologic score compared with controls.

The effects of PTH, ALN and Dicl in this model were consistent with the published data in rat bone healing models as determined by X-rays, densitometry, histology and biomechanics. Significant refinements using this model relative to other models include simple surgery, no immobilization, minimal limb stress, rapid healing and improved animal welfare.

Fracture Risk Classifiers based on Statistical Shape and Density Modeling of the Proximal Femur. Todd Bredbenner^{*1}, Robert L. Mason¹, Lorena M. Havill², Eric Orwoll³, Daniel P. Nicoletta¹. ¹Southwest Research Institute, USA, ²Texas Biomedical Research Institute, USA, ³Oregon Health & Science University, USA

The performance of fracture risk classifiers based on statistical shape and density modeling (SSDM) methods was investigated using a case-cohort sample of individuals from the Osteoporotic Fractures in Men (MrOS) study. Baseline QCT data of the right femur were obtained for 512 individuals, including 45 who fractured a hip (mean 6.9 year observation, validated by physician review) and a random sample of 472 men.

To date, QCT data were processed for 450 individuals (40 fracture cases and 410 non-cases; all processing was performed while blinded to fracture status) to develop volumetric models describing geometry and spatial BMD distribution of the 450 right proximal femurs. Each 3D model consisted of ~57,000 variables (i.e. spatial location and density at each mesh node located at corresponding anatomic positions for all femurs). Mean fracture and non-case models were created and complex variations in geometry and BMD distribution were demonstrated between the mean models (Figures 1a and 1b).

SSDM, based on Principal Component Analysis, was used to describe variation in 3D bone geometry and BMD distribution within the set of 450 individual femurs by reducing the ~57,000 highly correlated variables for each model to a set of 449 uncorrelated and independent principal components (e.g. composite geometry and BMD traits) without loss of information. Logistic regressions were used to model the relation of baseline hip aBMD (DXA QDR 4500W; Hologic) and principal component weighting factors to the occurrence of hip fracture. A classifier based on stepwise selection of 40 of the 449 weighting factors and adjusted for age and BMI had an area under the receiver operating characteristic (ROC) curve (AUC) of 0.994 and a classifier based on aBMD, age, and BMI had an AUC of 0.838. The SSDM-based classifier correctly identified 25 out of 40 cases compared to 7 out of 40 for the aBMD-based classifier in leave-one-out cross-validation analyses.

Fracture risk predictions based on SSDM outperformed that of aBMD in classification accuracy and AUC values, regardless of age and BMI inclusion. Principal components defined using SSDM identify complex combinations of structural bone traits (e.g. geometric and BMD distribution traits) that appear to indicate fracture risk. Finally, description of bone sample variation using SSDM allows investigation of important structural differences that may allow improved prediction of those at risk for future hip fracture.

How Tough is Brittle Osteogenesis Imperfecta Mice Bone?. Alessandra Carriero^{*1}, Elizabeth Zimmermann², Bjoern Busse², Sandra J. Shefelbine¹, Robert O. Ritchie². ¹Imperial College London, United Kingdom, ²University of California, Berkeley, USA

Osteogenesis imperfecta (OI) or 'brittle bone disease' is a major birth defect occurring in approximately 1 in every 20,000 human births. It is caused by bone fragility and skeletal deformities due to mutation in the collagen type I genes. As bone fracture is the primary symptom of OI, it is crucial to understand how this mutation affects the initiation and growth of the crack on small length-scales as well as larger length-scales.

A mouse model of the disease, B6C3fe-a/acoli1a2oim/oim (oim), was used to characterize the toughness and crack propagation of oim bones in comparison to control (WT). Fresh frozen femora of contralateral sides of 9 oim and 11 WT mice were dissected and notched on the posterior surface of the mid-diaphysis with a razor blade irrigated with 0.5 µm diamond suspension. To characterize changes in bone toughness, the left femora were tested in three-point bending immersed in HBSS using an EnduraTec Elf 3200 machine. To determine the origin of toughness and define changes in crack path at the microstructural level, 2D crack propagation was observed in an environmental scanning electron microscope (ESEM); the right femora were polished on the periosteal surface, soaked in HBSS for at least 12 hours and tested in three-point bending using a GATAN in situ loading stage within an ESEM. All femora were loaded under displacement control at a rate of 0.001 mm/sec.

Results showed that oim bone exhibited classic brittle behavior with fracture occurring just after the yield point of the tissue. The area of stable crack growth and maximum loads were much smaller in oim bone. The coefficient of toughness k (calculated with the instability method) of oim bone was significantly lower than for WT bone ($p \leq 0.001$). High resolution real-time ESEM images of the crack propagation showed that in both oim and WT crack initiated at the notch root and propagated through the canals. Oim bone did not exhibit any mechanism to resist crack growth, and the crack propagated quickly and transversally. In the WT the crack deflected and resisted propagation with typical toughening mechanisms such as forming uncracked-ligament bridges. These results suggest that the lack of lamellar structure in oim bones may have implications for fracture toughness. We believe that differences between oim bone and WT bone nanostructure behavior may further help to explain the dramatic increase in fracture rates.

Image Quality Control for the Detection of Subject Motion in HR-pQCT. Yves Pauchard^{*1}, Anna-Maria Liphardt¹, Eva Szabo², Heather Macdonald³, David Hanley¹, Steven Boyd¹. ¹University of Calgary, Canada, ²Roger Jackson Center for Health & Wellness Research, University of Calgary, Canada, ³University of British Columbia, Canada

Subject motion during high-resolution peripheral quantitative computed tomography (HR-pQCT) causes image artifacts that affect morphological analysis of bone quality.

The aim of our study was to develop an automated quality control method and compare it to manual motion grading in vivo.

An automated technique was developed to measure in-plane translation (XYtrans) and rotation (XYrot) using CT projection data (Pauchard, et. al. IEEE ISBI 2009), as well as longitudinal translation (Ztrans). For validation, a phantom containing sections of distal cadaver radii was attached to a mechanical device and precisely controlled in-plane rotation and longitudinal translation was intentionally added during HR-pQCT data acquisition. Motion measured by the new technique was compared to applied motion, and morphological parameters were calculated to obtain percent error with respect to motion free images. Following validation, subject data was assessed for motion with both the new automated technique and manual grading (0=best, 4=worst) in N=137 image pairs (scan/re-scan) from Canadian Multicentre Osteoporosis Study (CaMos) Calgary cohort (Macdonald, et. al. JBMR, 2011). The coefficient of variation (CV) was calculated based on scan pairs below defined grading levels (see Table 1).

Morphological parameter error graphed as a function of measured motion shows a non-linear increase in parameter error with increased motion (Fig. 1). Paired t-tests showed that XYtrans is independent of bone type and robust to longitudinal motion ($p < 0.05$). CV results (Table 1) demonstrate improved reproducibility when only low motion images were included as determined by manual grading and automatic motion measurement. Consistent with previous data, Tt.BMD was most robust, Ct.Th decreased and Tb.N increased with increased motion.

Out of the three automated motion components considered, XYtrans was the most accurate and robust measure. Both automatic (XYtrans) and manual grading are suitable measures for image quality control in the presence of subject motion in vivo. To obtain reproducibility as reported earlier images should not exceed a manual grading of 2 or an automatic XYtrans grading of 1.2.

The automated technique provides fast and objective image quality control for subject motion in HR-pQCT scanning. It can be performed retrospectively based on original scan data. The technique is well suited for multicentre studies as well as any research where objective quality control is paramount.

Fig. 1 Morphological error versus automatically detected motion type.

Influence of Model Parameters in Large Scale Finite Element Simulations When Evaluating Stress Field in Human Trabecular Bone. Baptiste Depalle^{*1}, Roland Chapurlat², Benyebka Bou-Said³, Helene Follet⁴. ¹INSERM, UMR 1033 ; Universite de Lyon, France, ²E. Herriot Hospital, France, ³Universite de Lyon, CNRS, INSA-Lyon, LaMCoS UMR5259, France, ⁴INSERM, UMR1033 ; Universite De Lyon, Fra

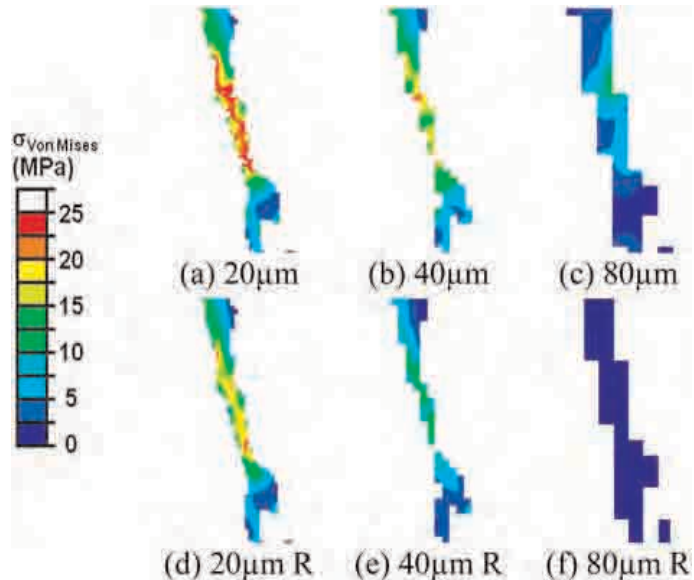

Numerical simulation using finite element models (FEM) has become more and more suitable to estimate the mechanical properties of trabecular bone. The size and kind of elements involved in the models, however, may influence the results. The purpose of this study is to analyze the influence of the element formulation on the evaluation of mechanical stress applied to trabeculae bone during the compression test simulation.

Trabecular bone cores (D=8.2mm, L=15mm) were extracted by necropsy from 18 L2 vertebrae (12 women and 6 men, mean age: 7611, BV/TV=7.51.9%). Samples were micro-CT scanned at 20µm isotropic voxel size. Micro-CT images have been sub-

sampled (20, 40 and 80µm) to create 5.6mm cubic FEM. For each sample, six models of a compression test have been created, two for each voxel size, with and without reduced integration formulation. Bone mechanical properties have been supposed isotropic, homogenous, following a linear elastic behavior law (Young modulus: 8GPa, Poisson ratio: 0.3).

Increasing voxel size led to micro-architecture modifications (loss of connectivity, trabeculae thickening) and changed stress distribution in bone tissue. Even if apparent mechanical properties were similar, stress concentrations were altered. Increasing the voxel size leads to a higher underestimation of stress magnitude and to a smoother distribution. This trend was amplified with reduced integration formulation. With 80µm size reduced elements, as used clinically, few stress variations were detectable (Figure). These observations also depended on trabecular thickness. Less than 2 elements within the trabeculae led to poor stress distribution assessment.

In conclusion, we found that the element size and the integration formulation influence trabecular mechanical behavior evaluation. This statement should be accounted for in clinical measurements.

Von Mises stresses in a trabeculae depending of both voxel size and elements formulation (R=reduced)

Modeling the Load Capacity of the Proximal Femur. Joyce Keyak^{*1}, Thomas Lang². ¹University of California, USA, ²University of California, San Francisco, USA

Purpose: Although finite element analysis (FEA) is used to evaluate hip strength, FEA strength is usually not the actual load capacity of the hip. Thus, we developed an FEA method to explicitly compute the hip's load capacity.

Methods: Quantitative computed tomography (QCT) scans of 17 matched pairs of cadaveric femora (age 52-92 yr) were obtained (GE 9800, 1.08mm pixels, 3mm slices, 80kVp, 280mAs). One femur from each pair was randomly selected for FEA and mechanical testing to failure under single-limb stance loading; the other was studied under posterolateral fall (Plfall) loading. Nonlinear mechanical properties, including post-failure strain-softening, were derived from QCT BMD. Displacement was applied to the femoral head, the shaft was constrained and, for fall loading, the greater trochanter surface was constrained. As displacement was incrementally applied, the FEA computed the femoral head reaction force, thereby producing a force-displacement curve and explicitly computing the load capacity (peak load) of the hip (Figure). Initially, to optimize material modeling, iterative analyses were used to maximize the correlation coefficient (R) between FEA and measured load capacity. For Plfall, 8 femurs were selected randomly for optimization; the other 9 were used to evaluate R independently. Stance loading was reported previously; results are included here for completeness. Precision in vivo was evaluated for stance, Plfall, lateral fall (Lfall), and posterior fall (Pfall) by performing repeat CT scans with repositioning and FEA of 9 postmenopausal women (age 47-71 yr), and calculating the root-mean-square percentage coefficient of variation (%COV). For comparison, % COV was computed for yield loads defined as the load at which 0.4cc had yielded.

Results: Compared with FEA yield loads, FEA peak loads were more strongly associated with measured peak loads for stance (peak, R=0.91-0.96; yield, R=0.78; published data) but similarly associated with measured peak loads for Pfall (peak, R=0.90; yield, R=0.93; for the 9 femurs). The %COV's were generally smaller for peak loads than for yield loads (%COV peak vs yield: Stance=1.6% vs 13.1%, Plfall=4.9% vs 6.4%, Lfall=5.4% vs 5.0%, Pfall=5.8% vs 9.5%).

Conclusions: The FEA-computed load capacity of the hip provides better reproducibility and equal or better predictions of measured peak loads compared with FEA yield loads. Thus, FEA-computed load capacity may be an improved measure for assessing hip fracture risk.

N-acetyl Cysteine Supplementation Mitigates Deterioration of Bone Microstructure in Mice Fed a High-Fat Diet. Brian Gregoire¹, Jay Cao^{*2}. ¹USDA ARS Grand Forks Human Nutrition Research Center, USA, ²USDA ARS, USA

Studies have demonstrated that obesity induced by high-fat diet increases bone resorption, decreases trabecular bone mass, and reduces bone strength in various animal models. This study investigated whether N-acetyl cysteine, an antioxidant, supplementation ameliorates deterioration of bone microstructure in mice fed a high-fat diet. Forty-eight 6-wk-old male C57BL/6 mice were randomly assigned to four treatment groups (n=12/group) and fed either a low-fat diet or a high-fat diet at libitum with or without N-acetyl cysteine supplementation (1 g/kg diet) for 3 months. Bone microarchitecture of distal femur was evaluated using micro-computed tomography. Body weight was recorded. Serum leptin concentrations were measured. Bone marrow cells were harvested for osteoclast formation. Compared to the low-fat diet, the high-fat diet increased body weight, serum leptin, osteoclast number, trabecular separation, and structural model index, while decreased bone mineral density, trabecular bone volume, connectivity density, and trabecular number. N-acetyl cysteine supplementation increased bone volume/total volume, connectivity density, and bone marrow osteoclast number in high-fat obese mice. These results indicate that antioxidant supplementation is beneficial to bone structure of obese mice induced by a high-fat by decreasing bone resorption.

Non-invasive Quantification of Changes in Bone Micro-architecture and Strength: Three Year Follow-up at the Distal Radius. Ingrid Knippels^{*1}, L. Joseph Melton², Shreyasee Amin², Steven Boonen³, Sundeep Khosla⁴, Harry Van Lenthe⁵. ¹KULeuven, Belgium, ²Mayo Clinic, USA, ³Center for Metabolic Bone Disease & Division of Geriatric Medicine, Belgium, ⁴College of Medicine, Mayo Clinic, USA, ⁵Katholieke Universiteit Leuven, Belgium

With the introduction of high-resolution peripheral quantitative computed tomography scanners, detailed 3-dimensional *in vivo* imaging of human radii has become possible. Therefore, modeling and remodeling of bone in the distal radius can now be quantified in individual patients in terms of microstructural changes. The aim of this study was to measure changes in bone microarchitecture taking place during three years and to quantify the effects on bone strength.

In 119 adults (14 male, 105 female, age 6216) we scanned one of the distal radii twice with an interval of approximately 3 years (Mayo Clinic, Rochester, Minnesota, USA). Measurements at the first timepoint (TP1) were made with a prototype of the scanner while the measurements at TP2 were made using the XtremeCT (Scanco Medical AG, Brütisellen, Switzerland). Three-dimensional image registration [1] was performed to determine the bone volume common to both scans. 12 data sets had to be excluded for technical reasons, leaving 107 data sets for morphometry analysis. These analyses were performed on the volume that was present at both TPs using the standard evaluation protocol provided by the scanner manufacturer. Measures of volumetric bone mineral density (vBMD), trabecular bone volume fraction (BV/TV), trabecular number (Tb.N), trabecular separation (Tb.Sp) and cortical thickness (Ct.Th) were taken. Bone strength was determined from finite element (FE) analyses using a previously validated modeling approach [2]. All measurements of TP2 were corrected based on a cross-over study between the scanners used at TP1 and TP2 [3].

In this diverse group of adults, we found significant changes in vBMD, Ct.Th and Tb.N (Table 1). In individual subjects, up to 40% reductions in Ct.Th and 20% reduction in strength were found. Loss in vBMD was the best single predictor of bone strength reduction, although it only explained 31% of the variance.

In summary, we quantified changes in bone microarchitecture and strength at the distal radius occurring over a period of three years. Our data underline the strong patient-specific nature of longitudinal changes in bone.

Transiliac crest bone biopsy is a useful invasive means to assess bone histology. Accordingly, paired bone biopsies are also used to evaluate the effect of an osteoactive compound over an administration period. Data about a potentially existing side to side variance between paired biopsies are scarce.

Aim of the current study was to analyze the variance of paired transiliac crest biopsies that had been obtained under ideal conditions. Samples were taken in a population of brain-dead organ donors as part of explant surgery. The two biopsies were performed by the same surgeon directly after organ explantation. Consecutive organ donors between 10/2009 – 12/2010 were included into the study. The included donors were very carefully defined and healthy; donors with history of fractures or who had received any osteoporotic treatment or medication with impact on bone metabolism were excluded from the presented study. Histomorphometric analyses were performed in duplicates by the same technician who was blinded to patient's identity.

The total number of patients was 46 (27 males, 19 females) median age was 52.5 + 13 with a BMI of 23 + 2.1. All parameters investigated were comparable between men and women. Intraindividual variation coefficients ranged between 4.2 % (BV/TV) – 9.8 % (TbPf). The results of the histomorphometric analysis are listed in table 1. No differences between the sides of the paired biopsies were observed variance ranged from 0.9% (QS/BS) to 22% (ES/BS).

Histomorphometric analysis of bone biopsies – at least performed under standardized conditions - is a high sensitive approach to assess bone metabolism. As bone biopsies showed comparable results between both sides they might represent a possibility to investigate effects of specific medications even in small populations.

Table 1:

Left Right Delta (%) p-value	
BV/TV (%)	24.4 + 4 24.5 + 5 3 + 5 p = 0.79
BS/BV (%)	18 + 3 17 + 2 5 + 5 p = 0.14
OS/BS (%)	6.4 + 2.3 6.6 + 2.1 6 + 15 p = 0.32
ES/BS (%)	2.4 + 1 2.3 + 1 22 + 27 p = 0.79
QS/BS (%)	91 + 3 91 + 2 0.9 + 1 p = 0.74
Tb.N. (mm-1)	1.8 + 0.4 1.7 + 0.3 7 + 4 p = 0.37
Tb.Th (µm)	142 + 26 140 + 25 3.6 + 7 p = 0.22
Tb.Sp (µm)	420 + 87 426 + 100 4.5 + 7 p = 0.31

BV/TV (bone volume/tissue volume), BS/BV (bone surface/bone volume), OS/BS (osteoid surface/bone surface), ES/BS (eroded surface/bone surface), QS/BS (quiescent surface/bone surface), Tb.N (trabecular number), Tb.Th (trabecular thickness), Tb.Sp (trabecular separation rate)

Prediction of Apparent Modulus, Ultimate Stress and Ultimate Strain of Human Vertebrae using a Viscous Damage Model with Softening. Jakob Schwiedrzik*, Enrico Dall'Ara, Philippe Zysset. Vienna University of Technology, Austria

Approximately 750000 osteoporosis-related vertebral compression fractures occur in the US every year. Quantitative computed tomography (QCT)-based finite element (FE) is an increasingly accepted method to assess vertebral strength in clinical studies. This work aimed at validating an improved QCT-based FE model featuring viscous damage and softening with in vitro experiments. The model was intended to extend the current predictions of apparent modulus (Y) and ultimate stress (σ_u) with the prediction of ultimate strain (ϵ_u) of vertebral bodies based on QCT scans obtained in vitro.

For the experiments, the endplates and posterior elements of 37 human thoracolumbar vertebral bodies (donors: 7 male, 3 female, 44-82 yrs) were removed. The vertebral sections were scanned with QCT and tested in monotonic compression at a rate of 5 mm/min. A ball joint allowed rotation of the loading plate during testing. The position of the upper loading plate was measured directly with 3 sensors to minimize the errors induced by machine compliance.

A nonlinear anatomy-specific FE model was generated for each vertebra from the vBMD-calibrated QCT images. Coarsened CT voxels were converted into finite elements with constant material orientation and BMD based material properties. Transverse isotropy in the cranial-caudal direction was assumed. Material parameters for viscous damage and softening were identified from the compression experiments optimizing the correspondence between FE predictions and experimental results. The FE models were loaded by a rigid loading plate, which motion reproduced the one recorded during the experiments.

Predicted Y, σ_u and ϵ_u were compared to the experimental data for each vertebral section. The FE model featuring viscous damage and softening predicted both Y ($p < 0.001$, $R^2 = 0.68$) and σ_u ($p < 0.001$, $R^2 = 0.77$) well. The correlation for ϵ_u was also significant ($p < 0.001$), however the R^2 was low ($R^2 = 0.37$) due to small range in ultimate strain. The predicted average ϵ_u was significantly lower than the experimental one ($p = 0.01$), but the relative difference was small ($< 10\%$). The linear regressions of the FE prediction for Y, σ_u and ϵ_u were close to the 1:1 relation. The model was able to predict vertebral Y, σ_u and ϵ_u of specific vertebrae under realistic boundary conditions with sufficient accuracy. It remains to be verified if the predictions remain accurate for in vivo scans which would make FE a possible predictive tool in future clinical studies.

Prediction of Forearm Failure Load in Women: the OFELY Study. Nicolas Vilayphiou*, Stephanie Boutroy¹, Elisabeth Sornay-Rendu¹, Bert van Rietbergen², Roland Chapurlat¹. ¹INSERM UMR1033, Université de Lyon & Hospices Civils de Lyon, France, ²Department of Biomedical Engineering, Eindhoven University of Technology, Netherlands

There is a growing interest for in vivo assessment of bone strength. However, the necessary technique for this evaluation - microfinite element analysis (μ FEA) - is highly demanding in computational resources. So, we sought to predict one of the outcomes of μ FEA by variables easily obtained by high resolution peripheral QCT (HR-pQCT) imaging of the distal radius.

Our cross-sectional analysis involved 831 women from the OFELY cohort who had a valid HR-pQCT radius scan. There were 228 pre- and 603 postmenopausal women, aged 407 and 679 years old respectively.

Distal radius HR-pQCT scans were used to measure volumetric BMD (vBMD), bone geometry and microarchitecture parameters, after segmentation of cortical (Ct) and trabecular (Tb) bone with advanced algorithm (Burghardt, Buie et al. Bone 2010). Estimated failure load for a fall on the outstretched hand was assessed on those segmented bone volumes by μ FEA. Areal BMD was measured at the ultradistal radius (UDR) by DXA at the same visit.

In premenopausal women, most parameters did not vary with age, thus they were used as reference data to calculate standardized T-scores for the variables included in the prediction model.

First, univariate regression models showed that the failure load was best predicted by UDR aBMD ($R^2 = 0.79$, $p < 0.001$). Among HR-pQCT parameters, it was the Ct area (CtAr) that was the best predictor of the failure load ($R^2 = 0.68$, $p < 0.001$). It was followed by total, Ct and Tb vBMD, and Ct thickness, with R^2 ranging from 0.49 to 0.61 ($p < 0.001$). Age and other microarchitectural or geometrical parameters were poor predictors of bone strength (all $R^2 < 0.31$, $p < 0.001$).

In ascending multivariable regressions using only HR-pQCT parameters, the best surrogate variables to predict failure load included only Ct.Ar and Tb.vBMD, with $R^2 = 0.85$ ($p < 0.001$). The addition of other microarchitectural parameters, age or UDR aBMD did not improve significantly the R^2 coefficient (up to $R^2 = 0.89$).

In conclusion, Ct.Ar combined with Tb.vBMD may be a surrogate variable of μ FEA estimated failure load. Without running μ FEA, this method could help to estimate indirectly and more quickly bone strength based only on HR-pQCT measurement in large datasets. Further validation will be needed regarding its use in fracture risk assessment.

Radius and Tibia Strength Assessed by High Resolution pQCT Micro Finite Element Analysis: Effects of Age and Gender. Jennifer Walsh*, Margaret Paggiosi², Richard Eastell³. ¹NIHR Bone Biomedical Research Unit, United Kingdom, ²Sheffield Teaching Hospitals NHS Foundation Trust, United Kingdom, ³University of Sheffield, United Kingdom

We have previously reported that there are gender and age differences in cortical and trabecular microarchitecture assessed by HR-pQCT. Men have greater cortical perimeter than women at all ages. In men and women, cortical tissue mineral density is lower and cortical porosity is higher at age 16-18 and after age 70 compared to age 30-32. Micro-finite element modelling can be applied to HR-pQCT images to determine measures of bone strength. The aim of this study was to identify whether these differences in microarchitecture result in differences in bone strength between the end of longitudinal growth, peak bone mass and older age.

We conducted a cross-sectional observational study of 179 healthy men and women in three age groups; 16-18 (younger), 30-32 (peak bone mass) and 70+ (older). HR-pQCT images of the distal radius and distal tibia, acquired using the XtremeCT device (Scanco, Switzerland), were analysed with Imaging Processing Language software (Scanco) to obtain measures of stiffness and ultimate failure load in simulated compression. ANOVA with age group and gender as fixed factors and linear contrast were used to compare groups.

In all age groups, failure load and stiffness measures for the radius and tibia were greater in men than in women ($p < 0.001$). In men and women, failure load and stiffness measures for the radius and tibia were lower at older age than at peak bone mass.

In men, but not in women, radius failure load and stiffness were lower in younger adults than at peak bone mass. There were no significant differences in tibia failure load or stiffness between younger adults and peak bone mass in men or women.

We conclude that bone strength is greater in men than women which may be due to greater bone size. Despite different patterns of trabecular loss, both men and women demonstrate a reduction in bone strength with aging, and so the reduction in strength may be mostly due to cortical changes. The differences in radius stiffness and failure load between younger men and those at peak bone mass may reflect ongoing bone modelling with cortical consolidation. This may not have been apparent in women in this study due to the earlier onset and end of female puberty. There were no differences in tibia bone strength measures between the end of longitudinal growth and peak bone mass in men or women. This suggests that the age of completion of bone modelling may differ between weight-bearing and non-weight bearing sites.

		Radius		Tibia	
		Stiffness, kN/mm	Failure load, kN	Stiffness, N/mm	Failure load, kN
Women	16-18	71.7 (12.9)	3.67 (0.63)	215.9 (30.3)	10.93 (1.56)
	30-32	73.2 (12.2)	3.72 (0.60)	211.2 (32.3)	10.57 (1.52)
	70+	59.6* (13.9)	3.07* (0.69)	173.8* (33.7)	8.77* (1.62)
Men	16-18	95.5* (23.3)	4.90* (1.11)	294.7 (46.9)	14.93 (2.91)
	30-32	112.0 (22.8)	5.64 (1.04)	304.8 (46.9)	15.14 (2.24)
	70+	95.0* (20.7)	4.91* (0.99)	266.7* (43.7)	13.39* (2.10)

Role of Glycation in Microdamage Morphology in Cancellous and Cortical Bone. Lamya Karim*, Deepak Vashishth, Rensselaer Polytechnic Institute, USA

Factors other than low bone mass, such as changes in bone quality, may contribute to fracture risk. Non-enzymatic glycation (NEG) alters bone's extracellular matrix (ECM) and creates crosslinks known as advanced glycation end products (AGEs) that accumulate and increase bone fragility [1]. Elevated levels of AGEs may affect bone fracture resistance mechanisms such as the formation of microdamage since NEG stiffens bone's organic matrix and compromises its ability to dissipate energy. The goal of this study was to investigate the link between microdamage and NEG in both cancellous and cortical bone. 22 trabeculae were extracted from human cancellous bone cores that were mechanically tested and stained to detect microdamage [2]. Trabeculae were imaged with microcomputed tomography. Structure Model Index (SMI) was computed to categorize trabecular structure, and damaged surface area to volume ratio (DS/DV) for microdamage was calculated to characterize its morphology. Trabeculae were quantified for AGEs [3]. 9 human cortical bone beams were fatigue tested and stained with basic fuchsin to target microdamage. They were sectioned transversely into 4 μ m thick sections and mounted on membrane slides. Linear microcrack (LMC) and diffuse damage (DD) regions were laser-microdissected and collected in isolation caps. An extraction buffer was added to each tube and incubated to extract proteins (24 hours, 4C). Protein extracts were dialyzed against 1x PBS (24 hours, 4C), and extracts were used for AGEs quantification [4]. T-tests were run between AGEs quantity in LMC and DD regions while correlation tests were run between SMI and DS/DV; and between SMI and AGEs. Trabecular rods, which produced crack-like microdamage ($p<0.05$), were highly glycated ($p<0.05$) compared to trabecular plates. Similarly in cortical bone, regions of LMC were more glycated than regions of DD ($p=0.06$). Our results demonstrate that ECM property changes via NEG are responsible for the formation of specific morphologies of microdamage. This mechanism is similar in both cancellous and cortical bone where highly glycated regions of bone produce LMC that results in decreased fracture resistance.

The Ability of Quantitative Ultrasound in Predicting the Principal Structural Orientation of Trabecular Bone. Liangjun Lin*¹, Christopher Lin², Frederick Serra-Hsu³, Jiqi Cheng¹, Yi-Xian Qin¹. ¹State University of New York at Stony Brook, USA, ²Ward Melville High School, USA, ³State University of New York, Stony Brook, USA

Introduction: Trabecular bone has the ability to adapt its microstructure to the loading environment [1]. The propagation of ultrasonic wave in trabecular bone is closely associated with the anisotropic mechanical properties and structural orientation [2]. The main objective of this study is to investigate the feasibility of using quantitative ultrasound to non-invasively predict the principal structural orientation of trabecular bone.

Materials and methods: A trabecular bone ball (diameter 25mm) was machined from bovine femur. Three main axes of superior-inferior (SI), antero-posterior (AP),

and medio-lateral (ML) orientations were marked on the surface of the bone ball. A quantitative ultrasound scanning system with 1MHz confocal transducers was used for the ultrasound tests. Ultrasound velocity (UV), attenuation (ATT) and broadband ultrasound attenuation (BUA) were recorded from the ultrasound test. The bone ball was rotated 10 degrees between ultrasound scans around each axis, resulting total $36 \times 3 = 108$ scans. To analyze the data, a 5×5 mm² region of interest (ROI) was selected in the center of the bone ball for each ultrasound image.

Results: Ultrasound scans around axis SI (Figure 1) did not showed particular results in any scanning direction for all three recorded parameters. But results around AP (Figure 2) and ML (Figure 3) axes showed that ultrasound signal in certain directions are stronger or weaker than in the others. In both AP and ML results, high peaks of BUA and UV curves appeared in the same scanning angle where low valleys appeared in the ATT results. And these high peaks and low valleys were symmetric: two peaks/valleys in every curve were located approximately 180 degrees from each other, indicating they were from the ultrasound scan along the same path in opposite directions.

Conclusion: Our quantitative ultrasound device provided the preliminary evidence that the results of ultrasound scans for trabecular bone are closely associated with different scanning directions. The symmetry of the data also revealed the repeatability and the validity of the results. The relation between the ultrasound results and the structural orientation needs to be further confirmed by computer tomography and mechanical testing in the future work.

Modulation of Bone's Mechanical Properties by its Architecture, Chemical Composition, and Age. Andrea Trinward^{*1}, Steven Tommasini¹, Alvin Acerbo², Lisa Miller³, Stefan Judex¹. ¹Stony Brook University, USA, ²Brookhaven National Laboratory, USA

Osteoporosis is associated with bone loss and a deterioration in tissue quality. Drugs such as alendronate (ALN), parathyroid hormone (PTH) and sodium fluoride (NaF) target bone loss differently leading to drug-specific changes in bone architecture, chemical composition, tissue age and ultimately, strength. To determine how drug-induced changes to bone quality relate to mechanical strength, we subjected OVX rats to 6mo of varying doses of ALN, PTH and NaF and analyzed cortical and trabecular bone through μ CT analysis, dynamic histomorphometry, FTIR and correlated to mechanical properties. Six mo old Sprague Dawley rats (n=10/group) were assigned to aged-matched controls (AM), OVX controls, OVX treated with high (H), medium (M) or low (L) doses of PTH (60, 15, or 0.3 μ g/kg/d), OVX treated with H, M or L-ALN (100, 10 or 1 μ g/kg/2xwk) or OVX treated with H or L-NaF (500 or 100ppm). At 12mo of age, OVX had 46% less trabecular bone in the L-4 vertebral body than AM. H- and M-doses of ALN, PTH and NaF maintained trabecular architecture while H-PTH increased cortical & trabecular thickness (Tb.Th) by 29% and 32% compared to AM (p<0.05). Mineral apposition rates increased by 35% in OVX and 55% in H-PTH (p<0.01), decreased by 74% in H-ALN (p<0.001), and were similar in H-NaF compared to AM controls. FTIR was performed on newly formed and pre-existing older bone. Compared to OVX, H-ALN rats had more phosphate in old bone and a greater mineral/matrix ratio in new trabecular bone (p<0.05). Crystallinity of NaF rats was greater than H-PTH in new cortical bone, greater than OVX and H-PTH in new trabecular bone, and greater than H-ALN and H-PTH rats in old trabecular bone (p<0.05). NaF rats also had higher phosphate levels in old cortical bone compared to AM, OVX and H-PTH. Tb.Th (r²=0.59) and mineral/matrix ratio (r²=0.33) were positively correlated to maximum load while apparent mineral density (μ CT) was not (r²=0.07). In summary, PTH treatment increased bone formation and Tb.Th, thereby producing newer, less mineralized bone. By maintaining existing bone, ALN caused more mineralized, older bone. In contrast, H-NaF maintained architecture with elevated phosphate and crystallinity. The correlations between chemical, histologic, and mechanical properties emphasize that bone volume and mineral density alone cannot predict fracture risk and that the modulation of bone strength by microarchitecture and chemical composition may be specific to any given drug intervention.

Short-term Parathyroid Hormone Treatment Improves Cortical Bone Microstructure. Maria-Grazia Ascenzi^{*1}, Vivian Liao¹, Brittany Lee¹, Robert Lindsay², Felicia Cosman², Jeri Nieves³, John Bilezikian⁴, David Dempster³. ¹University of California, Los Angeles, USA, ²Helen Hayes Hospital, USA, ³Columbia University, USA, ⁴Columbia University College of Physicians & Surgeons, USA

We sought to identify cortical micro-structural features responsible for reduced fracture risk associated with short-term treatment with PTH. On 7 μ m-thin sections of iliac crest biopsies, we analyzed separately the architecture of type I collagen and the degree of calcification, which independently affects bone strength *in vitro*, in: 1] 8 postmenopausal patients with osteoporosis (mean SE, age 5410 years), pre- and post-treatment with recombinant human PTH (1-34); 2] 5 premenopausal patients with mild primary hyperparathyroidism (PHPT) (mean age 415 years), previously found to have preserved cancellous architecture; and 3] 5 healthy women (mean age 372 years). We measured i) collagen anisotropy by birefringence of circularly polarized light, ii) collagen orientation for specific birefringence by confocal and electron microscopy and iii) degree of calcification by micro-X-ray. For each input variable, a paired *t*-test established significance for pre- and post PTH treatment differences, while ANOVA and Tukey's post-hoc test established significant differences among the post-PTH, PHPT and healthy subject groups. Compared to the pre-PTH subjects, the post-PTH group exhibited a 12% decreased area of bright birefringence (p<0.01), a 38% increase in the number of osteons with bright and extinct lamellar alternation (p=0.03) and a 20% increase in lamellar thickness (p<0.03; Figure). These post-PTH parameters were not statistically different from those in the younger healthy group, but the percent area of bright birefringence was 17% greater (p=0.04) and lamellar thickness 24% greater (p<0.01) in the PHPT group compared to the healthy group. The collagen orientation with respect to the longitudinal direction showed predominant larger angles (4510) in birefringent bright, and smaller angles (23) in birefringent extinct regions. Both post-PTH and healthy groups showed a significantly higher percentage of osteons at initial rather than low-intermediate degree of calcification (p<0.04). Further, the post-PTH group showed a significant difference between low- and high-intermediate levels (p= 0.04) that the healthy group did not. In conclusion, PTH treatment restores tissue anisotropy, while the presence of PHPT shifts it away from a healthy premenopausal phenotype. If confirmed by a larger study at weight bearing locations, the observed anisotropy may help explain the change in fracture risk, reduced with post-PTH treatment and increased with PHPT.

The Effect of Zoledronic Acid on Cancellous and Cortical Bone Matrix Mineralization in Postmenopausal Osteoporotic Patients. Paul Roschger^{*1}, Barbara Misof¹, Daniela Gabriel¹, Eleftherios Paschalis¹, Erik Eriksen², Juerg Gasser³, Klaus Klaushofer¹. ¹Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK & AUVA Trauma Centre Meidling, 1st Medical Department, Hanusch Hospital, Vienna, Austria, ²Hormonlaboratoriet, AUS Aker Universitetssykehus Trondheimsveien, Oslo, Norway, ³Novartis Institutes for BioMedical Research, Basel, Switzerland

Background: Annual intravenous administration of zoledronic acid (ZOL) for 3 yrs has been shown to reduce fracture risk in postmenopausal women with osteoporosis (HORIZON pivotal fracture trial). Histomorphometric analysis of transiliacal bone biopsies of a subgroup of these patients revealed significantly improved trabecular architecture and reduced bone remodelling for the ZOL versus placebo treated patients. The aim of our study was to evaluate the mineralization of the bone matrix in these same biopsies.

Materials & Methods: We have measured entire transiliacal bone biopsy samples (previously used for the histomorphometric analysis) for cancellous and cortical bone mineralization density distribution (BMDD) by quantitative backscattered electron imaging (qBEI). Eighty-two patients were treated with ZOL (yearly doses of 5mg), 70 were treated with placebo and all received adequate Ca and VitD supplementation. To be enrolled in the study, the patients had to have a T-score \leq -2.5 or a T-score \leq -1.5 with evidence for at least 1 vertebral fracture. The patients were classified into 2 strata (I without concomitant treatment, II with concomitant other osteoporosis therapy, such as hormone replacement, selective estrogen receptor modulators, etc.).

Results: In both cancellous and cortical bone, all BMDD derived variables were significantly different between ZOL and placebo treatment (all p<0.001): the average (mean) and most frequent (mode) calcium concentrations (CaMean +3.2% and +2.7%; CaPeak +2.1% and +1.5%, cancellous and cortical bone, respectively) and the portion of highly mineralized bone areas (CaHigh +64% and +31%) were higher in ZOL than placebo, while the heterogeneity of mineralization (CaWidth -14% and -13%) and the percentage of areas undergoing primary mineralization were lower (CaLow -22% and -26%). Similar differences were observed when the study groups were considered for each stratum separately.

Discussion: The observed differences in BMDD vs. placebo are in excellent agreement with the strong reduction of bone turnover in the ZOL treated patients as reported by the histomorphometric results of the HORIZON study. A considerable and rapid decrease in bone turnover causes a reduction in the amount of new bone formation and a prolonged time for secondary mineralization of existing bone packets. Our findings demonstrate that both cancellous and cortical bone mineralization were affected by ZOL in a similar manner.

Viscoelastic Response of PTH, Ibandronate and Combination Treatment in Ovariectomized Rat Femur Correlating with BMD. Xiao Yang^{*}, Yong Hoow Chan, Padmalosini Muthukumaran, Taeyong Lee. National University of Singapore, Singapore

Aim

Viscoelastic response upon loading is one of the mechanical properties exhibited by bone. Little has been reported on viscosity changes existing in osteoporotic bone and with treatments. Since bone viscoelasticity correlates to load-bearing capacity, the aim of this study is to investigate the viscoelastic properties of ovariectomized and drug-treated rat femurs.

Methods

15 female SD rats were subjected to ovariectomy or sham surgery. They are divided into 5 groups: (1) SHM group with sham surgery; (2) OVX group underwent ovariectomy surgery and treated with vehicle saline; (3) PTH group: 10 μ g/kg PTH treated ovariectomized rats; (4) IBN group: 7 μ g/kg ibandronate treated ovariectomized rats; (5) COM group: ibandronate and PTH concurrent treatment on ovariectomized rats. Weekly treatments were administered subcutaneously from 4th week post-surgery. On week 12, all rats were euthanized. After metaphyseal region scanning by both μ CT and pQCT, femurs were embedded in epoxy and polished. After rehydration, nanoindentation was conducted using continuous stiffness measurement (CSM) to determine elastic modulus (E) and hardness (H). Basic creep test was also conducted using the Voigt model. Viscosity (η) is computed based on the curve fitting of creep displacement by non-linear regression.

Results

μ CT analysis suggested that IBN and COM group had a better effect than PTH in preserving trabecular bone properties in terms of BV/TV, Tb.Th, SMI, BS/BV, Tb.Sp and Tb.N. In BMD and viscosity, COM group were significantly higher than the other two monotherapy groups. In 12 wks, BMD and viscosity are positively correlated (R=0.94, p<0.05), whilst the BMD and E showed weak correlation (R=0.47). η had power-law correlation with E (p<0.05) in each group respectively. There was 18% increase in E and 44% increase in η for SHM compare to OVX.

Conclusions

Our results suggest that the osteoporotic deterioration do exist in bone viscosity while different drugs have varied ability to restore η . The source of creep may

contribute to the internal friction at cement lines [1]. Osteoporosis results in an increased number of newly formed cement lines. Thus more creep deformation (lower η) would take place under constant loading from daily activity. The strong positive correlation of η and BMD can be interpreted that the increase in the mineral portion of bone matrix may limit the interfibril motion of collagen which results in increased viscosity.

Differences in Tibia Morphology Between the Lower Limbs of AFO-using Survivors of Stroke. Kyle Sherk¹, Vanessa Sherk¹, Mark Anderson², Debra Bembien¹, Michael Bembien¹. ¹University of Oklahoma, USA, ²University of Oklahoma Health Sciences Center, USA

Previous work has determined that bone losses occur on the affected side following a stroke, while the sound side may actually improve as it is heavily favored throughout the rehabilitation process for strength and stability. The use of gait aids in survivors of stroke is often mentioned in literature, but their effect on bone morphology has not been assessed. The purpose of this study was to examine the differences between the affected and sound lower limbs of ankle foot orthosis (AFO)-using chronic (>2 years post) survivors of stroke. Methods: 10 ambulatory survivors of stroke (ages 52-74 years) had their affected (6 left) and sound side tibias scanned at 4%, 38%, and 66% of the limb length with pQCT (XCT 3000) to assess volumetric BMD (vBMD), bone mineral content (BMC), and areas of the total, trabecular, and cortical bone. Periosteal (PeriC) and endosteal (EndoC) circumferences, cortical thickness (CTh), bone strength index (BSI) and strength strain index (SSI) were determined. Data were compared by paired t-tests in SPSS v18.0. Significance was set at $p \leq 0.05$. Results: Men ($n=6$) were taller than women ($n=4$) ($p < 0.001$). There were no gender differences in age, weight, time since stroke, or lapse of time from stroke to walking. Total BMC was greater on the sound side at all 3 sites ($p < 0.02$). Total vBMD was greater on the sound side at the 4% and 66% sites ($p < 0.001$). The 4% tibia site showed 22% greater trabecular BMC ($p < 0.01$) and 20% greater trabecular vBMD ($p < 0.01$). BSI at the 4% site was 41% smaller on the affected side ($p < 0.01$). The 38% site showed the total area to be 4% greater on the sound side ($p < 0.02$). Cortical area at the 38% and 66% sites were larger by 5% and 16%, respectively, on the sound side ($p < 0.05$) with larger CTh ($p < 0.001$). These resulted from smaller EndoC ($p < 0.01$) on the sound side at both sites. Cortical BMC was also larger on the sound side at both the 38% (8% difference) and 66% (15% difference) sites ($p < 0.02$). The 66% site revealed an 11% difference in SSI, with the sound side being greater ($p < 0.01$). Imin was only found to be greater at the 66% site ($p < 0.02$), leading to a significant difference ($p < 0.05$) in the Imax/Imin ratio with the affected side being the larger ratio. Conclusions: Hemiplegic side's trabecular and cortical tibia morphologies are affected following a stroke. It is still unknown if AFO use to maintain mobility accelerates or mediates these losses.

Evaluation of HR-pQCT in Non-human Primates for Monitoring the Effect of Odanacatib on Bone Microarchitecture. Richa Jayakar¹, Antonio Cabal¹, John Szumiloski¹, Swanand Sardesai¹, Eual Phillips², Christopher Winkelmann¹, Paul McCracken³, Thomas Hangartner⁴, DON WILLIAMS⁵. ¹Merck & Co., Inc., USA, ²University of Pennsylvania, USA, ³Merck Research Laboratories, USA, ⁴Wright State University, USA, ⁵MERCK, USA

High Resolution peripheral Quantitative Computed Tomography (HR-pQCT) is gaining popularity in clinical studies for bone evaluation, but published literature in animal models is scarce. Pre-clinical studies are imperative for drug development and provide a test bed for designing clinical studies, but HR-pQCT performance in these smaller species needs to be evaluated. The objective of this study was to longitudinally evaluate HR-pQCT imaging (XtremeCT, Scanco Medical) for variability, stability, and sensitivity to change in an ovariectomized (OVX) non-human primate (NHP) model of bone loss, treated with odanacatib (ODN), a Cathepsin K inhibitor, being developed by Merck for treatment of osteoporosis. Rhesus monkeys were divided into 3 groups: Intact ($n=10$; non-ovariectomized), OVX-VEH ($n=11$; vehicle treated) and OVX-ODN ($n=10$; 30 mg/kg/day ODN). In-vivo scanning was performed at the ultradistal (UD) and distal 1/3 radius and tibia at 12 and 20 months post-OVX. The UD sites were located immediately distal to the growth plate of the radius and tibia, respectively. The distal 1/3 sites were located at 1/3 of the bone length measured from the distal end. Vendor software was used to analyze volumetric bone mineral density (vBMD) and micro-architectural parameters. Finite element analysis was performed on in-vivo images and the results validated by ex-vivo mechanical compression testing ($R^2=0.9$). To assess the test-retest variability of the imaging method, an off-study monkey and an excised radius and tibia were scanned five times during each scan period at the same anatomical sites. The coefficients of variation of various parameters in the off-study monkey and excised bones across all sites ranged from 0.1% to 7.4%. Pair-wise comparisons of OVX-VEH vs. Intact monkeys demonstrated a model effect showing decreases in parameters consistent with bone loss. Treatment effects were observed with pair wise comparisons of OVX-ODN vs. OVX-VEH at 20 months ($p < 0.05$) in vBMD (477 27 vs. 364 22 mg HA/cm³) and Cortical Thickness (CTh) (0.90 0.07 vs. 0.64 0.04 mm) at the UD radius, CTh (2.15 0.28 vs. 1.56 0.08 mm) at the distal 1/3 radius, and CTh (1.05 0.08 vs. 0.86 0.05 mm) at the UD tibia. We conclude that HR-pQCT serves as a reliable technique to longitudinally monitor osteoporosis treatment in rhesus monkeys; the OVX procedure results in bone loss, while ODN treatment increases bone mass, as evidenced by micro-architectural and density parameters.

In Vivo Mesenchymal Stem Cell Proliferation Promoted by Dynamic Fluid Flow Stimulation. Minyi Hu¹, Robbin Yeh¹, Michelle Lien¹, Yi-Xian Qin². ¹Stony Brook University, USA, ²State University of New York at Stony Brook, USA

Osteoporosis gives rise to weaker bones that are more susceptible for fractures due to decreased bone mass and minerals. Our group has recently introduced a novel, non-invasive dynamic hydraulic stimulation (DHS) that enhanced bone structure, as 3Hz DHS inhibited disuse bone loss. Mesenchymal stem cells (MSCs) are able to self-renew and potentially differentiate into the cells that form tissues such as bone. To further illustrate the cellular effect of DHS and its potential mechanism in bone, the goal of this study was to quantify MSC populations in response to in vivo mechanical signals driven by DHS. Female Sprague-Dawley virgin rats (5m) were divided into 3 groups: hindlimb suspended (HLS, $n=10$), HLS+static ($n=6$), and HLS+3Hz ($n=4$). Stimulation were given to right tibia by an inflatable cuff with 30mmHg static +30mmHg dynamic pressures, for 10min on-5 min off-10min on, 5d/wk for 4 wks. Bone marrow was harvested from the right tibia at the end of the experiment. Quantification of MSC populations in the bone marrow was determined using flow cytometry. Red blood cells in the cell extracts were lysed by Pharmlyse (BD Bioscience). Appropriate antibodies (CD29, CD49e and CD45; BD Biosciences, BioLegend) with suggested concentrations were applied. Flow cytometry data were collected using FACS ARIA at Stony Brook Research Flow Cytometry Core Facility. Flow cytometric measurements indicated MSC population as represented by cells positive for CD29 and CD49e, and negative for CD45. DHS-treated animals (HLS +3Hz) had 88% ($p > 0.05$) increase in MSC population compared to HLS, while HLS +static had 74% ($p > 0.05$) increase. Previous studies had shown strong inhibition affect of DHS on disuse bone loss, indicating its enhancement on bone structural quality. This flow cytometry experiment suggests the ability of DHS in MSC proliferation to elicit phenotypic changes in the skeleton, which coincide our previous finding. The mechanical signals derived from DHS may bias the differentiation of MSCs towards osteoblastogenesis, promoting bone formation in disuse condition. MSCs express surface markers including CD29 and CD49e. CD45 was included as an HSC marker. The use of all these markers was to identify MSCs with higher specificity. This population showed an increase in response to DHS compared to HLS. Overall, these data indicate that the MSC pool, expressed by both positive and negative markers, has been positively influenced by mechanical signals driven by DHS.

Bone Mass And Microarchitecture Changes In Subchondral Bone During Osteoarthritis: Influence Of Prior Mechanical Loading?. Arnaud Boudenot^{*1}, Stephane Pallu², Nathalie Presle³, Christelle Jaffre⁴, Claude Laurent Benhamou⁵. ¹Inserm Unit U658, Hopital Porte Madeleine, France, ²INSERM U 658 / University of Orleans, France, ³UMR CNRS-UHP 7561, France, ⁴INSERM U658, Caracterisation du Tissu Osseux par Imagerie : Techniques et applications, France, ⁵INSERM Orleans-France, France

Although osteoarthritis (OA) is considered as a primary disorder of articular cartilage, the architecture and properties of the periarticular cortical and trabecular bone are also modified during the course of the disease. In an experimental model of OA, we have previously shown by DXA a bone loss in the epiphyseal area adjacent to the knee, and a protective effect of exercise on this parameter. The current study aimed to investigate changes in bone mass and trabecular microarchitecture in both the lateral and medial parts of rat knee joints in an OA model. Male Wistar rats (n=48) were divided into two groups: exercise (Ex) or non exercise (NEx). Ex rats were subjected to intermittent progressive training 1h/day, 5 d/week for 10 weeks. At the end of the training period, experimental OA was induced by intraarticular injection of 1 mg monoiodoacetate (MIA) in each half group (Ex-MIA and NEx-MIA). Rats in the other half were injected with saline as controls (Ex-C and NEx-C). Hematoxylin-eosin-safran and safranin-O-fast green stainings were performed on femoro-tibial joint sections to determine the severity of OA cartilage lesions. The proximal extremity of the tibia was imaged with Skyscan 1072 μ CT device. An analysis method has been developed to separate 2 ROIs, one from the lateral part, the other one from medial part. The ROI was a cylinder (volume: 2.13 mm³), the resolution was 12.02 μ m. Our data indicated that the lateral part of the knee joint exhibited significantly higher BV/TV and Tb.Th than the medial part. Exercise and OA did not alter the microarchitecture in the medial part. A lower BV/TV was found in the lateral part from rats injected with MIA (NEx-MIA vs Ex-C: 34.195.91 vs 42.213.34; p<0.01; Ex-MIA vs Ex-C: 32.816.31 vs 42.213.34; p<0.01). Lateral Tb.N was also reduced in both MIA groups (NEx-MIA vs Ex-C: 3.090.44 vs 3.610.25; p<0.01; Ex-MIA vs Ex-C: 3.040.38 vs 3.610.25; p<0.01), and lateral Tb.Th was significantly lower in the MIA groups compared to controls (NEx-MIA vs Ex-C: 0.110.01 vs 0.120.01; p<0.05; Ex-MIA vs Ex-C: 0.110.01 vs 0.120.01; p<0.05). Previous exercise had no effect on these parameters in this model. These data suggest that MIA-induced OA is associated with bone loss and changes in the trabecular subchondral bone from the load-bearing area of the knee joint. This chemical effect of the MIA seems finally differentially translated in the lateral vs medial part of subchondral OA bone, suggesting an interaction with mechanical properties of the rat knee.

Effects of Pulsed Electromagnetic Field Stimulation on Transient Gene Expression Related to Bone Formation in Old Rats. Hiroyuki Tamaki^{*1}, Atsumu Yuki², Kounosuke Tomori³, kengo Yotani⁴, Hikari Kirimoto¹, Hideaki Onishi¹, Norikatsu Kasuga². ¹Niigata University of Health & Welfare, Japan, ²Aichi University of Education, Japan, ³Kanagawa University of Human Services, Japan, ⁴National Institute of Fitness & Sports, Japan

Aging is associated with bone loss resulting from low bone formation characterized by reductions in biological activity and numbers of osteoblasts. Pulsed magnetic stimulation (PMS) has been used to treat bone disorders and reportedly modifies differentiation, proliferation and mineralization of osteoblasts in vitro. We examined the in vivo effects of repetitive pulsed magnetic stimulation (rPMS) on bone formation in aged rat tibiae and femurs. Unilateral hindlimbs of male old rats (95-149 weeks) and young rats (6-8 weeks) were held on the table in the prone position and the PMS probe was placed 10-20 mm from the thigh and leg. Rats underwent rPMS at 25-

60% stimulation intensity at a frequency of 0.2-1 Hz, for 5-10 min. After sacrifice, tibiae were analyzed by quantitative histomorphometry and femora were used for analysis of bone morphogenetic protein (BMP)-2, transforming growth factor (TGF)- β 2, collagen (Col)-I, and osteocalcin (OC) mRNA expression by real-time reverse transcriptase-polymerase chain reaction (RT-PCR). Morphometric analysis was performed by micro-computed tomography and observation using a digital microscope comprising a video monitor and personal computer with image analysis software. Lower trabecular bone area and osteoid thickness were observed in old rats compared to young rats. RT-PCR showed that rPMS stimulated mRNA levels of BMP-2 and TGF- β 2 after 24 h of treatment compared to the contralateral hindlimb in young rats. In old rats, rPMS at higher intensity did not up-regulate mRNA expression levels of osteoblast marker genes. The beneficial effects of rPMS on gene expression levels related to bone formation may thus be associated with age and/or stimulation intensity.

Fluid Flow Induced Early Response Genes Are Selectively Altered by Age. Leah Worton^{*1}, Ronald Kwon², Edith Gardiner¹, Ted Gross¹, Sundar Srinivasan¹. ¹The University of Washington, USA, ²La Jolla Bioengineering Institute, USA

There is controversy regarding whether bone's mechano-responsiveness is altered with age, as studies have noted enhanced, unchanged and muted tissue adaptation. To begin to explore whether and how aging might modulate mechanotransduction, we examined the early gene expression responses to fluid flow in cells derived from senescent (22 Mo, n = 5) and young adult female C57BL/6 mice (4 Mo, n = 5). Osteoblast/osteocyte cells were recovered from bone fragments from mice, were passaged, seeded and exposed to fluid flow-induced shear stress for 1h using a rocking platform (~0.5Hz, ~0.05Pa). Cells showed a 1.5-fold increase of COX-2 mRNA expression with flow vs. no flow regardless of animal age. Interestingly, both baseline and shear stress induced levels of COX-2 were lower in the cells from senescent vs. adult mice (p<0.05). While c-fos expression was also significantly increased in both groups by flow (11- and 18-fold in adult and senescent, respectively), neither baseline nor flow-induced levels of c-fos differed with age.

To explore the age-related differences in COX-2 and c-fos expression in response to shear stress, osteoblast and osteocyte expression markers were analyzed. Interestingly, cell cultures grown from senescent mice had greater expression of Runx2, Osx and ALP (1.8-, 2.2-, 2.1-fold higher vs. adult, respectively), but lower levels of the early osteocyte marker E11. The 'osteocytic' expression of genes involved in phosphate regulation was more complex; expression of DMP1 and PHEX was enhanced in senescent mice (2.7- and 4.4-fold vs. adult cells), while there was no age effect on the expression of FGF23 and MEPE. There was also no difference in expression of the late osteocyte marker SOST between these cell populations.

In combination, these data suggest that aging has the potential to selectively degrade early gene expression responses to mechanical stimuli. Further, while cell responses to fluid flow are undoubtedly governed by their baseline states, the differential responses observed could also arise due to differences in cell populations that emerged from the bones of senescent (more osteoblastic) vs. younger adult animals. An extension of this approach to examine higher-order cell functions downstream of interactions between degraded and intact pathways may definitively elucidate whether (and how) aging suppresses the osteogenic response to mechanical stimuli.

Impact of Deleting the IGF-1 Receptor in Mature Osteoblasts on the Skeletal Response to Unloading and Reloading. Takuo Kubota^{*}, Hashem Elalieh, Muriel Babey, Yongmei Wang, Daniel Bikle. University of California San Francisco/VA Medical Center, USA

Mechanical loading has a prominent influence on bone remodeling. Insulin-like growth factor 1 (IGF-1) signaling also plays an important role in bone remodeling. IGF-1 production is increased in osteoblasts after mechanical load. In addition, skeletal unloading causes a decrease in bone mass with suppressed bone formation and enhanced bone resorption associated with resistance to the anabolic effect of IGF-1. Thus, we hypothesized that IGF-1 signaling mediates the skeletal response to unloading and reloading. In the present study, to prove our hypothesis, we assessed mice in which the IGF-1 receptor was deleted with osteocalcin-driven cre recombinase. These mice were hindlimb unloaded for two weeks and then reloaded after unloading for two weeks. Micro CT analysis showed that bone volume (BV/TV) in trabecular bone was reduced in knockout (KO) mice at baseline compared to that in control (CL) mice. The BV/TV in both KO and CL mice fell with unloading and then increased after reloading. The loss in BV/TV in KO female mice (92% reduction) tended to be more profound after unloading compared to that in CL female mice (78% reduction). Surprisingly the recovery of BV/TV with reloading was comparable. Bone histomorphometry showed that BV/TV and bone formation rate (BFR/BS) in trabecular bone was diminished at base line and after reloading in the KO mice compared to that in the CL mice, although there were no differences in osteoblast number between the KO and CL mice. Osteoclast number and eroded surfaces with osteoclasts tended to be reduced at base line and after reloading in the KO mice

compared to those in the CL mice. In addition, the KO mice exhibited a smaller and thinner cortical bone at baseline by micro CT analysis than the CL mice. The difference between the KO and CL mice in cortical bone was maintained after unloading and reloading. BFR/BS in the periosteal surface at the tibiofemoral junction of the KO mice after reloading remained suppressed (98% below the CL mice) unlike the partial recovery observed in the CL mice. These results suggest that the IGF-1 receptor in mature osteoblasts plays a modest role in the skeletal response to unloading and reloading, affecting both bone formation and resorption, but at least in trabecular bone IGF-1 resistance is likely manifested in less mature osteoblasts and osteoprogenitors which are responding normally in this mouse model.

Pleiotropy Involving Skeletal, Vascular, and Reproductive Phenotype in Recombinant Congenic Mice via the Endothelin Signaling. Robert Blank¹, michael johnson², Jasmin Kristianto², Suzanne Litscher², Naomi Chesler², Zhijie Wang², Jacqueline Fisher². ¹University of Wisconsin, USA, ²University of Wisconsin-Madison, USA

There is a well established epidemiological association between skeletal fragility, atherosclerosis and low birth weight. Our lab has isolated pleiotropic quantitative trait loci (QTL) region in mouse chromosome 4 that is responsible for bone remodeling in response to loading via the study of recombinant congenic mice HcB-8 and HcB-23. Recombination during the strains' construction limits the QTL region to ~6.5 Mb and includes Ecel gene, encoding endothelin converting enzyme 1 (ECE1). We hypothesized that the QTL-mediated modeling differences in response to mechanical loading are shared between bones and blood vessels. The two strains harbor alternate genotypes for a chromosome 4 QTL that results in distinct bone phenotype between HcB-8 (low modeling) and HcB-23 (high modeling). HcB-8 carotid arteries have a smaller diameter at 90 mm Hg and are less compliant to increases in luminal pressure than HcB-23 carotids ($p=0.026$, $p=0.036$ respectively). Hence, we further hypothesized that the poor vascular modeling in HcB-8 may lead to lack of reproductive performance in comparison to HcB-23. HcB-8 litters are smaller than HcB-23 litters (4.4 ± 1.8 v 5.8 ± 2.0 , $p < 10^{-3}$) and HcB-8 pups are lighter at birth (1.2 ± 0.2 g v 1.5 ± 0.2 g, $p < 10^{-20}$). Based on CT scan data, all 4 pregnant HcB-8 females had at least 1 resorbed embryo while none were observed in HcB-23 ($N = 4$). Placental insufficiency may account for these differences. We also examined Ecel expression level in HcB-8 and HcB-23 heart and vessel tissues by real-time PCR and western blotting. At the mRNA level, HcB-23 expresses nearly 3-fold more Ecel ($p < 10^{-3}$), with the protein data showing a similar pattern. Immunohistochemistry of day 17 placentas shows higher ECE1 and NOS3 levels in HcB-23. Endothelin signaling through the B type receptor is known to induce Nos3, and endothelin signaling has also been shown to promote bone growth. These findings suggest that Ecel expression differences underlie the multi-system pleiotropy of the chromosome 4 QTL. In addition, the data indicate that the pleiotropy effect of chromosome 4 QTL extends beyond the skeletal system. Therefore, we propose that mechanically-induced modeling is the common mechanism linking the various traits controlled by the chromosome 4 QTL. We also speculate that the impaired response to mechanical loading may be a common underlying cause of intrauterine growth retardation.

Prolonged Unloading in Growing Rats Reduces Cortical Osteocyte Lacunar Density and Volume in the Distal Tibia. Hayley Britz^{*1}, Yasmin Carter¹, Jarkko Jokihaara², Olli Leppanen³, Teppo Jarvinen⁴, George Belev⁵, David Cooper¹. ¹University of Saskatchewan, Canada, ²University of Tampere, Canada, ³University of Tampere, Finland, ⁴University of Tampere/IMT, Finland, ⁵Canadian Light Source, Canada

Load-related stimuli play an important role in the health of the skeleton which is able to dynamically adapt to the environmental demands placed upon it. It has been postulated that osteocytes sense changes in these stimuli and initiate adaptive responses, across a number of scales, through a process known as mechanotransduction. While gross morphological and tissue-level adaptation have been the focus of much research, relatively little is known regarding the relation between cellular-level features (e.g. osteocyte lacunar density, shape, volume) and loading. The increasing availability of high resolution 3D imaging modalities, including synchrotron-based technologies, has made studying 3D cellular-level morphology feasible on a scale not previously possible. The aim of this study was to experimentally test the hypothesis that unloading during growth results in altered osteocyte lacunar density and volume in the rat. Left tibial diaphyses from six female rats (30 weeks old) that had been immobilized by sciatic neurectomy for 27 weeks and those from six age and sex-matched controls were scanned with a 2 micron voxel size at the Canadian Light Source synchrotron. The Biomedical Imaging and Therapy bending magnet beamline (BMIT-BM; 05B1-1) was employed. Lacunar density and volume were quantitatively assessed within the complete distal diaphyses along 0.5 mm of their length. Qualitative observations of lacunar distribution in 3D revealed a marked regional variation about the tibial cross section. In some areas, the midcortical regions exhibited high concentrations of lacunae while periosteal bone tended to have fewer more regularly arranged lacunae. Overall lacunar density was found to be significantly ($p=0.039$)

higher in the control bones ($63,138 \pm 1,956$ lacunae per mm^3) than in the immobilized bones ($49,642 \pm 11,955$ lacunae per mm^3). It was also found that the mean lacunar volume for control bones ($284 \pm 28 \mu\text{m}^3$) was significantly higher ($p=0.039$) than for the immobilized bones ($209 \pm 72 \mu\text{m}^3$). Our results revealed that extreme differences in loading conditions, such as those created by paralysis, do indeed result in changes in osteocyte lacunar features. Further investigation is warranted to examine relations between these parameters and more subtle variation in loading as well as potential links to pathological states which have been linked to altered mechanotransduction.

Resistance to ER Stress Is Improved via Mechanical Input in MSC. Maya Styner^{*1}, Kornelia Galior¹, Natasha Case¹, Buer Sen², Zhihui Xie¹, Janet Rubin¹. ¹University of North Carolina, Chapel Hill, School of Medicine, USA, ²University of North Carolina At Chapel Hill, USA

Endoplasmic reticulum (ER) stress occurs in all cells when overwhelmed by misfolded proteins and is a common final pathway in diverse pathologic states including aging and oxidative stress. Exercise has been recently reported to protect against mutations that cause protein misfolding/dysfunction in the brain. Ablation of a key ER stress mediator, PERK, results in skeletal defects including deficient mineralization and osteoporosis suggesting a role for ER function and stress in bone formation. Given that mesenchymal stem cells (MSC) are responsible for bone formation, we hypothesized that mechanical input, analogous to exercise, might improve osteogenic capacity by decreasing MSC ER stress. C3H10T1/2 MSCs and/or marrow derived MSCs were cultured in the presence of the ER stress inducer tunicamycin. Mechanical stimuli were applied using a Flexcell device at 2%, 300 cycles per bout, 2 bouts per day, a regimen previously shown to repress MSC adipogenesis. Tunicamycin led to a rapid rise in the apoptosis marker CHOP at 6-8 hours followed by a steady decline. Spliced XBP1, another participant in ER stress, rose along with CHOP. The early increases in CHOP and XBP1s were followed by a rise in the chaperone BiP peaking at 24-48 hours. This pattern of increased BiP with decreasing CHOP is consistent with recovery from ER stress. Mechanical pre-treatment of MSC, dosed daily for 4 days, decreased ER stress. First the mechanical treatment increased the expression of the chaperone BiP 1.5-fold of control level suggesting induction of an increased ER capacity as BiP populates existent ER. Secondly, when ER stress was induced by tunicamycin (1 $\mu\text{g}/\text{ml}$), the untreated MSC demonstrated 2-fold higher elevations in CHOP compared to those pre-treated with mechanical stimulus. Our data suggests that MSC respond to mechanical input by expanding ER capacity, an effect which increases cellular resistance to multiple stressors. As such, mechanical regulation of ER stress in MSC is a mechanism by which exercise could improve skeletal health.

A 14-week Initial Military Training Regimen Led to Distal Trabecularization and Diaphyseal Cortical Thickening in Tibiae of Men and Women. Charles Negus^{*1}, Rachel Izard², Julie Greeves³, William Fraser⁴. ¹L-3 Applied Technologies, USA, ²HQ ARTD, MOD, United Kingdom, ³HQ Army Recruiting & Training Division, United Kingdom, ⁴Norwich Medical School, University of East Anglia, UK, United Kingdom

Recent interventions by the British Army have reduced the incidence of medial tibial stress syndrome and lower limb stress fracture among recruits undertaking the 14-week Initial Training program. Women are still at higher risk of stress fracture than men and the effect of this intense training on the functional adaptation of bone in either sex is unknown. The purpose of this study was to compare tibial adaptations between men and women to 14 weeks of initial military training.

Of 248 recruits at Army Training Centre Pirbright who entered the study, 203 (82 men age 21.63 \pm 3.06 yrs; 121 women age 20.96 \pm 2.94 yrs) underwent pQCT (peripheral quantitative computed tomography) scans at both week 1 (pre) and 14 (post) of training. Scans were collected at 4%, 38%, and 66% of tibial length from the distal end plate. The Bone Alignment and Measurement Package (BAMpack) was used to align pre and post images of each subject, rotate images consistently, and calculate measures for the whole-cross section and in 60 sectors. Measures included Trabecular Density (TrDn), Cortical Density (CtDn), Bone Mineral Content (BMC), Trabecular Area (TrAr), Cortical Area (CtAr), Total Area (TtAr), Cortical Thickness (CtTh), Periosteal Perimeter (PPm), Endosteal Perimeter (EPPm), polar moment of inertia (I), mass moment of inertia (MMI), and Bone Strength Index (BSI). Only images with minimal motion artifacts and alignment error were used for statistical analysis at each site. Within-sex pre-post changes were assessed with paired t-tests, while sex-time interactions were assessed with repeated measures ANOVA analysis.

Results are summarized in Table 1. Both sexes experienced a significant pre-post increase in TrDn at 4% site (Figure 1), though women increased TrDn significantly more than men. At 38%, both men and women experienced significant increases in TtAr, CtAr and CtTh (primarily on the medial aspect), and PPm. The only significant change in CtDn at 38% was an increase in the anterior-posterior sectors of women. Adaptations at 66% were similar to the 38% site.

Both men and women increased mineralization at the distal tibia and exhibited signs of periosteal expansion in the cortical shaft. These adaptations are similar to

This work was sponsored by the UK Ministry of Defence (Army).

(+30.5%) weeks of full WB. A novel skeletonization algorithm implemented to define the topology of pore structures demonstrated that cortical pores became more interconnected on the affected side, as quantified by an increase in canal junctions (+37.6%, $p < 0.05$). Small decreases in BMD and Ct.BMD were detected following the non-WB period (-1.6% and -1.1%, $p < 0.05$), likely driven by the increase in Ct.Po. No changes in Ct.Po, pore structure, or densitometric parameters were detected on the contralateral side. Finite element analysis showed significant changes in biomechanics on the affected side following the non-WB period, including decreased stiffness and estimated failure load (-4.0% and -3.4%, $p < 0.05$). These biomechanical measures remained depressed following 6 and 12 weeks of full WB. Our results suggest that detectable microarchitectural and biomechanical degradation occurs as a result of non-WB and persists following return to normal loading. A better understanding of these microarchitectural changes and their short- and long-term influence on biomechanics may have clinical relevance in developing targeted countermeasures to prevent bone loss.

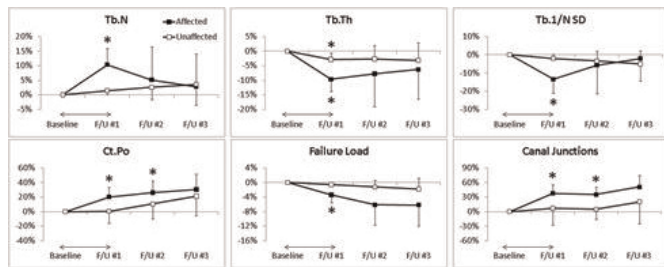

Figure 1. Longitudinal assessment of trabecular number (Tb.N), thickness (Tb.Th), and heterogeneity (Tb.L/N SD), cortical porosity (Ct.Po), estimated failure load, and canal junctions following a 6-week period of non-weight bearing (double arrows). Significant changes from baseline values are denoted with an asterisk ($p < 0.05$).

Non-invasive (pQCT) Analysis of Different Patterns of Structural/Bio-mechanical Relationships Along the Human Tibia in Healthy Volunteers and Long-Distance Runners. Ricardo Francisco Capozza¹, Sara Feldman², Pablo Mortarino¹, Paola Reina¹, Jose Ferretti^{3,4}, Joern Rittweger⁴, Gustavo Roberto Cointy¹. ¹Center of P-Ca Metabolism Studies (CEMFOC), Natl Univ of Rosario, Argentina, Argentina, ²Laboratory for Bone Biology & Emerging Therapies (LABOATEM), Natl Univ of Rosario, Argentina, ³National University of Rosario, Argentina, ⁴Div Space Physiology, Institute of Aerospace Medicine, German Space Agency (DLR), Germany

In a serial pQCT study of the leg (XCT-2000, Stratec, Germany) of sedentary healthy men and women aged 20-40 y ($n=10/10$, J Anat 216:470,2010) we had shown that bone mass distribution along the tibia reflected a structural adaptation to the variable stress pattern imposed by the mechanical usage of the limb. This study extends that observation to further 10/10 men and women of similar age chronically trained in long-distance running, aiming to analyze the interrelationships between indicators of bone mass (total and cortical BMC -ToC, CtC-, cortical cross-sectional area -CtA-, material "quality" (cortical vBMD -CtD-) and diaphyseal design (periosteal perimeter -PoPm-, thickness -CtTh-, circularity, and moments of inertia -MIs- of the CtA) as determined in slices taken at every 5% of height throughout the bone (sites S5 to S95), and of muscle force (maximal calf muscle cross-sectional area -MA-).

As previously observed, all the allometrically-related indicators (ToC, CtC, CtA, PoPm, MIs, MA) were higher, while CtD was lower, in men than women and in trained than in sedentary individuals ($p < 0.05$ - $p < 0.001$). All allometric bone indicators correlated positively with MA ($p < 0.05$ - $p < 0.01$). Circularity was maximal while ToC and MIs were minimal toward S15. ToC increased proximally, especially at sites closer to the knee. The MIs increased geometrically with bone height from S30 upwards. CtTh increased toward the central diaphysis and decrease more proximally. The analysis of all individuals together showed single-curve correlations between MIs and bone mass indicators, CtD and MA, with a maximal significance toward the central region of the bones. All these associations were independent of the degree of physical activity.

Results suggest that there would be three regions of the human tibia in which the structural features correspond specifically to three different patterns of usage-derived stress. In these regions the available bone mass would tend to be distinctly distributed in order to optimize predominantly the resistance to 1. uniaxial compression (distal end of the bone, approximately from S5 to S30), 2. anterior-posterior or lateral bending and torsion (central diaphysis, S30-S70), and 3. bi-axial compression (proximal end of the bone, S75-S95). This distribution would be highly oriented by the contractions of regional muscles, and were shown to be independent of the gender, anthropometric characteristics and degree of activity of the individual.

Rapid Subchondral Bone Changes Immediately Following Non-Invasive Knee Injury In Mice. Blaine Christiansen*, Matthew J. Anderson, Joel C. Williams, Cassandra A. Lee, Dominik R. Haudenschild. University of California - Davis Medical Center, USA

Traumatic joint injuries commonly lead to osteoarthritis within 10-20 years after injury. Substantial changes to the subchondral bone can also occur during the development of post-traumatic osteoarthritis (PTOA), including thickening of the subchondral plate and degeneration of underlying trabecular bone. In animal models of PTOA, these changes occur within the first several months after injury. However, the time course of bone changes immediately after joint injury has not been defined. Early bone changes (<4 weeks) may predispose the joint to longer-term degeneration, and may help determine the "window of opportunity" for treatments aimed at delaying or preventing the onset of PTOA. In this study, we induced non-invasive knee injury in mice using tibial compression. This loading method causes anterior translation of the tibia relative to the distal femur, reproducibly injuring the soft tissues of the knee at compressive loads of 10-12 N. A single dynamic axial compressive load (1 mm/s loading rate) was applied to the right knee of mice, to a target compressive load of 12 N to induce knee injury. Mice were euthanized at 1, 3, 7, 14, 28, or 56 days after knee injury ($n=6$ mice/time point). Another 6 mice served as uninjured controls. Bilateral knees were scanned using micro-computed tomography (SCANCO μ CT 35, Bassersdorf, Switzerland). Trabecular bone was analyzed at the distal femoral epiphysis, proximal tibial epiphysis, and proximal tibial metaphysis. Cortical bone was analyzed at the tibial plateau. At the distal femoral epiphysis and proximal tibial epiphysis we observed a rapid and substantial loss of trabecular bone, reaching a minimum near 7 days post-injury (-44% BV/TV at the femoral epiphysis, -40% BV/TV at the tibial epiphysis). This was followed by a partial recovery of trabecular bone volume back to a new (but lower) steady state by 28 days (Fig. 1). There was a similar, but milder response in the contralateral limb, indicating a systemic effect, possibly due to the inflammatory response after injury. No significant changes were observed at the tibial metaphysis or tibial plateau cortical plate. This immediate loss of trabecular bone volume following injury is a novel and important observation, and may be crucial for determining the window of opportunity for treatments aimed at slowing the development of PTOA. If a similar change occurs in humans, it could fundamentally change treatment methods following traumatic knee injuries.

Site-Specific Skeletal Advantages at the Proximal Femur and Forearm in Young Female Gymnasts. Jodi Dowthwaite*, Paula F. Rosenbaum¹, Tamara Scerpella². ¹SUNY Upstate Medical University, USA, ²University of Wisconsin, USA

Purpose:

We evaluated site-specific skeletal adaptation to loading during growth, comparing radius (RAD) and proximal femur (PF) DXA scans in young female gymnasts (GYM) and non-gymnasts (NON).

Methods:

Subjects from an ongoing longitudinal study (8-17 yrs old) underwent annual DXA scans (PF, forearm, total body) and anthropometry, completing maturity, nutrition and physical activity questionnaires. This cross-sectional analysis used the most recent data for which subjects met the following criteria: gynecological age ≤ 2.5

years (post-menarche); GYM annual mean gymnastic exposure ≥ 5.0 h/wk in the prior year. Maturity was coded as M1 (Tanner I breast), M2 (pre-menarche, \geq Tanner II breast) or M3 (post-menarche). Scans for 173 subjects were analyzed (Hologic software v.12.7), deriving bone geometric and strength indices via hip structural analysis (femoral narrow neck, NN) and similar RAD formulae (1/3 and Ultradistal (UD)). ANOVA and chi square compared descriptive data. Two factor ANCOVA adjusted for age and height, evaluating interactions and main effects for gymnastic exposure and maturity.

Results:

No differences were detected for GYM vs. NON in age, lean mass, arm length, Tanner breast stage or maturity ($p>0.05$). NON means were greater for height, weight, waist circumference and % body fat, whereas non-aquatic physical activity was greater in GYM ($p<0.05$). Maturity x activity interactions were detected for: BMC at all sites; aBMD (femoral neck (FN), NN & UD); 1/3 width & area; NN & 1/3 cCSA; NN cortical thickness (CT) & buckling ratio (BR); 1/3 Z; UDIBS ($p<0.05$). For RAD, all bone means were greater for GYM than NON (M1-3: $p<0.05$), with largest advantages in M3. At PF, in M1 & M3, GYM means were greater than NON for all but FN area, NN width & NN BR (NON > GYM, $p<0.05$). In M2 at PF, GYM bone means were similar to NON for all but: FN area, NN width, NN BR (NON > GYM); NN Z (GYM > NON) ($p<0.05$). Indices suggested greater bone strength in GYM than NON (M1-3: NN BR, Z (NN, 1/3), UDIBS, $p<0.05$).

Conclusions:

Maturity-specific comparisons suggest site-specific skeletal adaptation to loading during growth, with greater benefits at RAD than PF. At RAD, GYM advantages include bone width as well as cortical CSA and thickness; in contrast, at PF, GYM cortical CSA and thickness are greater, but bone width is less than NON. Thus, gymnasts gain skeletal strength through site-specific modes of geometric adaptation.

Figure 1: Main effects are depicted as percent differences in GYM vs. NON, with NON means as the zero reference.

- a Main effect for GYM vs. NON difference $p<0.05$
- b Gymnastics x Maturity Interaction $p<0.05$

A Novel Imaging Technique and Mouse Model for Evaluation of Osteoarthritis. Zhechao Ruan^{*1}, Brian Dawson², Ming-Ming Jiang², Frank Gannon², Michael Heggenes², Brendan Lee³. ¹Baylor College of Medicine, USA, ²BCM, USA, ³Baylor College of Medicine & Howard Hughes Medical Institute, USA

Osteoarthritis (OA) is a common clinical condition with a prevalence of 40 million people in the United States, resulting in an annual cost of \$100 billion. It is characterized by degeneration of articular cartilage with intraarticular inflammation and synovitis, manifesting as pain and debilitation. In spite of the relative high frequency of OA, as of yet, no efficient treatment has been established. In part, implementation of new therapies has been limited due to a lack of a relevant mouse model of OA. In addition, evaluation of OA severity in the current available mouse models is difficult and not quantitative. Using a novel mouse model that mimics the human post-traumatic OA, we developed a grading system that is based on an imaging technique that combines phase-contrast optics with high resolution microCT, permitting three dimensional reconstructions of the knee joints including the cartilage. This technique allowed us to delineate and quantify histological changes in mouse knee joints including cartilage loss and bone remodeling for the first time. We correlated our OA imaging based grading with functional, behavioral studies and tissue histology. Hence, our data establishes novel technology for quantitatively assessing OA changes in articular cartilage in a surgical model in mice.

Muscle and Bone Loss after Botox Injection in the Rat (MicroCT study). Beatrice Bouvard^{*1}, Erick Legrand², Maurice Audran³, Daniel Chappard⁴. ¹university hospital of Angers, France, ²Centre Hospitalier d'Angers, France, ³Universite et CHU Angers; INSERM U922, France, ⁴INSERM, U922- LHEA, France

Bone and muscle grow in proportion to one another. Muscles impose large load on bone and skeletal unloading induces muscle loss and bone loss. Animal models for studying disuse use limb immobilization or tail suspension. Transient muscle paralysis using botulinum toxin A (BTX) has been shown to induce a remarkably rapid bone loss with the cessation of active muscle contraction and weight-bearing activity. The aim of our study was to evaluate the evolution of muscle and bone loss in Copenhagen rats by in vivo microcomputed tomography (microCT) after BTX injection.

Twenty-five 4-month-old female Copenhagen rats weighing about 180 grams were randomized in 5 groups. Rats were injected intramuscularly with 1.5 units BTX (Botox® Allergan, Inc.) dissolved in 0.2 mL physiological saline. Injections were performed under Isoflurane inhalation anesthesia in the quadriceps muscle of the right hindlimb in two anterior injection points and with saline in the left hindlimb which served as an internal control. Experimentation lasted 4 weeks and one group was sacrificed each week (D0, D7, D14, D21, and D28). After euthanasia, microCT was performed on each tibia and a stack of 2D-sections was obtained. Bone mass and microarchitecture were measured at the primary and the secondary spongiosa of the tibia. After reconstruction, 3D models from the stack of 2D sections were performed to create 2 models: one after bone thresholding, and the other after muscle thresholding. The two models were overlaid and a slice was done just under the growth plate of tibias, perpendicularly to the axis of tibia, to measure bone area and muscle area. Muscle area surface (MSA) was obtained subtracting bone area to muscle area for each tibia.

Gait dysfunction was detectable as soon as D1. At day 7, weight loss was about 3 % and was stable thereafter in each group. Significant differences in MSA and in bone trabecular volume (BV/TV) between right and left legs occurred at day 14. At day 28, MSA difference between right and left leg was 30% ($p<0.01$) and BV/TV difference was 47% ($p=0.01$). Differences in Tb.Th, Tb.N, Tb.Sp and Tb.Pf between left and right legs were also significant at D28.

This is the first study observing the effects of BTX on bone and muscle of Copenhagen rats. Muscle and bone loss were rapid and not recovered at D28. MicroCT is a useful tool to follow muscle and bone loss. Longer experiments are needed to study muscle and bone recovery.

Osteoarthritis (OA)-Induced Pain Assessment. Rana Samadfam^{*1}, NANCY DOYLE², Luc Chouinard³, Susan Y. Smith¹. ¹Charles River Laboratories, Canada, ²CHARLES RIVER, Canada, ³Charles River Laboratories, PCS Montreal, Canada

Major findings in basic science of pain have failed to bring new drugs into clinical practice, partly due to the fact that the preclinical models used for pain assessments do not adequately represent the clinical condition. A potentially useful approach to evaluate antinociceptives is using animal models with diseases similar to humans such as OA. The objectives of this study were to determine the optimal dose of MIA (Monosodium Iodoacetate) to induce joint discomfort in rats and to develop/validate relevant pain endpoints. Measurement of dynamic weight bearing (DWB) has the advantage of quantifying a spontaneously emitted behavior, providing more clinically relevant results compared to reflexive measurements (Von Frey filament (VFF) or pinch). Adult rats were assigned to three groups, each receiving an intra-articular injection of saline or MIA at 1 or 3 mg/dose in the right knee. Osteoarthritis was confirmed and graded by histology evaluations. Pain was evaluated at Day 14 using: body position, gait, toe pinch, modified grip strength test VFF and DWB. Animals with more severe symptoms of OA were treated with Naproxen and pain was evaluated once predose, 4 and 6 hours post dose. Animals treated with MIA at 1 mg/dose generally had less severe OA symptoms but with normal body position and gait and only trends of an altered weight bearing of the right rear paw compared to controls. Animals treated with MIA at 3 mg/dose had more severe OA with normal gait but clearly showed signs of joint discomfort (right rear paw) as measured by DWB. Modified grip strength test indicated the right rear paw was weaker than the untreated left rear paw. The VFF test was the most sensitive endpoint for this model with significant differences between the right and left rear paws. Naproxen reduced pain in the majority of the 3 mg/dose animals as evidenced by balanced weight distribution and comparable use of both rear paws. These results indicate that reflexive pain measures were successfully measured at 1 mg/dose. However, the 3 mg/dose produced consistent quantitative changes and was considered the optimal dose of MIA to assess pain under more clinically relevant conditions (spontaneously emitted behavior) using DWB.

Osteonectin Expression in Synovial Fluid of Artificial Hip Joints with Different Articular Couplings. Monica Montesi^{*1}, Alina Beraudi¹, Susanna Stea¹, Francesco Traina², Stefano Squarzone³, Stefano Falcioni¹, Aldo Toni². ¹Laboratorio di Tecnologia Medica, Istituto Ortopedico Rizzoli, Italy, ²Divisione di Ortopedia Traumatologia e Chirurgia Protesica e dei Reimpianti dell'anca e del ginocchio, Istituto Ortopedico Rizzoli, Italy, ³Istituto di Genetica Molecolare- CNR-, Italy

Osteonectin is an important matrix glycoprotein highly expressed in bone (1). In several in vitro and animal in vivo studies it is used as indicator of good integration and tolerance to biomaterials or implanted devices (2; 3; 4; 5). Up to now, not even one study was conducted ex vivo on humans, to investigate the expression of osteonectin in synovial fluid harvested from artificial hip joints with different couplings.

Aim of our study was to assess the expression of osteonectin in the synovial fluid of patients with metal-on-metal (MoM) and ceramic-on-ceramic (CoC) couplings, compared to that of natural hips from patients before a primary total hip arthroplasty. We evaluated also if osteonectin level was correlated with the age of patients, the life of the device and the presence of periprosthetic osteolysis and debris in synovial fluid.

The expression of osteonectin was evaluated by ELISA assay, while the presence of debris was assessed by digestion and EDX Spectroscopy of samples (6).

The expression of osteonectin in patients with CoC coupling was significantly higher (53,2 pg/ml) than in controls (16,9 pg/ml) and in MoM ones (19 pg/ml), while the values in MoM group was not significantly different compared to control (figure 1). The expression of osteonectin was not correlated with the age of patients, the life of the implanted device, and the presence of periprosthetic osteolysis and debris.

Our results suggested that the presence of an artificial hip joint could induce a high expression of osteonectin as indicator of healing and integration. Compared to the metal the ceramic increased the level of osteonectin as indicator of improved biocompatibility.

Mechanisms of Longitudinal Overgrowth Following Circumferential Periosteal Division of Rat Femur. Shinjiro Takata^{*1}, Tetsuya Enishi², Nori Sato², Mitsuhiro Takahashi², Natsuo Yasui². ¹Institute of Health Biosciences, University of Tokushima Graduate School, Japan, ²Tokushima University Hospital, Japan

INTRODUCTION

Circumferential periosteal division (CPD) of rat tibia produces an increase in its growth rate and in the activity of both the proliferative and hypertrophic zones (Taylor FJ et al. J Anat 151:221-231,1987). This study showed mechanisms of longitudinal overgrowth following CPD of femur of developing rat.

METHODS

Thirty-five Sprague-Dawley rats aged 8 weeks were used for this study. CPD was performed at the diaphysis of rat femur. Rats were sacrificed 2 weeks, 4 weeks and 6 weeks after CPD. The longitudinal length of femur (n=11), rate of longitudinal growth and bone turnover by bone histomorphometry 2 weeks (n=6), 4 weeks (n=6) and 6 weeks (n=6) after CPD, and the microarchitecture of trabecular bone by trabecular analysis of secondary spongiosa by micro CT 6 weeks after CPD (n=6) were compared with between ipsilateral and contralateral sides.

RESULTS

Longitudinal length of rat femur of ipsilateral and contralateral sides were 41.793 ±0.753 mm and 40.272 ±0.690 mm, respectively (p<0.0001), showing that CPD for 6 weeks produced an approximately 3.8% increase of rat femur compared with contralateral femur. Bone histomorphometry shows that the rate of longitudinal growth of femora of ipsilateral and contralateral sides 2 weeks after CPD was 97.17.8 and 84.37.2 µm/day, respectively (p=0.0003), 4 weeks after CPD was 92.35.3 and 54.44.6 µm/day, respectively (p<0.0001), and 6 weeks after CPD was 44.13.4 and 27.65.1 µm/day, respectively. Mineral apposition rate of femora of ipsilateral and contralateral sides 2 weeks after CPD was 4.680.63 and 3.330.44 µm/day, respectively (p<0.0001), 4 weeks after CPD was 3.900.38 and 3.070.25 µm/day, respectively (p=0.0004), and 6 weeks after CPD was 3.350.21 and 2.880.18 µm/day, respectively (p=0.0296).

Micro CT revealed that trabecular separation on ipsilateral and contralateral sides 6 weeks after CPD was 200.732.4 µm and 234.339.4 µm, respectively (p=0.0302), and that trabecular spacing on ipsilateral and contralateral sides was 263.730.3 µm and 300.337.6 µm, respectively (p=0.0261).

DISCUSSION

These results showed that unilateral CPD produces longitudinal overgrowth of ipsilateral femur compared with contralateral one of developing rats. The facts suggest that unilateral CPD stimulates endochondral ossification of ipsilateral femur, and that unilateral CPD might be a promising procedure to correct leg length discrepancy and bone atrophy.

Nitric Oxide Synthase (NOS) in Mouse Femur during Endochondral Ossification. Hiroki Watanabe, Toshihiro Nakagawa, Yuriko Moro, Shinya Takahashi, Kimihiaru Ambe*. Ohu University School of Dentistry, Japan

Recently it has become evident that Nitric oxide (NO) has a pleiotropic role, though NO was first identified as endogenous vasodilator factor (gas). NO plays an important role in several physiological processes, such as vascular relaxation, neurotransmission, and in immune regulation. NO is generated by nitric oxide synthase (NOS), which demonstrates three isoforms, a neuronal form (nNOS), an endothelial form (eNOS) and an inducible form (iNOS). We investigated the expression and cellular localization of NOS isoforms in mouse femur using immunohistochemistry and in situ hybridization in order to clarify its possible role in endochondral ossification. At postnatal 3 weeks, the immunoreactivity of nNOS was observed on chondrocytes from the resting zone to hypertrophic zone. The immunoreactivity of iNOS was localized to part of the chondrocytes in the proliferative zone and prehypertrophic zone, but the many chondrocytes in the prehypertrophic zone and hypertrophic zone were positive for anti-nNOS. The immunoreactivity of eNOS was observed on chondrocytes from the resting zone to hypertrophic zone. At postnatal 18 weeks, the proliferative zone and hypertrophic zone disappeared from the growth plate in femur, and the growth plate was not observed at the proliferation and differentiation of chondrocyte. There was no immunoreactivity for any of the NOS isoforms in chondrocytes. Expression of each NOS mRNA was not detected at chondrocytes. Osteoblasts and osteoclasts were positive for anti-nNOS, iNOS, eNOS until 18 weeks. Expression of NOS mRNA on in situ hybridization showed results approximately similar to those on immunohistochemistry. These findings suggest that each NOS may be related to trabecular bone growth and remodeling in the mouse femur. In addition, NO may play an important role in proliferation and differentiation in chondrocytes.

A Novel Double Fluorescent Strategy to Prospectively Isolate Label Retaining Chondrocytes at the Top of the Growth Plate. Noriaki Ono*¹, Takao Hirai², Henry Kronenberg³. ¹Massachusetts General Hospital & Harvard Medical School, USA, ²Kyoto Prefectural University of Medicine, Japan, ³Massachusetts General Hospital, USA

Slowly dividing cells at the top of the growth plate cartilage are the sources of all other chondrocytes in the growth plate and probably share some characteristics of postnatal stem cells. Slowly dividing cells retain nuclear labels longer than their more rapidly dividing progeny (label-retaining cells or LRCs). To prospectively isolate LRCs in the growth plate, we generated mice expressing a tetracycline-controlled transactivator under a type2 collagen promoter (Col2a1-tTA) and conducted a pulse-chase experiment based on a Tet-Off system and a histone 2B (H2B)-bound EGFP label. Col2a1-tTA; Col1a1-TRE-H2B-EGFP (a type1 collagen locus with Tet-responsive element (TRE)-H2B-EGFP cassette insertion) mice were fed with doxycycline for 5 weeks to shut off EGFP expression and sacrificed at 8 weeks of age. We found that the H2B-EGFP signal was largely abrogated in the growth plate region, and only a small fraction of cells near the top of the growth plate retained H2B-EGFP. However, we also found that a low level of H2B-EGFP signal persisted in osteoblasts/cytes even after the chase, perhaps because the TRE-H2B-EGFP cassette had been inserted in the Col1a1 locus. To distinguish the EGFP-labeled chondrocytes from osteoblasts/cytes, we attempted to label all chondrocytes in the growth plate with a red fluorochrome, using an inducible Col2a1-CreERT system that activated a Rosa26 cytomegalovirus enhancer/chicken beta-actin promoter (CAG)-tandem dimer (td) Tomato reporter locus. We confirmed that tamoxifen injection during a week earlier gave rise to Tomato(+) cells mostly within the growth plate. Col2a1-CreERT; Rosa26-CAG-tdTomato; Col2a1-tTA; Col1a1-TRE-H2B-EGFP quadruple mutant mice were fed with doxycycline for 5 weeks and injected with tamoxifen during a week prior to analysis at 8 weeks of age. We found that Tomato(+) chondrocytes near the top of the growth plate retained a higher level of H2B-EGFP expression. Epiphyses of long bones were dissected and serially digested by collagenase to release cells for flow cytometry. Growth plate chondrocytes defined as a Tomato(+) population represented 17% of non-hematopoietic cells. A Label-retaining population with >10⁴ unit of GFP (GFP^{high}) represented 1% of the Tomato(+) population. Distinct GFP^{mid} non-label-retaining and GFP^{low} populations were also observed. This study indicates the feasibility of our double fluorescent strategy to isolate label-retaining chondrocytes by cell sorting to study their gene profiles.

Acceleration of Chondrocyte Differentiation with a Peptide Exhibiting Osteoclastogenesis Inhibitory Activity and Osteogenesis Stimulatory Activity. YURIKO FURUYA*, KOJI UCHIDA, HISATAKA YASUDA. ORIENTAL YEAST CO.,LTD, Japan

Introduction: A TNF α antagonistic peptide is known to inhibit osteoclastogenesis by blunting RANKL-RANK interaction. We reported that the peptide enhanced osteoblastic differentiation/mineralization in vitro and also increased bone formation in vivo in the previous meeting. Here we evaluated whether the peptide had a chondrocyte differentiative effect using mouse prechondrocytic ATDC5 cells and human mesenchymal stem cells (hMSCs).

Methods: ATDC5 cells and hMSCs were cultured in chondrocytic conditions with or without the peptide for 2 weeks and stained with alcian blue. The effect of the peptide was examined on 3 dimensional (3D) hMSC pellet cultures for 2 or 3 weeks. The synergistic effects of the peptide with TGF- β 3 or BMP-2 were examined in 3D hMSC pellet cultures. Formalin-fixed, paraffin-embedded 3D pellet sections were stained with safranin O and alcian blue, respectively, for detection of cartilage matrix. Gene expression in hMSCs treated with the peptide for 24, and 96 hr was examined by Gene chip assay.

Results: Alcian blue staining revealed that the peptide differentiated ATDC5 cells to chondrocytes in a dose-dependent manner. Similar observations were also found in hMSCs culture. The peptide enlarged markedly alcian blue-positive 3D hMSC pellets in a dose-dependent manner compared with the control. Simultaneous treatment of the 3D pellet cultures with the peptide and TGF- β 3 or BMP-2 markedly enhanced the alcian blue staining and safranin O staining, respectively, but TGF- β 3 or BMP-2 showed no additive effects on enlargement of the pellets cultured with the peptide. Gene expressions of cartilage matrix proteins and IGF-1 were significantly upregulated in hMSCs treated with the peptide for 24 and 96 hr.

Discussion: A peptide exhibiting osteoclastogenesis inhibitory activity and osteogenesis stimulatory activity induced chondrocytic differentiation in ATDC5 and hMSCs. The peptide also increased the production of cartilage matrix proteins and synergistically enhanced their production with TGF- β 3 or BMP-2. The peptide may be useful for and applicable to the treatment of chondropathy such as osteoarthritis and cartilage injury. The mechanism by which the peptide inhibits osteoclastogenesis and stimulates osteogenesis and chondrogenesis remained to be elucidated.

Activation of Wnt Planar Cell Polarity (PCP) Signaling Promotes Columnar Architecture of Growth Plate Chondrocytes In Vitro. Rachel Randall*¹, Yvonne Shao², Lai Wang¹, Robert Ballock³. ¹Cleveland Clinic, USA, ²CCF, USA, ³The Cleveland Clinic Foundation, USA

Background: Although the cellular and molecular mechanisms governing the morphogenesis of columnar growth plate cartilage are currently unknown, the activity of the Wnt Planar Cell Polarity (PCP) signaling pathway has been implicated in this process. We hypothesized that growth plate column formation can be recapitulated in vitro through activation of Wnt PCP signaling.

Methods: Epiphyseal chondrocytes were isolated from 4-day old Sprague-Dawley rats, digested, and transfected with plasmid DNA encoding the full-length Fzd7 receptor, or a deletion mutant of the Fzd7 receptor lacking the Wnt-binding domain, and cultured as three-dimensional cell pellets. Recombinant Wnt5a was added to the culture medium for up to three weeks. The alignment of cells into columns was assessed by histomorphometric measurements.

Results: Columnar architecture of growth plate chondrocytes was enhanced in cell pellets in which Wnt PCP signaling was activated by Fzd7 overexpression with addition of Wnt5a.

Conclusions: Activation of the Wnt PCP signaling pathway, through overexpression of the Fzd7 receptor and addition of exogenous Wnt5a, appears to promote columnar chondrocyte architecture of isolated growth plate chondrocytes in vitro.

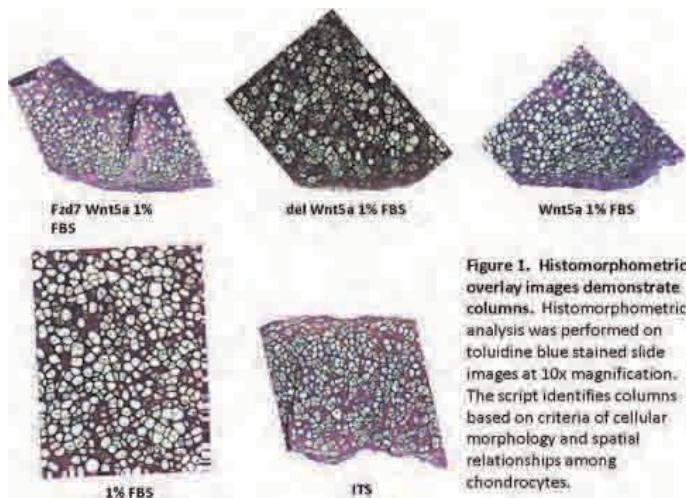

Figure 1

Figure 2. Percentage of cells in oriented columns. Histomorphometric analysis of toluidine blue stained images determined columns based on cellular morphology and spatial relationships among cells. Values shown are percentage of cells in the 10x image participating in columns of at least three cells and orientation between 65-115 degrees from a predetermined reference line. Treatment groups include isolated rat growth plate chondrocytes transfected with Fzd7, a deletion mutant of Fzd7 lacking the CRD, addition of exogenous Wnt5a, 1% FBS, or ITS (serum-free medium).

Essential Role of Cdc42 in Chondrogenesis and Interdigital Programmed Cell Death During Limb Development. Ryo Aizawa¹, Atsushi Yamada¹, Dai Suzuki², Hidetoshi Kassai³, Takeshi Harada³, Masayuki Tsukasaki¹, Gou Yamamoto¹, Tadahiyo Iimura⁴, Akira Yamaguchi⁵, Kazuki Nakao³, Matsuo Yamamoto¹, Atsu Aiba³, Ryutaro Kamiyo¹. ¹Showa University School of Dentistry, Japan, ²Showa University, Japan, ³The University of Tokyo, Japan, ⁴Tokyo Medical & Dental University, Global Center of Excellence Program, Japan, ⁵Tokyo Medical & Dental University, Japan

Cdc42, a member of the Rho family of small GTPases, is known to be a regulator of multiple cellular functions, including cytoskeletal organization, cell migration, proliferation, and apoptosis. However, its tissue-specific roles, especially in mammalian limb development, remain unclear. To investigate the physiological functions of Cdc42 during limb development, we generated a limb bud mesenchyme-specific inactivated Cdc42 mouse model (*Cdc42^{fl/fl}; Prx1-Cre*) by crossing *Cdc42^{fl/fl}* mice with *Prx1-Cre* transgenic mice, since *Cdc42^{-/-}* embryos die before embryonic day (E) 7.5. Although most of the *Cdc42^{fl/fl}; Prx1-Cre* mice were viable at birth, all died within 1 day. Anatomical analyses demonstrated that *Cdc42^{fl/fl}; Prx1-Cre* neonates had short limbs and body, skull hypoplasia, a complete cleft palate, disruption of the xiphoid process, and short and thick mineralized bone in the limbs as compared to *Cdc42^{fl/fl}* neonates. Detailed analyses of *Cdc42^{fl/fl}; Prx1-Cre* limbs revealed severely disorganized growth plates with a wider hypertrophic zone and altered cell shape of chondrocytes. In addition, *Cdc42^{fl/fl}; Prx1-Cre* mice presented with syndactyly characterized by fusion between the second and third phalanges. Defects in the expression patterns of *Sox9*, *Glil*, *Patched1*, and *Hoxd13* were apparent in *Cdc42^{fl/fl}; Prx1-Cre* mice as early as E12.5, consistent with the abnormal calcification and fusion of phalanges. Furthermore, cutaneous syndactyly with webbing of the interdigital skin

appeared in these mice. To determine whether webbing of the interdigital skin was due to a defect of interdigital programmed cell death, TUNEL assays were performed using limb buds obtained from E12.5-E14.5 mice, which demonstrated a significant reduction of interdigital programmed cell death. *Bmp2* expression was also down-regulated in the interdigital region of the limbs as compared to those of *Cdc42^{fl/fl}* mice, as were the expression of *Msx1* and *Msx2*, which are known as downstream target genes of BMP signaling and promote intense apoptosis in limb development. Taken together, these results demonstrate that Cdc42 is essential for chondrogenesis and interdigital programmed cell death during limb development.

Expression of Sclerostin in the Developing Zebrafish Brain and Skeleton. Melissa McNulty¹, THEODORE CRAIG¹, Victoria Bedell¹, Tammy Greenwood¹, Stephen Ekker¹, Rajiv Kumar². ¹Mayo Clinic, USA, ²Mayo Clinic College of Medicine, USA

Sclerostin (sost) is a secreted glycoprotein that influences skeletal development by modulating the activity of bone morphogenic proteins, LRP 5/6, *cyr61*, and the *erbB3* receptor. To gain insights into the ontogeny of zf sclerostin expression, we performed in situ hybridization with sense and anti-sense RNA probes 15-120 hpf. Embryos were fixed with paraformaldehyde, washed and treated with proteinase K. Approximately 400-500 bp-long digoxigenin-labeled sost RNA probes were hybridized to treated embryos. Following hybridization and extensive washing, zf embryos were treated with buffer containing 2 mg/mL BSA, and 2%-sheep serum. Digoxigenin antibody, 1/6000 dilution, pre-blocked with fish powder, was added and embryos incubated overnight. Embryos were washed with PBST and treated with AP buffer (Tris 100 mM, MgCl2 50 mM, NaCl 100 mM). AP substrate (NBT, BCIP) was added to the embryos. Substrate buffer was removed and embryos were washed with PBST. Localization of probes was visualized by light microscopy. Whole mount immunofluorescence was performed using polyclonal antibodies directed against zf sclerostin. Fixed embryos were digested with acetone or proteinase K. Embryos were blocked with 2% goat serum and 1% BSA in PBST. Anti-ZF-sclerostin antibodies (1:5000) were applied in blocking buffer. Following extensive washes, anti-rabbit Alexa Fluor555 antibodies (1:1000) were applied. Composite images of embryos were generated. Paraffin sections (4 µm) of adult zf were processed using the aforesaid antibodies.

Results: With an anti-sense sost probe, sost RNA was noted as early as the 12 somite stage. 20 hpf, sost RNA was detected in the nervous system (figure 1A). By 48 hpf, sost RNA was detected in the cartilage of the pharyngeal arches and the mandibular arch (figure 1B). Sost RNA was clearly seen in these structures 72 and 96 hpf, as well as, in developing dorsal fins (figure 1C and figure 1D). Experiments with sense probes showed no signal throughout the zf embryonic development. In 24 hpf embryos sclerostin epitopes were identified in the nervous system. In adult zf, sclerostin antibodies detected epitopes in osteoblasts of zf bone. **Conclusions:** Sclerostin RNA is detected in pharyngeal and mandibular cartilage of the developing zf demonstrating that it may play a role in cartilage development. In addition, sclerostin RNA is detected early in the developing neural system suggesting a role for this protein in nervous system physiology.

MEPE-ASARM Peptides: Novel Regulators of Growth Plate Mineralisation. Colin Farquharson¹, Vicky MacRae², Katherine Staines². ¹Roslin Institute, University of Edinburgh, United Kingdom, ²The Roslin Institute & R(D)SVS, The University of Edinburgh, United Kingdom

Advances in the understanding of hypophosphatemic disorders have identified a novel group of molecules (FGF23, PHEX, MEPE, DMP1) involved in phosphate homeostasis. The specific binding of PHEX to MEPE regulates the release of ASARM peptides, implicated in osteoblast mineralisation directly. Although the growth plates of MEPE transgenic display severe morphological disruption, the expression and function of MEPE in growth-plate mineralisation remains largely undefined.

Proximal tibiae from 3-week-old wild-type mice were analysed for *Mepe* expression by hybridisation and growth-plate microdissection. Gene expression by the ATDC5 chondrogenic cell-line was examined by RT-qPCR over a 20-day calcifying culture period. 20µM phosphorylated (pASARM) and non-phosphorylated ASARM (npASARM) peptides were added to ATDC5 cultures, and to embryonic metatarsal explants.

Mepe expression was abundant throughout the growth-plate as shown by *in situ* hybridisation. Microdissection of the growth-plate confirmed an increased expression of *Mepe* in the hypertrophic chondrocytes compared to proliferative chondrocytes ($P < 0.05$). ATDC5 cells showed an initial decrease in *Mepe* expression at day-10 of culture, after which expression increased at day-15. Treatment of ATDC5 cells with pASARM peptide caused an inhibition of mineralisation, determined by alizarin red staining ($P < 0.01$). Treatment with npASARM promoted mineralisation ($P < 0.01$). The growth rate of 15 and 17-day-old embryonic metatarsals and the proliferation of chondrocytes within were not affected by treatment with 20µM pASARM or npASARM peptides. This indicates that the peptides were not toxic and the bones were still viable after 7 days of culture. However, in 17-day-old embryonic metatarsals, the growth of the central diaphyseal mineralisation zone was inhibited in bones treated with 20µM pASARM ($P < 0.001$). In 15-day-old embryonic metatarsals, the central mineralised core only forms after 7 days in culture. Treatment with 20µM pASARM peptides completely prevented mineralisation. Alkaline phosphatase activity was unchanged between the treated and untreated bones, suggesting that the observed inhibition of mineralisation is not a result of decreased enzyme activity.

Our findings indicate that MEPE is expressed by growth-plate chondrocytes and that it is likely to have a developmental role in the inhibition of cartilage matrix mineralisation through its cleavage and subsequent phosphorylation of the ASARM peptide.

Notch Signaling during Chondrogenesis. Shan Chen^{*1}, Jianning Tao¹, Ming-Ming Jiang¹, Terry Bertin¹, Brendan Lee². ¹Baylor College of Medicine, USA, ²Baylor College of Medicine & Howard Hughes Medical Institute, USA

Notch signaling is critical during development directing binary cell fate between progenitors and differentiated cells. Aberrant Notch function causes several human skeletal diseases such as Spondylocostal dysostosis (SCDO) and Alagille syndrome. Recently, cartilage specific gain- or loss- of-function of Notch mouse models have been made in our and other laboratories. Although detailed phenotypic studies of these mice have been conducted, a full knowledge of the mechanisms of the pathway is still lacking. The canonical Notch pathway involves Rbpj as a co-factor to induce target gene expression. However several findings suggest Rbpj-independent mechanisms exist to promote Notch signaling transduction. Our goal is to unravel the molecular mechanisms by which Notch signaling controls cartilage development. We hypothesize that the function of Notch signaling is mediated by both the canonical and non-canonical pathways. To study the gain-of-function of Notch in cartilage, we crossed a Col2a1-cre line with a line having a conditionally activated allele of Notch1 intracellular domain (N1ICD). Resulting mutant mice have shortened limbs, undersized ribs, and virtual absence of the spine and tail. Decreased Alcian blue staining highlights the general defects of chondrogenesis. The decreased expression of Sox9, Col2, Col10 in the mutant suggests the inhibition of chondrocyte differentiation by Notch signaling. On the other hand, complete loss-of-function of Notch (achieved by deleting Presenilin 1/2 in cartilage) causes undersized and underdeveloped skeletal elements. The limbs and spine are about 40% shorter in the mutants at 3 weeks of age. Interestingly, cartilage specific deletion of Rbpj causes only a mild phenotype. The body weight and histology of cartilage appear to be normal at 3 weeks of age. To test whether Notch signal transduction depends on Rbpj, we made mice with deficient Rbpj on the Notch gain-of-function background. These mice have nearly normal limb structure but demonstrate irregular curvature of the spine with a shortened tail, suggestive of incomplete rescue. To completely map the Notch signaling pathway, we are identifying Notch targets by a CHIP-seq approach in the ATDC5 cells, a chondrocyte cell line. We have achieved high specificity and enrichment of the occupancy of the Notch targets using a tagged system. We hope to identify differential targets of canonical vs. noncanonical Notch signaling using this approach.

PDGF-BB and CCL21 Mediate TGFβ-Induced Migration during Development of Dorsal Vertebrae. Ying Wang^{*}, Rosa Serra, University of Alabama at Birmingham, USA

During vertebrae development, sclerotome, a population of undifferentiated mesenchymal cells, differentiates and migrates to give rise to distinct parts of the vertebrae and ribs. Our laboratory has shown that deletion of TGFβ type II receptor (*Tgfr2*) in Col2a expressing tissue in mice results in small vertebrae and failure in the formation of the spinous process, mimicking spina bifida occulta, a common congenital malformation in humans. Mechanisms mediating closure of the dorsal vertebrae are not clear. In this study, we aimed to determine whether the missing dorsal structures in *Tgfr2* mutant mice are due to defects in migration of sclerotome and surrounding mesenchyme, and to further clarify the underlying mechanism of TGFβ-mediated migration.

We first crossed the Col2aCre mice to the Rosa26 reporter strain to show that TGFβ signaling is required for dorsal closure of vertebrae and formation of the spinous process, and that the disruption to development is evident by E16.5 days. We then used a chemotaxis migration assay to show that TGFβ signaling promotes the migration of embryonic sclerotome and associated mesenchyme, and this action is mediated by the downstream effector PDGF-BB. We found that PDGF-BB is mainly expressed in the sclerotome that forms future cartilage, whereas PDGFRβ is dominantly expressed in the surrounding mesenchyme. Previous studies have shown that PDGF signaling promotes migration of sclerotome associated mesenchymal cells, which secrete chondrogenic factors required to form dorsal cartilage. Using microarray technology, we also identified CC-chemokine ligand 21 as a downstream target of TGFβ signaling, which we propose is also involved in TGFβ-mediated migration and formation of the spinous process. Our study suggests that TGFβ signaling is required for dorsal closure of vertebrae and formation of the spinous process. This action is likely mediated by the downstream effectors PDGF-BB and CCL21 and their role in regulating migration of sclerotome and associated mesenchyme. These findings suggest that TGFβ potentially could be a therapeutic target for osteoarthritis or fracture repair, which also involve migration of chondrogenic mesenchymal cells.

The Alk2 R206H (FOP) Mutation Causes Lower Limb Chondrodysplasia in Mice. Salin Chakkalakal^{*1}, Andria Culbert¹, Michael Convente¹, Devy Zhang¹, Frederick Kaplan², Eileen Shore¹. ¹University of Pennsylvania, USA, ²University of Pennsylvania Hospital, USA

Mutations in the ALK2 BMP type I receptor (encoded by the *ACVR1* gene) cause fibrodysplasia ossificans progressiva (FOP), a disabling human disease characterized by progressive heterotopic endochondral ossification and malformations of the great toe. Most individuals with FOP have the identical single nucleotide activating missense mutation (c.617G>A; R206H) in the GS regulatory subdomain of ALK2. We developed a heterozygous Alk2 R206H knock-in mouse in which the mutated allele is regulated by the endogenous *Acvr1* promoter. While mice chimeric for cells with the R206H mutation are viable and show all of the characteristic clinical features of FOP, germline transmission of the heterozygous mutant allele is perinatal lethal. By whole mount skeletal staining and microCT imaging, these one day old heterozygous Alk2 R206H mice have reduced body size compared to controls and exhibit malformations and joint ankylosis primarily affecting the tibia, fibula, and foot of the hind limbs, while, as with FOP patients, forelimbs were generally unaffected. Histological analysis of one-day old mutant mice showed defective growth plate morphology with expansion of proliferative chondrocytes, decreased hypertrophic and hypertrophic zones, and reduced metaphyseal ossification. Consistent with these altered patterns of chondrocyte differentiation and endochondral ossification, immunohistochemistry and/or quantitative RT-PCR revealed increased Sox 9 and collagen type II expression and decreased collagen type X and Runx2 expression. BrdU labeling of 18.5 dpc embryos showed increased proliferation of immature chondrocytes and an accumulation of labeled prehypertrophic chondrocytes (with limited progression to hypertrophic chondrocytes). Phosphorylated Smad1/5/8 was increased in both proliferating and hypertrophic chondrocytes, indicating enhanced BMP signaling in these cells. These studies indicate that the canonical Alk2 R206H FOP mutation in mice causes lower limb chondrodysplasia characterized by enhanced proliferation and accumulation of immature chondrocytes and decreased maturation and ossification of hypertrophic chondrocytes.

The Role of Neogenin in Osteoarthritis Pathogenesis. Zheng Zhou^{*}, Lin Mei, Wencheng Xiong, Georgia Health Sciences University, USA

Osteoarthritis (OA) is the most common joint disease caused by aging, joint injury and heredity. However, molecular mechanisms underlying OA pathogenesis are largely unknown. Neogenin is identified as a member of cell surface receptor for neuronal axon guidance cue netrins and RGMs (repulsive guidance molecules), and is

involved in axon guidance, neuronal differentiation, and apoptosis. Recently, we have demonstrated that neogenin regulates endochondral bone development and iron homeostasis via BMP signaling. In light of these observations, we speculate a potential function of neogenin in articular chondrocyte differentiation and function, and loss of neogenin function may underlying OA pathogenesis. Here, we provide evidence from our preliminary studies that supports this hypothesis. Neogenin was expressed in articular chondrocytes. Neogenin heterozygous mice showed spontaneous OA-like phenotypes, including damage of articular cartilage, loss of proteoglycan, increased expression of degradative proteinases such as MMPs and ADAMTS. DMM (Destabilization of the medial meniscus) accelerated the OA-like phenotypes in neogenin heterozygous mice. The underlying molecular mechanism remains to be further investigated.

Identification of Human Bone Cell Characteristic Transcripts and their Interactions Using Online Browser Based Search In a Giant Correlation Matrix. Sjur Reppe^{*1}, Daniel Sachse¹, Ole K. Olstad¹, Vigdis T. Gautvik², Paul Sanderson³, Harish Datta⁴, Jens P. Berg¹, Kaare Gautvik¹. ¹Oslo University Hospital, Norway, ²University of Oslo, Norway, ³Newcastle General Hospital, United Kingdom, ⁴Newcastle University, United Kingdom

Bone development, and remodeling is primarily dependent on complex interaction among 3 defined cell types: osteoblasts (OB) and osteocytes (Ocy) responsible for formation and osteoclasts (OC) causing resorption. To further understand the regulation of skeletogenesis it is important to have an overview of the characteristic cell-specific transcriptomes as well as of gene interactions and signaling pathways involved in the various physiological processes. Global gene expression analysis of iliac crest bone biopsies from 84 postmenopausal ethnic Norwegian women allowed defining the molecular skeletal phenotype through quantifications of ~23000 mRNA species. These mRNAs were inter-correlated giving an array containing >260 000 000 pairwise correlations with p- and Pearson r-values. An online browser was programmed for targeted search, thus enabling identification of transcripts which were correlated to those characteristic for Ocy, OB and OC. We found very high correlations between ensembles of known or uncharacterized transcripts linked to cell lineage-specific genes, and were able to define interacting molecular networks across the cell types. For validation of the browser based results we used experimentally proven interactions between the ubiquitous glucocorticoid receptor, the central bone transcription factors SATB2 or RUNX2 and their responsive genes. The matrix, recapitulated more than 92%, 81% and 55%, respectively, of documented interactions as significant correlations. A similar high degree of correlations related to bone cell characteristic transcripts were reproduced in a replica array originating from trabecular vertebral bone biopsies from British Caucasian males. The results provide a unique platform for the identification and further characterization of key functional and regulatory molecules in bone and possibly other tissues and cell types

In Vivo Study of Mxsl Involvement in Alveolar Bone Growth. Sylvie Babajko^{*1}, Ibtisam Senussi², Fleur Meary³, Sophia Loidice⁴, Ariane Berdal⁵. ¹INSERM, France, ²Inserm U872 Université Paris 6, France, ³Inserm U872, France, ⁴Inserm U872 Université Paris 7, France, ⁵Université de Paris 7, France

Mxsl homeogenes play an important role in epithelial-mesenchymal interactions leading development. Mxsl is relevant for dental and craniofacial morphogenesis, as suggested by phenotypes of Mxsl mutations in human and Mxsl knock-out (KO) mice. During post-natal development and adulthood, Mxsl is still expressed in the skeleton where its role is largely unknown. Mxsl function in mandibular and maxillary bones was investigated by comparing the phenotype of Mxsl KO mice and a transgenic mouse line recently established for this study, with Mxsl expression under the control of the 2.3 kb collagen 1 alpha 1 promoter.

In the absence of Mxsl, mandible and alveolar bone morphology observed by micro-CT was affected suggesting Mxsl involvement in bone morphogenesis during embryonic development. On the other side, in Mxsl transgenic (Mxsl Tg), the overall morphology appeared similar even if the alveolar bone was thicker.

Histological analysis of the mandibles at one day after birth showed an accumulation of bone in Mxsl Tg mice compared to wild types. The greatest differences were observed in bone surrounding the incisor and the molars with an increased bone volume containing more trabeculae. On the contrary, Mxsl KO mice have already been shown to produce less alveolar bone. In parallel, our results showed that Mxsl increased cell proliferation as well as apoptosis investigated by caspase-3 expression and TUNEL activity assays. They suggest that Mxsl could be considered as a bone trophic factor leading to an increased cell number explaining the greater bone remodeling.

Is Serum Amyloid A3 (Saa3) a Link Between Hyperhomocysteinemia and the Development of Degenerative Skeletal Pathologies?. Roman Thaler^{*1}, Monika Rumpel², Silvia Spitzer², Eleftherios Paschalis³, Sonja Gamsjaeger², Klaus Klaushofer⁴, Franz Varga². ¹Ludwig Boltzmann Institute of Osteology, Austria, ²Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK & AUVA Trauma Centre Meidling, 1st Medical Department, Hanusch Hospital, Austria, ³Ludwig Boltzmann Institute for Osteology, Austria, ⁴Hanusch Hospital, Austria

Hyperhomocysteinemia is related to cardiovascular diseases, diabetes, osteoarthritis and bone fragility. We recently showed that homocysteine (Hcys) alters collagen cross-linking by hindering the expression of the collagen cross-linker lysyl-oxidase (Lox) through an epigenetic mechanism. In mice, Saa3 was identified as an inflammatory acute-phase reactant, while in rabbits SAA3 was shown to be highly up regulated in Ag-induced arthritis. In pre-osteoblastic MC3T3-E1 cells its mRNA expression is significantly upregulated by Hcys. C3H10T1/2, ST2, MC3T3-E1, 3T3-L1 and C2C12 cells were cultured up to 21 days with several Hcys conc. and/or inhibitors of signal transduction pathways. Osteoblastic cells were reseeded onto Hcys marred extra cellular matrix (ECM) produced by MC3T3-E1 cells. Gene expression was analyzed by GeneChip, qPCR and immuno-blotting. To study transcriptional regulation by Hcys, truncated and mutated variants of the Saa3 promoter were cloned into SEAP2-reporter vector, transfected into MC3T3-E1 cells, which were treated without or with Hcys. Promoter binding and localization of transcription factors were studied by chromatin immunoprecipitation (ChIP) assays and immunofluorescence. Collagen cross-links were measured by FTIR and collagen helix formation was analyzed by a discriminative antibody. Only osteoblastic cells showed a strong, time dependent up-regulation of Saa3 by Hcys treatment. Similarly, compared to untreated ECM, reseeding of MC3T3-E1 cells onto Hcys marred ECM increased Saa3 expression. Both conditions activated focal adhesion kinase and Paxillin and increased cytoplasmic accumulation of b-Catenin (bCat). Transfection of a cytoplasmic bCat-mutant increased strongly Saa3 expression which failed after mutation of a RELA site on Saa3 promoter. Comparison of Saa3 transfected and Hcys treated MC3T3-E1 cells to controls by GeneChip analysis revealed up regulation of Mmp13, the pro-apoptotic gene Fas and of several chemokines like Ccl2, 5, 7 and 9, Cxcl10, Il6 and Il33 in both cases. Mmp13 was up regulated via MAPK and AP-1. Hcys treatment changed collagen cross-linking and fibrillogenesis as shown by FTIR and immunofluorescence, respectively. Our results show that Hcys induces inflammatory genes via Saa3 by marred ECM. This regulation is mediated by FAK, Paxillin, bCat and RelA, as shown by ChIP. In conclusion, we propose Saa3 as new link between hyperhomocysteinemia and the development of degenerative skeletal diseases.

Pannexin 3 Plays a Critical Role for Odontoblast Differentiation. Tsutomu Iwamoto^{*}, YU SUGAWARA, Mariko Ono, Aya Yamada, Takashi Nakamura, Satoshi Fukumoto. Tohoku University Graduate School of Dentistry, Japan

Gap junction proteins play a crucial role in the development of tooth that has well-organized hard tissue structures in enamel and dentin. Pannexin (Panx) is a recently discovered gap junction protein in human and mouse genome. Here, we found that Panx3 was strongly expressed in tooth. Northern blotting revealed that Panx3 is preferentially expressed in tooth, compared to other tissues. In situ hybridization showed that Panx3 mRNA was expressed in preodontoblasts that are a responsible for a dentin formation. To analyze the function of Panx3, we used an odontoblastic cell line, mDP6. Expression of Panx3 was progressively induced in differentiating mDP6 cells after stimulation of BMP-2. Interestingly, overexpression of Panx3 inhibits cell proliferation and promotes their differentiation. Conversely, knockdown of endogenous Panx3 expression by siRNA inhibits BMP-2 induced odontoblast differentiation. Next, we examined whether Panx3 affect BMP-2-smad signaling. BMP-2 induced the phosphorylations of smad1/5/8 in mDP6 cells, but suppression of endogenous Panx3 reduced their phosphorylations levels. In conclusion, our results showed that Panx3 inhibits odontoblastic cell proliferation and promotes cell differentiation, indicating that Panx3 plays an important role in odontoblast differentiation.

RNA Editing Occurs in the Bone and is Modulated by Dietary Fat Intake. Tongjun Gu, Cheryl Ackert-Bicknell, F. William Buaas, Allen Simons, Robert Braun, Matthew Hibbs^{*}. The Jackson Laboratory, USA

Studies have demonstrated that a high fat diet can influence bone mass, but the molecular mechanisms are not well characterized. RNA editing is a wide-spread, evolutionarily conserved RNA processing event that alters the sequence of RNA by changing single bases in transcripts. Edits can diversify the functionality of the

transcriptome (and then proteome) and non-coding edits can modulate protein regulation (e.g. modifications to miRNA target sites). In mammals, two classes of RNA editing have been characterized: adenosine to inosine (read as guanine; A->G), and cytidine to uridine (C->U). Editing has been primarily studied in the brain, where defects in editing are associated with several neurological disorders. Here we report one of the first studies that demonstrates RNA editing in bone. Further, we show that environmental perturbations can affect RNA editing in a tissue specific manner. Specifically, total RNA was isolated from femur, liver, and white adipose tissue from C57BL/6J female mice fed a either a low fat diet or a high fat diet from 8 to 16 weeks of age. Sequencing was performed using an Illumina GAIIX instrument, producing hundreds of millions of 75 base pair long, paired-end reads. These reads were aligned to the mouse reference genome using an algorithm that can tolerate mismatches due to editing. After filtering for read quality and base conservation, we identified genomic locations where aligned reads contained replicated mismatches as sites of RNA editing. We identified thousands of novel RNA editing sites across all three tissues, both common and unique. While many of these sites represent canonical editing, we have also observed significant numbers of non-canonical edits, such as U->G and A->C edits. We have experimentally verified over a dozen of these novel edit sites through Sanger sequencing and restriction fragment length polymorphism (RFLP) assays. By applying a multi-factor ANOVA model we determined that overall levels of RNA editing are significantly altered based on tissue, diet, and the interaction of tissue-by-diet. This work demonstrates that RNA editing occurs in the bone and is modulated by dietary fat; future efforts will continue to characterize the physiological implications of RNA editing in the bone.

Hox11 Genes in Musculoskeletal Patterning, Integration and Fracture Repair. Ilea Swinehart^{*1}, Kenneth Kozloff², Steven Goldstein³, Deneen Wellik⁴. ¹University of Michigan, USA, ²University of Michigan Department of Orthopaedic Surgery, USA, ³University of Michigan Orthopedic Research Labs, USA, ⁴University of Michigan Medical Center, USA

Development of the vertebrate musculoskeletal system requires precise coordination between muscles, tendons and bones to form an integrated and functional system. Recent data from our lab suggests that Hox genes play a key role in this process *in vivo*. Hox genes are established regulators of skeletal morphology. Loss-of-function mutation of the *Hox11* paralogous genes results in dramatic malformation of limb zeugopod elements (radius/ulna, tibia/fibula). Utilizing a *Hoxa11:eGFP* knock-in allele, our lab has demonstrated that *Hox11* gene expression is, surprisingly, excluded from skeletal elements. However, expression is observed in the outer perichondrium surrounding zeugopod elements, as well as in tendons and muscle connective tissue in the same region of the limb. Further, this expression is maintained through adult life, suggesting a role for these genes in the maintenance and repair of these tissues. Consistent with this expression data, *Hox11* mutants develop with significant muscle and tendon defects in addition to the skeletal defects. *Hox11* mutants display defects in muscle splitting as well as loss of muscle groups in the zeugopod region. Additionally, these genes are highly up-regulated following fracture injury in multiple cell types suggesting a role in fracture healing and remodeling responses. Taken together, these data clearly highlight a role for *Hox11* genes in the development and repair of the musculoskeletal system.

Disclosures: Ilea Swinehart, None.

A Homozygous Lethal Mutation in Connexin 43 Leads to Abnormal Skeletal Development in Zebrafish. Juann-Huey Lin¹, Yvonne Matos¹, Matthew Goldsmith^{*2}. ¹Washington University in St. Louis, USA, ²Washington University School of Medicine, USA

Purpose: Mechanisms that regulate skeletal growth and homeostasis are protean and incompletely understood. We recently identified a new zebrafish mutant with short skeletal appendages. Because zebrafish harboring connexin 43 (*cxn43*) mutations have previously shown to have a similar short fin phenotype, we hypothesized that our newly identified mutant might represent a novel *cxn43* allele.

Methods: Based on a candidate gene approach, a single exon containing the entire *cxn43* coding sequence was amplified from both genomic and cDNA and sequenced (mutant and wild type). Skeletal histomorphometry, including Alcian blue, Alizarin red and calcein staining, along with microCT were used to further characterize the skeletal phenotype.

Results: An ENU-based forward genetic screen revealed a new zebrafish mutant with short skeletal appendages (fins). This short fin mutant has a decrease in both fin ray segment length and fin ray segment number when compared with unaffected siblings. Sequencing revealed a novel mutation (V96F) in the *cxn43* coding sequence. Unlike previously described zebrafish *cxn43* (*short fin*) mutants, homozygous *cxn43*^{V96F} mutants do not survive past 18 days of life, suggesting that V96F is a complete loss of function allele. Unlike mammals, early development of the axial skeleton appears normal in *cxn43*^{V96F} mutants.

Conclusions: We have identified a new *cxn43* allele. Unlike previously identified *cxn43* (*short fin*) mutants, *cxn43*^{V96F} appears to be homozygous lethal. However, that fact that *cxn43*^{V96F} survives until ~18 days of life may offer insight into the essentiality of *cxn43* function at various stages of development. Functional studies (membrane localization and dye coupling) of the V96F mutant CXN43 protein are currently underway. In addition, we are investigating the histomorphometric effects of several different *cxn43* mutations on development of the axial skeleton in post-larval and adult zebrafish.

Allogenic Demineralized Dentin Matrix, an Ideal Bone Graft Biomaterial. Neema Bakhshalian^{*1}, Shirin Hooshmand¹, Sara Campbell², Bahram Arjmandi¹. ¹Florida State University, USA, ²Rutgers University, USA

The objective of this study was to evaluate the osteopromotive property of allogenic demineralized dentin matrix. There are different kinds of grafts and biomaterials being used for bone regeneration that are neither cost effective nor free of complications. Therefore, it would be ideal to utilize teeth that are extracted from other individuals (due to orthodontic treatments or wisdom teeth extractions, which are routinely discarded) to make an appropriate bone regenerative material, allogenic DDM. We hypothesized that allogenic DDM has bone regenerative properties. To test this hypothesis 30 New Zealand White rabbits were used. The rabbits were divided into four groups and sacrificed after 15, 30, 60, and 90 days. The thickness of bone specimens were measured before utilizing for micro-CT. Blood samples were collected from all rabbits at each time point. Average bone thickness was increased by 54% in experimental group and was significantly higher at all time points. Moreover, microstructural properties showed superior bone quality in experimental group. White blood cell count was numerically higher in control rabbits compared to experimental rabbits ruling out any inflammation or infection due to allogenic DDM. The results of the present study indicate that allogenic DDM significantly improves both bone quantity and quality through its osteoinductive and osteoconductive properties.

Disclosures: Neema Bakhshalian, None.

Characterization of A Non-Invasive Model of Periodontitis and Alveolar Bone Loss in Rice Rats (*Oryzomys palustris*). J. Aguirre^{*1}, Mohammed Akhter², Donald Kimmel³, Jennifer Pingel⁴, Xuechun Xia⁴, Aly Williams⁵, Marda Jorgensen⁵, Kent Edmonds⁶, Ju-Youn Lee⁷, Lakshmyya Kesavalu⁷, Thomas Wronski¹. ¹University of Florida, USA, ²Osteoporosis Research Center, University of Florida, USA, ³Kimmel Consulting Services, USA, ⁴Department of Physiological Sciences, University of Florida, USA, ⁵Cell & Tissue Analysis Core, McKnight Brain Institute, University of Florida, USA, ⁶Department of Biology, Indiana University Southeast, USA, ⁷Department of Periodontology & Oral Biology, College of Dentistry, University of Florida, USA

The rice rat (*Oryzomys palustris*) develops periodontitis-like lesions when feeding a powdered diet high in sucrose and casein (H-SC). To our knowledge, no studies involving this animal species, in the context of dental research, have been reported in several decades. We aimed to reestablish whether this model can accurately and conveniently mimic the development of human periodontitis. For this purpose, 28 day-old rice rats (n=15/group; 10 males and 5 females) were randomly assigned to pelleted standard (STD) or H-SC diets. Animals were sacrificed after 6, 12 and 18 wks of diet feeding. Mandibles and maxillae were removed and processed for morphometric, histologic, histomorphometric and microCT analyses. We found mild to moderate periodontal lesions in the mandibles of rats fed the H-SC diet for 12 and 18 wks, respectively. Lesions were characterized by hyperplasia and/or ulceration of the gingival epithelium, leukocyte infiltration of the underlying connective tissue, and disruption of the transeptal fibers of the periodontal ligament. Morphometric analysis revealed a progressive increase in horizontal alveolar bone loss area with age in maxillae of males and females fed the STD diet. The H-SC diet exacerbated horizontal alveolar bone loss area at the lingual, but not the buccal surface, at 12 and 18 wks in both genders. No vertical alveolar bone loss at the interproximal space between the first and second molars occurred with age in males or females fed the STD diet. Conversely, significantly increased vertical bone loss was found in mandibles and maxillae of males and females fed the H-SC diet at 12 and/or 18 wks. Remarkably, the H-SC diet significantly increased mineralizing surface, mineral apposition rate, bone formation rate, eroded surface and osteoclast number, but did not alter bone volume, at the interproximal alveolar bone of rats fed for 6 wks, but not in those fed for longer periods. These findings indicate that the H-SC diet induced a transient increase in alveolar bone remodeling, which is followed by accelerated horizontal and vertical bone loss characteristic of moderate periodontitis. These data supports the use of rice rats fed a STD diet as a spontaneous animal model of horizontal alveolar bone loss (mild periodontitis) and a pelleted H-SC diet as an animal model for accelerated horizontal and vertical bone loss (moderate periodontitis).

Fourteen-month Changes in Volumetric BMD of Radius and Tibia upon Antidepressant Drug Administration in Young Depressive Patients. Laima Winterhalder¹, Jolanda Widmer², Prisca Eser², Peter M Villiger², Daniel Aeberli^{*3}. ¹Private psychiatric clinic Wyss, Switzerland, ²Dept. of Rheumatology/Clinical Immunology University Hospital Berne, Switzerland, ³Dept. of Rheumatology & Clinical Immunology/Allergy University Hospital, Switzerland

Background: Depression has been associated with lower areal BMD(aBMD) at the hip and spine and increased fracture risk compared to healthy controls. Cross-sectional studies in patients using antidepressant drugs, particularly selective Serotonin Reuptake Inhibitors (SSRI), also found lower aBMD and increased risk for osteoporotic fractures. However, because most of the previous studies included postmenopausal patients, the contribution of depression and use of antidepressant drugs to low bone strength compared to other confounding variables is unknown. Using peripheral quantitative computed tomography (pQCT), the aim of the present study was to determine the longitudinal changes in trabecular volumetric BMD (vBMD) in young depressive patients under therapy with either SSRI versus other antidepressants (such as tricyclics [TCA] or serotonin- norepinephrine reuptake inhibitors [SNRI]).

Methods: Consecutive male and female (premenopausal) patients on therapy with SSRI or non-SSRI (TCA or SNRI) seen at a private psychiatric clinic were recruited. pQCT measurements were performed at baseline and after 12 months at the distal 4% site of the radius and tibia. Of the epiphyseal bone scans cross-sectional area (CSA), total BMD and trabecular BMD (of the central 45% of total CSA) were analysed. Diaphyseal scans at the radius and tibia were performed at 66% from distal bone ends. From these, cortical CSA, total bone CSA, and cortical BMD were measured. Cortical wall thickness was calculated on the basis of a cylindrical model. Reproducibility measurements resulted in a smallest detectable difference for trabecular vBMD at the radius of 4.74 mg/cm³ and of 3.92 mg/cm³ at the tibia.

Results: A total of 40 patients (34 females and 6 males) were recruited, of whom 26 were on SSRI and 14 on non-SSRI (TCA and SNRI) therapy. Mean age was 37 years (range 18-55 years), and mean follow-up period 13.9 months (range 11.4-16.7 months). Age, follow-up period, sex ratio, and height were comparable between groups. Weight was significantly greater in the non-SSRI group (79.2 kg versus 68.6 kg in the SSRI group). Within the SSRI group, none of the bone parameters changed between baseline to follow-up measurement. Within the Non-SSRI group trabecular vBMD increased by 1.8% at the distal radius (p=0.021) and by 1.0% at the distal tibia (p=0.025). When longitudinal changes were compared between the two groups, trabecular vBMD at the distal radius and total vBMD at the distal tibia increased significantly more in the non-SSRI group (p=0.031 and 0.038, respectively).

Conclusion: This longitudinal prospective pQCT study of the radius and tibia in young patients on antidepressant drug therapy does not support previous findings that use of SSRI and/or depression leads to bone loss. Under therapy with TCA or SNRI a small increase in vBMD at the distal radius and tibia was noted.

Identification of Adipocyte Mediated Osteogenesis. Adam Taylor^{*1}, Alan Boyde², Jonathan Jarvis³, Lakshminarayan Ranganath³, James Gallagher¹. ¹University of Liverpool, United Kingdom, ²Institute of Dentistry, Barts & The London School of Medicine & Dentistry, United Kingdom, ³Musculoskeletal Biology, University of Liverpool, United Kingdom

It is the dominant concept that remodelling of bone is a process in which resorption is coupled with subsequent formation by osteoblasts. Using 3D SEM & qBSE-SEM, we have recently discovered non-coupled deposition of mineralised bone in patients with arthropathies. New structures appear in numerous forms including new bone packets and projections laid upon resting trabecular surfaces (Taylor, 2011). These appear in numerous types, are hypermineralised and often poorly integrated with pre-existing matrix. Others appear as partially resorbed trabeculae which have been smoothed over by new bone deposition. Further study was instigated by the outline and shape of some of these structures not being congruent with typical osteoblastic bone formation. This revealed a close association of adipocytes with some of these structures, which showed indented, rugged surfaces. Subsequent histological examination revealed that adipocytes exactly fitted the contours of the bone surfaces. A role for adipocytes as bone lining cells has been suggested previously (Boyde, 2006), but there is no literature proposing a role for adipocytes in templating or moulding the surface of bone. Immunohistochemistry shows that there is collagen VI in these excrescences. These results suggest that the deposition of the bone matrix within these mineralised excrescences is at least templated and modulated by adipocytes. However, the absence of osteoblasts from the forming surfaces raises the question of whether the matrix which is subsequently mineralised is partially synthesised by the adipocytes. Furthermore, it provides unequivocal evidence that adipocytes rather than inactive osteoblasts are the *de facto* lining cells on some bone surfaces. It is well recognised that adipocytes and osteoblasts can be derived from the same mesenchymal stem cells under the influence of different transcription factors. Furthermore there is evidence of

transdifferentiation between the cell types. However, this is the first report of an intimate role for adipocytes in osteogenesis. References: Taylor A, Boyde A, et al. (2011). Identification of trabecular excrescences, novel microanatomical structures, present in bone in osteoarthropathies. Submitted. Molecular Mechanism of CIZ Actions to Exacerbate Inflammation in Serum-induced Arthritis Based on Formation of Positive Feedback Loop with IL-1 Beta. Tetsuya Nakamoto^{*1}, Takayuki Motoyoshi², Makiri Kawasaki², Tomomi Sakuma¹, Tadayoshi Hayata³, Yoichi Ezura⁴, Masaki Noda¹. ¹Tokyo Medical & Dental University, Japan, ²Department of Molecular Pharmacology, Medical Research Institute, Tokyo Medical & Dental University, Japan, ³Medical Research Institute, Tokyo Medical & Dental University, Japan, ⁴Tokyo Medical & Dental University, Medical Research Institute, Japan

Rheumatoid arthritis deteriorates the quality of life in a large number of patients but the cause of this disease is still not understood. CIZ (Cis interacting zinc finger protein) is a transcription factor that regulates the transcription of MMPs. We have observed that CIZ deficiency suppressed the inflammation, cartilage destruction, osteoclast activation in serum-induced arthritis model in vivo, accompanied by the impaired induction of IL-1 beta, MMP-3, and RANKL in the joints. However, molecular bases were not known. Therefore, we investigated cellular and molecular bases to obtain mechanistic insights into the link between CIZ and IL-1 beta in inflammation. Primary chondrocytes from newborn mouse ribs expressed CIZ and the levels of the expression correlated with the chondrocyte differentiation. When chondrocytes were stimulated with IL-1 beta, the expression of CIZ increased up to 1.6 fold dose-dependently. Concurrently IL-1 beta also stimulated the expression of IL-1 beta itself and overexpression of CIZ in chondrocytes enhanced the upregulation of IL-1 beta in response to the stimulation by IL-1 beta, suggesting the role of CIZ in the transcriptional regulation of IL-1 beta. Therefore, we examined the effect of CIZ to IL-1 beta promoter. ChIP assay using anti-CIZ antibody confirmed that CIZ bound to sequences in the IL-1 beta promoter, which include CIZ-binding consensus sequences. Furthermore, overexpression of CIZ enhanced the promoter activity from the IL-1 beta promoter in osteoblastic cell line, MC3T3-E1 cells. To examine involvement of secreted IL-1 beta in induction of CIZ expression, we applied the blocking antibody to IL-1 beta to ATDC5 chondrocytic cell lines stimulated with LPS, and confirmed that CIZ upregulation was suppressed by the antibody. These in vitro results that (1) CIZ expression is induced by IL-1 beta and (2) the overexpressed CIZ enhances the expression of IL-1 beta, reveal the mechanism underlying CIZ actions to exacerbate arthritic inflammation.

Standardization of proteoliposome systems containing Alkaline Phosphatase and Annexin V: kinetic characterization at physiological pH. Mayte Bolean^{*1}, Ana Maria Simao², Tina Moreira³, Marc Hoylaerts⁴, Jose Luis Millan³, Pietro Ciancaglini¹. ¹FFCLRP-USP, Brazil, ²University of Sao Paulo - USP, Brazil, ³Sanford-Burnham Medical Research Institute, USA, ⁴Center for Molecular & Vascular Biology, University of Leuven, Belgium

The biomineralization process is initiated inside matrix vesicles (MVs). The crystalline hydroxyapatite generation and its deposition is accomplished by the activities of proteins involved in Ca²⁺ and Pi homeostasis, among them Annexins (Anx V), Pi-transporters, PHOSPHO1 and tissue-nonspecific alkaline phosphatase (TNAP). Anx V mediates Ca²⁺ influx. TNAP hydrolyze phosphomonoester with release of Pi and alcohol. Dipalmitoylphosphatidylcholine (DPPC) and dipalmitoylphosphatidylserine (DPPS) are lipids found in the MV membranes that play a crucial role in the biomineralization process, regulating both Ca²⁺ entry into the MVs and formation of HA crystals. Since the presence of DPPS is necessary for the ability of Anx V to mediate Ca²⁺ flux across the membrane, but it reduces the activity of TNAP, we studied the best lipid composition to optimize the incorporation and functionality of both proteins. So, TNAP and Anx V were incorporated into liposomes of various lipid compositions, i.e. DPPC alone or DPPC:DPPS in different molar ratios (5, 10 and 15%). The presence of both proteins in the proteoliposomes was confirmed by Western blots. The kinetic parameters for the hydrolysis of ATP, ADP and PPI by TNAP, in the absence and presence of Anx V, were determined at physiological pH. DPPS-only liposome prevented the p-NPPase activity of TNAP. Hydrolysis of ATP was positively cooperative in all proteoliposomes and K_{0.5} values were similar (around 0.2 mM). The V_m values decreased by half with the increasing DPPS ratio. For ADP, negative cooperativity was observed in DPPC-proteoliposomes, but positive cooperativities were detected in the presence of DPPS. Lower K_{0.5} values were obtained for DPPC:DPPS-proteoliposomes (9.3 to 30.8 μM) when compared with the absence of DPPS (60.1 μM). The proteoliposome with DPPS 5% showed the highest V_m value (11.6 U/mg). It was observed negative cooperativities in all systems during PPI hydrolysis by TNAP-proteoliposomes. These vesicles showed the highest

K_{0.5} value (0.23 mM) and V_m values decreased strongly (46.2 to 24.8 U/mg) with the increase in DPPS ratio. Thus, the best catalytic efficiency was obtained with 10% DPPS, for all substrates, and with this condition we will examine the ability of AnxV-containing proteoliposome to flux Ca²⁺. Our ultimate goal is to evaluate the interplay of PHOSPHO1, AnxV, Pit-1, TNAP and NPP1 in a complex proteoliposome system that will mimic the initial events that lead to MV-mediated calcification.

Determining the Function of WISP-1/CCN4 in Mineralized Tissue. Azusa Maeda^{*1}, Mitsuaki Ono¹, Tina Kiltz¹, Kenn Holmbeck², Karen Lyons³, Marian Young¹. ¹National Institutes of Health, USA, ²NIDCR, USA, ³University of California, Los Angeles, USA

WISP-1 (CCN4) is a CCN family member that is highly expressed in mineralizing tissues however its function in bone is unclear. To examine this we generated mice unable to make WISP-1 (WISP-1 KO) by gene targeting. Northern blotting, RT-PCR and western blotting confirmed that WISP-1 was depleted in the WISP-1 KO mice and their bones were subsequently analyzed by Dual Energy X-Ray Absorptiometry (DEXA) and micro computerized tomography (μCT). In 1 month-old WISP-1 KO mice there were no significant differences in the total bone mineral density (BMD) compared to normal (wild type/WT) mice, however, by 3 months of age the WISP-1 KO mice had significantly lower BMD compared to WT mice, and this persisted until 9 months of age. μCT analysis of 3 month-old femurs revealed numerous changes in the WISP-1 KO bones compared to WT bones. In the trabecular region, female KO mice had lower BMD, lower trabecular numbers and more trabecular separation, as well as greater bone surface/bone volume all indicating a decrease in bone mass. In the cortical bone, both male and female KO mice had decreased cortical area, decreased cross sectional area and decreased mean thickness, which is likely the basis for the decrease in total BMD noted from the DEXA scans in the WISP-1 KO animals. In addition to the changes in the trabecular and cortical bone character and architecture, the μCT analysis showed that the femurs from the WISP-1 KO male mice were shorter than WT controls. To understand the mechanism for these differences, osteogenic progenitors were obtained from the bone marrow (bone marrow stromal cells/BMSCs) of 6 week-old female mice and tested for their ability to differentiate towards osteogenesis. BMSCs from the WISP-1 KO mice had dramatically reduced levels of alkaline phosphatase, osteocalcin and bone sialoprotein mRNA that was accompanied by a significant reduction in Alizarin Red staining. To further understand the effects of WISP-1 depletion on BMSC, the ability of the cells to proliferate was examined and showed that WISP-1 KO mice had higher levels of BrdU incorporation compared to WT BMSCs, indicating they proliferated faster. Considering that in WISP-1 deficient BMSCs the differentiation of osteogenic progenitors was decreased while the proliferation levels were increased, it is proposed that WISP-1 potentially regulates bone mineral density and cortical bone thickness by balancing the proliferation and differentiation levels of osteogenic precursors.

Fluid Osteocalcin Levels Correlate to Bone and Cartilage Matrix Measures in a Small Study of Men with Severe Osteoarthritis and Co-morbid Diabetes Mellitus. Karen King^{*1}, Trevor Oren², Allan Bucknell². ¹University of Colorado School of Medicine, USA, ²Eastern Colorado Health Care System, USA

Osteoarthritis patients with diabetes mellitus (DM) that receive total knee joint replacement (arthroplasty) are more vulnerable to complications, including aseptic loosening and need for revision surgery. To elucidate mechanisms related to arthroplasty failure in DM, we examined serum and synovial fluid biomarkers as well as collagen cross-links in bone and cartilage from twenty male patients (10 with DM, 10 without DM) undergoing this procedure at the Denver VAMC.

Subject age, HbA1c, and body mass index (BMI) were obtained from patient files. Bone alkaline phosphatase (BAP) and osteocalcin (OC) were measured in blood serum and index joint synovial fluid by ELISA. The contents of the cross-links hydroxylsypyrindinoline (HP), lysylpyrindinoline (LP), and pentosidine (Pen) were measured by HPLC in tissue obtained during the surgical procedure. Differences between groups and correlations between measures were analyzed ($\alpha < 0.050$ a priori).

Mean HbA1c was higher in the DM group (6.58 vs. 5.25, $P = 0.003$) while mean BMI was higher but not statistically significant (30.37 vs. 28.14, $P = 0.054$). Pen levels in joint tissues from the DM group were higher than non-DM group (significant in bone: $P = 0.050$; not significant in cartilage: $P = 0.075$). OC levels in synovial fluid were negatively correlated with HP levels in cartilage in all subjects when controlling for age and BMI ($\beta = -0.232$, $P = 0.033$). OC levels were also negatively correlated with Pen levels in cartilage when controlling for age and BMI, but only in the DM group ($\beta = -0.4750$, $P = 0.007$). The DM and non-DM groups differed in the direction of correlation between serum BAP and cartilage HP (DM: $r = -0.643$, $P = 0.045$; non-

DM: $r = 0.472$, $P = 0.168$). The relationship for the DM group, however, was not significant when adjusting for age and BMI ($\beta = -0.057$, $P = 0.065$).

These differences between the DM and non-DM groups suggest that a further relationship may exist between DM and OC. Returning to our data, an inverse relationship between serum OC and HbA1c was suggested by data in the DM group only, but this was not significant ($r = -0.466$, $P = 0.174$). The non-DM group data suggested an opposite effect ($r = 0.507$, $P = 0.134$). There was no such relationship between synovial fluid OC and HbA1c.

Data from this small study suggest a potential relationship between DM, OC, and joint tissues. However, further study is required elucidate the metabolic mechanism(s) for arthroplasty failure in patients with diabetes.

Periostin: A Novel Serum Marker of Cortical Bone Formation. Nicolas Bonnet^{*1}, Jean Charles Rousseau², Patrick Garnero³, Serge Ferrari⁴. ¹Division of Bone Diseases, Geneva University Hospital & Faculty of Medicine, S, Switzerland, ²INSERM UMR 1033, Université de Lyon, France, ³INSERM UMR 1033, Université de Lyon & Cistbio Bioassays, France, ⁴Geneva University Hospital & Faculty of Medicine, Switzerland

Biochemical markers are valuable tools to monitor the overall bone turnover, but they do not provide specific information on the modeling/remodeling rate in different compartment(s). Periostin is a matricellular protein which in bone is mainly expressed by periosteal cells and osteocytes and which regulates Sost expression. We previously reported that periostin-deficient mice (Postn^{-/-}) have low bone mass and a diminished anabolic response to loading and PTH. The aim of this study was to investigate changes in serum periostin, as measured by an in-house ELISA specific for the rodent protein in response to ovariectomy (OVX), PTH and androgens (DHT). Six month-old female mice were OVX or Sham-operated and administered intermittent PTH (40ug/kg/day), continuous DHT (7.5mg/kg) or vehicle (Veh) for 5 weeks. The relation between periostin levels and histomorphometrical and biochemical indices of bone turnover, including PINP and TRAP was also examined. In parallel, Postn mRNA levels were evaluated by qRT-PCR on whole femur extracts after 24h of treatment.

PTH significantly increased Postn mRNA expression (+62% vs Veh, $p < 0.01$) whereas OVX, and DHT did not change Postn gene expression. Compared to Sham, OVX decreased PINP (-23.4% vs +10.7%, $p < 0.05$) and TRAP (-20.8% vs +10.7%, $p < 0.05$) but not periostin. Compared to OVX Veh, PTH tend to reduce the decreased of PINP (-11.6%), and significantly increased TRAP (+10.7%, $p < 0.05$) without any changes in periostin, whereas DHT tend to reduce decreased of PINP (-15.8%), and significantly decreased TRAP (-72.5%, $p < 0.05$) and periostin (-29.5% in DHT vs -1.6% in Veh, $p < 0.01$). Regression analysis indicates that periostin changes were weakly correlated with changes of TRAP and PINP ($r = 0.27$ and $r = 0.18$, respectively, ns). Whereas serum PINP measured at sacrifice was better correlated than periostin with endocortical bone formation, periostin levels, but not PINP, correlated with periosteal BFR/BPm and MAR, as well as Ct.BV and the moment of inertia (table).

In conclusions, serum periostin levels were not affected by OVX or PTH, but decreased in response to DHT, and this effect was mostly independent of changes in PINP and TRAP.

Despite periostin ELISA were not able to detect increased in Postn gene expression induce by PTH, it revealed that compare to PINP, serum levels of periostin could reflect specific bone formation activities at the periosteal surface.

r^2	MAR Ec	BFR/BPm Ec	MAR Ps	BFR/BPm Ps	Ct.BV	M. inertia
Postn	0.11 ($p = 0.05$)	0.11 ($p = 0.05$)	0.14 ($p = 0.03$)	0.14 ($p = 0.02$)	0.15 ($p = 0.01$)	0.11 ($p = 0.05$)
PINP	0.17 ($p = 0.02$)	0.20 ($p = 0.01$)	0.014 ($p = 0.63$)	0.049 ($p = 0.23$)	0.025 ($p = 0.34$)	0.006 ($p = 0.63$)

Quantitative Analysis of Fibronectin Fibril Assembly Dynamics in Living Osteoblast Cultures. Aditya Roshan^{*}, Ganesh Thiagarajan, Sarah Dallas. University of Missouri - Kansas City, USA

Fibronectin (FN) is an extracellular matrix (ECM) glycoprotein expressed in skeletal tissues. We have shown that FN regulates osteoblast differentiation and orchestrates the assembly of multiple bone ECM proteins. Understanding the mechanism of FN assembly is therefore key to understanding how bone matrix is formed. Our time lapse imaging studies in living osteoblasts have shown that FN assembly is a highly dynamic process that appears to be driven by cell motility. To further understand this process, time lapse movies of FN assembly were analyzed using a Digital Image Correlation technique to quantitate the mechanical strains experienced by FN fibrils during assembly and track their motion paths.

FN assembly was imaged in 2T3 osteoblasts by time lapse imaging over 48hr using an alexa555 labeled FN probe. FN was found to first assemble on the cell surface. Multiple cells then pool their surface assembled FN to build progressively larger fibrils. Pseudocoloring of forming fibrils showed that single fibrils receive contributions from up to 6-8 cells and as far away as 170μm. Cell motion continually stretches,

contracts and reorganizes the FN fibrils as the matrix matures. Movies were analyzed using a Digital Image Correlation (DIC) algorithm developed in Matlab that was manually validated. In this technique, markers are positioned on individual fibrils and the DIC algorithm compares each image to the previous image to match up image features within a defined search window and calculate fibril displacements and strains. Analysis of fibrils in the 24-36h movie segment showed strains ranging from -65,000 to 60,000 $\mu\epsilon$. The strains were intermittent, with fibrils repeatedly being subjected to tensile and compressive strains and not all points on the fibril moving in the same direction. Analysis of the same fibrils in the 36-48h segment showed strains from -27,500 to 42,415 $\mu\epsilon$ suggesting that fibrils are subjected to lower strain as the matrix matures. Individual fibrils showed distinct strain profiles over time, which were related to the underlying cell motion. These data suggest that during assembly, FN fibrils are subjected to strains generated by motile osteoblasts that are an order of magnitude higher than strains measured on bone surfaces during normal activity. Mechanical stretching of ECM fibrils may facilitate matrix assembly by exposing cryptic binding sites for ECM molecules and/or may alter cell behavior through "shedding" of ECM-bound growth factors.

Moderate Joint Loading Downregulates MMPs 1, 3, and 13 in Mouse Articular Cartilage. Hiroki Yokota^{*1}, Daniel J. Leong², Robert Majeska³, Herb Sun². ¹Indiana University Purdue University Indianapolis, USA, ²Mount Sinai School of Medicine, USA, ³City College of New York, USA

Cartilage destruction is a hallmark of both osteoarthritis and rheumatoid arthritis. While the factors causing these diseases undoubtedly differ, the upregulation of the matrix metalloproteinases (MMPs) largely responsible for degrading cartilage extracellular matrix is common to both. We previously showed that mechanical loading, one of the most influential factors in maintaining cartilage homeostasis, is a potent modulator of MMP expression and activity. In vitro, moderate loading levels applied in several modalities (fluid shear, hydrostatic pressure and axial strain) downregulated MMPs 1 and 13 in normal and arthritic chondrocytes. We have also shown that passive joint rotation in vivo downregulates MMPs 1 and 3. Since chondrocytes are responsive to various types of mechanical stimuli, we hypothesize that a novel joint loading modality, which applies cyclic loads in the mediolateral direction and promotes bone formation throughout long bones, will downregulate several MMPs at the loaded joint. We first examined gene expression (by RT-PCR) and enzyme activity (by fluorogenic assay) in articular cartilage subjected either to elbow loading (0.2N to 2.0N, peak-to-peak) at 5 Hz, or to passive joint rotation (range of motion 65-125 at 2 cycles/min) both for 1 hour. The results showed that the effect of joint loading on MMP expression and activity in the ulna were loading intensity-dependent. Moderate loading at 0.2 N and 0.5 N downregulated mRNA expression of MMPs 1, 3, 8, 13 and decreased activities of gelatinase, collagenase, MMP-1 and MMP-13, with no effect on MMP-14. In contrast, higher levels of loading at 2 N did not change expression of MMPs 3, 8, 13, and 14 and activities of gelatinase and collagenase, and slightly upregulated MMP-1 expression and activity. In comparison, moderate joint rotation downregulated MMPs 1, 3, 13, but had no effect on MMP-8 expression. Together, our study suggests that moderate intensities of joint loading and joint rotation exert a potentially protective effect on articular cartilage by downregulating expression and activities of MMPs 1, 3 and 13. Given the fact that arthritis patients may have limited range of motion and pain due to joint motion, joint loading could offer an effective, anti-catabolic loading modality. Furthermore, in patients who do not have a restricted range of motion, the combination of both joint motion and joint loading may result in a synergistic effect, which will be tested in future studies.

Matrix Metalloproteinase-13-mediated Cortical Bone Remodeling Is Required for the Post-natal Maintenance of Bone Quality. Simon Tang^{*}, Tamara Alliston. University of California, San Francisco, USA

The maintenance of bone mass and quality throughout post-natal life is critical for the ability of bone to resist fracture. Although normal bone maintenance relies largely on the coupled activity of osteoclasts and osteoblasts, matrix metalloproteinases (MMP) may also contribute to the matrix remodeling of connective tissues. Specifically, MMP-13 is a collagenase expressed by hypertrophic chondrocytes, osteoblasts, and osteocytes that degrades collagen fibrils and has been implicated in bone development and fracture healing. However, much less is known about bone remodeling by osteoblasts and osteocytes. Therefore, this study examines the role of MMP-13 in post-natal bone remodeling and in the maintenance of bone quality using a murine knock-out model.

Mouse tibiae and femora were collected from 2-month old MMP-13 deficient (-/-) mice and their WT littermates (n=6-9). Immunohistochemistry (IHC) for anti-MMP-13 on WT bone shows the preferential localization of MMP-13 in the mid cortical region between the endo- and peri-osteal surfaces (Fig 1A). Strikingly, microCT analyses of the same regions in MMP-13 deficient mice show severe defects in the mineral distribution (Fig 1BCD), suggesting that the absence of MMP-13 results in mineral abnormalities. Unlike unresorbed calcified cartilage in cortical bone in previous reports, these hypermineralized zones do not resolve with age. These defects

were not accompanied by changes in osteoclast activity. Bone formation rates in WT and MMP-13^{-/-} animals were indistinguishable (p=0.734). The absence of MMP-13 did not affect osteoclast activity as measured by deoxypyridinoline (p=0.421), nor TRAP staining (p=0.313). Thus MMP-13-mediated, osteoclast-independent bone remodeling may be required to maintain the normal organization of mineral in cortical bone matrix. Failure to remodel cortical bone matrix in this way has adverse consequences on fracture resistance. MMP-13^{-/-} mice showed increased fragility through reduced post-yield work-to-fracture (p<0.001) under and reduced fracture toughness (p<0.001). These changes occurred in the absence of significant changes in the geometry of MMP-13 deficient bone.

Taken together, the loss of MMP-13 resulted in significant disruptions in the mineral distribution of bone that is associated with increased fragility without changes in osteoclast activity, revealing the importance of osteoclast-independent cortical bone remodeling for the maintenance of bone quality.

Calcitonin Receptor Peptide: A Novel Peptide That Enhances Osteoblast Differentiation and Matrix Mineralization. David Komatsu^{*1}, Srinivas Pentyla², Julie Miller², Supriya Mishra², Kyle Urbanczyk², Sirish Kondabolu², Joshua J. Hinkle³, Michael Hadjiargyrou⁴. ¹Stony Brook University, Dept. of Orthopaedics, USA, ²Stony Brook University, Dept. of Anesthesiology, USA, ³Stony Brook University, Dept. of Biomedical Engineering, USA, ⁴State University of New York at Stony Brook, USA

Osteoporosis is one of the most prevalent musculoskeletal disorders with a global prevalence of ~168 million. Antiresorptives are the predominant treatment and while effective in arresting bone loss, they are not anabolic. The sole FDA approved anabolic treatment is Teriparatide, but its utility is hampered by daily injections and limited treatment duration. As such, an urgent need exists for new anabolic osteoporosis treatments. We recently used an algorithm and identified a potential bioactive peptide mapped to the C-terminal region of the calcitonin receptor termed, Calcitonin Receptor Peptide (CRP). A series of studies was conducted to study the effects of CRP on osteoblast proliferation and activity, as well as to try and identify endogenous forms of CRP. We used MC3T3 (mouse calvarial), and hFOB (human fetal osteoblast) cells to assess: 1) Osteoblast differentiation; 2) Matrix mineralization, and; 3) Simulated wound healing. Immunohistochemical (IHC) analyses of d10 rat calluses were also conducted. Western analyses showed that in the absence of CRP, osteocalcin (OC) levels were undetectable in hFOB, while CRP dose dependently induced OC expression. Consistent with these results, CRP also dose dependently increased the number and size of alizarin stained nodules in MC3T3 and hFOB cells. Quantification of eluted alizarin from the MC3T3 cells showed that treatment with 1 and 10 μ M CRP generated 1- and 10-fold increases in mineralization, respectively. Simulated wound healing was then studied in hFOB cells by scrapping a line through confluent cultures. 24 hours following scrapping, cultures treated with CRP were almost completely recolonized while untreated cultures showed few cells in scrapped areas. Lastly, IHC identified strong CRP labeling on woven bone surfaces in the hard callus (likely osteoclasts) and along the periosteum, with additional diffuse staining seen in regions of osteoid. Taken together, the in vitro results indicate CRP promotes osteoblast proliferation and matrix production, and may also stimulate proliferation or migration. As osteoblasts do not express the calcitonin receptor, these data suggest CRP acts independently of the receptor, possibly through direct stimulation of G-proteins. The IHC results intimate that, in addition to binding to the receptor, an endogenous form of CRP may be present in osteoid. We are currently working to identify the cellular localization of CRP binding, its binding partners, and its downstream signaling pathways, as well as seeking to identify any endogenous forms of CRP. In addition, a series of in vivo studies to assess the anabolic efficacy of CRP in vivo is ongoing. Completion of these studies will enable us to determine if CRP has the potential to facilitate the development of a new class of skeletal anabolic therapies for treating osteoporosis.

Deletion of Cyp24a1 in Klotho-Null Mice Leads to Early Death. Xiuying Bai^{*1}, Dinghong Qiu¹, Rene St-Arnaud², David Goltzman³, Andrew Karaplis⁴. ¹Lady Davis Institute, Canada, ²Shriners Hospital for Children & McGill University, Canada, ³McGill University Health Centre, Canada, ⁴McGill University, Can

Mice homozygous for the null *Klotho* allele have a short lifespan and show biochemical and morphological features consistent with premature aging-like phenotype. In this study, we have used a mouse genetic approach to generate *Cyp24a1*^{-/-} mice and investigate *in vivo* the role of *Cyp24a1* in the *Klotho*-null background. *Cyp24a1*^{-/-} mice were sacrificed and serum and tissues were procured for analysis and comparison to *WT*, *Cyp24a1*^{-/-} and *Kt*^{-/-} controls.

At birth, there was no difference in body weight and gross appearance among *WT*, *Cyp24a1*^{-/-} and *Kt*^{-/-} controls and *Cyp24a1*^{-/-}*Kt*^{-/-} mice. However, by 48 hrs after birth (AB) *Cyp24a1*^{-/-}*Kt*^{-/-} and *Cyp24a1*^{-/-} mice displayed low body weights compared to their *WT* and *Kt*^{-/-} littermates. Although a number of *Cyp24a1*^{-/-}*Kt*^{-/-} mice survived up to 96 hrs, most of them died at 48-72 hrs AB.

When examining the changes in serum calcium from 12-72 hrs AB, an aberrant difference in *Cyp24^{-/-}/Kl^{-/-}* mice was observed. At 12 hrs AB, serum calcium level (mg/dl) was 5.62 0.50, higher than wild type (4.86 0.60). At 24 hrs AB, serum calcium level was 5.49 but ranged from 2.75 to 10.97. At 48 hrs AB, serum calcium level was 11.33 with a wide range from 8.94 to 14.33. At 72 hrs AB, in surviving animals, serum calcium level was 7.95 (range from 2.64 to 15.13).

From 24 hr AB onward until their demise, *Cyp24^{-/-}/Kl^{-/-}* mice constantly had higher serum inorganic phosphorus levels compared to WT mice.

At 24 hrs AB, serum FGF23 level was dramatically elevated in *Cyp24^{-/-}*, *Kl^{-/-}*, and *Cyp24^{-/-}/Kl^{-/-}* mice. Low serum 1,25 (OH)₂D₃ levels were exhibited in *Cyp24^{-/-}*, *Kl^{-/-}*, and *Cyp24^{-/-}/Kl^{-/-}* mice (219.7 17.33) (pmol/L) at 24 hrs AB compare to WT mice (351.3 31.52). However, by 48 hrs AB, serum 1,25 (OH)₂D₃ levels in *Cyp24^{-/-}/Kl^{-/-}* mice increased to 380.7 27.57, and examination of *Cyp27b1* expression in kidney at 24 hrs AB by Northern blot showed that *Cyp24^{-/-}* and *Cyp24^{-/-}/Kl^{-/-}* mice had low expression level of *Cyp27b1* compare to WT and *Kl^{-/-}* mice. Considering the absence of *Cyp24a1* and *Klotho*, *Cyp24^{-/-}/Kl^{-/-}* mice could produce more 1,25(OH)₂D₃ than WT and *Kl^{-/-}* mice. There was no significant change in serum PTH levels at 24 hrs AB.

In summary, *Cyp24^{-/-}/Kl^{-/-}* mice succumb to aberrant regulation in calcium and phosphate homeostasis. Our findings therefore substantiate *in vivo* the essential role of *Cyp24a1* in the *Klotho*-null phenotype as its ablation leads to early demise.

Effect of Phosphate Overload on Podocyte of Glomerulus in the Kidney.

Sahoko Sekiguchi-Ueda¹, Shogo Asano², Megumi Shibata³, Yasumasa Yoshino⁴, Hiroyuki Hirai⁴, Yoshiteru Maeda⁴, Masaki Makino⁴, Nobuki Hayakawa⁴, Atsushi Suzuki⁵, Mitsuyasu Itoh⁴. ¹Fujita Health University, Division of Endocrinology, Jpn, ²Toyokawa City Hospital, Japan, ³Fujita Health University, Division of Endocrinology, Japan, ⁴Fujita Health University, Japan, ⁵Fujita Health University Division of Endocrinology, Japan

Phosphate (Pi) uptake at the cellular membrane is essential to maintain the cell activity because Pi has to be supplied for ATP synthesis. On the contrary, accumulating evidence suggests that Pi overload from the extracellular milieu would be stressful for the cells. We have previously reported Pi-induced damage of filtration barrier at glomerulus in the kidney of type III Pi transporter (Pit-1)-overexpressing rats (TG). In the present study, we further explore the effect of Pi overload on podocyte of glomerulus in the kidney.

Their podocytes lost their foot processes and underwent effacement in TG rats. Immunofluorescence microscopy showed that the markers of podocyte injury such as desmin and connexin43 in TG rats were more remarkable than WT in the early stage of the pathological proteinuria. On the other hand, there was little difference of the podocyte constituent proteins such as nephrin, podocin, synaptopodin and podocalyxin between WT and TG rats. TG rats showed higher Pi uptake of the primary cultured podocytes than WT rats, especially at low Pi concentration. However, Pi uptake of the podocytes from TG rats was finally caught up with those from WT at higher Pi concentration. In conclusion, these finding suggests us that even the small increase of extracellular Pi could affect podocyte function in the kidney, and self-limiting system to restrict the excess of Pi influx seems to exist in these cells.

PHEX and Fat Energy Metabolism across a Bone-Renal Axis. Peter Rowe¹, Anne-Marie Hedge², Yan Hong², Valentin David³, Lesya Zelenchuk². ¹University of Kansas Medical Center, USA, ²KUMC, USA, ³UTHSC, USA

PHEX defective mice (HYP) have hypophosphatemic rickets, abnormal vitamin D metabolism and increased FGF23. HYP mice are also hyperglycemic and hypoinsulinemic with increased osteoblastic, renal and hepatic gluconeogenesis. ASARM-peptides play a key role by decreasing cellular pH. Here we describe the changes in glucose metabolism and bone-renal mineralization following 28-day infusion of SPR4 peptide (4.2 kDa) in wild type (WT) and HYP mice. SPR4 competitively inhibits PHEX by binding to its physiological substrate, ASARM-peptide.

We infused vehicle (0.9% NaCl) or SPR4-peptide (276 nmol/hr/kg) into WT or HYP mice (n=5, male) for 28 days (osmotic-pumps). On day 28, mice were sacrificed after overnight metabolic-cage housing and serum-urine chemistries measured. Femurs and kidneys were scanned by micro computed tomography (μCT). Fat mass and aBMD were measured by DEXA on days 0 and 28.

HYP-mice SPR4-peptide treatment (HYPSPR4) corrected the HYP-mice (HYPVE) hyperglycemia (+78%; p<0.01) and hypoinsulinemia (-54%; p<0.01). Decreased serum leptin levels (-75%; p<0.01) occurred in HYPVE compared to wild type vehicle-mice (WTVE). Wild-type mice infused with SPR4-peptide (WTSPR4-mice) had reduced serum leptin (-60%; p<0.01) and osteocalcin (-32%; p<0.01) compared to WTVE-mice. HYPVE-mice had a 6 fold decrease (p<0.01) in bone glyceraldehyde phosphate dehydrogenase (GAPDH) expression compared to WTVE-mice. In contrast, HYPSPR4 and WTSPR4 mice had increased GAPDH of 68X and 6X respectively (p<0.01; Fig1). Also, increases in the fat-mass to weight ratio

occurred with HYPSPR4 (9.6X; p<0.01) and WTSPR4 (4.3X; P<0.01) mice over 28 days compared to the respective control vehicle-mice. Coordinate with these changes, HYPVE mice showed a 6X increase in bone SOST expression and levels compared to WTVE mice (p<0.01). In contrast, SPR4 peptide reduced bone SOST expression in wild type and HYP mice by 4X and 11X respectively (p<0.01), figure 1. Remarkably, these treated mice had significantly increased bone resorption, decreased bone volume, impaired mineralization and abnormal trabecular structure with increased PTH, osteopontin and FGF23 levels and expression. We propose a new model that integrates regulation of phosphate mineral homeostasis by the PHEX, FGF23 and ASARM axis to the established leptin, insulin and osteocalcin energy-metabolism pathway. SPR4-peptide and/or ASARM-peptides may be of clinical use in modulating this pathway.

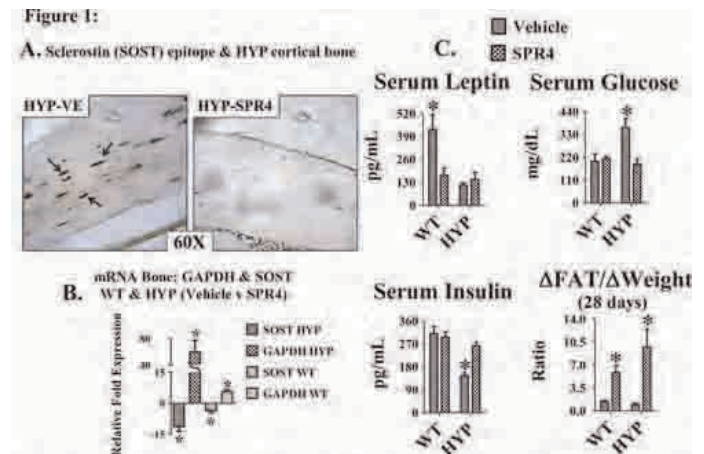

Fig 1 (A) immunohistochemistry of Sclerostin (SOST) epitopes in cortical bone, (B) Changes in mRNA expression of GAPDH & Sclerostin in HYP cortical bone following SPR4 treatment (C) Changes in serum markers and fat/weight ratio in WT & HYP mice treated with SPR4 peptide.

Phosphate and Vitamin D Homeostasis after Live Donor Nephrectomy: Activation of the FGF-23 pathway. Ann Young¹, Anthony Hodsman¹, David Goltzman², Amit Garg¹, for the Donor Nephrectomy Outcomes Research (DONOR) Network¹. ¹University of Western Ontario, Canada, ²McGill University Health Centre, Canada

Living kidney donation offers a unique setting to study changes in phosphate and vitamin D homeostasis attributable to mild, isolated decrements in glomerular filtration rate (eGFR).

Methods: We performed a retrospective cohort study comparing biochemical markers of Chronic Kidney Disease-Mineralizing Bone Disorder in 198 Living Kidney Donors (LKD) and 98 Non-Donor Controls (NDC). Participants were recruited from 1140 eligible LKD and 421 potential donor-identified NDC from 9 transplant centres. Median follow-up time after donation was 5.3 (interquartile range: 3.8–8.4) years. Estimated GFR (eGFR) was calculated using the CKD-EPI formula.

Results: At assessment, LKD had a lower eGFR than NDC (7315 vs. 9814 mL/min/1.73m², p<0.0001), and were slightly older (44 vs. 41 yr., p=0.03). Within the LKD group, 68% had eGFR levels classifying them as Stage II CKD, and 18% as Stage III CKD; comparable data within the NDC group were 28% and 0% respectively. Serum fibroblast growth factor-23 (FGF-23) was significantly higher in LKD (38.115.7 vs. 29.710.6 pg/mL, p<0.0001). For every 10 mL/min/1.73 m² decline in eGFR, FGF-23 increased by 3.2 pg/mL (95%CI:2.0, 4.4). Compared to NDC, LKD showed higher renal tubular fractional inorganic phosphate excretion (FExPi) (17.87.9 vs. 12.35.2%, p<0.0001), lower serum Pi (0.970.16 vs. 1.020.21 mmol/L, p=0.03), and lower serum calcitriol (6321 vs. 7724 pmol/L, p<0.0001). Multivariable adjusted models indicated that serum FGF-23 was strongly correlated with serum Pi (z' = 0.20, p=0.004) and modestly correlated with renal FExPi (z' = 0.15, p=0.03). Furthermore, serum FGF-23 was inversely correlated with serum calcitriol (z' = -0.41, adjusted: 5.6 pmol/L decrease for every 10 pg/mL increase in FGF-23, p<0.0001). Plasma iPTH was significantly higher in donors (5.72.4 vs. 5.02.1 pmol/L, p=0.03). However, there was no significant linear correlation between serum FGF-23 and plasma iPTH (z' = 0.04, p=0.61), between serum Pi and plasma iPTH (z' = -0.11, p=0.06), or between serum calcitriol and plasma iPTH (z' = -0.04, p=0.56).

Conclusion: The FGF-23 pathway may be activated in living kidney donors who show early biochemical changes compatible with mineralizing bone disorder. In these subjects with early stages of CRF, serum FGF-23 was more clearly correlated with phosphate homeostasis than plasma PTH. Whether these changes influence bone mineral density and fracture rates after kidney donation warrants future study.

Administration of PTH1-34 Partially Rescues Hematopoietic Defects in Bmi1 Null Mice by Improving the Hematopoietic Microenvironment. Ruinan Lu^{*1}, Qian Wang¹, David Goltzman², Dengshun Miao³. ¹Nanjing Medical University, China, ²McGill University Health Centre, Canada, ³Nanjing Medical University, Peoples Republic of China

We assessed whether PTH administration could rescue hematopoietic defects in *Bmi1* null mice by activating the Notch pathway and improving the hematopoietic microenvironment. We treated *Bmi1*^{-/-} mice, with 80µg PTH1-34/Kg, sc, daily from 1 to 4 weeks of age and compared them with vehicle-treated *Bmi1*^{-/-} and wild-type (WT) mice. Using techniques of histopathology, immunohistochemistry, real-time RT-PCR, Western blots, immunofluorescent staining and flow cytometry, we examined osteoblastic bone formation, the numbers of total bone marrow cells, hematopoietic stem cells (HSC) and hematopoietic progenitor cells (HPC) in bone marrow and peripheral blood cells, and Notch signal pathway-related molecules. Vehicle-treated *Bmi1*^{-/-} mice exhibited a phenotype of premature osteoporosis characterized by decreased trabecular bone volume, decreased osteoblast number, decreased alkaline phosphatase (ALP)-positive, type I collagen-positive and osteopontin-positive bone matrix, down-regulation of ALP and osteocalcin gene expression and of Runx2, PTHR and IGF1 protein expression. In addition, there were increased numbers of adipocytes within bone marrow, which were associated with the up-regulation of PPAR γ protein expression. PTH1-34 administration significantly increased all parameters related to osteoblastic bone formation, and significantly reduced the number of adipocytes and PPAR γ protein expression, but these parameters did not reach the control levels observed in vehicle-treated WT mice. The total number of bone marrow cells, the numbers of Sca-1⁺c-kit⁺Lin⁻ HSC and Sca-1⁺c-kit⁺Lin⁺ HPC in each femur, and the number of white blood cells and lymphocytes in peripheral blood were all decreased significantly in vehicle-treated *Bmi1*^{-/-} mice. These parameters were all increased significantly in *Bmi1*^{-/-} mice by the administration of PTH1-34, but did not reach the control levels observed in vehicle-treated WT mice. The number of Notch ligand Jagged1 positive cells and percentage of Notch intracellular domain (NICD) positive bone marrow cells were decreased significantly in vehicle-treated *Bmi1*^{-/-} mice, and were all increased significantly in *Bmi1*^{-/-} mice by the administration of PTH1-34, but did not reach the control levels observed in vehicle-treated WT mice. Results from the present study indicate that the administration of PTH1-34 partially rescues hematopoietic defects in *Bmi1* deficient mice by improving hematopoietic microenvironment and activating the Notch pathway.

Anabolic Skeletal Effects after Discontinuation of Human Synthetic Parathyroid Hormone 1-34 (PTH) Replacement Therapy in Hypoparathyroidism (HPT). Rachel Gafni^{*1}, C. Michele Christie², Marilyn H. Kelly³, Beth A. Brillante³, James Reynolds¹, Hua Zhou⁴, David W. Dempster⁵, Michael Collins¹. ¹National Institutes of Health, USA, ²Department of Pediatrics, Kaiser Permanente, USA, ³SCSU, CSDB, NIDCR, National Institutes of Health, USA, ⁴Helen Hayes Hospital, USA, ⁵Regional Bone Center, Helen Hayes Hospital, USA

PTH 1-34 replacement therapy in hypoparathyroidism (HPT) maintains eucalcemia while converting quiescent bone to high turnover bone, as evidenced by bone markers and histomorphometry. However, the skeletal effects of PTH discontinuation are unknown.

Subject #1 is an 18 y/o man with congenital HPT who received PTH x 18 mos. Pre-PTH therapy was calcium (Ca) 1200 mg/d and calcitriol (1,25D) 0.75 mcg/d. At PTH start (15 1/2 y/o), he was in late puberty. Osteocalcin (OC), bone-specific alkaline phosphatase (BSAP), and N-telopeptide (NTX) were appropriately increased for age, and rose further with PTH. Iliac crest biopsy after 1 y of PTH showed increased bone volume, trabecular number, mineralizing perimeter and bone formation rate, compared to baseline. However, areal BMD by DXA changed little at most sites and declined at the radius. For 9 wk after stopping PTH, he required high doses of Ca and 1,25D to maintain serum Ca in the target range (7.6-9 mg/dL)-up to 4200 mg/d Ca and 1.5 mcg/d 1,25D. Doses were gradually weaned until he reached pre-PTH treatment doses 6 mos after stopping PTH. By 6 mos post-PTH, OC, BSAP, and NTX had declined to the adult normal range. BMD at 6 and 12 mos post-PTH rose markedly at the spine, hip, and total body with Z-score increases of 0.5-1 SD. Radial BMD also increased without Z-score change.

Subject #2 is a 43 y/o woman with surgical HPT who received PTH x 33 mos. Pre-PTH therapy was Ca 1200 mg/d and 1,25D 0.5 mcg/d. As in other HPT adults, PTH dramatically increased OC, BSAP, NTX, and hip BMD. Rather than stopping PTH abruptly, her PTH dose was weaned over 8 wk as oral Ca and 1,25D were increased to maintain serum Ca within the target range-up to 5400 mg/d Ca and 2.75 mcg/d 1,25D (Fig); doses were then weaned. Thirteen weeks after stopping PTH, she developed acute hypercalcemia (14.7 mg/dL) at doses of Ca 3600 mg/d and 1,25D 2 mcg/d. Supplements were stopped and she received treatment at her local hospital. She was restarted on Ca 2400 mg/d and 1,25D 0.5 mcg/d with stabilization of her serum Ca.

The transient increased Ca and 1,25D requirements accompanied by an increase in BMD Z-scores after cessation of long-term PTH therapy in HPT suggest an uncoupling of bone turnover favoring anabolic effects while transitioning from a high

turnover state. Further study and close monitoring of such patients is required to ensure safe transition to conventional therapy and to elucidate the physiological mechanism of this phenomenon.

Dynamic formation of a PTH/PTHrP receptor-arrestin-Gs signaling complex in bone cells. Vanessa L. Wehbi^{*1}, Timothy N. Feinstein², Guillermo Romero², Jean-Pierre Vilardaga³. ¹University of Pittsburgh, USA, ²University of Pittsburgh, School of Medicine, Department of Pharmacology & Chemical Biology, USA, ³University of Pittsburgh, School of Medicine, USA

Arrestins and heterotrimeric G proteins ($G\alpha\beta\gamma$) regulate G-protein-coupled receptors (GPCRs) signaling and trafficking. Arrestins binding to activated GPCRs terminate receptor and G protein coupling, and promote receptor internalization. The binding of the β -arrestins and G proteins on activated GPCR is thought to be mutually exclusive. Here we show that β -arrestins prolong rather than shut down PTH/PTHrP receptor (PTHR) signaling. By using optical approaches (confocal microscopy, FRAP, TIRF, fluorescence correlation spectroscopy, and FRET) in bone- and kidney-cell derived lines (ROS 17/2.8 and HEK293) in real time we found that PTHR forms a ternary complex with β -arrestin1/2 and $G\beta\gamma$ subunits in response to PTH stimulation. We further confirmed the formation of a PTHR-arrestin- $G\beta\gamma$ complex in response to PTH(1-34) binding by coimmunoprecipitation assays. Additionally, we showed that the rapid ($t_{1/2} < 60$ s) assembly/disassembly dynamics formation of a multimeric receptor complex that contains PTH, PTHR, arrestin, and $G\beta\gamma$ subunits regulates cAMP levels in magnitude and duration. These data raise the novel model whereby the formation of a long-lived PTHR- $G\beta\gamma$ -arrestin ternary complex contributes to prolonged receptor signaling by mechanisms that presumably permit multiple rounds of $G\alpha\beta$ subunit coupling and activation.

Disclosures: Vanessa L. Wehbi, None.

Elderly Men in Hong Kong Have Higher Serum Vitamin D and Lower Serum Parathormon Compared to Gothenburg. Mr Os. Ewa Waern^{*1}, Claes Ohlsson², R Chan³, Timothy Kwok³, PC Leung⁴, Egil Haug⁵, Magnus Karlsson⁶, Osten Ljunggren⁷, Dan Mellstrom¹. ¹Sahlgrenska University Hospital, Sweden, ²Center for Bone Research At the Sahlgrenska Academy, Sweden, ³The Chinese University of Hong Kong, Hong Kong, ⁴The Chinese University of Hong Kong, Hong Kong, ⁵Hormone Laboratory, Aker University Hospital, Norway, ⁶Skane University Hospital Malmö, Lund University, Sweden, ⁷Uppsala University Hospital, Sweden

Vitamin D is mainly produced in the skin in humans and increasing northern latitude, should influence both mean values and seasonal variation. However genetic, cultural, nutritional and anthropometric factors might have importance for the variation in serum vitamin D. The purpose of this study was to compare serum vitamin D and serum parathormon in Gothenburg (latitude 570 N) and Hong Kong (latitude 220 N).

Elderly men participated (69-80 years) in the population based Mr OS Sweden, Gothenburg (n = 1010) and Mr OS Hong Kong (n = 939).

Serum 25-hydroxyvitamin D (25 OH) and serum parathormon (PTH) was analysed at the same laboratory in Oslo, Norway.

25 OH was measured with competitive RIA (Dia Sorin, Stillwater, MN).

Intraassay and interassay variations were 5 % and 9 % respectively. PTH was measured with an immunoluminometric assay (Immulite 2000, Diagnostic Products Corporation, Los Angeles, USA). Intraassay variation was 5 % and interassay variation 9 %.

Vitamin D (25 OH) was higher in Hong Kong mean 78.3 (21.4) nmol/l compared to 66.7 (19.0) nmol/l in Gothenburg $p < 0.0001$.

Serum PTH was lower in Hong Kong 42.9 (22.7) ng/l compared to 51.9 (23.5) ng/l in Gothenburg ($p < 0.0001$). The correlation between 25 (OH) and PTH was ($r = -0.17$ $p < 0.0001$) in Hong Kong and ($r = -0.15$ $p < 0.0001$) in Gothenburg.

The mean body weight in Hong Kong was 61.7 (9.5) kg vs 80.9 (12.2) kg in Gothenburg $p < 0.0001$. The average height in Hong Kong was 163.1 cm vs 175.7 cm in Gothenburg $p < 0.0001$.

BMI was lower in Hong Kong 23.2 (3.2) vs Gothenburg 26.2 (3.5). BMI correlated to 25 (OH) in Hong Kong ($r = -0.08$ $p < 0.01$ and in Gothenburg ($r = -0.17$ $p < 0.0001$). In Hong Kong 1.7 % had obesity BMI > 30 vs 12.4 % in Gothenburg. Serum PTH correlated to body height in Gothenburg ($r = 0.07$ $p = 0.03$) but not in Hong Kong ($r = 0.01$ ns). The proportion of hyperparathyroidism PTH > 65 ng/l was in Gothenburg 21.1 % and in Hong Kong 11.4 %

$p < 0.0001$. In Hong Kong 51 % had 25 OH > 75 nmol/l vs 31 % in Gothenburg. Only 7 % had 25 (OH) < 50 nmol/l in Hong Kong vs 20 % in Gothenburg. Seasonal variation occurred in both cities. Figure.

We conclude that vitamin D is higher and PTH lower in Hong Kong compared with Gothenburg. Vitamin D correlated inversely to BMI. Hyperparathyroidism was more prevalent in Gothenburg.

Disclosures: Ewa Waern, None.

Nuclear Actions of PTHrP Contribute to the Differentiation of the Mammary Mesenchyme. Kata Boras-Granic^{*1}, Pamela Dann¹, Andrew Karaplis², John Wysolmerski¹. ¹Yale University School of Medicine, USA, ²McGill University, Canada

Parathyroid hormone-related protein (PTHrP) is responsible for the clinical syndrome of humoral hypercalcemia of malignancy and it also contributes to osteolytic bone metastases from breast cancers. It is related to parathyroid hormone and binds to and activates a common type 1 PTH/PTHrP (PTHR1) receptor. Unlike PTH, PTHrP also contains canonical nuclear localization sequences in its mid-region and c-terminus that allow for its import into the nucleus. The functions of PTHrP in the nucleus is not known, but mice in which the native PTHrP gene has been replaced with a truncated form of PTHrP (1-86) (PTHrP (1-86)-knockin mice), that can be secreted but not enter the nucleus, are grossly normal at birth but fail to grow well and die at about 2 weeks of age. The exact cause of death in PTHrP (1-86)-knockin mice is unclear but they demonstrate widespread cell senescence. We examined the development of the mammary gland in PTHrP (1-86)-knockin mice. Global PTHrP and PTHR1 knockout mice demonstrate a failure of embryonic mammary development at the bud stage due to a failure of mammary mesenchyme development. One consequence of the disruption in mammary mesenchyme differentiation is a failure of the androgen-dependant destruction of the mammary bud. In PTHrP (1-86)-knockin embryos the mammary buds appeared grossly normal at E15. There appeared to be the initiation of ductal outgrowth in some buds, but the ducts were small and stunted compared to WT controls in PTHrP (1-86)-knockin neonates. Surprisingly, in male PTHrP (1-86)-knockin embryos, the mammary buds were retained at E15, suggesting a failure of the normal androgen response. This prompted us to examine markers of mammary mesenchyme differentiation. We found that loss of nuclear PTHrP led to a loss of mesenchymal estrogen receptor expression and reductions in the expression of beta-catenin and Lef1. These results partially phenocopy the results in global PTHrP and PTHR1 knockouts. Since PTHrP is only produced by epithelial cells and the PTHR1 is only expressed on mesenchymal cells, these results suggest that secreted PTHrP may bind to the PTHR1 receptor on mesenchymal cells and be internalized and traffic to the nucleus of these cells in order to modulate their differentiation.

p85 α Subunit of PI3K Mediates Bone Loss Induced by Continuous PTH Infusion. Rajendra Kedlaya^{*1}, Reuben Kapur¹, Alexander Robling². ¹Indiana University School of Medicine, USA, ²Indiana University, USA

Osteoclastogenesis and activity is mediated by a number of signaling events, including M-CSF signaling through the M-CSF receptor, RANKL signaling through the RANK receptor, and integrin signaling through $\alpha\beta3$. A key downstream mediator of these receptors is the phosphoinositide-3 kinase (PI3K). Class 1A PI3Ks are heterodimers comprised of two subunits—a p110 catalytic subunit and a p85 regulatory unit. We showed previously that deletion of the p85 α subunit resulted in increased trabecular bone mass and architectural properties in mice. These mice also had elevated but functionally compromised osteoclasts, resulting in reduced resorption. Modulation of p85 α might present a viable target for mitigating osteoclast-mediated bone loss. To explore this proposal, we treated 12-wk female p85 α -/- mice with a pro-resorptive, catabolic stimulus by continuously infusing them with 40 μ g/kg/dy of PTH 1-34. Infusions lasted for 3 wks, and changes in bone mass

were measured using DEXA. In WT mice, 3 wks of vehicle infusion resulted in a 10.5% increase in whole body (WB) BMC, whereas PTH infusion resulted in a -1.2% decrease in WB BMC ($p < 0.05$). In p85 α -/- mice, vehicle infusion resulted in a 7.2% increase in WB BMC, whereas PTH infusion resulted in a 5.7% increase in WB BMC ($p = 0.74$). Similar results were found when the spine was analyzed in isolation. Having found that the p85 α -/- mice were resistant to the catabolic effects of continuous PTH, we assessed whether the anabolic effects of intermittent PTH were affected by p85 α deletion. PI3K mediates downstream signaling activity of many RTKs, including the IGF-1 receptor, which is crucially important for the anabolic effects of intermittent PTH. Male 10-wk old p85 α +/+ and p85 α -/- mice were given whole-body DEXA scans while under general anesthesia, then administered daily subQ injections of 40 μ g/kg/dy PTH, 7dy/wk, for 6 wks. In WT mice, 6 wks of vehicle treatment resulted in a 4.6% increase in WB BMC, whereas intermittent PTH resulted in a 18.0% increase in WB BMC ($p < 0.05$). In p85 α -/- mice, vehicle treatment resulted in a 12.1% increase in WB BMC, whereas intermittent PTH resulted in a 32.1% increase in WB BMC ($p < 0.05$). 2-way ANOVA yielded no significant interaction term, indicating that PTH induced similar anabolic effects regardless of genotype. In summary, the p85 α subunit of PI3K appears to modulate the catabolic effects of PTH signaling, but the same hormone maintains its anabolic properties in the absence of p85 α .

Parathyroid Hormone Reduces Oxidative Stress in Bone by Preventing Activation of p66^{Shc} and by Stimulating the Expression of Aldehyde Dehydrogenase 3a1. Robert Jilka^{*}, Annick DeLoose, Kanan Vyas, Maria Almeida, Stavros Manolagas, Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA

Daily injections of PTH increase bone mass in postmenopausal women and elderly hypogonadal men, but the underlying mechanisms have not been established. It was shown previously that PTH-stimulated bone formation is greater in old as compared to young C57BL/6 mice, and is associated with reversal of the increased oxidative stress (OS) seen in the skeleton of aged mice. As shown elsewhere in this meeting, the level of OS in bone is determined in part by activation of p66^{Shc} - a redox sensitive adapter protein that amplifies the production of reactive oxygen species (ROS) by mitochondria. Lipid oxidation also contributes to OS via generation of 4-hydroxynonenal (4-HNE), which lowers the level of the important anti-oxidant glutathione. Oxidized lipids may also increase ROS levels by activating NADPH oxidase (Nox). Mechanistic studies have established that PTH suppresses the H₂O₂- and 4-HNE-stimulated increase in activated p66^{Shc} in osteoblastic cells via a protein kinase A- and protein kinase C-dependent mechanism. We now report that RNA and protein synthesis are also required as both actinomycin D and cycloheximide prevented the attenuating effect of PTH on H₂O₂-induced p66^{Shc} activation. Microarray studies revealed that PTH increased the expression of aldehyde dehydrogenase 3a1 (Aldh3a1) in murine vertebral bone by 10-fold, measured 1 h after injection of the hormone. Aldh3a1 detoxifies 4-HNE, and also produces NADPH needed for the synthesis of glutathione via the glutathione peroxidase/reductase system. Furthermore, PTH increased Aldh3a1 expression, and aldehyde dehydrogenase activity, in osteoblastic cells cultured from neonatal calvaria. On the other hand, PTH had little if any effect on the expression of other anti-oxidant enzymes including glutathione reductase and thioredoxin reductase, as well as peroxiredoxin and thioredoxin, in vivo or vitro. PTH also had no effect on the expression of Nox. We propose that intermittent PTH reduces OS, at least in part, by suppressing the activation of p66^{Shc} and by increasing the synthesis of Aldh3a1. Further studies are needed to establish the significance of the anti-oxidant property of PTH for its anabolic efficacy in the aged skeleton.

Persistently Elevated Parathormone after 12 months of Parathyroid Adenoma Surgery. Rabindera Mehrotra^{*}, Apollo Hospitals, India

We retrospectively analysed data of 25 patients who under went surgery for Primary Hyper Parathyroidism at our Hospital. 2 patients with multi gland disease (Hyperplasia) and 2 patients with associated CKD were excluded. For 11 patients data at 1 year was available for review.

Diagnosis of Primary hyper parathyroidism was based on elevated calcium with unsuppressed PTH. 10 were below 30 years of age. In all subjects single adenoma was localized in at least 1 of the imaging. Some subjects had markedly elevated levels of PTH (147-4560 ng/ml). Subjects with significant bone disease had markedly elevated PTH and higher values of alkaline phosphatase. Bone disease manifestation included X Ray evidence of sub periosteal re absorption and osteitis fibro cystica. At surgery all subjects had uni lateral exploration of neck. Effort was made to biopsy the remaining gland to confirm the diagnosis of Parathyroid adenoma. All 11 subjects had under gone neck exploration and single adenoma was removed. All biopsy reports were confirming to the diagnosis of parathyroid adenoma. In the post op period all subjects had significant hypo calcemia because of hungry bone disease. They were treated with oral and Intra venous calcium infusions. 125 Vit D3 analogues had to be used for a varied interval of time. Subjects with severe bone disease had more severe hypo calcemia They also received 4,000 units of chole claciferol every day. In follow

up there was symptomatic improvement, alkaline phosphatase started to decline and requirement of oral calcium supplements also declined. In some of the patients we had done DXA. BMD increase was noticed. The skeletal lesions healing was seen over a period of 6-12 months. 8 subjects had elevated PTH levels even after 1 year of follow up. All 8 subjects had normal calcium levels (even after correcting for albumin). In 3 subjects PTH even after 24 months PTH was elevated. No patient developed recurrent hyperparathyroidism. The elevated levels of PTH and ALP may be explained by continuing bone mineralization.

As these subjects were young and the skeleton had been demineralized because of hyperparathyroidism. They have increased requirement of calcium and Vitamin D for a prolonged period of time which may last for more than a year. Only dietary supplements would not be sufficient. The requirement is many times of RDA. Replacing Vitamin D and calcium in adequate dosages would help to recover the lost BMD.

PTH Skeletal and Bone Healing Efficacy in T-Cell Deficient and Normal Rats are Similar. Masahiko Sato¹, M.D. Adrian¹, Matt Hamang¹, Q.Q. Zeng¹, Yanfei Ma². ¹Lilly Research Labs, USA, ²Eli Lilly & Company, USA

T lymphocytes were shown previously to mediate the skeletal efficacy of PTH in mice, because nude mice exhibited a blunted skeletal response to PTH (M. Terauchi et al. 2008). The goal for this study was to compare the skeletal and bone healing responses to PTH in athymic nude and normal rats. Male, 14 week old, athymic nude rats (NIHRNU-M, NTac:NIH-Whn, Taconic), Hsd:RH-Foxn1nu (Harlan) and normal SD rats (Harlan) were maintained on a 12hr light/dark cycle at 22°C with ad lib access to food (TD 89222 with 0.5% Ca and 0.4%P, Teklad, Madison, WI) and water; and then were subjected to bilateral cortical defect surgery through both anterior and posterior cortices (D. Komatsu et al. 2009). Animals were weighed, and randomized into groups treated with 0, 5 or 30 µg/kg/d sc hPTH1-38 for 7 weeks of treatment, starting 8 days post-surgery. Relative to age-matched vehicle controls at necropsy, PTH dose-dependently enhanced BMD of the whole femoral diaphysis (24%, 60%, 35%) and the intramedullary spaces (95%, 401%, 243%) at the cortical defect site for NTac:NIH-Whn, Hsd:RH-Foxn1nu, and normal rats, respectively. Region specific analyses showed PTH enhanced healing of the anterior cortex for Hsd:RH-Foxn1nu (60%), but not for NTac:NIH-Whn or normal rats, relative to controls. Load to failure analyses at the cortical defect site showed dose dependent enhancement of femoral strength (17%, 39%) for NTac:NIH-Whn and Hsd:RH-Foxn1nu, respectively, but not for normal rat femoral diaphyses relative to controls. PTH dose-dependent efficacy was also observed at non-fractured sites as increased femoral neck strength (38%, 30%, 32%) and vertebral BMD (14%, 22%, 24%), for NTac:NIH-Whn, Hsd:RH-Foxn1nu, and normal rats, respectively. Longitudinal analyses showed that PTH enhanced bone healing by stimulating woven bone formation in the intramedullary spaces and stimulating endocortical mineral apposition resulting in stronger femora for 2 athymic rat strains in a manner that compared favorably to normal rats. Bone histomorphometric analyses showed higher mineralizing surface, mineral apposition rate, and bone formation rate in vertebra for both athymic rat strains. The data taken together also showed that systemic PTH skeletal efficacy in the athymic nude rats were also comparable to PTH efficacy in normal SD male animals, and that rats may differ from mice.

The Effect of JTT-305 (MK-5442), an Orally Active Calcium-sensing Receptor Antagonist, on Calcium Metabolism in Parathyroidectomized Rats. MIKIO HAYASHI*, Takashi Nakagawa, Mariko Maekawa, Shuichi Kimura. Central Pharmaceutical Research Institute, JAPAN TOBACCO INC., Japan

JTT-305 (MK-5442) is a novel, orally active calcium-sensing receptor (CaSR) antagonist. In an in vitro study, JTT-305 showed specific binding ability to human CaSR (K_d: 6.2 nM) and inhibited the increase in intracellular Ca concentrations produced by extracellular Ca exposure in CaSR-transfected cells (IC₅₀: 86 nM). In an in vivo rat study, JTT-305 stimulated the transient secretion of endogenous parathyroid hormone (PTH) and prevented OVX-induced bone loss by stimulating bone formation. JTT-305 elevated serum Ca concentrations in a dose-dependent manner, while rat PTH(1-84) did not affect it.

The objective of this study was to examine the mechanism by which JTT-305 increases serum Ca in rats. In this study, parathyroidectomized (PTX) rats were used to investigate the effect of JTT-305 on Ca metabolism in the absence of parathyroid cells. After PTX, a micro-osmotic pump was implanted, and PTH was infused for 5 days in order to restore normal serum Ca levels. JTT-305 was administered at a dose of 10 mg/kg, and serum Ca was measured at 0.5, 1, 2, 4 and 8 hours after dosing. Urine was collected during 4, 8, and 24 hours, and urine Ca measured. Serum calcitonin was also measured in order to study the effect of JTT-305 administration on thyroid cells.

After administration of JTT-305, serum Ca was elevated from 0.5 hours to 8 hours in PTX rats. However, the changes in serum Ca concentrations in PTX rats were almost identical to those in intact rats. Conversely, urine Ca excretion was reduced

over the following 24 hours (vehicle vs. JTT-305: P<0.05). JTT-305 did not reduce serum calcitonin. Since CaSR is expressed in the parathyroid gland and the kidney, JTT-305 may increase serum Ca in rats via a renal mechanism. In summary, it is believed that the increase in serum Ca produced by JTT-305 is likely due to an effect on the renal CaSR and not to changes in endogenous PTH or calcitonin.

TWEAK and FN14 Signaling Through NFκB is Necessary for the RAS Effector Mutant Human Prostate Cancer Cell Line DU145/Ras^{V12G37} to Form Bone Metastasis. Kristin J Lastwika¹, Victoria Seng², Kirsten Tracy², Juan Juan Yin³, Kathleen Kelly². ¹George Washington University Institute for Biomedical Sciences, USA, ²Cell & Cancer Biology Branch, Center for Cancer Research, National Cancer Institute, USA, ³National Cancer Institute, USA

Prostate cancer is the third leading cause of cancer-related deaths in the Western world male population and bone metastases are the leading cause of mortality in prostate cancer patients. Understanding the mechanisms mediating this process is critical to the prevention of bone metastases. Our lab has previously reported that the *H-RAS* effector mutant DU145/G37 Ras^{V12G37} human prostate cancer cell line significantly increases bone metastatic capability. Three clones isolated from the bone metastasis showed a further increase in the rate of bone metastases. The bone clones and the parental DU145/G37 Ras^{V12G37} cell line were then compared by protein microarray to identify bone specific markers. All three of the metastatic bone clones had a significantly higher expression of the cytokine TNF-like weak inducer of apoptosis (*TWEAK*) and its receptor fibroblast growth factor-inducible 14 (*FN14*). Subsequent knockdown of *FN14* in the bone isolates decreased the number of bone metastasis to 30%, indicating that *FN14* expression is integral for these prostate cancer cells to colonize bone. *FN14* knockdown did not have an effect on brain metastases, suggesting that *FN14* expression is specific to bone metastatic growth. *TWEAK-FN14* binding has been shown to activate many different signaling cascades, including *PI3K*, *MAPK*, *NFκB* and *JNK*. In our system, the tumor bone clones use both the canonical and non-canonical *NFκB* signaling pathway to mediate their effects. We are currently investigating this *TWEAK-FN14* mediated *NFκB* pathway rescue and an *FN14* receptor rescue through *in vivo* experiments to monitor bone metastasis formation. The identification of this *TWEAK-FN14* signaling specific to prostate cancer cell growth in the bone microenvironment gives new insight into mechanisms mediating metastatic growth. These findings could potentially aid in the development of targeted therapeutics to prevent bone metastases.

A Non-invasive Way to Target microRNA-21 and to Prevent Osteometastatic CSF-1 Expression by the Human Breast Cancer Cells via PTEN. Chandni Mandal¹, Triparna Ghosh-Choudhury², Goutam Ghosh Choudhury¹, Nandini Ghosh-Choudhury¹. ¹University of Texas Health Science Center at San Antonio, USA, ²Baylor College of Medicine, USA

Extravasation of circulating breast tumor cells produce micrometastasis to form osteolytic lesions in skeleton. We recently identified that fish oil diet targets and restores the expression of the tumor suppressor protein PTEN, a negative regulator of PI 3 kinase/Akt signaling, as one of the mechanisms to block growth and bone metastasis of MDA MB-231 breast cancer cell (MDA) *in vivo*. Here we report a novel mechanism for fish oil diet-induced PTEN expression and inhibition of osteolytic metastasis. Along with PTEN haploinsufficiency, oncomiR (oncogenic microRNAs) addition drives cancer metastasis. Interestingly, fish oil diet attenuated expression of miR-21 in mouse tumor xenografts. DHA and EPA, the key ω-3 fatty acids in fish oil, inhibited miR-21 expression in MDA. miR-21 expression increased migration of MDA and partially reversed DHA- or EPA-mediated migratory inhibition of MDA. PTEN mRNA 3'UTR contains miR-21 recognition element. Expression of miR-21 blocked the activity of PTEN 3'UTR-Luc reporter enzyme, indicating functional targeting of PTEN mRNA by miR-21 in MDA. Conversely plasmid-coded anti-miR-21 sequences (Sponge) increased PTEN 3'UTR-Luc activity. Moreover, expression of either miR-21 or miR-21 Sponge in MDA significantly suppressed or increased the expression of PTEN. Colonized breast cancer cells secrete osteoclastogenic cytokines, including colony stimulating factor-1 (CSF-1) to facilitate bone metastasis. qRT-PCR analysis of CSF-1 mRNA expression in the MDA-derived tumor xenografts showed significant inhibition by fish oil diet. *In vitro*, a direct correlation was observed for the CSF-1 mRNA and protein expressions and the bone metastatic potential of the breast cancer cells. DHA and EPA, inhibited CSF-1 mRNA and protein expression in MDA cells. We investigated the involvement of PTEN in CSF-1 expression by breast cancer cells. Cotransfection of the CSF-1 promoter-driven luciferase plasmid (CSF-1-Luc) in MDA with PTEN or dominant negative (DN) PI 3 kinase or DN Akt, inhibited the transcription of CSF-1. Next, we examined the involvement of miR-21 in regulating CSF-1 expression. Expression of miR-21 enhanced while miR-21 Sponge reduced abundance of CSF-1 mRNA via transcriptional regulation. Together these results uncover a novel function of fish oil, which beheads miR-21 signaling to increase

PTEN expression and in turn dampen expression of CSF-1 thus preventing osteoclastogenesis and osteolytic lesions in breast cancer bone metastasis.

Breast Cancer Stem Cells Metastatize to Bone in a Human in Mice Model.

Lucia D'Amico^{*1}, Salvatore Patane², Cristina Grange³, Benedetta Bussolati³, Patrizia D'Amelio⁴, Giancarlo Isaia⁴, Riccardo Ferracini⁵, Ilaria Roato⁶. ¹Azienda Ospedaliero-Universitaria Molinette San Giovanni Battista, Italy, ²CeRMS, Italy, ³Department of Internal Medicine, Molecular Biotechnology Center, University of Turin, Italy, ⁴University of Torino, Italy, ⁵Department of Orthopaedics, A.O.U. San Giovanni Battista, Italy, ⁶A.O.U. San Giovanni Battista, Italy

Background. Bone metastases represent a common complication for breast cancer which is characterized by a selective bone tropism. Despite their clinical relevance, the mechanisms ruling bone metastatic process are not completely clear. Breast tumors are known to be composed of different cells, but it is not clear which of these cells contribute to tumor development and progression. The currently prevailing models explaining intratumor heterogeneity include the cancer stem cell hypothesis focused on a subset of tumor cells called cancer stem cells (CSCs), which are able to self renew and to differentiate in a heterogeneous tumor cell population. In breast cancer, CSCs were isolated and identified as a CD44+CD24- population. Many of the properties proposed for CSCs have identified them as candidates for mediating metastatic progression but no data are available on their ability to promote bone metastases.

Methods. We used a NOD/SCID human-in mice model. Briefly, we implanted fragments of human bone under the mice skin, then we injected CD44+CD24- breast CSCs transduced by luciferase-lentiviral vector to study their ability to metastatize to bone. Mice were divided according to the CSCs injection root: subcutaneously and intracardiac injection. After 8 weeks, mice were sacrificed and H&E staining was performed on bone and lung. Then CK, vimentin and EMA were studied by IHC. Moreover, we isolated and characterized by flow cytometry the metastatic breast CSCs from bone metastasis.

Results. Our model is a viable tool to study human bone metastases in animals, because H&E staining of the implanted bone showed its viability, activity and the presence of human neo-vascularization, detected by staining for human CD34. By in vivo imaging system we monitored the tumor growth and detected bone localization of breast CSC-Luc injection. H&E staining of bone showed the presence of bone metastatic lesions, with tumor cells positive for EMA, CK and vimentin. At last, we isolated from the implanted bone and characterized the breast metastatic CSCs, which exhibited a CD44-CD24+ phenotype.

Conclusions. We demonstrated the ability of breast CSCs to promote bone metastasis and we isolated for the first time the breast metastatic CSCs. This result opens new perspectives to define the precise nature of the cells that promote bone metastases.

Characterization of the Bone Metastatic Potential of Different Tumor Cell Lines.

Sophie Baret^{*}, Ingrid Stockmans, Riet Van Looveren, Geert Carmeliet. Katholieke Universiteit Leuven, Belgium

Bone metastasis is a major complication in patients with breast or prostate cancer. The use of preclinical models is of utmost importance to evaluate and validate the efficacy of novel therapeutic approaches. Intracardiac inoculation of tumor cells in mice is considered as the preclinical model of choice, but a thorough comparison between different tumor cell lines is still lacking.

We compared the bone metastatic potential and characteristics of 4 different tumor cell lines, which form predominantly osteolytic lesions. We used 3 breast tumor cell lines (human MDA-MB-231, human CN34-BoM2 and murine 4T1 cells) and 1 human prostate tumor cell line (PC3). Tumor cells were intracardially injected in mice and the development of bone metastasis was evaluated by μ CT imaging. The latency period before osteolytic lesions were first noticed, was longer for the PC3 and CN34 cells. The osteolytic pattern was clearly different in the PC3 cell line. Here, bone resorption was observed as separated round cavities scattered over the bone cortex whereas the breast tumor cell lines caused more diffuse osteolytic areas in the trabecular region. Histological data confirmed this pattern and revealed additional differences. The breast cancer cells expanded at first between the bone trabeculae and resorbed the metaphyseal bone before they destroyed the cortex. The CN34 and 4T1 cells showed a very infiltrative growth compared to the MDA cells. This growth pattern is in contrast with the prostate tumor cells which expanded radial in the cortex and formed multiple separated tumors. CD31 staining showed that PC3 metastases are surrounded by blood vessels with few vessels inside the tumor. In all the breast tumors abundant vessels were observed penetrating the tumor whereas the tumor borders were less marked off by vessels. TRAP staining revealed that osteoclasts encircled the PC3 tumors, whereas they were scattered at sites of contact between tumor cells and bone trabeculae in the breast tumor cell lines. In CN34 tumors TRAP positive cells were even noticed inside the tumor with no bone contact.

Our study revealed clear differences in the bone metastatic potential and characteristics of the different tumor cell lines. This information may help in

evaluating different anti-tumor therapies: potent therapeutics will be effective in the different models while others may seem to be more specific for a certain type of metastasis.

Current Practices of Screening, Prevention and Treatment of Androgen Deprivation Therapy (ADT) induced Osteoporosis in patients with Prostate Cancer.

Arthur Lau^{*1}, Humaid Al-Shamsi², Kartika Malik³, George Ioannidis¹, Jonathan Adachi⁴, Alexandra Papaioannou⁵. ¹McMaster University, Canada, ²McMaster University, Department of Medical Oncology, Canada, ³University of Toronto, Department of Geriatrics, Canada, ⁴St. Joseph's Hospital, Canada, ⁵Hamilton Health Sciences, Canada

Introduction:

In Ontario, Canada, prostate cancer is the most common cancer in men. Androgen deprivation therapy (ADT) is commonly used as an adjuvant for locally advanced and high risk localized disease. ADT's effects on bone metabolism are well documented. The goal of this study was to assess the care gap in this population regarding screening, prevention and treatment of osteoporosis. We also assessed the characteristics of the patients who were more likely to be screened for osteoporosis.

Methods:

Patients diagnosed with non-metastatic prostate cancer on ADT were assessed. Charts were assessed for utilization of DXA scan, prescription of calcium, vitamin D, calcitonin and bisphosphonates. Pre-specified osteoporosis risk factors were also abstracted. In addition, any new fractures incurred during the follow-up were also recorded. Bivariate analysis was used to determine the effect of numerous patient characteristics and likelihood for osteoporosis screening.

Results:

In total, 149 charts were assessed, with 3 year mean follow-up. 58.8% of men received a baseline DXA, of which 20.3% had a repeat DXA at any point within their individual follow-up periods. Bisphosphonates, calcium, vitamin D and calcitonin were prescribed to 12.7, 35.6, 36.9% and 1.3% respectively. In all, 28% were appropriately screened and managed for osteoporosis (received repeat DXA or bisphosphonate). During their follow-up, 0.7%, 2%, and 5.4% had a hip fracture, vertebral fracture and other fractures respectively.

In bivariate analysis, number of ADT injections was significantly associated with being screened. Mean number of injections in patients who received follow-up DXAs or bisphosphonates was 13.1 versus 7.9 ($p < 0.0001$). Age, Gleason score, and PSA at initial visit were not associated with increased screening.

Conclusions:

To prevent osteoporosis in patients on ADT, clinicians have been advised to screen patients prior to the initiation of ADT. Despite these recommendations, our study shows a care gap exists in the screening, prevention, and treatment of osteoporosis in this population. This is quite concerning since they're at high risk for bone loss and fractures. Patients with more ADT injections were more likely to be screened. Our results suggest more education is required for the physicians and healthcare providers treating prostate cancer to help prevent and treat osteoporosis in this susceptible population.

Dual Actions of Klotho in Breast Cancer Cells Cause Resistance to TGFbeta and Vitamin D.

Pierrick Fournier^{*}, Daniel Edwards, John Chirgwin.

Indiana University, USA

Klotho was discovered as an anti-aging gene and subsequently found to be the specific co-receptor for osteocyte-secreted FGF23. FGF23 signals via binding to klotho in the kidney to induce the transcription factor EGR1 and regulate phosphate homeostasis and vitamin D catabolism. Breast cancer expression of klotho increases with increasing tumor grade, and MCF7 human breast cancer cells, which cause bone metastases in nude mice, express klotho and the FGF receptor 1iic isoform. We previously reported that treating these cells with 100ng/ml recombinant FGF23 rapidly increased EGR-1 mRNA 30X by 1hr, followed at 2 hrs by a 10X increase in vitamin D-inactivating 24-hydroxylase, CYP24A1, while 1-alpha hydroxylase was unchanged. Treatment with 100nM 1,25-dihydroxyvitamin D3 for 6 days inhibited cell growth 90%, while FGF23 increased cell numbers by 215% ($p < 0.05$) in the presence of 1,25-dihydroxyvitamin D3.

FGF23 treatment of MCF7 cells rapidly increased mRNAs encoding the early response genes Cyr61 13X & CTGF 280X, respectively. Cyr61 & CTGF are related extracellular matrix proteins that stimulate growth of tumor and bone cells. Klotho is a 1012 aa C-terminally anchored transmembrane protein (mKL), which can be shed by extracellular proteolysis. The shed form consists of a two repeated domains and inhibits TGFbeta signaling by competing with nM affinity for ligand binding at the type II receptor subunit (Doi et al, JBC, 2011). Many cells also express an alternatively spliced transcript encoding a constitutively secreted, single-domain protein of 549 aa (sKL). We tested the effects of overexpression of mKL & sKL in MDA-MB-231 breast cancer cells, which respond to TGFbeta but express very low klotho mRNA. When cells were cotransfected with a TGFbeta reporter, (CAGA)

9-luciferase, sKL but not mKL, decreased TGFβ-induced luciferase activity from 270 to 160 RLU ($p < 0.05$; $n = 3$), indicating that single-domain sKL, like two-domain shed klotho, inhibits TGFβ signaling.

The data show that klotho plays two roles in metastatic tumor cells, acting in cis and in trans: 1) Membrane klotho confers tumor cell responsiveness to osteocyte-produced FGF23, activating early pro-metastatic gene expression (EGFR1, Cyr61, CTGF) and inactivating vitamin D metabolites (via Cyp24A1); 2) Secreted and shed forms of klotho inhibit TGFβ signaling, which can alter the bone phenotype at sites of metastases.

Induction of perlecan/HSPG2 Expression in Desmoplastic Bone Marrow Stromal Cells. Curtis Warren*, Daniel Carson, Mary Farach-Carson. Rice University, USA

Perlecan/HSPG2 is the most abundant heparan sulfate (HS) proteoglycan in bone marrow stroma, where prostate cancer (PCa) cells undergoing epithelial-mesenchymal transformation (EMT) find a metastatic niche in disease progression. HS is essential to growth factor signaling in PCa cell growth and angiogenesis, and perlecan expression increases in PCa-associated fibroblasts where it plays a key role in tumor growth. We hypothesized that the desmoplastic response that increases perlecan expression during PCa growth is driven by similar cell signaling processes in the bone marrow and prostate gland. To test this, we first studied perlecan regulation in reactive bone marrow stromal cells. An *in silico* analysis of conserved transcription factor binding sites in the proximal promoter region of the perlecan gene led to the hypothesis that growth factors and cytokines present in the tumor microenvironment activate transcription factors leading to perlecan promoter activation. This analysis revealed a conserved putative NFκB consensus element in the 2.6 kb proximal promoter region. Using the 2.6 kb human perlecan proximal promoter region to drive a firefly luciferase reporter, we found activation of the perlecan promoter by Tumor Necrosis Factor-α (TNFα) in the human bone marrow stromal cell line, HS-27a, a cell line used to model desmoplastic processes. Deletion analysis of the proximal promoter region in reporter assays demonstrated that the TNFα responsive *cis*-element is encoded in the distal portion of the 2.6 kb promoter region where a consensus NFκB binding site resides. Real-time RT-PCR and dot-blot based analysis of mRNA and protein extracts, respectively, of TNFα treated HS-27a cells confirmed an increase (2-3 fold) in steady state levels of both transcript and protein after 72 hours of TNFα treatment. Ongoing studies include mutation of the perlecan promoter construct to identify the active *cis* element(s) responding to TNFα treatment and further characterization of the intracellular mechanism of perlecan transcriptional activation in HS-27a, primary bone marrow stromal cells, and prostatic fibroblasts. Disruption of paracrine signaling interactions between PCa cells and surrounding stroma that increase perlecan expression during desmoplasia is expected to inhibit disease progression toward lethality.

Disclosures: Curtis Warren, None.

Number Needed to Treat and Risk Benefit Analysis of Denosumab Versus Zoledronic Acid in the Treatment of Castrate-Resistant Prostate Cancer Patients with Bone Metastases. Andrew P Yu¹, Melissa Diener¹, Eric Q Wu¹, Madhav Namjoshi². ¹Analysis Group, Inc., USA, ²Novartis Oncology, USA

Purpose: Approximately 70% of patients with castrate-resistant prostate cancer (CRPC) experience bone metastases which lead to the development of skeletal related events (SREs) such as fractures. Zoledronic acid (ZOL) and denosumab (Dmab) have been shown to prevent or delay SREs in CRPC patients with bone metastases. A phase III trial (NCT00321620, Amgen) compared ZOL and Dmab in patients with CRPC. Results suggest that Dmab is superior in delaying time to SREs, whereas overall survival and disease progression rates are comparable, and ZOL appears to have better safety profile. The objective of this project was to conduct a risk-benefit analysis (RBA) comparing the number needed to treat (NNT) and the number needed to harm (NNH) for Dmab versus ZOL.

Methods: Results from the phase III trial were used to assess the benefits and risks of using Dmab versus ZOL. The NNT calculated the number of patients who would need to be treated with Dmab versus ZOL to prevent one additional fracture, whereas the NNH calculated the number of patients who would have to be treated with Dmab versus ZOL for one additional patient to experience a grade 3 or 4 adverse event (CTCAE3/4). The risk-benefit ratio (RBR), calculated as NNT/NNH, determines whether fewer patients will need to be treated to achieve a benefit than will be treated to experience one additional AE. A sensitivity analysis varied the treatment outcomes from pathological fracture to SRE, and the adverse event outcome from CTCAE3/4 to hypocalcaemia.

Results: For NNT analysis, 162.4 additional patients would need to be treated with Dmab versus ZOL to avoid one additional pathological fracture (absolute risk reduction 0.6% [95% CI: -2.6% to 3.8%]). NNH results showed that 18.4 more patients will experience a CTCAE3/4 with Dmab versus ZOL. The RBA of 8.8 indicates that over 8-fold more patients would need to be treated to prevent a pathological fracture than to have one additional CTCAE3/4. A sensitivity analysis showed that NNT for

any SRE was 21.3, whereas NNH for hypocalcaemia was 14.3, with RBA as 1.5, consistently indicating that the added risk of an AE is higher than the added benefit of SRE prevention by using Dmab.

Conclusion: The number needed to treat as well as the high risk-benefit ratio suggests that despite the better efficacy of Dmab, its benefits may not outweigh its added risks. Decision makers should therefore carefully consider these aspects prior to reimbursement decisions and formulary inclusion.

Osteoporosis-specific Quality of Life Change in the B-ABLE Cohort of Women on Aromatase Inhibitor Therapy: Predictors at 1-year Follow-up. Daniel Prieto-alhambra¹, Sonia Servitja², Laia Garrigos², Elisa Torres², Maria Martinez-Garcia², Josep Blanch³, Joan Albanell², Adolfo Diez-Perez⁴, Ignasi Tusquets², Xavier Nogues⁵. ¹Institut Municipal D'Investigacio Medica, Spain, ²Medical Oncology Department, Breast Cancer Unit. Molecular Therapeutics & Biomarkers in Breast Cancer, Cancer Research Program, IMIM-Hospital del Mar, Autonomous University of Barcelona, Barcelona, Spain, Spain, ³Rheumatology Department, Parc de Salut Mar, Barcelona (Spain), Spain, ⁴Department of Internal Medicine, URFOA IMIM-Hospital del Mar, Parc de Salut Mar, Autonomous University of Barcelona, RETICEF (Red Tematica de Investigacion Cooperativa en Envejecimiento y Fragilidad), Instituto Carlos III, Barcelona, Spain, Spain, ⁵RETICEF (Red Tematica de Investigacion Cooperativa en Envejecimiento y Fragilidad), Instituto Carlos III, Barcelona, Spain, Spain

PURPOSE Aromatase Inhibitors (AIs) are first-line therapies for early breast cancer. Their main side effects are increased bone loss and peripheral arthralgia, which can affect health-related quality of life. We aimed to study the patterns and predictors of bone-specific quality of life at three points in time: baseline (before AI initiation), at 3-months, and at 1-year.

METHODS Participants: 275 women with hormone-positive early breast cancer eligible for AI therapy were consecutively recruited in our hospital (Oncology and Bone Metabolism Units, Parc de Salut Mar, Barcelona (Spain)), and followed up for 1 year. Measurements: Drugs use, years since menopause, body mass index (BMI), previous chemotherapy, radiotherapy and tamoxifen use, smoking/drinking status and dietary calcium intake were collected at baseline. Self-reported osteoporosis-specific quality of life using the validated ECOS-16 questionnaire, arthralgia (using visual analogue scale) and serum Vitamin D (25-hydroxy-D) were measured at the three time points. Statistics: Wilcoxon signed rank tests for paired samples were used to compare ECOS-16 score at three time points. Uni and multivariate linear regression models were fitted to assess predictors of ECOS-16 change (as defined by follow-up minus baseline scores) at 3 months and 1 year. Models were adjusted for years since menopause, baseline Vitamin D and season when samples were drawn.

RESULTS Baseline ECOS-16 was significantly lower than 3-months (mean difference 3.35 [95%CI 2.19 to 4.50], $p < 0.001$) and 1-year scores (4.50 [95%CI 3.20 to 5.81], $p < 0.001$). By contrast, no significant differences were seen between ECOS-16 scores at 3 months and 1 year ($p = 0.13$). Main predictors of ECOS-16 change at 3 months were previous use of tamoxifen (adjusted beta (adjbeta) -3.80 [-6.49 to -1.12], $p = 0.006$), and arthralgia-related change in VAS score (adjbeta 0.50 [0.001 to 0.02], $p = 0.049$). Predictors at 1-year were Vitamin D at 1 year ≥ 30 mg/dl (adjbeta -6.6 [-10.67 to -2.51], $p = 0.002$ [see Figure 1]) and change in arthralgia score (adjbeta 1.60 [0.92 to 2.29], $p < 0.001$).

DISCUSSION Women with early breast cancer experience a significant loss in osteoporosis-specific quality of life after initiating AI therapy. This loss is produced mostly in the first 3 months of therapy, and highly driven by AI-related arthralgia. Previous tamoxifen use, and Vitamin D concentrations ≥ 30 mg/dl at 3 months protect from quality of life loss in this population.

The Vitamin D Receptor Promotes Human Prostate Cancer Cell Growth via a Ligand Independent Pathway. Yu Zheng^{*1}, Difei Deng², Dennis Basel², Trupti Trivedi¹, Julian Kelly², Robert L Sutherland³, Colin Dunstan⁴, Dr. Hong Zhou⁵, Markus Seibel⁵. ¹Bone Research Program, ANZAC Research Institute, The University of Sydney, Australia, ²ANZAC Research Institute, The University of Sydney, Australia, ³Cancer Research Program, Garvan Institute of Medical Research, Australia, ⁴University of Sydney, Australia, ⁵Bone Research Program, ANZAC Research Institute, The University of Sydney, Australia

Prostate cancer is the most prevalent malignancy in men, with 20-40% of patients developing metastatic disease. Bone is a frequent site for metastasis. Epidemiological evidence suggests that vitamin D has a chemo-preventative role in prostate malignancy. We have previously reported that vitamin D deficiency promotes human prostate cancer cell growth in the bone microenvironment of nude mice. However, little is known about the role of the vitamin D receptor (VDR) in this context. The present study aimed to define the role of the VDR in human prostate cancer growth *in vitro* and *in vivo*.

VDR expression was knocked down by stable expression of shRNA in PC3 cells (PC3-VDR-KD), with non target cells (PC3-NT) generated as controls. mRNA knock down was 85% and induction of CYP24 mRNA expression by 1,25(OH)2D3, normally seen in VDR expressing cells, was abrogated in PC3-VDR-KD cells, indicating effective disruption of VDR signaling.

Treatment of PC3-NT cells with 1,25(OH)2D3 significantly reduced cell growth by up to 51% as compared to untreated PC3-NT cells. Surprisingly, growth of PC3-VDR-KD cells in ligand-free cultures was also reduced by 49% (compared to NT cells). Moreover, cell migration was increased by 10% in PC3-VDR-KD cells. Of note, PC3-VDR-KD cells did not respond to treatment with 1,25(OH)2D3. These *in vitro* results suggest that VDR knockdown in human prostate cancer cells results in reduced tumor cell growth and increased cell migration, providing evidence that the VDR may have ligand-independent functions in promoting proliferation and suppressing migration of cancer cells independent of its liganded form.

To further investigate the effects of VDR knockdown *in vivo*, PC3-NT and PC3-VDR-KD cells were implanted subcutaneously in nude mice, and tumor growth was monitored for 69 days. Compared to NT cells, VDR knockdown resulted in significantly smaller tumors from day 12 onwards ($p < 0.05$). Similarly, when PC3-NT or PC3-VDR-KD cells were implanted into the tibiae of vitamin D sufficient mice, disruption of VDR signaling resulted in significantly smaller osteolytic lesions from day 17 onwards ($p < 0.05$, by X-ray analysis).

In summary, our results suggest a novel ligand-independent role of the VDR in promoting prostate cancer cell growth and suppressing invasive cell potential. This novel function of the unliganded VDR contrasts with the known anti-proliferative actions of the liganded VDR and may offer new therapeutic approaches in cancer treatment.

TRPV6 Ion Channels Modulate Human Metastatic Prostate Cancer Cell Migration and Adhesion. Sarah McCarthy^{*}, Ronald R. Gomes. Penn State Hershey, USA

We have previously reported that intermittent parathyroid hormone 1-34 administration enhances the colonization of human osteoblastic prostate cancer cells to murine bone. While the mechanism is unknown, we propose that transient increases in serum calcium following parathyroid hormone 1-34 administration, confer a metastatic advantage to circulating prostate cancer cells, signaled, in part, via TRPV6 ion channels. We tested the hypothesis that TRPV6 ion channels are required for prostate cancer cell metastatic potential, *in vitro*. To test our hypothesis, shRNA lentiviral particles were employed to knock down TRPV6 expression in C4-2 prostate cancer cells. Knockdown was confirmed by qRT-PCR, Western blot analysis, and immunocytochemistry. Proliferation, transwell migration, and heterotypic cell adhesion (C4-2:human bone marrow endothelial (hbmE) cells) assays were employed to evaluate the metastatic potential of C4-2 cells with reduced levels of TRPV6 relative to wild type and control shRNA cells. QRT-PCR and Western blot analysis identified several clones that expressed reduced TRPV6 protein (40-63%). Confocal micrographs of paraformaldehyde fixed (4%) cells probed with TRPV6 specific antibodies, confirmed TRPV6 localization in knockdown clones was reduced at the cell surface. Relative to control cell lines, cells with decreased TRPV6 expression had a slower rate of proliferation. Transwell migration assays suggested that increased extracellular calcium (2.5 mM CaCl_2) enhanced migration of wild type and control cell lines; however, relative to controls, migration was reduced by 49% in knockdown clones treated similarly. Interestingly, heterotypic cell adhesion assays demonstrated cells with reduced TRPV6 expression were less adherent (-34%) to hbmE cells. Pre-treatment of prostate cancer cells with increased extracellular calcium (2.5 mM CaCl_2) did not alter their adhesion to hbmE cells. Surprisingly, pre-treatment of hbmE cells with 2.5 mM CaCl_2 enhanced adhesion of control cells by 78%; however, this response was abolished in TRPV6 knockdown clones. This is the first report employing shRNA to stably knockdown TRPV6 in a human osteoblastic prostate cancer cell line. Our observations support our hypothesis and suggest, for the first time, that TRPV6 may

PTHrP Promotes Epithelial-To-Mesenchymal Transition and the Acquisition of Cancer Stem Cell-Like Properties in Prostate Cancer. Douglas Burton^{*1}, Weg Ongkeko², Alan Kiang³, Eric Abhold³, David Yi³, Leonard Deftos⁴. ¹VA San Diego Healthcare System / University of California, San Diego, USA, ²University of California San Diego / VMRF, USA, ³University of California San Diego, USA, ⁴Veterans Administration San Diego Healthcare System & University of California, USA

Background: The mechanism by which tumor cells become invasive and eventually metastatic is a crucial question in cancer biology. The metastatic process requires that a cell acquire a motile phenotype to penetrate tissue and reach the vasculature and lymphatics. Parathyroid hormone-related protein (PTHrP), an oncoprotein, has been implicated in the pathogenesis and progression of several cancers, including prostate cancer.

Methods: In this study, we compared the parental prostate cell lines with their corresponding derivatives that stably overexpress PTHrP *in vitro* and *in vivo*. We used qPCR, western blot analysis, and immunofluorescence to analyze EMT and stem cell markers, and an invasion assay to investigate PTHrP-mediated migration and invasion. GFP expression was used to monitor prostate cancer tumorigenesis, growth, and metastasis in the mouse model.

Results: We observed that PTHrP-overexpressing derivatives were 2-3 fold more invasive than their parental counterparts. PTHrP derivatives promoted epithelial-to-mesenchymal transition (EMT). Cells that overexpressed PTHrP had decreased levels of the epithelial marker, *E-cadherin*, increased levels of the mesenchymal marker, *vimentin*, and increased levels of the EMT regulator, *Snail*, as measured by qPCR. These results were supported by immunofluorescence data. Prostate cancer cells that had high levels of PTHrP also exhibited induction of the stem cell genes *CD133*, *Oct4*, and *Nanog*. In the mouse model of prostate cancer, DU 145 prostate cancer cells that normally are incapable of forming tumors when implanted subcutaneously into immunocompromised mice were transformed to highly tumorigenic cells when engineered to express high levels of PTHrP. In the orthotopic model, mice that were implanted with PTHrP overexpressing cells exhibited highly efficient tumorigenesis and metastasis compared to the parental cells in which there were very few, small discrete tumors. This finding was further confirmed in an intraosseous prostate model in which DU145 parental cells or those transfected with empty vector formed no tumor when injected into mice tibia while those that expressed PTHrP resulted in tumor formation, invasion, and destruction of bone.

Conclusions: Recent evidence suggests that the induction of EMT in cancer cells leads to the development of cancer stem cell traits. PTHrP appears to play an important role in EMT and acquisition of cancer stem cell properties in prostate cancer.

Disclosures: Douglas Burton, None.

serve an important role in modulating metastatic prostate cancer cell migration and adhesion to bone marrow endothelial cells, *in vitro*.

SQSTM1 Mutations Are not Common in Pagetic Osteosarcomas nor in High Grade Osteosarcomas. Pui Yan Jenny Chung¹, Piero Picci², Marco Alberghini³, Lars-gunnar Kindblom⁴, Patrick D'Haese¹, John-Paul Bogers¹, Leida Rozeman⁵, Pancras Hogendoorn⁵, Wim Van Hul^{*1}. ¹University of Antwerp, Belgium, ²Istituto ortopedica Rizzoli, Italy, ³Istituto Ortopedica Rizzoli, Italy, ⁴Royal Orthopedic Hospital, United Kingdom, ⁵Leiden University Medical Center, Netherlands

Paget's disease of bone (PDB) is, with a prevalence of 2-5% in the Caucasians above 55 years of age, the second most frequent metabolic bone disease, next to osteoporosis. Characteristics of PDB are bone lesions with an imbalanced bone remodelling, resulting in disorganised and non-fully-fledged new bone. The only disease-causing gene identified so far is the sequestosome1 (SQSTM1) gene. SQSTM1 mutations have been found in one third of families and in about 9% of isolated cases with PDB. All mutations are clustered in and around exon 7 and 8. Osteosarcomas are the most severe complications of PDB and occur more frequently in PDB patients, suggesting that PDB increases the risk for the development of an osteosarcoma. A previous study reported the presence of the recurrent SQSTM1 P392L mutation in 3 out of 5 osteosarcoma tissues from PDB patients, but not in adjacent normal tissues. In this study, we performed SQSTM1 mutation screening in 24 frozen osteosarcoma samples and 8 matching normal tissues from 22 PDB patients as well as in 26 frozen osteosarcoma samples and 10 matching normal tissues from 26 elderly patients with high grade osteosarcoma. At first, the samples were checked for the homogeneity of the tissue. If a tissue was not homogeneous, we either performed microdissection or laser capture microdissection, before DNA isolation. Then, mutation analysis of the exon 7 and 8 of SQSTM1 was performed by DNA-sequencing. In the Pagetic osteosarcoma tissues, we were able to detect, besides 2 unannotated intronic variants in 2 samples, the P392L mutation in only 1 sample out of the 24 tissues (4%). No normal tissue from this case was available. No SQSTM1 mutation was found in all pathological samples from elderly osteosarcoma patients. In conclusion, in this study we were not able to confirm a high frequency of SQSTM1 mutations in Pagetic osteosarcomas. Furthermore, SQSTM1 mutation seems not to be common in high grade osteosarcomas.

Altered Bone Marrow Adiposity Following Localized Irradiation in Juvenile Mice. Lihini Keenawinna^{*1}, Megan Oest¹, Timothy Damron². ¹SUNY Upstate Medical University, USA, ²State University of New York Upstate Medical University, USA

Introduction: Clinical radiation therapy is often complicated by decreased bone strength and quality, often resulting in late-onset fracture.¹ Clinical radiology studies after radiotherapy typically show increasing marrow adiposity over time.^{2,3} The biological mechanisms mediating these adverse skeletal effects are not well understood, although we suspect differential effects on multipotent MSCs.

Hypothesis: We hypothesized that irradiated hindlimbs would demonstrate elevated marrow fat content compared to untreated hindlimbs.

Methods: Eight 4-week-old C57Bl/6 mice were anesthetized and exposed to unilateral, localized hindlimb irradiation at a dose of 20Gy (300kV, 10mA). One week post-irradiation, animals were euthanized for retrieval of tibias and femurs. Samples were fixed in 10% buffered formalin, then decalcified (12% buffered EDTA), and stained with 2% aqueous OsO₄. This process increases the radio-opacity of marrow lipids *in situ*, permitting micro-computed tomographic imaging using a 12 mm voxel resolution (Scanco Micro-CT 40). Total lipid volume of each bone was quantified using global digital thresholding.

Results: Contrary to our hypothesis, mean intraosseous lipid volume was lower after irradiation in femurs and tibias (Figure 1). However, statistical analysis detected no significant differences between treatment groups.

Discussion: Previous studies in our laboratory have qualitatively demonstrated increased marrow adiposity following localized skeletal irradiation in mice (Figure 2). Differing results between the studies could be due to the juvenile age of the current animals, as the earlier study used 12-week animals. MSCs from young donors exhibit greater plasticity and proliferative capacity and hence may be less susceptible to radiation-induced damage than mature animals. Additionally, the current animals were euthanized at 1 week post-irradiation whereas the previous animals were euthanized at 6 weeks. While cultured osteoblastic cells demonstrate decreased mineralization and proliferative capacities by one week post-irradiation,⁴ this may be insufficient time for effects to manifest in whole tissues. Ongoing studies with 26-week-old mice will allow us to determine if marrow adiposity subsequent to radiation therapy is an age-dependent outcome.

Cisplatin Treatment Inhibits Bone Healing: Implications for Osteosarcoma Surgery. Larry Suva^{*1}, Kimo Stine¹, Elizabeth Wahl¹, Lichu Liu¹, James Aronson¹, Robert Skinner¹, Kathryn Thrailkill², Corey Montgomery¹, John Fowlkes¹, David Becton¹, Charles Lumpkin¹. ¹University of Arkansas for Medical Sciences, USA, ²Arkansas Children's Hospital, USA

Osteosarcoma (OS) is the most common primary bone cancer that affects children and adolescents. The majority of patients are treated by a closely timed combination of chemotherapy and surgery, yet these patients continue to be at risk for postoperative complications especially in the area of bone repair. Cisplatin is a drug

commonly used for treatment of OS, yet the effects of cisplatin on bone regeneration are not well studied. As a result, the bone health of both childhood and adult OS survivors requires increased attention. Therefore, we tested the effects of two regimens of cisplatin dosing in a unique model of bone repair and regeneration, namely, distraction osteogenesis (DO) in mice. C57BL/6 male mice (n=20) underwent the standard DO protocol. Based on current clinical practices, cisplatin exposure can occur preoperatively, postoperatively, and even simultaneously with bone repair and/or regeneration. The dose of CDP was 60 mg/M2/day. Group 1 mice had surgery and started cisplatin simultaneously for 5 days; group 2 mice underwent DO surgery one week after receiving 2 doses of cisplatin; control mice received placebo. All mice were distracted for 11 days at a rate of 0.075 mm b.i.d. Animal weights at sacrifice were not significantly different. In Group 1, comparison of the distracted tibial radiographs demonstrated a dramatic and significant decrease in the mineralized area of distraction gaps of cisplatin-treated mice (3.6% + 2.1) versus vehicle treated (63.3% + 5.8) mice. Detailed histological analysis of the DO gaps confirmed the significant decrease in bone formation observed in the radiographs of the cisplatin-treated mice (7.6% + 7.0) versus the vehicle controls (75.4% + 5.5). Furthermore, microCT evaluation of the endosteal and periosteal bone volume in the DO gap demonstrated significant inhibition of both endosteal and periosteal new bone formation. Similarly in group 2, there was a significant decrease in the mineralized area of distracted gaps of cisplatin-treated mice (15.5% + 9.0) versus vehicle treated (42.8% + 12.6) mice that was also confirmed by microCT. These results demonstrate the severe inhibitory effects of cisplatin administration on bone healing and regeneration and suggest that increasing the time interval between the final cisplatin injection and any subsequent surgical intervention may be required for normal bone healing in surgical OS patients.

Development and Validation of a Pre-clinical Model of Radiation Impaired Fracture Healing. Katarina Janic^{*1}, Fred Nicholls², Tom Willett³, Marc Grynpas³, Peter Ferguson⁴. ¹Mount Sinai Hospital, Samuel Lunenfeld Research Institute, Canada, ²University of Toronto, Department of Surgery, Division of Orthopedic Surgery, Canada, ³Samuel Lunenfeld Research Institute, Canada, ⁴Division of Orthopedic Surgery, Mount Sinai Hospital, Canada

Background: Currently, surgical excision combined with radiotherapy provides the best opportunity for local control in patients with soft tissue sarcoma. While there is increased benefit to combined modality therapy, complications are also increased. Pathologic fracture, one arising from no or minimal trauma, occurs within the site of irradiation in 2-10% of patients. Non union rates exceed 80% in these fractures, where after amputation is not uncommon and patient morbidity is increased.

Objectives: 1) Create an animal model for the study of non-union in patients undergoing multi-modal therapy for soft tissue sarcoma

2) Characterize the effect of combined modality therapy on bone biology

Method: 72 Wistar rats were randomized to 4 groups: I)Control, II)Radiotherapy, III)Periosteal Stripping, IV)Combination therapy. All groups underwent controlled fracture at nine weeks. Micro computed tomography, back scattered electron microscopy and static and dynamic histomorphometry were used to evaluate data.

Results: MicroCT results reveal greater bone volume, mineralized tissue and callus volume in control animals compared to any irradiated groups and periosteal stripped animals ($p < 0.001$). Histomorphometric analysis reveals increased osteoid and cartilage formation in control and periosteal stripped animals compared to both irradiated groups.

Conclusion: All animals that underwent radiotherapy failed to form callus and went on to form atrophic non-union. Future work will investigate the effects of a single implant of bone growth factor OP-1 into the intramedullary canal immediately prior to fracture.

Epigenetic Signatures of Osteosarcoma. Emma Baker^{*1}, Dario Strbenac², Thomas John Martin³, Louise Purton¹, Mark Robinson⁴, Carl Walkley¹. ¹St. Vincent's Institute, Australia, ²Garvan Institute of Medical Research, Australia, ³St. Vincent's Institute of Medical Research, Australia, ⁴WEHI, Australia

Purpose: Osteosarcoma (OS) is the most common malignancy of bone, and is the second leading cause of cancer related death in children. OS survival rates have plateaued since the 1980s. Patients presenting with metastatic or recurrent disease have less than 20% survival at 5 years. New therapeutic treatments are desperately needed to improve patient outcomes. It is clear that epigenetic changes play a major role in cancer initiation and progression, however the contribution of epigenetic instability to OS, especially metastatic disease, remains largely unknown. Understanding the specific epigenetic changes associated with OS disease onset, progression and metastasis will be important for developing new treatment options. **Methods:** We

have utilized low passage cell lines established from paired primary and metastatic tumours from a mouse model of OS¹, and normal osteoblasts derived by *in vitro* differentiation of Kusa4b10 cells² to identify epigenetic signatures that define OS. Genome-wide promoter maps of epigenetic modifications in OS and normal osteoblast cells were generated using NimbleGen ChIP-Chip arrays. **Results:** Gene expression profiling of OS cells and normal osteoblast cells showed a number of enzymes responsible for mediating epigenetic modifications are differentially expressed. Differences in expression were also apparent in cells derived from primary and metastatic tumours from the same mice. Genome-wide promoter mapping of modifications mediated by these enzymes identified an OS specific epigenetic signature that distinguishes the disease from normal osteoblasts. The signatures encompass both RefSeq annotated genes and miRNAs. **Conclusions:** Aberrant expression of epigenetic modifying enzymes in OS correlates with a specific epigenetic signature that distinguishes the disease from normal osteoblasts. Further profiling of the metastatic disease is warranted, as disease location appears to be associated with specific epigenetic enzyme gene expression. Identifying OS specific epigenetic signatures will provide invaluable knowledge of OS biology, potential markers of metastatic disease development and new therapeutic targets.

Locally Administered Zoledronic Acid Therapy for Giant Cell Tumor of Bone. Toshihiko Nishisho^{*1}, Naoyoshi Hanaoka², Kenji Endo², Mitsuhiro Takahashi², Natsuo Yasui³. ¹The University of Tokushima, Institute of Health Bioscience, School of Medicine, Japan, ²Department of Orthopedics, The University of Tokushima, Japan, ³University, Japan

Giant cell tumor of bone (GCTB) is a locally aggressive tumor and typically occurs in the meta-epiphyseal region of long bones. Intralesional curettage alone has a high local recurrence rate. In the present study, zoledronic acid, a nitrogen-containing bisphosphonate, was administered locally as an adjuvant during a biopsy. An otherwise healthy 43-year-old male was admitted to our hospital with pain and swelling in the right knee following a fall 1 month earlier. Plain radiographs and MRI demonstrated an osteolytic tumor of the right proximal tibia. An open biopsy was performed and the intra-operative pathologic diagnosis was GCTB (Fig A). Following biopsy the defect was filled with beta-tricalcium phosphate (OSferion®), and 4 mg of zoledronic acid was locally administered into the tumor lesion. MRI performed 2 months after the biopsy demonstrated poor gadolinium enhancement of the residual tumor. Subsequently, curettage and bone grafting were performed. Sections were obtained during the curettage for histology, to evaluate the response to bisphosphonate treatment. Histologic examination revealed massive tumor cell death in the lesion in which both stromal cells and osteoclast-like giant cells were necrotic (Fig B). Curettage was performed and the defect was filled with a commercial preshaped hydroxyapatite-tricalcium phosphate (HAP/TCP) bone substitute (Cerattite®, Kobayashi Medical, Osaka, Japan). There were no serious complications directly associated with curettage or the local administration of zoledronic acid. Eighteen months after curettage, the patient had regained full range of motion and good function of the knee, and radiographs of 18 months after curettage revealed no recurrence of GCTB. Moreover, no side effects were observed during the treatment. In the present case, the local administration of zoledronic acid induced tumor cell death and may also have suppressed recurrence. This is the first report of local administration of bisphosphonates for the treatment of GCTB. This method of bisphosphonate administration may be suitable for other bone disorders such as metastatic bone disease. Written informed consent was obtained from a patient with GCTB and the treatment protocol was approved by the Ethics Committee of Tokushima University.

Mechanical Signals Partially Preserve Bone Quality in Animal Models of Ovarian Cancer While Promoting the Mesenchymal Progenitor Pool's Efficacy in Slowing Complications of the Disease. Gabriel Pagnotti^{*1}, Benjamin Adler¹, Danielle Green¹, Ete Meilin Chan¹, Wesley Beamer², Kenneth Shroyer³, Clinton Rubin⁴. ¹Stony Brook University, USA, ²The Jackson Laboratory, USA, ³Stony Brook University Medical Center, USA, ⁴State University of New York at Stony Brook, USA

The progression and subsequent treatment of cancer is often complicated by a rapid decline in bone quality, yet mounting concerns exist regarding the use of anabolic agents in preserving skeletal morphology as these factors may inadvertently exacerbate tumorigenesis. Low intensity vibration (LIV), a systemically-delivered, low magnitude mechanical signal that promotes osteoblastogenesis, could represent a non-invasive strategy to prevent cancer-induced skeletal atrophy but only if it does not facilitate disease progression.

Seventy 12w female F1-SWRxSJL mice, a strain highly susceptible to developing granulosa cell tumors, were randomly divided into baseline control (n=10), age-matched control (n=30), and LIV (n=30), which received mechanical signals (90Hz @ 0.3g) for 15m/d, 5d/w over the course of 1y. Survivability curves for both groups followed identical trends indicating longevity over the course of 1y was unaffected by LIV (9 lost/group). In those that survived 1y, μ CT of the proximal tibiae indicated trabecular bone volume was +25% (p=0.03) greater in LIV over control but had fallen markedly from baseline values (-40%; p<0.01). While primary ovarian lesions and peripheral metastases to lungs, lymph nodes, and liver were apparent in both study groups, the overall tumorigenic incidence was 37% lower in LIV-treated animals (NSD). FACS analysis detected shifts in mesenchymal stem cells (MSC) within the bone marrow, as MSC trends in LIV were 52% (p=0.01) lower than age-matched control and 31% (p=0.2) lower in non-pathologic mice, suggesting that decreased MSC levels are associated with suppressed pathology. Indeed, MSCs are known to contribute to neoplasias preceding tumorigenic events. These preliminary data indicate that mechanical signals, recognized as anabolic to bone, will not perturb the longevity index of animals that are highly susceptible to cancer. Further, these mechanical signals helped to preserve the bone quality of diseased animals, potentially contributing to a reduced risk of fracture. Perhaps these low intensity mechanical signals mimic the benefits of exercise in the preservation of clinically-relevant bone indices and, like exercise, contribute to a non-drug means of suppressing neoplastic endpoints.

Novel Biomarkers and Therapeutic Agents for Osteosarcoma Stem Cells. Vaibhav Saini^{*1}, Curtis Hose², Anne Monks², Mark Burkett², Bingnan Han², Dianne Newton³, Angelena Millione², Jalpa Shah², Melinda Holingshead³, Kunio Nagashima², Rene Delosh², Karen Hite², Thomas Silver², Dominic Scudiero², Paola Pajevic Divieti⁴, Robert Shoemaker³. ¹Research Fellow, MGH, Harvard Medical School, USA, ²SAIC, USA, ³NCI, USA, ⁴MGH- Harvard Medical School, USA

Osteosarcoma is the 6th most common pediatric tumor in the under 15 age group. Its 40% mortality rate has not improved since the 1970s. Osteosarcoma stem cells (OSCs) have been implicated in tumorigenesis and relapse. Thus, OSC ablation could improve treatment outcomes. Therefore, we hypothesized that characterizing OSCs could yield novel biomarkers and therapeutic targets. To obtain OSC-enriched sphere cultures, monolayer cultures of CHA59, HuO9, and Saos-2 osteosarcoma cell lines in fetal bovine serum (FBS) medium, previously implicated in promoting cancer stem cell differentiation, were transferred to stem cell enriching (SS) medium. Monolayers in FBS yielded

spheres in SS. Spheres demonstrated higher clonogenicity and tumorigenicity in NOD/SCID mice as compared with monolayers, indicating OSC enrichment in spheres. Spheres expressed osteosarcoma markers, such as alkaline phosphatase and osteocalcin, and produced osteoid as observed by H&E staining of xenograft sections. Transmission electron microscopy revealed organelle-devoid cells, previously reported as stem cells in breast cancer, in spheres and none in monolayers, confirming that sphere culture can recapitulate in vivo OSC features. Using the xCELLigence system, which monitors cell migration in real-time, we developed a novel kinetic 7-day assay, as opposed to the static 2-day boyden chamber assay, to compare sphere vs. monolayer migration ability. Individual cells derived from spheres migrated significantly more than those from monolayers towards the SS medium. After 7 days, we harvested spheres from the lower chamber that contained migrated cells, providing direct evidence that the cells migrating towards the SS medium are the sphere forming cells. Transcriptome, proteome, immunophenotyping, and bioinformatic analyses revealed significantly decreased CD326, CD24, CD44, and increased CBX3, ABCG2, ABCA5 (a newly discovered ABC transporter), aldehyde dehydrogenase expression in spheres as compared with monolayers. Upon high-throughput drug resistance analysis, spheres demonstrated higher resistance than monolayers to the majority of anti-tumor agents, except decitabine (DMNT inhibitor) and telomerase inhibitors. In summary, we identified two novel OSC-enrichment biomarkers (CBX3 and ABCA5), developed a kinetic 7-day migration assay, and identified epigenetic and anti-telomerase agents for targeted OSC ablation. With further research, these agents could be developed for translational osteosarcoma therapy.

Potential Risk Factors for Bisphosphonate-related Osteonecrosis of the Jaw: Retrospective Analysis of 576 Cancer Patients. Vivek Thumbigere-Math¹, Lam Tu¹, Sabrina Huckabay¹, Scott Lunos², Arkadiusz Dudek³, Karen Swenson⁴, Joseph Leach⁴, Pamela Hughes¹, David Basi¹, Raj Gopalakrishnan^{*5}. ¹University of Minnesota School of Dentistry, USA, ²University of Minnesota CTSI Academic Health Center, USA, ³University of Minnesota Cancer Center, USA, ⁴Park Nicollet Institute, USA, ⁵University of Minnesota, USA

We conducted a retrospective study to evaluate the frequency, risk factors, clinical presentation, and management of Bisphosphonate-Related Osteonecrosis of the Jaw (BRONJ) in cancer patients treated with intravenous Bisphosphonate (BP). Patients treated with intravenous BP therapy between January 2003 and December 2007 were identified through respective institute's pharmacy databases. Of the 576 identified patients, 18 (3.1%) developed BRONJ which included 8 of 190 (4.2%) patients with breast cancer, 6 of 83 (7.2%) patients with multiple myeloma, 2 of 84 (2.4%) patients with prostate cancer, 1 of 76 (1.3%) patients with lung cancer, 1 of 52 (1.9%) patients with renal cell carcinoma and in none of the 73 patients with other malignancies. Tooth extraction was the BRONJ inciting event in 10 patients (59%), whereas 7 (41%) patients reported no history of previous traumatic episode (missing data for one subject). BRONJ patients had received significantly higher number of mean BP infusions (38.119.06 vs 10.512.81, p<0.0001) and longer duration of BP treatment (months, 44.324.34 vs 14.618.09, p<0.0001) compared to patients without BRONJ. Diabetes (HR=3.40; 95% CI=1.11-10.11; p=0.028), hypothyroidism (HR=3.59; 95% CI=1.31-9.83; p=0.013), smoking (HR=3.44; 95% CI=1.28-9.26; p=0.015), and higher number of zoledronate infusions (HR=1.07; 95% CI=1.03-1.11; p=0.001) were found to be significant risk factors for developing BRONJ using multivariate Cox proportional hazards regression analysis. Based on the AAOMS staging system, one patient was initially diagnosed with Stage I lesion, 10 patients with Stage II and 4 with Stage III lesions. Initial management of BRONJ was non-surgical, with debridement performed at subsequent visits if needed. BRONJ lesions healed completely in 2 patients (11%), healed partially in 5 (28%), remained stable in 5 (28%), and progressed in 6 (33%). Among the identified risk factors, hypothyroidism is a novel finding contributing to BRONJ development. Further, increased cumulative doses and long-term intravenous BP treatment were found to be the most significant risk factors.

Radiation Induced Bone Loss: A Dose Response PET-CT Study. Orhan Oz^{*1}, Jon Anderson², Rohama Khajia³, Keenan Brown³, Paul Medin². ¹University of Texas Southwestern Medical Center, Dallas, USA, ²UT Southwestern Medical Center at Dallas, USA, ³Mindway Software, USA

Radiosurgery of the spine is used to treat patients with spinal metastases and cord impingement from tumors. Recent clinical studies have shown increased fracture risk in patients treated with high doses of external irradiation. We are interested in knowing whether there is a dose response relationship between prescribe radiation and induced bone loss. In a study approved by the UT Southwestern Medical Center's Institutional Animal Care and Use Committee, three cervical vertebral bodies (C5-C7) of 10 ~50 week old Yucatan minipigs were irradiated with a 6 MV image-guided linear accelerator. Stereotactic targeting was performed using stereoscopic kV x-rays. Pigs were stratified into 2 dose groups of 16 (n=5) and 24 Gy (n=5). Dose was prescribed to the 90% isodose line. The mini-pigs were scanned on a Siemens Biograph 64 PET/CT scanner prior to irradiation, 1 month and 3 months after irradiation. Following

acquisition of the CT scans the mini-pigs were injected with ^{18}F FDG, a glucose analog. CT scans of C3 through T1 for each animal were analyzed using the Mindways "Bone Investigational Toolkit" ("BIT") version 2.0. BMD profiles approximately along the central axis for each vertebra were generated in BIT. Endplate-to-endplate distance was estimated by the distance between endplate peaks in the mass profiles. Total vertebral volume was estimated by the bone volume between endplate peaks. Average volumetric BMD and cross-sectional area were calculated for the central 75% of the distance between endplates. Volumetric BMD was estimated for both the total vertebral body and for the trabecular bone. A cortical threshold of 450 mg/cm³ was used to segment the bone into "cortical" and "trabecular" compartments. To date we have determined that trabecular bone loss is greater and occurs earlier in the group treated with the highest dose. ^{18}F FDG retention in the vertebral bodies was quantified as a standardized uptake value (SUV). Visually, there was decreased activity in the irradiated bones of the spines in both groups. Statistical evaluation of the mean SUV/treatment group and analysis of average volumetric BMD and cortical bone volume is underway.

Raman Spectroscopy Demonstrates Amifostine-Induced Protection of Bone Quality In The Irradiated Murine Mandible. Catherine Tchanque-Fossuo¹, Bo Gong², Behdod Poushanchi², K. Kelly Gallagher², Deniz Sarhaddi², Alexis Donneys², Sagar S. Deshpande², Michael Morris², Steven Goldstein³, Steven R. Buchman². ¹Plastic Surgery Research Fellow, USA, ²University of Michigan, USA, ³University of Michigan Orthopedic Research Labs, USA

Purpose: Adjuvant radiotherapy (XRT) in the management of head and neck cancer remains severely debilitating. Fortunately, newly developed agents aimed at decreasing XRT-induced damage have shown great promise. Amifostine (AMF) is a drug which confers radio-protection to the exposed normal tissues, such as bone. Our intent is to utilize Raman spectroscopy (RS) to demonstrate how AMF preserves the mineral composition of the murine mandible following human equivalent XRT.

Methods: 6 Sprague Dawley rats were randomly assigned into 2 groups: XRT (n=3), AMF (n=3). Both groups underwent bioequivalent XRT of 70Gy in 5 fractions to the left hemimandible. AMF was administered 45min prior to XRT. 56 days post-XRT, the hemimandibles were harvested, and Raman spectra with 4 cm⁻¹ spectral resolution taken in the region of interest spanning 5.1 mm posterior to the last molar. A contralateral hemimandible from XRT served as Control. Bone mineral and matrix-specific Raman bands were observed and analyzed using One-way Anova, with statistical significance at p<0.05.

Results: The XRT group exhibited greater signs of radiation-induced stress, including alopecia, mucositis and weight loss compared to AMF. Gross examination demonstrated a reduction in angular cortical density. Mineral crystallinity, determined by the width of the primary phosphate band, which is fitted to obtain the full-width half-maximal-FWHM was calculated. FWHM demonstrated significant difference between AMF and XRT (p=0.005) and XRT and Control (p=0.021). There was no difference between AMF and Control (p=0.901; Fig1). There was an important shift in the peak position of the major phosphate band to higher wavenumber. These results are consistent with XRT-induced changes in mineral composition and crystallinity. Additional computer-aided spectral subtraction further confirmed these results (Fig2). AMF was spectrally similar to the Control in the same region thus demonstrating AMF protective effect from XRT-induced mineral damage.

Conclusion: Our novel findings demonstrate that AMF prophylaxis maintains and protects bone quality in the setting of XRT. RS is an emerging and exceptionally attractive clinical translational technology to investigate and monitor both the destructive effects of XRT and the therapeutic remediation of AMF on the structural, physical and chemical quality of bone. With noninvasive fiberoptic probe this technology holds the potential for diagnostic use in humans.

Role of CIZ in Melanoma Activity for Metastasis. Hiroaki Hemmi¹, Takuya Notomi², Tetsuya Nakamoto³, Tadayoshi Hayata⁴, Yoichi Ezura⁵, Tomomi Sakuma³, Masaki Noda³. ¹Immunology Frontier Research Center, Osaka University, Japan, ²GCOE, Tokyo Medical & Dental University, Japan, ³Tokyo Medical & Dental University, Japan, ⁴Medical Research Institute, Tokyo Medical & Dental University, Japan, ⁵Tokyo Medical & Dental University, Medical Research Institute, Japan

Bone Metastasis causes severe pain and multiple complications in locomotor system. However the mechanism of bone metastasis has not yet been fully understood. As bone metastasis is depend on diverse steps, which starts from the migration of the cells and metastasizing to the bone environment, attachment proteins would be involved in this process.

CIZ is a protein that has been known to be involved in regulation of genes related to metastasis such as MMPs. We examined the role of CIZ in B16 cells with respect to its actions for a migration and cell activities. CIZ expression levels in B16F10 were higher than those in B16 cells. This is correlating to the high metastatic activities in B16F10 than B16 cells. When we knocked down CIZ by using siRNA, B16 cells exhibited less migration activity upon the deletion of CIZ. In contrast enhanced expression of CIZ increased melanoma cell migrations. The size of migrated melanoma cells was also reduced by CIZ knocked down. By using intra-cardiac injection model, CIZ deficient host exhibited reduction in metastasis to bone, suggesting that the host CIZ may have a role in supporting the metastasis of B16 cells. With respect to cytokine, RANKL treatment enhanced CIZ expression in B16 cells. CIZ over expression activated the promoter of RANKL via the CIZ response elements located in RANKL gene. CIZ as well as RANKL promoted the migration of B16 melanoma cells and modulate cytoskeletal structures.

These observations suggested that CIZ regulates the property of metastatic B16 melanoma cells.

Development of a High-throughput Screening (HTS) Assay for the Identification of Small Molecule Modulators of Gsa. Nisan Bhattacharyya¹, Dr. Catherine Chen², Dr. Wei Zheng², Dr. John K. Northup³, Dr. Susanne Neumann⁴, Dr. Michael T. Collins⁵. ¹NIDCR, NIH, USA, ²National Chemical Genomics Center, NHGRI, NIH, USA, ³Laboratory of Cell Biology, NIDCD, NIH, USA, ⁴Clinical Endocrinology Branch, NIDDK, NIH, USA, ⁵Skeletal Clinical Studies Unit, CSDB, NIDCR, NIH, USA

Somatic mis-sense mutations in the small subunit of the G-protein, Gs α (gsp), distributed in a mosaic pattern, are directly correlated with the occurrence of fibrous dysplasia of bone/McCune-Albright syndrome (FD/MAS), a disease that is defined by skeletal abnormalities that can be associated with various forms of hyperfunctioning endocrinopathies. The biochemical outcome of these mutations (R201H or R201C) is increased cAMP levels due to the impaired GTPase negative feedback regulatory step that converts active GTP-bound adenyl cyclase to the inactive GDP-bound form. Of interest is the fact that higher levels of cAMP may also correlate with the increased apoptosis that is observed in skeletal cells and is responsible for the age-related quiescence that is seen in FD. As such, certain endocrine tissues may benefit from gsp inhibition, while in skeletal tissue further gsp activation may speed apoptosis of mutation-bearing cells. The aim of this study is to develop an assay system that can be

used to discover small molecule inhibitors and activators specific for the mutated Gsx. Engineered CHO cells (Invitrogen) were stably transfected with either wild-type or mutated of Gsx (R201 and R201H). Several stable cell lines that showed equal expression of transfected Gsx were tested for cholera toxin-indifferent cAMP generation as the assay readout. One cell line from each set (WT9, C6 and H2), was selected for further studies and the assay optimized for use in a 1536 well format. The ability of activated Gsx to be inhibited and further stimulated was confirmed by testing with various adenylyl cyclase and adrenergic receptor inhibitors, and forskolin. Assay validation was carried out by screening the Library of 1280 Pharmacologically Active Compounds (LOPAC-1280) and a subset of 30976 compounds from the Molecular Library Probe Center Network (MLPCN) library. These validation screens showed hit rates of 0.16% and 0.5% against the LOPAC-1280 and partial MLPCN libraries, respectively. Screening of the full 300,000 compound Molecular Libraries is underway. Various bone- and endocrine-specific cell culture and animal models are in preparation for secondary and tertiary screening of compounds identified in HTS. Some of these compounds eventually may be developed into drugs for the treatment FD/MAS, as well as other gsp-mediated diseases.

Elevated sclerostin in individuals with High Bone Mass. Celia Gregson^{*1}, Kenneth Poole², Susan Steel³, John Ayuk⁴, Emma Duncan⁵, Eugene McCloskey⁶, William Fraser⁷, J.H. Tobias⁸. ¹University of Bristol, United Kingdom, ²University of Cambridge, United Kingdom, ³Hull & E Yorks Hospital Trust, United Kingdom, ⁴University Hospitals Birmingham NHS Foundation Trust, United Kingdom, ⁵Royal Brisbane & Women's Hospital, Australia, ⁶University of Sheffield, United Kingdom, ⁷Norwich Medical School, University of East Anglia, United Kingdom, ⁸Avon Orthopaedic Centre, United Kingdom

Introduction

Sclerosteosis is a rare autosomal recessive disorder associated with High Bone Mass (HBM), caused by a loss-of-function mutation in the *SOST* gene encoding sclerostin, an osteocyte-derived inhibitor of bone formation. We recently recruited a large cohort of HBM individuals from systematically searching DXA databases around the UK; although to date sequencing has not identified any *SOST* gene mutations, we hypothesized that disordered sclerostin production might contribute to raised BMD in this context.

Methods

406 HBM index cases were identified by screening DXA databases from 4 UK centres (n=219,088). HBM was defined as a) L1 Z-score of $\geq +3.2$ plus total hip Z-score of $\geq +1.2$ or b) total hip Z-score $\geq +3.2$. Cases with significant osteoarthritis and/or other causes of raised BMD were excluded. Relatives & spouses were recruited, in whom HBM affection status was defined as L1 Z plus total hip Z-score $\geq +3.2$. Controls comprised unaffected relatives & spouses. Total body DXA and sclerostin measurements were performed in all. None had parathyroid disease. Analyses used multiple linear regression in Stata 11, adjusting for gender, menopausal status, weight & height and subsequently age.

Results

As expected, sclerostin increased with age in HBM cases (151 index cases + 47 affected relatives) (0.66 [0.15, 1.17] p=0.01), and controls (87 unaffected relatives + 36 spouses) (1.08 [0.68, 1.47] p<0.001) (results show adjusted beta coefficients with 95% confidence interval, per yearly increase in age). Sclerostin was higher in HBM cases than controls, mean (sd) 89.6 (40.7) vs. 66.4 (32.3) pmol/L, p<0.001, which persisted after adjustment, mean difference 23.9 (15.6, 32.2) pmol/L, p<0.001. After adjustment, sclerostin levels were positively related to total body BMD amongst HBM cases (12.3 [6.6, 17.9] p<0.001) to a greater extent than controls (6.6 [0.9, 12.2] p=0.02) (β equals sclerostin increase per 0.1mg/cm³ increase in BMD [95%CI]), interaction p=0.02.

Conclusion

We conclude that sclerostin concentrations are increased in HBM cases when compared with controls and that the relationship between bone density and sclerostin is stronger in HBM cases than controls. Elevated bone density in HBM does not fully explain the associated increase in sclerostin, suggesting other factors are implicated.

Modest Reversal of Metabolic Syndrome Manifestations with Vitamin D Correction: A 12-month Prospective Study. Nasser Al-Daghri^{*}. King Saud University, Saudi Arabia

Background

Numerous cross-sectional studies have noted significant negative associations between circulating levels of vitamin D and cardio-metabolic risk factors, highlighting potential extra-skeletal functions of this steroid hormone. Prospective studies, however, have been limited and hence no cause and effect relations can be inferred. This study

aims to determine whether vitamin D correction can reverse already established manifestations of the metabolic syndrome (MetS).

Methods

A total of 59 adult non-diabetic, overweight and obese Saudis (65 males, 42 females) were randomly recruited in this prospective 1-year interventional study. Anthropometry and biochemical evaluation were performed, including determination of serum vitamin D, calcium and phosphorous concentrations, as well as fasting blood glucose and lipid profile. At the initial baseline visit, the prevalence of both low HDL-C and hypertension was significantly increased among patients with vitamin D deficiency (p<0.05), even after adjusting for gender and BMI. Subjects were advised to regularly expose themselves to sunlight and increase intake of vitamin D-rich foods. All measurements were repeated 6 and 12 months later.

Results

Overall prevalence of MetS patients by the modified NHANES ATP III definition decreased from 25.2 % to 13.0 % and this was largely due to a parallel decrease in the prevalence of low HDL-cholesterol, triglycerides and hypertension.

Conclusion

Optimization of vitamin D levels through sun exposure and increased intake of a vitamin D-rich diet can lead to an improved cardio-metabolic profile, offering a promising non-pharmacologic approach in the prevention of MetS manifestations.

Severity of Knee Osteoarthritis Correlates with Estradiol and Leptin Levels in Serum and Synovial Fluid of Osteoarthritic Patients. Shirin Hooshmand^{*1}, Jenna Schmidt², Bahram Arjmandi¹. ¹Florida State University, USA, ²Florida State University, USA

Currently 21 million Americans are affected by osteoarthritis (OA) and to date, neither its etiology is well understood nor are effective therapies to prevent or halt OA available. Aside from inflammation, current evidence suggests that there is a relationship between estrogen and the development of OA. Evidence also suggests that loss of body fat is more important to decrease risk of OA than general weight loss emphasizing the role of fat tissue and its secretions and suggesting a metabolic link between obesity and OA. Therefore, the overall goal of this project is to improve cartilage health by exploring the relationship between synovial fluid and serum concentrations of leptin and estradiol and the degree of OA. To achieve this goal, a total of 80 mobile men and women, between the ages of 45 and 75 years with knee OA who were going under arthroscopic surgery or total knee replacement recruited. Blood samples and synovial fluid aspirated from their knee joints were obtained by an orthopedic surgeon as part of their surgery. Synovial fluid and serum samples were analyzed in duplicate using ELISA method to determine the concentration of leptin and estradiol. Our findings show a distinct correlation between BMI and serum leptin levels in both males and females (R=0.505, p=0.02; R=0.569, p=0.008). We found that in both men and women, the degree of OA was associated with serum leptin concentrations (R=0.487, p=0.02; R=0.498, p=0.04). Our data shows that females have higher levels of leptin in both serum and synovial fluid than males. In our study, as the severity of OA increased in females, the estrogen level in both serum and synovial fluid also tended to increase. However, this relationship was not found in male patients with OA. Women with severe OA had significantly higher levels of E₂ in their synovial fluid while E₂ levels in synovial fluid of men were not affected with degree of OA. In women, BMI was significantly correlated with level of estrogen in synovial fluid and tended to be significantly correlated with E₂ levels in serum (R=0.49, p=0.03; R=0.39, p=0.1). Although our results are promising in terms of relation among leptin and estradiol levels in synovial fluid and serum and the degree of OA, further studies are needed to investigate the exact role of leptin and estradiol in increasing the severity of OA.

RANKL Over-Expression and Enhanced Bone Marrow Monocyte Response to RANKL Contribute to Low Bone Mass in Genetic Hypercalciuric Stone-Forming (GHS) Rats. Hongwei Wang^{*1}, Honggang Ye¹, Jinhua Wang¹, Soo Young Park¹, David Bushinsky², Murray Favus¹. ¹University of Chicago, USA, ²University of Rochester, USA

GHS rats are a useful model for human idiopathic hypercalciuria (IH), as both share increased intestinal Ca absorption and bone resorption, decreased renal tubule Ca reabsorption, Ca kidney stone formation and low BMD. Low bone mass is accompanied by changes in cortical bone that make it more brittle and fracture-prone. This study investigates the molecular mechanisms that may mediate low bone mass in GHS rats. Gene microarray analysis on bone marrow stromal cells (BMSC) revealed increased expression of several genes related to bone resorption including RANKL, RANK, GM-CSF, TNF α , and IL1, while genes related to bone formation (BMP2, Sppl, Sost) were decreased in GHS rats compared to Sprague Dawley (SD) control rats. Gene array analysis on splenic CD14⁺ monocytes from GHS and SD rats indicate that signaling pathways for VDR, TNF and IL-17 are up-regulated (CEBPB, CAMP, TNFR1 and IL-17R α). Real-time PCR results confirmed the microarray analyses. GHS rat bone marrow monocytes cultured in vitro with RANKL (100ng/

mL) showed greater stimulation of gene expression of osteoclast markers including integrin β , CAII, cathepsin K and TRAP. Mature osteoclast cell number increased 4.5 fold in GHS (vs SD) rats ($P < 0.05$). Mature osteoclasts from GHS rats were increased in number and individually larger compared to SD rats. Immunostaining demonstrated greater expression of RANKL in BMSCs from GHS rats. In conclusion, our results demonstrate that the low bone mass in GHS rats is due in part to greater RANKL expression in BMSCs, resulting in larger and more numerous osteoclasts. Suppression of osteoblast-specific genes suggests that decreased bone formation may also contribute to reduced BMD.

Disclosures: Hongwei Wang, None.

SU0162

Treatment of Tumor Induced Osteomalacia with CT-guided Percutaneous Ethanol Ablation and Percutaneous Cryoablation. Erik Olson, Sean Tutton, David King, Joseph Shaker*. Medical College of Wisconsin, USA

Tumor induced osteomalacia (TIO) is a rare condition often caused by a benign mesenchymal tumors (MT). Biochemical findings include hypophosphatemia (low P) with renal phosphate wasting (RPW) and 1,25(OH) $_2$ D levels which are lower than appropriate in the setting of low P. Production of FGF-23 by the tumor is often causal. In the absence of localization, medical therapy with phosphate salts and calcitriol results in improvement. When the tumor is found, resection results in biochemical and clinical resolution. Because of the risk of recurrence, wide excision (WE) has been advised.

A 51 YO M was evaluated in June, 2010. In February, 2008 he had a stress fracture of the right proximal femur which was treated with a total hip arthroplasty (THA). In February, 2010 he developed right knee pain and was found to have a stress fracture of the distal femur. He had weakness in his legs and slowing of gait. In January of 2009, he had a partial right nephrectomy for renal cell carcinoma. At that time, a lytic lesion was noted in the right iliac crest and was biopsied (consistent with reparative changes). On exam, he had weakness of the thigh flexors. There were no unusual skin lesions. The serum P was 1.4-1.7 mg/dl with RPW. The FGF-23 was high-normal. Reevaluation of the iliac lytic lesion was consistent with MT and immunocytochemistry was strongly positive for FGF-23. WE was advised, however, the prior THA complicated this option. The patient declined WE and opted for image-guided ablation (IA). He was treated with CT-guided percutaneous ethanol ablation (PEA) and cryoablation (PCA). This resulted in prompt normalization of P and FGF-23 as well as dramatic clinical improvement.

IA is established in the management of osteoid osteoma. In a prior report of IA for TIO, 2 ablations (RFA) were necessary and the 2nd RFA resulted in biochemical normalization. RFA uses radiofrequency energy to cause heating of tumor cells and has been associated with post-procedure pain. Many interventionalists have converted to PCA. We used a combination of PEA and PCA in an effort to prevent recurrence. Our patient appears to have had biochemical resolution, but will need long-term surveillance. In conclusion, we report a patient with a MT causing TIO who has had biochemical remission after IA. Although wide excision remains first-line therapy, IA may be an option in patients who cannot have or decline surgery.

What Is the Minimal Serum 25-hydroxyvitamin D (25-OHD) Level for Optimal Skeletal Mineralization?. Sudhaker Rao*, Shijing Qiu, Tarlisha Eskridge, Nayana Parikh, Saroj Palnitkar. Henry Ford Hospital, USA

Background: There is currently an intense debate on optimal serum 25-OHD level for skeletal and non-skeletal health. Implicit in the recent IOM report was its reliance on evidence, but very little is known about the relationship between 25-OHD (the best available index of vitamin D nutrition) and osteoid indices (a measure of mineralization), in otherwise healthy individuals. Accordingly, we examined the relationship between 25-OHD and osteoid indices in 85 healthy women who were part of a study on bone effects of age and menopause.

Methods: Acquisition and analyses of relevant data are published. In this study we examined the prevalence of mineralization defect defined as Osteoid Thickness (O.Th) $> 12.5 \mu\text{m}$, or Osteoid Surface/Bone Surface (OS/BS) $> 20\%$, or Osteoid Volume/Bone Volume (OV/BV; derived from O.Th and OS/BS) $> 2\%$, cut-offs based on patients with osteomalacia (OM), an unambiguous condition with mineralization defect, or secondary hyperparathyroidism due to vitamin D depletion. Mineralization Index (MI), a composite index derived from OS, O.Th, OV, bone formation rate and osteoid maturation time, was also calculated; an MI > 10 suggests OM.

Results: In the entire group or in the sub-sets of ethnicity and menopause, there was no regression of O.Th, OS/BS, OV/BV, BFR or MI, or age on 25-OHD (range 12-55 ng/ml). Although the intercepts for each biopsy variable were different in the sub-sets, none of the differences were significant. PTH was inversely related to 25-OHD ($r = -0.24$; $p < 0.02$), but none had PTH $> 72 \text{ pg/ml}$, suggesting that lower 25-OHD ($< 20 \text{ ng/ml}$) in some women were of recent nature. In women with 25-OHD $< 20 \text{ ng/ml}$ none of the biopsies showed O.Th $> 12.5 \mu\text{m}$, except one ($12.6 \mu\text{m}$). Biopsies with OV/BV $> 2\%$ were distributed similarly among three 25-OHD groups: < 20 (n=17), 20-30 (n=21) or > 30 (n=13) ng/ml, but none $> 5\%$ (a conservative estimate of mineralization defect) in $> 30 \text{ ng/ml}$ group. Number of biopsies with OS/BS $> 20\%$ were similar in the 2 lower groups (n=13 & 17 respectively), but much less in $> 30 \text{ ng/ml}$ group (n=6). The

increase in OV/BV $> 2\%$ was mainly due to an increase in OS/BS but not in O.Th, hallmark of OM. Finally, MI was < 10 in all, which excludes OM.

Conclusions: In healthy women, a 25-OHD of $> 20 \text{ ng/ml}$ appears sufficient for bone mineralization, with small additional effect up to 30 ng/ml . None had OM implying that it is a function of both the degree and duration of vitamin D depletion.

SU0164

Double Blind, Double Dummy, Randomized Controlled Trial of Oral Bisphosphonates (OB) in the Treatment of Active Pagets Bone Disease (PBD). Juan Carlos Barreira¹, Zulema Man², Claudia Gomez Acotto³, Emilio Roldan^{*4}. ¹Hospital Britanico, Argentina, ²Centro Medico TIEMPO, Argentina, ³Maimonides Univ., Argentina, ⁴Gador S.A., USA

The prevalence of PBD seems to be decreasing, notwithstanding subjects in the active phase (symptoms, plus abnormal biochemistry and positive scintigraphic images) demand intervention. Following previous criteria the suppression of bone resorption during 1-2 weeks promotes protracted post-treatment periods free of symptoms, and OB are adequate agents, but tolerability and a number of failures still cause concern. Hence olpadronate (OPD), the only soluble OB (crystal form A), showing previous rates of efficacy as high as I.V. therapies will be compared with the current accepted OB therapy in the country, pamidronate (APD), 400mg/day, during 4 months. OPD was administered at 200mg/day for only 12 days, randomized in a 1:2 schedule. Both formulations were double dummy with placebos in a group of 27 subjects with active PBD in spite of previous therapies. In a preliminary analysis 21 patients completed the protocol schedule, after 6 months mean bone sAP from basal was -39.4 % with APD, and -42.0 % with OPD (t test n.s.). Patients achieving normal values were 40.0 % with APD and 56.2% with OPD (Yates < 0.14). All patients with APD reported at least one digestive event, instead 39% of OPD patients were free of events (Fisher's $p < 0.05$). Although sample size limitations, because this is a rare condition, OPD performance, with a 10 fold shorter intervention, differs from APD being patients best controlled with the former compound. Hence, more patients are expected to benefit from this ultra short oral intervention with OPD.

Prediction of Paget's Disease of Bone Using Genetic Profiling. Omar Albagha^{*1}, W.D. Fraser², P.L. Selby³, Stuart Ralston¹. ¹University of Edinburgh, United Kingdom, ²Royal Liverpool University Hospital, United Kingdom, ³Manchester Royal Infirmary, United Kingdom

Paget's disease of bone (PDB) is characterised by focal increases in bone remodelling leading to bone pain and other clinical complications such as deformity, fracture, deafness, and osteoarthritis. Genetic factors are known to be important in PDB. Mutations in *SQSTM1* cause a high penetrance form of the disease but are only present in 10% of cases. In a recent genome wide association study we identified seven further loci that predispose to PDB risk on chromosomes 1p13, 7q33, 8q22, 10p13, 14q32, 15q24, and 18q21 by genome wide association study (Albagha *et al*, Nature Genetics, 2011 in press). Individually these loci increased the risk of PDB by 1.3 to 1.8 fold but together they had a large effect with a 10 fold difference in risk according to the number of risk alleles carried. Since PDB often presents after irreversible skeletal damage has already occurred, it would be advantageous to be able to identify high risk patients before the disease has become advanced so that prophylactic treatment can be given. The aim of this work was to evaluate the predictive power of genetic profiling in PDB using these markers, along with established risk factors such as family history and *SQSTM1* mutation status in 649 well-characterised PDB cases and 248 matched controls from the PRISM study. Each of these factors was entered into a predictive model and evaluated using receiver operating characteristic (ROC) curve analysis. Family history was found to predict the disease with a high specificity (97%) but poor sensitivity (13%) and accuracy (36%) and a total area under curve (AUC) of 0.55. Similarly, *SQSTM1* mutation status had high specificity (99.6%) but poor sensitivity (8%) and accuracy (33%) with an AUC of 0.54. The inclusion of both family history and *SQSTM1* mutation into the analysis was found to slightly improve the sensitivity (18%) and accuracy (40%) with limited changes in specificity (97%) and AUC (0.58). However, when risk allele scores were added to the analysis, we found a substantial improvement in both sensitivity (84%) and accuracy (70%) of the model with an AUC of 0.67, although specificity was lower (30%). This means that the combined model correctly identify the majority of true positive cases (84%), but a significant number of false positive cases were detected. This model was found to outperform the predictive value of bone mineral density with or without the FRAX algorithm in osteoporotic fracture prediction (AUC = 0.62 – 0.64; Bolland *et al*, JBMR, 2011). In conclusion our study has shown that genetic profiling may well be useful in predicting individuals at risk for developing PDB. Further studies are now indicated to investigate the feasibility of combining genetic testing with targeted therapeutic intervention to determine if this could prevent the development of morbidity in PDB.

Aortic Valve Calcification is Increased in Mild Primary Hyperparathyroidism. Marcella Walker*, Shinichi Iwata, Eiichi Hyodo, Zhezheng Jin, Rui Liu, Marco DiTullio, Shunichi Homma, Shonni J. Silverberg. Columbia University, USA

Aortic valve calcification is associated with cardiovascular death and myocardial infarction. Aortic valve calcification is a frequent complication of uremic secondary hyperparathyroidism, and although it was common in classical primary hyperparathyroidism (PHPT), little is known about aortic valve calcification in biochemically mild disease. 51 patients with mild PHPT (mean SD age: 617 yrs; serum calcium: 10.40.5 mg/dl; PTH: 8533 pg/ml) and 49 age- and sex-matched controls (age: 635 yrs) underwent echocardiography. Calcification area for each aortic valve leaflet was measured at mid-systole, and the sum of the calcification areas of all three aortic valve leaflets was calculated (aortic valve calcification area, AVCA) in both groups. Data were adjusted for cardiovascular risk factors. The peak transaortic pressure gradient was similar among PHPT patients and controls (62 vs. 62 mmHg; $p=0.2$). AVCA was, however, significantly higher in patients with PHPT (0.24 vs. 0.17 cm² $p<0.01$). AVCA was positively associated with PTH levels ($r=0.34$, $p<0.05$), while no association was found with serum calcium or 25-hydroxyvitamin D. Serum PTH level remained independently associated with AVCA after adjustment for cardiovascular risks known to affect aortic valve calcification (see table, Model R²=0.306; $p=0.037$). In this model, PTH was the only independently significant predictor, while traditional cardiovascular risk factors known to affect aortic valve calcification were not. PTH levels accounted for 17% of the known variance in AVCA. In summary, mild PHPT is associated with subclinical aortic valve calcification. PTH level, but not serum calcium concentration, is an independent predictor of AVCA. We conclude that in mild PHPT, PTH is a more important predictor of aortic valve calcification than well-accepted cardiovascular risk factors.

Asymptomatic Normocalcemic Primary Hyperparathyroidism: Characterization of a New Phenotype of Normocalcemic Primary Hyperparathyroidism. Natalie Cusano*, Patty Wang², Serge Cremers³, Elizabeth Haney⁴, Douglas Bauer⁵, Eric Orwoll⁴, John Bilezikian¹. ¹Columbia University College of Physicians & Surgeons, USA, ²Department of Medicine, Oregon Health & Science University, USA, ³Columbia University, USA, ⁴Oregon Health & Science University, USA, ⁵University of California, San Francisco, USA

Primary hyperparathyroidism (PHPT), a common endocrine disorder, is defined by elevated PTH and hypercalcemia. A newer presentation of PHPT has been described in which serum calcium (Ca) is normal and PTH is elevated, in the absence of secondary causes of hyperparathyroidism, such as renal disease or vitamin D deficiency. Recognition of this phenotype of PHPT, normocalcemic PHPT (NPHPT), supports a biphasic chronological time course, in which PTH levels are first elevated but serum Ca is normal, followed by the development of frank hypercalcemia. Although NPHPT was recognized by the Third International Workshop on the Management of Asymptomatic PHPT (JCEM, 2009), little is known about its epidemiology. Reports of NPHPT have largely come from referral centers in which subjects were seen for a metabolic bone disease. Our cohort of NPHPT came from patients referred to our metabolic bone disease unit and at diagnosis, 57% had osteoporosis by BMD and 11% had documented fragility fractures. We hypothesized that screening an unselected, non-referral population would identify asymptomatic subjects with NPHPT. The Osteoporotic Fractures in Men (MrOS) study is a cohort of US community-dwelling men ≥ 65 yrs at enrollment. We analyzed data from a random subset of 1504 men in whom PTH (Scantibodies IRMA, inter-assay CV 8.4%, intra-assay CV 5.6%) and serum Ca values were available. NPHPT was defined as serum PTH >66 pg/ml with normal albumin-adjusted serum Ca. 3 men were identified with hypercalcemic PHPT (excluded) and 45 had elevated PTH and normal serum Ca. We excluded all common secondary causes of hyperparathyroidism: renal

insufficiency (eGFR >40 cc/min, 12 excluded), vitamin D deficiency (<20 ng/mL, 17 excluded), and thiazide diuretic use (6 excluded). We identified 10 subjects (prevalence, 0.7%) with NPHPT as defined. There were no significant differences between subjects with and without NPHPT in terms of age, height, weight, BMI, phosphorus, bone turnover markers (P1NP, β CTX, TRAP5b), testosterone, estradiol, SHBG or femoral neck BMD (table). The men with NPHPT had a significantly higher lumbar spine BMD compared to the normal subjects (1.4 vs. 1.2 g/cm²; $p=0.01$), which may be due to the early anabolic effects of PTH on cancellous bone. The results identify an asymptomatic phenotype of NPHPT from an unselected community-dwelling cohort, which is distinctly different from previously described symptomatic cohorts.

Table. Characteristics of men with normocalcemic primary hyperparathyroidism (NPHPT) and comparison with normal men.

Parameter	Men with NPHPT (N = 10)		Normal men (N = 1481)		P value
	Mean \pm SD	Missing	Mean \pm SD	Missing

Basal Insulin Secretion is Correlated with Serum Undercarboxylated Osteocalcin (ucOC) Levels in Patients with Primary Hyperparathyroidism. Hisanori Suzuki*, Akira Takeshita¹, Megumi Miyakawa¹, Daishu Miura², Yasuhiro Takeuchi³. ¹Toranomon Hospital Endocrine Center, Japan, ²Department of Breast & Endocrine Surgery, Toranomon Hospital, Japan, ³Toranomon Hospital, Japan

Backgrounds: Osteocalcin (OC), a member of bone matrix proteins, is synthesized by mature osteoblasts. OC carboxylated by γ -carboxylase in a vitamin K-dependent manner is accumulated in bone matrix. Some OC molecules are not fully carboxylated or decarboxylated during bone resorption and released into circulation as undercarboxylated osteocalcin (ucOC) molecules. Recent animal studies have shown that ucOC could stimulate insulin secretion. However it remains unclear whether ucOC is actually involved in insulin secretion in humans. We have found serum ucOC levels are significantly higher in patients with primary hyperparathyroidism (pHPT) than controls.

Purpose: To clarify relationship between serum ucOC and insulin secretion in patients with pHPT.

Materials & Methods: We obtained data from clinical records of patients with pHPT who underwent parathyroidectomy at our hospital since April 2008. We analyzed data of fasting plasma glucose, insulin, biochemical bone markers [ucOC, OC, bone alkaline phosphatase, urine NTX], Ca, 1,25-dihydroxyvitamin D, intact PTH before surgery. Patients with diabetes mellitus or obesity (BMI more than 30) were excluded.

Results: We analyzed data of 22 patients in the present study. HOMA- β (homeostasis model assessment of β cell function) was significantly and positively correlated with ucOC, OC and bone alkaline phosphatase. HOMA- β had no correlations with BMI, age, Ca, intact PTH. HOMA-IR (homeostasis model assessment of insulin resistance) had no significant correlations with ucOC and OC. Among ucOC, OC and bone alkaline phosphatase, ucOC was indicated to be a predictor of HOMA- β with multiple regression analyses.

Conclusion: Basal insulin secretion estimated by HOMA- β is correlated with serum ucOC level at least in patients with pHPT. It is thus suggested that ucOC is involved in glucose metabolism via the regulation of basal insulin secretion in human.

CDKN1B/p27^{kip1} Gene: Sequence Analysis in a Group of Sporadic Parathyroid Adenomas. Claudio Marcocci¹, Elena Pardi², Simona Borsari², Benedetta Raspini², Elena Paltrinieri², Federica Saponaro², Chiara Banti², Antonella Picone², Piero Berti³, Paolo Miccoli³, Filomena Cetani¹. ¹University of Pisa, Italy, ²University of Pisa Department of Endocrinology & Metabolism, Italy, ³University of Pisa Department of Surgery, Italy

Primary hyperparathyroidism (PHPT) is one of the most common endocrine disorders, especially in postmenopausal women, in whom it reaches a prevalence of 2-3%, and in the majority of cases has a sporadic presentation. Independent genetic events were associated with the development of a subset of these tumors, namely cyclin D1 overexpression (20-40%), loss of heterozygosity at chromosome 11q13 (40%) and/or somatic mutations of MEN1 gene (15-20%). A number of other genes have been studied for pathogenetic mutations in adenomas, but none has been found. Breaks in cell cycle control is a key event in tumorigenesis. Cyclin D1 promotes the G1-S-phase transition, probably by activating a cyclin-dependent kinase, and menin, the protein encoded by MEN1 gene, is also involved in the cell cycle control through its participation in functional dynamics of chromatin and regulation of transcription. Recently has been proved that menin directly regulates expression of the cyclin-dependent kinase inhibitors like p27Kip1. Inactivating mutations in *CDKN1B/p27^{kip1}* gene have been recently described in 6 families affected by MEN1-like syndromes or related states. The aim of our study was to evaluate the role of the *CDKN1B/p27^{kip1}* gene in a group of sporadic parathyroid adenomas (n = 102). Tissues were snap frozen after surgery. DNA from parathyroid tumors was prepared by a commercial kit that includes a preliminary proteinase K treatment. DNA was PCR amplified with primers for the two coding exons of *CDKN1B/p27^{kip1}* gene and direct sequencing was performed with a BigDye Terminator chemistry. No pathological variation in the coding region, nor in the splice site junctions of *CDKN1B/p27^{kip1}* were detected. We identified three, already reported, polymorphisms: a nucleotide substitution 79 bases before ATG (rs34330), a non synonymous mutation at codon 109, changing a valine for a glycine residue (rs2066827) and a silence mutation at codon 142 (Thr142Thr). We also reported a novel polymorphism 80 bases before ATG (c.1-80C>T). Our results exclude a role in sporadic parathyroid tumorigenesis for *CDKN1B/p27^{kip1}*, even if we can't exclude alterations of the regulatory region of the gene or post-transcriptional mechanisms, such as methylation, that could have a role in impairing protein function.

Depression in Primary Hyperparathyroidism: Prevalence and Sustained Benefit of Parathyroidectomy. Rachel Espiritu, Ann Kearns, Kristin Vickers, Douglass, Clive Grant, Euijung Ryu, Robert Wermers*. Mayo Clinic, USA

Context: Most patients with primary hyperparathyroidism (PHP) in the current era lack classical manifestations of the disease. However, often patients with PHP report nonspecific symptoms involving disturbances in neuromuscular function, cognition, and mood.

Objective: To determine the frequency of depression in an adult PHP cohort using a validated depression questionnaire and assess its response to parathyroidectomy.

Methods: A prospective case-control study utilizing the Patient Health Questionnaire-9 (PHQ-9) was performed in observed (n = 81) and surgically treated (n = 88) patients with PHP and patients with benign non-toxic surgical thyroid disease (n = 85). The PHQ-9 was performed at baseline then once again at 1 month, 3 months, 6 months, and 12 months after surgery or after the initial questionnaire in the observed PHP group. The associations between PHQ-9 scores and serum calcium, PTH, and PHP clinical feature as well as response to surgery were assessed.

Results: The three groups were similar with respect to gender, history of depression, antidepressant use, and psychotherapy, but PHP patients were older. Baseline PHQ-9 scores were 1.71 points higher in PHP patients than controls after adjusting for age and gender (p = .004). Clinically significant PHQ-9 scores (≥ 10) were twice as common in PHP subjects (31.4%) compared to thyroid surgery subjects (15.3%). Parathyroidectomy resulted in significant and sustained reductions in PHQ-9 scores in patients with PHP, which were greater than was seen in observed PHP subjects at all time points (p < .001). PHP patients with clinically significant PHQ-9 scores dropped to 7.4% (p < .001) and 7.6% (p < .001) at 1 month and 1 year after parathyroidectomy with declines that were also significantly greater than seen in observed PHP subjects. When compared to thyroid surgery, there were greater declines in PHQ-9 scores in surgical PHP patients at 1, 3, and 6 months (p < .001) and 1 year (p = .061).

Conclusions: Depressive symptoms are more common and severe in patients with PHP compared to those without the disease. Parathyroidectomy results in significant improvement in depressive indices in PHP compared to thyroid surgery and observed PHP subjects. The PHQ-9 questionnaire may be a useful tool in the evaluation of PHP patients, and scores of > 10 or ongoing depression may be appropriate indications for consideration of parathyroid surgery.

Establishment of Parathyroid hormone (PTH) Reference Range on 10 Different Assay Kits: Impact of the Recruitment of the Population. Etienne Cavalier¹, Jean-Claude Souberbielle². ¹University of LiegeCHU Sart-Tilman, Belgium, ²Hopital Necker-Enfants malades, France

Introduction: Reference values (Rv) for serum PTH levels are generally obtained by measuring PTH in a population of apparently healthy subjects. Exclusion criteria for this population are important and should correspond to any causes of altered PTH secretion, including vitamin D (VTD) insufficiency, which is very frequent in the general population and thus should be prevalent in an apparently healthy group. However, excluding VTD insufficient subjects from the reference group requires measuring the 25-hydroxy vitamin D (25OHD) level in all subjects, which was not considered in most studies which provided serum PTH Rv for different immunoassays. Some studies have shown that this could decrease the upper normal limit for PTH by 25-35% depending on the assay considered. Thus, for a given PTH assay, the Rv may significantly vary, depending on the reference population that has been recruited, and especially whether the VTD status has been taken into account.

Objective: We used the same reference population of VTD-replete normal subjects to establish Rv for 10 commercial PTH kits and compare them with those provided by the manufacturers. We thus selected 120 women (48.615.2 y., min-max: 20-79), and 120 men (51.517.5 y., min-max: 19-80). All were Caucasians and apparently healthy. Inclusion criteria were a 25OHD concentration (DiaSorin Liaison) ≥ 75 nmol/L, serum calcium and phosphate levels comprised between 2.15 and 2.60 and 0.74 and 1.51 mmol/L, respectively, and an estimated GFR (MDRD formula) ≥ 60 mL/min/1.73 m². The use of drugs known to influence bone and calcium/phosphorus metabolism was an exclusion criteria.

Results: There was no significant difference in PTH levels nor in age between men and women in our reference population. With all the tested PTH assays, the distribution of the concentrations was Gaussian. The results that we observed were lower than the Rv provided by the manufacturers with an upper normal limit only slightly different for 3 kits (Abbott Architect, DiaSorin Liaison N-tact and Ortho Vitros) but frankly lower (21 to 46.1 % lower) for the 7 other kits. The difference was most important for the Beckman Access kit (-46.1%), the DiaSorin N-tact IRMA (-33.9 %), and the DiaSorin Liaison 1-84 kit (-32.8 %).

Conclusions: An important multicentre work should be performed to recruit a very extensive reference population of vitamin D-replete, apparently healthy subjects in order to establish the PTH Rv for all the available kits.

Germline and Somatic DNA Variants in Cyclin-Dependent Kinase Inhibitor Genes in Sporadic Parathyroid Adenomas. Jessica Costa-Guda¹, Chen-Pang Soong², Andrew Arnold². ¹University of Connecticut Health Center, USA, ²University of Connecticut School of Medicine, USA

The molecular pathology of sporadic parathyroid adenomas remains incompletely understood. The possibility that alterations in genes encoding cyclin-dependent kinase inhibitors (CDKIs) might contribute to the development of sporadic adenomas was initially raised by discovery of cyclin D1's pathogenic role, and then by the finding of rare germline variants in several CDKI genes in patients with multiple endocrine neoplasia type 1 and related familial, syndromic and/or multiglandular hyperparathyroid disorders. Indeed, a recent report has implicated *CDKN1B*, encoding p27^{kip1}, in the pathogenesis of sporadic adenomas through the identification of both predisposing germline sequence alterations and clonal, tumor-specific mutation; however, other CDKI gene family members have not been similarly analyzed. We therefore sought to determine whether mutations/variants in *CDKN1A*, *CDKN2B* and *CDKN2C*, encoding the p21, p15 and p18 CDKIs respectively, might also contribute to the development of typical parathyroid adenomas. The coding regions and intron-exon boundaries of *CDKN1A*, *CDKN2B* and *CDKN2C* were sequenced in a series of 80 adenomas from patients with typical, sporadic presentations of primary hyperparathyroidism, and the germline/somatic status of each identified variant was determined by sequencing matched germline control DNA. DNA variants were identified in 5 adenomas (6%). Two tumors contained distinct heterozygous variants of *CDKN1A*, one germline and one somatic. One patient had a *CDKN2B* germline alteration, accompanied by loss of the normal allele in the tumor (LOH). Two distinct variants of *CDKN2C* were identified in two cases, one somatic and the other a germline change accompanied by LOH. None of the identified DNA changes were found in the latest build of dbSNP (132), which includes data from the 1000 Genomes Project, predicted to contain most genetic variants that have frequencies of at least 1% in the general population. The finding of somatic alterations in *CDKN1A* and *CDKN2C* suggests a directly conferred selective growth advantage in parathyroid tumorigenesis. The presence of germline variants of multiple CDKI-encoding genes in patients with sporadic presentations provides additional evidence for the concept that rare predisposing alleles in this gene family may collectively make an important contribution to the development of typical parathyroid adenomas.

Relative Prevalence of Normocalcemic and Hypercalcemic Hyperparathyroidism in a Community-Dwelling Cohort. Claudia Berger^{*1}, Lisa Langsetmo², David Hanley³, Jonathan Adachi⁴, Christopher Kovacs⁵, Jacques Brown⁶, Robert Josse⁷, David Goltzman⁸. ¹McGill University, Canada, ²Canadian Multicenter Osteoporosis Study, Canada, ³University of Calgary, Canada, ⁴St. Joseph's Hospital, Canada, ⁵Memorial University of Newfoundland, Canada, ⁶Laval University, Canada, ⁷St. Michael's Hospital, University of Toronto, Canada, ⁸McGill University Health Centre, Canada

We assessed the prevalence of primary hyperparathyroidism in a cross-sectional sample of 1305 women and 566 men, aged 31-97, participating in the population-based Canadian Multicentre Osteoporosis Study (CaMos) during study year 10 (2005-2007). Samples were analyzed for PTH and 25-hydroxyvitamin D [25(OH)D] with a Diasorin Liaison machine and for calcium and albumin using an autoanalyzer. Laboratory-specified reference ranges were 2.13 to 2.60 mmol/L for serum calcium levels, 17.3 to 72.9 pg/ml for PTH, and 34 to 48g/L for albumin. Serum calcium was corrected for albumin when albumin levels were outside the normal range. Among those who had blood samples at year 10, samples were also available from 300 participants at baseline and 691 participants at year 5.

There were 444 participants (315 women and 129 men) with increased serum PTH and normal serum calcium at year 10. In these participants, serum 25(OH)D was <50nmol/L in 132, 50 to 75 nmol/L in 182, and >75nmol/L in 130. Assuming a lower limit of 25(OH)D of 50nmol/L, 70.3% of the participants with high PTH and normal serum calcium had evidence of "normocalcemic hyperparathyroidism", which represents 16.7% of the study population at year 10 (17.4% of the women and 15.0% of the men).

There were 12 participants (0.6% of the population) with concomitantly high PTH and high serum calcium. In this group, 4 had serum 25(OH)D<50nmol/L, 5 had serum 25(OH)D between 50 and 75nmol/L, and 3 had serum 25(OH)D>75nmol/L. Among 7 with earlier blood samples, 6 had normal serum calcium and elevated PTH levels in earlier measurements (entry in the study or Year 5). These studies suggest that the normocalcemic hyperparathyroidism at baseline may have progressed to subsequent hypercalcemic hyperparathyroidism.

These results indicate that concomitant elevated serum PTH and calcium, suggestive of primary hyperparathyroidism, is rare in this cohort, but may be observed even in those with low serum 25(OH)D. Normocalcemic hyperparathyroidism, however, is 27 times as prevalent, but the morbidity associated with this condition requires further study.

Repair of Fracture Nonunion Using a Combination of Low Dose rhFGF-2 and rhIGF-I; Case Report. Ashraf Moharam¹, Hsiu Ying Sherry Wang², Marina D'Angelo³, Abdulhafez Selim^{*4}. ¹Orthopedic Surgery, Cairo University School of Medicine, Egypt, ²Inspire Pharm, Egypt, ³Philadelphia College of Osteopathic Medicine, USA, ⁴Center for Chronic Disorders of Aging, PCOM, USA

Nonunion fractures present a challenge to orthopedics with no optimal solution. One of the greatest needs in the nonunion fractures field is a bioactive agent to stimulate bone formation. Fibroblast growth factor-2 (FGF-2) exhibited strong anabolic actions on angiogenesis and bone formation. IGF-I, another bone anabolic growth factor, is known to promote mesenchymal cell as well as osteoblast proliferation. Moreover, FGF-2 and IGF-I have synergistic effects of FGF-2 on the proliferation of human chondrocytes. Aiming at a clinical application, this study was undertaken to clarify the effect of a single local application of low doses of recombinant human FGF-2 and IGF-I on fracture healing. A fifty three year old healthy female was diagnosed with comminuted distal femur intercondylar fracture on May 2009. The patient was treated with fixation using single plate and nails. On May 2010, failure of fixation and evidence of nonunion was established by X-Ray and CT scan. Revision surgery was recommended. The patient was treated with fixation using double plating with synthetic calcium sulphate graft loaded with combination of rhFGF2 (500 microgram) and rhIGF-I (100 microgram). No side effects were observed postoperatively. Union was achieved 4 month postoperatively as evidenced by clinical and imaging. This is the first clinical case to show efficacy and safety of using low dose combination of FGF2 and IGF1 loaded on a synthetic carrier that had achieved union on a previously nonunion fracture.

Daily Activity and Tests of Muscle Strength Are Associated With Fractures in Stage 3-5 Chronic Kidney Disease. Sarah West^{*1}, Charmaine E. Lok², Maryum Chaudhry², Scott G. Thomas¹, Sophie Jamal¹. ¹University of Toronto, Canada, ²Toronto General Hospital, Canada

Purpose: Fractures are common in patients with chronic kidney disease (CKD). Tests of neuromuscular function (NMT) discriminate well among fractured and non-fractured patients with stage 5 CKD on dialysis. The ability of NMT and daily activity to discriminate among fracture status in men and women with stages 3-5 CKD is unknown.

Methods: We utilized baseline data from an ongoing prospective study of patients, age ≥18 yrs, with stages 3-5 CKD (using NKF criteria by MDRD eGFR) to determine if NMT (the timed up and go test [TUG] and 6 minute walk test [6MW]), and/or daily activity (sedentary, light, or moderate/vigorous activity measured by triaxial accelerometry [StayHealthy, RT3]) could discriminate among those with and without fractures (self-reported low trauma fractures after age 40 and/or prevalent vertebral fractures identified by morphometry). Results are expressed as areas under the receiver operating characteristic curves (AUROC) with 95% confidence intervals (CI), adjusted for age and weight.

Results: Data was available for 128 men and 86 women; of these, 32 completed accelerometry. Compared to non-fractured patients (n=143), those with fractures (n=70) were older (5916 vs. 6914 yrs, p<0.001), had a reduced 6MW distance (335.587.1 vs. 289.9142.2 m, p=0.04), and participated in more sedentary and less light daily activity (min/day, p<0.05). All other demographic variables were similar among those with and without fractures. The mean weight of study subjects was 79.919.8 kg, most were Caucasian (70.0%), over 40% had diabetes, and 74% patients were categorized into stage 4 or 5 CKD. The mean duration of CKD was 8.010.3 yrs, and 30.2% reported a fall in the past 12 months. The TUG (mean 12.35.7 sec) was able to discriminate among those with and without fractures (AUROC: 0.70 [95% CI: 0.61-0.80]), as was the 6MW test with an AUROC: 0.69 (95% CI: 0.59-0.80). As determined by accelerometry, sedentary activity (min/day) was able to discriminate fracture status (AUROC: 0.71 [95% CI: 0.51-0.93]), as was light activity (min/day), which gave an AUROC of 0.76 (95% CI: 0.56-0.95).

Conclusions: NMT and accelerometry can discriminate among those with and without fractures. The AUROC was greater for more sensitive tests of daily activity, i.e. accelerometry, indicating that in early stages of CKD more sensitive tests of

physical function may be the best tool to discriminate among those with and without fractures. Further prospective studies are needed.

Evidences That PTH Can Be Directly Involved In The Regulation Of The Secreted Frizzled Related Proteins (sFRPs) And The Wnt Signaling Pathway. Natalia Carrillo-Lopez¹, Lucía Martín-Gutiérrez¹, Pablo Roman-García¹, Sara Panizo¹, Manuel Naves-DÚaz¹, Jorge Cannata Andía². ¹Bone & Mineral Research Unit. Hospital Universitario Central de Asturias. Instituto Reina Sofía de Investigación. REDinREN del ISCIII. Universidad de Oviedo. Oviedo, Asturias, Spain, ²Hospital Universitario Central de Asturias, Spain

PURPOSE: The aim of this study was to evaluate *in vivo* and *in vitro* the effect of different degrees of secondary hyperparathyroidism (sHPT) and different PTH concentrations on bone turnover-related and Wnt pathway signaling-related gene expression.

METHODS: In the *in vivo* study, chronic renal failure (CRF) was induced in 36 rats by 7/8 nephrectomy then, rats were divided in 2 groups, one was fed normal phosphorus (P) diet (NPD) (0.6% P) and other was fed high P diet (HPD) (0.9% P). A group with normal renal function and NPD diet was used as reference group. Rats were sacrificed at 8, 16 and 20 weeks. Blood samples were collected and the left tibia was removed to assess bone turnover-related and Wnt pathway-related gene expression. In the *in vitro* study, UMR-106 cells were grown in DMEM (with standard P concentration) with 10% FCS and then exposed to vehicle (ethanol) or different concentrations of PTH (1-34) (10^{-8} , 10^{-7} and 10^{-6} M) for 24 hours in the culture medium. Cells were collected and total RNA was extracted to study bone turnover-related and Wnt pathway signaling-related gene expression.

RESULTS: After 20 weeks, CRF rats fed HPD diet showed a remarkable significant increase in serum PTH and P levels, together with a significant decrease in serum calcium (table 1). The bone gene expression of bone turnover markers was significantly increased (table 2). Moreover, secreted Frizzled Related Protein (sFRP) 1, 2 and 4 and Dkk1 (inhibitors of the canonical signaling of Wnt pathway) were significantly over-expressed (table 2). In the *in vitro* study, cells exposed to PTH were able to significantly increase FGF23, osteocalcin, OPG, Cbfa1 and cathepsin K gene expression in a concentration dependent manner (table 3). As in the *in vivo* experiments, PTH was able also to significantly increase sFRP1, 2 and 4 gene expressions in a concentration dependent manner; however Lrp5 and Dkk1 did not show changes (table 3).

CONCLUSIONS: *In vivo*, the increase in PTH was associated with a significant increase of genes involved in bone turnover. In addition, an increased expression of the Wnt signaling pathway-related genes (including the inhibitors of the pathway) was observed. *In vitro* results confirmed part of the *in vivo* results, demonstrating for the first time that PTH directly increase the sFRPs, suggesting that PTH is directly involved in the sFRPs and Wnt pathway signaling regulation.

Role of Akt-eNOS Signal Pathway in the Endothelial Dysfunction induced by Chronic Kidney Disease with Hyperphosphatemia. Tan Vu Van¹, Yutaka Taketani¹, Eriko Watari¹, Tomoyo Kitamura¹, Ken-Ichi Miyamoto², Hironori Yamamoto³, Eiji Takeda⁴. ¹University of Tokushima, Japan, ²Tokushima University School of Medicine, Japan, ³University of Tokushima, Japan, ⁴University of Tokushima School of Medicine, Japan

Generally, endothelial dysfunction plays a pivotal role in the development and progression of atherosclerosis, even in the chronic kidney disease (CKD) patients. Accumulation of endogenous inhibitor for endothelial nitric oxide synthase (eNOS) such as asymmetric dimethylarginine (ADMA) has been accused of accelerating progression of arteriosclerosis and increasing cardiovascular morbidity and mortality in CKD patients. In addition, recent studies have demonstrated that hyperphosphatemia can be involved in endothelial dysfunction as well as vascular calcification, suggesting that would be a linking mechanism between cardiovascular disease and CKD-MBD. However, it has not been clarified the detailed mechanism how hyperphosphatemia deteriorate endothelial function. In this study, we investigated the effect of lowering serum phosphate (P) level by dietary P restriction on the phosphorylation of eNOS and Akt in the adenine-induced CKD rats with hyperphosphatemia. Treatment with 0.75% adenine-containing diet for 3 weeks caused hyperphosphatemia, and decreased the phosphorylations of both eNOS at 1177 and Akt at 473 in the rat thoracic aorta with significant decrease in acetylcholine-dependent vasodilation. Lowering serum P levels by the treatment of

dietary P restriction for 2 weeks ameliorated not only the impaired vasodilation, but also the phosphorylations of eNOS at 1177 and Akt at 473. However serum ADMA, BUN, and creatinine levels were not improved by the ingestion of low P diet. These observations suggest that Akt-eNOS signal pathway plays an important role in the pathogenesis of endothelial dysfunction in CKD. In addition, hyperphosphatemia may be involved in the down-regulation of Akt-eNOS signal pathway in CKD. Treatment of hyperphosphatemia may be beneficial for vascular health by, at least, activating Akt-eNOS signal pathway.

Adipocytokines Affect the Bone Metabolism of Rheumatoid Arthritis Patients-TOMORROW study. Yuko Sugioka*, Tadashi Okano, Masahiro Tada, Tatsuya Koike. Osaka City University Medical School, Japan

Introduction: Adipocytokines may be implicated in the pathophysiology of rheumatoid arthritis (RA), but the relationship among adipocytokines, inflammation and bone metabolism remain unproven. We conducted a prospective cohort study to evaluate risk factors in RA patients associated with disease activity (Total Management Of Risk factors in Rheumatoid arthritis patients to IOWer morbidity and mortality: TOMORROW study, UMIN000003876). This study was designed to evaluate serum adipocytokines (adiponectin and leptin) concentrations in relation to inflammatory markers and bone mineral density in RA patients. Here we report the cross-sectional analysis at baseline.

Subjects and methods: Two hundred eight RA patients (112 patients received biologic agents and 96 patients received conventional therapy) and 205 age, sex-matched healthy volunteers (control) were enrolled in this study. Serum levels of adipocytokines and bone mineral density (whole body dual X-ray absorptiometry, Hologic QDR-4500) were measured.

Results: Subjects included 349 females and 64 males with a mean age of 57.9 (20.9-79.3) years. Serum level of both leptin and adiponectin were higher in RA patients than control ($p < 0.01$). Also RA patients showed higher fat rate, lower whole lean mass, and lower BMDs of spinal and extremities. Adiponectin levels inversely correlated with BMDs of thoracic vertebra and lower extremities ($r = -0.319$, $r = -0.364$, $p < 0.001$) and positively correlated with disease activity score (DAS) 28 ($r = 0.248$, $p = 0.003$). Serum adiponectin was negatively associated with thoracic spine ($\beta = -0.143$, $P = 0.022$) and leg ($\beta = -0.114$, $P = 0.034$) BMDs after adjusting for age, BMI, disease duration, DAS28-ESR, and whole lean mass (Table). In RA patients, leptin concentrations significantly correlated with % of fat rate ($r = 0.719$), but with neither disease activity nor bone mineral density.

Conclusion: The results confirm adiponectin concentrations were associated with the disease activity and bone mineral density. Whether adiponectin plays a pro-inflammatory role or simply concentrates in the presence of inflammation is unclear. Leptin has been reported to promote immune response. However, no correlation was identified between leptin and disease activity in our study. Leptin levels only reflected body composition. Further longitudinal study should give the insight for relationship of RA and adipocytokines.

Bariatric Surgery Results in Significant Loss of Cortical Bone. Emily Stein^{*1}, Polly Chen², Angela Carrelli³, Donald McMahon¹, Kavita Pandit², Marc Bessler², Beth Schroppe², Elizabeth Shane¹, Shonni Silverberg². ¹Columbia University College of Physicians & Surgeons, USA, ²Columbia University, USA, ³New York Presbyterian- Columbia University, USA

Background: Substantial bone loss at weight bearing sites occurs after bariatric surgery, but the underlying mechanism and significance of this loss are not known. Recent reports of increased fractures following bariatric surgery raise concern that bone quality may be compromised.

Methods: This prospective study assessed changes in bone density and microarchitecture following bariatric surgery. Subjects undergoing Roux-en-Y gastric bypass (RYGB) and gastric banding (GB) were evaluated at the time of surgery and at 12 months post-operatively. Areal bone mineral density (aBMD) at the lumbar spine (LS), total hip (TH), femoral neck (FN) and 1/3 radius (1/3R) was measured by dual energy x-ray absorptiometry. Trabecular (Tb) and cortical (Ct) volumetric BMD and microstructure at the distal radius and tibia were measured by high resolution peripheral quantitative computed tomography (HRpQCT, voxel size ~82 μm).

Results: 14 women (age 43.10 yrs, 21% Caucasian, 64% Latina, 14% African American or mixed race, mean BMI 45.6 kg/m²) were enrolled. Ten subjects underwent RYGB and 4 GB. Mean weight loss was 283 kg ($p < 0.0001$). At baseline, mean T-scores were normal at all sites (LS:-0.10.3, TH:0.70.2, FN:0.10.2, 1/3R:0.10.3). aBMD decreased by 5.5% at the TH and 5.6% at the FN ($p < 0.01$ for both). There was no significant change in BMD at the LS or 1/3R. The amount of bone loss at the total hip was associated with the extent of weight loss ($r = 0.66$, $p < 0.01$). As expected, women who underwent RYGB had greater weight loss (RYGB:-34 kg vs GB:-16 kg; $p < 0.004$) and bone loss at the TH (RYGB:-8.1% vs GB:-0.9%; $p < 0.002$) and FN (RYGB:-8.2% vs GB:-0.8%; $p < 0.02$). Microarchitecture was assessed in RYGB. There were no significant changes at the radius on HRpQCT, mirroring the lack of change seen by DXA at non-weight bearing sites. However, HRpQCT revealed significant declines in cortical bone at the tibia. Ct area decreased by 3.3% ($p < 0.03$), Ct density by 2.2% ($p < 0.03$), and Ct thickness by 2.7% ($p < 0.04$). No significant changes in trabecular density or microstructure were observed.

Conclusions: Bone loss after bariatric surgery occurs at weight bearing sites by DXA (TH and FN but not LS or 1/3R) and HRpQCT (tibia but not radius). The small but consistent and significant microarchitectural changes we have observed suggest that cortical bone loss at weight bearing sites may explain the increased propensity to appendicular fractures in this population.

Expression of DKK-1 and Sclerostin in Osteoarthritis. Allahdad Zarei^{*1}, Cyrus Cooper², Muhammad Javaid³, Afsie Sabokbar⁴. ¹Botnar Research Centre, University of Oxford, United Kingdom, ²University of Southampton, United Kingdom, ³University of Oxford, United Kingdom, ⁴University of Oxford, Botnar Research Centre, United Kingdom

Osteoarthritis (OA) is the commonest arthritis in the elderly, and the characteristic changes of OA involve both changes in subchondral bone as well as cartilage. The current phenotyping of the bone response in OA is incompletely understood but the Wnt pathway has been implicated in osteophyteogenesis. The purpose of this study was to assess and correlate the differential expression of Dickkopf-related protein 1 (DKK-1) and sclerostin (*SOST*), natural antagonists of the Wnt signalling pathway, in osteocytes in patients with end stage OA.

Bone core samples (6 x 15mm) were obtained from specific regions for each excised femoral head at the time of hip arthroplasty for OA. These regions were identified as F1: where complete absence of cartilage and deeply fissured subchondral bone was noted; F2: where there was margin of full thickness deficit; F3: this core sample was taken through the base of osteophyte and F4: represented the normal, macroscopic undamaged cartilage from the same femoral head. Bone samples were fixed in formalin, decalcified in EDTA, embedded in paraffin and 4μm sections were examined histologically and stained immuno-histochemically for DKK-1 and *SOST*.

Our data suggested that the expression of DKK-1 and *SOST* by osteocytes, inversely correlated with the local severity of OA within the same femoral head, as assessed using macroscopic, clinical and histological grading system. DKK-1 and *SOST* expression was most clearly noticeable in osteocytes in the normal/macroscopically undamaged bone or cartilage (F4 cores). In the complete absence of cartilage (F1 core) or samples taken from the base of the osteophytes (F3 cores), the expression of DKK-1 and *SOST* was not evident in osteocytes. In summary, we have shown that cortical and trabecular bone are active compartments in the disease process of OA and that DKK-1 and *SOST*, molecules involved in the down-regulation of bone formation, are differentially expressed in the same femoral OA hip. Furthermore, this is the first study to report DKK-1 expression by osteocytes in osteoarthritic bone.

Long Term Anti TNF α Therapy for Inflammatory Rheumatic Disease is Associated with Increased Bone Mineral Density and Paradoxical Elevation of TRAP5b Serum Levels. Eric Toussiot*¹, Laurent Mourot², Emilie Grandclement³, Daniel Wendling⁴, Gilles Dumoulin⁵. ¹University Hospital J Minjoz, France, ²EA3920 Physiopathologie Cardiovasculaire et Prevention, France, ³Explorations fonctionnelles et biochimie endocrinienne et metabolique, France, ⁴University Hospital Minjoz, France, ⁵Explorations fonctionnelles et biochimie hormonale et metabolique, France

Purpose: Rheumatoid arthritis (RA) and ankylosing spondylitis (AS) are inflammatory rheumatic diseases associated with increased risk of fractures, low bone mineral density (BMD) and increased levels of markers of bone resorption with normal or decreased values for bone formation markers. Anti-TNF α agents are very effective in treating clinical symptoms of RA and AS and suppressing inflammation.

Objectives: we evaluated the long term changes in bone mass and metabolic bone markers in patients with RA or AS while receiving anti-TNF α agent.

Patients and Methods: 20 patients (6 F) were evaluated (12 AS [modified NY criteria], age [mean SD]: 40.7 16.1 yrs; and 8 RA [ACR criteria], age 60.5 9.7 yrs; disease duration: 9.6 9.8 yrs). They all received anti-TNF α agent (adalimumab: 12; etanercept: 6; infliximab: 2). At baseline and at 1, 3, 6, 12, 18 and 24 months (M) after initiating anti-TNF α treatment, we measured both serum tartrate resistant acid phosphatase isoform 5b (TRAP5b, EIA, Quidel) and bone alkaline phosphatase (BAP, RIA, Beckman), as enzymatic markers of osteoclast and osteoblast, respectively, as well as serum beta CTX-I (EIA, IDS Nordic Bioscience), as marker of bone resorption. Serum osteocalcin (OC; RIA, Cisbio) and P1CP (Quidel) were measured as markers of bone formation. Osteoprotegerin (OPG, EIA, Quidel), an inhibitor of bone resorption was also evaluated. BMD at the lumbar spine and the hip was measured at baseline and after 6, 12 and 24 M by DEXA (iDXA, Lunar). No patients had bisphosphonate treatment. Nine patients were under low dose corticosteroids (< 10 mg prednisone).

Results: All the patients responded to the treatment with clinical improvement and decline in erythrocyte sedimentation rate ($p=0.006$) and CRP levels ($p=0.003$). Compared to baseline, lumbar spine and hip BMD at M24 increased (+ 6.3% and + 2.4% respectively), with significant changes at the spine ($p<0.001$). Beta CTX-I and OPG remained stable over the 24 M period while we observed a progressive and marked increase in TRAP5b (baseline: 1.21 0.74; M24: 2.44 1.05 U/L) ($p<0.001$). BAP also increased at M3 but not significantly. OC and P1CP similarly increased at M1 and M3 with significant change for P1CP ($p=0.04$), then returning to baseline values.

Conclusion: This study confirms the beneficial effects of anti-TNF α agents on BMD, mainly at the lumbar spine. On the contrary of previous study, we did not observe a decrease in bone resorption markers (beta CTX-I) but we found a paradoxical increase in TRAP5b. By contrast, bone formation markers (BAP, OC) were unchanged or transiently increased (P1CP). These results suggest that anti-TNF α agents may increase osteoclast activity, but without stimulation of bone resorption since there was no parallel increase of beta CTX-I and no deleterious effect on BMD. We conclude that prolonged treatment with TNF α blocking agents has a favorable effect on bone mass in patients with RA or AS.

Disclosures: Eric Toussiot, None.

Safety of High Dose Vitamin D Therapy in Lung Transplant Recipients. Caroline Ball*¹, Daniel Dilling², Charles Alex², Pauline Camacho³. ¹Loyola University Chicago Stritch School of Medicine, USA, ²Loyola University Medical Center, USA, ³Loyola University of Chicago, USA

Introduction: Vitamin D deficiency is highly prevalent in lung transplant patients. We previously reported a prevalence of 80% among pre-transplant and 77% among post-transplant patients (ASBMR 2009). The standard therapy utilized in our institution is ergocalciferol at 50,000 IU weekly followed by every other week or lower doses determined by repeat levels at 3 months. We recommend 1200-1500 mg calcium per day. In non-transplant patients vitamin D toxicity as evidenced by hypercalcemia is virtually nonexistent at this dose. However, we have noted higher rates of hypercalcemia in transplant recipients. It is not clear whether this occurs due to interaction with transplant medications. No prior studies have looked at the safety of high dose vitamin D therapy after transplantation.

Methods: This is a retrospective study of 98 lung transplant patients from 2005 to 2010. Baseline information gathered from the electronic medical records included patient age and sex, reason for transplant, 25 OH-vitamin D, serum total and ionized calcium, PTH and creatinine. Treatment regimens with ergocalciferol and calcium were documented for 6 months following transplantation. Hypercalcemia was defined as serum calcium (CA) over 10.5 mg/dL or ionized calcium (ICA) over 1.3 mmol/L.

Results: 61 of the 98 (62%) lung transplant patients were treated for Vitamin D deficiency. One patient was excluded from the study because of sarcoidosis. The cohort consisted of 34 female and 27 male patients with a mean age of 51.57 14.37. Mean 25 OHD was 30.92 15.51 ng/mL, CA was 8.95 0.57 mg/dL, ICA was 1.20 0.11 mmol/L, PTH was 78.09 116.2 pg/mL and creatinine was 0.89 0.39 mg/dL. 6 patients (9.84%) treated for Vitamin D deficiency developed hypercalcemia, with a mean CA of 9.03 0.71 mg/dL and ICA of 1.32 0.05 mmol/L within 6 months of surgery. Of

these 6 patients 4 were female and 2 were male. The mean creatinine was 1.60 mg/dL. Hypercalcemia was documented at 74 41 days post-transplant. There were no demographic differences between patients who developed hypercalcemia and those who did not.

Conclusions: The data suggests that lung transplant recipients, in comparison to the general population are at a slightly higher risk of hypercalcemia with high dose vitamin D therapy, and in particular those who develop renal insufficiency post-transplant. Cautious utilization of vitamin D and monitoring of serum calcium and creatinine levels will help avoid vitamin D toxicity.

Cell Density Governs Self-Organization into Patterns in Calcifying Vascular Cells. Henry Cheng*¹, Aneela Reddy¹, Andrew Sage², Alan Garfinkel¹, Yin Tintut¹, Linda Demer³. ¹University of California, Los Angeles, USA, ²University of Cambridge, United Kingdom, ³David Geffen School of Medicine At University of California Los Angeles, USA

In embryonic development, formation of patterned biological structures such as bone and vasculature may occur via the phenomenon of reaction-diffusion, in which a morphogen pair (activator and inhibitor) guides cells into periodic patterns. This mechanism has been posited in bone development and vascular calcification, and recent studies identified the morphogen pair as BMP-2 and MGP. We previously showed that calcifying vascular cells, which undergo osteochondrogenic differentiation and mineralization, also self-organize into periodic patterns of swirls, spots, or labyrinths as computationally predicted by a reaction-diffusion model. To test the model prediction that local cell density affects cellular self-organization, we varied cell-plating density using cloning rings and monitored the rate of progression and types of patterns formed.

Calcifying vascular cells were seeded onto 6-well plates (2×10^4 cells/well). At confluence (2 days), a 1 cm cloning ring was placed in each well, and a second set of cells was plated (at range of densities from $2 - 32 \times 10^4$ cells/well) within the cloning rings. A second, control ring with no added cells was placed elsewhere in each well. After 2 days, the cloning rings were removed, and the pattern formation was monitored daily for 8 days by phase-contrast photomicrography.

Within the cloning ring site, cells organized at steady-state into a pattern of spots, consisting of discrete raised nodules, clearly distinct from the labyrinthine pattern formed in the surrounding monolayer and at the sites of the control rings, largely consistent with the model predictions. When the second layer was plated at a cell density of 2×10^4 , the cells progressed from a uniform monolayer at day 2 to a swirling pattern (local alignment) at day 4, a labyrinthine pattern at day 6, and discrete spots by day 7. The rate of pattern progression from swirls to spots increased with increasing cell density. The relationship between cell density and rate of pattern progression from swirls to spots was nonlinear. At a density of 16×10^4 the relationship between density and progression saturated.

These findings suggest that cell density strongly influences the rate of self-organization and pattern formation via reaction-diffusion in calcifying vascular cells, a type of osteoprogenitor cell. This phenomenon may contribute to mechanisms of embryonic development of patterned structures, such as the vasculature and skeletal bone.

Toluidine blue stain shows spot pattern in site of higher cell density (A) but labyrinthine pattern in control ring (B) and well monolayer.

Loss of Equilibrative Nucleoside Transporter 1 (ENT1) Leads to Progressive Hypermineralization of Paraspinal Tissues: A Novel Murine Model Resembling Diffuse Idiopathic Skeletal Hyperostosis (DISH) in Humans. Derek Bone, Sumeeta Warraich, Diana Quinonez, David Holdsworth, S. Jeffrey Dixon*, Cheryle Seguin, James Hammond. The University of Western Ontario, Canada

DISH is a non-inflammatory spondyloarthropathy, characterized by calcification of joint capsules, ligaments and entheses, especially in paraspinal tissues, that occurs in 6-12% of North Americans, most over the age of 50. Symptoms include spine pain and stiffness and, in severe cases, dysphagia and compression of the spinal cord and nerve roots. The etiology of DISH is unknown and there are no specific treatments. ENT1 is a protein that transfers hydrophilic nucleosides such as adenosine across the plasma membrane of many cell types. In mice lacking ENT1 (KO), we observed the development of calcified lesions with remarkable resemblance to DISH in humans. At 8-12 months of age, KO mice exhibited signs of spinal stiffness, hind limb dysfunction and eventually paralysis. MicroCT analyses of KO mice revealed hypermineralized lesions starting in the cervical-thoracic spine that extended to the lumbar region with advancing age. Eventually, aberrant mineralization (with density exceeding that of cortical bone) bridged the vertebrae. Histological examination of decalcified samples revealed large, irregular accumulations of eosinophilic, amorphous material in paraspinal and intervertebral regions with no apparent inflammation. Severe lesions involved intervertebral discs and impinged on the spinal cord, leading to compression that was likely the source of the paresis and paralysis observed in aged KO mice. We found no evidence for ectopic mineralization of appendicular joints or blood vessels, indicating tissue specificity. HPLC analyses of plasma showed a 2.8-fold increase in adenosine levels in KO compared to wild-type mice. In contrast, there were no significant differences in levels of the adenosine metabolites xanthine or uric acid, arguing against lesions being due to deposition of monosodium urate crystals. The large difference in plasma adenosine levels is consistent with loss of function of ENT1 – one of the primary uptake pathways for adenosine into cells. Together, the remarkable radiographic, histological and spatiotemporal similarity of lesions in KO mice and DISH patients suggests a link between loss of ENT1 function and development of DISH. Our findings validate the ENT1 KO mouse as a disease model, providing – for the first time – a means to investigate mechanisms underlying ectopic mineralization of paraspinal tissues and, eventually, to evaluate therapeutics for preventing pathological calcification in DISH and related disorders in the elderly.

Severe Skeletal Toxicity from Protracted Etidronate Therapy for Generalized Arterial Calcification of Infancy (GACI). Gary S. Gottesman*¹, Jesse E. Otero², William H. McAlister³, Katherine L. Madson¹, Steven Mumm⁴, Michael P. Whyte⁴. ¹Shriners Hospital for Children, St. Louis, USA, ²Washington University in St. Louis School of Medicine, USA, ³Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, USA, ⁴Shriners Hospital for Children & Washington University School of Medicine, St. Louis, USA

We report a 7-year-old boy with GACI (OMIM #208000) who was treated life-long with etidronate (EHDP) at another facility and was referred for severe skeletal dysmorphism. GACI is an autosomal recessive disease caused by loss-of-function mutations in the ectonucleotide pyrophosphatase/phosphodiesterase-1 gene (ENPP1: OMIM #173335). Decreased ENPP1 activity leads to low extracellular inorganic pyrophosphate (ePPi) and vascular mineralization with hydroxyapatite deposition in elastic fibers of arteries. If untreated with EHDP, 85% of patients die by age 6 months from cardiac ischemia and congestive heart failure. Survivors have normal skeletons although some arterial and peri-articular calcification may persist. Rickets can appear with chronic EHDP exposure.

EHDP, a 1st-generation bisphosphonate analog of PPI, inhibits both skeletal mineralization and resorption, eliminating arterial calcification in GACI by 2 weeks to 2 years of therapy. EHDP is then stopped. Our patient's arterial calcification resolved by age 6 months, yet intra- and peri-articular calcifications progressed. He remained on EHDP (200 mg/day).

At our research center, he had odynodysphagia, opioid-controlled body pain, facial asymmetry, plagiocephaly, proptosis, and joint contractures leaving him wheelchair bound. Biochemical parameters of mineral and skeletal homeostasis including serum calcium, phosphate, 1,25(OH)₂D, PTH, and total and bone-specific alkaline phosphatase were essentially normal. Osteocalcin was low suggesting reduced skeletal turnover. Radiographs revealed cranial synostosis, long-bone bowing, widened physes with osteosclerosis and "tongues" of radiolucency, along with metaphyseal cupping and fraying reminiscent of pediatric hypophosphatasia (Fig. A). Erlenmeyer flask deformity of the femurs, elevated serum creatine kinase (brain isoform) and TRAP-5b, and lumbar spine osteosclerosis along with a DEXA z-score of +5.7 suggested EHDP-induced osteopetrosis (Fig. C, D). ENPP1 gene analysis revealed an apparent homozygous mutation (c.653A>T, p.Asp218Val). Six weeks after cessation of EHDP his skeleton showed marked improvement (Fig. B).

Our patient with GACI, treated life-long with high-dose EHDP, showed profound but reversible inhibition of skeletal mineralization and decreased resorption. Although EHDP is life-saving in GACI, surveillance for resolution of arterial

calcification and the development of rickets is paramount to prevent severe skeletal toxicity.

Figure. EHDP-induced rickets in a boy with GACI.

(A) Left wrist at 6-11/12 years-of-age while taking EHDP. Here, features of hypophosphatasia include: 'tongues' of radiolucency (arrows), metaphyseal osteosclerosis, and irregularity in the provisional zones of calcification with widened physes (asterisks). Intra-articular calcification is noted (black arrow). (B) Six weeks after stopping EHDP, tongues of radiolucency are markedly improved, the provisional zone of calcification is more regular, physes have narrowed, while intra-articular calcification is unchanged (black arrow). (C) While taking EHDP, lateral lumbar spine demonstrates diffuse and end-plate sclerosis of the vertebrae with fusion of the posterior elements (arrows). (D) Left distal femur at 6-11/12 years shows Erlenmeyer flask-like deformity along with focal sclerosis and irregularity of the physal lines. (E) Lateral right knee demonstrates massive intra- and peri-articular calcification. Lucent areas with sclerotic borders are noted in distal femur and proximal tibia (arrow). Physes are irregular and widened (arrowheads). Femur shows severe bowing deformity.

The Role of ApoE/Lrp5/6 in Aortic Valve Calcification: LDL-Density-Pressure Theory. Nalini Rajamannan*. Northwestern University Medical School, USA

Calcific Aortic Valve Disease is the number one indication for cardiac valve replacement in the US. The mechanisms of valve calcification are under intense investigation. Mutations in the low-density lipoprotein-related receptor 5 and 6 have been implicated in a number of disease processes in the field of bone, cancer, eye, neurodegenerative disease, congenital heart abnormalities and cardiovascular disease. This study proposes to test the effect of the LDL-Density-Pressure Receptor mechanism on the development of valvular heart disease. To test this hypothesis in an experimental hypercholesterolemia mouse model ApoE^{-/-}, Lrp5^{-/-}, ApoE^{-/-}/Lrp5^{-/-} mice (n=120) were tested. Group I (n=20) normal diet, Group II (n=20) 0.25% cholesterol(chol) diet (w/w), for the development of calcification. The aortic valve (AVA) was examined for calcification, and bone matrix markers. Bone formation was assessed by micro Computed Tomography (microCT), Lrp5, Lrp6, and cbfa-1 expression. Echocardiographic measurements were performed using the Vevo mouse echo machine to determine hemodynamic progression with the diets. Echocardiographic Peak Jet Velocity (control vs chol) ApoE^{-/-} 1.60.1m/sec vs 1.70.1m/sec, Lrp5^{-/-} 1.30.1m/sec vs 1.560.1m/sec, ApoE^{-/-}/Lrp5^{-/-} 1.840.3m/sec vs 2.030.3m/sec, (p>0.05 for all groups). Calcification analysis demonstrates increased calcification for the ApoE^{-/-}, and ApoE^{-/-}/Lrp5^{-/-} mice in the chol treatments but no evidence in calcification for the Lrp5^{-/-}, cholesterol treatments by MicroCT and Synchrotron measurements. RTPCR analysis demonstrates ApoE^{-/-} increase in Runx2 and Lrp5 in the chol treatment (p<0.05) Lrp5^{-/-} no change in Runx2 and no expression of Lrp5 in the chol treatment, ApoE^{-/-}/Lrp5^{-/-} increase in Runx2 and Lrp6 in the chol treatment (p<0.05). This data demonstrates ApoE, Lrp5 and Lrp6 are critical in the development of valve calcification and that a combination of these receptors play a unique role in the development of calcification in the aortic valve.

Application of iPS Cells to the Research of Fibrodysplasia Ossificans Progressiva. Yoshihisa Matsumoto^{*1}, Makoto Ikeya², Akira Nasu², Isao Asaka², Takanobu Otsuka³, Edward Hsiao⁴, Junya Toguchida².

¹Department of Cell Growth & Differentiation, Center for iPS Cell Research & Application, Kyoto University, Department of Orthopedic Surgery, Graduate School of Medicine, Nagoya City University, Japan, ²Department of Cell Growth & Differentiation, Center for iPS Cell Research & Application, Kyoto University, Japan, ³Department of Orthopedic Surgery, Graduate School of Medicine, Nagoya City University, Japan, ⁴Gladstone Institute of Cardiovascular Disease, USA

Fibrodysplasia ossificans progressiva (FOP) is a rare genetic disease characterized by progressive ectopic ossification, which severely inhibits patients' ADL. The responsible gene for FOP is the ALK2 (activin like kinase 2) gene, which is one of type I receptors for BMP. Mutations found in patients transform ALK2 protein into a constitutive active form, which transduces the BMP signal without a ligand binding. This causes ectopic ossification in muscles, tendons, and ligaments, although precise mechanisms are not yet known. Harvesting target tissues from patients is strictly prohibited because tissue damage accelerates the ectopic ossification. This issue now can be overcome by using iPS cells derived from patients. We have established iPS cells from Japanese patients with FOP, from which cells in mesenchymal lineages are induced such as bone, cartilage, muscle, or tendon cells. We are currently analyzing the difference between wild type iPSCs and FOP-iPSCs during osteogenesis and chondrogenesis. We also try to recapitulate disease's phenotype in vitro by the stimulation with factors related to tissue damage. In this poster presentation, we will report our recent data and discuss the possibility of drug discovery by using our system.

A Transcriptomic Analysis of Type II Autosomal Dominant Osteopetrosis Osteoclasts : Identification of New Disease Markers. Amelie COUDERT^{*1}, Robert OLASO², Corinne COLLET¹, Marie-Christine De Vernejoul¹.

¹INSERM, France, ²CEA, France, ³Federation De Rhumatologie Et INSERM U606, France

Type II autosomal dominant osteopetrosis (ADO II) is a rare bone disorder characterized by an increased bone mass. About 80 % of ADO II are related to mutations in the chloride channel 7 gene (CLCN7), which encodes a chloride channel found on the ruffled border of the osteoclasts. The ADO II disease is characterized by a default in the resorption process. In order to gain insights in the mechanism of this default, we decided to carry out an analysis of the transcriptome of osteoclasts from ADO II patients versus the one from controls. Hence, we recruited 16 ADO II patients and 31 controls. Each patient was genotyped for CLCN7 mutations. Among our patients, we have found 2 yet undescribed CLCN7 mutations. PBMC from both osteopetrotic patients and controls were cultured with M-CSF and RANK-L to be differentiated into osteoclasts for 14 days. At the end of the culture, the number of multinucleated TRAP positive cells and the osteoclastic differentiation marker genes (TRAP, CATSK RANK) evaluated by qPCR were identical in the osteopetrotic and control cultures. We then hybridized RNA on the Illumina BeadChip. Microarray results showed a higher expression of ITGB5 (Integrin β 5) (x1.5). We therefore confirmed a significant higher expression of ITGB5 by qPCR. We also showed a higher expression of Integrin β 5 by western blot and by immunofluorescence with the expected intracytoplasmic localization. The mRNA of other integrins (Integrin β 3 and β 1) and members of the downstream pathway (vav3, src) were unchanged. In addition, we confirmed by qPCR several other genes that were differentially expressed in the microarray and we observed in ADO II patients a significantly higher expression of the mRNA of CES1 (1.5) and a lower expression of Perforin 1 (0.5), Serpine 2 (0.6) and WARS (0.7). In conclusion, our data showed higher expression of integrin β 5 in ADO II osteoclast and this can be associated with the low resorption capacity responsible of the bone phenotype of the patients. And the significant difference in several other gene expression in ADOII osteoclasts could defined them as new markers of osteoclast dysfunction in this disease.

Altered Transcript Pattern During Osteoblast Differentiation Associated With Improved Bone Phenotype In Homozygous Osteogenesis Imperfecta Brlt Mice. ADI REICH^{*}, Wayne A. Cabral, Joan Marini. National Institute of Child Health & Human Development, USA

Osteogenesis Imperfecta (OI), or "brittle bone disease", is a disorder of connective tissue characterized by skeletal fragility and deformity, and short stature. Most cases have autosomal dominant mutations in type I collagen. The Brlt knock-in mouse, with a G349C substitution in one COL1A1 allele, develops typical OI features, including osteoporosis, decreased BMD, fractures, and small size. Perinatal lethality

of heterozygous pups is 30%. Because it is typical that a dominant negative disorder is more severe in homozygous (HZ) than heterozygous (HET) form, we expected HZ Brlt mice to be lethal. Surprisingly, HZ survival was equal to WT, and their phenotype was intermediate between HET and WT. To investigate the amelioration in HZ phenotype, we compared the differentiation of cultured calvarial osteoblasts (OB) from WT, HZ & HET BRLT offspring over three weeks using Osteogenesis PCR Arrays and qPCR. Expression of OB differentiation markers was variably altered in HZ cells, rather than being restored to WT levels or expression intermediate between HET and WT. HZ OB displayed increased expression vs WT and HET OB of Cadherin 11, important for cell-cell adhesion, and Integrin α 2, that mediates cell attachment to the ECM. Paradoxically, the normal increase in gene expression on differentiation days 9-18 of Dmp1, Sost, Phex and Bmp2 by WT OB, associated with bone mineralization, was blunted in OI mice. Dmp1 and Bmp2 expression in HET and HZ cells, respectively, peaked at about half and 25% of WT, while Sost expression attained only 30% and 6% of WT levels. Phex expression in both OI genotypes increased minimally during differentiation. Furthermore Colla1, Colla2, Atp, Runx2, Tgfb1 expression were all consistently lower in HZ than HET or WT, throughout differentiation. In femoral tissue RNA from 2-month Het and HZ mice, Sost, Osx and Bmp2 expression was also decreased vs WT while Vegfa expression dramatically decreased in HZ mice. Immune staining of Dmp1 showed different localization and intensity patterns in the cortical bone of HET and HZ mice, in agreement with Dmp1 gene expression. These altered HZ expression patterns suggest that a compensation mechanism involving bone mineralization and remodeling as well as cell-matrix attachment, rather than a correction to WT patterns, improves the HZ bone phenotype. Cell-matrix exchange experiments are ongoing to determine the extent to which matrix structure and homogeneity influence OB cellular differentiation.

Fragility Fracture Family History and Rate of Bone Loss—Volumetric Cancellous Spinal Bone Change in Premenopausal Women. Jerilyn Prior^{*1}, Christine Hitchcock¹, Yvette Vigna¹, Vanadin Seifert-Klauss². ¹University of British Columbia, Canada, ²Technical University of Munich, Germany

Numerous large and sophisticated genetic studies (candidate gene-focussed cohort studies, genome-wide association studies, etc.) are currently being performed to understand the heritable aspects of human osteoporosis. A person whose biological relative had a fragility fracture is known to be at increased risk of lower areal bone mineral density (BMD) and at a higher likelihood of fragility fracture. What is not known is whether a fragility fracture family history (FFFH+) is a risk factor for an increased rate of BMD loss. A post-ovariectomy sham-controlled rodent study showed widely varying rates of BMD loss or gain in different inbred strains suggesting that genetics influences rodent BMD change 1. However, several prospective human studies of BMD change by genetics or osteoporosis family history and found no clear 2-tailed differences²⁻⁵. Data were available on 1-yr quantitative computed tomography (QCT) spinal cancellous bone change in active, healthy premenopausal women from Vancouver, Canada (n=66) and 2-yr change in older, healthy premenopausal women from Munich, Germany (n=20). The Vancouver cohort was mean age 34, BMI 22 with FFFH+ present in 33%—all were initially ovulatory and 65% were runners. The Munich cohort was mean age 43.5, BMI 24 with FFFH+ present in 45%. Consistent with age differences, initial QCT values differed by center: Vancouver 15422, Munich 14221 mg/cm³ (95% CI of difference = -15, -12.8). QCT change/yr, however, did not differ: -3.55.1 Vancouver, -2.03.4 Munich (95% CI of difference = -3.9, 0.9). Within each cohort those with and without FFFH+ did not differ in any non-bone characteristic. However, in combined data, QCT annual change differed: FFFH-, -2.24.4; FFFH+, -4.95.0 mg/cm³/y (95% CI diff 0.7, 4.8) (Figure). By ANOVA, study center did not reach significance (F1, 83=2.41, P=0.124) but FFFH+ made a major contribution to annual QCT change (F1, 83=7.88 P=0.006). FFFH+ explained 7.7% of the variance in yearly QCT cancellous spinal bone change in these 86 premenopausal women. Thus, this prospective study in healthy premenopausal women from two cohorts shows clearly, for the first time, that having a biological relative with a fragility fracture is associated with a greater rate of human bone loss.

Heterozygous Carriers of the SOST Mutation Demonstrate Reduced Sclerostin and Increased PINP Concentrations. Antoon Van Lierop^{*1}, Herman Hamersma², Neveen Hamdy¹, Socrates Papapoulos¹. ¹Leiden University Medical Center, The Netherlands, ²Flora Clinic, Department of Ear-Nose-and_Throat, South Africa

Introduction

Homozygous null mutations of the SOST gene, encoding sclerostin, an osteocyte derived negative regulator of bone formation, lead to sclerosteosis, a rare sclerosing bone dysplasia. Heterozygous carriers of this mutation have no apparent bone phenotype, but demonstrate an increase in bone mineral density (BMD). We addressed the question whether this increase in BMD may be due to impaired sclerostin synthesis, leading to increased bone formation.

Method

We measured levels of sclerostin, PINP, and CTX in serum of 12 genetically confirmed sclerosteosis patients and 22 heterozygous carriers of the SOST mutation. Serum levels of these parameters compared between patients, carriers and 77 healthy controls.

Results

Sclerostin was undetectable in the serum of patients, but was measureable in all carriers (mean:15.5 pg/ml; 95%CI:13.7-17.2pg/ml), in whom it was significantly lower than in healthy controls (40.0pg/ml; 95%CI:36.9-42.7pg/ml; $p < 0.001$). PINP levels were highest in patients (132.5ng/ml; 95%CI:78.9-186.3ng/ml), but carriers also had significantly higher PINP levels (58.3ng/ml; 95%CI:46.8-69.8ng/ml) than controls (37.8ng/ml; 95%CI:34.9-42.0ng/ml; $p < 0.05$). Using linear regression analysis sclerostin levels were significantly correlated with those of PINP ($B = -0.41$, $p = 0.005$) in a pooled cohort of carriers and age and gender matched controls. Mean CTX levels were significantly higher in patients (0.40ng/ml; 95%CI:0.22-0.57ng/ml) than in carriers (0.13ng/ml; 95%CI:0.09-0.17), although this was no longer the case after correcting for age ($p = 0.15$). PINP levels were negatively correlated with age in patients ($r = -0.74$, $p = 0.006$), but not in carriers ($r = -0.19$, $p = 0.40$) or controls ($r = -0.07$, $p = 0.56$). Serum levels of PINP and CTX were significantly correlated in both patients ($r = 0.88$, $p < 0.001$) and carriers ($r = 0.64$, $p = 0.001$).

Conclusion

Our data show that heterozygous carriers of the SOST mutation demonstrate reduced circulating levels of sclerostin and increased levels of PINP compared to healthy controls, suggesting that the effect of sclerostin on bone formation can be titrated.

Histidine Decarboxylase is a Candidate Gene for a Quantitative Trait Locus Affecting Peak Bone Density and Strength in Mice. Robert Klein^{*1}, Emily Larson², Wendy Wagoner², Amy Carlos², Terry Morgan². ¹Portland VA Medical Center, USA, ²Oregon Health & Science University, USA

The identification of genes underlying quantitative-trait loci (QTL) for complex diseases, such as osteoporosis, is a challenging and difficult task. We previously identified a QTL on chromosome 2 (chr 2) associated with variation in peak bone mineral density (BMD) in C57BL/6 (B6) and DBA/2 (D2) mice. Selective breeding was used to transfer the chromosomal fragment containing the chr 2 QTL interval (between 21 Mb and 152 Mb) from D2 onto a B6 genetic background (Bg). Comparison of the resulting D2 allele-bearing congenic (Cg) mouse strain with the B6 Bg strain established that the D2 genomic interval, in isolation, conferred increased

bone mass and strength. Peak whole body BMD, femoral BMD and vertebral BMD (determined by DXA in 20-wk-old mice) were 6%, 6% and 7% greater, respectively, in the Cg mice ($n = 50$) compared to the Bg mice ($n = 85$; $p < 0.01$). Consistent with the increased BMD, femoral mid-shaft failure load and stiffness (determined by 3-point bending) of the Cg mice were increased by 6% and 22%, respectively compared to the Bg mice ($p < 0.01$). A portion of the chr 2 introgressed region is homologous with a region in the human genome (15q21) that has been linked with variation in proximal femoral bone structure. Taking advantage of the synteny between human genome sequence and the murine chr 2 introgressed region, we identified histidine decarboxylase (Hdc), the rate-limiting enzyme in the biosynthesis of histamine, (residing at 15q21.2 in the human genome and at 126 Mb on chr 2 in the mouse genome) as a positional candidate gene for the observed variation in bone traits. Targeted deletion of Hdc in mice is known to increase bone formation and the expression of HDC in circulating monocytes is increased in osteoporotic women. Compared to Bg mice, bone marrow isolated from Cg mice had markedly reduced Hdc mRNA expression and Western immunoblotting and tissue immunohistochemistry confirmed reduced marrow Hdc protein expression in the Cg mice (see figure). Consistent with the differences in enzyme expression, marrow histamine levels were 81% lower in the Cg mice compared to the Bg mice ($p < 0.01$). We hypothesize that local histaminergic signaling is an important determinant of bone development in laboratory mice and that inherited variation in the activity of the enzyme responsible for histamine synthesis, HDC, may explain some proportion of the natural variation in peak bone density and strength in human populations.

HDC

Microarray-based Copy Number Analysis Can Identify Genomic Disruptions of PHEX Causing X-linked Hypophosphatemic Rickets. Steven Mumm^{*1}, Deborah Wenkert², Margaret Huskey³, Valerie A. Wollberg², Michael P. Whyte¹. ¹Shriners Hospital for Children & Washington University School of Medicine, St. Louis, USA, ²Shriners Hospital for Children, St. Louis, USA, ³Washington University in St. Louis School of Medicine, USA

Heritable forms of hypophosphatemic rickets (HR) include X-linked dominant HR (XLH, caused by de-activating mutations in the PHEX gene), autosomal recessive HR (ARHR, caused by de-activating mutations in the DMP1 gene), and autosomal dominant HR (ADHR, caused by activating mutations in the FGF23 gene). Over the past 27 years, we have cared for 268 pediatric HR patients from throughout the United States. After excluding 12 patients with HR from McCune-Albright syndrome, epidermal nevus syndrome, tumor-induced rickets, or cystinosis, etc., there were 72 sporadic cases diagnosed clinically with XLH. We are investigating 30 of these 72 sporadic patients (those for whom DNA is available) to identify their genetic defect causing rickets. In 2009, we reported that no mutations in the DMP1 or FGF23 genes were identified among these 30 sporadic HR cases (Mumm et al, 2009 ASBMR meeting). We have now sequenced the PHEX gene in all 30 cases and identified mutations in 8 patients, and used microarray-based copy number analysis to identify apparent genomic disruptions in the PHEX gene for another 4 patients.

Genomic DNA was isolated from blood leukocytes. All 22 coding exons and adjacent mRNA splice sites of the PHEX gene were amplified by PCR and sequenced. The patients' DNA sequences were analyzed by alignment to a control sequence using VectorNTI AlignX software, and by examining DNA sequence electropherograms. For 8 patients, PHEX defects were found, including splice site and nonsense mutations, and small insertion/deletions. Genomic DNA was also subjected to microarray-based copy number analysis using Affymetrix SNP 6.0 arrays. Data analysis was performed with Partek Genomics Suite. Copy number changes, indicating genomic disruption of the PHEX gene, were found in 4 additional HR patients. One girl had a large heterozygous deletion that removed exons 13-22 and extended beyond the 3' end of the gene but did not appear to disrupt neighboring genes. Two unrelated male patients had an apparent copy number amplification of exons 13-15, and another boy had an apparent copy number amplification of exons 6-9. All of these disruptions must be confirmed using a complementary method. No copy number changes in PHEX, DMP1, or FGF23 were seen in the remaining sporadic HR patients.

After search for genetic defects in PHEX, DMP1, and FGF23, only 40% of our sporadic HR patients have PHEX mutations. For 60% of our sporadic HR patients, their underlying genetic defect remains unknown.

Osteoporosis Pseudoglioma Syndrome (OPPG): Severity of abnormal bone geometry varies with genotype. Sheila Ramirez¹, Mary Leonard², Rita Herskovitz², Elizabeth Streeten^{*3}. ¹University of Maryland, Endocrinology, USA, ²Children's Hospital of Philadelphia, USA, ³University of Maryland School of Medicine, USA

Introduction: OPPG is a rare autosomal recessive disorder of juvenile osteoporosis, due to reduced bone formation, and congenital blindness due to mutations in *LRP5*. We have observed fractures in OPPG after attainment of normal Z-scores by DXA after bisphosphonate (BP) treatment. We hypothesized that cortical bone geometry is abnormal in OPPG, even following longterm BP treatment and may be affected by genotype. No information is published on bone geometry in humans with OPPG. In our kindred of 12 affecteds, 2 different *LRP5* mutations have been found, both in exon 6, termed here A (W425X) and B (T409A).

Methods: We performed pQCT of the tibia on 6 patients with OPPG (Two AA homozygotes; 4 AB compound heterozygotes) and 11 unaffected first degree relatives (4 heterozygote A, 1 heterozygote B and 6 with unknown genotype). Age of OPPG affecteds was 8-22 yo (mean 14); unaffecteds 6-41 (mean 14.6). pQCT results were converted to race and sex specific Z-scores based on reference data in over 1000 healthy participants. Cortical geometry phenotypes were adjusted for tibial length. Comparisons were made for pQCT phenotypes between affecteds vs unaffecteds and between affecteds with AA vs AB genotype.

Results: Both affecteds and unaffected 1st degree relatives were shorter than reference normals, height Z -1.5+1.3 and -0.52+70 respectively. OPPG participants, compared to unaffecteds, had lower section modulus (SM) -2.4 + 0.83 vs 0.12 + 0.28, p=0.002 and lower periosteal circumference -2.45 + 0.79 vs 0.22 + 0.28, p=0.0011 but similar endosteal circumference -1.66 + 0.57 vs 0.71 + 0.25, p=0.09. Results for affecteds' Z-scores for cortical density (CD), trabecular density (TD), cortical diaphysis section modulus (SM), periosteal circumference (PC), and endosteal circumference (EC) are shown in the table below. The two AA OPPG patients had contemporaneous DXA-derived Z-scores in the hip of -1.8 and -0.6 (baseline Z-scores prior to BP -4.7, -2.9)

Conclusions: Patients with OPPG had extremely abnormal bone geometry, with low bending strength (SM), compared to unaffected relatives, attributable to low periosteal circumference. In AA genotype affecteds, pQCT identified severely low SM, more helpful clinical information than the normal DXA-derived Z-scores achieved after BP therapy. The high CD in AA patients was likely due to BP treatment. We conclude that pQCT is a useful tool to assess bone strength in OPPG in response to treatment.

	CD (Z-score)	TD (Z-score)	SM (Z-score)	PC (Z-score)	EC (Z-score)
AA (n=2)	1.84 ± 0.053	-2.03 ± 1.80	-4.96 ± 0.03	-4.88 ± 0.33	-3.03 ± 0.97
AB (n=4)	-1.43 ± 0.34	-1.52 ± 0.63	-1.15 ± 0.32	-1.23 ± 0.21	-0.6 ± 0.54

Possible Hypophosphatasia in Personalized Medicine Research Project. Less Shrestha^{*1}, Fergus McKiernan¹, Richard Berg², Jay Fuehrer². ¹Marshfield Clinic, USA, ²Medical Bioinformatics, Marshfield Clinic Research Foundation, USA

PURPOSE: The purpose of our study was to identify subjects with possible hypophosphatasia (HPP) in the Personalized Medicine Research Project (PMRP).

BACKGROUND: PMRP is a population-based cohort of ~20,000 adult subjects recruited from among residents of a geographic region where a very high percentage of all healthcare encounters occur at Marshfield Clinic (MC). MC maintains a comprehensive, searchable electronic medical record that includes lab data since 1960, ICD-9 diagnosis codes since 1980 as well as stored DNA, plasma and serum for PMRP participants. HPP is a genetic metabolic disorder of skeletal mineralization with an estimated prevalence for severe disease of 1/100,000. We postulated that mild forms of HPP are more prevalent in an adult population than currently appreciated.

METHODS: The MC electronic medical record of all PMRP enrollees with recorded serum alkaline phosphatase (ALP) values mostly ≤ 30 IU/L (normal 40-120 IU/L) were manually searched for diagnostic terms, ICD-9 codes and laboratory values suggesting the presence of HPP. Individual radiographic reports and all available radiographs were reviewed for chondrocalcinosis and metatarsal stress fractures. Previously unrecognized HPP was considered possible when, in the judgment of the PIs, the available clinical, biochemical and radiographic evidence suggested its presence.

RESULTS: 21 subjects (14F/7M) were identified whose serum ALP was mostly ≤ 30 IU/L. Chondrocalcinosis was present in 7/21 and often characterized as extensive. 6/21 had suspected or proven acute crystalline arthritis or calcific tendinitis. 5/21 had calcaneal spurs or symptomatic foot exostoses. 4/21 had ≥ 1 metatarsal or femur shaft fracture. 2/21 had hip dysplasia. 2/3 subjects with available DXA scans had axial Z-scores ≥ +2.5. One subject each had kyphoscoliosis, mild hypermobility, clavicular

osteolysis or fibromyalgia. Onset of acute crystalline arthritis and metatarsal fractures was typically 20-40 years of age. No subject had alternate explanations for these conditions (e.g., hyperparathyroidism) or previously diagnosed HPP. At least 7 of 21 subjects in PMRP were considered likely to have previously unrecognized mild HPP.

CONCLUSION: Subjects with persistently low serum ALP appear to have significant musculoskeletal disease burden and some may have previously unrecognized HPP. Further clinical and biochemical investigation is warranted.

A Novel Gain-of-Function Mutation of the Calcium-Sensing Receptor Gene, *CaSR* D410E might be associated with Autosomal Dominant Hypocalcemia: A Series of Korean Hypoparathyroidism Registry Study (2). Byoungcho Choi^{*1}, Young Mi Kim², Yoon-Sok Chung³, Tae Sik Jung⁴, Chul Hoon Kim⁵, Suntaek Hong², Sihoon Lee¹. ¹Gachon University School of Medicine, South Korea, ²Gachon University of Medicine & Science, South Korea, ³Ajou University School of Medicine, South Korea, ⁴Gyeongsang National University School of Medicine, South Korea, ⁵Yonsei University College of Medicine, South Korea

Background: Autosomal dominant hypocalcemia (ADH) is a rare disorder characterized by benign hypocalcemia, inappropriately low parathyroid hormone (PTH) levels and mostly hypercalciuria. ADH can be caused by activating mutations of the calcium-sensing receptor (*CaSR*) gene located on chromosome 3q13.3-21. Calcium-sensing receptor plays a pivotal role in the regulation of calcium homeostasis and is abundantly expressed in parathyroid gland, thyroid C cell, and renal tubular system. Activation of *CaSR* by increased Ca^{2+} inhibits PTH secretion, stimulates calcitonin secretion, and promotes urinary Ca^{2+} excretion, and thereby maintains the Ca^{2+} at the normal level. Herein, we report a novel activating mutation in the *CaSR* gene in a Korean family with ADH.

Method: We identified a 55-yr-old woman with mild hypocalcemia (8.0 mg/dL) and hypercalciuria (24-hr urine Ca: 441 mg/d) caused by missense mutations of the *CaSR* gene. She showed low normal serum PTH level (10.14 pg/mL). We performed mutational analysis of the genes encoding GCMB, pre-pro-PTH, and *CaSR* using PCR-amplified genomic DNA from her family. The ability of wild-type and mutant *CaSR* to activate the MAPK signaling cascade was assessed by examining phosphorylation of ERK1/2.

Result: Direct sequencing analysis of the *CaSR* gene showed that the patient possesses a T to A transition at nucleotide 1230 resulting in a D410E missense mutation in exon 4 of the *CaSR* as well as R990G. *CaSR* R990G is already known to be one of the most frequently found SNP and is associated with gain-of-function. No mutation was detected in GCMB, Prepro-PTH. HEK293 cells were transfected with plasmids encoding wild-type, mutant A (D410E + R990G), mutant B (D410E), Mutant C (R990G) and Mutant D (P221L). Stepwise increase of the extracellular Ca^{2+} concentration from 0.5 to 5.0 mM resulted in increased phosphorylation of ERK1/2 in each mutant than wild-type indicated that D410E might be associated with ADH in this family.

Conclusion: Over 60 activating mutations in the *CaSR* gene have been identified to cause ADH so far. Here we add one more potential activating mutation that causes ADH. This could be of interest because this novel mutation occurred in the loop 3 region of the VFT domain in *CaSR* where little was known to be important in its function. Further study is undergoing to elucidate the molecular mechanisms about this novel mutation such as intracellular Ca^{2+} measurement by Fura-2.

Disclosures: Byoungcho Choi, None.

A Novel Non-synonymous Coding Variant in the Frizzled-1 Gene is Associated with Enhanced Activation of the Canonical Wnt Signaling Pathway. Yingze Zhang^{*1}, Shibing Yu², Allison Kuipers³, Yanxia Chu¹, Cara Nestlerode¹, Joseph Zmuda³. ¹University of Pittsburgh, USA, ²University of Pittsburgh Medical Center, USA, ³University of Pittsburgh Graduate School of Public Health, USA

Frizzled-1 (FZD1) is a coreceptor for Wnt ligands. We have reported genetic associations of a novel non-synonymous SNP (c.190G>A/p.A64T) and BMD phenotypes among Afro-Caribbean men. However, the functional consequence of this FZD1 protein variant is not known. We cloned both the WT and the 64T variant of FZD1 (FZD1/64T) in expression vectors and analyzed their effects on the canonical Wnt signaling pathway using the Top-Flash system. In osteoblast-like, Saos2, cells, transient expression of both WT and FZD1/64T significantly increased the TOP-Flash luciferase activities. Addition of Wnt3A, a known Wnt ligand for FZD1, to the transfected cells dramatically enhanced the FZD1 dependent up-regulation of the TOP-Flash luciferase activity. Compared to WT, there was a 4.4 fold increase in TOP-Flash luciferase activity for FZD1/64T, while there was only a 1.2 fold increase in luciferase activity for the FOP-Flash plasmid. We further confirmed the FZD1 dependent up-regulation of the TOP-Flash luciferase activity in both HEK293 and cos7 cells, which are commonly used for studying gene regulation by transient expression. Compared to WT, there was a 4.9 and 2.0 fold increase in TOP-Flash

luciferase activity for FZD1/64T in cos7 and HEK293 cells, respectively. There were minimal effects detected for the luciferase activity with FOP-Flash plasmid in all cell lines for both of the WT and FZD1/64T plasmids. Our study suggests that A64T variation may lead to a more active protein associated with increased canonical Wnt signaling. This may be one of the molecular mechanisms of the genetic associations between the FZD1 c.190G>A/p.A64T variant and BMD observed in Afro-Caribbean men. Additional studies elucidating the molecular basis of the FZD1/64T variant mediated up-regulation of FZD1 function are underway.

A Variant Near RUNX2 Is Associated with BMD and Cartilage Thickness. Martha Castano-Betancourt^{*1}, Karol Estrada¹, Hanneke Kerkhof², Albert Hofman³, Andre Uitterlinden⁴, Fernando Rivadeneira¹, Joyce Van Meurs⁵, GEFOS Consortium². ¹Erasmus University Medical Center, The Netherlands, ²Internal Medicine, Erasmus MC, Netherlands, ³Department of Epidemiology, Erasmus MC, Netherlands, ⁴Rm Ee 575, Genetic Laboratory, The Netherlands, ⁵Erasmus Medical Center, The Netherlands

Background. Osteoarthritis (OA), one of the most common locomotor disorders, is characterized by osteophyte formation and cartilage degradation, which is radiographically visualized as a reduction in the joint space width. OA has been associated with a systemically higher BMD. Recently, a meta-analysis of femoral neck (FN-) and lumbar spine (LS-) BMD within the GEFOS consortium identified 82 loci associated with BMD at suggestive or genome-wide significant (GWS) level. Aim. To determine whether the 82 BMD loci are associated with minimal joint space width (MJS), as a proxy for cartilage thickness.

Methods. This study is part of the Rotterdam study (RS); a large prospective population based cohort study of diseases in the elderly. We examined 4643 men and women of RSI and 1750 participants of RSII for replication, with radiographic measurements of minimal joint space width (Xray), anthropometry, FN- and LS-BMD (DXA) and GWAS data. Association of SNPs with MJS was tested in linear regression models adjusted for age and gender and as a secondary analysis additionally adjusting for height and BMD. Associations were significant at $P < 6.1E-04$ (Bonferroni correction).

Results. A SNP at chromosome 6p21.1 (minor allele frequency=0.42) mapping near RUNX2 was associated with MJS (beta minor allele: -0.067, se: 0.016, p: 4.93E-05). This association was significant in both men and women ($p=0.003$ and $p=0.001$). After correction for height and BMD the beta slightly decreased and the association remained significant (beta: -0.061, se: 0.015, p: 7.6 E-05). The association was also seen in subjects without OA ($p: 1.09E-04$), suggesting it is arising from cartilage thickness rather than cartilage degradation. The minor allele from this SNP was found associated with decreased BMD in the GEFOS consortium at GWS level. Another SNP, located 450 KB downstream and on moderate LD, was previously found associated with height within a large meta-analysis, indicating a pleiotropic role of this locus in skeletal cell differentiation.

Conclusions. We identified a SNP near RUNX2 associated with cartilage thickness. RUNX2 is an important transcription factor in skeletal system playing a major role in the development, growth and maturation of bone and cartilage. Further, this SNP and correlated variants have also been associated with BMD and height. These findings make RUNX2 a strong candidate for underlying the pleiotropic associations found in different skeletal traits.

Genetic Control of Ca Absorption and BMC Differs Dependent on Dietary Calcium (Ca). Rebecca Replegle^{*1}, Libo Wang², Min Zhang², James Fleet¹. ¹Purdue University, USA, ²Purdue University Dept. of Statistics, USA

Genetic variation has been shown to influence bone phenotypes in mice and humans. However, it is unclear whether the penetrance of these genetic effects is influenced by low Ca stress or whether new variants affecting bone or Ca metabolism can be revealed under these conditions. We conducted a study to identify genetic loci controlling Ca/bone phenotypes in the BXD recombinant inbred mouse panel under normal and low dietary Ca conditions. Male mice from 51 BXD lines were placed on modified AIN93G diets containing 200 IU vitamin D and either 0.5% or 0.25% Ca at 4 wks of age ($n=8$ /line/diet). At 12 weeks of age Ca absorption (Ca Abs) was measured by Ca^{45} appearance in the blood 10 min after oral gavage, mice were then sacrificed and tissues collected. Bone mineral content (BMC) was assessed using DXA. Multiple linear regression identified significant covariates influencing BMC (femur length and body weight), and Ca Abs (femur length). Residuals were used for all further analyses. Linkage mapping was conducted using a Bayesian QTL method, loci with a Bayes factor >6 were considered significant. Narrow-sense heritability for Ca Abs was 0.37 and 0.56, and for BMC was 0.41 and 0.49 in mice fed the 0.5% and 0.25% Ca diets, respectively. Seven QTL affecting Ca Abs were identified in the 0.25% Ca group on ch 1, 2, 4, 5 (2), 7, 9 while 2 QTL were identified in the 0.5% Ca group on ch 4 and 8. Ca Abs was strongly correlated between the two Ca diets ($r=0.71$, $p<0.0001$) but only the ch 4 QTL was common across diet groups. With the exception of PTH near the ch 7 QTL and calbindin D9k near the ch 8 QTL, no Ca

homeostasis-regulating genes were found around these QTL suggesting the potential for novel gene discovery affecting Ca Abs. Six QTL affecting BMC were identified in the 0.25% Ca group on ch 5, 7, 11, 15 (2), 20 and 5 were identified in the 0.5% group on ch 2, 6, 9, 15, 20. BMC was correlated between the Ca diet groups ($r=0.81$, $p<0.0001$) but only two shared QTL were identified, on ch 15 and 20. The ch 15 locus is within 10cM of candidate genes VDR and Wnt10b but the ch 20 locus has not been identified previously. Our results indicate that baseline Ca-related phenotypes are influenced by genetics and that dietary Ca restriction reveals new QTL controlling these traits.

Casein Kinase II Activates Bone Morphogenetic Protein Receptor Type Ia in the Absence of Bone Morphogenetic Protein 2 Driving Osteoblast Differentiation. Beth Bragdon^{*1}, Oleksandra Moseychuk², Lauren Gurski², Hemanth Akkiraju², Jeremy Bonor², Anja Nohe². ¹University of Maine University of Delaware, USA, ²University of Delaware, USA

Bone Morphogenetic Protein 2 (BMP2) is a growth factor that is crucial for the proliferation and differentiation of osteoblasts. The absence of BMP2 can lead to the inability to heal spontaneous bone fractures in mice. Although BMP2 signaling is highly regulated we recently identified Casein Kinase II, CK2, to interact and regulate downstream BMP2 signaling. Three blocking peptides were developed to block the interaction between BMPRIa and CK2 which all led to increased BMP2 signaling and osteoblast differentiation in the absence of BMP2 with the cell line C2C12. In this study we were able to verify the specificity of the three blocking peptides by creating three different single point mutations of BMPRIa disrupting the each CK2 phosphorylation site. These mutants when overexpressed increased osteoblast differentiation and expression was determined by confocal microscopy. One mutant did show increased mineralization compared to the others, suggesting the role of one phosphorylation site is increased. Further the knockdown of BMPRIa eliminated all three blocking peptide effects on signaling. These results indicate the blocking peptides specifically inhibit the regulation by CK2 and allow for the activation of downstream signaling events leading to osteoblast differentiation without BMP2. The blocking peptide that correlated with the mutant with the increased mineralization was used for subcutaneous injections over mice calvaria. The blocking peptide injection led to increased bone area and bone mineral apposition rate. These results suggest osteoblast differentiation can be initiated through the BMP2 mechanism although BMP2 is absence.

Wnt3a Stimulates Bmp2 Expression in Osteogenic Cells that Are Epigenetically Ready. Young-Dan Cho^{*}, Woo-Jin Kim, Won-Joon Yoon, Kyung Mi Woo, Jeong-Hwa Baek, Hyun-Mo Ryoo. Seoul National University, School of Dentistry, South Korea

Background: Wnt and Bmp are two of the most important extracellular signals that control osteoblast differentiation and bone mineralization. While there are many reports indicating the signal cross-talks between Wnt and Bmp downstream molecules, no direct evidence has been demonstrated that Wnt regulates Bmp expression or vice versa. Specific aim of this study was illuminating a possible cross-regulation between the two strongest osteogenic signals. Results: We found that a canonical Wnt pathway activator, Wnt3a, strongly stimulated *Bmp2* mRNA expression while Bmp2 could not stimulate *Wnt3a*. Overexpression or knockdown of canonical Wnt downstream molecules, β -catenin and Lef1, clearly indicated that they are positive regulators of *Bmp2* mRNA expression. In order to clarify a direct regulatory relationship, mouse *Bmp2* proximal promoter was analyzed. There are two strong Lef1 response elements and both are contributed Wnt3a-induced *Bmp2* transcription. The analysis of conditioned media of Wnt3a treated cells showed that Bmp2 protein level was highly increased so that the conditioned media treatment is good enough to stimulate Smad1/5/8 phosphorylation and Alp activation. Dkk1, a Wnt inhibitor, or noggin, a Bmp inhibitor, suppressed Alp staining or Alp mRNA level indicating both Wnt and Bmp signals are contributed to Alp expression and staining. Next question was addressed whether *Bmp2* induction by Wnt3a is a general phenomenon to all type of cells or is specific for osteogenic cells. *Bmp2* mRNA expression was increased 8 to 20 folds by Wnt3a treatment in cells having osteogenic potential such as MC3T3-E1, C2H10T1/2, ST2 and C2C12. Meanwhile, in cells having very low osteogenic potentials, 3T3-L1 or NIH3T3, *Bmp2* expression was not increased by Wnt3a. Other osteogenic marker genes, including *Alp*, expression showed similar pattern in the osteogenic and low osteogenic cell groups. We suspected that the difference came from their differences in epigenetic states because *Bmp2* or *Alp* mRNA level was increased by Wnt3a after trichostatin-A, a strong HDAC inhibitor. The analysis of acetylation and methylation state of histones in the promoter of Bmp2 and bone marker genes indicated that they are epigenetically not ready for expression. Conclusion: Wnt3a stimulated osteoblast differentiation directly through the canonical Wnt signaling and indirectly through Bmp2 induction in osteogenic cells. Meanwhile epigenetic modification would be required in nonosteogenic cells.

Expression of Subtilisin-like Proprotein Convertases (PCSKs) in FGF23 Producing Extravillous Trophoblast of Human Placenta. Masanori Takaiwa^{*1}, Koji Kadoya², Kosei Hasegawa³, Kunihiko Aya³, Hiroyuki Tanaka⁴, Tsuneo Morishima³, Motofumi Yokoyama⁵, Youichi Kondo¹, Nobuyuki Kodani¹. ¹Dept. of Pediatrics, Matsuyama Red Cross Hosp., Japan, ²Dept. of Pathology, Matsuyama Red Cross Hosp., Japan, ³Dept. of Pediatrics, Okayama University Graduate School of Medicine, Dentistry & Pharmaceutical Sciences, Japan, ⁴Okayama Saiseikai General Hospital, Japan, ⁵Dept. of Obstetrics & Gynecology, Matsuyama Red Cross Hosp., Japan

We have previously reported that circulating fibroblast growth factor 23 (FGF23) is predominantly inactivated in the human infant at birth. This observation suggested that a subtilisin-like proprotein convertases (PCSKs) dependent proteolysis plays crucial role in the physiological regulation of FGF23 activity during the perinatal period. We also demonstrated that FGF23 is expressed in the human placenta. As previously reported in a study regarding abundant FGF23 expression in non-calcified organs of rodent fetus, our observations reinforced that the inactivated FGF23 is substantially secreted from non-calcified organs including placenta in human fetus and neonates. Thus, it might be useful to study human placenta in order to seek an unidentified specific PCSK for the FGF23 inactivation in the physiological condition. In this study we analyzed mRNA and protein expressions of six PCSKs (PCSK1, PCSK2, FUR, PCSK4, PCSK5 and PACE4) in human placentas using RT-PCR, Western blot analysis and immuno-histochemical studies.

RT-PCR and Western blot analysis revealed that FGF23 and GALNT3 transcript and proteins are detectable in the samples prepared from whole human placentas. We also confirmed that expressions of PCSK1, PCSK4 and PCSK6 are abundant and those of FUR and PCSK5 are detectable at lower levels. In order to estimate the possible linkage between these PCSKs and FGF23 degradation in the placenta, we performed immuno-histochemical studies on paraffin embedded human placentas. As we previously demonstrated, positive staining of FGF23 was mainly localized in clusters of extravillous trophoblast of the Langerhans' fibrinoid layer that migrated in the chorionic plate of placenta. A specific antibody against PCSK1, but not those for PCSK4 and PCSK5 probed the clusters of extravillous trophoblast. Additionally, weaker positive staining for FUR and PCSK5 were observed in the chorionic plate of the placenta, resembling the distribution of the FGF23 positive trophoblasts. Thus, although further study is required, it will be useful to investigate whether PCSK1 is playing a crucial role in the enhanced FGF23 degradation specifically observed in the human newborns.

Osteostatin Improves the Osteogenic Capacity of Fibroblast Growth Factor-2 Coated onto Si-Doped Hydroxyapatite in Osteoblastic Cells. Daniel Lozano^{*1}, MJ Feito², Sergio Portal-Nunez¹, RM Lozano³, MC Serrano⁴, M Vallet-Regu⁵, MT Portoles⁶, Pedro Esbrit⁷. ¹Instituto de Investigacion Sanitaria-Fundacion Jimenez DUaz, Spain, ²Dpto. de Bioquímica y Biología Molecular I, UCM, Spain, ³Centro de Investigaciones Biológicas, CSIC, Spain, ⁴Instituto de Ciencia de Materiales, CSIC, Spain, ⁵Departamento de Química Inorgánica y Bioinorgánica, UCM, Spain, ⁶Departamento de Bioquímica y Biología Molecular I, UCM, Spain, ⁷FUNDACION JIMENEZ DIAZ, Spain

Si-doped hydroxyapatites (Si-HA) have been proposed as matrices for the controlled release of biological agents to improve bone repair following skeletal injuries, namely fractures. Fibroblast growth factor (FGF)-1 and -2 are known modulators of osteoblastic proliferation and differentiation, as well as inducers of angiogenesis, an important process during bone repair. Recently, we demonstrated that these growth factors immobilized on powdered Si-HA and their scaffolds improve osteoblast adhesion and proliferation. In addition, we showed that parathyroid hormone-related protein (PTHrP) (107-111) (named osteostatin, OST) induces osteogenic features by directly acting on osteoblastic cell cultures and in vivo in rabbits. We aimed to evaluate and compare the efficacy of FGF-2 immobilized on powdered Si-HA, alone or combined with exogenous OST (100 nM), to affect osteoblastic growth and function. Osteoblastic MC3T3-E1 cells were grown in differentiation medium (α -MEM with 50 μ g/ml ascorbic acid, 10 mM β -glycerolphosphate and 10% FBS), with the tested materials for 4-12 days. Cell proliferation and viability (assessed by optical microscopy and flow cytometry), Ca^{2+} transients (by flow cytometry), mineralization (alizarin red), and gene expression analysis (by real-time PCR) were determined. Secreted vascular endothelial growth factor (VEGF) by MC3T3-E1 cells was determined by evaluating the proliferation of pig endothelial-like cells derived from endothelial progenitor cells (EPCs) induced by MC3T3-E1 conditioned-medium in the presence or absence of a VEGF neutralizing antibody. FGF-Si-HA, with or without soluble OST, similarly increased (50%) MC3T3-E1 cell proliferation. However, gene expression of both Runx2 and osteocalcin increased with FGF-Si-HA but was significantly higher (50%) in the presence of OST. VEGF (gene expression and secretion) and VEGF receptors 1 and 2 also increased (up to 2-fold) by OST. Similarly, the matrix mineralization capacity of this material was significantly

improved by the latter peptide. As an initial characterization of the underlying mechanism of the observed effects of OST, we found that this peptide induced a synergistic Ca^{2+} transient in MC3T3-E1 cells. In conclusion, these in vitro findings indicate that OST can improve the osteogenic efficacy of FGF-Si-HA biomaterial in osteoblastic cells. This supports the usefulness of these type of biomaterials for bone tissue repair.

A Reappraisal of the Skeletal Phenotype of Leptin Signaling-Deficient Mice: Implications for the Physiological Role of Leptin as a Regulator of Bone Metabolism. Russell Turner^{*1}, Kenneth Philbrick¹, Satya P. Kalra², Urszula Iwaniec¹. ¹Oregon State University, USA, ²University of Florida McKnight Brain Institute, USA

The cellular basis for the skeletal phenotype of leptin signaling-deficient mice forms a cornerstone for the traditional model of neuronal regulation of bone metabolism. Leptin, by acting through a hypothalamic relay, is proposed to negatively regulate bone mass by suppressing bone formation. However, this antiosteogenic model of leptin action is not supported by long duration gene therapy studies which showed no detrimental effect of increased hypothalamic leptin levels on bone metabolism. We therefore sought to clarify the physiological actions of leptin on the skeleton by reevaluating the cellular mechanisms underlying changes in bone architecture in femur and vertebra of leptin receptor-deficient db/db, leptin-deficient ob/ob, and ob/ob mice treated with leptin. Decreases in bone growth, osteoblast perimeter and bone formation rate (please see table for representative data in db/db mice) were observed in leptin signaling-deficient mice. Also, indices of bone growth and turnover were greatly increased in ob/ob mice following short duration (3 weeks) sc administration of leptin or long-duration (15 weeks) hypothalamic leptin gene therapy. In spite of normal or increased osteoclast-lined bone perimeter, leptin signaling-deficient mice exhibited a mild but generalized osteopetrotic-like (calcified cartilage encased by bone) skeletal phenotype. Thus, impaired bone resorption rather than increased bone formation, as originally reported, is responsible for site-specific increases in bone volume of ob/ob and db/db mice. In summary, these data do not support the hypothesis that leptin reduces bone mass by inhibiting bone formation. Instead, they show that in the absence of leptin signaling bone fails to mature normally. We conclude that leptin, by enhancing bone growth, bone formation and bone turnover, plays an important physiological role in skeletal maturation.

Bone formation rate/bone perimeter ($\mu\text{m}^2/\mu\text{m}/\text{d}$) in 17-week-old female WT (C57/BL6) and db/db mice.

Acerogenins, a Natural Compound Isolated from *Acer nikoense* Maxim, Stimulates Osteoblast Differentiation through Bone Morphogenetic Protein Action. Ji-Won Lee^{*1}, Takayuki Yonezawa², Tasuku Kihara¹, Hiroyuki Akazawa³, Toshihiro Akihisa³, Akira Yamaguchi⁴, Je-Tae Woo⁵. ¹Section of Oral Pathology, Graduate School of Medical & Dental Sciences, Tokyo Medical & Dental University, Japan, ²The University of Tokyo, Japan, ³College of Science & Technology, Nihon University, Japan, ⁴Tokyo Medical & Dental University, Japan, ⁵Research Institute for Biological Functions, Chubu University, Japan

In the present study, we investigated the effects of eight compounds, which had been isolated from the stem barks of *Acer nikoense* Maxim, on osteoblastogenesis. Osteogenic activity of six diarylheptanoids, (1)acerogenin A, (2)(R)-acerogenin B, (3) aceroside I, (4)aceroside B1, (5)aceroside III and (6)(?)-centrolol and two phenolic compounds; (7)(+)-rhododendrol and (8)(+)-catechin was evaluated by measuring alkaline phosphatase (ALP) activity as a marker for early osteoblast differentiation. We found that the diphenyl ether-type cyclic diarylheptanoids [(1)-(5)] promoted ALP activity in MC3T3-E1 osteoblastic cells without affecting cell proliferation, but linear-type diarylheptanoids (6) and phenolic compounds (7) and (8) did not. Diphenyl ether-type cyclic diarypheptanoids (1)-(4) also increased protein production of osteocalcin, a late stage marker for osteoblast differentiation, and induced osteoblastic mineralization. Structure-activity relationships of these compounds demonstrated that the stimulatory efficacy of aglycones was higher than that of its glycosides. Among these compounds, acerogenin A stimulated the cell proliferation of RD-C6 osteoblastic cells (Runx2-deficient cell line) as well as MC3T3-E1 cells. It also increased ALP activity in MC3T3-E1 and RD-C6 cells and calvarial osteoblastic cells isolated from the newborn mice. Acerogenin A increased the expression of mRNAs

related to osteoblast differentiation, including Osteocalcin, Osterix and Runx2 in MC3T3-E1 cells and primary osteoblasts: it also stimulated Osteocalcin and Osterix mRNA expression in RD-C6 cells. The acrogenin A treatment for 3 days increased *Bmp-2*, *Bmp-4*, and *Bmp-7* mRNA expression levels in MC3T3-E1 cells. Adding noggin, a BMP specific-antagonist, inhibited the acrogenin A-induced increase in *osteocalcin*, *Osterix* and *Runx2* mRNA expression levels. These results indicated that acrogenin A stimulates osteoblast differentiation through BMP action, which is mediated by Runx2-dependent and Runx2-independent pathways.

Divergent Effects of Partial (*obl/+*) and Complete (*ob/ob*) Loss of Leptin Production on Cortical Bone. Kenneth Philbrick*, Russell Turner, Ursula Iwaniec. Oregon State University, USA

Morbidly obese leptin-deficient *ob/ob* mice cannot produce the adipokine leptin and develop a skeletal phenotype where, depending upon site and age, bone mass can be normal, increased, or decreased. Compared to wild type (WT) mice, heterozygous *obl/+* mice are heavier but produce leptin. We therefore evaluated bone metabolism in *obl/+* mice to determine whether reduced leptin production by adipocytes maintains a normal skeletal phenotype. This was accomplished by examining femora and lumbar vertebrae (LV5) in 7-week-old WT, *obl/+*, and *ob/ob* mice using DXA, μ CT, and histomorphometry. Selected results are summarized in the Table below. Body mass and abdominal white adipose tissue (WAT) mass were greater in the *obl/+* mice than in WT mice but lower than in *ob/ob* mice. Significant differences in serum leptin were not detected between *obl/+* and WT mice, suggesting that *obl/+* mice compensate for reduced leptin production by individual adipocytes by an increase in adipose tissue mass. Total femur length and bone mineral content (BMC) were greater in *obl/+* mice than in WT mice. In marked contrast to the low cortical bone mass observed in *ob/ob* mice, *obl/+* mice have higher than normal cortical bone mass. Cancellous bone volume adjusted for tissue volume (BV/TV) in distal femur metaphysis and vertebral body did not differ between *obl/+* and WT mice. Similarly (data not shown), significant difference in femoral and vertebral cancellous bone formation rates were not detected between *obl/+* and WT mice. Bone marrow adiposity (adipocyte area/tissue area, Ad.Ar/T.Ar), which is dramatically higher in distal femur metaphysis of leptin-deficient *ob/ob* mice, did not differ between *obl/+* and WT mice. In summary, *obl/+* mice have increased femoral length and cortical bone mass but normal cancellous bone mass and turnover. These findings suggest that increased body mass enhances the growth promoting effects of leptin on the mouse skeleton.

Endpoint	WT	<i>obl/+</i>	<i>ob/ob</i>	ANOVA (P <)*

Immune Cell Populations, Severely Compromised Following Long Term High Fat Diet, Are Partially Restored by Low Intensity Mechanical Signals. Ete Meilin Chan*, Benjamin Adler¹, Danielle Green¹, Ada H. Tsoi¹, Mario E. Botros¹, Clinton Rubin². ¹STONY BROOK UNIVERSITY, USA, ²State University of New York at Stony Brook, USA

Immune system dysfunction resulting from obesity, as reflected by a marked decrease in immune cell populations, precipitates a susceptibility to life-threatening diseases including osteoporosis. We examined here whether obesity damages the bone marrow niche where progenitors critical to bone remodeling and immunity originate. With evidence that low intensity vibration (LIV) can bias mesenchymal stem cell differentiation towards osteoblastogenesis, we further hypothesized that these mechanical signals would modulate other bone marrow cells types and, more specifically, help restore that population of immune cells placed at risk by a long-term high fat diet. Twenty male C57BL/6J mice, age 2 mo., were randomly assigned into four groups (n=5): regular diet (RD); RD+LIV; high fat diet (HFD); and HFD+LIV. Obesity was then established in each HFD groups using a high fat diet (45% kcal from fat). At 5 months of age, the RD+LIV and HFD+LIV were subjected to four months

of LIV (0.2g, 90Hz, 15m/d, 5d/w), while RD and HFD were treated as sham controls. As compared to RD, 7-month HFD induced 41% higher body weight and 5-fold higher insulin resistance (p<0.01), representing a severely obese phenotype. B & T cells in blood and bone marrow were analyzed using FACS, and visceral adipose tissue volume (VAT) was measured by μ CT. VAT in HFD was significantly higher than both RD groups (+69.3%, p<0.01), while HFD+LIV was not different from RD (+44.5%, p=0.26). Circulating B cells in HFD were significantly lower than RD groups (-36%, p=0.01), while the HF+LIV circulating B cell population was higher than HFD (+57%, p=0.02), maintaining B cells to the level measured in RD (p=0.97). Although a HFD impact on circulating T cell and bone marrow T & B cells was not evident compared to RD (p=0.07, 0.36 & 0.11), both circulating (r=-0.52, p=0.04) and bone marrow B cells (r=-0.73, p=0.01) had a significant negative correlation with VAT. Also, circulating T cells (r=-0.61, p=0.01), but not bone marrow T cells (r=0.03, p=0.94), were negatively correlated with the VAT. An increasing adipose burden is associated with the decline of immune cells critical for immune surveillance and response. It is known that exercise is considered beneficial to the control of obesity and enhancing the immune system. In this study, LIV facilitated the recovery of the B-cell population, even in the face of obesity, potentially through modulating hematopoietic progenitors originated from the bone marrow.

Interferon γ Inhibits Bone Marrow Adipogenesis. Sandra Bermeo-Serrato*, Christopher Vidal², Lee Wei Li³, Dao Chao Huang⁴, Richard Kremer⁵, Gustavo Duque⁶. ¹PhD Student, Australia, ²University of Sydney, Australia, ³University of Sydney, Nepean Clinical School, Australia, ⁴McGill University Royal Victoria Hospital, Canada, ⁵McGill University, Royal Victoria Hospital, Canada, ⁶Ageing Bone Research Program, University of Sydney, Australia

Interferon gamma (IFN γ) has been recently identified as to induce osteoblastogenesis *in vitro* and bone formation *in vivo*. Since this anabolic effect could be exerted by inducing osteoblast differentiation of mesenchymal stem cells (MSC) at the expense of adipogenesis, in this study we aimed to assess whether IFN γ has and anti-adipogenic effect both *in vitro* and *in vivo*. Human MSC were induced to differentiate into adipocytes for two weeks in the presence or absence of IFN γ (1, 10 and 100 ng/ml) in the media. Adipocyte differentiation was assessed by morphologic and enzymatic analysis and by quantification of protein expression and mRNA of adipogenic markers. Oil red O, was used to quantitate the extent of lipid accumulation within the MSC. By this morphologic criteria, IFN γ inhibited adipogenesis at a concentration of 100 ng/ml (p<0.001), the same dose that has been reported as strongly osteogenic *in vitro* (Duque et al, Stem Cells, 2009). This correlated with decreased levels of adipocyte specific enzymes and significantly lower expression of protein and mRNAs for PPAR γ and CEBP α (p<0.01), two major adipogenic factors. For our *in vivo* experiments, 8 week-old ovariectomized C57BL/6 mice were treated with osteogenic doses of IFN γ (2,000 and 10,000 IU, IP, 3 times a week for 6 weeks). After von Kossa staining of distal femur (Figure), treated mice showed significantly lower levels of fat volume/total volume (p<0.01), adipocyte number (p<0.01) and adipocyte diameter (p<0.01) as compared with the placebo treated mice. Together, these findings demonstrate that IFN acts as adipogenic antagonist supporting the hypothesis that the anabolic effect of IFN γ on bone involves the reciprocal regulation of adipogenesis and osteogenesis in the bone marrow microenvironment.

Lipoteichoic Acid from *Enterococcus faecalis* Induces Chemokine Expression in Murine Macrophages via Toll-like Receptor 2/CD14/MyD88 Signaling Pathways. Ok-Jin Park^{*1}, Ji Young Han², Jung Eun Baik², Seulgie Choi², Jun Ho Jeon³, Cheol-Heui Yun³, Hong-Hee Kim⁴, Seung Hyun Han¹.

¹School of Dentistry, Seoul National University, South Korea,

²Department of Oral Microbiology & Immunology, DRI, & BK21 Program, School of Dentistry, Seoul National University, South Korea,

³Department of Agricultural Biotechnology & Research Institute for Agriculture & Life Sciences, Seoul National University, South Korea,

⁴Seoul National University, South Korea

Enterococcus faecalis is closely associated with refractory apical periodontitis often causing apical bone loss and its lipoteichoic acid (LTA) is considered as one of the major cell-wall virulence factor because of the inflammatory activity. It has been shown that chemokines facilitate differentiation of osteoclasts. In the present study, we purified LTA from *E. faecalis* and investigated the effect of LTA on the expression of chemokines in murine macrophages and used as an osteoclast precursor cell model. LTA from *E. faecalis* stimulated the expression of chemokines such as interferon- γ -inducible protein 10 (IP-10), macrophage inflammatory protein 1 α (MIP-1 α), and monocyte chemoattractant protein 1 (MCP-1) at both protein and mRNA levels. Toll-like receptor 2 (TLR2), CD14, and MyD88 appear to be essential for the expression of chemokines since such induction was not observed in the macrophages deficient in TLR2, CD14, or MyD88. Western blot analysis demonstrated that the LTA induced phosphorylation of MAP kinases including p38 kinase, JNK, and ERK. In addition, the LTA enhanced the DNA-binding activities of transcription factors, NF- κ B, AP-1, and NF-IL6, all of which are known to regulate the expression of chemokines. Further study using inhibitors demonstrated that the induction of IP-10 required ERK, JNK, p38 kinases, protein tyrosine kinases, phosphoinositide 3-kinases, and reactive oxygen species (ROS). However, interestingly, p38 kinases and ROS were not necessary for the induction of MCP-1 and MIP-1 α expressions while the other signaling molecules were required. These results suggest that *E. faecalis* LTA induces the expression of chemokines IP-10, MCP-1, and MIP-1 α , all of which require TLR2/CD14/MyD88, but through different signaling pathways in murine macrophages.

Nalp3 Inflammasome Activation Mediates Peri-implant Osteolysis. Ed Purdue^{*}, Nikolaus Binder, Krista Bohnert, Bryan Nestor, Thomas Sculco, F. Patrick Ross, Steven Goldring. Hospital for Special Surgery, USA

Aseptic loosening related to peri-implant osteolysis is the major cause of implant failure after total joint replacement surgery. The osteolytic process has been attributed to the release of implant particulate wear debris, inducing a granulomatous inflammatory reaction. Pro-inflammatory cytokines have been implicated as important mediators of particle-mediated inflammatory bone loss and, more recently, inflammasome and caspase-1 mediated processing and release of interleukin 1 beta (IL1 β) have been shown to be a significant component of myeloid cell responses to particulate danger signals such as those presented by orthopedic wear. Based on these observations we hypothesized that inflammasome signaling would contribute to osteolysis induced by particles of polymethylmethacrylate (PMMA) and ultra high molecular weight polyethylene (UHMWPE). Consistent with inflammasome signaling, LPS primed human peripheral blood monocytes and mouse bone marrow derived macrophages released IL1 β protein only after challenge with wear particles. This effect was dependent upon particle phagocytosis and caspase activity. Furthermore, macrophages deficient in components of the Nalp3 inflammasome (Nalp3, ASC, caspase-1) were defective in particle induced release of IL1 β , but unimpaired in production of TNF α and IL-6, neither of which requires activation of the inflammasome for their release. The pro-inflammatory effects of wear particles on IL1 β release from LPS primed cells were counterbalanced by repression of LPS induced expression of IL1 β mRNA by particle phagocytosis. This provides a possible mechanism for limiting inflammasome responses to particle phagocytosis. Macrophages lacking Nalp3, ASC or caspase-1 showed no defects in RANKL-induced osteoclastogenesis *in vitro*. In contrast, caspase-1 deficient mice were partially protected from orthopedic wear particle induced calvarial osteolysis. Our results provide evidence that the inflammasome pathway is activated in myeloid cells in response to orthopedic wear particles, resulting in caspase-1 dependent production of the pro-inflammatory cytokine IL1 β . Marked attenuation of osteolysis in caspase-1 deficient mice provides direct evidence *in vivo* implicating the inflammasome pathway in particle-mediated osteolysis. Inflammasome activation in response to orthopedic wear is also seen in human monocytes, providing evidence that this pathway represents a relevant therapeutic target in patients with periprosthetic osteolysis.

Platelet-derived Growth Factors (PDGFs) Functions in Tooth Development. YU SUGAWARA^{*}, Tsutomu Iwamoto, Masaharu Futagi, Mariko Ono, Aya Yamada, Takashi Nakamura, Satoshi Fukumoto. Tohoku University Graduate School of Dentistry, Japan

Tooth is a specific hard tissue, because the developmental process is well-regulated by reciprocal epithelial-mesenchymal interactions that are mediated by effective growth factor series. Platelet-derived growth factors (PDGFs) play crucial roles in organogenesis including tooth. Previously, we have reported that PDGFs regulates tooth size and shape during embryogenesis. However, the mechanisms of PDGFs during tooth development have not been clearly elucidated. Here, we focused on the identification of mechanisms of PDGFs on tooth cells including dental epithelial cells, ameloblasts, and dental mesenchymal cells, odontoblasts. RT-PCR and immunostaining revealed that PDGF ligands, PDGF-A and PDGF-B, and their receptors, PDGFR α , and PDGFR β , were expressed throughout the initial stages of tooth development. In organ culture of tooth germ, exogenous AG17, a tyrosine kinase inhibitor specific for PDGF signaling, suppressed the numbers of bromodeoxyuridine (BrdU) positive cells in both dental epithelium and mesenchyme. As the results, growth and cusp formation of molar tooth germ were inhibited. Next, we examined whether PDGF-AA or -BB affect dental epithelial cell differentiation. Dental epithelial cell line, SF2 cells were cultured with PDGF-AA or -BB. PDGF-AA, but not -BB, was strongly induced the expression of ameloblastin gene, a marker of differentiated ameloblasts. Further, we examined the effects of PDGF-AA and -BB on cell proliferation of the dental papilla cell line SP cells. PDGF-BB promoted SP cells proliferation, whereas PDGF-AA did not. In conclusion, our results indicate that PDGF-AA accelerates ameloblast differentiation and PDGF-BB promotes odontoblast proliferation, suggesting that PDGFs have important roles in tooth development.

PTH Stimulates Osteoblastic VEGF-A Expression in a Differentiation-Dependent Manner. Julianne Smith^{*1}, Jonathan Weber¹, Laura Calvi².

¹University of Rochester School of Medicine & Dentistry, USA,

²University of Rochester School of Medicine, USA

New vessel formation is required for both developmental bone growth and adult bone remodeling. The bone marrow (BM) sinusoidal vasculature is a key component of hematopoietic stem cell (HSC) trafficking and recovery from myeloablation. Osteoblastic activation of the PTH1R and systemic PTH treatment increase trabecular bone and expand HSCs. We hypothesized that PTH may exert its action on HSCs in part through effects on the BM microvasculature. In the tibial and femoral metaphyseal regions of c57/b6 mice, PTH increased microvessel number (16718.1 vs 34839.3 microvessels/hindlimb, n=5 mice per group, p= 0.0030) and vascular area (mm²): 0.1350.0194 vs 0.2810.00951, n=5 mice/group, p= 0.0001) measured by histomorphometry. To determine if PTH increases osteoblast-derived angiogenic signals, MC3T3 cells were differentiated in mineralizing media and treated with PTH(1-34) at various stages of maturation. Differentiation of MC3T3 cells did not affect baseline VEGF-a expression. PTH induced VEGF-a expression in day 7 cells at two hours, an effect that peaked at six hours (3.831.76 vs 50.79.72, n=3, p=0.0090) and was sustained 24 hours after treatment. The magnitude of the effect increased throughout differentiation and was maximal at 28 days. PTH also increased *in vitro* levels of secreted VEGF-A protein at corresponding time points (VEGF-A(pg/mL): 43.42.27 vs 46424.2, n=3, p< 0.0001). Surprisingly, *in vivo* BM plasma VEGF-A levels were decreased both in a transgenic mice with osteoblastic activation of the PTH1R (VEGF-A (pg/mL): 74.27.05 vs 44.03.67, n=3-5 mice per group, p=0.0054) and intermittent PTH treatment (VEGF-A (pg/mL): 1056.62 vs 78.64.95, n=9 mice per group, 2 independent experiments, p=0.0057), while serum VEGF-A levels were unchanged. VEGF-A bioavailability can be regulated by alternative splicing of VEGF-a pre-mRNA. Specifically, VEGF189 possesses endothelial mitogenic activity but is predominantly cell and matrix-bound. In MC3T3 cells, PTH strongly increased expression of the VEGF-a variant encoding VEGF189 six hours after treatment of maturing MC3T3 samples (1.701.100 vs 11325.1, n=2-3, p=0.0416). In conclusion, PTH increases marrow microvasculature *in vivo* in spite of decreased levels of BM soluble VEGF-A. Since PTH stimulates osteoblastic expression of matrix-bound VEGF-A, PTH-dependent proangiogenic signals in the BM microenvironment may be highly localized via modulation of VEGF-a pre-mRNA splicing in osteoblastic cells.

Synergistic Effects of Oncostatin M and IL-1 β in an Arthritic Chondrocyte Model. Liliana Mellor^{*}, Cheryl Jorcyk, Julia Oxford. Boise State University, USA

Osteoarthritis (OA) remains one of the few chronic diseases of aging without an effective treatment due to the lack of understanding of the underlying mechanisms leading to cartilage degeneration. Homeostasis between pro-inflammatory and anti-inflammatory cytokines that control the balance between matrix-degrading

metalloproteinases (MMPs) and tissue inhibitors of metalloproteinases (TIMPs) is essential to prevent increase in catabolic rate that leads to cartilage degradation. Oncostatin M (OSM), a member of the interleukin-6 (IL-6) cytokines family, and IL-1 β have been reported to act synergistically to induce gene expression of MMPs and ADAM-10 in articular cartilage, and elevated levels of both cytokines have been reported in the synovial fluid of patients with rheumatoid arthritis (RA) and OA. Our goal is to investigate the individual and synergistic effects and signaling pathways of OSM and IL-1 β on cartilage degradation. Using a cytokine array panel to detect over-expression of different cytokines and chemokines in the media of rat chondrosarcoma cells (RCS) treated with OSM, IL-1 β and OSM+IL-1 β , we found up-regulation of IL-8 (CINC-1), sICAM-1 and VEGF in all three conditions when compared to the untreated control. In addition, cells treated with both OSM and IL-1 β together showed expression of IL-6 and MIP-3 α (CCL20) while control cells and cells treated with OSM or IL-1 β alone showed no expression. These preliminary data suggests a novel synergistic effect of OSM and IL-1 β in chondrocytes that leads to cartilage degradation. In addition, IL-6 and MIP-3 α have also been found in the synovial fluid of arthritic patients, suggesting that the combination of IL-1 β and OSM may trigger a positive feedback mechanism in articular cartilage that leads to an increased catabolic rate. Future treatments for arthritis may be more efficient if both pro-inflammatory cytokines (IL-1 β and OSM) are targeted rather than individual treatments.

System Engineering Approach to Optimize the Multi-cofactor Combination of Osteogenic Cocktail with Minimized BMP-2 Doses. Yoshitomo Honda¹, Xianting Ding², Federico Mussano³, Akira Wiberg⁴, Chih-ming Ho², Ichiro Nishimura⁵. ¹UCLA / Tohoku University, USA, ²Department of Mechanical & Aerospace Engineering, Center for Cell Control, UCLA, USA, ³UCLA School of Dentistry and University of Turin, Italy, USA, ⁴The Weintraub Center for Reconstructive Biotechnology, UCLA school of Dentistry, USA, ⁵University of California, Los Angeles, USA

Objectives: Bone morphogenetic protein 2 (BMP-2) is known to be a potent osteogenic factor. However, relatively supraphysiological concentrations are required to achieve its therapeutic effect, resulting in the healthcare cost and side effect issues that may prevent its routine clinical use in dental and orthopedic fields. Drug cocktails are often more effective than single drug administration, although the identification of such the optimal drug cocktail is extremely challenging due to the large number of possible combinations arising from multiple drugs and their doses. Recently, the feedback system control (FSC) technique using an engineering scheme has been shown useful as a tool to effectively search for the optimal drug combinations, rather than screening all the possible combinations by applying the traditional high-throughput screening. The objective of this study was to apply FSC to identify potent osteogenic drug cocktails including BMP-2 at lower concentrations. **Methods:** FSC was performed by repeating the following processes: 1) Preparation of various drug cocktails. BMP-2 and six selected co-factors at ten possible concentrations were mixed in the Dulbecco's Modified Eagle Medium with fetal bovine serum and antibiotic, which were utilized as the prototype of drug cocktails. 2) Bioassays. Bone marrow derived murine mesenchymal stem cell line (D1 cell) was stimulated by the drug cocktails. The level of alkaline phosphatase (ALP) and mineralization were measured at day 3 or 6, respectively, as indicator of the potency of each drug cocktail. 3) System engineering approach. The results of bioassay were fed into a stochastic search algorithm (Differential Evolution Algorithm) to elicit modified prospective drug combinations. **Results:** None of random selected drug cocktails induce obvious mineralization, while the candidate drug combinations started to emerge after 9 iterations of FSC with ALP assay and further 6 iterations with mineralization assay. One combination induced a 37% mineralization relative to that of high-dose BMP-2 (100 ng/ml) despite the concentration of BMP-2 in that cocktail reduced to 1/64. **Conclusion:** The result indicates that FSC successfully identified candidate drug cocktails that enhanced the ALP secretion and mineral deposition, out of a possible 10 million different combinations. FSC may serve as a useful tool for identifying potent osteogenic combinatory drugs for bone regenerative medicine.

The Level of Osterix Expression in Bone Is Important to Prevent Chronic Inflammation. Wook-Young Baek¹, Eun-Hye Lee¹, Tae-Hwan Kwon², Kwon-Moo Park³, Jung-Eun Kim⁴. ¹Cell & Matrix Research Institute, Department of Molecular Medicine, Kyungpook National University School of Medicine, South Korea, ²Cell & Matrix Research Institute, Department of Biochemistry & Cell Biology, Kyungpook National University School of Medicine, South Korea, ³Department of Anatomy, Kyungpook National University School of Medicine, South Korea, ⁴Kyungpook National University School of Medicine, South Korea

Osterix (Ox) is an essential transcription factor for osteoblast differentiation and bone formation. Ox null mutants died perinatally with a complete absence of bone formation and osteoblast-specific Ox conditional knockouts showed the osteopenic phenotype after birth. Even in Ox heterozygous mice with normal bone morphology, the reduced cortical thickness and osteoblast differentiation were observed by qCT and in vitro cell culture, respectively. This result exhibited that the level of Ox expression was still important for in vivo and in vitro bone formation. Here, we questioned whether physiological homeostasis is maintained by Ox expression. In Ox heterozygous mice with a low expression of Ox in bone, the expression levels of pro-inflammatory and anti-inflammatory cytokines were significantly altered, indicating that their body due to the reduced Ox expression may remain a chronic inflammatory state. Especially, the expression of IL-6, a key mediator of chronic inflammation, was increased in Ox heterozygotes and decreased in Ox overexpressed osteoblastic cells. Kidney as well as bone is one of the most important organs in order to maintain a physiological balance controlled by numerous endocrine factors. The cross-talk between the bone and kidney for physiological homeostasis has been studied for a long time. In Ox heterozygous mice compared to wild-type, no significant difference was observed in renal morphology and functions. However, the renal regeneration after ischemic damage was remarkably delayed in Ox heterozygous mice, as indicated by elevated blood urea nitrogen and creatinine levels, and morphological alterations consistent with acute tubular necrosis. Eventually, the low level of Ox expression caused a chronic inflammation in the body, resulting in the enhanced susceptibility to renal injury after ischemia/reperfusion. This study suggests that Ox expression in bone is important to prevent chronic inflammation and maintain physiological homeostasis.

New Mechanisms Accounting for a Fine Tuning Regulation of Osteoblast and Osteoclast Activity. Barbara Peruzzi¹, Alfredo Cappariello², Andrea Del Fattore², Nadia Rucci¹, Fabrizio De Benedetti², Anna Teti¹. ¹University of L'Aquila, Italy, ²Ospedale Pediatrico Bambino Gesù, Italy

The cytokine IL-6 and the tyrosine kinase c-Src reduce osteoblast (OB) activity *in vitro* and *in vivo*. Hence we hypothesized that they might establish a functional loop to maintain OBs in an immature status. In c-Src-inhibited OBs IL-6 mRNA was reduced by decreasing STAT3 transcription factor activation, suggesting that c-Src and STAT3 converge regulating IL-6 expression. To evaluate if this interplay has a role *in vivo*, WT, IL-6 overexpressing transgenic (TG) and inflammatory agents-treated mice were treated with the c-Src inhibitor CGP76030, which reduced STAT3 activation and mouse IL-6 mRNA in whole bones. Histomorphometric analysis showed that CGP76030 treatment significantly improved TG mice bone phenotype, demonstrating c-Src inhibitor anabolic and antiresorptive effects. Moreover, we evaluated IL-6 in mice carrying bone metastases induced by the human breast cancer MDA-MB231 cells. BALB/c-nu/nu mice intracardially injected with MDA-MB231 and treated with CGP76030 showed decreased incidence of bone metastases, with a reduction of both human (derived by MDA-MB231) and mouse IL-6 in sera and in the bone metastasis tissue. Therefore, c-Src exerts a leading role on IL-6 induced osteopenic phenotype *in vivo*. IL-6-treated OBs increased c-Src activation in long-term treatment, suggesting the involvement of mediators. Although IGF-1 could be instrumental to link IL-6 and c-Src pathways, IL-6-treated OBs showed no changes of IGF-1, while IGFBP5 mRNA was increased. IGFBP5-treated OBs showed increased c-Src activation, proving a direct role for IGFBP5 in IL-6/c-Src interplay in OBs. Since, unexpectedly, also c-Src inhibition increased IGFBP5 mRNA, we analysed the IGFBP5 promoter, identifying a responsive element for Runx2, that was up-regulated by c-Src inhibition. Consistently, Runx2-over-expression increased IGFBP5 mRNA in OBs. To test if this effect depended on OB maturation, IGFBP5 was administered to OBs at subconfluence (immature) and at overconfluence (mature). At variance with subconfluent cells, in overconfluent OBs c-Src was barely expressed and, hence, insensitive to IGFBP5-induced activation. To test if in this context other cells were targeted by IGFBP5, osteoclast (OC) precursors and mature OCs were treated with IGFBP5, which induced an increase of both osteoclastogenesis and bone resorption, thereby indicating a novel role for IGFBP-5 in bone homeostasis that could provide new insights in inflammation-related and cancer-related bone pathologies

Aptamer-Functionalized Stable Nucleic Acid Lipid Particles for siRNA Cell-specific Delivery to Osteoblast Cells. Heng WU^{*1}, Tao Tang¹, Baosheng GUO², Baoting Zhang³, Zhiyun YANG⁴, Leungkim HUNG⁵, Ningsheng SHAO⁶, Lingqiang ZHANG⁷, Ling Qin⁸, Ge Zhang⁹. ¹The Chinese University of Hong Kong, Hong Kong, ²Prince of Wales Hospital, Hong Kong, ³Prince of Wales Hospital, The Chinese University of Hong Kong, Hong Kong, ⁴Hong Kong Baptist University, China, ⁵The Chinese University of Hong Kong, China, ⁶Beijing Institute of Basic Medical Sciences, China, ⁷Beijing Institute of Radiation Medicine, China, ⁸Chinese University of Hong Kong, Hong Kong, ⁹Prince of Wales Hospital, Hong Kong

Introduction: RNA interference could facilitate translation from negative regulator gene of bone formation to clinical treatment by knocking down the negative regulator genes. Unfortunately, systemic administration of small interference RNA (siRNA) requires greater therapeutic doses, which will carry a greater risk on non-bone tissues. Accordingly, the clinical application of therapeutic siRNA largely depends on specific delivery system, which possesses high selectivity for osteoblast and excellent transfection efficiency. Since aptamer could provide excellent alternatives to antibodies as cell-specific agents, so the objective of the present study is to prepare and evaluate stable nucleic acid lipid particles (SNALP) modified by L6-CELL-3 aptamer screened for rat osteoblast (ROS 17/28).

Methods: The L6-CELL-3 aptamer was attached to SNALP by post-insertion to form L6-SNALP, which was further optimized in terms of particle size, encapsulation efficiency and knockdown efficiency. The effect of L6-CELL-3 aptamer on binding and selectivity of L6-SNALP as well as the cellular uptake of CKIP-1 siRNA was determined by flow cytometry. The stability in serum and cytotoxicity of the L6-SNALP were also evaluated by agarose gel electrophoresis and MTT, respectively. After administration of L6-SNALP via tail vein injection, the rats were sacrificed at 4 hours and the distal femurs were dissected for immunohistochemistry analyses using ALP and RUNX2 antibodies as markers to evaluate the cell-specific delivery in vivo.

Results: After optimization, the average particle size of L6-SNALP was 906 nm and encapsulation efficiency was 864.6%. It demonstrated excellent knockdown efficiency at low concentration of 8 nM CKIP-1 siRNA. L6-SNALP also suggested selective binding and facilitated the cellular uptake of CKIP-1 siRNA in ROS17/28 cell compared with control-SNALP. In addition, it was stable in serum up to 12 h and possessed low cytotoxicity compared with traditional delivery system. The immunohistochemistry results suggested numerous instances of co-localization of the FAM-labeled siRNA with the RUNX2- or ALP-positive cells in L6-SNALP, which indicated this delivery system facilitated siRNA targeting osteoblast cell.

Conclusions: L6-SNALP suggested high knockdown efficiency at low siRNA dose and favorable targeting with osteoblast cell. It could be a potential cell-specific delivery system for targeting osteoblast cell with high efficiency, selectivity and low cytotoxicity.

Deficiency of Bax Expression Prevents Diabetes-induced Osteoblast Death and Bone Loss. Lindsay Martin-Coe^{*1}, Laura McCabe². ¹New York University College of Dentistry, USA, ²Michigan State University, USA

T1-diabetes is a metabolic disorder associated with bone loss. Both bone formation and density are decreased, however the exact mechanisms accounting for diabetic bone loss remain unknown. Previously, our lab reported an elevation in osteoblast apoptosis in diabetic mouse bones illustrated by increased TUNEL positive osteoblasts and Bax mRNA expression. Bax is a pro-apoptotic factor that mediates the intrinsic death pathway. Intrinsic apoptosis has also been associated with osteoblast death and bone loss in models of unloading and aging. Here we hypothesize that the diabetes-induced increase in Bax expression mediates osteoblast death. To test this, we examined the effect of diabetes on bones in Bax deficient mice. Diabetes was induced in 16-week-old male C57BL/6 Bax deficient and wild type littermates. Bones were examined for markers of osteoblast apoptosis, as well as bone formation and resorption. Our findings indicate that Bax deficiency protects osteoblasts from diabetes-induced osteoblast death. Decreases in trabecular BV/TV and markers of bone formation observed in diabetic bone were fully attenuated in Bax deficient diabetic mice compared to vehicle treated mice, while markers of bone resorption remained unchanged. Since diabetic marrow induces osteoblast apoptosis, we examined if Bax deficient osteoblasts were protected from diabetic marrow-induced osteoblast death. Co-culture studies demonstrate that Bax deficient osteoblasts are protected from diabetic marrow induced increases in osteoblast caspase 3 activity. Our results suggest a role for Bax in T1-diabetes-induced osteoblast death and bone loss. Therefore, targeting Bax expression through pharmaceuticals could prevent diabetes-induced osteoblast death and ultimately bone loss. One commonly used therapy for osteoporosis; bisphosphonates reduces osteoblast death while inhibiting osteoclast activity. Therefore we examined the effects of bisphosphonates on diabetic bone pathology. Our results illustrate that bisphosphonate therapy protects against diabetes-associated elevations in Bax mRNA levels and death, as well as bone loss. Taken together, our results suggest that inhibition of Bax-mediated osteoblast death prevents diabetes-induced bone loss.

Disclosures: Lindsay Martin-Coe, None.

Vitamin C Administration Markedly Ameliorates Bone loss by Restoring the Osteoblastic Viability in Sod1-deficient Mice. Hidetoshi Nojiri^{*1}, Yoshitomo Saita², Daichi Morikawa³, Keiji Kobayashi⁴, Mitsuru Saito⁵, Kazuo Kaneko⁶, Takahiko Shimizu⁷. ¹Juntendo University, School of Medicine, Japan, ²Department of Orthopaedics, Juntendo University School of Medicine, Japan, ³Juntendo University, Japan, ⁴Molecular Gerontology, Tokyo Metropolitan Institute of Gerontology, Japan, ⁵Jikei University School of Medicine, Japan, ⁶Department of Orthopaedics, Juntendo University, Japan, ⁷Tokyo Metropolitan Institute of Gerontology, Japan

We have reported bone phenotypes in SOD1 deficiency, such as decreased bone mass and senescent cross-linking (Nojiri, H. et al. 2009 ASBMR and Saita, Y. et al. 2010 ASBMR). In comprehensive antioxidant treatments using Sod1-deficient mice for the rescue experiment, we found that several compounds, including vitamin C, were useful for improving the bone mass of Sod1-deficient mice (unpublished results). The mice were given 1% vitamin C (VC) in drinking water for 12 weeks from 4 weeks of age. In osteoblast culture, VC was added to produce a final concentration of 50 µg/ml for 24 hr for the ROS measurement and for 48 hr for the BrdU incorporation assay and cell death measurements. The oral administration of vitamin C completely restored the osteoporotic features of Sod1-/- mice, indicating that superoxide-induced bone loss could be improved by antioxidant treatment. These results also imply that the bone phenotypes in SOD1 deficiency were caused by excess oxidative stress, rather than by the lack of SOD1 itself. The total body BMD, as measured by DEXA; the BV/TV of the tibia, as measured by pQCT; and the femoral bone weight were significantly improved after vitamin C treatment, without any change in the length of the long bones. In addition, bone strength was markedly improved by VC administration. Interestingly, VC treatment also produced a partial improvement in the composition of collagen cross-links. In cellular experiments, VC treatment markedly suppressed the level of DCF-reactive ROS in Sod1-/- osteoblasts. In addition, the BrdU and TUNEL assays showed complete restoration of cell proliferation and apoptosis in Sod1-/- osteoblasts after the addition of VC. These results indicate that VC treatment completely restored osteoblast viability through the elimination of intracellular ROS, suggesting that VC treatment rescues osteopenia by restoring the osteoblastic viability in Sod1-/- mice.

These results imply that an intracellular redox imbalance caused by SOD1 deficiency plays a pivotal role in the development and progression of bone fragility both in vivo and in vitro.

Angiotensin II induces osteoblast production of MMP-3 and MMP-13 via the AT₁ receptor. Kumiko Nakai^{*1}, Takayuki Kawato², Masafumi Motohashi³, Masao Maeno⁴. ¹Division of Oral Health Sciences, Japan, ²Nihon University School of Dentistry, Tokyo, Japan, ³Department of Oral Health Sciences, Nihon University School of Dentistry, Japan, ⁴Nihon University School of Dentistry, Japan

Objective: Angiotensin II (Ang II), which acts via Ang II type 1 (AT₁) and/or type 2 (AT₂) receptors, not only regulates systemic blood pressure through a direct vasoconstrictive effect but has also been shown to regulate bone metabolism by stimulating osteoblasts. However, the role of Ang II in the turnover of bone matrix proteins by osteoblasts is unclear. Therefore, we examined the effect of Ang II on the expression of matrix metalloproteinases (MMPs), plasminogen activators (PAs), and their inhibitors, including tissue inhibitors of metalloproteinases (TIMPs) and PA inhibitor-1 (PAI-1), in osteoblasts.

Methods: Rat ROS 17/2.8 osteoblast-like cells were cultured for up to 7 days with Ang II (0, 10⁻⁸ M, 10⁻⁷ M or 10⁻⁶ M) in the presence or absence of the AT₁ receptor blocker losartan (5 µM) or the AT₂ receptor blocker PD123319 (5 µM). Expression of the AT₁ and AT₂ receptors, MMPs, TIMPs, PAs, and PAI-1 was examined at the mRNA and protein levels by real-time PCR and Western blotting, respectively.

Results: Both the AT₁ and AT₂ receptors were expressed in ROS 17/2.8 cells. While cell proliferation was not affected by treatment with Ang II, alkaline phosphatase activity decreased. The expression of MMP-3 and MMP-13 increased significantly as a result of treatment with 10⁻⁶ M Ang II, whereas the expression of MMP-2, MMP-14, urokinase-type PA, tissue-type PA, TIMPs-1, -2, -3, and PAI-1 was unaffected by Ang II. Expression of MMP-1 and TIMP-4 was not detected. Losartan blocked Ang II-induced expression of MMP-3 and MMP-13, whereas PD123319 did not completely block these responses.

Conclusion: These results suggest that Ang II stimulates the resorption process that occurs during the turnover of osteoid by increasing the production of MMP-3 and MMP-13 in osteoblasts via the AT₁ receptor. Furthermore, they suggest that Ang II does not influence the plasminogen/plasmin pathway in osteoblasts.

Bone Size QTL Gene Located in Mouse Chromosome 4 is a Mechanoresponsive Gene. Jon Wergedal*, Chandrasekhar Kesavan, Subburaman Mohan, Jerry L. Pettis Memorial VA Medical Center, USA

Periosteal bone formation rate (BFR) is an important determinant of bone cross sectional size; and therefore of bone strength. Therefore, identification of genes that regulate periosteal bone expansion and elucidation of their molecular pathways are essential to develop strategies for a therapeutic strengthening of long bones. In previous work, we have identified a key bone size QTL on mouse chromosome (Chr) 4 using different inbred strain mouse crosses. Furthermore, we have demonstrated that a congenic line B6.C3H-4T-3 (4T3) of mice with a small region (129-139 Mbp) of Chr 4 from C3H/HeJ (C3H) in a C57/BL6 (B6) background exhibited an increased femur cross sectional size. We examined other bones and found the increased size phenotype in the tibia (242%, n=10, p<.01) and radius (122%, n=10, p<.01), indicating a general effect of the QTL gene on the bone size phenotype. Because mechanical strain is a known regulator of periosteal expansion, we hypothesized that the bone size QTL gene in Chr 4 is a mediator of mechanical strain response in the skeleton. To test this hypothesis, 11 4T3 congenic and 8 B6 control mice were subjected to external loading using a 4-point bending device. A 9n cyclic load was applied at a frequency of 2 hertz for 36 cycles. The force was applied to the tibia once daily for 6 days and the mice were euthanized on the 9th day. The mice were injected with tetracycline on day 4 and calcein on day 8 to label newly formed bone. Histomorphometric analysis revealed that the basal BFR in the externally unloaded left tibia was lower in the 4T3 congenic than in the B6 control mice (-3213%, p<.001) which was due to reduced bone forming surface (BFS) (-299%, p<.01). External loading significantly increased the BFR in the right tibia compared to the contralateral tibia in both 4T3 and B6 mice. However, the mechanical loading-induced increase in the BFR was 33% higher (p<.05) in 4T3 mice compared to B6 mice. This mechanical loading-induced increase in BFR was primarily due to a 37% increase in BFS (p<.05) in the 4T3 mice compared to the B6 mice. Conclusions: 1) The bone size QTL gene, located in the 129-139 Mbp of Chr 4, is a mediator of mechanical strain response in the skeleton. 2) Because the greater increase in the BFS in the 4T3 congenic mice in response to loading indicates an increased number of osteoblasts and because Wnt4, a known inducer of bone cell proliferation, is present in this Chr region, the Wnt4 gene could be a candidate for the Chr 4 bone size gene.

Clopidogrel (Plavix®), a P2Y₁₂ Receptor Antagonist, Inhibits Osteoblast Function *in vitro* and Decreases Trabecular Bone *in vivo*. Isabel Orriss*¹, Susanne Syberg², Andrea Brandao-Burch¹, Mark Hajjawi¹, Timothy Arnett¹, Peter Schwarz³, Niklas Jorgensen⁴. ¹University College London, United Kingdom, ²Copenhagen University Hospital Glostrup, Denmark, ³Glostrup Hospital, Denmark, ⁴Copenhagen University Hospital Glostrup, Denmark

It is evident that extracellular nucleotides, signalling through P2 receptors (P2R), play a significant role in bone, modulating both osteoblast (OB) and osteoclast (OC) function. Clopidogrel (Plavix®) is a selective P2Y₁₂R antagonist and, currently, is the only P2R antagonist available for therapeutic use. It is an antithrombotic, prescribed to reduce the risk of heart attack and stroke, acting via inhibition of platelet aggregation. In this study, we investigated the effects of clopidogrel treatment on (1) OB formation, differentiation and activity *in vitro*; and, (2) trabecular and cortical bone parameters *in vivo*. OBs were obtained from rat calvaria and cultured with clopidogrel (1-50µM) for up to 14d. P2Y₁₂R expression was confirmed using qPCR and western blotting. ADP (≤100µM), an agonist at the P2Y₁₂R had no effect on OB differentiation and function. Clopidogrel at 10µM and 25µM inhibited mineralised bone nodule formation by 50% and >85%, respectively. Clopidogrel slowed OB proliferation with dose-dependent decreases in cell number of 25-40% in differentiating OBs (d7). One dose of 10-25µM clopidogrel to mature OB also decreased cell viability by 15%. At 14d, ≥10µM clopidogrel reduced ALP activity by ≤70% and collagen formation by 40%. Total E-NPP activity was unaffected. Activation of P2Y₁₂R receptors by ADP caused decreased intracellular cAMP levels; a single dose of 1-10µM clopidogrel to mature OB increased cAMP levels by 35%. qPCR array analysis of clopidogrel treated osteoblasts (14d) showed no change in ALP or collagen expression, however, levels of FGF1 and FGF3 were increased up to 9-fold. A second P2Y₁₂R antagonist, ARC-66096, exhibited similar effects on osteoblast function *in vitro*. 20-week old mice (n=10-12) were ovariectomised or sham treated and dosed orally with clopidogrel (1mg/kg) or vehicle (NaCl) daily for 4 weeks. DEXA analysis showed clopidogrel treated animals had decreases of 2% and 4% in whole body and femoral BMD, respectively. Detailed analysis of trabecular and cortical bone using µCT showed decreased trabecular bone volume (BV/TV) in the tibia (24%, p<0.05) and femur (18%, p<0.05) of clopidogrel-treated mice. Trabecular number was reduced 20% (p<0.01), whilst trabecular separation was increased up to 15% (p<0.05). Trabecular thickness and cortical bone parameters were unaffected. Combined, these findings indicate that long-term exposure of bone cells to clopidogrel *in vivo* could directly impact bone health.

Deregulation of Wnt Signaling in the Fracture Callus Following Binge Alcohol Exposure is Attenuated by Lithium Chloride Treatment. Kristen Lauing*¹, Philip Roper², Rachel Nauer³, John Callaci⁴. ¹Loyola University Medical Center, USA, ²Loyola University Medical Center, Cell Biology, Neurobiology, & Anatomy Program, USA, ³Loyola University Medical Center, Department of Orthopaedic Surgery, USA, ⁴Loyola University of Chicago, USA

Binge alcohol consumption is a contributing factor in up to 40% of all orthopaedic trauma cases and is associated with delayed or incomplete fracture healing. The Wnt pathway, through strict temporal regulation of β-catenin, is essential for the formation of new bone and cartilage during repair. Lithium treatment (LiCl) is known to indirectly stimulate the Wnt pathway. We have previously shown that binge alcohol exposure decreases callus strength and quality, modulates the total expression of canonical Wnt transcriptional activation and downstream Wnt target gene expression, and perturbs the protein levels of β-catenin in the fracture callus. This study aims to investigate whether LiCl treatment can restore normal bone healing in a murine binge alcohol-tibial fracture model. Mice were administered alcohol (2 g/kg) or saline intraperitoneally once per day for 3 consecutive days, and subjected to a stabilized, mid-shaft tibial fracture. Four days post-fracture, mice were given either standard drinking water or 0.015M LiCl in water daily to examine the effects of exogenous Wnt pathway enhancement during healing. Mice were sacrificed 3, 6, 9, 14, or 21 days post-fracture.

Histological analysis revealed that alcohol was associated with decreased callus size and suppression of endochondral ossification with increased fibrous tissue formation, and inhibition of chondrocyte maturation and hypertrophy in the cartilaginous callus. The temporal expression of β-catenin in callus tissue was significantly disrupted by alcohol throughout day 21 of healing, which corresponds to previously observed alcohol-induced changes in Wnt transcriptional activity in the callus. Using a customized 4-point bending apparatus, we found that fracture calluses from binge-alcohol treated mice were significantly weaker than those from saline-treated controls. LiCl treatment attenuated alcohol-related damage to the fracture callus and Wnt signaling by augmenting β-catenin protein levels to those seen in saline-treated mice, restoring endochondral ossification, and increasing callus strength in alcohol-treated mice.

These data show that deficient fracture repair in alcohol-abusers may be due in part to deregulation of Wnt/β-catenin signaling during early stages of healing, leading to damaging effects on the biomechanical and cellular aspects of healing. Exogenous activation of the Wnt pathway during healing may improve fracture repair in patients at risk for alcohol-related complications.

Effects of Focused Shock Wave (FSW) on Cementoblasts *in vitro*. Dawei Liu*. Marquette University School of Dentistry, USA

Root resorption (RR) is a pathological consequence of orthodontic treatment, which may cause mobility and eventual loss of teeth. How to prevent and repair RR is critical to the quality of orthodontic care. Similar to ultrasound therapy, focused shock wave (FSW) has been applied to enhance angiogenesis, growth and healing of bone, however its effects on RR have never been studied. The purpose of this study was to investigate the effects of FSW on cementoblasts, the cells forming and repairing cementum - the out layer of dental root, in attempt to find evidence to support potentially using FSW to treat RR. Based on current knowledge, we hypothesized that FSW at a certain level induces anabolic responses in cementoblasts. To test our hypothesis, OCCM.30 cementoblasts were prepared in suspension with a density of 10⁷/ml. One ml of the cell suspensions were prepared in eppendorf tubes which were geared to the FSW stimulator (Storz Medical AG, Switzerland). The cells were subjected to a single dose of 2000 impulses of FSW at 3 different dose levels (0.1mJ/mm², 0.25mJ/mm² and 0.5mJ/mm², respectively). Immediately after FSW, an aliquot of cell suspension was collected and spin to test ATP released - an early signal in bone metabolism. After 24 hours of post-incubation, the cells were centrifuged and lysed to test protein productions of sclerostin (SOST) - a negative regulator of bone formation and receptor activator of NFκB ligand (RANKL) - a direct stimulator of bone resorption. Controls were set under identical conditions without FSW application. To test the proteins, 50 micrograms of cell lysates were resolved through 10% SDS-PAGE, immunoblotted with the 1st antibodies against SOST and RANKL, followed by the 2nd antibody incubation and gel documentation. Densities of the gel bands of interest were equalized by that of a cytoskeletal protein vinculin. One-way ANOVA was used to compare the differences among the groups with p value set at 0.05. As results, ATP release was significantly increased in a dose-dependent manner (n=6, p=0.000). SOST protein was significantly decreased only at the dose level of 0.25mJ/mm² (n=3, p<0.05). RANKL protein was significantly increased at 0.1 and 0.5 (n=3, p<0.01) but not at 0.25mJ/mm² levels. Our data suggest (1) FSW at 0.25mJ/mm² level anabolically modulates bone remodeling by decreasing SOST production but not decreasing RANKL production; (2) FSW might potentially be used to treat root resorption in orthodontics.

Hairy and Enhancer of Split Related with YRPW Motif (Hey)2 Uncouples Bone Formation from Bone Resorption. Stefano Zanotti^{*}, Ernesto Canalis, St. Francis Hospital & Medical Center, USA

Notch signaling inhibits osteoblastogenesis and maintains bone marrow precursor cells in an undifferentiated state. In osteoblasts, Notch signaling induces the expression of proteins encoded by *Hairy and Enhancer of Split (Hes)1* and *Hes-related with YRPW motif (Hey)1*, *Hey2* and *HeyL*. Although the canonical signaling pathway mediates the actions of Notch in osteoblasts, the contributions of each target gene have been only partially explored. In fact, misexpression of *Hes1* in cells of the osteoblastic lineage does not phenocopy all the actions of Notch *in vivo* and *in vitro*, suggesting that alternate Notch targets mediate its activity in osteoblastic cells. *Hey1* misexpression has limited impact on skeletal homeostasis, and global *Hey2* inactivation is lethal, not allowing its study in the postnatal skeleton. In an effort to discern the skeletal activity of Notch targets, transgenics overexpressing *Hey2* under the control of a 3.6 kilobase fragment of the collagen type I $\alpha 1$ promoter were created in a tropism for Friend Virus-B genetic background. *Hey2* transgenics were viable and healthy, and bone microcomputed tomography revealed normal cancellous bone volume and trabecular microarchitecture. Bone histomorphometric analysis demonstrated a 40 to 50% decrease in mineralizing surface and bone formation rate, associated with a 20 to 30% increase in eroded surface and osteoclast number, demonstrating an uncoupling of bone formation from bone resorption in *Hey2* transgenic male mice. *Hey2* overexpression in female mice decreased osteoblast number and mineral apposition rate but had no effect on eroded surface or osteoclast number. To understand the mechanisms of *Hey2* action, osteoblasts were isolated from *Hey2* transgenics and control littermates. In agreement with the phenotype observed *in vivo*, *Hey2* inhibited alkaline phosphatase mRNA levels and activity, and suppressed osteocalcin transcripts. Osteoblasts from *Hey2* transgenic male or female mice induced resorption by co-cultured osteoclast precursors, suggesting that the resorptive phenotype in female mice was suppressed by estrogens. Since the *in vivo* and *in vitro* cellular effects were not translated in changes in skeletal microarchitecture, these results suggest that either the consequences of *Hey2* overexpression are transient, or that *Hey2* activates protective mechanism to preserve bone mass and skeletal integrity. In conclusion, overexpression of *Hey2* in osteoblasts uncouples bone resorption from bone formation.

Heparanase is a Physiologic Regulator of Bone Formation and Bone Mass. Vardit Kram^{*}¹, Eyal Zcharia², Orr Ofek¹, Alon Bajayo³, Malka Attar-Namdar¹, Yoav Smith¹, Jin-Ping Li⁴, Israel Vlodavsky², Itai Bab⁵. ¹Hebrew University of Jerusalem, Israel, ²Technion, Israel, ³Hebrew University Faculty of Dentistry, Israel, ⁴Uppsala University, Sweden, ⁵The Hebrew University, Israel

Heparanase (Hpse) is an endoglycosidase, which cleaves the heparan sulfate sugar moieties of heparan sulfate proteoglycans (HSPGs). Hpse has been implicated mostly in pathological processes. We have previously shown that Hpse is normally expressed in osteoblasts and promotes bone formation primarily by increasing osteoblast number. Hpse transgenic mice have a high bone mass phenotype attributable mainly to increased bone formation, with an additional spectrum of extraskeletal abnormalities. These mice also show decelerated skeletal elongation. By contrast, we show here that the only phenotype exhibited by Hpse deficient (*Hpse*^{-/-}) mice is skeletal, which mirrors the transgenic skeletal phenotype, namely, low bone mass (LBM) and accelerated longitudinal growth. The LBM is due to both reduced bone mass accrual and accelerated age-related bone loss and is manifested mainly in females; only the accelerated age-related bone loss is shared by *Hpse*^{-/-} males. Hpse-deficient osteoblasts have a reduced proliferative capacity, which is also demonstrable by wild type osteoblasts treated with a Hpse inhibitor. Although HSPGs regulate SMAD signaling, Hpse failed to activate this pathway in osteoblasts. A gene array analysis comparing *Hpse*^{-/-} and wild type osteoblasts suggests that the sexual dimorphism seen in the Hpse deficient animals could be related to androgen protection against reduced bone formation associated with impairments to the β -catenin pathway, such as increased caveolin-1 expression. The gene array analysis further shows the involvement of multiple growth and differentiation pathways in the *Hpse*^{-/-} skeletal phenotype. Both Hpse null males and females show marked decreases in *Ibsp* and *Ost-PTP* expression. The expression of both genes is highly upregulated in the Hpse transgenic animals. These changes are accompanied by a slight interference with energy metabolism. Because LBM is the only spontaneous phenotype so far identified in the Hpse mutant mice, it appears that the main physiologic involvement of Hpse is associated with a normal rate of bone mass accrual and maintaining bone remodeling at balance, thus protecting the skeleton against age-related LBM.

Mechanism of Formation of Novel Bone Forming Cells (monoosteophils) from LL-37 Treated Monocytes. Zhifang Zhang^{*}¹, John Shively². ¹City of hope, USA, ²Department of Immunology, City of Hope, USA

BACKGROUND: Bone generation and maintenance involve osteoblasts, osteoclasts, and osteocytes. However, an incomplete understanding of bone forming cells during wound healing has led to an unmet clinical need such as nonunion of bone fractures. Recently, our published paper showed that LL-37, the active peptide of human cathelicidin, has an ability to induce monocyte differentiation to a new type of bone forming cells (monoosteophils). We now have investigated the mechanism of monoosteophil formation. **RESULTS:** Treatment of monocytes from blood with LL-37 for 6 days resulted in their differentiation to monoosteophils. Monoosteophil on osteologic discs built bone-like nodules which consist of calcium and phosphorus. *In vivo* transplantation studies in NOD/SCID mice show that LL-37-differentiated monocytes form bone-like structures similar to endochondral bone formation. Monoosteophils are identified by up-regulation of integrin $\alpha 3$ and $\alpha 3 \beta 1$ and down-regulation of CD14, CD16, CD32, and CD163 on the membrane. Microarray analyses indicated the differential expression of 206 genes in the formation of monoosteophils. Among these genes we found elevated level of CCL22. **CONCLUSION:** Blood derived monocytes treated with LL-37 can be differentiated into a novel bone forming cell that functions both *in vitro* and *in vivo*. We propose the name monoosteophil to indicate their monocyte derived lineage and their bone forming phenotype. Integrin $\alpha 3$ and $\alpha 3 \beta 1$, CD14, CD16, CD32, and CD163 can be used as differentiation markers of monoosteophils and that the chemokine CCL22 may be involved in their formation.

Fig 1. LL-37-differentiated monocytes built nodule-like structure on osteologic discs. Monocytes were incubated in the presence of M-CSF/RANKL (both at 25 ng/mL, A, D) or 5 μ M LL-37 (B,C,E,F) on BioCoat™ Osteologic™ Discs in 5% CO₂ atmosphere. After incubation for 3 weeks, cells were removed with bleach and observed by phase contrast microscopy (magnification $\times 200$, A, B) or scanning electron microscopy (SEM) (C). After incubation for 7 weeks, pit formation and osteoclast are shown on the disc incubated with M-CSF/RANKL-differentiated monocytes by using SEM (D), and built-up structures and cells are shown on the disc of LL-37-differentiated monocytes (E-F).

Opto-Functional Control of Intracellular RANKL Transport/Secretion in Osteoblasts to Enhance Coupling With Osteoclasts Based on Photo-Energy Conversion of Molecularly-Engineered Channel-Rhodopsin. Takuya Notomi¹, Miyuki Kuno², Yoichi Ezura³, Masaki Noda⁴. ¹GCOE, Tokyo Medical & Dental University, Japan, ²Osaka City University, Japan, ³Tokyo Medical & Dental University, Medical Research Institute, Japan, ⁴Tokyo Medical & Dental University, Japan

Lysosomal vesicles (Lv) have a key role for transport of intracellular RANKL to membrane-bound RANKL (mBRANKL), however, its mechanism remains unclear. The Lv fusion is related to the change of membrane potential (MP). Thus, MP could regulate osteoblast (OB) function and RANKL secretion. So far little is known about the role of MP on bone physiology, because it is hard to control temporal patterns of MPs. To challenge this difficulty, we developed a genetic and cellular strategy to evoke light-inducible modulation of MP in OBs and show the novel mechanism of intracellular transport of RANKL via regulation of MP.

For controlling MP, we genetically modified OBs (MC3T3) by permanently transfecting Channel rhodopsin Wide Receiver (ChWR) which converts photo-energy (blue light) into channel activation and causes the permeation of cations. After establishing the stable cell lines of ChWR (WR) or control vector (C) expressing OBs, the MP was recorded under the whole cell clamp configuration. These cells were exposed to a series of blue light stimulus (BLS; (2" stimulus - 1" rest) × 10 times). We found that MPs in WR were depolarized immediately (< 20 msec) after the on-stimulus (AMP: 16.3 ± 1.1 mV) and were returned to the pre-stimulus potential after the off-stimulus. No changes were recorded in C. Thus, we established a new illumination system that enables us to optically control the temporal patterns of MP.

We went on to elucidate functional aspects of the relationship between RANKL secretion and MP in OBs. Although the BLS did not increase mBRANKL in RANKL-overexpressed (R-OE) C, mBRANKL was increased 5-fold in R-OE WR at 10 min after BLS. The BLS also increased the endogenous RANKL mRNA expression 5-fold at 120 min after BLS. For functional analysis, co-culture (RAW267.4 and R-OE WR or C) was subjected to BLS once a day for 5 days. No osteoclasts were observed in C. In contrast, biochemical TRAP activities in WR were increased 4-fold and the development of mature osteoclasts was observed. These results indicate that light-controlled membrane depolarization promotes osteoblastic RANKL expression in cell membrane that leads to enhanced coupling to stimulate osteoclastogenesis.

In conclusion, photo-energy conversion via ChWR regulates mBRANKL expression and osteoclast formation. Our system of photo energy conversion could trigger RANKL secretion whenever we need and provide a powerful tool to analyze osteoblastic control for osteoclasts during remodeling.

Osteoblastic Wnts Regulate Postnatal Bone Remodeling through Maintaining BMSC and Inhibiting Inflammation. Wan Yong¹, Cheng Lu², Jingjing Cao², Zhengju Yao³, Gang Ma¹, Xizhi Guo¹. ¹Shanghai Jiao Tong University, Peoples Republic of China, ²colleague, China, ³mentor, China

Inflammatory bone loss is a puzzling and not well-defined process prevailing in arthritis. Previous study has shown that Wnt signaling plays an important role in embryonic osteoblastogenesis and bone formation. To understand the elaborate function of Wnts in postnatal bone homeostasis, we block the secretion of Wnts from osteoblasts through conditionally inactivating Wntless (Wls) gene by Col1(3.6kb)-Cre and Osteocalcin (Osc)-Cre. Most of the *Col1^{cre/+}*; *Wls^{cl}* displayed various defects of osteopenia, scoliosis and inflammation in bone marrow. The mutant mice showed high activity of bone turnover with increased bone resorption and decreased bone formation. *Osc^{cre/+}*; *Wls^{cl}* mice exhibited similar but milder defects as that of *Col1^{cre/+}*; *Wls^{cl}* mutant. In addition, the maintenance of bone marrow stem cell (BMSC) was impaired in *Col1^{cre/+}*; *Wls^{cl}* mutant. Extensive T cell infiltration was also detected in bone marrow upon inactivation of osteoblastic Wnts. IHC analysis revealed that Wnt5a and Wnt10b were the major osteoblastic Wnts that orchestrated postnatal bone remodeling, maintained BMSC capacity and protected from inflammatory bone loss.

Neuropeptide Y1 Receptor Antagonist Reduces Periosteal Bone Formation and Mitigates the Bone Response to Mechanical Loading. Edith Gardiner^{*}, Leah Worton, Steven Bain, Ted Gross, Sundar Srinivasan. University of Washington, USA

Reports indicating that neuropeptide Y (NPY) inhibits bone formation through osteoblastic Y1 receptor provide a basis for therapeutic targeting of NPY signaling. Furthermore, given evidence that NPY signaling is involved in bone cell mechanotransduction, we sought to explore whether suppression of endogenous inhibitory signaling (NPY) in the context of an anabolic stimulus (exogenous mechanical loading) would prove to be synergistic. We tested this concept by exposing mouse tibiae to exogenous mechanical loading with/without a Y1 receptor antagonist. Experimentally, the right tibiae of C57BL/6J mice were loaded (18 wk old, 8-11 per treatment group, 1600 μ s at 1 Hz, 50 cycles/day, 3 times/wk for 3 wk) and mice received the selective Y1 receptor antagonist BIBO3304 (0.12 or 0.4 mg/kg body weight, i.p.) or vehicle, 1 hr before (n=4 males, n=4 females/group) or 4 hr after (n=3 males/group) loading. Bone formation was assessed in contralateral and externally loaded tibiae by standard dynamic histomorphometry. Mean values for vehicle- and BIBO3304-treated groups were compared by t-test. Initial data analyses revealed no differences due to gender or pre/post loading treatment; all mice were therefore combined for statistical analyses. In contrast to genetic models in which Y1 gene deletion increased periosteal bone formation, both doses of BIBO3304 reduced periosteal mineralized surface (p.MS/BS, -73%) and bone formation rate (p.BFR/BS, -78%) vs vehicle on non-loaded contralateral limbs but did not alter periosteal mineral apposition rate (Table 1). Y1 antagonist treatment at the higher concentration also inhibited the loading-induced increase in p.MS/BS (-53%), p.BFR/BS (-53%), and mineral apposition rate (p.MAR, -37%). One possible reason for the unexpected mitigation of basal and mechanically induced bone formation is varied antagonist effects depending on osteoblastic maturity. Alternatively, BIBO3304-induced alterations in sympathetic tone may also contribute to the effects observed here. Clarifying the differences between the effects of constitutive gene deletion and those of acute pharmacological intervention will be critical in enabling therapeutic targeting of Y1 receptor to stimulate a robust bone anabolic response with or without exercise.

bone metabolism. Using picosecond time-resolved fluorescence microscopy and G protein-coupled receptor conformation-sensitive fluorescence resonance energy transfer (FRET), we investigated conformational transitions in PTH1R and 5HT1b. Genetically engineered PTH1R and 5HT1b sensors containing an intramolecular FRET pair were used to enable the detection of conformational changes in single Human Embryonic Kidney (HEK) 293 cells in response to stimulation with different fatty acids. Downstream PTH1R and 5HT1b pathway activation was confirmed by monitoring ERK 1/2 phosphorylation through western blot analysis. (1) Stimulation of PTH1R and 5HT1b sensors with EPA or DHA caused significant conformational changes in the receptors. (2) The response to EPA stimulation in the PTH1R sensor was inhibited in the presence of the PTH1R antagonist [Nle8,18,Trp34]PTH(3-34). (3) Activation of PTH1R and 5HT1b downstream signaling with EPA or DHA resulted in a significant increase in ERK phosphorylation in western blot analysis. (4) ERK phosphorylation by activation of PTH1R with EPA or DHA was inhibited in the presence of PTH1R antagonist [Leu11-D-Trp12]PTH-rP(7-34). In conclusion, increased levels of EPA and DHA cause a change in the confirmation in PTH1R and 5HT1b receptors that leads to downstream activation and ultimately results in an increase of ERK phosphorylation. These results indicate that the fatty acids, EPA and DHA, can modulate the action of PTH1R and 5HT1b receptors and consequently provide a putative molecular mechanism for the anabolic effect of omega-3 fatty acids in bone

Recombinant Activated Protein C Stimulates Bone Nodule Formation and Osteocalcin Expression in Osteoblasts. Kaitlin Shen¹, Benjamin Chan², Meilang Xue³, Colin Dunstan⁴, Hala Zreikat⁴, Christopher Jackson³. ¹Kolling Institute of Medical Research/University of Sydney, Australia, ²Royal North Shore Hospital, Australia, ³Kolling Institute of Medical Research, Australia, ⁴University of Sydney, Australia

Introduction: Activated Protein C (APC) is a natural anticoagulant with strong anti-inflammatory and cytoprotective properties. It has a potential therapeutic role in rheumatoid arthritis (RA) by reducing activation of synovial fibroblasts and monocytes, however, the effects of APC on RA are not fully understood. This study aims to determine the effect of APC on bone turnover through its effects on osteoblast proliferation, differentiation and maturation.

Method: Human bone derived cells (HBDCs), isolated from RA or OA subchondral bone post knee replacement surgery and the mouse pre-osteoblast MC3T3-E1 cell line were used in this study. The expression of APC and its receptor, endothelial protein C receptor (EPCR) and type I collagen in HBDCs was determined by immunofluorescence/immunocytochemistry. The effect of recombinant human (rh) APC on HBDC and MC3T3-E1 proliferation was quantified by MTT assay and cell counts at 24, 48 and 72 hours. Reverse transcriptase qPCR was used to examine the mRNA transcripts of MC3T3-E1 cells modulated by rhAPC over 22 days. The effect of rhAPC on *in vitro* bone nodule formation was visualized by alizarin red staining.

Results: Immunofluorescence showed prominent expression and colocalization of APC and EPCR in HBDCs. Proliferation studies demonstrated that rhAPC significantly decreased MTT incorporation over 72 hours and also dose-dependently decreased cell count, by up to 40% when used at 10µg/mL. However, this suppression of proliferation was accompanied by a marked increase in type I collagen production over 24 hours after treatment with 10µg/mL of rhAPC, indicative of an early effect on osteoblast differentiation. The addition of rhAPC to MC3T3-E1 cells stimulated *in vitro* bone nodule formation by increasing both number of bone nodules (~30%) and alizarin red staining of calcified osteoblast monolayer. This effect may be partly explained by an average 32% upregulation of osteocalcin expression beyond 4 days of rhAPC treatment, suggesting that later stages of osteoblastic differentiation are maintained.

Conclusion: APC and EPCR are co-localized in osteoblasts and exogenous APC stimulates bone nodule formation possibly by increasing type I collagen and osteoblastic differentiation. Further investigations will determine the underlying mechanisms and implications for diseases such as rheumatoid arthritis.

Reduced Accumulation of Bone in Mice Lacking the *Men1* Gene in Osteoblasts. Ippei Kanazawa¹, Geeta Nayak², Lucie Canaff¹, Monzur Murshed¹, Geoffrey Hendy³. ¹McGill University, Canada, ²McGill University, Canada, ³McGill University, Royal Victoria Hospital, Canada

Homozygous inactivation of the multiple endocrine neoplasia type 1 (*Men1*) gene encoding menin in mice is embryonic lethal at 12 days and fetuses exhibit clear defects in cranial and facial development, whereas the heterozygous phenotype is similar to that of the *MEN1* syndrome in humans with endocrine tumors developing later in life. This suggested that menin plays a role in bone formation. *In vitro*, menin promotes the commitment of pluripotent mesenchymal stem cells to the osteoblast lineage, whereas, in mature osteoblasts, menin retards their later differentiation. To further understand the role of menin in bone development *in vivo* we are generating mouse models in which the expression of the *Men1* gene is altered only in bone cells.

Mice lacking *Men1* in osteoblasts were generated by crossing OC(Osteocalcin)-Cre mice with homozygous conditional mutants carrying modified *Men1* alleles with loxP

sites flanking exons 3 and 8. The OC-Cre^{+/+};Men1^{lox/lox} mice were viable and fertile and after a second round of mating, these mice (*Men1* KO) were compared with their control littermates (WT) lacking the OC-Cre transgene. There were no differences in growth rate between *Men1* KO and WT mice. In 9-month-old female mice while serum calcium and phosphate were normal, histomorphometric analysis showed that bone volume/total volume (BV/TV) (9.73 ± 0.35 n=5 vs. 14.10 ± 0.90 n=7, *P*=0.003) and bone surface/total volume (BS/TV) (7.28 ± 0.30 vs. 9.58 ± 0.66, *P*=0.019) were reduced in the *Men1* KO mice vs. WT mice.

To overexpress *Men1* specifically in osteoblasts, we made a *Col1a1*-*Men1* transgene construct in which a 2.3-kb *Col1a1* promoter fragment drives a Flag-tagged-menin cDNA. Two of the independent lines generated by mating each of seven *Col1a1*-*Men1* founder mice with WT mice demonstrated bone-specific transgenic expression. At three months of age, the *Flagmen1* mice (male and female) were not different from WT in growth rate, bone mineral density (DEXA), fat pad weight and serum calcium and phosphate levels.

Taken together, the data indicate that menin has a role in bone formation especially in older mice. Depletion of menin in the osteoblast leads to a reduction in bone whereas overexpression has no effect at least in younger mice. Hence, maintenance of menin expression and function in bone is important to avoid decreased bone formation. Therefore, menin is a potential target in combating the bone loss of disorders such as osteoporosis in the elderly.

Resolution of Inflammation Modulates Wnt Signaling and Promotes Osteoblast-mediated Erosion Repair in Inflammatory Arthritis. Melissa Matzelle¹, Maxime Gallant², Keith Condon², Nicole Walsh³, Catherine Manning¹, Jane Lian¹, David Burr², Ellen Gravalles¹. ¹University of Massachusetts Medical School, USA, ²Indiana University School of Medicine, USA, ³St Vincent's Institute of Medical Research, Australia

Inflammation-induced bone loss results from an imbalance of bone resorption relative to bone formation. In rheumatoid arthritis, a disease characterized by inflammation-induced articular bone erosion, pro-inflammatory cytokines expressed by the synovium drive osteoclast-mediated bone resorption and simultaneously inhibit bone formation by osteoblasts. While effective therapies can halt the progression of bone erosion, repair is uncommon. To determine whether resolution of inflammation can promote anabolic osteoblast activity, inflammatory arthritis was induced by transfer of arthritogenic K/BxN serum to C57BL/6J mice and arthritis was allowed to resolve. Midfoot bones of the hind paws were evaluated by histology and histomorphometry; quantitative RT-PCR (qPCR) was performed on synovial tissue. In this model, inflammation peaked ten days after initial serum injection, with complete resolution of inflammation between days 28 and 38. qPCR of synovial tissue confirmed a 20-fold induction of IL-1β mRNA and 1.5-fold induction of TNF at day 10, both of which returned to non-arthritic levels by day 28. RANKL/OPG mRNA ratios also correlated with inflammation, favoring osteoclast-mediated resorption at day 10 and protection from resorption beginning as early as day 15. Dynamic histomorphometric analyses of fluorochrome incorporation at sites of erosion demonstrated that inflammation at the bone interface (day 10) was accompanied by a BFR similar to the rate in non-arthritic mice. However, resolution of inflammation from days 28 to 48 was accompanied by a significant increase in MS/BS, MAR, and BFR, correlating with striking repopulation of the bone surface by osteoblasts expressing alkaline phosphatase and osteocalcin. Modulation of inflammation was accompanied by dramatic changes in the synovial expression of components of the Wnt/β-catenin pathway. Inflammation induced gene expression of the Wnt antagonists sFRP1 and sFRP2. Furthermore, the downregulation of sFRP1 and sFRP2 expression with resolving inflammation paralleled the induction of the anabolic and pro-matrix mineralization factors Wnt10b and DKK2. Thus, in murine inflammatory arthritis, resolution of inflammation promotes osteoblast-mediated repair of articular bone erosions. As such, in diseases of inflammatory bone loss, strict control of inflammation may be essential for the creation of an anabolic microenvironment that supports bone formation and restoration of normal bone architecture.

Runx2 Promotes both Osteoblastogenesis and Novel Osteoclastogenic Signals in ST2 Mesenchymal Progenitor Cells. Sanjeev Baniwal¹, Parantu K. Shah², Yunfan Shi³, Josephine Haduong⁴, Yves DeClerck³, Yankel Gabet⁵, Baruch Frenkel¹. ¹University of Southern California, USA, ²Dana-Farber Cancer Institute, Harvard School of Public Health, USA, ³Keck School of Medicine, University of Southern California, USA, ⁴Keck School of Medicine, University of Southern California, USA, ⁵Tel Aviv University, Israel

In addition to being a master regulator for osteoblast differentiation, Runx2 controls osteoblast-driven osteoclastogenesis. Previous studies profiling gene expression during osteoblast differentiation had limited focus on Runx2 or paid little attention to its role in mediating osteoblast-driven bone resorption. ST2/Rx2^{dox}, a

bone marrow-derived mesenchymal pluripotent cell line that expresses Runx2 in response to Doxycycline (Dox) was used to profile Runx2-modulated gene expression. Runx2-induced osteoblast differentiation was assessed based on alkaline phosphatase staining and expression of classical marker genes. Osteoclastogenic potential was evaluated by TRAP staining of osteoclasts that differentiated from primary murine splenocytes co-cultured with the ST2/Rx2^{dox} cells. The BeadChip™ platform (Illumina) was used to interrogate genome-wide expression changes in ST2/Rx2^{dox} cultures after treatment with Dox or vehicle for 24 or 48 hours. Expression of selected genes was also measured by RT-qPCR. Dox-mediated Runx2 induction in ST2 cells stimulated their own differentiation along the osteoblast lineage and the differentiation of co-cultured splenocytes into osteoclasts. The latter was attributable to stimulation of osteoclastogenic genes such as *Sema7a*, *Ltc4s*, *Efnb1*, *Apccdd1* and *Tnc*, as well as inhibition of anti-osteoclastogenic genes such as *Tnfrsf11b* (OPG), *Sema3a*, *Slco2b1*, *Ogn*, *Clec2d* (Ocil), *Il1rn* and *Rspo2*. Control of osteoblast differentiation and concomitant paracrine control of osteoclast differentiation, both through the activity of Runx2 in pre-osteoblasts, constitute a novel mechanism with a potentially crucial role in coupling bone formation and resorption.

Runx2 control of osteoclastogenesis

Sef (IL17RD) is a Negative Regulator of Osteogenic Differentiation and Bone Formation. Qing He^{*1}, Xuehui Yang², Robert Friesel². ¹Maine Medical Center - Hospital, USA, ²Maine Medical Center Research Institute, USA

Fibroblast Growth Factor signaling plays a significant role in skeletal development and bone formation. Mutation in FGF Receptors in the human genome causes a variety of skeletal disorders including dwarfism and craniosynostosis. Knockout of FGFR3 in the mouse results in skeletal over-growth. Several feedback inhibitory pathways including Sprouty and Sef (IL17RD) negatively regulate FGFR signaling. Sprys have been demonstrated to regulate both osteoblast and chondrocyte differentiation. However, little is known about the role of Sef during skeletal development. In this study, we examined the function of Sef in osteogenic differentiation and bone formation using a Sef transgenic mouse model as well as a KST223-Sef knockout mouse model. RT q-PCR assays measuring expression of osteogenic marker genes, such as osteopontin, alkaline phosphatase, osteocalcin and runx2 indicated over-expression of Sef significantly inhibited osteogenic differentiation while loss of expression of Sef promoted osteogenic differentiation. Alkaline phosphatase staining and alizarin red staining of differentiated osteoblastic cells from Sef knockout and transgenic mice confirmed Sef negatively regulates osteogenic differentiation. Femurs from Sef knockout mice assessed by microtomography and histological analysis suggested loss of Sef increases bone formation in vivo. Furthermore, over-expression of Sef inhibited FGFR-ERK signal pathways during osteogenic differentiation by down regulating phosphorylation of Raf, MEK and ERK. Sef may also regulate the canonical Wnt/ β -catenin pathway by interacting with β -catenin. Collectively, our results suggest that Sef negatively regulates osteogenic differentiation and bone formation both in vivo and in vitro. Sef inhibits osteogenesis in part through inhibition of FGFR-ERK pathway and may also regulate canonical Wnt signaling.

TRPV4 Deficiency Suppresses Fluid Flow Induced Activation of Calcium Oscillation in a Manner Dependent on Osteoblastic Differentiation. TAKAFUMI SUZUKI^{*1}, Takuya Notomi², Daisuke Miyajima¹, Yoichi Ezura³, Tetsuya Nakamoto¹, Tadavoshi Hayata⁴, Atsuko Mizuno⁵, Makoto Suzuki⁶, Fumitaka Mizoguchi¹, Yuichi Izumi⁷, Masaki Noda¹. ¹Tokyo Medical & Dental University, Japan, ²GCOE, Tokyo Medical & Dental University, Japan, ³Tokyo Medical & Dental University, Medical Research Institute, Japan, ⁴Medical Research Institute, Tokyo Medical & Dental University, Japan, ⁵Jichi Medical University, Japan, ⁶Department of Pharmacology, Jichi Medical School, Japan, ⁷Department of periodontology, Japan

Mechanical stress is an important factor to regulate bone homeostasis, and plays an important role in maintaining the bone structure and mass throughout life. TRPV4 is a Ca²⁺ and Mg²⁺ permeable non-selective cation channel, and activated by a variety of physical stimulation (cell swelling, heat, mechanical stress) and chemical reagents (endocannabinoids, arachidonic acid). TRPV4 is involved in bone formation

and remodeling as deficiency of TRPV4 suppresses unloading-induced osteoclast activation and osteoblast suppression. TRPV4 is expressed in osteoblasts and osteoclasts and plays a role in sensing mechanical stress and controlling bone remodeling in long bone. However, the function of TRPV4 in intracellular calcium regulation in osteoblasts is not known. The aim of our study is to investigate the possible role of TRPV4 in osteoblasts under mechanical stress.

We first examined TRPV4 expression level during osteoblastic differentiation. Osteoblasts were isolated from the calvaria of newborn WT and TRPV4 deficient mice, and cultured with osteogenic medium (100 μ g/ml ascorbic acid, 10mM β -glycerophosphate and 10n-100n-1 μ M dexamethasone). At 0-4-7 days, mRNAs were extracted and subjected to quantitative real-time PCR analysis. Under this condition, alkaline phosphatase expression was increased in a time dependent manner. We found that the expression of mRNA for TRPV4 was increased during the differentiation of osteoblastic cells.

Osteoblasts before changing osteogenic medium were seeded on BioFlux plate and loaded under fluid flow stress as mechanical stress. We adopted 5 dyn/cm² that is less than the rate used for endothelial experiments. Our results showed that the generation rate of calcium oscillation was markedly increased by fluid flow in WT osteoblasts ($p < 0.01$).

In addition, we examined osteoblasts after changing osteogenic medium. We found that the generation rate of calcium oscillation was significantly decreased in TRPV4 deficient osteoblasts ($p < 0.05$), suggesting that TRPV4 is involved in the generation of calcium oscillation during osteoblastogenesis.

In conclusion, we identified that expression of TRPV4 is developmentally regulated along with osteoblastic differentiation and this controls the generation of calcium oscillation.

Age Related Changes in FGF2 and Beta-Catenin Expression in Osteoblasts from Young, Middle Aged and Elderly Female Patients. Maria Marie Hurley^{*1}, Alycia Eslinger², Liping Xiao², Gloria Gronowicz². ¹University of Connecticut Health Center School of Medicine, USA, ²University of Connecticut Health Center, USA

Fibroblast growth factor 2 (FGF2) stimulates pre-osteoblast replication and previous studies demonstrated that knockout of the Fgf2 gene in mice resulted in progressive osteopenia with age associated with decreased wnt signaling. In addition targeted expression of FGF2 in osteoblast progenitors resulted in increased bone mass in mice via modulation of wnt signaling. However the importance of FGF2 in the maintenance of bone mass in humans is not defined. We tested the hypothesis that there is a progressive reduction of FGF2 with age in human osteoblasts. Human osteoblasts cultures were derived from the discarded bone of orthopaedic surgeries according to an approved IRB protocol. Bone chips were prepared and cultured for 2 weeks in DMEM/F-12 medium with 10% fetal bovine serum and antibiotics. Outgrowth cells were trypsinized and replated at the same density for subsequent experiments. More than 95% of the cells express high levels of alkaline phosphatase and therefore, were considered osteoblasts. Cells were cultured until confluent and total RNA was extracted to assess Fgf2, Beta-Catenin and FGF receptors 1, 2 and 3 mRNA by qPCR, while protein was extracted for Western blots. As shown in Figure 1A, mRNA levels of Fgf2 and Beta-Catenin in human osteoblast cultures (passage 2 or less) from female patients ages 32, 47 and 66 years decreased with age. However, the receptors did not demonstrate an age-related decline. Western blot (Figure 1B) of FGF2 protein levels in human osteoblast cultures (passage 4 or less) from female patients of ages 29, 41 and 67 years old showed that FGF2 protein also decreases with age. One additional experiments with separate subjects demonstrated similar results. FGF2 was previously shown to activate Beta-catenin, which can upregulate bone formation. In conclusion, reduction in Fgf2 expression in osteoblasts could contribute to age-related bone loss in humans and Beta-Catenin may be involved in the signaling mechanisms that lead to FGF2-mediated bone loss.

Fig. 1 (A) Beta-Catenin and Fgf2 mRNA in human osteoblast cultures from female patients ages 32, 47 and 66 years old were measured by qPCR. All Fgf2 groups were significantly different from each other (Student's t-test) and reduced with age. *: compared with 32 yr $p < 0.05$. #: compared with 47 yr $p < 0.05$.

(B) Western blot of FGF2 protein in human osteoblast cultures from female patients of ages 29, 41 and 67 years old. Equal amounts of protein were run per lane with β -actin as a loading control. An age-related decline was found.

Differential activation of the Alkaline Phosphatase promoter by pRB and p107. Stephen Flowers^{*1}, Elizabeth Moran². ¹NJMS-UH Cancer Center, University of Medicine of Dentistry of New Jersey, USA, ²University of Medicine & Dentistry of New Jersey, Cancer Center, USA

The retinoblastoma susceptibility gene, Rb1, is closely linked with osteosarcoma as well as retinoblastoma. Functional analysis of pRB and the related family members, p107 and p130, has tended to focus on repression of proliferation, but genetic evidence from our lab and others indicates an active requirement for pRB in osteoblast differentiation that correlates more directly with osteosarcoma susceptibility. pRB is linked with activation of the early osteoblast marker, alkaline phosphatase (the product of the *Alpl* gene). We have shown by chromatin immunoprecipitation (ChIP) that the active *Alpl* promoter is targeted directly by pRB and p107. pRB is required for several activation events, including displacing the histone demethylase, KDM5A, from the inactive promoter and recruiting the BRG1 subunit of the SWI/SNF complex to the active promoter. BRG1 in turn is necessary for the recruitment of RNA polymerase II.

The presence of p107 on the active *Alpl* promoter suggests it may also contribute to activation, but it is unknown if the function of p107 is redundant to the function of pRB. This issue is addressed with the use of shRNA to deplete p107 in the MC3T3-E1 preosteoblast line. Depletion of p107 resulted in impaired induction of alkaline phosphatase, demonstrating that it is also essential for activation. As with the pRB-depleted line, depletion of p107 resulted in failure of both BRG1 and RNA polymerase II to be recruited to the promoter. Transcription factors that target *Alpl* during activation have not been identified by ChIP, but SP1 and RUNX2 have been implicated. ChIP analysis, in parental cells, found both RUNX2 and SP1 bind the active promoter. Depletion of p107 did not affect the ability of either transactivator to associate with the promoter. In contrast, depletion of pRB resulted in the failure of both factors to be recruited. Unlike the pRB-depleted line, the p107-depleted line was able to displace KDM5A.

Our results reveal that pRB and p107 are both involved the activation of *Alpl* expression, but their roles at the promoter are not entirely redundant. Both pRB and p107 are needed for the recruitment of BRG1. However, p107 is dispensable for both the displacement of KDM5A and for the recruitment of both RUNX2 and SP1. Further study of the genes targeted in osteoblast by pRB and p107 during activation, and the contribution of each, will continue to increase our understanding of the specific role of pRB in suppression of osteosarcomas.

ER Membrane Bound Transcription Factor ATF6 Is Involved in BMP2-induced Osteoblast Differentiation and Osteocalcin Transcription in MC3T3E1 Cells. Won Gu Jang¹, Eun Jung Kim¹, In Hong Kang^{*2}, Keun-Bae Lee¹, Hueng-Sik Choi¹, Jeong-Tae Koh¹. ¹Chonnam National University, South Korea, ²Interdisciplinary graduate program in molecular medicine, South Korea

Endoplasmic reticulum (ER)-bound transcription factor families are involved in the control of various metabolic pathways through the unfolded protein response (UPR). Bone morphogenetic protein 2 (BMP2) induces mild ER stress followed by the activation of major UPR transducers such as PERK/ATF4 and OASIS in osteoblast cells. ATF6 is also one of ER-bound bZIP transcription factors, which is cleaved and

translocated into nucleus by ER stress. However, involvement of ATF6 in BMP2-induced osteoblast differentiation has not been elucidated. In the present study, BMP2 treatment markedly induced the expression and activation of ATF6 with the increase in ALP and OC expression in MC3T3E1. However, the ATF6 activation by BMP2 was not observed in Runx2-/- primary calvarial osteoblasts and Runx2 overexpression recovered the BMP2 action. BMP2 stimulated ATF6 transcription through enhancing the direct binding of Runx2 to osteoblast-specific cis-acting element 2 (OSE2, ACCACA, -205 ~ -200 bp) motif of ATF6 promoter region. In addition, overexpression of ATF6 increased OC promoter activity with enhancing the direct binding to a putative ATF6 binding motif (TGACGT, -1126 ~ -1121 bp). Inhibition of ATF6 function with dominant negative form of ATF6 (DN-ATF6) blocked BMP2- or Runx2-induced OC expression. Of interest, OASIS, structurally very similar to ATF6, cannot induce the OC expression. ALP and Alizarin red staining results confirmed that BMP2-induced matrix mineralization was also dependent on ATF6 in vitro. Taken together, these results suggest that ER stress-activated transcriptional factor ATF6 mediates BMP2-induced osteoblast differentiation via regulating the osteocalcin gene expression.

Frizzled 1 Promoter Activity and Expression Is Regulated by E2F1 in Osteoblasts. Shihong Yu^{*1}, Laura Yerges-Armstrong², Yanxia Chu³, Joseph Zmuda⁴, Yingze Zhang⁵. ¹University of Pittsburgh Medical Center, USA, ²University of Maryland, USA, ³University of Pittsburgh, Department of Medicine, USA, ⁴University of Pittsburgh, Department of Epidemiology, USA, ⁵University of Pittsburgh, USA

Frizzled family members initiate Wnt signal transduction. Genetics studies by our group demonstrated significant associations of promoter polymorphisms and haplotypes in Frizzled-1 (FZD1) with bone mineral density and bone geometry phenotypes. However, little is known about the transcriptional regulation of FZD1 in osteoblasts. To define the molecular mechanisms involved in the regulation of FZD1 gene expression, we characterized the FZD1 promoter in the Osteoblast-like cell, Saos2, using a promoter reporter system and determining FZD1 protein expression. We demonstrated that E2F1, a critical transcription factor in osteoblasts, transactivated a FZD1 promoter specific reporter construct consisting of -655 to +71 of the translation start site. FZD1 promoter activity was increased by 10.4 fold in Saos2 and by 8.9 fold in cos7 when E2F1 was transiently expressed in these cells. In addition, a deletion construct of the FZD1 promoter consisting of -141 to +71 did not abolish the transactivation by E2F1. Transient expression of E2F1 in Saos2 and cos7 cells resulted in 9 fold and 7.8 fold increases in the promoter activity of the deletion promoter construct, respectively. To our knowledge, this is the first report identifying FZD1 to be a direct transcriptional target of E2F1. Further experiments are needed to determine the potential binding domains of E2F1 in the FZD1 promoter region and how FZD1 is regulated by E2F1.

Identification of a Small Molecule Kinase Inhibitor That Enhances Osteoblastic Differentiation and In Vivo Bone Formation of Human Skeletal (Mesenchymal) Stem Cells Through Regulation of BMP Signaling. Abbas Jafari^{*1}, Basem Abdallah², Diyako M. Qanie³, Li Chen⁴, Nicholas Ditzel⁴, Moustapha Kassem⁴. ¹University of Southern Denmark, Denmark, ²Odense University Hospital, University of South Denmark, Denmark, ³Institute of Clinical Research, University of Southern Denmark, Denmark, ⁴Odense University Hospital, Denmark

To identify novel anabolic targets for enhancing bone formation, we screened a commercially available Kinase Inhibitor Library (containing 80 known protein kinase inhibitors that covers a wide spectrum of signaling pathways) for their anabolic effects on human bone marrow derived-mesenchymal stem cells (hMSC) and we employed quantitative alkaline phosphatase activity (ALP) measurement as a readout for effects on osteoblast differentiation of hMSC. The screen identified the protein kinase inhibitor K1x that targets protein kinases A, C, and G, with reproducible and significant stimulatory effects on ALP activity of hMSC. Further studies, demonstrated that K1x increased, in a dose dependent fashion, gene expression of early (Runx2, collagen type I) and late (osteopontin, bone sialoprotein) osteoblast differentiation markers and enhanced ex vivo matrix mineralization of hMSC. Treatment of hMSC with K1x for 6 days followed by in vivo implantation subcutaneously in immune deficient mice, led to significant increase in ectopic bone formed by the cells. Microarray analysis of K1x-treated hMSC cultures versus control cultures, revealed up regulation of bone morphogenetic protein (BMP) signaling and BMP6 gene expression in K1x treated cultures. Silencing BMP6 expression by siRNA, abolished the enhancing effect of K1x on osteogenic differentiation of hMSC. In conclusion, our data demonstrate that K1x is a potent stimulator of osteoblast differentiation of hMSC in vitro and in vivo and its effect is mediated by BMP6. This kinase inhibitor may thus be developed as a novel drug for enhancing bone formation.

Iron Decreases Osteoblastic Activity in Human MG 63 Cells. Mathilde Doyard*, Nadia Fatih, Marie-Laure Island, Patricia Leroyer, Gerard Chales, Olivier Loreal, Pascal Guggenbuhl, INSERM UMR 991, equipe Fer et foie : aspects physiologiques et pathologiques, Univ Rennes, France

Aim: iron overload in thalassemia and genetic hemochromatosis may cause osteoporosis. However, molecular mechanisms leading to iron-related bone loss are not fully characterized. Both, decrease osteoblasts and increase osteoclast activities have been suggested. Our aim was to analyze in vitro the impact of iron overload on human osteoblast cells.

Methods: MG-63 cell line from a human osteosarcoma was used as osteoblast model. Iron status was modulated by adding Ferric Ammonium Citrate (FAC) and/or Deferoxamine (DFO), an iron chelator. Quantitative RT-PCR was used to evaluate mRNA levels of: i) iron metabolism genes (Transferrin Receptor 1-TFRc-, hepcidin, hemojuvelin, ferroportin, and HFE), and ii) osteoblast phenotypic markers (alpha 1 collagen type I chain, osteocalcin and RUNX2). Ferritin level was evaluated by western-blot. Reactive oxygen species (ROS) level was quantified using cell-permeant fluorescent probe 2',7'-dichlorodihydrofluorescein diacetate (DCFH2-DA). Apoptosis was evaluated by measuring caspase 3 activity.

Results: MG-63 cells FAC exposure induced a dose-dependent decrease of TFRc mRNA level and an increase of intracellular ferritin level, reflecting the increase of intracellular iron. In addition, DFO alone increased TFRc mRNA and decreased ferritin levels; DFO added to FAC neutralized the iron impact on MG-63 cells. We found that ferroportin and HFE mRNAs were significantly expressed in basal conditions. Ferroportin mRNA level was induced by FAC whereas HFE mRNA level was slightly decreased. The mRNA levels of alpha 1 collagen type I chain, the major component of bone matrix, osteocalcin, a noncollagenous protein, and transcriptional factor RUNX2 were significantly decreased in presence of FAC. DFO addition to FAC, suppressed the iron impact. Iron exposure was responsible to ROS level increase in MG-63 cells. Such effect was prevented by concomitant DFO addition. Moreover FAC induced a caspase 3 activity increase.

Conclusion: our data in MG-63 cells showed that FAC exposure of human MG-63 cells: i) modulates intracellular iron status, ii) increases ferroportin mRNA expression level, iii) decreases the expression of genes associated to osteoblast phenotype. These effects are suppressed by DFO. In addition we found that: i) oxidative stress could contribute to these alterations and that iron favors MG-63 cells apoptosis. Taken together, our results support a role of osteoblast impairment in the iron-related osteoporosis.

Mannosyltransferase Alg2 Is a downstream Regulator of Schnurri-3 in Osteoblast Differentiation. Katsuyuki Imamura¹, Yasuhiro Ishidou¹, Ichiro Kawamura², Masahiro Yokouchi¹, Setsuro Komiya¹, Shingo Maeda¹. ¹Graduate School of Medical & Dental Sciences, Kagoshima University, Japan, ²Dept. of Orthopaedic Surgery Kagoshima University, Japan

Shn3 (Shn3, also known as Hivep3, ZAS3, KRC) was shown to promote proteasomal degradation of Runx2 protein by recruiting E3 ubiquitin ligase Wwp1. It was reported that Shn3 knockout mice demonstrated accumulated Runx2 protein in osteoblasts, accelerated osteoblast differentiation, and high bone mass in adult bone. On the other hand, two groups reported that, forced expression of Runx2 in osteoblasts in vivo (Col1a1-driven Runx2 transgenic mice) resulted in accumulation of immature osteoblasts and lowered bone mass, osteopenia. The contrary bone phenotypes between these two lines of mice with high Runx2 protein level, led us to hypothesize that Shn3 should have other roles to regulate osteoblast maturation. Because Shn3 is a large zinc-finger protein, originally characterized as a transcription factor, we searched for genes expressed downstream of Shn3 in osteoblasts. siRNA mediated knockdown of Shn3 in MC3T3-E1 did not alter expression of Runx2 mRNA, whereas Runx2 protein was slightly accumulated. Expression of early osteoblast differentiation markers, *Osx* and *Alp*, were mildly enhanced, while maturation markers bone sialoprotein (Bsp) and osteocalcin (Ocn) were significantly attenuated by Shn3 knockdown. These results suggested a crucial inhibitory role of Shn3 in maturation of osteoblasts. We analyzed the expression profile of Shn3 siRNA-transfected MC3T3-E1 by microarray, and found eight genes to be differentially expressed after Shn3 knockdown. Among them, we focused on asparagine-linked glycosylation 2 homolog (*Alg2*), because it was highly expressed in MC3T3-E1 cells, and it was confirmed to be up-regulated by Shn3 overexpression. To study the possible roles of *Alg2* in osteoblast differentiation, we transfected siRNA for *Alg2* in MC3T3-E1 osteoblasts and ST-2 bone marrow stroma cells. *Alg2* siRNA did not affect expression of Runx2 nor Shn3. However, loss of *Alg2* showed significantly accelerated activity of *Alp* in MC3T3-E1. In addition, in ST-2, *Alg2* knockdown resulted in a promoted osteoblast differentiation, characterized by up-regulated expression of *Osx*, *Alp*, Bsp, and Ocn. *Alg2* is a mannosyltransferase crucial in the dolichol pathway of N-linked protein glycosylation. We speculated that *Alg2* regulates glycosylation and activity of protein which acts upstream of *Osx*. In conclusion, we identified *Alg2* gene as a downstream mediator of Shn3 to regulate osteoblast differentiation.

NR2C2 Gene Regulated Osteoblasts Bone Formation Activity through Runx2 Stability. Shen-chin Hsu¹, Hsin Chiu Ho², Huei-Ju Ting², Shinjen Lin³, Tian-Fang Li², Mo Chen⁴, Jonathan Holz², Tzong-Jen Sheu², J. Edward Puzas⁵, Min-jon Lin⁶. ¹Chung Shan Medical University Hospital Dept of Pharmacy, Taiwan, ²University of Rochester, USA, ³Univeristy of Rochester, USA, ⁴Columbia University, USA, ⁵University of Rochester School of Medicine, USA, ⁶Chung Shan Medical University Dept of Biomedical Sciences, Taiwan

BACKGROUND: NR2C2 (nuclear receptor subfamily 2, group C, member 2) belongs to a nuclear receptor superfamily without an identified ligand. NR2C2 is closely related to TR2 and RXRs (19). The expression of NR2C2 was found in all tissues tested including metabolic system, and cardiovascular system. NR2C2-/- mice have significant growth retardation, impaired cerebella function. NR2C2 is also highly expressed macrophages. However, its roles within the osteoblasts remain unknown. **RESULTS:** We generated several MC3T3-E1 stable cell lines which were pBabe-NR2C2, pBabe-NR2C2 RNAi, pBabe GFP, pBabe-NR2C2 MC3T3-E1 cells had been confirmed with four folds NR2C2 over-expression by real-time PCR and western blot methods. pBabe-NR2C2 RNAi MC3T3-E1 cells had 80% knock-down efficiency. pBabe-GFP MC3T3-E1 did not show significant NR2C2 expression level difference between pBabe-GFP and non-stabilized MC3T3-E1 cells. In the osteoblast differentiation assay, NR2C2 enhanced the alkaline phosphatase activity and mineralization. On the contrary, knock-down NR2C2 showed decrease alkaline phosphatase activity and mineralization. In order to further understand the possible mechanism, we screened several osteogenic genes. Only osteocalcin and collagen I showed time-course change with NR2C2 (increase) and NR2C2 RNAi (decrease). These gene expression results correlated with the osteoblast differentiation results. We also tested if NR2C2 can directly regulate the osteocalcin gene? In the pBabe NR2C2 cells, the NR2C2 and osteocalcin reporter gene assay results showed 10 folds increase in both reporters. However, In the NR2C2 knock-down cells, the results showed 60% decrease on both NR2C2 and osteocalcin reporter results. Therefore, we looked at the RNA and protein level of runx2 in both pBabe NR2C2 and NR2C2 RNAi cells. The RNA level of runx2 was similar between these two cells. This indicated NR2C2 did not alter the RNA expression but enhanced the protein level of runx2. These results also were confirmed with the runx2 functional reporter gene assay (6XOSE2-OC-Luc). NR2C2 regulated the runx2 protein stability and subsequently changed the osteocalcin amount. By the way, we also confirmed the cell lines results with the runx2 immunoassaying and osteocalcin ELISA assay in the NR2C2 knockout mice. **CONCLUSIONS:** Our data suggested that NR2C2 plays a pivotal role in fundamental bone formation through runx2 stability.

Osteogenic Potential of Human Mesenchymal Stem Cells: Role of Specific Transcription Factors and Different Cell Culture Conditions. Elena Torreggiani¹, Elisabetta Lambertini², Letizia Penolazzi², Renata Vecchiati², Gina Lisignoli³, Claudio Nastruzzi⁴, Roberta Piva². ¹Department of Biochemistry & Molecular Biology, University of Ferrara, Ferrara, Italy; Department of Reconstructive Science, University of Connecticut Health Center, Italy, ²Department of Biochemistry & Molecular Biology, University of Ferrara, Italy, ³Laboratory of Immunorheumatology & Tissue Regeneration, Istituto Ortopedico Rizzoli, Italy, ⁴Department of Pharmaceutical Sciences, University of Ferrara, Italy

Bone regeneration by the means of induction of osteogenesis from mesenchymal osteoprogenitors (MSCs) offers a rational therapeutic option. Two of the most important challenges in this field are i. the development of novel culture systems of MSCs and ii. the identification of new factors with crucial role in the control of MSC differentiation program. In this context, the goals of our current work are to compare growth and differentiation of human MSCs cultured in different 3D systems including alginate beads, extracellular matrix (ECM) scaffold obtained from purified porcine urinary bladder matrix, and a rotating microgravity bioreactor (HARV technology), with cells cultured using standard 2D methodologies. We have immunophenotypically characterized hMSCs obtained from sources of different origin (bone marrow, PDL and umbilical cord Wharton's jelly) demonstrating that they are positive for CD90, CD73, CD105, CD146, but negative for CD31, CD3, CD14, CD34, CD45. The cells were assessed for viability with propidium iodide and Calcein-AM, analyzed for morphological changes by different microscopic techniques (optical microscopy, SEM, TEM), and analyzed for gene expression by qRT-PCR, immunocytochemistry, and Western blot. We demonstrated that 3D culture conditions and the use of Polymeric Micelles as delivery system for differentiating agents did not negatively affect viability and cell proliferation, enhanced cell adhesion and interaction, supported osteogenic differentiation positively affecting the expression of typical osteoblastic markers and deposition of mineralized matrix. Our data highlight the importance of the most appropriate combination between hMSCs and specific scaffolds.

In addition, we evaluated the effect of transcription factors (TFs) with crucial role in the control of hMSCs behaviour by using gene-silencing approach. We focused our

attention on Slug having identified it as TF promoting osteoblast maturation in an earlier study. We demonstrated that Slug has a novel crucial role for osteochondroprogenitor: in fact, its silencing leads to decreased hMSC migration, changes in the expression levels of Runx2, Sox5, Sox6, Sox9 and Stat1, and modulates the fate of the cells towards chondrocyte differentiation. These results encourage the development of alternative strategies to induce efficient differentiation of hMSCs for their clinical use in bone tissue engineering and repair.

Regulation of both Osteoblastic and Myogenic Differentiation by Proteasome Inhibitor Bortezomib. Maki Uyama*, Mari Sato, Masamitsu Kawanami, Masato Tamura, Hokkaido University, Japan

In eukaryotic cells, degradation of most intracellular proteins is realized by ubiquitin-proteasome pathway. The clinical efficacy of bortezomib (Bzb), a 26S proteasome inhibitor used in the frontline treatment of multiple myeloma as anticancer drug, has been linked to an increase in bone markers. Bzb has been recently reported to induce differentiation of osteoblast in vitro and in vivo. However, until now, little was known of the molecular basis of action of proteasome inhibitor such as Bzb on the regulation of cell differentiation. In the present study, we investigate that the effects of Bzb on differentiation of mesenchymal stem cells into osteoblasts or myotube. In myoblastic C2C12 cells in culture, Bzb inhibited myotube formation in low mitogen medium. Bzb also inhibited myogenic gene expression such as myogenin and muscle creatin kinase, and induced osteocalcin and alkaline phosphatase gene expression, indicating that Bzb have similar activities of BMP-2. To investigate the mechanisms by which Bzb activates osteocalcin transcription, transient transfection of osteocalcin (OG2) promoter-luciferase constructs into C2C12 cells with Bzb treatment resulted in a significant increase in luciferase activity. This result implies the presence of transcriptional machinery that is sensitive to interference by Bzb and that regulates transcriptional activity through interaction with the OG2 gene promoter via OSE1 and OSE2. Using reporter construct that have BMP-2 responsive elements of Id-1 gene, Bzb did not induce their transcription activities, suggesting that Bzb does not modulate Smad1/4-dependent BMP signaling pathway. In other hand, β -catenin is a well-known target of the ubiquitin-proteasome pathway. However, Bzb did not alter transcriptional activities of β -catenin dependent Top-flash reporter and canonical Wnt signaling target gene expression. These results show that the function of proteasome in controlling degradation of polyubiquitinated signaling molecules plays important role in decision of cell fate during differentiation such as osteoblasts or muscle cells.

The Orphan Nuclear Receptor COUP-TFII Negatively Regulates Osteoblast Differentiation through Inhibiting the Transcriptional Activity of Runx2. Kkot-nim Lee¹, Sin-Hye Oh¹, Hye-Ju Son², Won Gu Jang², In-Hong Kang², Sun-Hun Kim², Shee-Eun Lee², Jeong-Tae Koh^{*2}. ¹Chonnam National University School, South Korea, ²Chonnam National University, South Korea

Chicken Ovalbumin Upstream Promoter-Transcription Factor II (COUP-TFII; NR2F2) is an orphan nuclear receptor of the steroid-thyroid hormone receptor superfamily. COUP-TFII is widely expressed in multiple tissues and organs throughout embryonic development, and regulates cellular growth and differentiation and organ development. However, the role of COUP-TFII in osteoblast differentiation has not been elucidated. In this study, COUP-TFII was strongly expressed in multipotential mesenchymal cells and the endogenous expression level was decreased during osteoblast differentiation. Overexpression of COUP-TFII inhibited BMP2-induced osteoblastic genes expressions in C3H10T1/2 mesenchymal cell lines. The results of alkaline phosphatase and Alizarin-red staining and osteocalcin production assay showed that COUP-TFII overexpression blocked BMP2-induced osteoblast differentiation. In contrast, the down-regulation of COUP-TFII using shRNA synergistically induced BMP2-induced osteoblastic genes expressions and osteoblast differentiation. Furthermore, COUP-TFII significantly impaired the Runx2-dependent activation of osteocalcin promoter and immunoprecipitation assay showed the physical interaction between COUP-TFII and Runx2. In our chromatin immunoprecipitation assay, COUP-TFII repressed DNA binding of Runx2 on osteocalcin gene and blocked Runx2-induced osteoblast differentiation. Taken together, these results suggest that COUP-TFII negatively regulates osteoblast differentiation through inhibiting the transcriptional activity of Runx2.

The Transcription Factor Sox11 is Essential for the Early Osteoblast Development. Gadi Jogeswar^{*1}, Kwang Joon Kim², Ajita Jami³, Kyoung Min Kim², Hoon Choi⁴, Sung-Kil Lim². ¹Yonsei University College of Medicine Seoul South Korea, South Korea, ²Division of Endocrinology & Endocrine Research Institute, Department of Internal Medicine, Yonsei University College of Medicine, South Korea, ³Brain Korea 21 Project for medical sciences, Yonsei University College of Medicine, Seoul, Republic of Korea-120 752, South Korea, ⁴Inje University Sanggyepaik Hospital, South Korea

The high-mobility-group (HMG) domain containing gene, Sox11 has been shown to act as a transcriptional activator. Sox11 deficient mice exhibit severe developmental defects include heart defects, skeletal malformations with decreased bone size and bone density. Even though the studies on Sox11 deficient mice shows the significant effects on osteogenesis, the detailed functional role of Sox11 in osteoblast development has not yet been defined. We demonstrate here that Sox11 is expressed in different osteoblast cells and knock down of Sox11 significantly affects the proliferation and survival of primary calvarial and MC3T3-E1 osteoblast cells. Sox11 knockdown significantly affects the expression of osteoblast lineage transcription factors Runx2 and Osterix. In addition to this, we also identified the induced differentiation in osteoblast cells significantly decreased the expression of Sox11 after one week in differentiation medium, which suggested the role of Sox11 is restricted to the early stage of osteoblast development. From our studies, we hypothesize that Sox11 is necessary for the maintenance, proliferation and survival in the early steps of osteoblast development but not for the differentiation.

Toward Understanding the Balance Between Osteoblastogenesis and Adipogenesis in Bone Marrow Microenvironment. Basem Abdallah^{*1}, Moustapha Kassem². ¹Odense University Hospital, University of South Denmark, Denmark, ²Odense University Hospital, Denmark

The majority of conditions associated with bone loss, including osteoporosis were shown to be accompanied by increased marrow adiposity due to shifting in the balance between osteoblast and adipocyte differentiation of bone marrow skeletal stem cells (MSC). However, little is known about how the balance between osteogenesis and adipogenesis is regulated in the bone marrow microenvironment. Recently, we proposed a novel molecular model for lineage fate determination of MSC that is regulated through the cross-talk between two unique populations of pre-committed osteoblasts (MSC-OB) and adipocytes (MSC-Adipo) rather than through changes in the differentiation pathway of multipotent MSC (Ref. 1&2). Thus, we aimed in this study to identify novel secreted factors that mediating the cross-talk between osteoblasts and adipocytes in bone marrow. For that purpose, we used a combination of microarray (GeneChip® MG430A 2.0 Array) and mass spectrometry-based proteomics (secretome) to identify secreted proteins by MSC-OB (only can differentiate into osteoblast) versus MSC-Adipo (only can differentiate into adipocyte). Transcriptome and secretome profiles of these two cell lines were compared using different criteria including bioinformatics, function annotation analysis, gene expression analysis and extensive literature survey. After excluding all previously studied factors in MSC differentiation, we identified 7 novel secreted proteins (three proteins by MSC-Adipo and other 4 by MSC-OB). Studying the molecular function of these proteins in MSC cells revealed a selection of 3 secreted factors with the potential to control the commitment of MSC into either osteoblast or adipocyte lineage. In conclusion, cross-talk exists between different populations of pre-committed osteoblast and adipocyte cells in bone marrow to regulate differentiation of multipotent MSC through novel secreted factors.

A Novel Mechanism of Signal Transduction: Oxytocin Receptors Activated by the Ligand Translocate in the Nucleus to Enhance Osteoblast Specific Transcription. Adriana Di Benedetto¹, Stefania Dell'Endice², Graziana Colaiani¹, Roberto Tamma², Concetta Cuscito², Bice Nico², Bice Chini³, Damiana Calvano⁴, Carlo Zamboni⁴, Li Sun⁵, Mone Zaidi⁶, Alberta Zallone^{*1}. ¹University of Bari Medical School, Italy, ²Human Anatomy & Histology, University of Bari, Italy, ³Neuroscience, CNR, Milan, Italy, ⁴Department of Chemistry, University of Bari, Italy, ⁵Mount Sinai School of Medicine, USA, ⁶Mount Sinai Medical Center, USA

Oxytocin (OT), acting through a seven-transmembrane G-protein coupled receptor OTR, has a direct anabolic effect on bone (Tamma et al., 2009) upregulating the expression of osteoblast markers and transcription factors as Osterix, Schnurri 2 and 3, Atf-4, Osteocalcin and Osteopontin. Mice null for OT or OTR genes develop with time a reduced bone mass ascribable to a low turnover osteoporosis. OTRs activated by OT are known to signals through Gq/11, but after OT stimuli (15-30') we unexpectedly found OTRs largely relocated in osteoblast nuclei as identified by western blot analysis of cytoplasmic and nuclear extracts. These results were confirmed by immunogold identification of OTR in osteoblasts with TEM and by confocal immunofluorescence studies. Thus we asked the questions 1) how a GPCR receptor is transported to nuclei and 2) to do what.

Results 1) Within 2-3 min from OT treatment in primary osteoblasts OTRs were colocalized with β -arrestin1/2, thereafter, after β -arrestins detachment, were found colocalized with rab5 in the early endosomal compartment. Eventually the vesicles were taken in charge by transportin-1 and sorted to the nuclei. All these data were obtained by confocal microscopy of OTR-GFP in fixed and in living cells. MALDI-TOF analysis, performed on nuclear proteins, immunoprecipitated with anti-OTR 30' after OT treatment, revealed the presence of four peptides corresponding to OTR intracellular loops, further giving strong evidence to OTR nuclear localization.

Results 2) Both β -arrestin1/2 and Transportin-1 silencing in osteoblasts not only affected OTR nuclear localization but prevented OT induced up-regulation of several genes as ATF-4, Osterix and osteocalcin. Immunoprecipitation from nuclear lysates of OTR, or of the osteoblast transcription factor Runx2, and the transcription co-activator Schnurri-2 always demonstrated, but only after OT treatment, the three proteins immunoprecipitated together. Furthermore an OTR/Smad4 interaction was also found when osteoblasts were simultaneously stimulated with OT and BMP2.

Conclusion. Some OT anabolic effects on osteoblast activities are mediated by a novel mechanism involving OTR nuclear interaction with the BMP-2/ Runx2 pathway with an up-regulatory effect.

Angiotensin II regulates RANKL:OPG ratio potentially through transactivation of ErbB receptors by EGF-like ligands. Kirsty MacRae^{*1}, Conrad Sernia², Walter Thomas³. ¹University of Queensland, Australia, ²Associate Professor, Australia, ³Professor, Australia

Angiotensin II (Ang II) is a potent pressor hormone and a dominant causative factor in cardiovascular disease. Elderly hypertensives show reduced bone mineral density that appears to implicate a higher AngII-induced RANKL:OPG ratio. The cellular pathways underpinning these changes are uncertain but one hypothesis - which we investigate in this study - involves the transactivation of epidermal growth factor receptors (ErbB receptors) by the angiotensin type 1 receptor (AT1R). This pathway features the activation of ErbB receptors by the AT1R through the shedding of EGF-like ligands by disintegrin and metalloproteases (ADAMs).

Methods; Serum-deprived UMR-106 osteoblast cells were stimulated with Ang II, and the EGFR ligands epidermal growth factor (EGF), heparin binding-EGF (HB-EGF), betacellulin (BTC) and neuregulin 1 β (NRG1 β). In addition, cells were treated with AG1478 (a selective ErbB1 inhibitor) or TAPI-1 (a non selective ADAM inhibitor) 45 minutes prior to adding Ang II. Total RNA was isolated with Trizol and OPG, RANKL, ErbB1, ErbB2, ErbB3, ErbB4, ADAM 17, EGF, HB-EGF, BTC and NRG1 β expression analysed semi-quantitatively by RT-PCR. ERK activation by Ang II was also evaluated by Western Blotting.

Results; We confirmed that UMR-106 cells express the four ErbB receptor subtypes (ErbB1, ErbB2, ErbB3 and ErbB4) and several of their ligands. Western Blotting revealed ERK activation 1-3 min of Ang II treatment and this affect may be partially attenuated with the addition of AG1478. Ang II (1x10⁻⁸M) increased ADAM 17 expression 2-fold. There was also up-regulation of EGF (3.1 fold), HB-EGF (3 fold), BTC (2.3 fold) and NRG1 β (2.3 fold). All four ErbB receptor subtypes expression increased by 2.1-2.6-fold. In keeping with our hypothesis, the EGF-like ligands (EGF, HB-EGF, BTC and NRG) induced a significant 2-3 fold down-regulation of OPG expression and a significant 2-3 fold up-regulation in RANKL expression; and these effects were partially prevented by inhibitors AG1478 and TAPI-1.

Conclusion; These data support our hypothesis that Ang II increases RANKL:OPG ratio partly via transactivation of ErbB receptors by the AT1R. This novel finding provides an insight into the mechanism through which AngII-associated hypertension induces lower bone mineralisation.

SU0253

Duality of TRIP-1 Function in Regulating Osteoblast Activity *In Vitro*. Diana Metz-Estrella^{*1}, Tzong-Jen Shue¹, J. Edward Puzas². ¹University of Rochester, USA, ²University of Rochester School of Medicine, USA

The coupled processes of bone resorption and bone formation involve both a temporal and spatial component to maintain appropriate skeletal turnover. However, little is known about what controls the spatial component. We have put forward a hypothesis that molecules remaining at the reversal line during resorption can identify these sites for new bone formation. We posit that tartrate resistant acid phosphatase (TRAP) may be one of these molecules. TRAP has been shown to have an extremely high affinity for the TGF β receptor interacting protein (TRIP-1); an intracellular protein in osteoblasts. In this series of experiments we have characterized a dual role for TRIP-1 in mediating bone formation in osteoblasts. In the TGF β pathway TRIP-1 has been shown to be a regulator of gene expression. Our data with reporter assays show that TRIP-1 is essential for normal TGF β signaling. However, TRIP-1 is also known to be a subunit of the eIF3 complex; a complex involved in the initiation of protein translation. These facts imply that TRIP-1 has a dual role in the cell. Since TRIP-1 can be phosphorylated we believe the role of TRIP-1 in osteoblasts can be determined by its phosphorylation state. Examination under confocal microscopy showed that TRIP-1 can be localized in the nuclei of osteoblasts and its presence in the nucleus increased 44% following TGF β 1 treatment. Since TRIP-1 does not possess a nuclear localization signal we further investigated if it could enter the nucleus by interacting with Smads. Co-IP assays showed that TRIP-1 and Smad3 have a high affinity for each other, suggesting a possible mechanism for its nuclear internalization. To study the differential phosphorylation of TRIP-1 upon TGF β treatment we enriched cell lysates for phosphorylated proteins and then evaluated changes in phospho enriched TRIP-1 levels. Our results show that phospho-TRIP-1 levels are decreased 50% after treating osteoblasts with TGF β 1 for 30 minutes. In addition, phospho-TRIP-1 was mostly unchanged when osteoblasts were treated dually with okadaic acid and TGF β 1. This suggests that changes in TRIP-1 phosphorylation could be regulated at least in part by Ser/Thr phosphatases. Interestingly, a cell fractionation assay showed that phospho-TRIP-1 is almost exclusively present in the cytoplasmic fraction of osteoblasts. In conclusion, we believe that in the absence of TGF β 1, phosphorylated TRIP-1 is regulating protein translation in the cytoplasm. However, when TGF β 1 is present, phosphatases are activated and target cytoplasmic phospho-TRIP-1 allowing its nuclear translocation possibly through its interaction with Smad3. In the nucleus, unphosphorylated TRIP-1 will fulfill its role as a regulator of gene transcription.

Impaired Osteoblast Differentiation and PTH Response in Female Mice Lacking MAP Kinase Phosphatase-1. Chandrika Mahalingam¹, Tanuka Datta¹, Rashmi Patil¹, Jaclynn Kreider², Steven Goldstein², Abdul Abou-Samra¹, Nabanita Datta^{*1}. ¹Wayne State University School of Medicine, USA, ²University of Michigan, USA

Parathyroid hormone (PTH) is an important regulator of bone mass accrual that acts through PTH 1 receptor (PTH1R), and involves cAMP, PKC and MAPK pathways. MAPKs are negatively regulated by a family of dual-specificity phosphatases known as the MAPK phosphatases (MKPs). The role of MKP-1 in PTH anabolic action in bone is yet to be established. Previously, we have shown that female MKP-1 KO mice display osteopenia and PTH1R induction increases MKP-1 expression in differentiated osteoblasts both in vitro and in vivo. Here we show that primary calvarial osteoblasts derived from exon-2 deleted MKP-1 knock-out (KO) female mice display reduced and delayed expression of Alkaline Phosphatase (ALP), suggesting continued osteoblast proliferation and delayed differentiation. Genes associated with osteoblast maturation and functions were examined at basal state and after PTH treatment. Real-time PCR analysis showed significantly reduced ($p < 0.01$) levels of osteocalcin (OCN), osteonectin (ON) and Runx2 mRNA in osteoblasts isolated from KO females compared to those isolated from WT animals. PTH did not inhibit OCN, ALP, and Runx2 mRNA in cells from KO mice. In contrast to WT osteoblasts, ON expression was increased in MKP-1 null cells following PTH induction. To investigate the effect of MKP-1 deletion on the anabolic response to PTH in vivo, 4-day old WT and KO female mice were injected daily subcutaneously with 50 μ g/kg 1-34 hPTH or vehicle (0.9% saline) control for 21 days. Femora were isolated, dissected free of soft tissue, fixed and analyzed by micro-computed tomography. Images were reconstructed at 18 micron isotropic voxels. PTH significantly increased trabecular bone volume per total volume (BV/TV), trabecular thickness (TbTh) and trabecular number (TbN), by 85%, 33%, 27% respectively, in distal femora from WT mice compared to vehicle treated controls. The effect of PTH on BV/TV (45%), TbTh (23%) was less pronounced in KO animals relative to WT group when compared to respective controls. The increase in TbN (12%) between PTH and vehicle treated KO animals did not reach statistical significance. We conclude that MKP-1 is important for osteoblast differentiation and skeletal responsiveness to PTH.

Metabolic Acidosis-induced Stimulation of RANKL and Bone Resorption Requires G β Signaling. Nancy Kreiger^{*1}, Christopher Culbertson², David Bushinsky¹. ¹University of Rochester, USA, ²University of Rochester School of Medicine, USA

Chronic metabolic acidosis, an increase in proton concentration [H⁺] due to reduced [HCO₃], stimulates cell-mediated net calcium (Ca) efflux from bone. This efflux is mediated primarily through increased osteoblastic cyclooxygenase 2, leading to prostaglandin E₂-induced stimulation of RANKL and increased osteoclastic bone resorption. We and others have found that osteoblasts express OGR1, a H⁺-sensing G-protein coupled receptor (GPCR). We demonstrated that H⁺ activation of OGR1 increases intracellular Ca signaling in osteoblasts and that the OGR1 inhibitor, CuCl₂, blocks H⁺-induced bone resorption. Our findings suggest that OGR1, which is coupled to G β , is the sensor that detects the increased [H⁺] during metabolic acidosis and initiates subsequent osteoblastic signaling leading to increased osteoclastic bone resorption. We have recently found that metabolic acidosis inhibits osteoblastic RGS16, a regulator of G protein signaling which can limit GPCR activation. To further explore the regulation of this G-protein coupled signaling by acidosis we utilized gallein, a selective inhibitor of G β signaling activity. Neonatal mouse calvariae were incubated for 48h in physiologically neutral (Ntl, pH=7.50, Pco₂=34 mmHg, [HCO₃]=28 mM) or acid (Met, pH=7.17, Pco₂=33 mmHg, [HCO₃]=13 mM) medium 20 μ M gallein (Gal). Compared to incubation in Ntl (44280 nmol/bone/24h), Met induced net Ca efflux (133992, p<0.05); Gal did not alter Ca efflux in Ntl (21862) but blocked the increase with Met (264138, p<0.05 vs Met alone) (n=8/group, mean SE). To determine if Gal inhibited the acid-induced increase in RANKL, primary osteoblasts were isolated from neonatal mouse calvariae and incubated in Ntl (pH=7.43, Pco₂=39 mmHg, [HCO₃]=25 mM) or Met (pH=7.10, Pco₂=39 mmHg, [HCO₃]=15 mM) medium 20 μ M Gal. At 48h, cells were collected and RANKL mRNA levels were measured by real time PCR, normalized to RPL13A. Compared to incubation in Ntl (0.850.11), Met stimulated RANKL (1.2911, p<0.05); Gal did not alter RANKL in Ntl (0.690.06) but blocked the increase with Met (0.910.05, p<0.05 vs Met alone) (n=6/group). Thus gallein inhibited both acid stimulation of osteoblastic RANKL production and acid-induced net Ca efflux, a measure of bone resorption. These results, together with our previous finding of acid inhibition of RGS16, suggest that regulation of G β plays an important role in modulating the OGR1-mediated response of the osteoblast to metabolic acidosis.

The Role of Tmem119 in the BMP Signaling Pathway. Geoffrey Hendy¹, KENICHIRO TANAKA^{*2}, Lucie Canaff³, Toshitsugu Sugimoto², Hiroshi Kaji⁴, Riko Kitazawa⁵, Toshihisa Komori⁶, Susumu Seino⁷, Takenobu Katagiri⁸. ¹McGill University, Royal Victoria Hospital, Canada, ²Shimane University School of Medicine, Japan, ³McGill University, Canada, ⁴Kinki University Faculty of Medicine, Jpn, ⁵Kobe University, Japan, ⁶Nagasaki University Graduate School of Biomedical Sciences, Japan, ⁷Kobe University Graduate School of Medicine, Japan, ⁸Saitama Medical University Research Center for Genomic Medicine, Japan

Fibrodysplasia ossificans progressive (FOP) is a genetic disease in which heterotopic ossifications occurs in muscle tissue. The constitutively activating mutation (R206H) of the BMP type 1 receptor, ACVR1/ALK2 is thought to underlie the molecular pathogenesis of FOP. However, the details of the heterotopic ossification of muscle in FOP remain to be elucidated. We demonstrated that the Smad3 signaling rapidly induced by PTH, which is independent of TGF- β is important in bone anabolic effects. And we selected the bone formation-related factor, Tmem119 by comparative DNA microarray analysis between empty-vector-transfected mouse osteoblastic MC3T3-E1 cells and PD98059-treated stably Smad3-overexpressing MC3T3-E1 cells (JBC 2011). In the present study, we performed a comparative DNA microarray analysis between empty-vector- and ALK2 (R206H)-transfected mouse myoblastic C2C12 cells. Forty genes were identified whose expression was increased >3.5 times in the experimental groups versus the control. And this group included Tmem119. Stable Tmem119 overexpression induced the commitment and differentiation of myoblasts or mesenchymal cells into osteoblasts and mineralization. On the other hand, differentiation of myoblastic cells into myotubes was suppressed, and differentiation into chondrocytes was little affected. Moreover, transcriptional activity of the BMP-2 signaling molecules, Smad1/5 was increased in the absence of exogenous BMP-2 in C2C12 cells. Next, we analyzed the mechanism that Tmem119 induced the commitment and differentiation of myoblasts into osteoblasts using C2C12 cells. Tmem119 increased BMP-2 levels (Western, Real-time PCR), and Tmem119 siRNA antagonized BMP-2 levels. BMP-2/4 neutralizing antibody and dorsomorphin, an ALK2 inhibitor, antagonized Tmem119-enhanced ALP and OCN. Although Tmem119 interacts with Runx2, Smad1 and Smad5 physically and functionally, BMP-2 increased Tmem119 levels (Western, immunocytochemistry), Tmem119 siRNA antagonized the BMP-2-induced ALP and OCN, but not Runx2 and Osterix, mRNAs, in C2C12 cells. In this study, we showed that Tmem119 promotes the differentiation of myoblasts into osteoblasts induced by BMP-2 and the interaction with the BMP signaling pathway occurs downstream of Runx2 and Osterix in

myoblasts. Tmem119 may play a critical role in commitment of myoprogenitor cells to the osteoblast lineage.

Additive Effects of TBT and TCDD on Bone Cell Differentiation. Antti Koskela^{*1}, Juha Tuukkanen¹, Matti Viluksela², Merja Korkalainen². ¹University of Oulu, Finland, ²National Institute for Health & Welfare, Finland

Important environmental contaminants, tributyltin (TBT) and 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), are wide-spread and persistent in nature. They accumulate in the food chain and they may participate in the toxicological burden on the development of osteoporosis. They are chemically different with different mechanism of action, but both have been shown to affect bone development. We utilized differentiation of mouse bone marrow stromal cells and hematopoietic stem cells of monocyte macrophage lineage to study the combined effects of TBT and TCDD on osteoblastogenesis and osteoclastogenesis respectively. Stem cells were isolated from the bone marrow of femurs and tibiae of male C57BL/6J mice, and differentiated to both osteoblasts or osteoclasts. Cells were exposed to 10⁻¹⁰ – 10⁻⁸ M TBT, 10⁻¹¹ – 10⁻⁹ M TCDD and 10⁻⁸ M TBT + 10⁻⁹ M TCDD. The combined treatment with TBT and TCDD additively decreased the mRNA expression of alkaline phosphatase and osteocalcin. Osteoclastogenesis was also affected and there was clear additive effect of TBT and TCDD on resorption pit formation. PCR array analysis revealed that TBT and TCDD evoked different gene expression patterns and in combined exposure they affected more genes than individual exposures. In conclusion, these results indicate that TBT and TCDD affect both bone formation and bone resorption with very low concentrations and the effect is additive.

Aged Perivascular Mesenchymal Stem Cells Derived from Adipose Tissue are Hyperproliferative and Resistant to the Induction of Osteogenic and Adipogenic Differentiation. Matthew Stern^{*1}, Amber Stern¹, Christopher Bergman², Stephen Kritchevsky³, Mark Van Dyke². ¹University of Missouri-Kansas City, USA, ²Wake Forest Institute for Regenerative Medicine, USA, ³Wake Forest Baptist Medical Center, Sticht Center on Aging, USA

Adipose derived stem cells (ADSCs) are multipotent mesenchymal stem cells that reside within the microvasculature of adipose tissue. ADSCs can differentiate into the osteogenic, chondrogenic, myogenic, and adipogenic lineages within the musculoskeletal system. Age-associated increases in tissue adiposity are observed during the development of sarcopenia in muscle and also within aging bone. Two questions regarding aged ADSCs that have not been adequately addressed are 1) whether the aging process adversely affects the potential of ADSCs for use in therapeutic applications and 2) whether age-related changes in ADSCs contribute to the increased tissue adiposity observed in aging individuals. To address these questions, we obtained ADSCs from young (4-6-month-old) and old (> 22-month-old) rats and compared their ability to proliferate and differentiate into multiple cell lineages. ADSCs obtained from young and old animals exhibited the same cell surface and gross morphological phenotype; however, old ADSCs were significantly more proliferative. When induced to undergo adipogenic or osteogenic differentiation, young ADSCs exhibited significantly greater levels of staining for indicators of terminal differentiation and greater changes in the expression of several genes involved in differentiation. Our results suggest that ADSCs are subject to cell-intrinsic aging mechanisms that render aged cells more proliferative and less responsive to differentiation cues than young cells, even when cultured under identical conditions, and suggest a role for Wnt signaling in this process. These findings raise concern over the potential use of autologous ADSCs in therapeutic applications for elderly individuals and suggest that hyperproliferative ADSCs could play a role in the accumulation of adipose and adipose-like tissue within the musculoskeletal system of aged individuals.

Biomimetic Calcium Silicate Support Differentiation of Human Orofacial Bone Marrow Stromal Cells. Sara Shah¹, Maria Giovanna Gandolfi², Ruoxue Feng¹, Carlo Prati², Sunday Akintoye^{*3}. ¹University of Pennsylvania, USA, ²University of Bologna, Italy, ³University of Pennsylvania School of Dental Medicine, USA

Introduction: Human orofacial bone marrow stromal cells (OFMSCs) from maxilla and mandible have robust osteogenic regenerative properties. Furthermore, a combination of OFMSCs with bioactive calcium-releasing scaffolds can potentially improve OFMSC multi-lineage differentiation abilities, but biocompatibility of calcium silicate cements with OFMSCs is still unclear. We tested the hypothesis that

material extracts of calcium-releasing calcium-silicate scaffolds support biomimetic microenvironment for survival and differentiation of human OFMSCs.

Methods: Two formulations of experimental calcium-silicate cements 1) calcium-silicate mineral powder (wTC) containing di- and tricalcium-silicate, calcium sulphate, and calcium chloride and 2) wTC doped with alpha-tricalcium phosphate (wTC- α TCP) were prepared. Cement setting times were assessed by Gilmore needles; ability to release calcium and hydroxyl ion was assessed by potentiometric methods and OFMSC attachment to calcium-silicate discs was assessed relative to tissue culture plastic. Calcium-silicate material extracts were tested for ability to support OFMSCs survival as well as *in vitro/in vivo* differentiation.

Results: Fewer OFMSCs attached to calcium-silicate discs relative to tissue culture plastic ($p=0.001$). Extracts of calcium-silicate cements sustained OFMSC survival, maintained steady state levels of vascular cell adhesion molecule-1, alkaline phosphatase and bone sialoprotein while upregulating their respective gene transcripts. Adipogenic and *in vivo* bone regenerative capacities of OFMSCs were also unaffected by calcium-silicate extracts.

Conclusions: Ion-releasing calcium-silicate cements support a biomimetic micro-environment conducive to survival and differentiation of OFMSCs. Combination of OFMSCs and calcium-silicate support hard tissue regeneration. This work was supported by USPHS/NIH/NCI grant 5K08CA120875-04.

Characterization of Murine Telomerase Reverse Transcriptase (mTERT) Immortalized Osteoblast Cell Lines Generated from Wild-type and Nmp4-null Mouse Bone Marrow Stromal Cells. Marta Alvarez¹, Paul Childress¹, Binu Philip¹, Rita Gerard-O'Riley¹, Michael Hanlon¹, Brittney-Shea Herbert¹, Alexander Robling², Fredrick Pavalko¹, Joseph Bidwell¹. ¹Indiana University School of Medicine, USA, ²Indiana University, USA

Intermittent parathyroid hormone (PTH) adds new bone to the osteoporotic skeleton; the transcription factor Nmp4/CIZ represses PTH-induced bone formation in mice and as a consequence is a potential drug target for improving hormone clinical efficacy. To explore the impact of Nmp4/CIZ on osteoblast phenotype, we immortalized bone marrow stromal cells from wildtype (WT) and Nmp4-knockout (KO) mice using murine telomerase reverse transcriptase. Clonal lines were initially chosen based on their staining for alkaline phosphatase and capacity for mineralization. Disabling Nmp4/CIZ had no gross impact on osteoblast phenotype. WT and KO clones exhibited sustained growth, reduced population doubling times, extended maintenance of the mature osteoblast phenotype, and competency for differentiating toward the osteoblast and adipocyte lineages. We recently demonstrated that PTH-induced c-fos femoral mRNA expression is enhanced in Nmp4-KO mice; unexpectedly in the present study we determined that null primary and clonal cells expressed significantly less PTH receptor than WT cells nevertheless hormone stimulated an equivalent increase in c-fos in both cells suggesting that the mature osteoblast is not responsible for the enhanced hormone-stimulated c-fos response *in vivo*. However, the null osteoblasts were hyper-responsive to bone morphogenetic protein 2 (BMP2)-induced changes in genes that support osteoblast differentiation, consistent with the previously observed enhanced BMP2-induced bone formation in null mice. We speculate that Nmp4 may repress PTH-induced bone formation, in part, by attenuating cell responsiveness to hormone-stimulated local increases in BMPs. These immortalized cell lines will provide a valuable tool for disentangling the complex functional roles underlying Nmp4/CIZ regulation of bone anabolism.

Differential Effect of Arachidonic Acid and Beta-Cryptoxanthin on the Expression of Retinoic Acid Receptors Genes in Mesenchymal Stem Cells Differentiated to Osteoblasts and Adipocytes. Antonio Casado-Dúaz¹, Raquel Santiago-Mora², Jose Manuel Quesada Gomez³. ¹Hospital Reina Sofía, Spain, ²Universidad De Cordoba, Spain, ³Gabinete Quesper, Spain

The arachidonic acid (AA) is a ω -6 fatty acid which has the ability to favor the adipogenic differentiation of mesenchymal stem cells (MSC). The β -cryptoxanthin (β -Crx) is a carotenoid, abundant in quite a lot of fruits and vegetables that inhibits adipogenesis and enhances bone formation. These effects seem to be mediated by RARs and PPAR β/δ receptors. The high consumption of ω -6 in a large part of the population has a negative direct effect on bone health. The aim of this work is to study if β -Crx may decrease the adipogenic effect of AA in MSC induced to osteoblasts or adipocytes and its effect on the expression of the coding genes over their receptors.

Human MSCs were induced to differentiate to osteoblasts or to adipocytes. Additionally, MSC induced cultures were treated by using 20 μ M of AA and/or 10⁻⁶M or 10⁻⁵M of β -Crx. Osteogenic and adipogenic markers; the expressions of RAR α , β and γ , PPAR β/δ ; the cellular retinoic acid binding protein 2 (CRABP2) and Fatty acid-binding protein 5 (FABP5) genes were measured.

La β -Crx decreased the AA ability to increase adipogenesis in MSC induced to adipocytes, but not in MSC induced to osteoblast. The expression of RAR α and RAR γ in cells induced to adipocytes decreased in the presence of AA after 7 and 14 days of treatment, whereas it increased after 21 days. β -Crx prevented the inhibition of these two genes caused by the AA after 14 days. Oppositely, the expression of RAR β ,

PPAR β/δ , CRABP2 and FABP5 were increased by AA. Moreover, 10⁻⁶M of β -Crx, further enhanced the expression of these genes. In MSC induced to osteoblasts in presence of AA, appear adipocytes and the RAR α , β , γ and PPAR β/δ expression decreased. Additionally, CRABP2 decreased whereas FABP5 increased its expression after 7 days. The β -Crx promoted this increase even in presence of AA.

Our results show that RAR β are involved in the increase of adipogenic differentiation induced by AA, whereas RAR α and γ seem to be responsible for the diminution of the AA effect on adipogenesis mediated by β -Crx. The increase of CRABP2 and FABP5 expression in adipocytes with AA seem to indicate that their answer is mediated by a nuclear activation of RAR β and PPAR β/δ , which are coactivators, respectively. In MSC induced to osteoblasts, differentiation to adipocytes promoted by AA involves the inhibition of the 3 RARs genes, PPAR β/δ gene and the activation of FABP5 gene. This indicates a different mechanism for the induction of adipogenesis in these cultures.

Differential Requirement of SWI/SNF Chromatin Remodeling Complexes in Osteoblast Commitment and Differentiation *in vitro*. FUHUA XU¹, Stephen Flowers², Elizabeth Moran³. ¹New Jersey Medical School, UMDNJ, USA, ²NJMS-UH Cancer Center, University of Medicine of Dentistry of New Jersey, USA, ³University of Medicine & Dentistry of New Jersey, Cancer Center, USA

The commitment of the osteoblastic lineage, and further differentiation to osteoblasts and ultimately to mature osteocytes, is tightly regulated. Successive changes in gene expression patterns are controlled by specific transcription factors such as Runx2 and Osterix, acting in concert with histone modifiers and ATPase-dependent SWI/SNF chromatin remodeling complexes. BAF and PBAF, distinct subclasses of mammalian SWI/SNF complexes, share most subunits but are distinguished by unique subunits: ARID1A/B belong specifically to BAF and ARID2 is exclusive to PABF. The ATPase BRG1 can power either complex. Elucidating the mechanism of how BAF and PBAF differentially regulate genes required to osteoblast commitment and differentiation will be a significant step toward understanding bone development.

We have recently identified several gene expression patterns dependent on BRG1. Here we have considered whether these patterns segregate with BAF vs PBAF. Our results show induction of the osteogenic marker, alkaline phosphatase, is impaired in ARID1A or ARID1B depleted pre-osteoblasts in a milder version of the BRG1 depletion phenotype. ARID2 stable knockdown cells likewise fail to induce alkaline phosphatase and osteocalcin activity, implying non-redundant requirements for both BAF and PBAF in activation of osteogenic gene expression. Pre-osteoblasts express high levels of FGFR2, which is essential for maintaining osteoblast commitment status. Depletion of either BRG1 or ARID2 causes dramatic down-regulation of FGFR2 expression, suggesting PBAF is required for osteoblastic lineage commitment as well as for differentiation. Another phenotype of BRG1 depletion is inappropriate expression of the mature osteocyte markers Dmp1 and Phex in pre-osteoblasts, indicating that a BRG1 complex is required to repress premature expression of genes specific to the terminally differentiated osteocyte phenotype. Depletion of ARID2 does not cause premature expression of DMP1 or Phex, indicating that repression of osteocyte-specific genes in pre-osteoblasts is a BAF-specific function for which PBAF is not required. Collectively, these data identify some overlapping and some distinct functions for BAF and PBAF. To date, PBAF has segregated only with activation functions, while BAF participates in both activation and repression.

Distribution of Neural Crest-Derived Cells in Adult Mice and Their Induction into Osteoblastic Cells. Miki Ono¹, Masamichi Takami¹, Tetsuo Suzawa¹, Tomohiko Miyauchi¹, Atsushi Yamada¹, Junichi Watahiki¹, Kazuyoshi Baba¹, Masanori Nakamura¹, Kotaro Maki¹, Noriko Osumi², Ryutaro Kamijo¹. ¹Showa University School of Dentistry, Japan, ²Tohoku University Graduate School of Medicine, Japan

The neural crest is a type of embryonic tissue that transiently appears near the neural tubes during development. Neural crest cells migrate throughout the embryo and differentiate into various types of cells in different germ layers, including osteoblasts, neurocytes, myocytes, lipocytes, and cardiocytes. In adult tissues, subsets of neural crest-derived cells (NCCs) have been shown to reside as stem cells and are considered to be useful cell sources for regenerative medicine strategies. However, the distribution of NCCs in adults is not fully understood. To analyze the distribution and characteristics of NCCs in adult tissues, we utilized double transgenic mice in which NCCs expressed EGFP (enhanced green fluorescent protein) by mating protein 0 (a specific marker of the neural crest)-Cre transgenic mice with CAG-CAT-EGFP transgenic mice. GFP-positive cells were found in these double transgenic mice in a variety of tissues, such as the pancreas, stomach, skin, nasal conchae, palate, gingiva, oral vestibule, tongue, and buccal mucosa. On the basis of these findings, we focused on oral mucosa as a cell source for regenerative medicine, as buccal mucosal tissue abundantly exists and covers a broad area in the oral cavity and has a distinctive regenerative capacity. We surgically isolated buccal mucosa from the mice, then

digested the samples with collagenase and dispase to collect cells. A range of 1-4% of all buccal mucosa cells was found to be EGFP positive, indicating that they were identical to NCCs. We isolated EGFP-positive cells using a flow-cytometer equipped with a cell sorter and cultured them on low-adhesion culture plates. After 1 week, EGFP-positive cells formed spheres, typical cell clusters composed of stem cells, and expressed the stem cell marker *Musashi 1*, as well as the neural crest markers *p75*, *Twist*, and *Snail*, suggesting that the population contained neural crest-derived stem cells. Subsequently, we cultured EGFP-positive cells in osteoinductive medium with bone morphogenetic protein (BMP)-2 (100 ng/ml). After 14 days, those cells expressed alkaline phosphatase, and produced calcified substances detected by alizarin-red staining. These results suggest that NCCs reside in various regions throughout the body including buccal mucosa and possess a potential to differentiate into osteoblastic cells. Thus, NCCs may be a useful cell source for regenerative medicine strategies including bone regeneration.

Hematopoiesis and Leukocyte Distribution Within Bone Marrow Are Rapidly Disrupted by a High Fat Diet, While Daily Bouts of Mechanical Signals Enhance the Hematopoietic Repair Response. Benjamin Adler^{*1}, Danielle Green¹, Ete Meilin Chan¹, Clinton Rubin². ¹Stony Brook University, USA, ²State University of New York at Stony Brook, USA

Obesity increases lifetime susceptibility to a host of chronic diseases, implicating a suppressed immune system. Obesity also biases bone marrow stromal cells (BMSCs) towards the formation of adipose tissue, compromising the bone marrow progenitor pool. In contrast, mechanical signals stimulate proliferation of BMSCs and drive their differentiation towards the formation of bone, while suppressing adipogenesis and adiposity. Considering the consequences of obesity – and the benefits of exercise – on BMSCs, we hypothesize that a high fat diet (HFD) will impair hematopoiesis, compromising immune populations, while mechanical signals will help preserve the reparative capacity of hematopoietic stem cells (HSC). Seven week old male C57BL/6J mice were fed either a high fat diet (HFD: 60% Kcal from fat) or regular chow diet. One group of HFD mice were subject to 15min/day, 5 days/wk of mechanical signals delivered via low intensity vibration (HFV), and compared to both high fat controls (HFC) and regular diet controls (RDC)(n=10 per group). Bone marrow was analyzed using flow cytometry at 1 and 6 weeks to characterize hematopoietic cell populations. Within one week, the HFD induced an "aged" phenotype in bone marrow leukocytes, with B-cell proportions reduced by -10% compared to RDC (p<0.05). By 6w of HFD the "aged" phenotype was completely manifested as B-cells had collapsed by -25% and T-cells reduced by -33%, while the myeloid cell fraction increased by +16% as compared to RDC (p<0.01). By 1w, hematopoietic progenitors central to the repair of the leukocyte pool had already elevated by +16% in HFC, and +25% in HFV relative to RDC (p<0.05). By 6w, the progenitor population in the HFC had regressed to control levels, yet the mechanically stimulated HFV animals retained a +25% increase relative to RDC (p<0.05). Hematopoiesis is vulnerable to even short-term exposure to a high fat diet, which disrupts leukocyte allocations threatening adaptive immunity. The rapid expansion of the HSC progenitor pool seen as early as 1w reflects the activation of a repair mechanism to restore the damaged leukocyte populations, a response which fails in HFC by 6w despite the continued disruption of hematopoiesis. Mechanical signals serve to perpetuate this reparative response, providing insight into the role of physical stimuli, and exercise in general, in regulating osteoimmunology.

Stage-specific Embryonic Antigen-4 Identifies Human Dental Pulp Stem Cells. Noriaki Kawanabe^{*1}, Satoko Murata², Hiroaki Fukushima², Yoshihito Ishihara², Hiroshi Kurosaka², Hiroshi Kamioka³, Takashi Yamashiro². ¹Okayama University Hospital, Japan, ²Okayama University, Japan, ³Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sc, Japan

Embryonic stem cell-associated antigens are expressed in a variety of adult stem cells as well as embryonic stem cells. In the present study, we investigated whether stage-specific embryonic antigen (SSEA)-4 can be used to isolate dental pulp (DP) stem cells. In this study, DP cells showed plastic adherence, specific surface antigen expression, and multipotent differentiation potential, similar to mesenchymal stem cells (MSC), but did not display adipogenic differentiation potential. In addition, DP cells were positive for embryonic stem cell-associated antigens (SSEA-1, SSEA-3, SSEA-4, TRA-1-60, TRA-1-81, OCT4, NANOG, SOX2, and REX1) and alkaline phosphatase activity. Flow cytometric analysis demonstrated that 45.5% of the DP cells were SSEA-4+. When the DP cells were cultured in the presence of all-trans-retinoic acid, marked downregulation of SSEA-3 and SSEA-4 and the upregulation of SSEA-1 were observed. SSEA-4+ DP cells showed a greater telomere length and a higher growth rate compared to untagged and SSEA-4- cells. A clonal assay demonstrated that 65.5% of SSEA-4+ DP cells had osteogenic potential, and SSEA-4+ clonal DP cells showed multilineage differentiation potential toward osteoblasts, chondrocytes, and neurons. The presence of SSEA-4+ cells in DP tissue *in vivo* was also confirmed. Thus, our results suggest that SSEA-4 is a specific cell

surface antigen that can be used to identify DP stem cells. In addition, SSEA-4+ DP cells appear to be candidates for stem cells that can be used in regenerative therapy.

Therapeutic Potential of Glucocorticoid-Induced Leucine Zipper (GILZ) Protein in Rheumatoid Arthritis. Linlin He^{*1}, Nianlan Yang¹, Carlos Isaacs², Xing-Ming Shi². ¹Georgia Health Sciences University, USA, ²Medical College of Georgia, USA

Proinflammatory cytokines are known to inhibit osteoblastic differentiation and function while stimulating osteoclast differentiation and bone resorption. Steroid hormone glucocorticoids (GCs), which are superb anti-inflammatory agents, also cause bone loss resulting in osteoporosis. We showed previously that overexpression of a GC inducible protein Glucocorticoid-Induced Leucine Zipper (GILZ) can enhance osteogenic differentiation of bone marrow mesenchymal stem cells (MSCs). In this study we asked whether GILZ can override the inhibitory effect of tumor necrosis factor- α (TNF- α) on MSC osteogenic differentiation using both GILZ gain-of-function (retrovirus-mediated overexpression) and loss-of-function (lentivirus-mediated shRNA knockdown) approaches. Our results show that overexpression of GILZ antagonized the inhibitory effects of TNF- α on MSC mineralization and the levels of mRNA and protein of pivotal osteogenic regulators *Osx* and *Runx2*. Knockdown of GILZ had an opposite effect on MSC differentiation and gene expression. These actions appear to occur via mechanisms involving GILZ inhibition of TNF- α -induced mitogen-activated protein (MAP) kinase activation and E3 ubiquitin ligase-mediated protein degradation. Taken together, our studies show that GILZ has therapeutic potential for preventing bone loss caused by chronic inflammation such as rheumatoid arthritis.

Treatment of Skeletally Unloaded Mice With Sclerostin Antibody Increases Osteoblast Activity and Mineralization. Mohammad Shahnazari^{*1}, Vivian Chu², Marina Stolina³, Thomas Wronski⁴, Hua Zhu Ke³, Bernard Halloran⁵. ¹UCSF VA Medical Center, USA, ²VA Medical Center, USA, ³Amgen Inc., USA, ⁴University of Florida, USA, ⁵VA Medical Center (111N), USA

Sclerostin functions as an antagonist to Wnt signaling and has been shown to inhibit bone formation. Treatment with antibodies to sclerostin (Scl-Ab) stimulates bone formation and provides a means of treating patients with osteoporosis. Skeletal unloading or loss of weight is associated with a decrease in bone formation and bone loss. To determine the effect of Scl-Ab treatment on bone during skeletal unloading, male C57BL/6 mice (5 mo old) were hind limb unloaded or allowed normal ambulation and treated with Scl-ab (25mg/kg, day 1 and 4) or placebo (n=8/group) for 1 week. Bone marrow culture was performed after necropsies of the animals. Unloading induced a decrease in colony forming units (CFU) (-35%), alkaline phosphatase positive CFU (CFU-AP+) (-65%) and calcified nodules (-25%); and increased the population of TRAP+ multinucleated osteoclasts(+70%). Treatment of both unloaded and loaded mice with Scl-Ab increased CFU, CFU-AP+ and calcified nodules. Our data suggest that Scl-Ab treatment can prevent the loss of osteoprogenitors associated with skeletal unloading.

VDR Is Required for Anti-proliferative and Pro-osteoblastogenic Effects of 1,25(OH)₂D₃ in Adult Human Mesenchymal Stem Cells. Shuo Geng, Shuanhu Zhou^{*}, Julie Glowacki, Brigham & Women's Hospital, USA

INTRODUCTION: Anti-proliferative and pro-differentiation effects of 1,25(OH)₂D₃ have been described for many tumor and normal cell types. Classically, 1,25(OH)₂D₃ mediates its actions through activation of the Vitamin D Receptor (VDR), a ligand-dependent transcription factor. Proliferation of some tumor cell, however, remained inhibitable by 1,25(OH)₂D₃ after VDR-silencing (BMC Genomics 2009;10:499). Mineralization abnormalities in growing VDR-KO mice were corrected with rescue diet, but some cellular defects persisted (Ann NY Acad Sci 2006;1068:204). Several novel and D-independent functions of VDR have been uncovered in normocalcemic VDR-KO mice. These studies test the hypothesis that VDR is required for actions of 1,25(OH)₂D₃ in human mesenchymal stem cells (hMSCs).

METHODS: Human MSCs were isolated by expansion of adherent, low-density progenitor cells from marrow discarded during surgery. Transient transfection of siRNA into hMSCs was performed by electroporation (Human MSC Nucleofector Kit, Lonza/Amazax Biosystems) and either VDR-siRNA (Invitrogen) or non-silencing control siRNA (NC, Santa Cruz Biotechnology, Inc.). Growth medium was phenol red-free α -MEM, 10% fetal bovine serum-heat-inactivated (FBS-HI) and antibiotics.

Osteoblastogenic medium (1% FBS-HI) had supplements (10 nM dexamethasone, 5 mM β -glycerophosphate, 50 μ g/mL ascorbate-2-phosphate).

RESULTS: RT-PCR revealed downregulation of VDR expression in cells transfected with VDR-siRNA. In a short-term proliferation assay (3-day), the number of NC hMSCs incubated with 1,25(OH) $_2$ D $_3$ was 65.8 \pm 3.3% of the number without 1,25(OH) $_2$ D $_3$ ($p < 0.0001$). In sharp contrast, the number of cells that had been transfected with VDR-siRNA was not affected by exposure to 1,25(OH) $_2$ D $_3$ (103.1 \pm 1.0%, compared with those not exposed to 1,25(OH) $_2$ D $_3$). Osteoblast differentiation was measured 3 days after change to osteoblastogenic medium 10 nM 1,25(OH) $_2$ D $_3$ by RT-PCR for alkaline phosphatase (ALP) mRNA. In control hMSCs, 1,25(OH) $_2$ D $_3$ stimulated ALP, 162% of untreated. In contrast, in hMSCs that had been transfected with VDR-siRNA, there was no stimulation of ALP by 1,25(OH) $_2$ D $_3$ (89% compared with those not exposed to 1,25(OH) $_2$ D $_3$).

CONCLUSION: There were substantial differences in the effects of 1,25(OH) $_2$ D $_3$ on hMSCs after transfection with VDR-siRNA and non-silencing control siRNA. These studies indicate that the anti-proliferative and pro-osteoblastogenic effects of 1,25(OH) $_2$ D $_3$ in hMSCs depend upon the VDR.

Zinc Finger Targeting of Promoter-Reporter Constructs to a "Safe Haven" Site in Human Pluripotent Stem Cells to Facilitate Analysis and Therapy of Bone Disease. Xiaonan Xin*, Xi Jiang, Liping Wang, Mary Louise Stover, Hui-Chen Chan, Shuning Zhan, I-Ping Chen, Ernst Reichenberger, David Rowe, Alexander Lichtler. University of Connecticut Health Center, USA

Genetic bone diseases such as osteogenesis imperfecta (OI) and craniometaphyseal dysplasia (CMD) could be potentially studied and treated using induced pluripotent stem cells (iPSC) produced from patient cells. However, for this potential to be fully realized, it will be important to introduce ubiquitous and/or cell type specific marker genes into one or more site(s) in the human genome that both retain an active chromatin configuration and do not cause negative effects when constructs are inserted into them (referred to as "safe haven" sites). One such site is AAVS1, which is the insertion site of the common adeno-associated virus, which causes no known adverse effects. Because conventional gene targeting by homologous recombination in human embryonic stem cells (hESC) and iPEC is very inefficient, we are exploring zinc finger nuclease (ZFN) technology to increase the efficiency of homologous recombination at a specific site. We have delivered a construct containing the EF1 α promoter, which is widely expressed in cultured cells, driving an RFP-T2-puro expression cassette into H9 hESC AAVS1 site by co-transfection with AAVS1 site specific ZFN mRNA. Puromycin selection produced approximately 20 times as many colonies with the ZFN mRNA as without. We established colonies with more than 90% RFP expression. PCR demonstrated integration into the AAVS1 locus. Embryoid body formation showed that the EF1 α promoter is turned down in many differentiated cells. We plan to test the ubiquitin promoter for consistent expression in differentiated cells. To test the suitability of the AAVS1 site for supporting gene expression in osteoblasts, we used the Col2.3 promoter, which is most highly expressed in osteoblasts. Introducing Col2.3 promoter driven fluorescence protein expression into hESC/iPSC will be a useful tool for us to monitor hESC/iPSC differentiation into bone lineage. A Col2.3GFPmd construct has been introduced into hESC using ZFN technology, and targeted integration confirmed by PCR screening. Col2.3GFPmd expression in osteoblasts will be tested in teratomas, which we believe is currently the only method that reliably creates significant amounts of human cell-derived bone in mice. If results are positive, we will use these cells to test osteoblast differentiation protocols, which will be applied to iPSC. We are also developing reporter constructs that mark stages of mesoderm lineage progression toward different types of bone.

In Vitro Study on the Estradiol Dependent Changes on the Mechanical and Structural Properties of Human Fetal Osteoblasts cells. PADMALOSINI MUTHUKUMARAN*, Chwee Teck LIM, Taeyong Lee. National University of Singapore, Singapore

Aim

The most common form of osteoporosis is the postmenopausal osteoporosis, caused by estrogen deficiency. The pathogenesis of osteoporosis has been extensively studied in terms of the cellular and molecular effects of estrogen on osteoblasts and osteoblasts like cells. The aim of this study is to understand the mechanical basis of the pathogenesis of osteoporosis by assessing the direct effect of estradiol on the structural and mechanical properties of the human fetal osteoblasts (hFOB1.19).

Methods

The hFOB cells were seeded on sterile 13mm cover slips and allowed to reach confluency. The cells were then grown in either medium alone or medium supplemented with 10nM and 100nM β -Estradiol for 3 days. The cells were subjected to Atomic Force Microscopy (AFM) indentation. Hertz's contact equation was used to determine the apparent elastic modulus of the cell:

$$F(h) = (4/3) E^* h^{3/2}$$

where R = radius of probe, E* = apparent elastic modulus, h = indentation depth and F = indentation force. After treatment with estradiol the cells were stained with 0.1 μ g/ml TRITC-Phalloidin for F-Actin and imaged using confocal microscope. The cells were also tested for alkaline phosphatase (ALP) activity and mineralization.

Results

The cells treated with estradiol showed significantly lower apparent elastic modulus (10nM = 0.24kPa, 100nM = 0.26kPa) as compared to the control cells (0.42kPa) [Fig 1]. However there were no significant difference between the elastic moduli of 10nM Estradiol and 100nM Estradiol treated cells. The confocal images showed that the altered mechanical properties were associated with changes in the density of the actin filaments [Fig 2]. The quantified mineralization of all group cells remained the same. The ALP activity of estradiol treated cells significantly increased, concurring the literature data.

Conclusions

The results suggest that during the pathogenesis of osteoporosis the estrogen deficiency not only results in the changes in the physiological functions of osteoblasts but also is associated with changes in their elasticity. The confocal images showed that the changes in mechanical properties are due to changes in organization of actin filaments and not associated with difference in mineralization of the cells. Thus, this study shows that estradiol influences the mechanical properties of osteoblasts through cytoskeletal changes of the cells and that the mechanical property of the cells possibly influences their functions.

Characterization of Six Monoclonal Antibodies to Human Tartrate Resistant Acid Phosphatase (TRACP). Silvia D. Potenziani¹, Stephen Slone¹, Ranga Parthasarathy², Yi-Ying Wu³, Tsu-Yi Chao⁴, Lung Yam⁵, Anthony Jancik⁶. ¹Department of Pathology & Laboratory Medicine, University of Louisville, USA, ²Molecular Neuroscience & Bioinformatics, Robley Rex Louisville VA Medical Center, USA, ³Graduate Institute of Life Sciences, National Defense Medical Center, Taiwan, ⁴Department of Medicine, Taipei Medical University-Shuang Ho Hospital, Taiwan, ⁵Department of Medicine, University of Louisville, USA, ⁶Robley Rex Louisville VA Medical Center, USA

Purpose: Human serum TRACP5a is a potential marker for systemic macrophages and chronic inflammatory diseases. Serum TRACP5b is a marker of osteoclast number and bone resorption. In humans *Acp5* gene mutations with TRACP deficiency is causative for spondyloenchondrodysplasia (SPENCD), a disease of variable bone and autoimmune phenotype. Methods for immunoassay and immunodetection of TRACP isoforms are increasingly important. This study was undertaken to characterize six anti-TRACP monoclonal antibodies (mab) and determine their applications in various immunological methods.

Methods: Anti-TRACP mab9C5, 14G6, 162, 203, 220, and 89 were used as capture and detection antibodies in quantitative immunoassay, in western blot and in immunoprecipitation using serum TRACP5a and 5b and dendritic cell lysates as enzyme sources. Monoclonal antibodies were also tested for efficacy in immunohistochemistry of paraffin embedded tissues containing chronic inflammatory infiltrates. The clinical performance of mab14G6 for immunoassay of serum TRACP5b activity was compared to two commercial kit methods using sera from 20 patients with breast cancer and bone metastasis; 10 having clinical response to treatment and 10 with clinical progression. 15 patients without bone metastasis served as control.

Results: Mab9C5 reacted with a denatured epitope in the C-terminal portion of TRACP and was useful for western blot and IHC methods only. Mab14G6, 162, and 203 reacted with an epitope in the native conformation of both isoforms 5a and 5b.

They did not alter the pH optima of either TRACP5a or 5b, they had similar isoform specificity at pH 5.2 to 6.1 and may be similarly useful for quantitative immunoassay and immunoprecipitation of native TRACP. They were ineffective antibodies for western blot and IHC. Mab220 and 89 were specific for isoform 5a and useful in all applications. Both mabs increased the pH optimum and specific activity of serum TRACP5a in immunoassays. 14G6 performed equally to two commercial kit methods in terms of clinical sensitivity and specificity to detect clinical response or progression in breast cancer with bone metastasis.

Conclusion: Six monoclonal antibodies each had unique specificity for TRACP isoforms and were useful in selective applications. These antibodies will be important for clinical evaluation of disorders of bone metabolism and chronic inflammation. They also will aid in basic research of TRACP biochemistry and biology.

Small GTPases Rab14 and Rab4B are Required for Osteoclast Polarisation and Bone Resorption. Cecile Itzstein*, Denise Tosh, Miep Helfrich, Fraser Coxon, Michael Rogers. University of Aberdeen, United Kingdom

Osteoclasts are highly dependent on vesicular trafficking pathways to establish cell polarity and to degrade bone matrix. Ruffled border formation depends on polarised transport of acidic vesicles of the endocytic/lysosomal pathway, while degradation products are removed from the resorption lacuna by transcytosis. These vesicular trafficking pathways are regulated by the Rab family of GTPases. The expression profile and role of Rabs in osteoclasts is poorly understood.

We employed a proteomic approach to analyse the expression of abundant Rabs in human osteoclasts generated from peripheral blood monocytes. We identified nearly 20 Rabs, including Rab14 and Rab4B. These two GTPases are 58% homologous and both regulate endosomal trafficking pathways, particularly receptor recycling, for example of the transferrin receptor via their common effector RUFY1. Expression of Rab14 and Rab4B, analysed by qPCR, did not change during osteoclast differentiation. To determine the role of these two GTPases in osteoclast function, we knocked down their expression using siRNA. After expansion with M-CSF, human monocytes were cultured for 2 days with M-CSF and RANKL. The cells were then electroporated with 2 different Rab14 or Rab4B siRNAs, a GAPDH siRNA or a negative control siRNA. After 4 days of culture, osteoclasts were replated onto dentine discs and cultured for 48hr. Knockdown of Rab4B, Rab14 and GAPDH expression was confirmed by qPCR or western-blotting but had no effect on the formation of multinucleated osteoclasts. However, Rab4B knockdown caused a 40-70% decrease in both the number of polarised osteoclasts with actin rings and the amount of bone resorption. Similarly, Rab14 knockdown caused a 70-80% decrease in both these parameters. Moreover, when GFP-Rab14 was expressed in osteoclasts cultured on glass coverslips, the protein was found to colocalise in part with the endosomal marker EEA1 and the cis-golgi marker GM130, as previously described in other cell types. However, in 10% of the cells, GFP-Rab14 also colocalised with actin in podosomes. Our results indicate that both Rab4B and Rab14-regulated vesicular trafficking pathways are not involved in osteoclastogenesis but are required for osteoclast polarisation and activity. As Rab4 mediates integrin recycling in fibroblasts, Rab4B and Rab14 may both control $\alpha_v\beta_3$ recycling in osteoclasts, thereby regulating actin cytoskeleton reorganisation.

The Redundancy Between PTP Epsilon and PTP Alpha in Osteoclasts. Ari Elson, Eynat Finkelshtein*. Weizmann Institute of Science, Israel

Tyrosine phosphorylation plays a central role in regulation of cellular processes, among them bone structure and metabolism. We previously demonstrated that the non-receptor form of protein tyrosine phosphatase epsilon (PTPe), cyt-PTPe, is highly expressed in osteoclasts. Young female mice genetically lacking PTPe exhibit increased trabecular bone mass; their osteoclasts resorb bone less well in vitro and in vivo. These phenotypes are caused by reduced adhesion of PTPe-deficient osteoclast to bone, secondary to abnormal structure, stability and organization of podosomes, the adhesion structures of these cells. Most importantly, expressing cyt-PTPe in PTPe-deficient osteoclasts corrects the abnormal stability of podosomes in these cells. RPTPa is a very close structural relative of PTPe, and is also expressed at high levels in osteoclasts. However, our preliminary study of PTPa revealed no changes in bone matrix or osteoclast differentiation and their activity. Although the sequences of cyt-PTPe and RPTPa are very similar, Cyt-PTPe is predominantly cytosolic while RPTPa is an integral membrane protein. In order to determine if this difference prevented RPTPa from playing a significant role in osteoclasts we examined the ability of various forms of PTPe and PTPa to rescue the cellular phenotype of osteoclasts lacking PTPe, using podosomal organization as readout. We found that expression of cyt-PTPe or of an artificial cytosolic PTPa rescued the phenotype, while the receptor forms of PTPe (RPTPe) and PTPa (RPTPa) or of LCK-PTPe (a membrane-associated form of PTPe lacking an extracellular domain) cannot do so. We conclude that cytosolic localization of PTPe or PTPa catalytic activity is required to maintain proper organization and function of podosomes in osteoclasts.

Visualisation of the Apical Surface of Activated Osteoclasts. Kinga Szewczyk*, Karen Fuller¹, Raymond Moss¹, Timothy Chambers². ¹St. George's University of London, United Kingdom, ²St. George's Hospital Medical School, United Kingdom

Bone resorption occurs at the substrate-apposed, apical surface of osteoclasts, a surface that has not been accessible to direct visualisation. We have recently shown that it is the high affinity of bone mineral for vitronectin-receptor ligands that endows bone with the ability to activate osteoclasts. Consistent with this, osteoclasts secrete acid hydrolases and develop a ruffled border, as they do on bone, when they are incubated on vitronectin-coated plastic. Therefore, osteoclasts can be activated for resorption by substrates other than bone.

We have developed a novel approach to inspect the substrate-apposed surface of cells. To do this, cells are sedimented onto glass coverslips that have previously been coated with nail varnish. After incubation on such coverslips, the discs of nail varnish, with attached cells, are inverted onto a glass slide, and the nail varnish is removed with acetone. This exposes the underside of the cells, which can be inspected in the scanning electron microscope.

To analyse the substrate-apposed surface of activated osteoclasts, the nail varnish was coated with either vitronectin, or neonatal calf serum as a source of vitronectin. After incubation, the underside of osteoclasts showed a striking appearance. The whole undersurface was closely applied to the substrate, as it is on bone, in most osteoclasts. The central region was sometimes covered by fine, finger-like processes, often flattened against the substrate. More commonly the processes formed islands, or rings at the periphery of the central area. We also noted distinctive sucker-like structures of different sizes and shapes in almost all cells. Some of the central regions showed compartmentalisation, with compartmental walls similar in appearance to the stalks of 'suckers'. In some ruffled border regions we saw orifices, perhaps reflecting endocytic or exocytic processes.

The circumferential region appeared flat and featureless. However, if osmium tetroxide was omitted from fixation, rings, crescents and ridges of nodular protrusions, corresponding in position with podosomes, were observed circumferentially. The surface between and adjacent to podosomes, overlying the peri-podosomal cytoskeletal network, was extensively pitted.

This approach provides an exciting opportunity to characterise the morphological correlates of the resorptive process in osteoclasts.

Activation of the Prostaglandin D₂ CRTH2 Receptor Induces Apoptosis of Human Osteoclasts by the Intrinsic Apoptosis Pathway. Li Yue, Artur De Brum-Fernandes*. Universite De Sherbrooke, Canada

Osteoclasts (OCs) are the multinucleated giant cells of hematopoietic origin and participate in several pathologies associated with bone loss. Induction of OC apoptosis leads to decrease in bone resorption and affects the rate of bone remodeling, which is important to maintain normal bone turnover. Prostaglandin D₂ (PGD₂), a lipid mediator synthesized from arachidonic acid, is involved in various pathophysiological processes and diseases; it activates through two known receptors, DP1 and CRTH2. Previous results from our laboratory showed that treatment with PGD₂ induced human OC apoptosis in vitro through activation of CRTH2, but not through activation of the DP1 receptor. However, it is unclear which apoptotic pathway (i.e., intrinsic and extrinsic pathway) is involved in the PGD₂-induced OC apoptosis, and the objective of the present study is to elucidate this issue. Human OCs differentiated from peripheral blood mononuclear cells in the presence of rhRANKL (60 ng/ml) and M-CSF (10 ng/ml) for 21 days were treated with PGD₂ in the presence or absence of specific receptor agonists and antagonists for 24 hours. Caspase fluorogenic substrates assay and western blot analysis were performed to determine the activities and levels of caspase-3, -8, and -9 in cell lysates. The levels/activities of caspase-3 and -9 were increased after incubation with 10 nM PGD₂ and 10 nM CRTH2 agonist (13,14-dihydro-15-keto-Prostaglandin D₂, DK-PGD₂), but not with 10 nM DP agonist compound BW 245C. Decreased caspase-3 and -9 activities were observed after incubation with 10 nM of the CRTH2 antagonist compound CAY10471, but not 10 nM of the DP antagonist compound BW A868C. All results after treatment with PGD₂, DK-PGD₂ or CAY10471 were statistically different from untreated controls (p<0.05). Interestingly, treatment with 2 nM and 10 nM of PGD₂, DP agonist (BW 245C), CRTH2 agonist (DK-PGD₂), DP antagonist (BW A868C) or CRTH2 antagonist (CAY10471) did not change caspase-8 activity. The induction of PGD₂-CRTH2 dependent apoptosis is associated with the activation of caspase-9, but not caspase-8, leading to caspase-3 cleavage in human differentiated OCs. These data show PGD₂ induces OC apoptosis through activating CRTH2-dependent-intrinsic apoptotic pathway.

IL-23 Stimulates Human Osteoclast Formation and Bone Resorption In Vitro and IL-23 Neutralization Inhibits Bone Loss In Vivo. Iannis Adamopoulos^{*1}, Cheng-chi Chao², Eddie Bowman². ¹University of California, USA, ²Merck & Co., Inc., USA

We have recently shown that IL-23 is implicated in the pathogenesis of autoimmune arthritis, induces osteoclast differentiation in vivo in adult mice and IL-23p19 deficient mice have delayed osteoclast maturation. In this paper we translate our findings to an in vitro human system for direct relevance to human disease. We show that IL-23 induces the formation of multinucleated TRAP+ cells in human PBMC in vitro and dose dependently upregulates TRAF6 and NFATc1 message which are required for osteoclast differentiation. We also show that IL-23 induces the formation of F-actin rings and bone resorption in vitro. These effects correlate with a dose dependent upregulation of $\alpha\beta 3$ integrin and cortactin message which are required for osteoclast cytoskeletal organization. Moreover, we show that IL-23 neutralization in the collagen-induced arthritis model inhibits disease progression and arthritis-associated bone loss. Collectively our data suggest that IL-23 may be a promising target to combat pathological bone loss through osteoclast differentiation and activation in human autoimmune diseases.

Interleukin-10 Regulates Bone Metabolism by Suppressing Osteoclastogenesis In Vivo. Gunwoo Kim¹, Seungwoo Han^{*2}, Younkwan Jung³, Eunjo Lee³. ¹Department of internal medicine, Daegu Fatima hospital, South Korea, ²Daegu Fatima Hospital, South Korea, ³Laboratory for arthritis & bone biology, Fatima research institute, South Korea

Background: Recent studies showed IL-10 may down-regulate osteoclastogenesis through inhibition of the expression of NFATc1, c-Fos and c-Jun and inhibition of calcium signaling downstream of RANK by inhibiting transcription of TREM-2. However, there has been no study about the role of IL-10 in osteoclastogenesis in vivo and under inflammatory condition such as TNF- α induced osteoclastogenesis. **Objective:** To elucidate the role of IL-10 in osteoclast formation under physiological and pathological condition. **Methods:** 3-month old male IL-10 KO and WT littermates were used (n = 7 mice/group). We compared the bone phenotype by microcomputed tomographic analysis, histologic analysis and TRAP staining. And we conducted in vitro induction of osteoclast formation by bone marrow monocytes from IL-10 KO and WT mice. **Results:** We analyzed the IL-10-/- mice for abnormal bone phenotypes. Microcomputed tomographic analyses showed that these mice had severe osteoporosis accompanied by markedly lower trabecular bone volume, number, and thickness, as well as a smaller number of bone nodules compared to wild-type mice. Histomorphometric analysis also revealed reduced bone mass in the IL-10-/- mice. Notably, TRAP stain showed higher osteoclast numbers and larger osteoclast surface areas in these mice. Moreover, we observed a higher rate of bone formation accompanying the accelerated bone resorption rate in the IL-10-/- mice, suggesting that their osteoporosis was caused by enhanced bone turnover and remodeling. We then attempted to investigate the roles of IL-10 in the processes underlying pathological bone destruction. We examined the effect of TNF- α on osteoclastogenesis using IL-10-/- precursors, because TNF- α is a major mediator of inflammation induced by TLRs and has been suggested to be able to induce osteoclastogenesis. Consistent with previous reports, TNF- α induced the development of a small number of osteoclasts in cultures of wild-type precursor cells. Notably, osteoclastogenesis was enhanced in cultures of IL-10-/- precursor cells treated with TNF- α . The mRNA expression levels of Nfatc1 and Acp5 in the IL-10-/- osteoclast precursors were also augmented by TNF- α , indicating that IL-10 also has a suppressive role in TNF- α -induced osteoclastogenesis. **Conclusion:** Our results show that IL-10 inhibits osteoclast formation under physiological and pathological conditions and suggest a model where downregulation of IL-10 contributes to RANKL-mediated osteoclastogenesis.

Interplay Between Osteoclasts, Inflammatory Cells and Cytokines in the Pathogenesis of Periapical Bone Resorption. Lea da Silva¹, Sandra Fukada², Andiara De Rossi^{*3}, Marcos Rossi⁴. ¹Faculty of Dentistry of Ribeirao Preto, University of Sao Paulo, Brazil, ²Faculty of Pharmaceutical Sciences of Ribeirao Preto, University of Sao Paulo, Brazil, ³Faculty of Dentistry of Ribeirao Preto, University of Sao Paulo, Bra, ⁴Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Brazil

Endodontic infections occurs in consequence of polymicrobial infection of the dental pulp and root canal system, and ultimately results in destruction of periapical tissues including periodontal ligament, cementum and bone surrounding the tooth apex. However, the interplay between cells and cytokines involved in the destructive processes associated to inflammatory periapical bone loss has not been fully

elucidated. The aim of the present study was to evaluate the interplay between osteoclasts, inflammatory cells and osteoclastogenic factors in the progression of periapical lesions at different stages of development. Inflammatory periapical bone resorption was experimentally-induced in the lower first molars of male C57BL/6 wild-type mice, aging 6 to 8 weeks, by pulp exposure to the oral environment. Intact teeth were used as controls. At 0, 7, 21 and 42 days following pulp infection, the periapical region was evaluated under conventional microscopy (morphologic analysis), fluorescence microscopy (morphometric analysis), immunohistochemistry (neutrophils, macrophages and lymphocytes), immunofluorescence (RANK, RANKL and OPG), enzyme histochemistry (osteoclasts) and RT-PCR (RNA expression of IL-1 α , TNF- α , IL-10, IFN- γ , KC, IL-17, MIP-1 α , RANK, RANK-L, OPG and cathepsin K). Our results show a progressive increase in cementum and bone resorption, inflammatory cells and osteoclasts number, accompanied by enhanced mRNA levels of IL-1 α , IL-10, IFN- γ , KC, IL-17, MIP-1 α , RANK, RANKL, OPG and cathepsin K. This result suggests that these factors may be involved in the pathogenesis of periapical disease severity as modulator of cellular migration and osteoclasts differentiation and activity through RANK/RANKL/OPG signaling pathway. There was no significant enhancement in mRNA levels of TNF- α during all evaluated periods. Neutrophils were the most prevalent inflammatory cells at acute and chronic stages of the lesion development. **Conclusion:** our findings suggest that inflammatory periapical bone resorption are correlated with the osteoclasts and inflammatory cells number, and the severity of the lesions was directly correlated with the levels of IL-1 α , IFN- γ , IL-10, IL-17, KC, MIP-1 α , and cathepsin K, with RANK/RANKL/OPG pathway, but not with TNF- α .

STAT3 Is a Novel Target for Treating Bone Resorption in Rheumatoid Arthritis. Yoshiaki Toyama, Akihiko Yoshimura, Tomoaki Mori^{*}, Takeshi Miyamoto. Keio University School of Medicine, Japan

Joint destruction is frequently seen in chronic inflammatory diseases, such as rheumatoid arthritis (RA). Osteoclasts are implicated in such joint destruction by their bone resorbing activity. However, the mechanisms underlying how joint destruction in RA develop and are sustained chronically remain largely unknown. In this study, we show that STAT3 is the key mediator of joint destruction in RA by inducing Receptor activator of nuclear factor kappa-B ligand (RANKL). In RA patients, pro-inflammatory cytokines, such as IL-1 β , TNF α and IL-6 are up-regulated and implicated in disease activity. We found that IL-6 cytokine family, such as IL-6, LIF, IL-11 and OSM, and RANKL were significantly up-regulated in osteoblastic cells by the treatment with these inflammatory cytokines, and such up-regulation were significantly suppressed in STAT3-/- MEF cells compared with WT. IL-1 β , TNF α or IL-6 activated STAT3 either directly or indirectly and in turn induced expression of IL-6 family cytokines, further activating STAT3 in osteoblastic cells. STAT3 activation also induced expression of RANKL, and thus STAT3 is considered a therapeutic target to treat inflammation and joint destruction. We screened STAT3 inhibitor, and identified two possible inhibitors of STAT3. STAT3 pharmacological inhibition promoted significant reduction in expression of both IL-6 cytokine family and RANKL and inhibited osteoclastogenesis in coculture system with primary osteoblasts and bone marrow cells. STAT3 inhibition was also effective in treating an RA model, collagen induced arthritis (CIA), in vivo, and joint destruction was completely improved. In CIA model, by STAT3 inhibition, significant reduction in expression of pSTAT3, IL-6 cytokine family and RANKL in the joints was evident by immunoblotting analysis, ELISA, fluorescent immunohistochemistry and RT-PCR. Furthermore, the serum level of IL-6 was reduced by the administration of STAT3 inhibitor in CIA model. Thus our data provide new insight into RA pathogenesis and provide evidence that inflammatory cytokines trigger a cytokine amplification loop via STAT3 that promotes sustained inflammation and joint destruction.

Choline Kinase Beta is an Important Regulator of Bone Homeostasis. Jasreen Kular^{*}, Jennifer Tickner, Nathan Pavlos, Baysie Lim, Tamara Abel, Ming Hao Zheng, Jiaka Xu. University of Western Australia, Australia

The maintenance of bone homeostasis requires a tight balance between bone formation and bone resorption by osteoblasts and osteoclasts. The molecular mechanism(s) underlying the fundamental activities of these cells still remains largely unclear. In search of novel molecules that potentially play an important role in bone homeostasis we screened a number of ENU-induced mutant mouse lines. We identify choline kinase beta, a kinase that phosphorylates the first reaction in the biosynthesis of phosphatidylcholine, as a novel candidate regulator of bone homeostasis. Choline kinase beta mutant mice exhibit an osteoporotic phenotype as evidenced by microCT and histological assessment. *In vivo* and *in vitro* analysis reveals elevated osteoclast numbers in the mutant mice. Osteoclast precursors, derived from the bone marrow of choline kinase beta mutant mice, have an increased sensitivity to RANKL during osteoclastogenesis. Furthermore, osteoclasts from choline kinase beta mutant mice exhibit increased resorptive activity as compared to those of littermate controls. Treatment with CDP-choline *in vivo* and *in vitro* reduces osteoclast numbers, thereby

rescuing the osteoclast phenotype. *In vitro* assays show a reduction in bone mineralisation in osteoblast cultures derived from the bone marrow of mutant mice. Taken together, our data document, for the first time, that choline kinase beta plays an important role in bone homeostasis by regulating both osteoclasts and osteoblasts.

Disclosures: Jasreen Kular, None.

Double Stranded RNA Inhibits Osteoclast Differentiation via Interferon-beta/STAT1 Pathway and Increases Bone Mass in Osteoporosis Model Mice.

Arei Miyamoto^{*1}, Masamichi Takami², Yoichi Miyamoto³, Atsushi Yamada⁴, Mijung Yim⁵, Tomohiko Tamura⁶, Ryutaro Kamijo¹. ¹School of Dentistry, Showa University, Japan, ²Department of Biochemistry, School of Dentistry, Showa University, Japan, ³Showa University School of Dentistry, Japan, ⁴Showa University School of Dentistry, Jpn, ⁵College of Pharmacy, Sookmyung Women's University, South Korea, ⁶Department of Immunology, Graduate School of Medicine & Faculty of Medicine, Yokohama City University, Japan

Double stranded RNA, a ligand of Toll-like receptor (TLR) 3, is known to induce antiviral responses in the innate immune system. However, the effects of double stranded RNA on bone metabolism are unknown. We found that polyinosinic-polycytidylic acid [poly(I:C)], a double stranded RNA analog, markedly increased bone mass by inhibiting osteoclastogenesis. Six-week-old female mice were subjected to an ovariectomy (OVX) for an osteoporosis model or a sham operation for the control groups. After surgery, we intravenously administered poly(I:C) (250 µg) or PBS to the mice every 3 days for 4 weeks. Analysis of tibia using microcomputed tomography revealed that trabecular bone volume per tissue volume (BV/TV) in the sham/poly(I:C) group was significantly greater than that in the sham/PBS group (13.51.9% vs. 10.81.2%, $P < 0.05$). Similarly, BV/TV in the OVX/poly(I:C) group was significantly greater than that in the OVX/PBS group (13.51.4% vs. 8.30.6%, $P < 0.05$). Histomorphometric analysis of embedded femur sections revealed a significantly decreased number of osteoclasts in the OVX/poly(I:C) and sham/poly(I:C) groups as compared to the OVX/PBS and sham/PBS groups, respectively. To examine the effects of poly(I:C) on osteoclastogenesis, we cultured bone marrow-derived macrophages (BMMs) induced by M-CSF treatment for 3 days as osteoclast precursors in the presence of RANKL with or without poly(I:C). Osteoclastogenesis induced by RANKL was inhibited by poly(I:C) in a dose-dependent manner. We found that BMMs express TLR3 and produce interferon (IFN)-beta, an inhibitory factor of osteoclastogenesis, in response to poly(I:C). Next, we added antibodies for IFN-beta or its receptor to block IFN-beta stimulation of osteoclastogenesis. In the presence of these antibodies, osteoclastogenesis was successfully accomplished, even in the presence of poly(I:C). Subsequently, we prepared BMMs from mice deficient of STAT1, an intracellular signal transducer of IFN $\alpha\beta$ receptor, and cultured them with or without poly(I:C) in the presence of RANKL. Osteoclastogenesis of STAT1-deficient BMMs was not inhibited by poly(I:C). Furthermore, administration of poly(I:C) as well as PBS to STAT1-deficient mice did not increase bone mass in either the OVX or sham groups. These results suggest that poly(I:C) induces IFN-beta production in osteoclast precursors and inhibits osteoclastogenesis via the STAT1 signaling pathway, resulting in an increase of bone mass in both sham and OVX mice.

Human Osteoclastogenesis and Aging: Roles of PPAR γ and c-fos. Regina O'Sullivan^{*}, Ping-Lin Chung, Shuanhu Zhou, Meryl Leboff, Julie Glowacki. Brigham & Women's Hospital, USA

Age-related bone loss in humans results from more osteoclastic bone resorption relative to osteoblastic bone formation. It is known that c-fos is an essential mediator of osteoclastogenesis. Emerging evidence in mice suggests that PPAR γ regulates c-fos. We tested the hypothesis that PPAR γ and c-fos mediate the effect of age on human osteoclastogenesis.

Methods. We obtained discarded bone marrow from 19 patients (27 to 82 years) who underwent total hip replacement, with IRB approval. Mesenchymal and hematopoietic progenitors were enriched by density centrifugation with Ficoll/Histopaque 1077. Total RNA from low-density progenitor cells was extracted with Trizol reagent and PCR products were separated by agarose gel electrophoresis and were quantified by densitometry Image J software. Data were expressed by normalizing to GAPDH (internal control). Aliquots were cultured for 14 days (without added osteoclastogenic factors) in order to measure basal osteoclast differentiation by tartrate-resistant acid phosphatase (TRAP) expression. Low-density progenitor cells from old (PC^{OLD}) and young (PC^{YOUNG}) subjects were incubated overnight and treated with BADGE (PPAR γ antagonist), Rosiglitazone (Rosi, PPAR γ agonist) or vehicle (DMSO). Total RNA was extracted at intervals with Trizol reagent and were analyzed for endogenous PPAR γ and c-fos expression.

Results. There was an age-related increase in spontaneous osteoclastogenesis ($r = 0.60$, $p = 0.019$). Constitutive PPAR γ expression in fresh samples was 20.1-fold higher ($p = 0.0065$) from older subjects than younger subjects, with no difference in constitutive c-fos expression. In freshly-isolated PC^{YOUNG}, endogenous PPAR γ levels were undetectable; and BADGE reduced c-fos (64%, compared with vehicle) at 6

hours and Rosi upregulated c-fos (116%) at 12 hours. In PC^{OLD}, BADGE reduced endogenous PPAR γ (15%) and c-fos (43%) expression at 6 hours. In PC^{OLD}, Rosi had no effect on endogenous PPAR γ or c-fos levels.

Conclusions. There is an age-related increase in osteoclastogenic potential in human marrow progenitors. This study shows an age-related increase in constitutive expression of PPAR γ which may account for the age-related increase in human osteoclastogenesis. We show that PPAR γ -active agents modulated c-fos *in vitro*. The data suggest that PPAR γ may be an important factor in human skeletal aging, as has been reported in mice.

Hyperfunctions of Osteoclasts in a Rheumatoid Arthritis Model. Kazuma Matsumoto^{*1}, Naozumi Ishimaru¹, Takashi Izawa², Masahiro Hiasa¹, Yoshio Hayashi¹, Eiji Tanaka¹. ¹University of Tokushima Graduate School, Japan, ²Washington University in St. Louis, USA

[Objectives] Although osteoclasts (OCs) are known to play a key role in the pathogenesis of rheumatoid arthritis (RA), the precise mechanism how OCs are activated in the development of RA has been still obscured. In this study, we investigated functions such as bone absorptivity, migration, and antigen presentation of OCs from MRL/lpr mouse, an animal model for human RA, bearing a mutant of Fas gene. [Methods] Bone dynamics of knee joints and distal femurs in control MRL+/+ and MRL/lpr mice was scanned using a micro CT system. Moreover, bone marrow-derived OCs from control and MRL/lpr mice were generated by the culture with M-CSF and RANKL, and then their phenotypes, gene expressions, and functions were analyzed by TRAP staining, flow cytometry, pit formation assay, real-time RT-PCR, migration assay and confocal microscopy. Furthermore, to know the *in vivo* function of MRL/lpr OCs, the precursors were transferred in knee joints, and the phenotypes of peripheral immune cells and pathology of RA were analyzed. [Results] The bone finding of MRL/lpr mice showed significantly decreased bone density compared with that of controls, resembling osteoporosis. Pit formation assay revealed that function of OCs from MRL/lpr mice was more enhanced than that from control mice. The mRNA expressions of differentiation or activation-related genes of MRL/lpr OCs were up-regulated compared with those of control OCs. In addition, the migratory response of MRL/lpr OCs to sphingosin-1-phosphate (S1P) was significantly enhanced compared with that of control OCs. Furthermore, *in vitro* and *in vivo* experiments showed more enhanced function of MRL/lpr OCs as antigen-presenting cells to activate peripheral T cells. [Conclusions] The hyperfunctions of OCs in MRL/lpr mice play a potent role in the pathogenesis for RA with bone destruction. Fas signaling of OCs may regulate the differentiation, activation, or important function of OCs.

Involvement and Regulatory Role of Membrane Nanotubes in Fusion of Osteoclast Precursors: A Possible Migration and Penetration of DC-STAMP Protein into Osteoclast Precursors through Inter-Cellular Bridges. Akira Takahashi^{*1}, Akiko Kukita², Yin-ji Li³, Hisayuki Nomiya⁴, Yasunori Ayukawa⁵, Kiyoshi Koyano³, Toshio Kukita⁶. ¹Kyushu University, Japan, ²Saga Medical School, Japan, ³Kyushu University, Japan, ⁴Kumamoto University, Japan, ⁵Kyushu University, Japan, ⁶Kyushu University, Faculty of Dental Science, Japan

The membrane nanotubes are intercellular bridges bearing cylindrical structure with small diameters (50–300nm) with length of 10–100µm or more. Membrane nanotubes play important roles in cell-to-cell communication in immune cells. Recently, M-Sec gene has been revealed to be an essential gene for the formation of membrane nanotubes. The one purpose of this study is to clarify an involvement of membrane nanotubes in the process of fusion of osteoclast precursors to form multinucleated osteoclasts. The other purpose is to verify that DC-STAMP, a membrane protein required for fusion of pre-osteoclast, could migrate between osteoclast precursors through membrane nanotubes in osteoclastogenesis. We confirmed the presence of numerous tubular bridges with small diameter between cells observed *in vitro* culture system for osteoclast differentiation. These intercellular structures contain actin fiber detected with TRITC-labeled phalloidin. These intercellular bridges were disappeared and formation of osteoclasts was markedly inhibited when cells were treated with Latrunculin B, an inhibitor of actin polymerization. These results demonstrate an involvement of membrane nanotubes in osteoclastogenesis. Time course analysis using RT-PCR revealed that expression of M-Sec gene was up-regulated as osteoclasts differentiated. Formation of osteoclasts was significantly suppressed by siRNA specific to M-Sec. Meanwhile, we co-cultured DiD (red fluorochrome)-labeled RAW-D cells with DC-STAMP-GFP (green fluorescence)-transfected RAW-D cells followed by extensive observation of the fusion process under fluorescence microscope. We have obtained evidence suggesting transportation of DC-STAMP-GFP protein expressed in RAW-D cells into DiD-labeled RAW-D cells by use of membrane nanotubes. Current study suggests an importance of membrane nanotubes in the regulatory process of fusion among osteoclast precursors.

Mapping the Transcription Factor Regulatory Network Involved in Osteoclast Differentiation. Heather Carey*, Fei Gu, Lyudmyla Sharma, Anand Merchant, Raksha Adhikari, Victor Jin, Sudarshana Sharma, Michael Ostrowski. The Ohio State University, USA

Osteoclasts are bone resorbing cells which differentiate from myeloid precursors. The crosstalk between osteoblasts, bone-forming cells, and osteoclasts tightly regulates bone remodeling which is a dynamic and continuous process in vertebrates. Improper regulation of this delicate balance can lead to debilitating diseases such as cancer metastasis to the bone, osteoporosis, and osteoarthritis. The signaling cascades originating from two cytokines, CSF1 and RANKL are necessary and sufficient to induce osteoclast differentiation *in vitro*. However, the downstream effectors of these pathways leading to the transcription of genes necessary for osteoclast function are not fully defined. Using a candidate gene-based approach, our lab has previously shown that MITF and PU.1 bind to the promoters of *Acp5* and *Ctsk* to regulate transcription of these two genes required for osteoclast function. NFATc1 aids in the maintenance of transcription of these genes. In this study, we are delineating the role of these three factors on a genome-wide scale using chromatin immunoprecipitation and next generation sequencing (ChIP-Seq). ChIP-Seq analysis demonstrated that there are at least 9000 regions in the mouse genome enriched for PU.1 binding. Preliminary analysis of regions bound by PU.1, MITF and NFATc1 indicated PU.1 as a primary transcription factor that is present irrespective of the stage of differentiation. Nevertheless, PU.1 may interact with other cofactors depending on signaling cues. Thus, we utilized these PU.1 enriched regions to analyze the most probable binding partners of PU.1 using ChIPMotifs. This analysis indicated members of the IRF family of transcription factors as the most probable binding partners of PU.1. Overlapping our ChIP-Seq data with microarray data for transcription factors that are differentially regulated during osteoclast differentiation enabled us to draw a transcription factor regulatory network. Furthermore, twenty four genes encoding transcription factors regulated by PU.1 and differentially expressed during osteoclast differentiation were implicated in volumetric bone mineral density. Our results indicate that one or multiple IRFs may play a central role in regulating the transcription factors that are important for osteoclast differentiation. Identifying the transcription factors that control osteoclast differentiation will aid in the development of more specific therapies for diseases caused by deregulated osteoclast function.

Mechanisms for Radiation-Induced Bone Loss: Low Dose, Gamma Radiation Effects on Osteoclastogenesis and Osteoblastogenesis. Akhilesh Kumar*¹, Joshua Alwood¹, Luan Tran¹, Arundhati Balid¹, Charles Limoli², Ruth Globus¹. ¹NASA Ames Research Center, USA, ²University of California, USA

High total doses of ionizing radiation (here defined as $\geq 200\text{cGy}$) are known to cause bone loss both in humans and animals, although little is known about the cellular and molecular mechanisms involved. Furthermore, the potential influence of low dose radiation (radiation $\leq 10\text{cGy}$) on bone remodeling is not known. Here, we tested the hypothesis that low dose, low Linear Energy Transfer (LET) radiation can accelerate osteoclastogenesis and inhibit osteoblastogenesis of bone marrow-derived precursors. To induce osteoclast differentiation, non-adherent bone marrow cells isolated from C57BL/6J mice were treated with M-CSF (30 ng/ml) and RANKL (60 ng/ml), exposed to 10-200cGy of gamma radiation (Cs-137, 90 cGy/min) then cultured for 2-5 days. Osteoclastogenesis was assessed both by counting TRAP-positive, multinucleated cells and analyzing mRNA expression levels of osteoclast-related genes by RT-PCR. To assess osteoblast differentiation, adherent marrow cells grown with the addition of ascorbate (50 $\mu\text{g/ml}$) and beta-glycerolphosphosphate (10 mM), and were irradiated 2 days after plating. Osteoblastogenesis was assessed 15 days after irradiation by quantifying alizarin-red nodule formation and assessing expression levels of osteoblast-related genes. Both low dose (10cGy) and high dose (200cGy) radiation significantly increased the number of TRAP+ multinucleated osteoclasts (47% and 66%). Irradiation increased expression levels of differentiation (Nfatc1) and fusion-related genes (Atp6v0d2 and Tm7sf4), which were evident at an earlier time point (day 2) than sham-irradiated controls. In osteoblast cultures, high dose (200cGy) irradiation reduced mineralized nodule formation (61% decrease), compared to the sham-irradiated controls while lower doses (10cGy) had no effect. Similarly, the expression levels of differentiation-related genes (Runx2, Col1a1, Col1a2, Bglap, Ibsp) were lower than controls only in cultures irradiated with 200cGy. In sum, our results indicate that even low dose (10cGy) ionizing radiation stimulated osteoclastogenesis whereas osteoblastogenesis was not affected at this dose. Irradiation accelerated the expression of both differentiation and fusion-related genes by precursors to osteoclasts, providing a plausible explanation for the increased osteoclast number and bone loss observed acutely following irradiation *in vivo*. We conclude occupationally-relevant doses of ionizing radiation may influence bone health by stimulating osteoclastogenesis.

Mesenchymal Stem Cells markedly suppressed Inflammatory Bone Destruction in Rats with Adjuvant-induced Arthritis. Toshio Takano*¹, Yin-ji Li¹, Akiko Kukita², Takayoshi Yamaza¹, Yasunori Ayukawa¹, Kiyoshi Koyano¹, Toshio Kukita³. ¹Kyushu University, Japan, ²Saga Medical School, Japan, ³Kyushu University, Faculty of Dental Science, Japan

Mesenchymal stem cells (MSCs) are known to have potential to differentiate into multiple cell lineages and have widely been applied to regenerative medicine as the useful cellular sources of various tissues. Recently, it has been revealed that MSCs also have anti-inflammatory and immuno-modulatory functions. In this report, we investigated on the regulatory function of MSCs for the development of inflammation and bone destruction in rats with adjuvant-induced arthritis (AA-rats). MSCs were isolated from rat bone marrow tissues and proliferated in the presence of basic FGF. Adjuvant arthritis was induced in Lewis rats by intradermal injection of the complete Freund adjuvant (CFA) at the base of the tail. MSCs were intraperitoneally injected into AA-rats (2×10^7 cells/rat). The swelling score of the fore and hind paw, swelling volume of the hind paw and the body weight were measured from day 7 to day 28 after CFA-injection. On day 28, hind paws were examined radiographically and histologically. Although MSC-injected group did not show significant effects on the parameter of the swelling volume, MSC-administration significantly suppressed the swelling score and prevented body weight loss. Radiographical evaluation showed that MSC significantly suppressed bone destruction. The control group (CFA-injected rats without MSCs) showed remarkable bone destruction, thickened synovial membrane and marked infiltration of inflammatory cells with extremely high number of osteoclasts. In contrast, only very low level of bone destruction was observed in MSC-injected group with almost normal morphology of the joint cavity. Furthermore osteoclastogenesis was markedly suppressed in MSC-injected group in comparison to the control group. These data showed that MSC significantly suppressed inflammation and bone destruction in AA-rats. Current study demonstrates the potential utility of MSCs for the treatment of inflammatory bone destruction.

MicroRNA Targets of RANKL During Osteoclast Differentiation; miR-146a as a Lineage Determining Factor for Osteoclasts in Myeloid Precursors. Sudarshana Sharma*, Sankha Ghosh, Haritha Mathsvaraja, Jamie Wolf, Michael Ostrowski. Ohio State University, USA

The regulation of osteoclast (OCL) differentiation is a critical factor for normal bone remodeling and in bone related diseases such as osteoporosis, osteoarthritis and bone metastases. Two cytokines, CSF-1 and RANKL are sufficient to induce osteoclast differentiation *in vivo* and *in vitro*. While there are elegant studies about the signaling cascades and transcriptional regulators that are targets of these two cytokines and affect osteoclast differentiation, very little is known on the role of microRNAs (miRs), small noncoding RNAs which control expression of wide sets of genes. The objective of this study is to analyze the expression and regulation of differentially expressed miRs during osteoclast differentiation and their physiological significance.

We used a miR microarray to profile differentially expressed miRs. Validations were done using q-PCR assays. Transcriptional regulation of miRs was studied using ChIP seq and ChIP analysis. Knock down and overexpression of miRs were performed transiently in myeloid precursors using nucleofection procedure.

Global miR expression analysis recognized miR-146a as the only miRNA that is upregulated during osteoclast differentiation. However, ectopic expression of miR-146a in myeloid precursors resulted in decreased TRAF6 and IRAK1 protein levels, as well as attenuated osteoclast differentiation as represented by analysis of osteoclast specific markers. The regulation of miR-146a during osteoclast differentiation differed from the classical NF κ B dependent induction of miR-146a observed during inflammatory response in myeloid cells as demonstrated by ChIP. Further, knock down of IKK β which abrogated the LPS mediated miR-146a induction had no effect on RANKL mediated induction of miR-146a. The presence of conserved PU.1-Ebox binding sites prompted us to analyze association of MITF/PU.1 on this region by ChIP seq, as well as ChIP which confirmed association of MITF and PU.1 with this locus. This region exhibited the hallmark of an enhancer with high enrichment of monomethyl (K4) histone H3. The basal level of expression of miR-146a was maintained by EOS-CtBP corepressor complex which has been shown to be important in myeloid lineage determination. In conclusion our results indicate that miR-146a is regulated differentially to inflammatory signals from that of differentiation signals elicited by RANKL in myeloid cells and its expression in precursors inhibit osteoclast differentiation by TRAF6, IRAK1 downregulation.

Negative Regulation of Osteoclastogenesis by beta2 Integrin-Bcl6 Axis. Kyung-Hyun Park-Min^{*1}, Eun-Young Lee², Nick Brownell¹, Neal Moskowitz³, LIONEL IVASHKIV¹. ¹Hospital for Special Surgery, USA, ²Seoul National University, South Korea, ³Arthritis group, USA

Integrins are receptors that mediate attachment between cells and the surrounding tissues, which may consist of cells and extracellular matrix (ECM). Extracellular matrix (ECM) proteins regulate various cell functions including cell adhesion, differentiation, proliferation, migration, invasion and survival. We hypothesized that the type or timing of integrin signaling generated by cell-matrix interactions influences the differentiation of osteoclast precursor cells (OCPs). The most well studied integrin receptor in osteoclasts is integrin $\alpha V\beta 3$, which is induced during RANKL-induced osteoclastogenesis and plays an essential role in bone resorption in mature osteoclasts. However, OCPs express various other integrin receptors, whose role in osteoclast differentiation is not well understood. Thus, we investigated the effect of integrin ligation in OCPs on subsequent osteoclastogenesis. Among the integrin receptors, the expression of integrins $\beta 2$ and $\beta 5$, which are highly expressed in OCPs, are suppressed after RANKL stimulation, suggesting a possible negative role in regulating osteoclast differentiation. We found that fibrinogen, a potent endogenous ligand of $\beta 2$ and $\beta 5$ integrins, significantly inhibited osteoclastogenesis in both human and mouse OCPs. Concomitantly, RANKL-induced NFATc1 expression was decreased and the expression of osteoclast specific genes was down-regulated by fibrinogen ligation. Fibrinogen inhibited osteoclastogenesis via the interaction with $\alpha M\beta 2$ integrins. Deletion of integrin $\alpha M\beta 2$ (Mac1) in mouse OCPs resulted in the reversal of fibrinogen-mediated inhibition of osteoclastogenesis. Similar results were obtained in fibrinogen-induced human osteoclastogenesis using integrin $\alpha M\beta 2$ (Mac1) blocking peptides. The mechanism of inhibition partially involved the induction of a transcriptional suppressor, B cell lymphoma 6, by fibrinogen ligation. Thus, in contrast to $\alpha V\beta 3$ integrins, which promote the late phases of osteoclast differentiation, $\alpha M\beta 2$ integrins suppress early steps of osteoclastogenesis in OCPs. These findings identify cell-matrix interactions that are suppressive for osteoclastogenesis and a potential homeostatic mechanism that limits osteoclast differentiation after extravasation of monocytes in physiological and inflammatory settings.

Orai1-Mediated Calcium Entry Plays a Critical Role in Osteoclast Differentiation and Function by Regulating Activation of the Transcription Factor NFATc1. Sung-Yong Hwang^{*}, James Putney. National Institute of Environmental Health Sciences, USA

Bone diseases such as postmenopausal osteoporosis are primarily caused by excessive formation and activity of osteoclasts (OCL). Receptor activator of nuclear factor kappa B ligand (RANKL) is a key initiating cytokine for OCL differentiation and function. RANKL induces calcium (Ca^{2+}) oscillations, resulting in selective and robust induction of nuclear factor of activated T cells c1 (NFATc1), a Ca^{2+} -responsive transcription factor that drives osteoclastogenesis. Store-operated Ca^{2+} entry (SOCE) is a major Ca^{2+} influx pathway in most non-excitable cell types and is activated by any stimulus that depletes Ca^{2+} stores in the endoplasmic reticulum. Although the important role of Orai1, a store-operated Ca^{2+} entry channel in the plasma membrane, in maintaining Ca^{2+} oscillations and transactivation of NFAT in other cell types is well-known, its contribution to osteoclastogenesis remains unclear. We show here that silencing of the Orai1 gene with viral delivery of shRNA reduces SOCE and inhibits RANKL-induced osteoclastogenesis of RAW264.7 cells, a murine monocyte/macrophage cell line, by suppressing the induction of NFATc1. This was accompanied by defective induction of OCL-specific genes such as tartrate-resistant acid phosphatase and immunoreceptor OCL-associated receptor, which are known to be direct transcriptional targets of NFATc1 during osteoclastogenesis. In addition, maturation of OCLs was abrogated by defective cell fusion of pre-OCLs depleted of Orai1, consistent with defective RANKL-mediated induction of d2 isoform of vacuolar ATPase V_o domain that is involved in cell fusion of pre-OCLs. We found that the functional bone resorbing capacity was severely impaired in OCLs depleted of Orai1, potentially related to the observed decrease in the induction of cathepsin K, a major bone matrix degrading protease. We further investigated the role of Orai1 in OCL differentiation by using primary monocytes/macrophages isolated from bone marrow of Orai1-deficient (Orai1^{-/-}) mice. We found that monocytes/macrophages from Orai1^{-/-} mice lack SOCE. Consistent with the findings with the macrophage cell line, RANKL-induced osteoclastogenesis in vitro from Orai1^{-/-} mice was markedly impaired due to reduced fusion of pre-OCLs. Our results indicate that Orai1 plays a critical role in the differentiation and function of OCLs, suggesting that Orai1 might be a potential therapeutic target for the treatment or prevention of bone loss caused by OCLs.

Osteoclastogenesis is Highly Dependent on Exogenous Cholesterol, and Deficiency of Low Density Lipoprotein Receptor in Mice Causes Impaired Osteoclastic Cell Fusion and Increase in Bone Mass. Mari Okayasu^{*}, Chivomi Hayashida, Mai Nakayachi, Takuya Sato, Junta Ito, Naoto Suda, Yoshiyuki Hakeda. Meikai University School of Dentistry, Japan

Accumulating evidence indicates that dyslipidemia is closely associated with osteoporosis. However, the molecular mechanism of this association remains unclear. To clarify the relationship between lipid and bone metabolisms, we examined how cholesterol affected differentiation of osteoclasts by evaluating osteoclastogenesis in osteoclast progenitors isolated from low density lipoprotein receptor-knockout (LDLR-KO) mice. In vitro osteoclast formation in the culture medium with LDL-depleted FBS was suppressed compared to that in the medium with normal FBS. The down-regulation of osteoclastogenesis was restored by the addition of native LDL or oxidized LDL (ox-LDL) in a dose dependent manner. The restoration was seen in an additive manner. Supporting this finding, LDLR and scavenger receptor class A, which are receptors for native LDL and ox-LDL, respectively, were constitutively expressed and the expression levels did not change during the process of osteoclast formation regardless of RANKL stimulus. Osteoclastogenesis from LDLR-KO mice was significantly delayed than those of wild type (WT) littermate, and small-sized osteoclasts were noted in the culture of the former. The activation of Erk and Akt by RANKL, gene and protein expression of c-fos, NFATc1, TRAP and cathepsin K did not differ between cultures of both genotypes. Moreover, fusion index, represented as average number of nuclei per one multinucleated osteoclast, in culture from LDLR-KO mice, was about 20% of that in culture of WT mice, indicating the decreased osteoclast formation of gene-deficient mice is due to the impairment of cell fusion of mononuclear preosteoclasts to mature multinucleated osteoclasts. The expression of Atp6v0d2 and DC-STAMP mRNA, which are essential for cell-cell fusion of osteoclasts, did not differ between osteoclastic cells from genotypes, however, Atp6v0d2 in plasma membrane and lipid raft (cholesterol-rich micro domain in plasma membrane) of LDLR-KO osteoclasts was decreased compared to that of WT osteoclasts. Additionally, bone morphometric analysis showed that BV/TV and Tb.N were significantly increased. Taken together, osteoclast differentiation is highly dependent on exogenous cholesterol and the decrease in intracellular cholesterol level due to LDLR deficiency results in the reduction of cell-cell-fusion of preosteoclasts possibly via the impaired trafficking of osteoclast fusion protein such as Atp6v0d2 to the plasma membrane.

Osteoclastogenic Potential of Mandible vs Long Bone Marrow. Thawinee Chaichanasakul^{*1}, Olga Bezouglia², Tara Aghaloo¹, Sotirios Tetradis³. ¹University of California, Los Angeles, USA, ²UCLA School of Dentistry, USA, ³UCLA, USA

Maxilla and mandible possess unique metabolic and functional properties and demonstrate discrete responses to homeostatic, mechanical and developmental stimuli. Specific bone pathologies such as cherubism and osteonecrosis of the jaws (ONJ) only affect the maxilla and mandible. Importantly, systemic diseases such as osteoporosis and malnutrition affect the jaws differently compared to other bones. Osteogenic potential of marrow stromal cells (MSCs) differs between mandible (MB) vs. long bones (LB). Furthermore, MB vs. LB derived osteoclasts (OCs) have different functional properties. Here, we hypothesized that MB vs. LB marrows have disparate osteoclastogenic potential at basal and stimulated conditions. To test our hypothesis, non-adherent marrow cells were isolated and differentiated in the presence of RANKL and M-CSF. TRAP staining showed increased number of TRAP+ multinucleated cells (MNCs) in MB vs. LB cultures. Additionally, osteologic disc resorption pit assays revealed a significantly higher resorbed area for MB vs. LB OCs. We then explored the ability of MB vs. LB MSCs to support osteoclastogenesis at basal and stimulated conditions. Confluent MSCs were cultured in osteogenic differentiation media in the presence of vehicle (veh), parathyroid hormone (PTH, 10 nM), 1 α ,25-dihydroxyvitamin D3 (D3, 10 nM), or dexamethasone (Dex, 100 nM), alone or in combination, for 1 or 2 weeks, and then RANKL and OPG mRNA levels were determined. No statistical difference on RANKL and OPG expression was observed at baseline. However, LB MSCs expressed significantly higher RANKL and lower OPG mRNA with a resultant increase in RANKL/OPG ratio in the presence of D3 alone, PTH+D3, and D3+Dex. Thus, LB MSCs appear to possess a significantly higher osteoclastogenic potential in stimulated conditions compared to MB MSCs. Finally, we isolated and cultured whole MB and LB marrow, containing both non-adherent and adherent cells, in the presence or absence of PTH and D3 and performed TRAP staining. No TRAP+ cells were observed at basal conditions. However, TRAP+ MNCs were significantly increased in LB vs. MB marrow. Collectively, our data demonstrate that although MB marrow contains increased number of OC precursors, under PTH, D3 and Dex stimulation LB marrow has higher osteoclastogenic potential. This appears to be, at least in part, due to the higher RANKL stimulation and OPG inhibition of long bone vs mandibular MSCs by these hormones.

Pam3CSK4, a TLR2 Agonist, Induces In Vitro Osteoclastogenesis RANKL-independently and Resorbs Alveolar Bone in Rats. Akiko Yano^{*1}, Keiko Suzuki², Tomio Morohashi², Takafumi Arimoto², Akiko Karakawa¹, Takeshi Igarashi², Hisashi Shinoda³, Matsuo Yamamoto¹, Shoji Yamada². ¹Showa University School of Dentistry, Japan, ²Showa University, Japan, ³Tohoku University Graduate School of Dentistry, Japan

Bacteria are a common cause of periodontitis, in which accelerated alveolar bone resorption may ultimately lead to tooth loss. It is well established that bacteria interact with host cells through components of their cell wall by binding to corresponding *Toll*-like receptors (TLRs). Among these, LPS, a component of gram-negative bacteria and a ligand for TLR4, is the most clearly defined molecule as a potent inducer of osteoclastogenesis and bone resorption. On the other hand, the fact that TLR2, in addition to TLR4, was prominently expressed in both precursors and differentiated osteoclasts, raised the possibility that components of gram-positive bacteria are involved in periodontitis-associated osteolysis. However, studies on the effects of TLR2 agonists, including diacylated lipopeptide and peptidoglycan, on osteoclastogenesis have been performed in coculture with osteoblasts, which secrete RANKL, or preosteoclasts (pOCs) in the presence of exogenously added RANKL. Therefore, the involvement of TLR2 ligation on osteoclastogenesis remains unclear.

To clarify the functional role of TLR2 agonist in osteoclastogenesis, we stimulated RAW 264.7 cells and pOCs, prepared from bone marrow cells by removing macrophages and stromal cells, with synthetic tri-acylated lipopeptide, Pam3CSK4. Furthermore, we studied whether Pam3CSK4 and *Streptococcus mutans* (*S. mutans*) 109c, a gram-positive oral bacterium, caused bone resorption in vivo. The results showed that: i) Pam3CSK4 induced osteoclastogenesis both in RAW264.7 cell and mouse pOC cultures, without adding RANKL exogenously; whereas, LPS (Re mutant), a specific ligand for TLR4, did not, ii) Pam3CSK4-induced osteoclastogenesis was mediated by p38, JNK, PI3K and NFkB pathways, iii) Quantitative RT-PCR analysis showed that Pam3CSK4 up-regulated TRACP and cathepsin K, but not RANK or RANKL, iv) Both Pam3CSK4 and *S. mutans* 109c injected into palate bone were able to cause alveolar bone resorption in rats.

Taken together, these results provide important findings as follows: i) Pam3CSK4 induces osteoclastogenesis in a RANKL-independent manner, ii) Pam3CSK4 also causes alveolar bone resorption in vivo, indicating that components of gram-positive bacteria, as well as those of gram-negative bacteria including LPS, may be a periodontal pathogen which causes alveolar osteolysis.

Role of the Fatty Acid Receptor GPR40 in Bone Remodeling. Fabien Wauquier^{*1}, claire philippe², laurent leotoing², sylvie mercier², Jerome Guicheux³, Veronique Coxam⁴, Yohann Wittrant⁵. ¹INRA, UMR 1019, UNH, CRNH Auvergne, F-63009 Clermont-Ferrand, France, France, ²INRA, France, ³Inserm ADR Grand Ouest, France, ⁴INRA Theix, France, ⁵Institut National de la Recherche Agronomique, France

In a context of increasing life expectancy, the prevalence of age-related diseases such as osteoporosis is becoming a major social and economical issue. While nutritional strategies appears to be an excellent alternative to conventional treatments, the study of nutrients' biological activities remains marginal for some tissues and certain types of molecules. This is particularly the case for bone and lipids, most notably fatty acids. Current literature, although growing in size, contains mainly descriptive studies that do not fully explain the mechanisms involved. Recently, the membrane receptor GPR40 (G Protein Coupled Receptor 40) has been highlighted for its interaction with long chain free fatty acids. Because, we demonstrated its expression in bone cells at the mRNA and protein level, we hypothesized that this receptor may play a role in mediating the effects of fatty acids on bone remodeling parameters.

In this study, the analysis by μ Computed Tomography of the femurs of mice invalidated for GPR40 reveals a marked osteoporotic phenotype that supports a protective role of this receptor for bone health.

In vitro, the effects of a specific agonist of GPR40, the GW9508 were analyzed. At high doses, this compound inhibits the proliferation of osteoclast precursors (Raw 264.7), whereas it has no effect on the viability of MC3T3-E1 osteoblast lineage. In addition, at lower doses, this compound blocks the osteoclastic differentiation of Raw 264.7 induced by RANKL, by inhibiting the activation of ERK and NF-kB pathways. GW9508 also stimulates the early stages of differentiation of osteoblastic MC3T3-E1, induce a rise in activity ALP (Alkaline phosphatase) and an increased expression of osteocalcin transcript. Moreover, the study of a line RAW264.7 invalidated by RNA interference (shRNA) together with analysis of the effect of GW9508 on induced-bone loss by ovariectomy in wild-type mice supports the working hypothesis.

In conclusion, these studies reveal for the first time a protective role of GPR40 in the bone tissues leading to a new insight in the bone and lipid relationships.

TNF α Induced HLA-B27 Upregulation in Osteoclast Precursors Affects Osteoclast Development in a Rat Model of Spondyloarthritis. Gerlinde Layh-Schmitt^{*1}, Eva Yang², Robert Colbert². ¹National Institutes of Health, USA, ²National Institutes of Health, NIAMS, USA

Purpose: Spondyloarthritis (SpA) are immune-mediated inflammatory diseases, mediated in part by TNF α , that involve both systemic bone loss and aberrant bone formation in the spine, which can lead to fusion of vertebrae. The HLA-B locus encodes a major susceptibility allele (B27). Upregulation of B27 exacerbates its tendency to misfold, and can lead to unfolded protein response (UPR) activation in macrophages. The UPR promotes the production of certain cytokines suggesting an 'upstream' pro-inflammatory role for B27. The goal of this project was to examine whether B27 also exerts 'downstream' effects in cells involved in bone homeostasis. Using B27 transgenic (B27-Tg) rats that develop SpA-like disease, we examined whether B27 expression affects osteoclast precursors and their development into osteoclasts.

Methods: Monocytes were derived from bone marrow (BMMo) of wild type (WT) and B27-Tg rats prior to onset of inflammatory disease. Monocytes were treated for five days with MCSF and RANKL (10, 30, 100 ng/ml) or TNF α (7.5, 15, 30 ng/ml). Osteoclasts were quantified by counting (>3 nuclei) TRAP positive cells. Resorption activity was measured by pit formation on corning osteo assay surface plates. Expression levels of B27 and UPR-specific genes like BiP, CHOP, XBP1 and XBP1-s were examined by RT-PCR, Western blot (B27 and BiP), and Immunofluorescence (B27 and BiP).

Results: We identified markedly (2-3 fold) enhanced TNF α -induced osteoclastogenesis of HLA-B27 BMMo compared to WT monocytes (p<0.05). RANKL had no differential effect on osteoclast numbers, but size was increased. B27-Tg rat derived osteoclasts were larger than wild type osteoclasts (>10 nuclei in 50% of B27-Tg cells vs. 10% of WT; p<0.05. Protein and mRNA expression levels of HLA-B27 (2- and 20-fold respectively) and BiP (1.5 and 3-fold, respectively) were increased after TNF α treatment and misfolded forms of HLA-B27 accumulated. In addition, TNF α induced XBP-1 splicing only in B27 expressing monocytes, suggesting acute UPR activation. We are presently investigating whether UPR induced cytokines such as IL-1 α or IFN β play a role in TNF α -induced osteoclastogenesis.

Conclusion: In summary, our preliminary analyses indicate that TNF α can induce a UPR activation in B27-expressing BMMo which may affect OC development and activity.

(-)-Epigallocatechin-3-gallate (EGCG), an AMPK Activator, Inhibits Ovariectomy-Induced Bone Loss by Suppressing Bone Resorption. Sook-Young Park¹, Shin-Yoon Kim², Hong-Hee Kim³, Sun Wook Cho⁴, Hyung Jin Choi⁴, Seung Hun Lee^{*5}, Ghi Su Kim⁶, Young-Sun Lee¹, Chan Soo Shin⁴, Beom-Jun Kim⁷, Sun-Young Lee¹, Jung-Min Koh⁷. ¹Asan Institute for Life Sciences, South Korea, ²Kyungpook National University Hospital, South Korea, ³Seoul National University, South Korea, ⁴Department of Internal Medicine, Seoul National University College of Medicine, South Korea, ⁵Asan Medical Center, University of Ulsan College of Medicine, South Korea, ⁶Division of Endocrinology & Metabolism, Asan Medical Center, University of Ulsan College of Medicine, South Korea, ⁷Asan Medical Center, South Korea

Purpose: Previously, we showed that AMP-activated protein kinase (AMPK) negatively regulates receptor activator of nuclear factor- κ B ligand-induced osteoclast formation in vitro. The present study aimed to investigate the effects of various AMPK activators on ovariectomy (OVX)-induced bone loss in mice.

Methods: Female mice subjected to OVX were administered various doses of AMPK activators, including (-)-epigallocatechin-3-gallate (EGCG), resveratrol (RES) and berberine, for 8 weeks. We performed micro-computed tomography (micro-CT) analysis of the tibia and bone histomorphometric examination of the femur. Western blot analysis was additionally performed to detect the levels of phosphorylated and total forms of AMPK- α in calvaria extracts.

Results: EGCG prevented OVX-induced body weight gain. Micro-CT experiments revealed that EGCG induced a significant increase in trabecular bone volume and trabecular number, and a decrease in trabecular spacing, compared to the OVX control. Histomorphometric analyses further showed that EGCG suppressed osteoclast surface, osteoclast number, and bone resorption rate. Phosphorylated AMPK expression was significantly elevated in bone, following EGCG treatment. RES and berberine did not have a significant effect on OVX-induced bone loss.

Conclusions: Our findings collectively indicate that EGCG, an AMPK activator, inhibits OVX-induced bone loss via suppression of bone resorption.

Disclosures: Seung Hun Lee, None.

Anti-apoptotic Bcl-2 Family Member Mcl-1 Positively Regulates Cell Viability and Negatively Regulates Bone-resorbing Activity of Osteoclasts. Hironari Masuda^{*1}, Jun Hirose¹, Yasunori Omata¹, Hisataka Yasuda², Kozo Nakamura¹, Sakae Tanaka¹. ¹The University of Tokyo, Japan, ²Oriental Yeast Company, Limited, Japan

Mcl-1 is a member of Bcl-2 families that are known as regulators of apoptosis through mitochondrial pathway. Previous studies have suggested that an anti-apoptotic member Mcl-1 prolongs the cell viability of various cell types. However, only limited studies referred to the function of Mcl-1 in osteoclasts and it remains to be delineated. Our aim of this study was to elucidate the dynamics and the function of Mcl-1 in osteoclasts using techniques as overexpression, knockdown and knockout of Mcl-1 protein.

Mcl-1 protein levels in osteoclasts were increased in response to the addition of inflammatory cytokines such as TNF- α , IL-1 α and LPS. Mcl-1 exhibited a short half-life in osteoclasts, which was significantly prolonged by a proteasomal inhibitor MG132. We also found that Mcl-1 was markedly ubiquitinated, indicating the involvement of ubiquitin-proteasome pathways in the degradation process of Mcl-1 in osteoclasts.

When Mcl-1 expression was down-regulated by siRNA retrovirus introduction, osteoclasts had significantly shorter cell life than that of control osteoclasts, in spite of no significantly change in the cell differentiation or cytoskeletal organization. Conversely, Mcl-1 overexpression significantly prolonged cell life without showing significantly change in the cell differentiation.

We then examined the effect of Mcl-1 on the bone-resorbing activity of osteoclasts using pit-formation assay. Mcl-1 overexpressed osteoclasts by the adenovirus vector exhibited reduced bone resorbing area than control osteoclasts despite of their prolonged cell life. Mcl-1 knockout osteoclasts were generated by transducing Cre-recombinant adenovirus to osteoclasts from Mcl-1^{fllox/fllox} mice. Bone resorbing area of the Mcl-1 knockout osteoclasts was significantly increased despite of their short life time.

These results demonstrated that anti-apoptotic Bcl-2 family member Mcl-1 positively regulates cell viability and negatively regulates bone-resorbing activity of osteoclasts. Further studies are required to elucidate the role of Mcl-1 in physiological and pathological bone resorption by generating osteoclast-specific Mcl-1 knockout mice.

Estrogen does not Promote Apoptosis of Avian Osteoclasts in Medullary Bone of Estrogen-Treated Male Japanese Quails. Shinji Hiyama^{*1}, Misa Takahashi², Aya Oda², Takashi Uchida³. ¹Hiroshima University Graduate School of Biomedical Sciences, Japan, ²Hiroshima University, Faculty of Dentistry, Japan, ³Hiroshima University, Graduate School of Biomedical Sciences, Japan

Medullary bone (MB) is a unique tissue of female birds, which is remodeled in the bone marrow cavity of long bones during the reproductive period. This bone remodeling is under the influence of circulating estrogen. Namely, when the concentration of estrogen declines, this bone is vigorously resorbed by osteoclasts. On the other hand, when the concentration of estrogen increases, osteoclasts are resting on the bone surface and osteoblasts form actively this bone. Although osteoclasts undergo apoptosis by estrogen in mammal, avian osteoclasts may not induce apoptosis, because the rapid remodeling of MB is necessary to reserve and provide for calcium of egg-shell. Therefore, in this study, we initially examined the effects of estrogen on the differentiation and apoptosis of avian osteoclasts derived from bone marrow cells (BMC) during MB formation in estrogen (E2)-treated male Japanese quails. After E2 administration in 0, 1, 2 & 3 days, BMC from femurs were cultured in the presence of RANKL/M-CSF and 17 β -estradiol (17-b). These cultures in each day were formed TRAP-positive multinucleated cells regardless the presence or the absence of 17-b. The expression level of Fas mRNA was down-regulated in osteoclasts derived from BMC of 3 days after E2 administration. Further, the expressions of Blimp1 and Bcl6 were decreased in same cultures. Bone resorption assay resulted that 17-b inhibited bone resorption in a concentration-dependent manner. To address the question of the effects of E2 to osteoclasts in vivo, the quails at day 5 after E2 administration when osteoclasts are appeared on the surface of MB were carried out E2 readministration. At day 0, 1, 2, & 3 after E2 readministration, BMC, but not osteoclasts on MB, showed positive reaction of apoptotic cells by histochemical analysis. These results suggest that estrogen has no effect on apoptosis and differentiation of osteoclasts, but rather suppress bone resorption in medullary bone.

High Knockdown of TCIRG1 Protein Expression Is Required for Resorption Deficiency in CD34+ Derived Human Osteoclasts. Christian Thudium^{*1}, Ilana Moscatelli², Johan Richter², Kim Henriksen³. ¹Nordic Bioscience, Denmark, ²Lund University, Sweden, ³Nordic Bioscience A/S, Denmark

Gene/protein function studies in human osteoclasts have been hampered as these terminally differentiated cells are hard to manipulate genetically. The aim of this study was to derive functional osteoclasts from CD34+ human cord blood cells and investigate whether lentiviral vectors can be used to overexpress and/or knock down genes in these cells, and what degree is needed to affect osteoclast function.

Human cord blood CD34+ cells were cultured for 2 weeks in the presence of a cytokine cocktail. The cells expanded approximately 500-fold, and FACS analysis revealed gradual loss of CD34 expression while 50% of cells became CD14+. Non-adherent cells were then incubated with M-CSF and RANKL on bone for 10 days, where they developed into fully functional osteoclasts expressing TRAP, releasing calcium, forming actin rings and generating resorption pits on boneslices.

Cord blood CD34+ cells were transduced using lentiviral vectors with shRNAs targeting TCIRG1. Cells were either selected using a puromycin resistance gene or sorted for GFP expression, and were then differentiated to mature osteoclasts. qPCR analysis revealed decreased levels of TCIRG1 mRNA and western blot revealed decreased protein levels in the transduced cells compared to controls, although levels varied through experiments. When high knock-down levels were observed the osteoclasts had a 40% increase in TRAP expression whereas calcium release, pit formation on bone slices and CTX-1 levels in the medium were all lower, in line with the known phenotype of infantile malignant osteopetrosis (IMO). However, in cells where the knockdown was less significant, a small increase in TRAP was observed, but no relevant effect was seen on calcium or CTX-I release.

In conclusion osteoclast differentiation from lentivirally transduced CD34+ cells poses a way to generate and manipulate osteoclasts in vitro, providing a novel tool to study osteoclast development and function. Furthermore, the knockdown of TCIRG1 in CD34+ cord blood cells provides a human *in vitro* model of IMO. However, a high degree of knockdown is vital to an effect on function, which possibly can be attributed to the haploinsufficient nature of TCIRG1, as neither humans nor mice that are heterozygous for TCIRG1 mutations have any phenotype.

Disclosures: Christian Thudium, None.

Histone Deacetylase (HDAC) Expression and HDAC Inhibition in Different Pathogenic Bone Loss Diseases. Melissa Cantley^{*1}, David Fairlie², Peter Mark Bartold¹, Victor Marino², David Haynes¹. ¹University of Adelaide, Australia, ²University of Queensland, Australia

Inhibition of histone deacetylases (HDAC) is being investigated as a treatment for cancers and chronic inflammation. Class I HDACs are found in the nucleus and include 1,2,3 and 8 while class II are also found in the cytoplasm and include HDAC 4,5,6,7,9 and 10. We have recently reported that a novel HDACi compound targeting both HDAC classes, 1179.4b, suppressed human osteoclast resorption in vitro via down regulation of TRAF-6 during the late stages of development. This current study investigated the effect of 1179.4b on bone loss in animal models of human pathologies, periodontitis and peri-implant osteolysis. Expression of specific HDAC enzymes near sites of bone loss in periodontitis and peri-prosthetic osteolysis were also assessed in human tissues. In the peri-implant model, polyethylene particles were implanted onto the calvaria for 14 days to induce bone loss and 1179.4b was administered orally from day 7 (n=3 per group). For the mouse model of periodontitis, disease was induced via oral inoculations with *P.gingivalis* bacteria over 13 weeks. Once disease was established (week 7) mice were treated with 1179.4b daily for 6 weeks (n=4 per group). Live animal micro CT scanning was used to measure bone loss during the experiment. Expression of HDACs 1-10 mRNA was assessed by real time PCR. Human tissue samples from peri-implant tissues obtained during revision surgery (n=10) and osteoarthritic synovial tissues (n=5) from patients undergoing a primary implant at the Royal Adelaide Hospital were compared. Gingival tissue samples were obtained from patients with chronic periodontitis (n=9) and compared with normal gingival tissues (n=8).

1179.4b significantly (p<0.05) suppressed bone loss in the model of periodontitis despite not affecting inflammation. Interestingly, bone loss was not suppressed in the calvarial model by 1179.4b (p>0.05). Class I HDAC 1 was expressed at significantly higher levels in peri-implant tissues compared to OA tissues (p<0.05). In human periodontitis tissues HDACs from both classes I (1 and 8) and II (5 and 9) were highly expressed relative to normal tissue.

Differences in anti-resorptive activity of 1179.4b in the two pathologies may be due to different HDACs stimulating bone loss in each disease. This may also show differences in the importance of TRAF 6 signaling in the two diseases. This demonstrates developing HDAC therapies requires understanding the roles of individual HDACs in the pathology of specific diseases.

Snx10: a Sortin Nexin Required for Osteoclast Differentiation and Function. Cui Hua Zhu^{*1}, Leslie Morse², Ricardo Battaglini¹. ¹The Forsyth Institute, USA, ²Department of Physical Medicine & Rehabilitation, Harvard Medical School & Spaulding Rehabilitation Hospital, USA

Osteoclasts are exceptionally dependent on vesicular trafficking in order to form the ruffled border, a process essential for bone resorption. Consequently, disruption (genetic or pharmacological) of osteoclastic vesicle transport abolishes cellular resorptive activity. We performed a genome-wide screening to identify genes that are up regulated during RANKL-stimulation of osteoclast precursor cells and may be involved in the process of differentiation and or activation. In this report we describe the expression and functional characterization of Sorting Nexin 10 (*snx10*). Snx10 belongs to the sorting nexin (SNX) family, a diverse group of proteins with a common feature: the PX domain. PX-containing yeast proteins are involved in vacuole sorting, suggesting that SNXs can regulate membrane trafficking and cargo sorting in endosomes. SNX10 can also induce formation of giant vacuoles in transfected cells and may be involved in the regulation of endosome homeostasis. *snx10* is strongly up regulated during RANKL-induced osteoclast differentiation in vitro and in vivo. qPCR analysis confirmed a significant increase in the expression of *snx10* in *in vitro*-derived osteoclasts, femur and calvaria. To visualize *in situ* expression, we performed immunohistochemical analysis of mouse embryo sections and detected expression in bone, calvariae and developing teeth, in cells that also expressed TRAP, demonstrating osteoclastic localization. Confocal immunofluorescence analysis revealed Snx10 localization in the cytoplasm with a pattern that partially overlaps with that of the endoplasmic reticulum (ER) marker protein disulfide isomerase (PDI). To study a possible role for *snx10* in osteoclast differentiation and function we silenced *snx10* expression and found that *snx10* silencing inhibits RANKL-induced osteoclast formation, osteoclast resorption on hydroxyapatite and also 50% inhibition in TRAP secretion. Taken together, these results confirm that *snx10* is expressed in osteoclasts and is required for osteoclast differentiation and activity *in vitro*. Since inhibition of vesicular trafficking is essential for osteoclast formation and activity and SNX10 is involved in intracellular vesicular trafficking, these studies may identify a new candidate gene involved in the development of human bone diseases including osteoporosis and bone loss associated estrogen deficiency.

Syk Family Member ZAP70 Inhibits Syk-Mediated Osteoclast Function. Wei Zou^{*}, Tingting Zhu, Steven Teitelbaum. Washington University in St. Louis School of Medicine, USA

The $\alpha\text{v}\beta 3$ integrin stimulates the resorptive capacity of the differentiated osteoclast (OC) by organizing its cytoskeleton via the tyrosine kinase Syk. Thus, Syk-deficient OCs fail to spread or form actin rings, in vitro and in vivo. These cytoskeletal defects of Syk^{-/-} OCs arrest their bone resorptive capacity resulting in enhanced bone mass.

The Syk family of tyrosine kinases consist of Syk itself and ZAP70 which are expressed by different cell types. Syk appears in all myeloid cells and ZAP70 is primarily found in T-lymphocytes and NK cells. Because of their structural similarity we asked if ZAP70 can compensate for absence of Syk in OCs. To this end, we retrovirally transduced Syk^{-/-} macrophages (MΦ) with WT Syk or ZAP70 and cultured them into OCs. As expected, expression of Syk normalizes the cytoskeletal abnormalities of Syk^{-/-} OCs. ZAP70, however, fails to do so. In keeping with this observation, Syk, but not ZAP70, rescues $\alpha\text{v}\beta 3$ integrin-induced SLP76 phosphorylation in Syk^{-/-} OCs. These results suggest that Syk but not ZAP70 is capable of regulating OC function.

Both Syk and ZAP70 contain tandem SH2 domain and kinase domain. To determine the role of these motifs in OC function, we transduced Syk^{-/-} MΦ with 2 chimeras namely 1) Syk(SH2)-ZAP70(Kinase) and 2) ZAP70(SH2)-Syk(Kinase). While Syk(SH2)-ZAP70(Kinase) is ineffective in Syk^{-/-} OCs, ZAP70(SH2)-Syk(Kinase) substantially rescues their resorptive activity, establishing that Syk's kinase, but not adaptor function is required for OC activity. Consistent with these results, kinase-inactive but not SH2 domain mutant Syk, inhibits WT OC spreading and resorption.

While ZAP-70 fails to compensate for absence of Syk in OCs their structural similarity suggests ZAP-70 may inhibit Syk activity in WT cells. The relevance of this conjecture is underscored by the fact that Syk inhibitors are presently in clinical trial for treatment of inflammatory osteolysis. To address this issue, we retrovirally transduced ZAP70 into WT MΦ. Similar to kinase-inactive Syk, expression of ZAP70 inhibits WT OC spreading, actin ring formation and bone resorptive activity, but not differentiation. In keeping with arrested cytoskeletal organization, ZAP70 blocks integrin-activated endogenous Syk, SLP76 and Vav3 phosphorylation. Thus, the kinase domain of Syk is uniquely required for OC function. Furthermore, the apparent dominant/negative effects of ZAP70 suggest its candidacy as a therapeutic Syk inhibitor in osteolytic disorders.

Transcription Factor E47 Regulates Homeostatic Bone Remodeling Through Upregulation of Inhibitor CD38 in Osteoclast Precursors. Courtney Long^{*1}, Xiao-Hong Sun², Mary Beth Humphrey¹. ¹The University of Oklahoma Health Sciences Center, USA, ²Oklahoma Medical Research Foundation, USA

Osteoclast differentiation and bone resorption are activated through temporally spaced transcription factors that subsequently turn on genes involved in these processes. Here we elucidated a role for the basic Helix-loop-Helix (bHLH) transcription factor, E47, in osteoclast regulation. To do so, we analyzed the baseline bone mass of a transgenic mouse model, termed ET2, expressing a myeloid specific E47 gain-of-function transgene. By microcomputed tomography (microCT), ET2 mice have significantly increased bone volume/tissue volume (BV/TV) compared to controls. Thus, we hypothesized that E47 gain-of-function altered osteoclast maturation, survival or function. To analyze E47 gain-of-function changes in pre-osteoclasts at the molecular level, we stimulated precursors with RANKL for 24 hours, isolated RNA, and then measured differential expression of total RNA transcripts by Solid Sequencing. CD38, a known inhibitor of osteoclastogenesis, was among the genes upregulated in ET2 osteoclast precursors as compared to control precursors. Compared to control, CD11b+ ET2 osteoclast precursors had increased CD38 expression determined by flow cytometry. In vitro analysis of osteoclast assays revealed fewer but more complex ET2-derived osteoclasts compared to controls; whereas, ET2 and control osteoclasts exhibited similar resorption. These results suggested that ET2 pre-osteoclasts expressed more inhibitory CD38, and thus had a greater threshold to overcome to proceed towards osteoclast maturation. To determine if this inhibition could be overcome in vivo, we performed two studies of osteoclast activation: 1) direct stimulation of osteoclastogenesis through RANKL injections or 2) indirect stimulation of osteoclastogenesis through LPS injections. In both models, microCT analysis of pre- versus post- injections showed a significant decrease in bone volume in control and ET2 mice. These data indicate that increased E47 in myeloid cells negatively regulates basal osteoclastogenesis and that strong osteoclastic stimulation, as seen in our two models, can overcome this inhibition to drive functional osteoclasts. Our results suggest the role of E47 in vivo is to inhibit early osteoclast differentiation through upregulation of CD38, an osteoclast inhibitory protein.

A Novel Identification Schema For Osteoclast Progenitors In Mice And In Humans. Monique Bethel^{*1}, Brahmananda Chitteti¹, Yinghua Cheng¹, Angela Bruzzaniti², Edward Srouf¹, Melissa Kacena¹. ¹Indiana University School of Medicine, USA, ²Indiana University School of Dentistry, USA

There are a number of skeletal disorders in which alterations in osteoclast (OC) activity contribute to disease pathology, such as osteoporosis and the inflammatory bone disorders, rheumatoid arthritis and juvenile idiopathic arthritis. Identification of novel OC markers and functional cell surface receptors is critical for the development of innovative therapies for these disorders. Here we show for the first time that murine and human OC progenitors express CD110 (c-mpl), the receptor for thrombopoietin (TPO), which was previously thought to be restricted to cells of the megakaryocyte lineage. Using flow cytometry, we isolated cells expressing CD11b+ or CD14+, which are commonly used as markers of human OC progenitors, and further separated these cells based on the expression of CD110. Importantly, isolated cells from both CD11b+CD110+ and CD14+CD110+ populations resulted in robust generation of mature, TRAP+ OCs with >3 nuclei (855138 and 1150155 OCs/well, respectively), whereas the number of mature OCs generated by CD11b+CD110- and CD14+CD110- cells was almost undetectable, although precursor cell viability was unaltered. Interestingly, approximately 90% of OC progenitors defined as CD11b+CD110+ or CD14+CD110+ cells also expressed CD14+ or CD11b+, respectively. These findings suggest that utilization of CD110 in combination with traditional OC markers, either CD11b and/or CD14, results in a significant enrichment in OC progenitors. Indeed, CD14+CD11b+CD110+ cells gave rise to significantly more mature OCs than that observed in all other populations tested. We next determined the effect of CD110 activation on OC differentiation and function. Our data demonstrate that treatment of OC progenitors with the CD110 ligand, TPO, results in a significant dose-dependent increase in mature OC number, with 100 ng/ml of TPO inducing up to a 6-fold increase in OC number (p<0.01) relative to untreated control cultures. TPO also significantly increased the bone resorbing activity of mature OCs on dentin in vitro (p<0.05). The regulation of OCs by TPO highlights a novel therapeutic target for bone loss diseases and may be important to consider in the numerous hematologic disorders associated with alterations in TPO/c-mpl signaling as well as in the bone destruction associated with inflammatory bone disorders.

A Unique Cytoplasmic Domain in RANK Induces Long-term Signaling Required for Osteoclast Differentiation. Yuu Taguchi*, Jin Gohda, Jun-ichiro Inoue. The Institute of Medical Science, The University of Tokyo, Japan

Receptor Activator of NF- κ B (RANK) is a member of the TNF-receptor superfamily, and the signal transduction of RANK is mediated by the adaptor molecule, TRAF6, as with CD40. It is known that RANK, but not CD40, can induce osteoclastogenesis efficiently, which led us to think that a specific domain in the cytoplasmic tail of RANK in concert with the TRAF6-binding site may promote osteoclastogenesis. Here we identify such a domain, *highly conserved domain* in RANK (HCR), which is dispensable for the early phase activation of RANK signaling but is essential for their late phase signaling including sustained activation of NF- κ B and PLC γ 2 leading to induction of NFATc1, a master transcriptional factor in osteoclastogenesis. Moreover, we found that the HCR recruited an adaptor protein, Gab2, which further associated with PLC γ 2 in the late phase. Our experiment also revealed that Gab2 binds to TRAF6. These results suggest that the HCR provides a platform for forming the novel signal complex including Gab2, PLC γ 2 and TRAF6, and the formation of such a complex could account for the sustained activation of NF- κ B and PLC γ 2.

In a therapeutic point of view, we also found that expression of the HCR-peptide composed of 62 amino acids severely inhibited RANKL-induced activation of NF- κ B/ MAPKs and RANKL-induced formation of multinucleated TRAP-positive cells. These results indicate that the HCR peptide is a potent inhibitor of osteoclastogenesis presumably by quenching Gab2-containing signal complexes. Furthermore, expression of the amino- or carboxyl-terminal half on HCR-peptide also inhibited osteoclastogenesis, respectively. However, Gab2 could bind to only the carboxyl-terminal half on HCR-peptide, but not to amino-terminal half. Therefore, we think that HCR is comprised of two functionally distinct regions, and that peptides from each region are very useful for developing drugs to inhibit osteoclastogenesis. Because our search of the GenBank database did not hit any proteins homologous to the primary structure of HCR amino acid-sequences, the HCR-mediated signal complex may be a good target for developing drugs to treat bone diseases with minimal side effects.

Lysosomal Degradation of TRAF3 Is Important for RANKL/NF- κ B - mediated Osteoclastogenesis. Yan Xiu*¹, Zhenqiang Yao², Yoshikazu Morita², Lianping Xing², Brendan Boyce¹. ¹University of Rochester Medical Center, USA, ²University of Rochester, USA

Osteoclast (OC) formation is regulated by many factors including RANKL and TNF, which activate NF- κ B signaling using TNF receptor-associated factor (TRAF) complexes in OC precursors (OCPs) and mediate joint erosion in patients with rheumatoid arthritis. TNF limits OC formation through the inhibitory NF- κ B p100 protein and TRAF3. TNF increases and RANKL decreases p100 and TRAF3 protein levels in OCPs. However, the mechanisms by which cytokines control TRAF3 levels in OCPs are unknown. We report that TRAF3 expression levels decrease progressively during RANKL- but not TNF-induced OC formation suggesting that RANKL promotes TRAF3 degradation. TRAF3 retroviral over-expression in WT OCPs reduced OC numbers 2-fold suggesting that TRAF3 is a negative regulator of RANKL-induced OC formation. To explore this further, we examined protein levels of several NF- κ B components in TRAF3 over-expressing OCPs in response to RANKL and found reduced RelA, RelB, and NIK levels accompanied by decreased processing of NF κ B2/p100 to p52, while TRAF3 basal levels are significantly increased in RelB/p52 double knockout mouse OCPs, indicating a regulatory loop between TRAF3 and NF- κ B components. To examine how RANKL induces TRAF3 degradation, we treated bone marrow-derived OCPs with RANKL and the proteasome inhibitor MG132 or the lysosome inhibitors NH₄Cl or chloroquine (CQ) and found that only the lysosome inhibitors were effective. We next co-transfected 293T cells with RANK and WT or TRAF3 deletion mutants, treated them with RANKL, and found that the TRAF3 ring finger domain is required for RANKL-induced TRAF3 degradation. We then over-expressed a TRAF3-GFP fusion protein in OCPs and found using confocal immunostaining that TRAF3 co-localized with the lysosomal protein LAMP2. RANKL increased co-localization of TRAF3 and LAMP2 (242% vs 81% control) and this effect was prevented by CQ (91.5%). Our data indicate that TRAF3 negatively regulates RANKL-induced OC formation by suppressing both canonical (RelA and NIK) and non-canonical (RelB and p52) NF κ B signaling and that RANKL-induced lysosomal degradation of TRAF3 is an important step in RANKL-induced activation of NF- κ B pathways in OCPs. Mechanisms to increase cellular TRAF3 levels in OCPs, including inhibition of its lysosomal degradation by drugs such as CQ may thus limit NF κ B-dependent RANKL-induced OC formation and bone destruction in common bone diseases.

Protein Kinase D Regulates Osteoclast Differentiation. Eric Jensen*, Lan Pham, Raj Gopalakrishnan, Kim Mansky. University of Minnesota, USA

Osteoclasts, which are bone resorbing cells vital for skeletal homeostasis, are large multinucleated cells generated by fusion of precursor cells derived from the monocyte/macrophage lineage. One of the factors required for osteoclast differentiation is bone morphogenic proteins. Increased levels of BMP signaling *in vivo* leads to increased osteoclast activity, resulting in osteopenia, while blockage of BMP signaling prevents their formation *in vitro*. An important unresolved question is which molecular signaling pathways are required for this effect.

BMPs activate intracellular signal transduction pathways including SMADs, MAP kinases and protein kinase D. To characterize the molecular mechanisms through which BMPs regulate osteoclast formation, we examined the role of PKD. We find that BMP signaling stimulates protein kinase D activation in osteoclasts. Suppression of PKD expression or activity inhibits *in vitro* osteoclast formation, while overexpression of PKD enhances osteoclastogenesis. These data establish PKD as an important regulator of osteoclasts.

3D Visualization of Osteocyte Lacunae in the entire long bone. Yoshihiro Takeda¹, Yasunari Takada², Kazuhiko Omote¹, Koichi Matsuo². ¹Rigaku Corporation, Japan, ²School of Medicine, Keio University, Japan

The osteocyte is an important cell type responsible for bone metabolism. In recent years, sub-micron resolution x-ray computed tomography (CT) has been employed to analyze the three-dimensional shape of osteocyte lacuna and to measure lacunar volume. However, due to trade-offs between high resolution and a small field of view, it is difficult to obtain sufficient information by focusing on a partial bone area, which contains only a small population of osteocytes. Therefore, we investigated the micro structure of an entire mouse femur at submicron resolution. To achieve this goal, we developed an x-ray microscope capable of measuring large objects with submicron pixel size. The microscope consists of a high power x-ray source, a high resolution camera and motorized stages. Using this system, we obtained CT images of the entire femur (length ca. 10 mm) isolated from 7-week-old mice. The total number of voxels of each CT image was greater than 3,300 x 3,300 x 16,000 with the voxel size of 0.6 micron. CT images clearly depicted bone marrow, fine blood vessels, and osteocyte lacunae. Within cortical bone in a 6-mm diaphysis of the femur, more than 20,000 osteocyte lacunae were detected at the average density of 50,000 / mm³. Curiously, the lacunar density was periodically altered along the longitudinal axis. To our knowledge, this is the first report of periodicity in osteocyte lacunar density along the long bone.

An In Vitro Model for Osteocyte Differentiation. Ken Watanabe¹, Hirovuki Aburatani², Kyoji Ikeda¹. ¹National Center for Geriatrics & Gerontology, Japan, ²RCAT, The University of Tokyo, Japan

Osteocytes, terminally differentiated osteoblastic cells, have been suggested to play important roles in the regulation of bone metabolism. Evidences for *in vivo* function of osteocytes or their products have been accumulating from human as well as mouse genetics studies, while the mechanism underlying the terminal differentiation of osteocytes from osteoblasts remains to be defined at the molecular level. MC3T3-E1 is a pre-osteoblastic cell line that is widely distributed and utilized for bone research. MC3T3-E1 cells differentiate into mature osteoblasts, as evidenced by mineralization of extracellular matrix and expression of osteoblastic signature genes such as osteocalcin and bone sialoprotein. When the mineralizing culture was extended up to 7-9 weeks, expression of osteocytic genes, such as *Sost*, *Mepe* and *Fg23*, was observed, suggesting that the long-term culture recapitulates osteocytogenesis or osteocytic differentiation from osteoblasts. Using this mineralizing long-term culture (MLC) system, RNA was isolated at day 3, week 3 and 9, and the gene expression profiling was performed by microarray analysis. Expression of phosphate-regulating genes, *Phe*, *Enpp1* and *Phospho1*, was highly expressed at 8 weeks of MLC. Expression of known osteocytic genes, *Dmp1* and *Ibsp*, was also substantially increased in the MLC. In addition to *Sost*, another Wnt antagonist *Wif1* was expressed at 8 weeks of MLC. The expression of *Pthr1* encoding PTH receptor was increased during osteocytogenesis, and expression of *Sost* and *Axin2* was down- and up-regulated, respectively, by PTH treatment of MLC, suggesting that the MLC can mimic PTH response in osteocytes *in vivo*.

Sp7, encoding Osterix, has been demonstrated to play a critical role in terminal differentiation of osteoblasts into osteocytes. In addition to *Sp7*, genes encoding transcription factors such as *Dlx3*, *Tcf7*, *Mef2c* and *Epas1*, were upregulated during the osteocytic differentiation in MLC. Overexpression of these genes in MC3T3-E1 accelerated osteocytogenesis, as determined by osteocytic gene signature, while knockdown of *Dlx3* or *Mef2c* genes attenuated the transition from osteoblasts to osteocytes, suggesting that *Dlx3* and *Mef2c* may play roles in osteocytic differentiation. Thus, the MLC of MC3T3-E1 faithfully recapitulates osteocytic gene expression signature, and may provide a useful tool as an *in vitro* model for osteocytogenesis.

Connexin 43 Hemichannels Protect Osteocytes against Oxidative Stress Induced Cell Death. Rekha Kar^{*1}, Manuel Riquelme², Sherry Werner², Jean Jiang³. ¹The University of Texas Health Science Center, USA, ²University of Texas Health Science Center, USA, ³University of Texas Health Science Center at San Antonio, USA

Recent studies suggest that oxidative stress is a primary, underlying mechanism of aged-related bone mass and strength loss. The increasing osteocyte death during aging and oxidative stress is thought to be the principal cause contributing to the impairment of bone quality. However, the molecular mechanism of oxidative stress on osteocytes is poorly understood. Here, we treated MLO-Y4 osteocyte cells with different doses of oxidant, H₂O₂. H₂O₂ induced cell death of MLO-Y4 cells as shown by a dose-dependent increase of PI positive cells. Interestingly, H₂O₂ also caused a dose-dependent decrease in gap junction/hemichannel forming connexin 43 (Cx43) expression. Similar to our *in vitro* finding, the osteocytes in the bone sections from 20 month old mice showed much less Cx43 expression as opposed to the 5 week young animals. Microinjection dye transfer assay was performed to examine whether decreased Cx43 expression resulting from H₂O₂ treatment also affected the gap junction intercellular communication (GJIC). GJIC was evaluated using the alexafluor 488 coupling assay. Intercellular transfer of alexa fluor 488 from the microinjected cell to neighboring cells was reduced progressively after 30 min of H₂O₂ treatment in addition to complete uncoupling after 70 min. To evaluate the effect of H₂O₂ on Cx43 hemichannels, we measured uptake of ethidium (Etd) bromide by time lapse recording under resting conditions (basal) and after the addition of different concentrations of H₂O₂. In contrast to the effect on gap junctions, with increasing concentrations of H₂O₂, there was a dose-dependent increase of hemichannel function. To elucidate the functional role of increased hemichannel activity during oxidative stress, we blocked Cx43 hemichannel activity using the Cx43 (E2) antibody, a potent antibody which specifically blocks Cx43 hemichannel activity but not gap junction or any other channel activity. Cx43 (E2) antibody completely blocked dye uptake induced by H₂O₂ and further exacerbated H₂O₂ induced death of MLO-Y4 cells. This result suggests a protective role of Cx43 hemichannel against oxidative stress. Together, our study provides novel cell protective mechanism mediated by osteocytic Cx43 hemichannels against oxidative stress and aging.

Cox-2 Inhibition Suppresses the Response to Short Term Tibial Compression in Mice. Bryan Hackfort^{*1}, Gwendolin Alvarez¹, Mohammed Akhter², Diane Cullen¹. ¹Creighton University, USA, ²Creighton University Osteoporosis Research Center, USA

Osteoporosis is a disease that can lead to fractures and substantial morbidity. Anabolic treatments are necessary to help reverse the structural deterioration related to osteoporosis, yet we need to first understand the interaction of pathways on bone formation. PGE₂ and mechanical loading are known stimulators of bone formation. Previous studies have shown inhibition of prostaglandins with a selective Cox-2 inhibitor (NS-398) blocks the bone formation response in rats to a single mechanical load. NS-398 also blocks the prostaglandin response to fluid flow. Previously we looked at the long term adaption of bone to tibial compression *in vivo* (10 sessions, 3 weeks) while inhibiting the prostaglandin pathway with NS-398 in mice. As compared to the vehicle group, the NS-398 treatment resulted in a greater bone formation response to mechanical loading. These unexpected results prompted us to question the use of the mouse model in exploring the interaction of prostaglandins and mechanical loading. In this study, we used the tibial compression model to test the response of WT C57Bl/6 mice to a one time high mechanical load while injecting a Cox-2 inhibitor to block prostaglandins. The tibial compression model applies forces through the knee and ankle avoiding injury to the bone. We hypothesize that NS-398 will reduce the amount of bone formation stimulated by a single mechanical load using the tibial compression model in mice. Adult, female mice were injected 3 hours prior to mechanical loading with 10mg/kg NS-398, DMSO, or Saline. Mice were loaded at 11N (1430µe) for 360 cycles at 2Hz. Calcein was injected on days 5 and 9 with collection on day 12. Tibiae were fixed in 70% EtOH, dehydrated, and embedded in methyl methacrylate. Sections were cut at 80µm, 1-3 mm proximal to the TFJ region and mounted for histomorphometry. The net load response was calculated as Load-noLoad and differences due to drug treatment analyzed by planned contrasts (P<0.05). The differences due to loading in periosteal mineralizing surface (MS/BS) was reduced in the NS-398 treated group (4.40 2.71%) compared to its DMSO control group (17.49 4.03%). DMSO showed no effects on MS/BS compared to saline treatment (10.37 3.56%). In conclusion, the mouse model mimics the rat response to Cox-2 inhibition in short term tibial compression. These results suggest the response to Cox-2 inhibition may be different in short term vs. long term mechanical loading.

Load responsive Genes and Inflammation-Associated Genes are elevated in Dmp1 null Osteocytes while Genes associated with Bone Formation are Suppressed. Stephen Harris^{*1}, Marie Harris¹, Yong Cui², Lynda Bonewald³, Jian Feng⁴, Jelica Gluhak-Heinrich¹. ¹University of Texas Health Science Center at San Antonio, USA, ²UTHSCSA, USA, ³University of Missouri - Kansas City, USA, ⁴Texas A&M Health Science Center, USA

It has been proposed that the osteocyte lacunocanalicular network acts in an endocrine fashion to target tissues distant from bone. Osteocytes in Dentin Matrix Protein1, Dmp1, null bone highly express FGF23, osteocalcin, E11/gp38, Sost, and other osteoblast/osteocyte markers. To identify other regulatory factors produced by these cells, full genome expression microarray analyses were performed using *ex vivo* culture of calvarial bone fragments from WT and Dmp1 null animals, in which the osteoblasts were removed by serial collagenase-trypsin digestions and fragments cultured overnight in 10% FBS. Illumina Mouse-6 v2 arrays, Genome Studio-RNA expression module for normalization-statistic of n=2 arrays per group, David Bioinformatic, and Ingenuity Pathway Analysis for construction of literature based pathways and networks were used. Several mechanically responsive genes, such as Igf1, Mepe, Ccl7, 2 (MCP3,1) and Prostaglandin E synthetase were highly elevated suggesting osteocytes in the DMP1 null bones are experiencing elevated strain due to the hypomineralized "soft" matrix surrounding the cells. A massive increase (3 to 50 fold) in cytokines/chemokines involved in immune-inflammatory pathways and macrophage biology, such as CCL2, 7, 3, 14, CXCL1, 3, and ATF3 was also observed. Although, E11/GP38, involved in osteocyte embedding/dendrite formation was also increased, many genes involved in "tube" formation related to branching were reduced in the DMP1null osteocytes, including Csf1, Cx43, VegfA, and Ihh/Gli2, 3 genes. These may play a role in the formation of the lacunocanalicular system. Many of the semaphorins involved in axon guidance, normally highly expressed in osteocytes, were also reduced. In addition, a large number of genes in the Wnt pathway including Wnt1, 7b, axin1, Tcf7, and three calcium-calcineurin transcription factors, Nfatc1, 2, and 3 were reduced. 145 genes involved in transcription, including Sp7, Osterix, a key transcription factor in bone, were reduced in DMP1null osteocytes, (Sp7 over 7 fold), suggesting major alterations in the genetic program of the DMP1null osteocytes. Gene expression levels of Sp7, Ccl7, and Igf1 have been validated by *in situ* hybridization in WT and DMP1null animals (2 mo old). These studies have implications regarding the potential elevation of circulating cytokines in patients with hypophosphatemic rickets and design of potential treatment and preventive therapies.

MT1-MMP Affects the Mechanosensitivity of Osteocytes. Rishikesh N. Kulkarni¹, Astrid D. Bakker¹, Elisabeth V. Gruber², Thomas D. Chae³, Joris B. B. Veldkamp¹, Vincent Everts¹, Jenneke Klein-Nulend^{*1}. ¹ACTA-University of Amsterdam & VU University Amsterdam, Dept Oral Cell Biology, Research Institute MOVE, Netherlands, ²Medical University of Vienna, Bernhard Gottlieb School of Dentistry, Bone Research Group, Austria, ³Columbia University College of Dental Medicine, USA

Bone mass and architecture are continuously adapted to the prevailing mechanical loads. It is generally assumed that osteocytes act as key regulators of bone mass in response to mechanical cues that are perceived via their cell processes. Since matrix metalloproteinase-14 (MT1-MMP) is essential for osteocyte cell process formation *in vivo*, and also affects bone mass, we aimed to investigate whether MT1-MMP affects the osteocyte response to mechanical loading.

MT1-MMP positive and knockdown (siRNA) osteocytes were either or not stimulated by 1h pulsating fluid flow (PFF; 0.70.3Pa, 5Hz). The pulsating fluid flow-response was quantified by measuring c-jun, c-fos, and MT1-MMP mRNA expression, and nitric oxide (NO) production. Focal adhesions were visualized by paxillin immunostaining. Osteocyte number, number of empty lacunae, and length-to-width ratio of osteocyte lacunae were measured in long bones of MT1-MMP^{+/+} and MT1-MMP^{-/-} mice aged 14-50 days.

Pulsating fluid flow decreased MT1-MMP mRNA expression by 2.2-fold in MT1-MMP positive osteocytes, suggesting that mechanical loading affects pericellular matrix remodeling by osteocytes. Pulsating fluid flow increased NO production by 3.5-fold within 5 minutes in MT1-MMP positive osteocytes, whereas pulsating fluid flow increased NO production by 8.1-fold compared to static control conditions in MT1-MMP knockdown osteocytes. Pulsating fluid flow upregulated c-jun gene expression by 1.8-fold, and c-fos gene expression by 1.9-fold in MT1-MMP knockdown osteocytes, but not in MT1-MMP positive osteocytes. Interestingly, MT1-MMP knockdown increased number of focal adhesions in osteocytes. MT1-MMP deficiency enhanced osteocyte elongation and increased the number of osteocytes by 1.5-fold, and decreased the number of empty lacunae by 1.6-fold. The elongated osteocytes in MT1-MMP^{-/-} bone followed the principle loading direction, suggesting that they can sense mechanical loading despite lack of cell processes. This was supported by a low number of empty lacunae in MT1-MMP^{-/-} bone, as osteocytes lacking mechanical stimuli tend to undergo apoptosis.

In conclusion, MT1-MMP knockdown increased the osteocyte response to mechanical stimuli, demonstrating a novel and unexpected role for MT1-MMP in mechanosensing. Our results shed new light on the process of mechanosensing by

osteocytes and warrant further research in this direction, since this will undoubtedly contribute to new perspectives of bone tissue physiology.

Osteogenic Transcriptome Regulation in MLO-Y4 Osteocytes Exposed to Fluid Flow. Peter Govey¹, Norman Karin², Henry Donahue³. ¹Penn State College of Medicine, USA, ²Pacific Northwest National Laboratory, USA, ³The Pennsylvania State University College of Medicine, USA

The lacuno-canalicular niche of osteocytes positions them as prime candidates to transduce fluid shear stress to regulate bone remodeling. The purpose of this study is to establish the utility of high-throughput approaches, specifically gene transcript microarrays, to investigate this intricate response of osteocytes exposed to fluid flow. We hypothesize that gene expression levels in MLO-Y4 osteocyte-like cells exposed to fluid flow will reflect regulation of known mechano-sensitive signaling pathways.

MLO-Y4 were cultured on collagen I-coated glass slides two days prior to flow. Cells were then exposed to 2 hours oscillating fluid flow in parallel plate flow chambers, inducing 10 dynes/cm² shear stress at 1 Hz. Paired sham controls were maintained in identical, static chambers. Triplicates of both flowed and static cells were collected immediately (time 0) and following 2, 8, and 24 hours post-flow incubation in fresh media. Total RNA was isolated, biotin-labeled cRNA synthesized and fragmented, hybridized to Mouse Genome 430A 2.0 GeneChips and scanned. Gene set enrichment for gene ontology biological process annotation was calculated to identify the most significant cellular processes affected by flow.

After detection of approximately 14,000 gene expression levels, 788 gene products increased or decreased by at least 1.25-fold in flowed vs. non-flowed MLO-Y4. Importantly, regulation of these gene products corresponds with previously implicated osteogenic signaling pathways. Ptg2, which encodes osteogenic COX-2, increases 1.45-fold at 2 hours post-flow. Expression of LRP5, shown by others to be up regulated by flow, increased 1.25-fold immediately after flow. Anabolic LRP5 is a receptor in the Wnt/beta-catenin signaling pathway; inhibitors of this pathway, Dkk2 and Dkk3, decreased 1.37-fold and 1.27-fold at 8 hours, respectively. These changes are consistent with an anabolic effect of flow on osteocytes and demonstrate the power of this approach in revealing global gene expression pathways. Gene ontology assessment yielded statistically significant activity in cell metabolism, connective tissue function, and cell-to-cell signaling activity.

These results identify a composite mechano-sensitive response in flowed MLO-Y4. Furthermore, the transcriptome will provide context to explore novel mechano-sensitive pathways. Proteomic analysis will be useful in assessing post-transcriptional and post-translational regulation of these gene products.

Quasi-3D Dynamics of Actin and Microtubule Networks in Individual MLO-Y4 Osteocytes under Steady and Oscillatory Flow. Andrew Baik¹, Jun Qiu², Elizabeth Hillman¹, Cheng Dong³, X Guo¹. ¹Columbia University, USA, ²Tsinghua University, China, ³Penn State University, USA

Purpose: Osteocytes in vivo experience complex fluid shear flow patterns to activate biochemical pathways and the actin and microtubule (MT) cytoskeletal networks play mechanical roles to regulate this process. Due to high intercellular variability, the actin and MT networks were tracked in two orthogonal planes (dubbed quasi-3D) simultaneously in the same cell to observe the spatiotemporal differences of the two networks under fluid shear loading.

Methods: A quasi-3D two-microscope system consisting of an upright and inverted microscopes with individual cameras and beamsplitters allowed simultaneous 3D measurement of two fluorescent dyes in two orthogonal planes (bottom-view and a side-view) of a single cell. MLO-Y4 cells were transfected with TagCFP-Lifeact and mKate2-EMTB to visualize the F-actin networks in cyan and the microtubule networks in far-red. Cells were then plated in a flow and imaging chamber for a short period to ensure a rounded cell body that mimics the in vivo osteocyte shape (Fig. 1A). Steady (n=8) or 1 Hz oscillatory flow (n=7) with a wall shear stress of 1 Pa were applied to cells and imaged. Intracellular cytoskeletal strains were calculated using a digital image correlation technique. Paired t-tests were used to determine significant differences between the two networks' deformational behavior within single cells.

Results: Steady flow had a viscoelastic effect of creep and creep recovery on both the actin and microtubule networks (Fig. 1B), while oscillatory flow produced mainly "elastic" behavior (Fig. 1C). Steady flow developed higher shear strains in the cell body than in oscillatory flow. Under steady flow, actin normal strains were higher in the leading edge to flow compared to the MT normal strains in those areas at the end of the loading period (p<.05). Side-view shear Exz strain was higher in the actin networks in the basal part of the cell closer to the coverslip, possibly due to the presence of focal adhesions. Oscillatory flow strains left no visible residual strains after flow, further emphasizing the different nature of the two flow patterns.

Conclusion: These results demonstrate for the first time a dual simultaneous tracking of both actin and microtubule strains at the single cell level to our knowledge. The high temporal resolution of the quasi-3D system allowed full mapping of differences in the network deformational responses under steady and oscillatory fluid flow profiles.

Radiation-Induced Bone Loss: Role of the Osteocyte. Jeroen Buijs¹, Laura Tedeschi², Marc Mendonca¹, Teresita Bellido², Ted Bateman³, Khalid Mohammad¹, Theresa Guise¹. ¹Indiana University, USA, ²Indiana University School of Medicine, USA, ³University of North Carolina, USA

Patients with tumors in the pelvic region frequently receive radiation therapy, and as a result, bystander bone may experience adverse effects, including bone loss and increased fracture risk, particularly at the hip region. Earlier reports demonstrated that radiation-induced bone loss occurs via increased osteoclast activation in a mouse model. However, the exact mechanism through which osteoclasts are activated is unclear. Apoptosis of Osteocytes has been shown to trigger osteoclast progenitor recruitment and differentiation, and limited reports suggest that osteocytes might be radiosensitive. We hypothesized that radiation induces osteocyte apoptosis leading to increased osteoclastogenesis and subsequent bone loss.

We evaluated the effects of radiation on MLO-Y4 (osteocytes), MC3T3-E1 (osteoblast progenitor) and UMR-106-01 (osteoblast-like/osteosarcoma) cell lines. Osteocytes were exposed to doses of 2 to 10 Gy radiation, and cell death and apoptosis were determined by trypan blue exclusion and by caspase-3 activation and annexin-V expression using flow cytometry, respectively.

Radiation with 2Gy significantly increased the number of trypan blue positive MLO-Y4 cells up to 14.9%, 15.5% and 14.6% after 6, 24 and 48 hours respectively (vs 5.1-7.8% at Co levels), and 10Gy further increased these numbers up to 16.0%, 19.7% and 21.4%. The increase in trypan blue positive UMR-106-01 and MC3T3-E1 cells were most prominent 24 hours after 10Gy radiation (41.5% and 42.1% respectively).

While a marginal induction of apoptosis in MLO-Y4 cells was observed with 2Gy radiation, higher doses of radiation resulted in a much greater induction of apoptosis. At later time points (48hr + 7d), 10Gy radiation induced expression of the apoptotic markers in 50-60% of the MLO-Y4 cells. Similar trends were found for UMR-106-01 and MC3T3-E1 cells.

In conclusion, our findings demonstrate that radiation increases cell death and apoptosis in MLO-Y4 osteocytic cells, in a time and dose dependent fashion. Further studies are underway to functionally test whether radiation-induced bone loss is mediated via osteocytes. This may lead to rapid implementation of therapeutic interventions that can reduce bone loss and fracture risk in patients receiving radiation therapy.

Dose-dependent Effects of Glucocorticoid on Anti-Oxidation, Autophagy and Apoptosis. Junjing Jia¹, Wei Yao¹, Min Guan¹, Weiwei Dai², Jean Jiang³, Lynda Bonewald⁴, Nancy Lane¹. ¹University of California, Davis Medical Center, USA, ²Department of Medicine, University of California at Davis Medical Center Sacramento, CA, USA, ³University of Texas Health Science Center at San Antonio, USA, ⁴University of Missouri - Kansas City, USA

In response to stress such as oxidation, cells may be activated to undergo necrosis, apoptosis, or undergo a stress metabolism and autophagy, and the cell may go onto survive or go onto apoptosis depending on the duration and severity of the insult. As glucocorticoids (GCs) have been shown to induce both "a high oxidative state and osteocyte apoptosis and autophagy, we sought to determine if osteocyte cell fate in the presence of GCs was dose dependent using in vivo and in vitro approaches. We performed in vitro studies with MLO-Y4 cells that were transfected with the GFP-LC3 and then cultured with dexamethasone at 10⁻⁸-10⁻⁵ M doses for 24 hours. We also performed an in vivo experiment using three-month-old male Swiss-Webster mice were treated with slow release pellets prednisolone that delivered a day GC dose at 0 (placebo, PL), 1.4, 2.8 or 5.6 mg/kg/d for 28 days. RNA was extracted from cells or the femurs to perform RT-PCR gene arrays for anti-oxidant, autophagy and apoptosis. The prevalence of osteocyte autophagy and apoptosis were quantitated in vivo by immunohistochemistry in both trabecular and cortical regions. We found that in MLO-Y4 cells, GC exposure did not change their anti-oxidant responses but increased activation of autophagy associated genes, especially at the lower dose levels (10⁻⁷-10⁻⁶M). GC treatment in mice dose-dependently decreased the activations of the anti-oxidant, autophagic and anti-apoptotic gene pathways. The presence of osteocyte

autophagy, detected by immunostaining for LC3, increased about 50% in the distal femur cortical bone site at two lower dose levels (1.4 and 2.8mg/kg/d). There was no GC dose response association with osteocyte autophagy in trabecular bone. The percentage of apoptotic osteocytes dose dependently increased in the cortical bone and was the most significant at the highest dose (5.6 mg/kg/d). In conclusion, GCs appear to have a dose dependent effect on osteocyte cell fate, with lower doses favoring autophagy and higher doses favoring apoptosis. GC dose-dependently decreased both the anti-oxidant defense and autophagy in vivo. The anti-oxidant gene expressions were positively correlated to the activation of genes associated with autophagy but not apoptosis. Our findings suggest interventions that alter autophagy and oxidative stress as therapeutic approach to reduce GC induced bone fragility.

Mediators of Osteocyte Apoptosis in Chronic Kidney Disease. Renata Pereira^{*1}, Thomas Lisse², Harald Jueppner³, Isidro Salusky⁴, Katherine Wesseling⁵. ¹UCLA, USA, ²UCLA/Orthopaedic Hospital Research Center, USA, ³Harvard Medical School & Mass. General Hospital, USA, ⁴University of California, Los Angeles School of Medicine, USA, ⁵UCLA Medical Center, USA

Renal osteodystrophy (ROD), a condition marked by increased bone fragility and deformities, is characterized by osteocyte dysfunction, as evidenced by abnormal mineralization and increased osteocytic FGF-23 and DMP1 expression (Pereira et al. Bone 2009). Although osteocyte viability plays a major role in the maintenance of bone homeostasis and integrity, the factors regulating this process in chronic kidney disease (CKD) are unknown. Thus, the rate of osteocyte apoptosis was evaluated in bone biopsy specimens from 14 pediatric patients with CKD stages 3-5 with the following biochemical variables: Ca: 9.1±0.2mg/dl, P: 5.1±0.4 mg/dl, Alk P:tase: 364±70 IU/l, PTH (1st IMA, Immotopics): 357±100 pg/ml, C-term GF-23 (2nd generation, Immotopics): 1106±295 RU/ml. Bone histology was OF (n=1), mixed (n=4), adynamic (n=4), OM (n=2), and normal (n=3). Apoptosis in bone sections was assessed via in situ nick-end labeling (TUNEL) reaction using Klenow terminal deoxynucleotidyl transferase per manufacturer's instructions (Oncogene Research Products). Apoptotic osteoblasts and osteocytes were not detected in bone from CKD patients while 10-20% of osteocytes were apoptotic in normal controls. To assess potential mechanisms underlying this decreased apoptotic rate in CKD bone, the murine osteocyte cell line MLO-Y4 was cultured in serum-free conditions with either normal (1 mM Pi) or phosphate enriched (8 mM Pi) media in the presence of FGF-23 (50 or 100 ng/ml), DMP1 (40 or 100 ng/ml), or 1,25(OH)₂vitamin D (1, 10, or 100 nM) for 24 and 48 hours. Cell death was assessed by acridine orange/ethidium bromide and trypan blue staining and caspase-3 activity (Biovision) was measured in cell lysates. Higher Pi and the addition of 1,25(OH)₂vitamin D increased MLO-Y4 cell apoptosis as measured both by proportion of dead cells and by caspase-3 activity, the effect of Pi and vitamin D was additive. By contrast, FGF-23 decreased MLO-Y4 cell apoptosis at 24 and 48 hours; this effect was stronger in the presence of high phosphate. DMP1 had no effect on cell life span. In conclusion, osteocyte function is altered in patients with CKD and factors intrinsic to bone (such as FGF-23) and extrinsic to bone (such as circulating phosphate and 1,25(OH)₂vitamin D) influence osteocyte viability. Further studies are warranted to define the genes and mechanisms responsible for alterations in osteocyte cell cycle in CKD; defining this process will have implications for the treatment of ROD.

Ex-vivo Imaging of the Autonomous Intracellular Ca²⁺ Oscillations of Osteoblasts and Osteocytes in Bone. Yoshihito Ishihara^{*1}, Yasuyo Sugawara², Hiroshi Kamioka³, Noriaki Kawanabe⁴, Hiroshi Kurosaka⁵, Keiji Naruse⁶, Takashi Yamashiro³. ¹Okayama University, Japan, ²Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sc, Japan, ³Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sc, Japan, ⁴Okayama University Hospital, Japan, ⁵Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sciences, Japan, ⁶Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Science, Japan

Ca²⁺ is a ubiquitous second messenger in various physiological cellular processes. Bone cells form a complex three-dimensional network consisting of different types of osteoblasts and osteocytes embedded in mineralized extracellular matrices. Previous in vitro study indicated that the intermittent rise in intracellular Ca²⁺ concentration ([Ca²⁺]_i) oscillation has been observed in isolated osteoblasts. However, it has not been entirely clear whether the same [Ca²⁺]_i responses take place when the cells remain in the integrated system. In the present study, we developed for the first time an ex-vivo live Ca²⁺ imaging system that allows the dynamics of the [Ca²⁺]_i responses occurring in intact chick calvaria explants without damaging the complicate network of the bone. Our live imaging analysis revealed that both osteoblasts and osteocytes showed repetitive and autonomous [Ca²⁺]_i oscillations. In addition, thapsigargin, an inhibitor of

the endoplasmic reticular which empties intracellular Ca²⁺ stores, abolished the such [Ca²⁺]_i response both in osteoblasts and osteocytes. These results indicated that Ca²⁺ release from intracellular stores plays a key role in the oscillation of these bone cells in intact bone explants. Since calcium waves were propagated, at least in part, by gap junctional communication in other organs. We further investigate the possible roles of gap junctions in maintenance of such autonomous [Ca²⁺]_i oscillations in intact bones. Treatment with 18 α-GA, a reversible inhibitor of gap junctional intercellular communication, significantly reduced the ratio of the responsive osteocytes, but the relative calcium increase and the frequency of the [Ca²⁺]_i oscillations were not affected. In contrast, the gap junction inhibitor did not affect [Ca²⁺]_i oscillations in osteoblasts. These findings indicated that gap junction is specifically important in the maintenance of the responsive osteocytes in [Ca²⁺]_i oscillation. Taken together, we found that bone cells in intact bone explants showed autonomous [Ca²⁺]_i oscillation that require release of intracellular calcium stores. In addition, osteocytes specifically propagated intercellular calcium waves with cell-cell communication by gap junction, which maintains the responsive cells of the oscillation in bone.

Effects of Ovariectomy and PTH(1-34) on Osteocyte Lacunar Properties in Adult Rats. Donald Kimmel^{*1}, Tiffany Fong², Mohammed Akhter³, Thomas Wronski⁴. ¹Kimmel Consulting Services, USA, ²Xradia, Inc., USA, ³Creighton University Osteoporosis Research Center, USA, ⁴University of Florida, USA

Estrogen loss may increase osteocyte (Ot) apoptosis, reducing Ot lacunar (Ot.La) density. Parathyroid hormone (PTH) raises serum Ca by multiple means including Ot activity to increase Ot.La size. Synchrotron radiation (SR) microscopy achieves ~0.7μm pixel resolution (PR), resolving whole Ot.La in 3D images of intact mouse bone. Current laboratory 3D-imaging devices have difficulty resolving Ot.La in intact bones. We report Ot.La volume, density, and separation in PTH-treated, ovariectomized (OVX) rats, from measurement of 3D images acquired on a lab-based instrument that attains SR-like resolution (3D X-Ray Microscope; MicroXCT-200).

Female rats aged 13wks were OVXd (N=24) or Sham-OVXd. After 6wks, OVX rats were treated for 16wks with 0 [Veh] or 0.05 mg/kg PTH (1-34) [PTH] 5d/wk. Tibiae and L2 vertebrae (LV2) were fixed (70% ethanol). Histomorphometry showed typical OVX and PTH-induced changes in tibial bone. LV2 (4/grp) was trimmed of processes and embedded in methacrylate. 2X2X8mm sagittal samples of the LV2 body were scanned at 5μm PR in the central trabecular region just caudal to the cranial growth plate. Sub-volumes of interest (VOIs) were selected for non-destructive scanning by local 3D x-ray microscopy at ~0.6μm PR. 3D images of each sub-VOI were analyzed by RatoC Segmentation Software (RSS; Tokyo, JP) for Ot.La density (Ot.LaD) and volume (Ot.LaV). BaryCenter of each Ot.La was determined by RSS; separation of Ot.La was calculated (Ot.La.Sp). Ot.La were defined as discrete bone tissue voids >50 and <400μm³.

Data are presented (Table and Figure). OVX+Veh rats have smaller and fewer lacunae than Sham-OVX rats. PTH-treated OVX rats tend to have larger, more numerous lacunae than OVX rats. Bone marrow space is dark in the Figure.

Complete evaluation of bone quality is an unmet need in current fracture risk evaluation. Bone tissue with fewer, smaller Ot.La for early microcracks to encounter, could have reduced ability to slow microcrack propagation, leading to increased bone fragility. Lacunar properties may be yet another bone quality not addressed by current bone measurement methods. Our osteocyte lacunar data, resembling those from human biopsy specimens, may provide new information about bone quality that could explain an additional portion of increased bone fragility related to estrogen deficiency. These data also confirm past studies of Ot.LaV in PTH-treated rats, possibly suggesting a new effect of PTH on bone quality.

A Novel ELISA Assay for Detecting the Active Form of Cathepsin K in Human Serum. Yujia Ding¹, Qinlong Zheng¹, Morten Karsdal², Kim Henriksen^{*2}. ¹Nordic Bioscience Beijing, China, ²Nordic Bioscience A/S, Denmark

Cathepsin K plays essential roles in bone resorption and is an intensely investigated as a therapeutic target for the treatment of osteoporosis. Assessment cathepsin K may provide important biological information in many diseases in which increased bone erosion is a central part of the pathology such as osteoporosis, cancer and rheumatoid arthritis.

Presently there are no robust assays for the assessment of cathepsin K in serum. We focused on developing an ELISA-based assay specifically detecting active cathepsin K in serum samples from humans, rats and mice.

Mice were immunized with a peptide comprising the first 10 aminoacids of active cathepsin K linked to KLH. The antibody was IgG purified and HRP-labelled using commercial systems. A competitive ELISA was setup using a biotinylated coater peptide and a non-labelled peptide as the standard curve. Supernatants from human osteoclasts generated using CD14 magnetic bead sorting and culture were used as positive control. Recombinant cathepsin K, S and L were activated using low pH cysteine-containing buffers.

The inter and intra assay variations of the assay were below 10%. The dilution recovery was 95% until 1:4 dilution.

By using latent and activated Cathepsin K the assay was demonstrated to specifically detect activated cathepsin K. No cross-reactivity to the activated forms of the closely related cathepsin S and L was observed. Using immunoprecipitation it was shown that the antibody only recognizes native cathepsin K.

Quantification of the levels of active cathepsin K in supernatants of purified human osteoclasts compared to corresponding macrophages showed a 30-fold induction ($p < 0.001$).

Active cathepsin K was assessed in serum samples from rats collected at baseline and three weeks after ovariectomy. A 75% significant increase ($p < 0.01$) in active cathepsin K after OVX was observed, which correlated to the increase in bone resorption (CTX-I) ($R^2 = 0.4$, $p < 0.001$). A comparison of the levels of active cathepsin K were quantified in serum samples from patients with osteoclast-rich osteopetrosis (ADOI) and age and sex-matched controls, showed a 100% elevation in ADOI ($p = 0.05$).

In summary, we have developed a robust and sensitive assay specifically detecting the active form of cathepsin K. As cathepsin K is the primary protease in bone resorption, we speculate that the levels of active cathepsin K will prove useful for prediction of future bone loss.

Circulating OPG In Femoral Osteoporotic Fracture-Healing. Costantino Corradini^{*1}, Jacopo Bernieri², Vittorio Macchi², Emiliano Malagoli², Cesare Verdoia². ¹State University of Milan, Italy, ²University of Milan, Italy

Objective: Circulating OPG has been measured in different physiological and pathological processes. The main action remains probably the regulation of osteoclastogenesis. Recent studies have revealed opposite OPG serum levels at 6 and 12 months after assumption of antiosteoporotic drugs. Moreover it is still uncertain its role in osteoporotic fractures. The aim of this study was to assess serum OPG levels in elderly patients affected by a femoral osteoporotic fracture. **Material and Methods:** 58 females between 63 and 81 years old with osteoporosis but without important cardiovascular, renal and bowel co-morbidity were recruited. They were divided in two homogeneous groups for number and age on the basis of a presence or less at the moment of hospitalization of proximal femoral fracture treated with proximal femoral nail. Circulating OPG levels were measured in both groups by sandwich enzymelinked immunoassay at 0, 1, 3 and 6 month. **Results:** There is not a normality range of OPG but it was increased for decade and fractured patients revealed a further significant increase. This increase was more evident in the first period of fractures during healing process. During the period of 6 months there was a significant difference in serum OPG levels between fractured patients and unfractured patients. However circulating OPG was higher in fractured patients during the first 3 months, while at 6th month no statistical differences with unfractured were detected. **Conclusion:** the clinical relevance of this study is the increase of serum OPG levels in fractured vs unfractured osteoporotic population. Even if further study are necessary to define range of OPG in only osteoporotic patients and fractured ones, this study suggests an involving of OPG in fracture healing processes. **References:** Dobnig H. Ketonuria's Metabolic Benefits on Bone Metabolism in Korean Women. SANG HYEON JE^{*1}, Nam-Seok Joo², KYU-NAM KIM³, Kwang-Min Kim², Duck Joo Lee⁴. ¹Ajou University Hospital, Department of Family Medicine, South Korea, ²Ajou University Hospital, South Korea, ³Ajou University, South Korea, ⁴Ajou University School of Medicine, South Korea

Recent studies have reported that Ketonuria is related to obesity-related metabolic parameters such as body weight, waist circumference, body mass index (BMI), blood glucose, high density lipoprotein (HDL) cholesterol, triglyceride, blood pressure and insulin. Osteoporosis is a result of combination of diverse interactions in these parameters. In a cross-sectional study, we examined metabolic characteristics, including bone mineral density (BMD), in Korean women with ketonuria after a minimum 8 hr fast ($n = 14,193$).

The ketonuria group showed more favorable BMD than non-ketonuria group did. The ketonuria group also had lower prevalence of lower levels of body weight, triglyceride, fasting blood glucose, blood pressure, and homocysteine; and higher HDL cholesterol than the non-ketonuria group had. The correlation analyses showed that BMD and HDL cholesterol were significantly associated with ketonuria ($r = 0.128$ and $r = 0.151$, respectively). In the linear regression analyses adjusted for age and risk factors of atherosclerosis, BMD was significantly positively associated with risk of ketonuria (Odd ratios (OR), 1.88, 95% CI 1.57-2.24), but BMI was associated with a lower risk of ketonuria (OR 0.88, 95% CI 0.82-0.94).

The presence of ketonuria after at least an 8 hr fast may have metabolic benefits even in the bone mineral metabolism, other than obesity-related metabolism.

Serum PINP Predicts Changes Caused by Intermittent PTH(1-34) Treatment in Mechanical Properties and Other Bone Parameters in Adult Ovariectomized Osteopenic Rats. Jussi Halleen^{*1}, ZhiQi Peng¹, Katja Fagerlund¹, Tiina Suutari¹, Jukka Vaaranen¹, Mari Suominen¹, Jukka Rissanen², Harrie Boonen³, Trine Neerup⁴, Hanne Bak⁴, Jukka Morko¹. ¹Pharmatest Services Ltd, Finland, ²Pharmatest Services, Limited, Finland, ³University of Copenhagen, Denmark, ⁴Zealand Pharma A/S, Denmark

Procollagen I N-terminal propeptide (PINP) is a sensitive marker of bone formation for monitoring the efficacy of treatment with recombinant human parathyroid hormone (1-34) analog (PTH) in osteoporotic patients. We evaluated the value of serum PINP for predicting changes in bone parameters caused by intermittent PTH treatment in adult ovariectomized (OVX) osteopenic rats. Study groups included a sham-operated control group, an OVX-operated control group receiving vehicle, and OVX-operated groups receiving daily subcutaneous injections of 1.2, 4.0, 12.0, 40.0 and 120.0 µg/kg human PTH. Each group contained 12 animals that were 6 months of age at the time of the operations. Dosing was started at 7 weeks after OVX and continued for 6 weeks. PINP and other bone turnover markers C-terminal cross-linked telopeptides of type I collagen (CTX) and tartrate-resistant acid phosphatase 5b (TRACP 5b) were determined in serum before the start of treatment, at 2 weeks after the start of treatment, and at the end of the study. Bone parameters were determined in long bones and vertebra by peripheral quantitative computed tomography (pQCT), static and dynamic histomorphometry and biomechanical testing. PTH treatment showed strong anabolic effects and serum PINP values showed a strong dose-dependent increase by PTH treatment both at 2 weeks and at the end of the study. The PINP values showed strong correlations both at 2 weeks and at the end of the study with parameters of pQCT, including trabecular bone mineral density in tibial metaphysis and vertebra and cortical thickness in tibial diaphysis, with parameters of bone histomorphometry, including trabecular bone volume/tissue volume (BV/TV) and trabecular thickness (Tb.Th.) in tibial metaphysis and vertebra, and bone formation rate as determined by dynamic histomorphometry in vertebra, tibial metaphysis, and periosteal and endosteal surfaces of tibial diaphysis, and with serum TRACP 5b values, but not with serum CTX values. Most importantly, serum PINP values correlated strongly with mechanical properties of bones, including maximal load in femoral neck as determined by cantilever bending test, in tibial diaphysis as determined by three-point bending test and in vertebra as determined with compression test. These results demonstrate that serum PINP values predict changes caused by intermittent PTH treatment in mechanical properties and other bone parameters in adult ovariectomized osteopenic rats.

Usability of Serum Tartrate-resistant Acid Phosphatase Type 5b (TRACP-5b) in Rat Ovariectomy Model. Wataru Kikuchi¹, Yasuaki Namatame¹, Yuri Matsuki¹, Iwao Kiyokawa¹, Fumio Nomura², Kimimitsu Oda³, Toshihide Miura¹. ¹Nittobo Medical Co., Ltd., Japan, ²Department of Molecular Diagnosis, Graduate School of Medicine, Chiba University, Japan, ³Department of Oral Life Science, Graduate School of Medical & Dental Sciences, Niigata University, Japan

Background: We had developed a new EIA assay kit for TRACP-5b in rat serum, and reported the basic performance for the kit in ASBMR 2009 Annual Meeting. This time, we studied about the behavior of serum TRACP-5b levels in rat ovariectomy (OVX) model. And we had also evaluated the usefulness of monitoring TRACP-5b as a bone turnover marker with some drugs.

Methods: Twelve weeks old of female Wister rats were divided into five groups. Group 1 (Control group): sham operated given placebo. Group 2: OVX operated given placebo, Group 3: OVX operated given 17 β -Estradiol (E2), Group 4: OVX operated given Alendronate (ALN), Group 5: OVX operated given Calcitonin (CT). Blood was withdrawn before operation and every week after operation, and serum TRACP-5b and CTX was measured. All of rats were killed at the 5th week, and femur was harvested for measurement of pQCT analysis.

Result: A TRACP-5b level of OVX group (Group 2) was significantly declined compared with Sham group (Group1). This TRACP-5b change was opposite of changing in postmenopausal women. Reducing activity of TRACP-5b was inhibited with treatment of E2 (Group 3). These data suggested that deficient secretion of estrogen leads reducing of serum TRACP-5b in rat.

The result of pQCT analysis indicated that treatment of ALN (Group4) and CT (Group5) can significantly prevent the bone loss. Treatment of ALN reduced the level of TRACP-5b and CTX in a week. TRACP-5b kept 5 weeks on low levels, but CTX shifted to increase at the third week. In ALN-treated group, the level of BUN on 5th week was significantly higher than non-treated group. This may suggested that increasing of CTX is caused by declining of renal function.

Conclusions: TRACP-5b changed in early stage, and kept reflecting bone resorption significantly with some drugs. We conclude that TRACP-5b is very useful marker of bone resorption in rat model.

Central DXA Utilization in Medicare Beneficiaries in the Wake of Reimbursement Changes. Jie Zhang¹, Elizabeth Delzell¹, Hong Zhao¹, Andrew Laster², Kenneth Saag¹, Meredith Kilgore³, Michael Morrisey¹, Nicole Wright¹, Huifeng Yun¹, Jeffrey Curtis¹. ¹University of Alabama at Birmingham, USA, ²Arthritis & Osteoporosis Consultants of the Carolinas, USA, ³University of Alabama At Birmingham School of Public Health, USA

Purpose: Medicare gradually reduced payments for physician office based dual energy X-ray absorptiometry (DXA) services from an average of \$139 in 2006 to \$72 in 2009. In contrast, reimbursement for hospital based DXA services was unaffected. We investigated the utilization of central DXA services in the Medicare population before and after the reduction.

Methods: We identified individual from the 5% random sample of Medicare beneficiaries who were ≥ 65 years of age and continuously enrolled in Medicare Parts A and B but not in a Medicare Advantage plan for at least one full calendar year from 2002 through 2009. The first central DXA test for these beneficiaries in each calendar year was identified using Current Procedural Terminology codes. We classified each test as a facility (hospital based) or a non-facility (physician office based) DXA. For each calendar year, we calculated the proportion of beneficiaries who had at least one central DXA and the proportions of facility versus non-facility DXAs of all DXAs performed. The total number of DXA tests was multiplied by 20 to extrapolate to the entire nation's Medicare fee-for-service population.

Results: In 2009, the average age of all Medicare beneficiaries was 75.7 years; 58% were female; and 88% were Caucasians. From 2002 to 2006, the proportion of beneficiaries who had at least one central DXA increased from 7.7% to 9.6% at an average annual rate of 0.4%. The proportion continued to climb and peaked in 2008 at 9.9% and remained unchanged in 2009. Between 2007 and 2009, the annual rate of increase was 0.1% (Figure 1). Compared to 2006, in which 1,643,720 (69%) of DXAs were performed in physician offices, the absolute number and proportion of office based DXAs declined to 1,534,240 (66%) by 2009 (Figure 2). This decline was offset by an increase in the number of facility DXAs, which increased from 719,780 (31%) in 2006 to 804,000 (34%) in 2009.

Conclusions: Between 2007 and 2009, reductions in Medicare payment for physician office based central DXA services was associated with a slight slowing in the annual rate of growth in the overall number of DXAs performed and a modest shift in DXA use away from office based to hospital based DXAs in the Medicare fee for service population.

Figure 1 Proportion of beneficiaries who received at least one central DXA by calendar year

Comparison Of The Effect Of Surrounding Fat On Measurements Of BMD By DXA And High Resolution Quantitative Computerized Tomography. Edward Colt¹, Muhammad Akram², Fahad Javed¹, Elizabeth Shane³, Stephanie Boutroy⁴. ¹Columbia University & St. Luke's-Roosevelt Hospital, USA, ²St. Luke's-Roosevelt Hospital, USA, ³Columbia University College of Physicians & Surgeons, USA, ⁴Columbia University Medical Center, USA

Quantity of soft tissue may affect bone mineral density (BMD) measurements by dual energy X-ray absorptiometry (DXA). The purpose of the study was to compare the effect of surrounding fat on the measurement of bone density by High Resolution peripheral Quantitative Computerized Tomography (HRpQCT, Scanco Medical AG) and by iDXA (GE-Lunar).

We conducted two experiments, one with a thin lamb diaphyseal bone and 3 layers of lard, each of approximately 0.7-0.8 cm thickness and one with a thick beef diaphyseal bone and 1 layer of lard of 1.5 cm. The bones were scanned, surrounded or not by several layers of lard, 3 times each. Acquisition modes were the standard tibia acquisition for HRpQCT and whole body scan mode for iDXA.

On the lamb bone (Table), we observed that higher number of lard layers decreased measured areal BMD (aBMD) by DXA and total and cortical volumetric BMD (vBMD) by HRpQCT. The effect of lard was more marked on DXA results. Measurement of cortical thickness was minimally affected by fat. On the thicker beef bone, a single layer of surrounding lard decreased total and cortical vBMD by 4.5% and 6.7% respectively and cortical thickness by 0.3%. In contrast, aBMD increased by 7.4% with a layer of lard.

In conclusion, measurements of BMD were slightly affected by the amount of fat tissue surrounding bone, whether assessed three-dimensionally by HRpQCT or two-dimensionally by DXA. The effects of surrounding fat on DXA measurements were substantially greater than on HRpQCT measurements. A future analysis on a diaphysis will allow us to study the effect of surrounding fat tissue on trabecular density and microarchitecture. The discrepancy observed between the effect of fat on aBMD of thin lamb and thick beef bones by DXA requires further investigation

Areal and volumetric BMD of lamb bone surrounding by different layers

	mean value no. layer	% difference from no. layer

DXA and HR-pQCT Detect Minimal Bone Loss After Kidney Transplantation with Early Corticosteroid Withdrawal. Lucas Nikkel^{1*}, Chivuan Zhang², Sumit Mohan³, Bekir Tanriover³, David Cohen³, Lloyd Ratner³, Geoffrey Dube³, Stephanie Boutroy¹, Xiaowei Liu³, Donald McMahon³, Elizabeth Shane³, Thomas Nickolas¹. ¹Columbia University Medical Center, USA, ²Columbia University, USA, ³Columbia University College of Physicians & Surgeons, USA

With corticosteroid (CS)-based immunosuppression, areal bone mineral density (aBMD) declines by 4-9% during the first 3-6 months (m) after kidney transplant (KTx), particularly at trabecular (Tb) rich sites, such as the lumbar spine (LS). Moreover, fracture rates are very high at both spine and hip. Early corticosteroid withdrawal (ECSW) protocols, primarily based on calcineurin inhibitors (CNI), are increasingly utilized for immunosuppression after KTx. We hypothesized that KTx recipients managed with ECSW would not experience significant bone loss.

Included were KTx recipients ≥18 yrs and managed with ECSW after 4 days of induction solumedrol. At baseline, 3m and 6m post-KTx, we measured aBMD by dual energy X-ray absorptiometry (DXA) at predominantly Tb sites, including the LS and ultradistal radius (UDR), and cortical (Ct) sites, the total hip (TH), femoral neck (FN) and 1/3 radius (1/3R). High resolution peripheral quantitative computed tomography (HR-pQCT; XtremeCT; Scanco Medical, voxel size=82µm) was used to measure total, Ct and Tb volumetric BMD (vBMD); Ct thickness (CtTh); and Tb number (TbN), thickness (TbTh) and separation (TbSp) at the distal radius (RAD) and tibia (TIB). Comparisons were made using paired T-tests; results are expressed as MeansSD.

Of 55 subjects enrolled, 26 and 16 completed 3m and 6m of observation respectively. Age was 5013 years; 31% were women and 73% were white. BMI was 297 Kg/m². Mean baseline T-Scores were > -2.5 at all sites. At 3m, aBMD declined significantly only at the TH (-1.6%, p<0.001; mean T-score decrease -0.2SD, p<0.001), with recovery by 6m (p=0.15 compared to baseline). However, 6m UDR aBMD decreased by -3.7% (p<0.01; mean T score decrease -0.3SD, p<0.01). By HR-pQCT at 6m, RAD total vBMD decreased by -1.6% (p=0.03), Tb vBMD decreased by -2.6% (p=0.003), TbTh decreased by -5.6% (p<0.01) and there was a non-significant 1.6% decrease in TIB vBMD (p=0.06). TbN and TbSp were unchanged at both RAD and TIB at 6m.

After KTx, ECSW was associated with minimal bone loss at the LS, FN, TH and 1/3R, lower than previously reported for patients on CS. In contrast, significant bone loss occurred at the UDR. At the RAD, HR-pQCT suggested that Tb bone loss is due to Tb thinning rather than drop out. At the TIB, the mechanism of bone loss was unclear. Larger and longer studies are needed to assess the effects of ECSW protocols on bone mass microstructure and stiffness and fracture rates in KTx recipients.

Disclosures: Lucas Nikkel, None.

Influence of Vertebral Fracture Assessment on Osteoporosis Treatment. Violaine Carcasses^{1*}, Jacques Fechtenbaum², Christine Bonnet³, Pascale Vergne-Salle³, Alexandra Poinas³, Philippe Bertin³. ¹Hospital center, France, ²Centre D'Evaluation, Des Maladies Osseuses, France, ³University hospital center, France

Vertebral fracture is a severe complication of osteoporosis. Despite its common severity and its value to predict further osteoporotic fractures, vertebral fractures (VF) are underdiagnosed. Performing spine radiographs in all patients screened for osteoporosis is not thinkable according to time and cost parameters. With the last generation of dual energy X-ray absorptiometer, thoracic and lumbar spine scan are possible. Evaluation of vertebral fracture status on these images is called Vertebral Fracture Assessment (VFA). At present the place of VFA is not well definite in Europe in osteoporosis management and more specially in postmenopausal osteoporosis management.

The aim of the study was to evaluate if VFA among postmenopausal osteopenic or osteoporotic women naive of osteoporosis treatment could change therapeutic management according to french osteoporosis recommendations published in 2006.

Methods : This prospective study was realized from January to June 2010, on osteopenic or osteoporotic postmenopausal women, aged from 50 to 80 years old, referred for bone mineral density testing. Fracture evaluation (L4-T7) was performed semi-quantitatively using the Genant classification. Classic osteoporotic risk factors (tobacco use, age of menopause, personal and family history of fragility fracture..) were listed. Patients with neoplastic history, corticosteroid significant traitement or prior VF were excluded. Spine radiographs was made in case of VF or incertain diagnostic to confirm it and to eliminate secondary etiology.

Results : 42 patients were included. The percentage of readable vertebrae was 94.8% and prevalence rate fracture was 7%. For 5 patients VFA was considered as non informative due to unreadable vertebrae. For 37 patients, we could identify those with (3 patients (7%)) or with not (34 patients (81%)) management change. The management change consisted in anti-osteoporotic treatment indication thanks to VF diagnostic. The table summarize the densitometric status and impact of VFA on therapeutic management for the 37 patients.

Conclusions : we confirmed the easy realisation of this exam as a daily practice with a good percentage of readable vertebrae notably. The small effective and the low VF prevalence rate contributed to underestimate the main objective. Nevertheless 7% of the population included did profit of therapeutic proposition thanks to this exam and VF diagnostic which is consequent.

	Osteopenia	osteoporosis	All
Change therapeutic management	1	2	3
No change therapeutic management :			
- Treatment recommended before VFA	2	6	8
- No treatment confirmation	21	5	26

Table : Osteoporosis was defined by a T score at the lumbar spine or hip < -2.5; osteopenia by a lowest T score at the lumbar spine or hip between -2.5 and -1.

Disclosures: Violaine Carcasses, None.

Measurement of Bone Mineral Density and Bone Mineral Content Under an Oxford Hemi-Knee Arthroplasty Device – Precision Study. Allison Heard¹, Gary Hooper², Rachel March¹, Rod Maxwell², Christopher Frampton³, Ian Penny², Nigel Gilchrist^{4*}, Patricia Maguire¹. ¹CGM Research Trust, Christchurch, New Zealand, ²Department of Orthopaedic Surgery, Christchurch Hospital, New Zealand, ³Department of Medicine, Christchurch School of Medicine & Health Sciences, University of Otago, New Zealand, ⁴Department of Orthopaedic Medicine & Surgery, Christchurch Hospital, New Zealand

Introduction: Uni-compartment knee replacements are becoming more common. It is proposed that they preserve more bone, are less painful; require a shorter hospital stay with improved function and recovery, compared to total knee replacements. The development of the Lunar i-DXA bone densitometer with near xray quality images and better resolution enabled us to measure areas around the tibial component of an Oxford hemi-knee arthroplasty.

Methods: The study used the Lunar i-DXA densitometer with Version 13.1 software. A developmental orthopaedic knee software was used to complete and analyse tibial component bone mineral density (BMD) in each patient. Ethics Committee approval was obtained. Both knees in 20 patients were measured 3 times in the supine position with repositioning between each scan. The patient was centred on the table parallel to the long axis of the table with the patella upwards. Foam cushions were positioned under the scanned knee to flex the knee so that the tibial base plate was perpendicular to the direction of the beam, the ankle was then strapped. The i-DXA measurement commenced 10cm below the patella. We chose 7 regions of interest to evaluate the bone density under and beside the implant. Areas 1 and 2 were directly under the implant and the other areas were either adjacent or distal to the implant. Once a template was established this was used on the contra lateral knee, which was also scanned and compared.

Results: Twenty patients with the mean age of 69 years (13 females and 7 males) were scanned. Small but significant differences between the implant and non-implanted knee were noticed with the non-implanted knee having slightly higher BMD and bone mineral content (BMC) in areas 1 – 3 (p = <0.001) and area 6 (p = 0.002). There was higher BMD in area 4 (p = 0.028). The precision for BMD in the 7 areas of interest in the implanted knee varied between 0.55% - 4.04% and BMC 1.8% - 5.3%. There was no significant difference in the precision between the non-implanted and implanted knees.

Conclusion: We have established that with a dedicated knee software using i-DXA we can obtain very accurate and precise measurements of BMD and BMC underneath and around an Oxford hemi-knee replacement. We have a prospective study underway to assess the issue of stress loading and bone loss or gain, adjacent to these implants before and after surgery.

SU0331

The Prevalence of Vertebral fractures in Irish patient attending for Dual Emission X-ray Absorptiometry (DXA) using Lateral Vertebral Assessment (LVA). Bill Walsh¹, David Crosby¹, Kara Fitzgerald², Georgina Steen¹, Miriam Casey¹, James Walsh³, Joseph Browne^{*1}. ¹Bone Health & Osteoporosis Unit, St James's Hospital, Ireland, ²Bone Health & Osteoporosis Unit, St James's Hospital, Ireland, ³Trinity College Dublin, The University of Dublin, Ireland

Bone mineral density (BMD) alone underestimates the severity of osteoporosis in patients with previously undiagnosed vertebral fractures. Lateral vertebral assessment (LVA) may be used as a diagnostic tool for the identification of vertebral fractures (VFs) in patients attending for DXA and highlights patients who require additional assessment and treatment for optimal bone health. Additional risk factor assessment may highlight patients who are unaware that they have vertebral fractures.

The LVAs of patients attending for DXA were retrospectively reviewed at an Osteoporosis Clinic in Dublin, Ireland over a 6 year period between 2003 to 2008. An LVA was performed from T4 to L4 using a GE Lunar Prodigy DXA. Deformities were reviewed by 2 trained reviewers independently.

4248 patients attended for DXA and 152 (3.7%) patients excluded due to issues analysing their LVAs. Of the remaining 4096 patients (818 (19.96%) men and 3278 (80.04%) women), the mean age was 65.13 (+/-16.98) yrs (age range: 18 – 102). 3390 (63.35%) patients were 60 years or older. Semiquantitative measurements of the LVAs identified 664 (16.2%) patients with VFs with T8, T12 and L1 being the most common vertebrae to be fractured. VFs were more prevalent in older groups ($P < 0.001$). Younger male patients (40-49, 50-59 and 60-69 year old groups) had a higher prevalence of vertebral fractures compared to similar aged female patients ($p=0.02$, $p=0.001$ and $p=0.022$, respectively). Older female patients had a higher prevalence of VFs, with 45.08% women over 90 years identified with at least one VF. Patients with a history of a low trauma hip fracture had the highest prevalence of VFs (38.1%; age-adjusted OR 1.74, 95% CI 1.32 – 3.02; $p<0.001$), although they were comparatively older ($p<0.001$). Patients with a history of glucocorticoid use had a higher vertebral fracture prevalence and the risk increased two-fold over similar age-matched patients who were not on glucocorticoid therapy (OR 2.04, 95% CI 1.83 – 2.21, $p<0.01$). Other osteoporosis risk factors such as smoking, height loss and reduced BMI were associated with VFs ($p<0.001$).

There is a high prevalence of vertebral fractures identified on LVA in patients who attended our unit for DXA examination, particularly in those with significant risk factors for osteoporosis such as a previous fracture or a history of glucocorticoid use. Lateral vertebral assessments should be performed on all patients attending for a DXA scan.

Utility of FRAX and Q-fracture in the evaluation of T2DM patients. Pedro Rozas-Moreno¹, Rebeca Reyes-García², Antonia García-Martín^{*2}, Ines Luque-Fernandez², Miguel Aguirre³, Manuel Munoz-Torres⁴. ¹Endocrinology Division, Hospital General de Ciudad Real, Ciudad Real, Spain., Spain, ²Bone Metabolic Unit (RETICEF), Endocrinology Division, Hospital Universitario San Cecilio, Granada, Spain., Spain, ³Endocrinology Division, Hospital General de Ciudad Real, Ciudad Real, Spain., Spain, ⁴University Hospital, Spain

CONTEXT: The World Health Organization fracture risk assessment tool (FRAX) is implemented in several guidelines and most widely used at present, although the presence of diabetes is not included as a risk factor. Q fracture includes the presence of

diabetes, and could be better in the evaluation of patients with diabetes. Our objective was to evaluate the performance of FRAX tool and Q-fracture in a group of T2DM patients.

DESIGN, SETTING AND STUDY SUBJECTS: Cross-sectional study including 78 patients with T2DM. Lumbar spine and femoral BMD were measured by dual X-Ray absorptiometry (Hologic QDR 4500). Ten-year major osteoporotic fracture risk and hip fracture risk were calculated using FRAX tool and Q fracture. Results were analyzed using SPSS 15.0.

RESULTS: Mean age was 57.8 years (57.86.4). 44.8% were females (n=35) and 55.2% males (n=43). 22.4% of patients have densitometric criteria for osteoporosis and 9% had a previous fracture. Prevalent radiographic vertebral fractures were detected in 27.7%. Medium FRAX index was 2.521.95 for major osteoporotic fractures and 0.350.40 for hip fractures. If BMD values was added to calculation medium FRAX index was 2.772.38 for major osteoporotic fractures and 0.350.59 for hip fractures. There were no differences between medium FRAX index calculated with or without BMD. When treatment thresholds were applied (7% ten-year probability for major osteoporotic fracture and 3% ten-year probability for hip fracture) few patients were selected for treatment. 2.6% of patients had a ten-year probability for major osteoporotic fracture >7% and the percentage raised to 5.1% when femoral neck BMD was added ($p = 0.002$). No patients had a ten-year probability for hip fracture >3% and 2.6% meet criteria when femoral neck BMD was added. Using Q fracture, 3.8% of patients had high risk fracture and 1.3 % high risk of hip fracture.

CONCLUSIONS: In our group of T2DM patients a low percentage of T2DM patients are selected for treatment by FRAX tool or by Q fracture despite the high risk of fracture demonstrated by high vertebral fracture rate. Additional studies are needed to establish the performance of those scales in the evaluation of fracture risk in T2DM patients.

Disclosures: Antonia García-Martín, None.

Assessment of Microarchitectural Parameters in Transiliac Bone Biopsies of Females and Males with Fragility Fractures. Angela Trubrich^{*1}, Christian Muschitz², Roland Kocian³, Christina Bittighofer⁴, Thomas Pirker⁵, Thomas Gross⁶, Philippe Zysset⁷, Heinrich Resch⁸. ¹Austria, ²St. Vincent's Hospital, Austria, ³St. Vincent Hospital Vienna, Austria, ⁴Krankenhaus Barmherzige Schwestern, Austria, ⁵The VINFORCE Study Group - St. Vincent Hospital - Medical Department II, Austria, ⁶Institute of Lightweight Design & Structural Biomechanics, Technical University Vienna, Austria, ⁷Vienna University of Technology, Austria, ⁸Medical University Vienna, Austria

Purpose: Biomechanical characteristics of bone are not only determined by bone mass, but also by the geometry of cortical and trabecular microarchitecture and intrinsic material properties. Patients who sustain fragility fractures probably have reduced bone mass and alterations in their bone structure. Furthermore gender specific discrepancies are considered.

Methods: In this retrospective study we evaluated transiliac bone biopsies of 48 male patients (aged 18 to 71 years) and 36 female patients (aged 17 to 73 years), who sustained fragility fractures. All Samples were analysed by micro-tomographic imaging system (μ CT40, Scanco Medical AG, Brüttisellen, Switzerland). The following morphometric indices were determined: VOX-TV, VOX – BV, VOX-BV/TV, Conn-Dens., TRI-SMI, Dt-TbN, Dt-TbTh, Dt-Tb Sp, Dt-Tb(1/N).SD, Dt-Tb TH SD, Dt-Tb Sp SD, Apparent Density and Tissue Density. The total group was divided into age-related quartiles (<35.9; 35.9 – 43.11; >43.11-<54.71; >54.71yrs) and split in gender groups. Additionally, BMD and T-score of lumbar spine and hip, prevalent fracture status and previous medication were recorded. Laboratory tests did not reveal any evidence metabolic disorder or vitamin D deficiency.

Results: Despite significant differences in BMD of the total hip ($p=0.005$) in the total group we did not find significant gender specific differences in the microarchitectural parameters. Even the age quartiles showed no differences in the indices except the youngest and the oldest quartile. In these subgroups significant gender-specific changes in BMD of the total hip ($p=0.028$) were detected, furthermore VOX-BV/TV ($p=0.035$), Apparent Density ($p=0.041$) and Tissue Density ($p=0.029$) demonstrated significant differences in the youngest subgroup, but not in the other quartiles

Fracture status and previous medication demonstrated no distinctions in the subgroups and the total group.

Conclusions: According to our results we could not obtain significant genderspecific alterations in microarchitectural parameters in males and females with fragility fractures. Nevertheless there were significant changes in the BMD of the total hip. However these result did not correlate with the any values of the microarchitectural parameters. Our findings and the lack of gender specific differences seem to be not due to different patterns of microstructure but due to changes at the material level.

Conception and Validation of a Non-Threshold based Processing and Analysis of Bone Images. Roger Zebaze^{*1}, Ali Ghasem-Zadeh¹, Sandra Iuliano-Burns¹, Kylie King¹, Aloys Mballa², Ego Seeman¹. ¹Austin Health, University of Melbourne, Australia, ²Strax Corp, Australia

Background- Assessment of bone architectural and material composition requires two steps — (i.) image acquisition and (ii.) processing and analyses of the acquired image. Both steps are critical. We propose that difficulties to accurately quantify bone architecture are at least in large part, due to suboptimal image processing. For example, most if not all, image processing algorithms use thresholding at some stage of the processing. However, there is no universally acceptable thresholds that allow robust processing of all images without loss of information given the heterogeneity of bone material composition and structure. We test hypotheses that (i.) accurate segmentation and analysis can be achieved without thresholding (ii.) The results of such processing can be used to more accurately identify individuals with fractures.

Methods- Analyses of the radial density profile around the perimeter of the bone was used to achieve a non-threshold based segmentation of bone into compact-appearing cortex (CC), transition zone (TZ) and trabecular compartment. The algorithm was implemented in a software (StrAx1.0). Micrograph of bone from the hip with differing degree of porosity were collected. HR-pQCT images of 35 women with distal radius fracture (fx; n=35) and their age-matched peers (n=40) were analysed using StrAx1.0 to measure total, cortical and trabecular densities (TvbMD, CtBMD and TrvBMD) and porosity (CtPo) of the total cortex (CC+TZ). Standard HR-pQCT parameters were also measured.

Results- Porosity measured directly from micrographs correlated with porosity measured using StrAx1.0 ($r^2=0.85$). TvbMD, CtBMD and TrvBMD as measured by StrAx1.0 were lower in fx than in non-fx respectively 20.7% $p<0.0001$; 10.3% $p<0.007$; and 55.7% $p<0.0001$. Differences in these parameters between fx and non-fx were also observed with methods but were less TvbMD 15.6% $P=0.01$; CtBMD 1.89% $p=NS$ and TrvBMD 21.6% $P=0.004$. CtPo measured with StrAx1.0 was 14.6% $p=0.007$ higher in fx than non-fx cases.

Conclusion- Bone images can be accurately processed without using thresholding. This approach is robust and allows better identification of individuals at risk for fracture.

Effect of Age on Femoral Neck Bone Strength using Quantitative CT, DXA, and Biochemical Markers of Bone Metabolism of the Normal Postmenopausal Women. Shigeharu Uchiyama^{*1}, Shota Ikegami², Mikio Kamimura³, Yoshiyuki Sasaki⁴, Mitsutoshi Sugano⁵, Yoshikazu Ido⁶, Akiko Takata⁶, Kiichi Nonaka⁷, Toshihiko Imaeda⁸, Yukihiko Hata⁶, Hiroyuki Kato⁹. ¹Shinshu University, School of Medicine, Japan, ²Department of Orthopaedic, Japan, ³Kamimura Clinic, Japan, ⁴Radiology Division, Shinshu University Hospital, Japan, ⁵Laboratory Medicine, Shinshu University Hospital, Japan, ⁶Rehabilitation Center, Shinshu University Hospital, Japan, ⁷Elk Corporation, Japan, ⁸Department of Food & Nutritional Environment, Kinjo Gakuin University, Japan, ⁹Department of Orthopaedic Surgery, Shinshu University School of Medicine, Japan

The risk of femoral neck fracture has been previously assessed by examining the bone mineral density (BMD), bone geometry, as well as certain biochemical markers of bone metabolism. For effective assessment of the risk of fragility fracture, these different methodologies should preferably be combined. Thus, this cross-sectional study aimed at assessing the age-related trends in hip structure analyses using quantitative computed tomography (QCT), 12 biochemical markers of bone metabolism, and dual-energy X-ray absorptiometry (DXA)-derived BMD. [Methods] We recruited 79 healthy postmenopausal women who did not have any history of systemic diseases or fragility fractures. QCT of the femoral neck was performed, and the images were analyzed using Mindways QCT-PRO BIT software. The total cross-sectional area (total CSA), cortical cross-sectional area (cortical CSA), and average cortical thickness (ave cort thick) were considered as the geometrical parameters and measured; and the cross-sectional moment of inertia (CSMI), section modulus (SM), and buckling ratio (BR) were calculated as the measurements of bending strength and risk of buckling. DXA-derived BMDs of the proximal femur and lumbar spine were also calculated. Serum bone-specific alkaline phosphatase, osteocalcin, and under-carboxylated osteocalcin; serum and urinary pentosidine; plasma homocysteine, whole parathyroid hormone (wPTH), 1,25-(OH)₂ vitamin D, and 25-(OH) vitamin D; serum tartrate-resistant acid phosphatase 5b (TRACP); and urinary deoxypyridinoline (DPD) and N-terminal cross-linked telopeptide of type I collagen were measured as the biochemical markers of bone metabolism. Regression analysis was used to measure the effect of age on all the geometric and mechanical parameters and biochemical markers. In addition, correlation of each parameter was evaluated. [Results] DXA-derived femoral neck BMD, cortical CSA, ave cort thick, CSMI, and SM had significantly negative correlations with age and significantly positive correlations with BR. Those correlations were weak to moderate. Age did not affect

the total CSA ($p = 0.75$). A wide range of values for BR were observed when the BMDs were low. TRACP, serum pentosidine, homocysteine(weak) and DPD (moderate) were positively correlated with age. None of the biochemical markers were correlated with CSMI or SM. BR had weak positive correlation with TRACP or osteocalcin. Data obtained in each decade are presented in the table. [Conclusion] The geometric and mechanical parameters of femoral neck QCT, and the biochemical markers are affected by age, but correlation is weak to moderate. Further studies are required to assess whether DXA and QCT when used with the biochemical markers of bone metabolism can provide a more detailed risk assessment of bone fragility fracture.

Ethnic Variability in Bone Geometry as Assessed by Hip Structure Analysis: Study of Women Across the Nation (SWAN). Michelle Danielson^{*1}, Thomas Beck², Yinjuan Lian¹, Kristine Ruppert¹, Gail Greendale³, Arun Karlamangla³, Jane Cauley⁴. ¹University of Pittsburgh, USA, ²Quantum Medical Metrics, LLC, USA, ³University of California, Los Angeles, USA, ⁴University of Pittsburgh Graduate School of Public Health, USA

Racial/ethnic variation in bone mineral density (BMD) does not fully account for differences in fracture rates; indeed, some racial/ethnic groups with lower areal BMD have fewer fractures. This paradox may be explained, in part, by racial/ethnic differences in femoral hip geometry. To test this hypothesis, we conducted Hip Structure Analysis (HSA) on 1942 baseline DXA scans from SWAN participants. Women were pre-/early peri-menopause, mean age 46.4 y, and none were taking hormone therapy. Racial/ethnic composition was: Caucasian (n=966), African American (n=517), Chinese (n=220) and Japanese (n=239). We assessed HSA BMD (g/cm²), cross-sectional area (CSA, cm²), outer diameter (OD, cm), section modulus (SM, cm³) and buckling ratio (BR) at the femoral narrow neck and inter-trochanter regions; neck shaft angle (NSA, °) and neck length (NL, cm) were also measured. Higher values of BMD, CSA and SM are considered protective while higher values of OD, BR, NSA and NL are deemed detrimental to fracture risk. Multiple linear regression models, adjusted for covariates including age, height, weight, menopausal status, physical activity, smoking, dietary calcium, calcium supplement use, vitamin D supplement use, daily alcohol consumption, corticosteroid use, diabetic status, arthritis and study site, were used to compare mean values of HSA measures in each racial/ethnic group to those of the Caucasian referent. NL was adjusted for height only; NSA is not body size dependent so was not adjusted for height and weight. Shown in the Table, African American women had a significantly greater HSA BMD, CSA and SM, a smaller OD and NSA, and a lower BR. Japanese women also had a significantly greater HSA BMD, CSA, and SM and a lower BR. Chinese women had a significantly lower BMD, CSA and SM and a higher BR. These results support that, compared to Caucasian women, African American and Japanese women have greater, while Chinese women have lesser, geometric hip strength, independent of their body

size. We conclude that these geometric differences may help explain the racial/ethnic differences in hip fracture rates generally observed among women. **ACKNOWLEDGEMENTS:** SWAN is supported by NIH/DHHS (NR004061, AG012505, AG012535, AG012531, AG012539, AG012546, AG012553, AG012554, and AG012495). Evaluation of a Novel Approach for Automatic Delineation of Vertebral Contours in Radiographs. Peter Mvsling¹, Kersten Peter², Mads Nielsen², Martin Lillholm³. ¹Synarc Imaging Technologies & University of Copenhagen, Denmark, ²University of Copenhagen, Denmark, ³Synarc Imaging Technologies, Denmark

Purpose: Accurate measurement of vertebral shape is important in the development of novel procedures for quantitative vertebral fracture assessment. The purpose of this work was to investigate the feasibility of a novel, computational, fully automatic approach for measurement of vertebral shape in lateral radiographs.

Methods: We evaluated the technique on a data set of 157 manually annotated radiographs of the lumbar spine. The acquired radiographs were a subset of the Prospective Epidemiological Risk Factor (PERF) study cohort, containing a combination of baseline and follow-up images of postmenopausal women. Manual annotations of the vertebrae were performed by trained, blinded radiologists for the L1-L4 vertebrae. First, the radiologists were requested to place six points corresponding to the vertebra corners and end-plate mid-points. Subsequently, the same radiologist was requested to delineate the full vertebra contour by a polygonal line of an arbitrary number of landmarks. In cases of ambiguity because of double contours, the radiologists were requested to consistently annotate the lower contour. The evaluated technique detects the vertebral outlines in a hierarchical manner, moving from a coarse estimate of the spine alignment to a detailed description of the individual vertebral shapes. The technique was based on a statistical model of the vertebral shape and appearance and centered around a sampling-based segmentation scheme. The technique was evaluated in terms of the average point-to-contour errors and the average error in estimating the posterior, medial, and anterior vertebral heights, with respect to the manual annotations of the radiologists.

Results: Our experiments showed an average point-to-contour error of 0.81 mm (+/- 0.053, SEM), which compares favourably to the current state-of-the-art. Moreover, we were able to estimate the vertebral heights with an average error of 1.36 mm (+/- 0.076, SEM) and a coefficient of variation from the ground truth annotations of 5.1%.

Conclusion: Our experiments showed that the accuracy of the evaluated technique compares favorably to the current state-of-the-art in automatic vertebra segmentation. The automatic procedure was able to estimate the vertebral heights with considerable accuracy. We believe that our technique could be relevant in vertebral fracture detection and in the development of novel, automatic osteoporosis biomarkers based on vertebral morphometry.

Effect of Whole-Body Vibration on Calcaneal Quantitative Ultrasound Parameters in Osteopenic Postmenopausal Women: A Randomized Controlled Trial. Lubomira Slatkova¹, Shabbir Alibhai¹, Joseph Bevene², Queenie Wong¹, Angela Cheung¹. ¹University Health Network, Canada, ²McMaster University, Canada

Purpose: Effect of whole-body vibration (WBV) on calcaneal quantitative ultrasound (QUS) parameters has never been examined. We conducted a 12-month

randomized controlled trial with calcaneal QUS outcomes as prespecified secondary endpoints.

Methods: Postmenopausal women with primary osteopenia not on bone medications were randomized to one of three groups: 0.3g WBV at 90 Hz (90Hz, n=67), 0.3g WBV at 30 Hz (30Hz, n=68) and control (CON, n=67). Participants in 90Hz and 30Hz groups were asked to stand on a WBV platform 20 minutes a day at home and adherence was recorded by each platform. All participants were provided calcium and vitamin D supplements. QUS broadband attenuation (BUA), speed of sound (SOS) and QUS index (QUI) were obtained at the calcaneus at baseline and 12 months using a Hologic Sahara Clinical Bone Sonometer. Between-group differences in absolute 12-month change (final - baseline) in BUA, SOS and QUI were examined using one-way ANOVA with prespecified all pair-wise contrasts at p<0.05, and using intent-to-treat and per protocol approaches. Prespecified subgroups were also examined (≥80% adherent, <65 kg in mass, ≤60 years old or ≤10 years since menopause).

Results: QUS outcomes were missing or compromised in 27 participants due to drop-out (n=7), unattained final measurement (n=4), unsuccessful calibration (n=7), invalid measurement (n=7) or taking hormone therapy during study (n=2), and were thus imputed in the intent-to-treat approach but excluded from per protocol analyses (90Hz, n=58; 30Hz, n=60; CON, n=57). Median adherence to WBV ranged between 65-79% depending on definition used. After 12 months of WBV, BUA decreased in 90Hz (-0.4 dB·MHz⁻¹ / -0.2%) and 30Hz (-0.7 dB·MHz⁻¹ / -0.6%) groups and increased in controls (1.3 dB·MHz⁻¹ / 2.0%), leading to a significant between-group difference using the intent-to-treat but not per protocol approach. Pair-wise contrasts revealed significant decreases in BUA in 30Hz versus CON group using both intent-to-treat and per-protocol analyses, and in 90Hz versus CON group in the ≥80% adherent and <65 kg subgroups. Changes in SOS and QUI were similar between groups.

Conclusions: WBV produced statistically significant though clinically small decreases in calcaneal BUA in osteopenic postmenopausal women. Future studies are needed to confirm these unanticipated findings and to elucidate potential mechanisms.

Quantitative Ultrasound for Bone Loss at a Critical Fracture Site; the Distal Radius. Frederick Serra-Hsu¹, Jiqi Cheng², Yi-Xian Qin³. ¹State University of New York, Stony Brook, USA, ²SUNY Stony Brook, USA, ³State University of New York at Stony Brook, USA

In the US, osteoporosis is responsible for nearly 1.5 million fractures annually. The most typical fracture sites are the hip, spine, wrist (distal radius) and ribs. [NOF.org, 2005] Osteoporosis is characterized by a silent painless bone loss and alteration of bone micro-architecture. Mass loss and architecture changes result in altered load distribution through bone. Quantitative ultrasound (QUS) at the calcaneus has been shown to correlate well to both fracture risk and mechanical properties. [Xia, et al 2005] This research aims to expand QUS to the distal radius, a critical fracture site. Specifically, wave propagation must be investigated to determine which QUS parameters, if any can provide the most accurate picture of bone health. Le Floch et al. in 2008 showed that 2D simulated ultrasound propagation through a slice of the distal radius can yield ultrasound parameters that are related to structural properties of the bone. Here we have taken 23 fixed cadaver distal forearms for analysis. Structural properties were obtained with a SCANCO vivaCT. Wave3000 software was used to perform 3D wave propagation simulations to obtain theoretical QUS parameters that can be correlated to internal structural parameters. Simulations were run at 5 different angles of penetration. After simulations the cadaver forearms were scanned with current scanning QUS technology at the same penetration angles, and the same ultrasound parameters were calculated. In simulations, Net-Time-Delay and Speed-Of-Sound in bone correlate very well to structural parameters such as SMI, Tb, Sp., and density estimates such as BV/TV. Despite highly linear BUA frequency bands (p<0.001), BUA only moderately correlates to bone properties. At 10 supine penetration R² values for BV/TV to NTD and BUA are 0.84 and 0.50, respectively. Simulations show NTD correlated to SMI (a trabecular layout metric) with greater than R²=0.68 across all angles. Experimental QUS shows reduced predictive capability. At 10 supine penetration R² values for BV/TV to NTD and BUA are 0.22 and 0.16, respectively. NTD remains the best predictor of structural parameters at the wrist. The current data suggest that QUS at the distal radius is subject to complex bone geometry and wave propagation schemes. The data is being investigated for additional metrics of internal structure at this clinical fracture site. Mechanical testing will provide failure loads which can be used to determine true fracture risk predictability.

Ultrasonic Assessment of the Ultra-Distal Radius. Jonathan Kaufman¹, Gangming Luo¹, Xiaowei Liu², Fernando Rosete², Polly Chen³, Mafo Kamanda-Kosse², Donald McMahon², Emily Stein², Elizabeth Shane², Robert Siffert⁴. ¹CyberLogic, Inc., USA, ²Columbia University College of Physicians & Surgeons, USA, ³Columbia University, USA, ⁴The Mount Sinai School of Medicine, USA

The overall objective of this research is to develop an ultrasonic method for non-invasive assessment of the ultradistal radius (UDR). The specific objective was to examine the propagation of ultrasound through the UDR using 3D computer simulations, and to determine the relationships between bone mass and ultrasound, as well as the ability of ultrasound to discriminate between fracture and non-fracture cases. High-resolution peripheral-QCT (HR-pQCT) 3D images were obtained from a set of 110 adult female subjects that were part of a larger study on osteoporosis. Twenty-three of the subjects had experienced a UDR fracture within the past two years; the other 87 subjects served as age-matched controls. Each 3D image was used to simulate ultrasound measurements that would result from propagation through the UDR, from its posterior to its anterior surfaces. The simulation was carried out using Wave3000 (CyberLogic, Inc., New York, USA), which solves the full 3D viscoelastic wave equation using a finite difference time domain method. Bone mineral density at the UDR associated with each subject was computed from the HR-pQCT image and also determined using DXA at the UDR. An ultrasound parameter, known as the net time delay (NTD) was evaluated using the simulated measurements. NTD has been shown to be highly correlated with total bone mass in both *in vitro* and clinical studies. The *t*-test and area under the receiver operating characteristic (ROC) curve (AUC) were used to assess the ability of ultrasound to distinguish between fracture and non-fracture cases. Significant correlation was found between NTD and total bone mass (Fig. 1, $R^2=0.91$, $p<0.001$). The data also showed a statistically significant difference in ultrasound derived parameters for the fracture and non-fracture cases. In particular, the NTD ($t=3.80$) discriminated the fracture and non-fracture cases better than DXA ($t=2.95$), but not as well as the volumetric trabecular BMD as determined by HR-pQCT ($t=4.35$). However, when NTD was combined with a measure of UDR size (NTD/size), it provided the highest *t*-value of all ($t=4.60$). The AUC of the NTD/size, HR-pQCT trabecular density and DXA-UDR were 0.79, 0.78, and 0.74, respectively. On-going work involves imaging additional subjects with HR-pQCT and DXA-UDR, and obtaining clinical ultrasonic data with a new desktop device. This study suggests that bone mass and fracture risk can be assessed through ultrasonic measurement of the UDR.

Fig. 1. BMD as determined by HR-pQCT vs. the ultrasonic NTD.

Bone Mineral Density Is Cross Sectionally Associated with Cartilage Volume in Healthy, Asymptomatic Adult Females: Geelong Osteoporosis Study. Sharon Brennan¹, Julie Pasco², Flavia Cicuttini³, Margaret Henry⁴, Mark Kotowicz⁵, Geoff Nicholson⁶, Anita Wluka⁷. ¹Department of Epidemiology & Preventive Medicine, Monash University ²Northwest Academic Centre, Department of Medicine, The University of Melbourne, Australia, ³Deakin University, Australia, ⁴Department of Epidemiology & Preventive Medicine, Monash University, Australia, ⁵School of Medicine, Deakin University, Australia, ⁶Barwon Health, Australia, ⁷Rural Clinical School Research Centre I School of Medicine I The University of Queensland, Australia, ⁷Monash University & Alfred Hospital, Australia

Purpose: The association between osteoporosis and osteoarthritis is controversial. Whilst previous studies have shown an association between bone mineral density (BMD) and cartilage volume to be positively associated, and some data exist of the relationship between local BMD and knee structures, the association between distant site-specific measures of BMD and other knee structures is unknown. The aim of this study was to determine the associations between BMD at eight skeletal sites and knee structure in asymptomatic young to middle-aged females without any clinical signs of osteoarthritis.

Methods: One hundred and sixty healthy, females (29-50yr) without symptoms of osteoarthritis underwent magnetic resonance imaging of the knee. BMD was measured at the spine, hip, total body and forearm by dual energy x-ray absorptiometry, and SoS, BUA and SI were measured at the calcaneus by quantitative ultrasound (QUS). BMD was tested for an association with cartilage volume, defects, and bone marrow lesions (BMLs).

Results: Medial cartilage volume was positively associated with BMD at the total body, femoral neck, and Ward's triangle (all $p<0.05$). Non-significant associations in the same direction existed at the spine ($p=0.07$), and trochanter ($p=0.10$). Findings in the lateral compartment were similar. The presence of medial cartilage defects showed a non-significant association with BMD at the spine ($p=0.05$). BMD was not associated with lateral cartilage defects or BMLs. No associations were observed with QUS measures at the calcaneus.

Conclusions: Whilst site-specific BMD is associated with cartilage volume at the knee in asymptomatic females aged 29-50yr, peripheral BMD measures, and QUS measures of the calcaneus, showed no associations with knee structure. These data suggest that the association between cartilage volume and axial/ lower limb BMD may relate to common local, possibly biomechanical, factors.

Bone Mineral Density Screening and Osteoporosis Rates in Veterans. Robert Adler¹, Joanne LaFleur², Jonathan Nebeker³, Candace Hayden³, Scott DuVall³, Thomas Ginter³. ¹McGuire VA Medical Center, USA, ²University of Utah, USA, ³VA Salt Lake City Healthcare System, USA

Background: Osteoporosis is under-recognized and under-treated in men.

Purpose: The purpose of this analysis was to characterize the prevalence of bone density (BMD) screening among veterans age 65 and older and, among screened veterans, to estimate the prevalence and incidence of osteoporosis and osteopenia.

Methods: We identified all veterans age 65 and older in the Veterans Integrated Service Network (VISN) 19, the Rocky Mountain Region of the United States, who had outpatient encounters between 1999 and 2008 using administrative datasets. The date of the first outpatient encounter identified after age 65 was defined as the index date. For identified patients, BMD screening results were captured from radiology report using natural language processing (NLP) tools.

Results: There were 80,516 veterans with outpatient encounters included in the analysis. The mean (SD) age of the cohort was 72.3 (6.4). The prevalence of BMD screenings as of baseline was 0.23%. In the follow-up period, 1,471 patients (1.8%) went on to have BMD screens over an average follow-up period of 3.43 years, corresponding to an incidence of 5.3 screenings per 1000 person-years. Among screened patients, the mean (SD) T-score was -0.67 (SD 2.63). The incidences of osteoporosis and osteopenia at any site were 11.0 and 202.0 per 1000 person-years, respectively.

Conclusions: Although BMD screening is taking place among men, the rates are low.

Disclosures: Joanne LaFleur, None.

Epidemiologic Study on Osteoporosis in Polish Women: RAC-OST-POL. Wojciech Pluskiewicz^{*1}, Bogna Drozdowska¹, Aleksandra Czekajlo², Władysław Grzeszczak¹, Piotr Adamczyk¹. ¹Medical University of Silesia, Katowice, Poland, ²Nefrolux, Siemianowice, Poland, Poland

Purpose. The aim of epidemiologic study was to establish the prevalence of risk factors for osteoporosis and osteoporotic fractures, assess skeletal status and ten-year fracture risk and therapy used in population studied.

Method. The study was conducted in women aged over 55 y. from a district of Raciborz, Poland. In whole district was 17,500 such women and we randomly selected 10% of them. We collected data in questionnaire and BMD was measured at proximal femur using Lunar DPX (GE, USA). Skeletal status was also established using quantitative ultrasound at hand phalanges using DBM Sonic 1200 (IGEA, Italy); measured parameter Ad-SoS, m/s. Ten-year fracture risk was calculated using FRAX algorithm for US Caucasian and German population, and Garvan nomogram.

Results. 625 women were studied (35.7%). Mean age was 66.377.83 y, menopause 48.984.82 y, height 155.55.99 cm, weight 75.514.15 kg, BMI 31.235.53 kg/m². Osteoporotic fracture was reported by 176 women (28.16%), and forearm fracture was the most common (108 fractures). Paternal hip fracture was present in 47 subjects (7.52%). Other risk factors included: falls in last 12 months (324 falls in 211 women, 33.8%), secondary risk factors (n=74, 11.84%), smoking (n=70, 11.36%), rheumatoid arthritis (n=40, 6.4%), steroid use (n=30, 4.8%), alcohol use (n=4, 0.64%). Mean FN T-score was -1.260.92 and total hip T-score -0.481.19. T-score less than -2.5 for FN was in 23 women (3.72%) and for total hip T-score in 59 women (9.54%). Ad-SoS was 1951.254 m/s, T-score -3.421.09, Z-score 0.541.0. Ad-SoS correlated with FN BMD (r=0.30, p<0.0001). Ten-year fracture risk values were for any fracture for US, German, Garvan 12.086.02%, 8.416.1%, 18.113.1%, respectively. For hip fracture adequate values were: 2.444.06%, 2.484.06, 5.379.64%. Ad-SoS negatively correlated with ten-year fracture risk for any and hip fracture (r ranged from -0.145 to -0.225, p<0.0001). Antiresorptive therapy for osteoporosis (excluding HRT) was used in 97 women (15.52%), and the most commonly used was alendronate (n=42, 6.72%). 94 women reported use of calcium (15.04%), 84 vit. D (13.44%). HRT was prescribed in 135 women (21.6%).

Conclusion. In the study was presented the current status of osteoporosis epidemiology in Polish women aged over 55 y.

How Frequent Is Premenopausal Osteoporosis In Clinical Practice?. Alicia Bagur^{*}, Silvina Mastaglia, Diana Gonzalez, Candela Fernandez, Beatriz Oliveri, Carlos Mautalen, Centro de Osteopatías Médicas, Buenos Aires, Argentina

Premenopausal (preMP) osteoporosis (OP) may be idiopathic or due to diseases or treatments that affect bone mineral density (BMD). Aim: To identify the frequency and clinical characteristics of women with preMP OP in clinical practice. We reviewed the clinical records of 61 preMP women who were referred during the last 3 years for evaluation of OP or low BMD to an Institute of Metabolic Bone Diseases. Patients were either self-referred due to concern for the disease or referred from other physician mainly on the basis of a previous BMD measurement. The preMP OP represents ~0.3% of the total number of consultations for OP seen during that period. We analyzed the clinical relevant information such as personal and familiar history of fractures (Fx), BMD, biochemical bone markers, the final diagnosis and their treatments. BMD was considered normal as a Z score above -2.0 in the lumbar spine and/or total femur. Results: 23 out 61 (38%) were in the BMD osteoporotic values. In 9 out of 23 (39%) a diagnosis of idiopathic or primary (1♂) OP was made. Fourteen patients (61%) had secondary (2♂) OP due to the following diseases: pregnancy (3), celiac disease (2), hypercalciuria (2), 1♂ hyperparathyroidism (1), anorexia nervosa (1), hypothalamic amenorrhea (1), glucocorticoid (1), osteogenesis imperfecta (1), excess of T4 (1), and congenital adrenal hyperplasia (1). None of the women with 1♂ OP had Fx. Four out 14 women (29%) with 2♂ OP had Fx at the following site: wrist (2), vertebrae (1), and metatarsal (1). Five (55%) of the 1♂ OP women and 3 (21%) with 2♂ OP had a familiar history of Fx. The only differences between 1♂ and 2♂ OP were: Age was lower in 2♂ vs 1♂ OP (29.29 vs. 42.06, p<0.0001 respectively) and serum calcium was lower in 1♂ vs. 2♂ OP (9.10.3 vs. 9.50.3, p<0.03 respectively). PTH, 25OHD, CTX and BAP were similar in both groups. The 1♂ OP patients received the following treatments: Calcium and vitamin D (Ca+D) (6), bisphosphonate (B) (2), without treatment (1). Secondary OP patients received: Ca+D and

treatment according to the underlying disease. The PreMP visits represent ~0.3% of the total number of consultations for OP in our Center. Less than a half of preMP women who consult to evaluate their BMD have OP and ~40% of them are idiopathic. In the remaining 60% 2♂ OP was recognized. It is therefore important to rule out diseases and drugs that can affect BMD in these young women.

Occurrence of Falls in Elderly People in Brazil, There Is Something that Health Professionals Can do to Avoid?. Thais Braga, Roberto Queiroz, Fabiana Fonseca^{*}, Bianca Segantin, Manuela Santos, Ursula Karsch, Ana Elisa Segantin. PUC - SP, Brazil

According to a study conducted by the health department of the state of Sao Paulo between 2000 and 2008 rose from 7,600 to 28,400 the number of deaths per year in the elderly due to falls. This field study aimed to describe the occurrence of falls during the 01 years before the current fracture, in 40 elderly patients aged from 60 years in 2010 in the pre-operative femur surgery at the Hospital Server Public State of Sao Paulo. 77% of seniors reported that they often fell, and 32% of this group of elderly people suffered fractures different from today, over 05 years. Suggest specific and complex tests for balance and posture. Identify the possibility of falling is the duty of the health professional in order to have effectiveness in preventing falls and even decreased mortality of elderly individuals and our duty to the possible improvement of the quality of the biopsychosocial and elderly community.

Sclerostin is Associated with Age, BMI and Bone Mineral Content, but not Gender or Physical Activity in Healthy Adults. Karin Amrein^{*1}, Astrid Fahrleitner-Pammer², Steven Amrein³, Camilla Drexler⁴, Hans Dimai², Thomas R. Pieber⁵, Andreas Tomaschitz⁵, Harald Dobnig⁶. ¹Medical University of Graz, Austria, ²Medical University Graz, Austria, ³Medical University of Graz, Austria, Department of Anaesthesiology & Intensive Care Medicine, Austria, ⁴Medical University of Graz, Austria, University Clinic of Blood Group Serology & Transfusion Medicine, Austria, ⁵Medical University of Graz, Austria, Division of Endocrinology & Metabolism, Department of Internal Medicine, Austria, ⁶Diagnostikinstitut Univ.Prof.Dr.H.Dobnig GmbH, Aut

Introduction

Sclerostin is produced by osteocytes and potently inhibits bone formation through the Wnt/Ö-catenin signalling pathway. While the potential of sclerostin inhibition with a monoclonal antibody (Scl-Ab) is currently under investigation, limited data is available on the association of circulating sclerostin levels with important clinical parameters such as age, gender and bone mineral density (BMD) in humans.

Objective

We aimed to evaluate the gender specific distribution of circulating sclerostin levels and its correlation to age, BMD and physical activity (PA) in healthy adult men and premenopausal women with normal renal function.

Methods

In 161 healthy adults (21% premenopausal women) aged 19 to 64 years, serum sclerostin levels were measured with a quantitative sandwich enzyme-linked immunosorbent assay (Biomedica, Vienna, Austria). Body composition and BMD were measured by DXA (GE Lunar) and physical activity was assessed by a standardized questionnaire.

Results

The mean serum sclerostin level was 47.1 17.8 pmol/L (range 17.8 to 114.4). As shown in Figure 1A and 1B, there was a positive correlation between age and sclerostin in both men (r=0.37; p<0.001) and premenopausal women (r=0.66; p<0.001). Men had significantly higher sclerostin levels than women (49.8 17.6 vs. 37.2 15.2 pmol/L, p < 0.001), however, after adjustment for age and bone mineral content the difference of sclerostin levels did not reach statistical significance (47.3 in men vs. 46.4 pmol/L in women, p=0.817). Overall, we did not find a relevant association between the degree of physical activity and sclerostin levels. Partial correlation analysis revealed a significant positive correlation between sclerostin levels and bone mineral content (BMC), BMD at the lumbar spine and the left hip and body mass index (age and gender adjusted correlation coefficients 0.235, 0.215, 0.266 and 0.228 respectively), but not between sclerostin levels and estimated glomerular filtration rate.

Conclusion

Our data demonstrate that there is a significant relationship of serum sclerostin levels with age, BMI and BMD. Surprisingly however, no significant association between sclerostin and gender or PA was seen in this healthy population. Further studies are needed to confirm our findings and to evaluate whether circulating sclerostin levels accurately reflect sclerostin activity on tissue level.

The Relationship Between Inflammatory Bowel Disease and Bone Mineral Density. Results of a Population-Based Study. Laura Targownik*, Zoann Nugent, Charles Bernstein, William Leslie. University of Manitoba, Canada

Introduction: Patients with inflammatory bowel disease (IBD) are at higher risk of osteoporosis and related fractures. Most studies on IBD and BMD are from selected referral centres and do not delineate what aspects of IBD contribute to lower BMD

Methods: We created a linkage between the University of Manitoba IBD Epidemiologic Database, and the Manitoba BMD Database, which respectively capture virtually all persons in Manitoba, Canada, with diagnosed IBD and all persons with clinical DXA measurements, respectively. BMD was assessed at each of the lumbar spine (L1-L4), total hip, femoral neck, and greater trochanter. Multivariate linear and logistic regression were performed to determine the independent effect of an IBD diagnosis on T-scores and on the likelihood of having an osteoporotic T-score (-2.5 or lower) at each of the four BMD sites. We developed both a partially adjusted model (for age, sex, and body mass index [BMI]) and fully adjusted model (additionally adjusted for hormone replacement therapy [HRT], osteoprotective therapy [OTX], and recent systemic glucocorticoid [GC] use).

Results: 45714 patients age 20 and older underwent baseline BMD testing between 1997 and 2008, 1230 of whom had IBD. Compared with non-IBD subjects, subjects with IBD were more likely to be younger, male, and have lower BMI. IBD patients were significantly more likely to be recent GC users (26% vs 6%). When adjusted for age, sex, and BMI, IBD was associated with lower T-scores at each of the four assessment sites (Table 1). IBD was also associated with having an osteoporotic T-score at the L1-L4 and the total hip (Table 1). However, when the model was further adjusted for exposure to GCs, HRT, and OTX, IBD was associated with only a marginal reduction in T-scores at the total and the greater trochanter. Moreover, IBD

was not associated with a higher risk of having an osteoporotic T-score at any of the four sites in the fully adjusted model.

Conclusion: While patients with IBD are at higher risk for lower BMD and for osteoporosis, this effect is not seen after adjusting for exposure to GCs and other medications. This suggests that the deleterious effects of IBD on BMD are predominantly related to GCs rather than to the IBD itself. Further work is required to delineate the independent effects of IBD, inflammatory activity, and its therapies on BMD and fracture risk.

What Is The Value of Laboratory Testing to Identify Possible Secondary Contributors to Osteoporosis in Older Men? Howard Fink^{*1}, Stephanie Litwack-Harrison², Kristine Ensrud³, Eric Orwoll⁴, Douglas Bauer⁵.

¹GRECC, Minneapolis VA Medical Center, USA, ²San Francisco Coordinating Center, California Pacific Medical Center, USA, ³Minneapolis VA Medical Center / University of Minnesota, USA, ⁴Oregon Health & Science University, USA, ⁵University of California, San Francisco, USA

The value of laboratory testing to identify possible secondary conditions in osteoporotic (OP) men is unknown.

Cross-sectional analyses were performed using baseline data from the MrOS study, a prospective cohort of 5,994 community-dwelling men age ≥ 65 years. Men were defined as having OP by DXA BMD T-score of ≤ -2.5 at total hip, femoral neck, or lumbar spine. Laboratory data were available from 1571 men selected randomly from the cohort. Possible secondary conditions evaluated were low testosterone (total T < 250 ng/dl), vitamin D deficiency (25-OH-D < 20 ng/ml), renal insufficiency (estimated GFR [eGFR] < 60 ml/min/1.73m²), hypercalciuria (urine calcium/creatinine ratio > 0.14), hypothyroidism (TSH > 4.5 mU/L), hyperthyroidism (TSH < 0.5 mU/L), low estradiol (total E ≤ 16 pg/ml), and hyperparathyroidism (intact PTH > 66 pg/ml). Prevalence of each laboratory abnormality was calculated in OP and non-OP groups. Age and weight-adjusted risk (aOR) of each laboratory abnormality as a function of OP status was estimated using logistic regression, overall and in analyses stratified by median age (< 73 vs. ≥ 73 yr) and weight (< 82.6 vs. ≥ 82.6 kg), and by Z-score (< -2.0 vs. ≥ -2.0).

Within the random cohort, 163 men (10.4%) had OP. In these OP men, prevalence of possible secondary conditions varied widely by condition (Table). 64.9% of OP men had at least one laboratory abnormality and 27.6% had multiple abnormalities. However, only vitamin D deficiency (aOR 1.5, 95%CI 1.02-2.1) and low estradiol (aOR 1.8, 95%CI 1.3-2.7) were significantly more common in the OP men. OP men with lower weight also were significantly more likely to have low T (aOR 2.0, 95%CI 1.1-3.7). Only 10 men had a Z-score < -2.0 .

Laboratory testing older OP men identified many abnormalities, but few of these lab abnormalities were significantly more prevalent than in non-OP men. Testing yield may be higher in lower weight men. To further assess the value of laboratory testing in OP men, future studies will need to evaluate whether treatment of possible secondary conditions in OP men reduces fractures, and whether effects of OP treatments differ between men with secondary factors versus those without them.

Table II: Age, Height and Bone Mineral density at proximal femur in women.

	OP %	Non-OP %	aOR (95%CI)
Low T	15.2	13.6	1.5 (0.9-2.3)
Vitamin D deficient	30.7	24.8	1.5 (1.02-2.1)
eGFR < 60	17.1	17.9	0.8 (0.5-1.4)
Hypercalciuria	17.3	12.5	1.5 (0.9-2.3)
Hypothyroid	11.7	9.5	1.2 (0.7-2.0)
Hyperthyroid	2.5	2.0	1.4 (0.5-4.0)
Low E	28.9	18.2	1.8 (1.3-2.7)
Hyperparathyroid	6.2	3.4	1.9 (0.9-4.0)

Bone Mineral Density was Similar in Spanish Medieval Women and Higher in Medieval Men Compared to Actual Spanish Population. Belen Lopez¹, Carlos Gomez^{2*}, Pablo Manrique¹, Ana Gomez¹, Serafin Costilla³, Jorge Cannata Andia⁴. ¹Physical Anthropology, Department of Biology of Organisms & Systems, University of Oviedo, Spain, ²Hospital Universitario Central de Asturias, Spain, ³Department of Radiology, Hospital Universitario Central de Asturias University of Oviedo., Spain, ⁴Hospital Universitario Central de Asturias, Spain

Life span, lifestyle and survival to chronic diseases explain the epidemiology of osteoporosis in the last years. On the other hand bone mass is strongly linked to population genetic load.

Purpose: The aim of the study was to assess the possible differences in bone mineral density between a medieval population and the current Spanish population, both from the northern Spain.

Methods: The medieval skeletons came from the excavation of a cemetery in San Andres del Arroyo (Palencia, Spain) dated on 11th -12th century. From the 98 exhumed people we selected those subjects with 20 years-old or more. We also excluded those with impaired both femora (n = 5) or those with radiological presence of sand inside the bone (n = 4). Age, sex and height of the medieval sample were assessed using standard archaeological methods. For each one of the 37 people finally selected, we randomly chose two age and sex matched controls from our normative database (participants in the Spanish Normative Bone Mineral Density Study). Bone mineral density (BMD) was performed at proximal femur with the same DXA device (Hologic QDR-1000) according to the International Society of Clinical Densitometry rules. Isolated femora were placed in a box with 25 cm height of wheat flour to facilitate their placement and provide a similar soft tissue density around.

Results: Medieval male population had a significant lower height than current controls. Nevertheless BMD values trend to be higher with significant differences in trochanter and total hip (Table I). Medieval female population had also a significant lower height than their current controls (with a more relative difference than in males) but they had a similar BMD at all three regions of interest (Table II). The distribution according to the BMD categories using the WHO classification was similar in both populations. Fractures were present in four medieval men (2 clavicle, 1 vertebra and 1 fibula) and in two medieval women (1 clavicle and 1 vertebra) with no relationship with low BMD. One of the medieval women had bone deformities and histological evidence of osteomalacia.

Conclusions: Bone mineral density is similar in our contemporary women with regards ancestor medieval female population, whereas in males our medieval ancestors had a higher BMD. Perhaps, it could be explained by a more intense physical activity in medieval population and a higher reproductive effort (pregnancy and lactation) in the case of medieval women.

Calcium and Vitamin D intakes in Canadian Youth Ages 16-24 years: the Canadian Multicentre Osteoporosis Study (CaMos). Wei Zhou^{1*}, Lisa Langsetmo², Claudie Berger³, Suzette Poliquin³, David Goltzman¹, Stephanie Kaiser⁴, Jerilyn Prior⁵, Robert Josse⁶, Tanveer Towheed⁷, Tassos Anastasiadis⁷, K. Shawn Davison⁸, Christopher Kovacs⁹, Manny Papadimitropoulos¹⁰, Nancy Kreiger¹¹. ¹McGill University Health Centre, Canada, ²Canadian Multicentre Osteoporosis Study, Canada, ³McGill University, Canada, ⁴Dalhousie University, Canada, ⁵University of British Columbia, Canada, ⁶St. Michael's Hospital, University of Toronto, Canada, ⁷Queen's University, Canada, ⁸Laval University, Canada, ⁹Memorial University of Newfoundland, Canada, ¹⁰Eli Lilly Canada Inc., Canada, ¹¹University of Toronto, Canada

Calcium and vitamin D are nutrients essential for overall health, optimal bone mass, and prevention of osteoporosis and fractures in adulthood. Our objective was to estimate calcium and vitamin D intake among Canadian youth. CaMos recruited 1001 participants ages 16-24, randomly selected from within a 50 km radius of 9 cities across Canada in 2004-2006. A short interviewer-administered semi-quantitative food frequency questionnaire was given at baseline and Year 2 (2006-2008). Calcium intake from both diet and supplements, and vitamin D intake from milk and beverage fortification as well as supplements, were estimated cross-sectionally and longitudinally. Estimates of mean daily intakes for calcium and vitamin D were stratified by sex and age (16-18 years, 19-24 years). The study sample included 487 women and 458 men at baseline, and 396 women and 347 men at Year 2. The mean (standard error (SE)) daily intakes for calcium were 1077 (28) mg for women and 1361 (38) mg for men at baseline, and were 1083 (33) and 1276 (45) mg for women and men respectively at Year 2. For vitamin D, mean (SE) daily intakes were 4.0 (0.2) µg and 6.1 (0.3) µg for women and men respectively at baseline, and were 5.1 (0.3) and 6.6 (0.3) µg at Year 2. Participants reported no vitamin D supplement intake at baseline. Detailed baseline intake by age and sex is shown in Table 1, along with comparison to 2010 IOM dietary reference intakes. Median calcium intakes were above the estimated average requirement (EAR) in men and in women in the younger age group but not in women in the older group. Median intakes of vitamin D were well below the EAR. The resulting prevalence of youth below the EAR ranges from 29% to 47% for calcium, and 71% to 95% for vitamin D. The change of calcium intake in these groups over two years was only different from zero in the younger age group of women, in which calcium intake decreased by 184 (95% confidence interval (CI): 67, 301) mg/day. The mean changes of daily vitamin D intakes were 1.6 (95% CI: 0.7, 2.4) µg in the older group of women and 1.0 (95% CI: 0.2, 1.8) µg in the older group of men; but were not different than zero in the younger group in either sex. We observed a high prevalence of Canadian youth that did not meet the EAR established for calcium and vitamin D in the recent IOM report. Adoption of the new guidelines would have policy implications, as the goal would be to increase intake among those not currently meeting the EAR.

Age (years)	N	Calcium (mg/day) ^b			Vitamin D (µg/day) ^c

Dairy Calcium Intake Accompanied with Higher Intake of Vitamin D Could Efficiently Decrease Body Fat Mass and Increase Lean Mass without Decreasing BMD During Moderate Weight Loss in Normal Weight Young Japanese Women. Takako Hirota^{*1}, Izumi Kawasaki², Kenji Hirota³. ¹Kyoto Koka Women's University, Japan, ²Tsui Academy of Nutrition, Japan, ³Hanwa Sumiyoshi General Hospital, Japan

This study investigated whether intake of dairy calcium or vitamin D affected changes in body fat, lean mass, and bone mineral density (BMD) during weight reduction in normal weight young women.

One hundred female students (ages; 23-25 years, BMI; 21.5-23.3 kg/m², calcium intake; 4741.96 mg/d) who wanted to lose weight were randomly assigned either to drink milk (>200 ml/d; milk group, n=52) before dinner or were given no instructions on milk intake (control, n=48). All were advised to consume a moderately energy-restricted diet and to increase physical activity for 4 months. Their energy intake decrease (-2203.97 kcal/d) and the duration of physical activity were similar between the groups. All were asked to keep a diary of body weight, dairy intake, and physical activity. Baseline milk intake was 1161.15 ml/d. Body fat, lean mass, and BMD by DXA, blood pressure, and serum lipid profiles were measured at baseline and after 4 months.

Moderate energy restriction for 4 months resulted in significant decreases in weight (-0.91.8 kg), L2-L4 BMD, waist and hip circumferences, and blood pressure to the same extent in both the milk and control groups. Serum lipid profiles did not change in either group. Baseline calcium intakes were not associated with body weight, fat, or lean mass. However, body fat mass in the milk group was significantly decreased (-1.242.64 kg cf. -0.363.04 kg in the control group) and the body lean mass was increased (+0.272.03 kg cf. -0.452.62 kg) after intervention. Higher tertiles of milk intake were associated with increased fat mass loss (-0.48, -0.74, and -2.40 kg; p<0.05) and associated with increased lean mass gain (-0.10, -0.08, and +0.95 kg). Higher intake of vitamin D (>200 IU/d; median) increased the additional changes in the highest tertile of milk intake, although vitamin D levels did not affect the control group. The gain in lean mass was strongly correlated with a decrease in fat mass (r=-0.78), and an even stronger correlation (r=-0.85) was observed in the subjects with higher intake of vitamin D. Changes in lean mass were correlated with changes in L2-L4 BMD (p=0.05). The highest quartile of lean mass gain in the milk group did not decrease in L2-L4 BMD.

Intake of higher dairy calcium together with higher vitamin D is recommended to decrease body fat mass and to increase lean body mass without decreasing BMD during weight loss, to help prevent metabolic syndromes and osteoporosis.

Red Blood Cell n-3 and n-6 Fatty Acid Concentrations as Predictors of Inflammatory Markers in The Women's Health Initiative. Steven Ing^{*1}, Tonya Orchard¹, Andrea Lacroix², Charles Kooperberg², Aaron Aragaki², Martha Belury¹, Bo Lu¹, Rebecca Jackson¹. ¹The Ohio State University, USA, ²Fred Hutchinson Cancer Research Center, USA

Background: Inflammatory biomarkers, tumor necrosis factor-α soluble receptor (TNFα-sR) 1 and 2 are positively associated with incident total fracture. Diets high in n-3 polyunsaturated fatty acids (PUFA) may shift the balance of eicosanoid

production leading to decreased inflammation and bone turnover, thereby contributing to lower fracture risk.

Methods: A nested case-control study from the Women's Health Initiative Clinical Trial and Observational Study of hip fracture cases and matched controls (293 pairs matched on age, race, self reported or randomization to hormone therapy, and latitude). Baseline serum TNFα-sR1, TNFα-sR2 concentrations were previously measured and comprise the outcome variables of this study. We measured predictor variables - red blood cell (RBC) concentrations of total n-3, eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA), and alpha linolenic acid (ALA) using gas chromatography in frozen samples obtained at the baseline screening visit. The relationship between predictor and outcome variables was analyzed using a linear mixed model accounting for the paired design.

Results: In 586 cases and controls, TNFα-sR1 (n=271), TNFα-sR2 (n=271) and RBC fatty acid levels (n=208) were available for analysis, in part due to degradation leaving a final sample size of 208. Total n-3 PUFA by tertiles was negatively associated with TNFα-sR1 (p=0.0004) and TNFα-sR2 (p=0.0003). EPA+DHA, but not ALA, was negatively associated with TNFα-sR1 (p=0.0002) and TNFα-sR2 (p=0.0002).

Conclusion: Higher dietary fatty acid intakes of total n-3 PUFA and EPA+DHA are associated with decreased inflammatory markers in postmenopausal women and may modulate hip fracture risk.

Table: Inflammatory markers by fatty acids

Reduced T and Z Scores at the Femoral Neck and Lumbar Spine Are Associated With Increased Dietary Protein Intakes In UK Dwelling South Asian and Caucasian Postmenopausal Women. Andrea Darling^{*}, Kathryn Hart, Susan Lanham-New. University of Surrey, United Kingdom

There is a long standing controversy as to whether dietary protein is beneficial or detrimental to bone health. Dietary protein has known anabolic effects on bone via hormones (e.g.IGF1) and may increase dietary calcium absorption¹. However, high dietary protein intake may also increase physiological acid load and thus may increase urinary excretion of calcium and bone resorption². In Autumn 2006, n=38 postmenopausal South Asian (mean age 58+/-4 years) and n=138 postmenopausal Caucasian women (mean age 61+/-4.5 years) took part in the D-FINES study. A Dual X-ray Absorptiometry (DXA) scan (Hologic) was undertaken as well as completion of 4 day diet diaries. Relevant anthropometric and lifestyle information and serum 25 (OH)D were also obtained. Partial correlations were run using PASW 18.0 to examine associations between protein intake (adjusted per Kg body weight) and T and Z score bone indices. For the fully adjusted model (model 2), in both ethnic groups there was a significant (p<0.05) negative correlation between protein intake and T scores at the femoral neck (T-FN) and lumbar spine (T-LS), although in Caucasians this was only of borderline statistical significance. Also, for both groups a significant negative association between protein intake and Z scores at the femoral neck (Z-FN) and lumbar spine (Z-LS) was found. In comparison, model 1 shows the data that was not adjusted for micronutrients, which was only statistically significant in Asian for Z-FN and Caucasians for T-FN and Z-FN. There was no significant difference (p>0.05) in protein intake per Kg between the Asian and Caucasian groups (Asian mean= 0.98g/Kg body weight, sd=0.37) (Caucasian mean=1.07g/Kg body weight, sd=0.27). This negative relationship is very surprising considering most epidemiological studies and a recent meta-analysis³ have shown a positive association between dietary protein and bone health. Also, controlling for dietary vitamin C, Na, K, P and Mg (model 2) actually strengthened the association, not weakened it. Overall the strong negative association between dietary protein and bone indices found here in this group of older Asian and Caucasian women was unexpected and has not been examined before in the literature.

Dietary Vitamin D Intake and the Risk of Fracture and Osteoporosis. Greta Snellman¹, Eva Warensjö-Lemming², Liisa Byberg², Karl Michaelsson².

¹Department of surgical sciences, Uppsala University, Sweden, ²Uppsala Clinical Research Center, Sweden

Background: Vitamin D is important for optimal calcium absorption. Since calcium is needed for mineralization of bone, vitamin D insufficiency may lead to osteoporosis and fracture. Whilst supplemental vitamin D can decrease the risk of fracture among old frail women, less is known about the benefit of dietary vitamin D intake in community-dwelling women.

Method: 61,433 women, in the population-based Swedish Mammography Cohort were followed for 19 years. All fractures were identified from registry data. In a sub-cohort of 5,022 women, Swedish Mammography Cohort Clinical, osteoporosis was diagnosed by Dual-Energy-X-ray-Absorptiometry. Diet and supplemental vitamin use was assessed by repeated food-frequency-questionnaires. Associations between vitamin D intake, fracture and osteoporosis were determined.

Results: Mean age of the women at study start was 54 years (range 38-76). Mean vitamin D intake was 4.4 µg (SD 1.3). During follow-up, 14,738 women experienced any type of first fracture, and 3,871 of these were hip fractures. Twenty percent of the women in the subcohort were classified as osteoporotic. The multivariable-adjusted hazard ratio (HR) and 95% confidence interval (CI) for any first fracture were 1.06 (1.01-1.12) for the lowest (median intake 2.8 µg) and 1.07 (1.02-1.13) for highest quintile (median intake 6.3 µg) compared to the third quintile, that was set as a reference. The corresponding values for a first hip fracture were 1.05 (0.94-1.16) and 1.04 (0.94-1.15). The odds ratios for osteoporosis within lowest and highest quintiles of vitamin D intake was 1.03 (0.77-1.38) and 1.01 (0.81-1.27), respectively. Conclusions: We conclude that the dietary intake of vitamin D is of minor importance for the risk of osteoporosis and osteoporotic fractures in Swedish middle aged and elderly women.

Figure legend: Multivariable adjusted spline curve for the association between dietary vitamin D intake and risk of any type of first time fracture.

Final Results from a Population-Based Post-Fracture Intervention Based Upon Administrative Health Data: A Randomized Controlled Trial. William Leslie¹, Lisa Labine², Darlene Drelich², Penny Klassen², Patricia Caetano². ¹University of Manitoba, Canada, ²Manitoba Health, Canada

Post-fracture care is suboptimal and strategies to address this major "care gap" are urgently required. Case management is effective but is resource-intensive and difficult to deliver to a widely scattered population. HYPOTHESIS: Post-fracture mail notification to physicians and/or patients will lead to improved osteoporosis care. METHODS: An RCT (NCT00594789) was conducted across the Province of Manitoba, Canada, from June 2008 to May 2010, in which men and women age 50 or older with recently reported fracture (hip, spine, humerus, and forearm) from medical claims data, and without recent BMD testing (three years) or osteoporosis therapy (last year), were randomized to three groups: Group 1 (control) received usual care; Group 2 (MD only) had mailed notification to the reporting and primary care physicians (alert letter, BMD requisition, management flow chart); Group 3 (MD & Patient) had physician notifications and patient notification (alert letter). BMD testing and/or osteoporosis medication initiation to 12m was documented from population-based data sources. RESULTS: 5,349 fracture patients meeting the inclusion criteria were randomized. Group 1 (usual care) interventions at 12m were 15.3% in women and 6.6% in men (combined 12.3%). There was a significant improvement (P<.001) in all outcome measures for groups 2 (MD only) and 3 (MD & Patient), with no significant differences between Groups 2 and 3 (i.e., no additive benefit from patient notification). At 12m the absolute improvement in interventions for women and men combined was 13.9% (Group 2) and 14.9% (Group 3), with Number Needed to Notify=7. The adjusted odds ratio (aOR) for either intervention in Group 2 was 2.6 (95% CI 2.2-3.1) and in Group 3 was 2.8 (95% CI 2.3-3.3; P=0.409 for Group 2 vs 3). In addition to randomized group, factors associated with treatment initiation included sex (aOR men 0.4 [95% CI 0.4-0.5] versus women), age (aOR age 60-69 1.5 [1.2-1.8], age 70-79 1.7 [1.4-2.1] versus age 50-59) and fracture site (aOR spine 1.7 [1.3-2.0] versus forearm). CONCLUSIONS: This post-fracture intervention, based upon medical claims data, provides an easy way to enhance post-fracture care. The approach is scalable, can be delivered to a widely scattered population, and requires minimal infrastructure. This low cost intervention can complement more resource-intensive programs based on case managers.

Hip Extensor Lean Cross-Sectional Area Is Associated with Incident Hip Fracture: The Age/Gene/Environment Susceptibility Study-Reykjavik. Thomas Lang¹, Sigurdur Sigurdsson², KRISTIN SIGGEIRSDOTTIR³, Gyda Karlsdottir², Gudny Eiriksdottir², Joyce Keyak⁴, Vilundur Gudnason³, Tamara Harris⁵.

¹University of California, San Francisco, USA, ²Icelandic Heart Association, Iceland, ³ICELANDIC HEART ASSOCIATION RESEARCH INSTITUTE, Iceland, ⁴University of California, USA, ⁵National Institute on Aging, USA

Quantitative computed tomography (QCT) provides measures of proximal femoral density, structure and strength that are established predictors of hip fracture. QCT images also provide information on the cross-sectional area (CSA) and attenuation of the muscles surrounding the hip, and these measures may affect fracture risk through both an effect on hip strength and an effect on frailty-related risk factors for falling. There is no information about the association of these measures with incident fractures of the hip. We hypothesized that smaller CSA and lower attenuation would increase hip fracture risk independently of reduced muscle strength and slow gait. We analyzed CT scans of the hip for bone and muscle variables in 4000 subjects aged 65-90 years, 43% of them male, who were enrolled in the Age/Gene Environment Susceptibility Study - Reykjavik, a study of community-dwelling men and women in the Reykjavik area. CT scans were analyzed to obtain the lean cross-sectional area (ECSA) and mean attenuation of the hip extensor group as well as the volumetric bone mineral density of the total hip (vBMD). To assess fall-related measures of physical function and lifestyle, we measured the time to complete the Timed Up and Go (TUGO) test, as well as lifestyle factors including alcohol consumption, smoking, self-reported health status, and physical activity. We computed odds ratios (OR) (per standard deviation (SD) for hip fracture using three multi-variate logistic regression models relating vBMD, ECSA and attenuation to incident hip fracture (Table). Model A was adjusted for age and gender. Model B

added adjustments for height and BMI, and Model C added TUGO and lifestyle factors. Over a 7-year followup, 190 hip fractures occurred. ECOSA and vBMD, but not muscle attenuation, were independent hip fracture predictors in Models A and B. ECOSA was only of borderline significance after adjustment for TUGO and lifestyle factors, while vBMD remained strongly predictive of fracture. In conclusion, a one-SD reduction in ECOSA increased the risk of hip fracture by a third, even when vBMD was taken into account, and lifestyle factors attenuated this relationship. The combination of vBMD with a quantitative muscle assessment assessed from the same scan may improve estimation of hip fracture risk compared to vBMD alone.

	Model A	Model B	C
vBMD	2.30 (1.91, 2.79)	2.28 (1.88, 2.77)	2.11 (1.73, 2.58)
LCOSA	1.32 (1.05, 1.63)	1.32 (1.04, 1.71)	1.23 (0.94, 1.60)

Table: OR for Hip Fracture (95% Confidence Interval) per one SD decrease

Hospitalizations for Hip Fractures and Femur Fractures below Trochanter Follow Similar Trends in Women. Kurt Lippuner¹, Lisa Strahm¹, Albrecht Popp¹, Patrick Schwab², Christoph Senn¹, Romain Perrelet¹. ¹Osteoporosis Polyclinic, University of Bern, Switzerland, ²Swiss Federal Statistical Office, Switzerland

Purpose: It has recently been reported that hip (femoral neck and pertrochanteric) fracture incidence had declined between 1996 and 2006 in the US while the incidence of the more rare femur fractures distal to the lesser trochanter had remained stable over time (Nieves et al 2010). Whether similar trends exist in Switzerland is unknown.

Methods: The incidence of femoral fractures hospitalized in years 2000-2008 was determined by ICD-10 code, sex, and 10-year age categories using the medical database of the Swiss Federal Statistical Office (SFSO) which covered 81.2% (year 2000) to 98.8% (year 2008) of all hospitalizations. Raw data were extrapolated to 100%. The age-standardized incidence per 100000 women aged 45 years or older was calculated by 5-year age groups for each calendar year, using the Swiss population statistics of the SFSO. The standardized incidence rate ratio (IRR) and corresponding 95% confidence intervals were calculated for year 2008 compared to year 2000. Linear trends between 2000 and 2008 were analyzed by simple linear regression.

Results: The age-standardized incidence of hospitalizations for femur fractures by localization is shown in the table below. Hip fracture incidence decreased significantly by 18% with a significant trend over time ($p < 0.001$). Subtrochanteric fractures and total fractures below trochanter decreased significantly by 11% (p -value for trend = 0.004) and 9% ($p = 0.043$), respectively. The proportion of hospitalized hip fractures, below trochanter fractures, and other fractures remained stable over time at approximately 84%, 12%, and 4%, respectively.

Conclusions: Hip fractures and femur fractures below trochanter followed similar hospitalization trends between 2000 and 2008 in Swiss women.

Hyperkyphosis and Incident Fractures Older Community Dwelling Women: The Study of Osteoporotic Fractures (SOF). Deborah Kado¹, Dana Miller-Martinez², Lily Lui³, Kristine Ensrud⁴, Teresa Hillier⁵, Howard Fink⁶, Marc Hochberg⁷, Peggy Cawthon³. ¹University of California, Los Angeles, USA, ²David Geffen School of Medicine at UCLA, USA, ³California Pacific Medical Center Research Institute, USA, ⁴Minneapolis VA Medical Center / University of Minnesota, USA, ⁵Kaiser Center for Health Research, USA, ⁶GRECC, Minneapolis VA Medical Center, USA, ⁷University of Maryland School of Medicine, USA

While hyperkyphosis is strongly associated with osteoporosis, it is not known whether increased thoracic spine curvature, independent of vertebral fractures, may itself be a risk factor for future fracture. Therefore, we used data from the Study of Osteoporotic Fractures to assess whether women aged 65 and older with increased kyphosis may be at risk for non-spine fractures. We used the digitized Cobb angle (T4 – T12) derived from supine lateral thoracic spine radiographs to calculate the degree of kyphosis in 940 randomly selected women from the parent cohort who were then followed for an average of 17.7 years. Incident non-spine fractures were ascertained from postcard follow-up every 4 months and were confirmed by radiographic report ($n = 464$ women). At the baseline visit, participants were an average of 69.4 (SD = 4.0) years old and had a mean kyphosis angle of 44.9 (SD = 11.8) degrees. Multivariable Cox proportional hazards analyses were used to assess whether greater degrees of kyphosis, measured continuously or by the top quartile, were associated with an increased risk of non-spine fracture. In age and clinic adjusted models, with each 10 degree increase in kyphosis, there was a 1.13-fold increased risk of future non-spine fracture (95% CI: 1.04 – 1.22). After further adjustment for calcaneal bone mineral density, history of previous fracture and morphometric prevalent vertebral fracture, the risk was not substantially changed (H.R. = 1.09; 95% CI: 1.01 – 1.19). Consideration of other potential confounders including body mass index, self-reported health, and physical activity made no difference in the results. Although there is no widely accepted hyperkyphosis angle threshold, it is estimated that about 25% of the older population may be affected by accentuated thoracic curvature. In SOF, women in the top quartile of kyphosis (Cobb angle kyphosis of >53 degrees compared to the lower three quartiles) had a 1.32-fold increased risk of non-spine fracture (multivariate-adjusted 95% CI: 1.07 – 1.63). We conclude that older women with hyperkyphosis are at an increased risk of subsequent osteoporotic fractures, independent of a history of prior fracture, prevalent vertebral fractures, and bone mineral density.

SU0359

Incidence of Fractures after Cardiac and Lung transplantation: A Single Center Experience. Aileen Hariman^{*}, Charles Alex, Biljana Pavlovic-Suriancev, Alain Heroux, Pauline Camacho. Loyola University of Chicago, USA

BACKGROUND: Osteoporotic fractures are well-known complications of organ transplantation. Reports in the early 1990s documented fracture rates up to 35% following heart and lung transplantations. More recent studies demonstrated fracture rates as low as 7.6% following heart transplantation and 12% following lung transplantation. At Loyola University Medical Center, pre-transplant protocols routinely include DXA scans and aggressive vitamin D screening prior to and immediately post-transplantation. Antiresorptive medications are widely utilized. The aim of this study was to assess the incidence of fragility fractures following cardiac or lung transplantation.

METHODS: In a retrospective observational study conducted from 2005-2010, 210 patients who underwent lung transplantation (110 men, 100 women) and 105 heart transplantation (88 men, 17 women) at Loyola University Medical Center were analyzed through electronic medical records. Both clinical and radiographic fractures through review of medical records were recorded.

RESULTS: Out of 210 lung transplant recipients, 17 patients (8.0%) had fractures post-transplantation and out of 105 heart transplant patients, 9 patients (8.57%) had fractures. The incidence of fracture in lung transplant patients in years 1 to 5 were 4.76%, 0.95%, 0.00%, 0.95%, and 1.90%, respectively. The median time to the first fracture was 8 months and the mean time was 19.11 +/- 21.0 months. The incidence of fracture in heart transplant patients in years 1 to 5 were 3.81%, 1.43%, 1.90%, 0.48%, and 0.48%, respectively. The median time to the first fracture was 12 months and the mean time was 18.41 months. Heart transplant recipients who fractured were significantly older than those who did not (60.78 +/- 7.84 yrs vs 52.66 +/- 12.13, $p = 0.016$). A similar finding was seen in lung transplant patients (54.65 +/- 7.97 yrs vs 52.53 +/- 13.41, $p = 0.048$). The use of bisphosphonates in fracture and non-fracture groups did not differ in heart (55.56% vs. 33.33%, $p = 0.362$) or in lung transplant patients (52.94% vs. 28.87%, $p = .909$).

CONCLUSION: Our findings demonstrate a much lower incidence of fractures post-transplantation in heart and lung transplant recipients in comparison to earlier reports. Comprehensive bone care, including DXA scans, screening for vitamin D deficiency, and early initiation of antiresorptive therapy at the pre-transplant or

immediate post-transplant period, are possible contributors to these improved outcomes.

Incidence of Osteoporotic Fracture in Patients with High Plasma Homocysteine Level. Naohisa Miyakoshi¹, Yuji Kasukawa¹, Koji Nozaka^{*2}. ¹Akita University Graduate School of Medicine, Japan, ²Akita City Hospital, Japan

[Background]High plasma homocysteine(Hcy) levels, which are a useful surrogate marker for detecting osteoporosis caused by deterioration of bone quality, may also be a bone quality marker that enables predicting the risk of fracture, which cannot be assessed by bone mineral density alone. However, details on patients with high plasma Hcy levels undergoing clinical treatment for fractures remain unclear.[Objective]To retrospectively investigate patients with high plasma Hcy levels in order to elucidate: 1) the proportion of patients who have high plasma Hcy levels; 2) the incidence of fractures among patients with high plasma Hcy levels; and 3) the types of fractures among patients with high plasma Hcy levels.[Subjects and methods]Subjects were 137 patients who underwent plasma Hcy measurement (standard values: 3.7-13.5 nmol/ml) upon admission to our department or when visiting the outpatient department from among the 1639 patients for whom bone mineral density was measured at our hospital in 2009. "High plasma Hcy levels" were defined as plasma Hcy levels above the upper limit of the standard values, i.e., 13.6 nmol/ml.[Results]A total of 20.4% (28/137) of patients had high plasma Hcy levels. These patients included 8 men and 20 women, and had a mean age of 76.4 years (range, 54-94 years), mean plasma Hcy level of 18.8 nmol/ml (13.6-40.7 nmol/ml), and mean bone mineral density (%YAM) of 57.9% (29-88%; >70% of the YAM, n=6; <70% of the YAM, n=22). The incidence of fractures among patients with high plasma Hcy levels was 92.9% (26/28). The 26 fractures included vertebral fracture (n=14) of one vertebra (n=2) or multiple vertebrae (n=12). A total of 12 patients had non-vertebral fractures, and surgery was indicated for each of these patients. These fractures included hip fracture (n=5; surgery performed, n=3), tibial plateau fracture (n=3; surgery performed, n=2), distal tibia fracture (n=1; surgery performed, n=1), distal radius fracture (n=2), and proximal humerus fracture (n=1). A total of 24 of 26 (92.3%) patients had experienced fractures at multiple sites, and all 26 patients had low-trauma or non-traumatic fragility fractures.[Discussion]The incidence of fractures among patients with high plasma Hcy levels was 92.9%, which was much higher than anticipated, and many of the patients had a history of multiple fractures. Plasma Hcy measurement is a useful predictive marker of osteoporotic fractures.

Morbidity and Mortality After Hip Fracture with Using Jeju Cohort in South Korea : A Minimum 5 Year Follow-Up. Jae-Suk Chang¹, Yong-Chan Ha^{*2}, Young-Kyun Lee³, Hyun-Koo Yoon⁴, Deog-Yoon Kim⁵. ¹Ulsan University, Asan Medical Center, South Korea, ²Chung-Ang University College of Medicine, South Korea, ³Seoul National University Bundang Hospital, South Korea, ⁴Cheil General Hospital & Women's Healthcare Center, South Korea, ⁵Department of Nuclear Medicine, Kyung Hee University Medical Center, South Korea

Introduction: Since 2002, the author has been performing epidemiologic study in Jeju island South Korea. Jeju Island is geographically isolated from main land and patients with hip fractures typically require hospitalization, which makes ascertainment easier and much reliable than other types of fractures. This prospective study was performed to estimate the morbidity and mortality after hip fractures of people over 50 years of age, in Jeju island, South Korea.

Methods: Eight hundreds nine patients(820 hips) over 50 years of age who sustained a femoral neck or intertrochanteric fracture from 2002 to 2006 were followed-up for minimum 5 years (range; 5-8 years). Crude and standardized annual mortality ratio was calculated and comparison of mortality was made between hip fractured patients and general population in Jeju island. We accessed functional capacity before and after injury, including independence in activities of daily living and walking ability.

Results: The mean age of the patients at the time of fracture was 77.8 years (71.3 years in 179 men, 79.9 years in 630 women). Accumulated mortality was 52.3% (79/151 patients) at 8 years, 43.3%(350/809 patients) at 5 years, 16.2%(131/809 patients) at 1 year, respectively. Standardized mortality ratio at 5 year follow-up was 2.8 times of the general population. Patients who could recover preoperative activity after treatment were only 40.4%(190/470 patients) at the final follow-up.

Conclusion: Considering high mortality and poor activity at the minimum 5 years follow-up period, the hip fracture in older patients is life threatening factors. Prevention of falling and reduction of hip fracture risk are necessary.

Quality of Life in Community-Dwelling Elderly Women: The Impact of Asymptomatic Vertebral Fractures. JAQUELINE LOPES^{*1}, Leandro Fung², Carolina Cha², Camille Figueiredo², Liliam Takayama², Valeria Caparbo², Rosa Pereira³. ¹Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil, ²Division of Rheumatology (Bone Mineral Metabolism Laboratory), Faculdade de Medicina da Universidade de Sao Paulo, Brazil, ³Faculdade de Medicina da Universidade de Sao Paulo, Brazil

Purpose: To investigate the impact of asymptomatic vertebral fractures in the quality of life (QOL) of community-dwelling elderly women.

Methods: 180 elderly women with 65 years or older from community were evaluated. The Quality of Life Questionnaire of the European Foundation for Osteoporosis (QUALEFFO) was administered to all subjects. Total domain score was computed by summing the scores of all questions and submitting the sum to a linear transformation to a scale of 100. A low score domain indicates worse health and a high score indicates better health. Anthropometric data was obtained by physical examination and body mass index (BMI) was calculated. The participants underwent bone mineral density (BMD) measurements by DXA of the lumbar spine and hip, as well as thoracolumbar spine X-ray to identify asymptomatic vertebral fractures. According to the ISCD definition, subjects were classified in normal BMD, osteopenia, and osteoporosis. Vertebral fractures were diagnosed using semiquantitative method (Genant-1993).

Results: 41 (22.8%) elderly women presented asymptomatic vertebral fractures. QOL was inversely correlated with age (R²=0.02, p=0.03) and IMC (R²=0.05, p<0.01). The women with vertebral fractures had lower QUALEFFO score [64.3 (16.1) vs. 77.3 (15.0), p=0.02] and worse physical function domain [69.5 (20.1) vs. 77.2 (17.1), p=0.01]. Comparing women with normal BMD, osteopenia and osteoporosis, a significant difference was found only for physical function domain (p=0.04, by Kruskal-wallis). After, we separated both osteopenic and osteoporotic women according to whether or not they had vertebral fractures, and a significant difference was found only in osteoporotic patients for physical function domain [71.3 (17.1) vs. 79.9 (18.8), p=0.03] and total QUALEFFO score [65.2 (13.5) vs. 71.8 (16.6) p<0.03]. Stepwise multiple logistic regression analysis of the whole sample showed that older individuals (p=0.03), high BMI (p=0.04) and vertebral fractures (p=0.02) impair QOL physical function.

Conclusions: Our results showed that physical function of QOL appears to be impaired in patients with asymptomatic vertebral fractures.

Review of Lower Extremity Fractures in Veterans with Spinal Cord Injury. Helen Hoenig¹, Titilola Akhigbe^{*2}, Amy Chin¹, Stephen Burns³, Jelena Svircev⁴, Helen Hoenig¹, Frances Weaver⁵, Kim Seunghyun², Laura Carbone². ¹Department of Veterans Affairs, USA, ²University of Tennessee Health Science Center, USA, ³Puget Sound, USA, ⁴VA Puget Sound, USA, ⁵Edward Hines Jr. VA Hospital, USA

Purpose: The purpose of this study was to describe fracture circumstances and examine morbidities, receipt of pharmacological therapies to prevent future fracture and changes in functional status in the one year time period following an incident lower extremity fracture in Veterans with Spinal Cord Injury (SCI).

Methods: We used the VA Spinal Cord Disorders Registry and the National Patient Care Database to identify all Veterans with a traumatic SCI who sustained an incident lower extremity fracture from 2002-2007 who received care at one of the four sites of our study (Durham, Hines, Memphis, Puget Sound). Retrospective medical record reviews of these fracture cases were performed at each site.

Results: There were 155 incident lower extremity fractures in 136 Veterans. The majority of incident fractures occurred in the femur (n=49) or tibia/fibula (n=80). 99% of the fracture cases were male; 36% had a prevalent fracture, 52% were ASIA A, 20% ASIA B, and 4% ASIA C or D with the remainder unknown. Approximately 1/3 were current users of tobacco or alcohol. The majority (44%) of these fractures occurred while using a wheelchair. 15% of fractures required surgical treatment. In the first year following the fracture, approximately 21% of Veterans received additional treatment to prevent future fractures (20% calcium, 16% vitamin D supplements, 6% bisphosphonates, <1% other). Morbidity complications occurred in the majority of Veterans following fracture, principally urinary tract infections (55%), pressure ulcerations (45%), fracture non-union (13%) and amputation (6%). Pre and post fracture residences were unknown in 4% and 6% of patients respectively. Of the remainder, more individuals were at home without home health care prior to fracture than post fracture (58.52% vs.46.67%), whereas all categories requiring more services, including home health care services (32.59% vs. 34.07%), assisted living (2.96% vs.5.19%) and nursing home residence (2.22% vs.3.7%) increased following the fracture.

Conclusions. Wheelchair use is a common mechanism for lower extremity fractures in Veterans with SCI. Surgery is required for approximately 15% of these fractures. These fractures have a substantial impact on Veterans. However, only a minority receive pharmacological therapies for fracture prevention following fracture. Future studies are needed to determine whether strategies that focus on safe wheelchair use might prevent fractures in this population.

Review of Radiological Scoring Methods of Osteoporotic Vertebral Fractures for Clinical and Research Settings. Felisia Ly^{*1}, Ling Oei², Carola Zillikens¹, Andre Uitterlinden³, Gabriel Krestin¹, Fernando Rivadeneira², Edwin Oei¹. ¹Erasmus MC, Netherlands, ²Erasmus University Medical Center, The Netherlands, ³Rm Ee 575, Genetic Laboratory, The Netherlands

Osteoporosis is characterised by decreased bone density and bone quality resulting in an increased risk of fragility fractures. Vertebral fractures (VFX) are the most common osteoporotic fractures. There have been many publications on different criteria that are used to assess VFX. Such grading definitions are currently under debate. The purposes of this review are to high-light benefits and limitations across methods in terms of vertebral fracture (VFX); to illustrate how prevalence of VFX is influenced by different assessment methods; to discuss the application of scoring methods in scientific research and clinical practice.

Image examples from a population-based study will be used to illustrate different radiological scoring methods. We will discuss Quantitative morphometry (QM) and semi-quantitative (SQ) methods, which were developed to overcome the subjectivity of traditional visual diagnosis. QM ratios derived from exact measurements of the anterior, middle and posterior heights of vertebral bodies are used to define deformities, e.g. McCloskey-Kanis. SQ visual grading of VFX is done by trained readers according to height and area reduction, e.g. Genant. However, not all vertebral deformities are osteoporotic VFX. A newer algorithm-based qualitative (ABQ) method introduced a scheme to systematically rule out non-fracture deformities and diagnoses osteoporotic VFX based on endplate depression alone, regardless of vertebral height reduction. The methods discussed were developed based on conventional radiography, however they are also applicable to lateral dual-emission X-ray absorptiometry (DXA), magnetic resonance imaging (MRI) and X-ray computed tomography (CT).

As different scoring methods use different definitions of VFX diagnosis and severity, this may have implications for patient care and scientific research. So a standardized and accurate scoring method for osteoporotic VFX is desirable. Available standardized scoring methods for osteoporotic VFX can be implemented for different imaging modalities.

Serum Vitamin D Level and Functional Outcomes in Patients with Fragility Fractures, Shifting the Paradigm. Lohrasb Ahmadian^{*}, Joseph Lane. Hospital for Special Surgery, USA

Introduction: The goal of this study is to emphasize the importance of scientific measurement paradigm in testing the relationship of functional outcomes and serum vitamin D in patients with fragility fracture. **Methods:** We designed a cross-sectional study of community-living persons with the history of fragility fracture and/or low bone density. Lowest quartile of vitamin D concentration among study subjects was defined (<35 ng/ml). All self-reported functional outcomes were estimated using both standard method of summing Likert-type scores and Rasch analysis. Rasch analyses adjusted by age, sex, and comorbidity were performed on the responses to all functional and (QoL) measures. A series of multivariable linear and logistic regression models were used to evaluate the association between specific cutoff points of vitamin D concentration and functional and QoL outcomes. Odds ratios (ORs) were calculated for the lowest quartile of serum Vitamin D using other quartiles combined as the reference group. Finally, classification and regression tree (CART) analysis was performed to identify a hierarchical order of and potentially complex interactions between vitamin D level (continuous) and other variables. **Results:** The sample included 190 participants with average age of 71 (SD 11). The mean level of vitamin D was 43.7 ng/ml (SD 15.8 ng/ml), with 25% less than 35 ng/ml. Only raw scores of mental domain of QoL measures (SF12) in both unadjusted (OR, 3.42; CI, 1.25-9.24; p=.02) and adjusted models were significantly associated with the low level of vitamin D (<35 ng/ml vs ≥35 ng/ml). In all other unadjusted analyses, low level of vitamin D was not associated with the level of QoL, functional disability, ambulation, and fall risk measures. Most of the functional and QoL scales investigated showed valid acceptable person separation reliability but poor targeting and item performance. The Rasch person-item map showed that most of the items in functional and QoL measures have not good range and are not well centered with respect to the person measure distribution in patients with fragility fractures. **Conclusion:** We can conclude that the observed poor predictive relationship of low vitamin D and functional outcomes is the consequence of measurement insufficiency and major mismatch between self-reported item measures and person measures. To investigate the dose-response relationship of vitamin D and functional outcomes, the selected measures need to be adequate to describe the functional ability of the subjects in the study.

Osteoporotic fracture (OF) has become a matter of substantial morbidity and mortality in demographic changes of an aging populations. However, genetic contributions to OF risk assessment remain undetermined for the assignment of preventive measures. Although bone mineral density is a valuable parameter to predict OF risk, identifying a genetic susceptibility for OF itself as an end point would be more important. In an attempt to detect genetic liability to OF in East Asian populations, we conducted a GWAS as a screening in epidemiological cohort study (Korea Association Resource, KARE, n = 1,427). The lead SNP was replicated in hospital-based independent women, Korean (ACMC, n = 1,372) and Japanese (RIKEN, n = 929), respectively. In combined meta-analysis of osteoporotic vertebral fracture from a discovery cohort (KARE) and two de novo replication sets (ACMC and RIKEN), we found the most significant association in the same direction. Functionally, real-time PCR revealed that the differentiated osteoclasts expressed more of its transcript than pre-osteoclasts. Knock-down by MECOM siRNA suppressed osteoclastogenesis and expressions of marker genes for differentiated osteoclasts. These suggest that MECOM may stimulate osteoclastogenesis, resulting in the increased bone resorption. Bioinformatic analyses based on the identified SNP suggest functional connectivity underlying the suppressive effect in RANK signaling. Taken together, our observations suggest that the MECOM polymorphism represents a strong genetic determinant for OF risk in the East Asian individuals, and that the gene has a critical role on bone metabolism.

Aim: Bone mineral density (BMD), a heritable trait, is one of the major determinants of bone strength and a key predictor of osteoporotic fracture. Sexual dimorphism in various bone phenotypes is widely observed, which in genome-wide association studies (GWAS) meta-analyses can hamper the discovery of sex-specific effects. Such sex-specific genetic determinants influencing BMD variation will not rank high in GWAS combining sexes. Therefore we specifically examined genome-wide gene-sex interactions for BMD traits, seeking the identification of variants with opposing and/or sex specific effects.

Methods: We conducted a GWAS meta-analysis under the framework of the Genetic Factors of Osteoporosis (GEFOS) Consortium including ~25,000 individuals

(36% male) from seven cohorts. SNP-by-sex interaction on lumbar spine (LS-) and femoral neck (FN-) BMD, was modeled additively for ~2.5 million imputed SNPs across the genome using multivariable linear regression models with a statistical interaction (SNP*sex) term. Inverse variance weighted fixed effects meta-analysis was used to aggregate results from each study. A genome-wide significance (GWS) threshold was set at $P \leq 5 \times 10^{-8}$ and suggestive at $P \leq 1 \times 10^{-5}$. Sex-specific associations for the identified top SNPs were tested using a corrected $P < 0.0042$ as the significant threshold.

Results: We detected one novel genome-wide significant interaction associated with LS-BMD at the Chr3p26.1-p25.1 locus, near the GRM7 gene (male p -value = 3.0×10^{-5} ; female p -value = 3.3×10^{-2}) and eleven suggestive loci associated with either FN- or LS-BMD. All associations displayed opposite effect directions in men compared to women. Significance of association was attained in only one gender in all but one locus (XCL2 gene at Chr 1q24.2, significant in both genders, p -value = 5.7×10^{-4} and 1.2×10^{-4} for male and female, separately).

Conclusion: This collaborative work identified twelve loci suggestive of sex-specific effects on FN- and LS-BMD and corroborated sexual dimorphism of bone. These results are currently being replicated in an additional 4,600 male and 12,000 female Caucasian samples (the GENOMOS Consortium).

Genome-Wide Association Meta-Analysis of Cortical Volumetric BMD Identifies Three Known and One Novel Bone-Related Loci. Claes Ohlsson^{*1}, Lavinia Paternoster², Terho Lehtimäki³, Mika Kahonen⁴, Olli Raitakari⁵, Marika Laaksonen⁶, Vera Mikkilä⁶, Jorma Viikari⁷, Leo-Pekka Lyytikäinen³, John P Kemp², Adrian Sayers⁸, Maria Nethander⁹, Liesbeth Vandenput¹⁰, Jon H Tobias¹¹, Mattias Lorentzon¹, David M Evans². ¹Center for Bone Research At the Sahlgrenska Academy, Sweden, ²MRC Centre for Causal Analyses in Translational Epidemiology, University of Bristol; School of Social & Community Medicine, University of Bristol, United Kingdom, ³Department of Clinical Chemistry, University of Tampere & Tampere University Hospital, Finland, ⁴Department of Clinical Physiology, University of Tampere & Tampere University Hospital, Finland, ⁵Research Centre of Applied & Preventive Cardiovascular Medicine, University of Turku & the Department of Clinical Physiology, Turku University Hospital, Finland, ⁶Department of Food & Environmental Sciences, University of Helsinki, Finland, ⁷Department of Medicine, University of Turku & Turku University Hospital, Finland, ⁸University of Bristol, United Kingdom, ⁹Genomics Core Facility, University of Gothenburg, Sweden, ¹⁰University of Gothenburg, Sweden, ¹¹School of Clinical Sciences, University of Bristol, United Kingdom

Previous bone-related genome-wide association (GWA) studies have mainly focused on the identification of SNPs associated with areal bone mineral density (aBMD) as analysed by dual energy x-ray absorptiometry (DXA). However, this measure is influenced by several different skeletal parameters such as periosteal expansion, cortical volumetric BMD (cvBMD), cortical thickness, trabecular number and trabecular thickness, which may be under distinct biological and genetic control. Interestingly, cvBMD displays a weak correlation with femoral neck aBMD ($r_s = 0.039$ in the GOOD cohort), suggesting that the genetic determinants of cvBMD may differ from the earlier published genetic determinants of aBMD.

We, therefore, performed a GWA study of cvBMD, as measured by peripheral quantitative computed tomography (pQCT) in the tibial diaphysis, among 5,952 Caucasian subjects from three cohorts (ALSPAC, aged ~15 years, $n=3,456$; GOOD, aged ~19 years, $n=938$ and YFS 31-46 years of age, $n=1,558$). Inverse variance weighted fixed-effect model meta-analysis of study-specific results was performed. We identified genetic variants in four separate loci reaching genome wide significance. Three of these loci (RANKL, OPG and estrogen receptor- α) have earlier been reported to be associated with aBMD. We identified two strong hits (rs1021188, $p=1.5 \times 10^{-12}$, effect size 0.15 SD per allele and rs1325798, $p=4.1 \times 10^{-10}$, effect size 0.10 SD per allele), with $r^2 < 0.2$, in the RANKL (TNFSF11) locus, suggesting that there may be two independent signals in this locus. We have previously, in a small-scale meta-analysis, reported that the rs1021188 SNP is associated with cvBMD. The other two signals in known bone-related genes were located close to OPG (TNFRSF11B, rs7839059,

$p=4.1 \times 10^{-9}$, effect size 0.10 SD per allele) and estrogen receptor- α (rs6909279, $p=1.0 \times 10^{-8}$, effect size 0.09 SD per allele). Importantly, we identified one novel bone-related signal, located on chromosome 6 in the region of LOC285735 ($p=2.9 \times 10^{-11}$, effect size 0.11 SD per allele), to be consistently associated with cvBMD.

In conclusion, we identified genetic variants in one novel and three known bone-related loci to be associated with cvBMD. The three known loci include RANKL, OPG and estrogen receptor- α , strongly suggesting that the RANK/RANKL/OPG pathway and estrogen signalling are involved in the regulation of cvBMD. The mechanism/pathway for the influence of the novel chromosome 6 hit on cvBMD remains to be determined.

Genome-wide Association Study of Hip Fracture Suggests Loci in Biological Pathways Associated with Bone Remodeling. Rebecca Jackson^{*1}, Andrea LaCroix², Aaron Aragaki², David Duggan³, Chris Carlson⁴, Brent Richards⁵, Zari Dastani⁵, Tim Spector⁶, John Eisman⁷, Tuan Nguyen⁷, Stuart Ralston⁸, Eugene McCloskey⁹, Emma Duncan¹⁰, Geoffrey Nicholson¹¹, William Leslie¹², David Goltzman¹³, Subha Krishnan³, Charles Kooperberg². ¹The Ohio State University, USA, ²Fred Hutchinson Cancer Research Center, USA, ³Translational Genomics Research Institute, USA, ⁴University of Washington, USA, ⁵McGill University, Canada, ⁶King's College London, United Kingdom, ⁷Garvan Institute of Medical Research, Australia, ⁸University of Edinburgh, United Kingdom, ⁹University of Sheffield, United Kingdom, ¹⁰Royal Brisbane & Women's Hospital, Australia, ¹¹The University of Queensland, Australia, ¹²University of Manitoba, Canada, ¹³McGill University Health Centre, Canada

Background: Hip fractures are the most serious outcome of osteoporosis and one of the most disabling consequences of aging in women. Although twin and family studies suggest that up to half the variance of hip fracture is due to genetic effects, no genetic loci have been reported to be associated with hip fracture risk.

Methods: A genome-wide association study of hip fracture was conducted with individual genotyping (Illumina 550 and 610K) on 4432 postmenopausal European American women drawn from the Women's Health Initiative; 2055 hip fracture cases and 2377 controls with no history of postmenopausal fracture at baseline, matched to cases on age (+/-1 yr), year of enrollment, and clinical trial treatment group for the Hormone Therapy (HT) and Calcium plus vitamin D Trials. For cases not enrolled in the HT Trial, we matched on current estrogen use at baseline. Case definition was defined as an incident hip fracture: all hip fractures were centrally verified by masked review of radiographic and/or surgical reports. All controls had no prevalent or incident hip fracture by the end of follow up. Analyses used an additive regression model with age, height, weight and the first four principal components in the final model. Genome-wide Significance (GWS) was set at $P \leq 5 \times 10^{-8}$ and suggestive at $5 \times 10^{-8} < P < 5 \times 10^{-6}$. Replication involved *de-novo* genotyping (iSELECT) the 384 most strongly associated SNPs identified from the hip fracture discovery GWAS based on p values and linkage disequilibrium in 3776 independent samples including 1784 hip fracture cases and 1992 controls. Separate regression models were then fit for each cohort included in replication and results were combined via meta-analysis.

Results: We identified 5 loci (0 GWS and 5 suggestive) on chromosomes 2, 3, and 12 associated with incident hip fracture. Two of these loci map within or near genes involved in pathways that regulate bone resorption (NFKB1 and SPTBN1). There was no evidence of an age x SNP interaction. No SNP reached GWS when data were analyzed by fracture type (femoral neck versus intertrochanteric fracture). Further *in silico* replication of the top 384 SNPs is underway.

Conclusion: This large hip fracture GWAS has identified several suggestive loci involving pathways associated with bone remodeling. Meta-analyses with inclusion of carefully phenotyped incident hip fracture cases will help to further explore these findings.

Disclosures: Rebecca Jackson, None.

Increased Physical Activity Associated with Longitudinal Decrease in Weight, and Increase in Bone Mineral Density: The Canadian Multicentre Osteoporosis Study (CaMos). Lisa Langsetmo^{*1}, Christine Hitchcock², Elaine Kingwell², K. Shawn Davison³, Siri Forsmo⁴, Wei Zhou⁵, Claudie Berger⁶, Nancy Kreiger⁷, Jerilynn Prior². ¹Canadian Multicenter Osteoporosis Study, Canada, ²University of British Columbia, Canada, ³Laval University, Canada, ⁴Norwegian University of Science & Technology, Norway, ⁵McGill University Health Centre, Canada, ⁶McGill University, Canada, ⁷University of Toronto, Canada

Background: Physical activity (PA) has been identified as a modifiable factor for both weight (hence body mass index or BMI) and bone mineral density (BMD). Weight is strongly predictive of BMD. Our aim was to determine the cross-sectional and prospective associations between PA and BMD, taking weight into account.

Methods: The Canadian Multicentre Osteoporosis Study (CaMos) is a random, population-based, prospective cohort study of Canadian women and men. PA was determined from interviewer-administered questionnaires at Years 0 and 5 as daily energy expenditure, summarized as metabolic equivalent of task multiplied by minutes/day (MET*m/d). Height, weight, and total hip BMD were measured at Years 0 and 5. BMD was calibrated between centers and over time. General linear models were used to assess relationships between physical activity and BMD, both cross-sectionally (Year 0 PA with Year 0 BMD) and longitudinally (average PA and 5-y change in PA with 5-y change in BMD). Confidence intervals are denoted as CI. Weight was considered as a secondary outcome and mediating factor. Potential confounders included age, center, education, caffeine, alcohol, smoking, history of weight-cycling, and for women, age at menarche, past use of oral contraceptives, history of >3 months missed menstruation, menopausal status, and antiresorptive use (estrogen, bisphosphonates).

Results: The study sample included 2855 men and 6442 women. Cross-sectionally, higher PA was associated with lower weight, and longitudinally, 5-y increase in PA was associated with 5-y decrease in weight: 1.27 (95% CI: 0.69, 1.85) kg loss per 1000 MET*m/d PA increase (men) and 1.05 (95% CI: 0.61, 1.49) kg loss per 1000 MET*m/d increase (women). Weight was strongly associated with BMD; weight change was strongly predictive of BMD change ($p < 0.001$). However, despite previously noted relationships, 5-y increase in PA (no weight change adjustment) was associated with small 5-y increase in BMD: 0.004 (95% CI: 0.000-0.008) g/cm² per 1000 MET*m/d increase (men) and 0.003 (95% CI: 0.000-0.007) g/cm² per 1000 MET*m/d increase (women). Average PA was associated with a small, non-significant increase in BMD in men, but essentially no change in women.

Conclusion: An increase in PA over time was associated with a decrease in weight and a slight increase in total hip BMD, suggesting that population level measures to increase PA may be favorable for bone health.

Disclosures: Lisa Langsetmo, None.

SU0371

Effect of Menopause on Bone Loss in HIV-infected Women. Michael Yin^{*1}, Chiyuan Zhang¹, Polly Chen¹, Ivelisse Colon², Donald McMahon³, David Ferris⁴, Emily Stein³, Phyllis Tien⁵, Elizabeth Shane³. ¹Columbia University, USA, ²Columbia University Medical Center, USA, ³Columbia University College of Physicians & Surgeons, USA, ⁴Bronx Lebanon Hospital Center, USA, ⁵University of California, San Francisco, USA

Purpose: HIV infection is associated with chronic T cell activation and increased production of pro-inflammatory, pro-resorptive cytokines. Cytokine levels decline but do not completely normalize on antiretroviral therapy (ART). Since estrogen downregulates T cell activation and cytokine production, we hypothesized that bone loss will be accelerated in HIV-infected (HIV+) women after menopause.

Methods: We measured bone mineral density (BMD) by DXA and serum cytokines and a resorption marker, N-telopeptide (NTX), in two separate cohorts: 168 (100HIV+, 68HIV-) premenopausal (PreM) women and 187 (92 HIV+, 95 HIV-) postmenopausal (PM) women at baseline and 2 years. Premenopausal women were enrolled in the Women's Interagency HIV Study (WIHS) and PM women were from a New York City cohort.

Results: PreM HIV+ women were older (40±5 vs 36±7, $p < 0.01$), but had similar body mass index (BMI; 29±7 vs 30±7 kg/m²) and race than HIV- PreM women. PM HIV+ women were younger (56±1 vs 60±1, $p < 0.01$), had lower BMI (27±1 vs 31±1 kg/m², $p < 0.01$) and were more likely to be African American (37% vs 20%, $p < 0.05$) than PM HIV- women. Mean CD4 count was 438±273 cells/ul and 474±326 cells/ul in PreM and PM HIV+ women respectively; 59% and 78% were on ART, respectively. Baseline Tumor Necrosis Factor- α (TNF α) and NTX levels were higher in PM but not PreM HIV+ versus HIV- women (Table). In PreM women, annualized % change in BMD (Δ BMD) at the lumbar spine (LS) and femoral neck (FN) did not differ between HIV+ and HIV- groups, before or after adjustment for age, BMI, and baseline BMD. In PM women, annualized % Δ BMD in HIV+ women was similar at the LS and FN, but 2.2-fold and 3.7-fold greater at the total hip (TH) and distal radius (DR) respectively, before and after adjustment for age, race, BMI, and baseline BMD.

Conclusions: Serum TNF α and NTX were higher in HIV+ than HIV- PM but not PreM women. Rates of LS and FN bone loss did not differ by HIV status in either PreM or PM women. At the TH and DR, rates of loss were higher in HIV+ than HIV- PM. Although limited by lack of TH and DR data in WIHS, these results demonstrate that estrogen deficient PM HIV+ women are at greater risk for site-specific bone loss than HIV- PM. The mechanism of HIV-associated bone loss in PM women may be related to higher bone turnover secondary to upregulation of pro-resorptive cytokines.

Table	PreM			PM		
	HIV+	HIV-	P value	HIV+	HIV-	P value
NTX (nmol/BCE/L)	11.3±4.3	10.4±3.2	0.17	19.4±1.0	16.6±0.6	0.02
TNF- α (pg/ml)	3.7±6.5	2.8±4.0	0.36	43.1±2.9	30.5±1.6	<0.001
% Δ LS BMD	-0.7±0.3	-0.5±0.3	0.54	-1.2±0.3	-0.5±0.4	0.14
% Δ TH BMD	NA	NA		-1.6±0.4	-0.7±0.2	0.045
% Δ FN BMD	-0.6±0.2	-0.4±0.3	0.34	-1.2±0.3	-0.8±0.4	0.42
% Δ DR BMD	NA	NA		-1.1±0.2	-0.3±0.2	0.007

Pleiotropic Genetic Determinants of BMD and Ages at Menarche and Natural Menopause: Multivariate Genome-Wide Association Meta-Analyses.

Yi-Hsiang Hsu^{*1}, Xing Chen², Douglas Kiel², Brent Richards³, Cathy Elks⁴, Jane Cauley⁵, Karol Estrada⁶, Michael Econs⁷, Kathryn Lunetta⁸, Ken Ong⁹, John Perry¹⁰, Fernando Rivadeneira⁶, Lisette Stolk¹¹, Tim Spector¹², Andre Uitterlinden¹³, M Zillikens¹⁴, Joanne Murabito¹⁵, David Karasik². ¹Hebrew SeniorLife Institute for Aging Research & Harvard Medical School, USA, ²Hebrew SeniorLife, USA, ³McGill University, Canada, ⁴Inst of Metabolic Sci, Addenbrooke's Hosp, United Kingdom, ⁵University of Pittsburgh Graduate School of Public Health, USA, ⁶Erasmus University Medical Center, The Netherlands, ⁷Indiana University School of Medicine, USA, ⁸Boston Uni Sch Public Health, USA, ⁹Paediatrics, University of Cambridge, United Kingdom, ¹⁰Inst Biomedical Clinical Science, Peninsula Med Sch, United Kingdom, ¹¹Departments of Internal Medicine, Erasmus MC, Netherlands, ¹²King's College London, United Kingdom, ¹³Rm Ee 575, Genetic Laboratory, The Netherlands, ¹⁴Erasmus MC Rotterdam, The Netherlands, ¹⁵Boston Uni Sch Med, USA

Reproductive aging and menopause in women are associated with the risk of osteoporosis that may be due to the changes in ovarian hormone production that affects bone health. Previously, we conducted univariate genome-wide association studies (GWAS) and identified novel genetic variants that associated with reproductive aging (age at menarche and age at natural menopause from ReproGen consortium) and associated with BMD (lumbar spine and femoral neck, from GEFOS consortium) in women of European descent. To identify pleiotropic genetic variants that associated with both reproductive aging and BMD, we performed multivariate GWAS meta-analyses on ~2.5 million SNPs across genome. METH-ODS: To model age at menarche and BMD simultaneously (as well as age at natural menopause and BMD), multivariate GWAS were performed using an empirical-weighted linear-combined test statistics (eLC) approach. Results from univariate GWAS meta-analyses were obtained from the GEFOS consortium for BMD (23,678 women, mean age ~60.5 yrs) and from the ReproGen consortium for age at menarche and age at natural menopause (87,802 women and 38,968 women, respectively; excluding women with age at menarche < 9 years old and age at menopause < 40 or > 60 years). The eLC approach directly combines test statistics from each univariate meta-analysis while accounting for the correlation among phenotypes, providing an unbiased estimation of multivariate test statistics. Multivariate p-values $\leq 5 \times 10^{-8}$ were considered genome-wide significant. Only loci with multivariate p-values significantly less than univariate p-values (for the same SNPs) were considered as potential pleiotropic loci. RESULTS: We identified 11 genome-wide significant pleiotropic loci from multivariate GWAS analyses, including previously reported loci for BMD such as MEPE, C6orf97 (near ESRI) and WNT4. Novel genome-wide significant pleiotropic loci included genes located in chr. 6q22.3, 7p12.2, 11p13, 11p14-p13 and 16q12.1 for age at menarche and BMD; and chr11p14.1 and 22q13.1 for age at natural menopause and BMD. Gene-set enrichment analysis showed significant enrichment in steroid synthesis ($p = 3.5 \times 10^{-6}$) and generation of germ cells ($p = 1.1 \times 10^{-6}$). CONCLUSION: Using a multivariate GWAS approach, we discovered potentially-pleiotropic loci that may be involved in the regulation of bone density and reproductive aging. A replication and eQTL analysis are underway to further validate these findings.

Relative Contributions of Estradiol and Testosterone to the Determination of Bone Mineral Density in Vietnamese Men and Women. Lan T Ho-Pham^{*1}, Thai Q. Lai², Nguyen Nguyen³, Tuan Nguyen³. ¹Pham Ngoc Thach University of Medicine, Vietnam, ²People's Hospital 115, Vietnam, ³Garvan Institute of Medical Research, Australia

Estrogen is known as an important determinant of bone mass in women. However, recent studies in Caucasian populations indicated that estrogen is also an important determinant of bone mineral density (BMD) in men. The present study was designed to examine the relative contribution of estrogen and testosterone to the determination of BMD in Vietnamese men and women.

The study was designed as a cross-sectional investigation, which involved 200 men and 415 women aged between 18 and 89 years (median: 47 years), who were randomly selected from various districts within the Ho Chi Minh City (Vietnam) by a simple random sampling process. Bone mineral density at the spine and femoral neck was measured by DXA (Hologic QDR4500, Bedford, MA, USA) by a ICSD-certified technician. Serum concentrations of total testosterone (TT) and estradiol (E2) were measured by competitive electrochemiluminescence immunoassays on the 10100/201 Elecsys autoanalyzer (Roche Diagnostics, Indianapolis, IN). The association between TT, E2, and BMD was analyzed by the multiple linear regression model.

The mean E2 in men and women was 28 pg/mL (SD 42) and 80 pg/mL (SD 237), respectively. The mean TT in men and women was 487 ng/dL (SD 208) and 20 ng/dL (SD 32), respectively. Serum levels of E2 declined with advancing age more in women than in men. In women, after adjusting for age and body weight (or BMI), higher serum concentrations of E2, but not TT, were significantly associated with greater BMD at the femoral neck ($r=0.48$; $P<0.001$) and lumbar spine ($r=0.49$; $P<0.001$). In men, E2, but not TT, was significantly associated with femoral neck BMD ($r=0.19$; $P<0.009$). In the multiple linear regression model, age, body weight and E2 accounted for 50-55% variance in femoral neck BMD, and 25% (in men) and 48% (in women) variance in lumbar spine BMD. In the presence of age and weight, variation in the serum concentrations of E2 contributed between 1 and 2% of total variance in femoral neck and lumbar spine BMD.

Thus, these results indicate that estrogen may be more important than testosterone in the determination of age-related bone loss in Vietnamese men and women. However, the relative contributions of estrogen to the variance in BMD is likely to be modest.

Disclosures: Lan T Ho-Pham, None.

4-year Follow-up of the Bone Fracture Risk with FRAX in Patients not Treated with Antifracture Medicines. Pomost study. Jerzy Przedlacki^{*}, Krystyna Ksiezczepolska-Or^{oowska}, Artur Grodzki, Andrzej Swirski, Jan Musia^o, Ewa Loth, Pawe^o Teter, Andrzej asiewicz. National Center of Osteoporosis, Poland

It is not recommended not to use FRAX® in the follow-up of the fracture risk in patients treated with vitamin D and calcium.

The aim of the study was to assess the changes of 10-year fracture risk (10-FR) of the main bones with the use of FRAX® in patients not treated with antifracture medicines and the use of FRAX® in making therapeutic decisions in osteoporosis in these patients.

The study was performed in 107 patients (23 males and 84 females) aged 66.86.9 years not treated with antifracture medicines, and with 10-FR of the main bones $\leq 20\%$ (low and medium 10-FR) calculated with British version of FRAX®. Their age and T-score of femoral neck were changed during observation. Patients were supplemented with vitamin D (400-800 IU daily) and calcium (500-1000 mg daily).

There were not any new bone fracture and any other new clinical risk factors during observation. Baseline 10-FR was 9.03.7% (3.1-19%, median 8.6%). The controlled 10-FR was assessed in 70 patients after 1, in 56 after 2, in 51 after 3 and in 26 after 4 years. There was increase of 10-FR after 1-year in 39 patients (0.1-4.0 percentage points – PP; median 1 PP), after 2 in 39 patients (0.1-6.0 PP, median 1.0 PP), after 3 in 40 patients (0.3-9.0 PP, median 1.4 PP) and after 4 years in 25 patients (0.1-8.0 PP, median 1.5 PP). There was decrease of 10-FR after 1 year in 20 patients (0.2-7.1 PP, median 0.9 PP), after 2 years in 10 patients (0.1-2.2 PP, median 0.75 PP), after 3 years in 7 patients (0.5-4.0 PP, median 1.0 PP) and after 4 years in anybody. There was no change in 10-FR after 1 year in 12 patients, after 2 years in 4, after 3 years in 2 and after 4 years in 6 patients. There was change from low to medium 10-FR after 1 year in 2 patients (baseline 10-FR 18% and 19%), after 2 years in anyone, after 3 years in 1 (10-FR 17%) and after 4 years in 1 patient (10-FR 19%). Nobody had change of 10-FR from low to high during the whole observation.

There is not indication for the repeated DXA exam after up-to 4 years at least, in making decision on the treatment with antifracture medicines in patients with baseline low and medium (up to 16% in our study) 10-FR and any new clinical bone fracture risk factors. In patients with 10-FR in upper range of medium 10-FR ($\geq 17\%$ in our study) controlled DXA exam even after 1 year should be considered.

Depressive Symptoms on Balance Function and Osteoporosis: Result from CMC Study. Ki-Hyun Baek¹, Moo-Il Kang², Hyeon-Woo Yim³, Sun-Hee Ko², Seong-Su Lee⁴, Eunhee Jang^{*5}, Ki-Won Oh⁶. ¹St. Mary's Hospital, South Korea, ²Seoul St. Mary's Hospital, South Korea, ³Department of Preventive Medicine, The Catholic University of Korea, South Korea, ⁴Catholic medical college, South Korea, ⁵St.Mary's Hospital, Republic of Korea, ⁶Kangbuk Samsung Hospital, Sungkyunkwan University, South Korea

Objectives: Previous epidemiological study has suggested that depression might be associated declining physical function and lower BMD in older age. We aimed to investigate the impact of depressive symptoms score on balance test and BMD from community acquired cohort study in rural areas of Chungju, Korea.

Methods: One thousand six hundred sixty-four community dwelling subjects (Men:596/Women:1068) aged over 40 years old participated in the study by the stratified random cluster sampling in the Chungju, Korea. Anthropometric data, sociodemographic parameters and diet intake were collected by an skilled interviewer-administered standardized questionnaire. Depressive symptoms were assessed using the Center for Epidemiologic Studies Depression Scale (CES-D). Bone mineral density were measured by central bone densitometry (Hologic QDR4500). Balance function was estimated with one-leg-stand test (OLST) in all participants.

Results: Mean age of participants was 66.9 years old (meansSD), their mean BMI was 22.93 kg/m². After age adjustment, CES-D score showed negative correlation with OLST (male $r=-0.366$, female $r=-0.208$), not BMD in an elderly Korean population. Results were not substantially altered when adjusted for potential confounders (body weight, medical history, calcium intake). In multiple regression analysis, age and CES-D score persisted negative influence on balance function regardless of gender (male $R^2=0.089$, female $R^2=0.142$).

Conclusions: We concluded that depressive symptoms score was more correlated with balance function, not BMD in our study.

Genome-wide Copy Number Variation Analysis on the Risk of Osteoporotic Fractures in Caucasian Men and Women: The Framingham Osteoporosis study. Kannabiran Nandakumar^{*1}, Ching-Lung Cheung², Huanvui Zhou³, Ching-Ti Liu⁴, Serkalem Demissie⁵, David Karasik⁶, Adrienne Cupples⁵, Douglas Kiel⁶, Yi-Hsiang Hsu⁷. ¹Hebrew Senior Life Harvard Medical School, USA, ²The University of Hong Kong, Hong Kong, ³Hebrew Rehabilitation Center, USA, ⁴Boston University School of Public Health, USA, ⁵BUSPH, USA, ⁶Hebrew SeniorLife, USA, ⁷Hebrew SeniorLife Institute for Aging Research & Harvard Medical School, USA

Copy number variations (CNVs) are sequence structure variations that are commonly found in the human genome. Studies have reported association between CNVs and cis-transcript levels that are not explained by SNPs. Although, GWAS have successfully discovered novel SNP variants associated with bone health phenotypes, up to date, those common SNP variants only explain 10% of BMD variability in Caucasians. To discover additional genetic determinants of bone health phenotypes, we conducted a genome-wide CNV association analysis on osteoporotic fractures in 8,700 adult men and women from the Framingham Study. The CNVs were called from Affymetrix 500K chip by PennCnv package and then confirmed by GoldenHelix SVS CNV module. A total of 112,745 CNV events were estimated in the Framingham population. Non-vertebral osteoporotic fractures (excluding high-impact trauma, fractures at head, spine, fingers and toes) were either ascertained by medical records/X-ray images or self-reported. There are 1,671 men and 2,160 women with at least one non-vertebral osteoporotic fracture. Association analysis was performed by using a burden test for rare/low frequent CNV regions (frequency $< 1\%$). From the burden test we found chromosomes 8, 9 and 15 significant based on the number of segments and proportion of samples with one or more segments. To further identify rare events, regional tests were performed for cnv regions in each chromosome. One of the regions in the region 15q11.2 was shown to be significantly associated with non-vertebral fracture. In conclusion, we identified a CNV that may increase susceptibility to osteoporotic fracture risks.

Hypovitaminosis D in Postmenopausal Women with a Distal Radius Fracture. Woo Young Chang, Hyun Sik Gong^{*}, Cheol Ho Song. Seoul National University Bundang Hospital, South Korea

Purpose: Although hypovitaminosis D is reported to be common in the general population, few reports have examined vitamin D levels in patients with a distal radius

fracture (DRF). The authors hypothesized that postmenopausal women with a DRF may have depressed vitamin D levels.

Methods: The data of 104 postmenopausal women treated for a distal radius fracture (DRF group) and 107 age-matched control patients with soft tissue disease, such as tenosynovitis or lateral epicondylitis (control group) were compared. Serum vitamin D levels (25-hydroxycholecalciferol, 25(OH)D3) and the levels of several bone metabolism markers including serum parathyroid hormone, osteocalcin, C-telopeptide, and urine N-telopeptide were sampled and compared.

Results: Mean levels of the serum 25(OH)D3 in the DRF and control groups were 36.38 20.48 ng/mL and 47.16 17.69 ng/mL, respectively, and this difference was significant ($p < 0.001$). In particular, patients in their sixth and seventh deciles in the DRF group had significantly lower vitamin D levels than patients in the control group. Twenty-seven patients (26%) and 19 patients (18%) in the DRF group were vitamin D insufficient (defined as a serum level of 20-32 ng/mL) or vitamin D deficient (defined as a serum level of < 20 ng/mL), respectively, as compared with 12 patients (11%) and 2 patients (2%) in the control group (Figure 1). A weak positive correlation was found between femur neck BMD and serum 25(OH)D3 levels in the DRF group ($r = 0.22$, $p = 0.02$). However, the levels of the assessed markers of bone metabolism were similar in the two groups.

Conclusions: Postmenopausal women with a DRF were found to have significantly lower serum vitamin D levels than the control. Since vitamin D is required for bone metabolism and musculoskeletal function, further studies are warranted to determine whether hypovitaminosis D is a risk factor for DRF and whether vitamin D supplementation helps rehabilitation and the prevention of future fractures in patients with a DRF.

Prevalences of hypovitaminosis D in the DRF and Control groups

Incidence of Multiple Falls and Risk Factors in a Longitudinal Population-Based Cohort Study in Japan: The ROAD Study. Shigeyuki Muraki¹, Toru Akune¹, Hiroyuki Oka¹, Kozo Nakamura², Hiroshi Kawaguchi³, Noriko Yoshimura¹. ¹22nd Century Medical & Research Center, University of Tokyo, Japan, ²The University of Tokyo, Japan, ³University of Tokyo, Faculty of Medicine, Japan

Multiple falls are the most serious cause of fractures in the elderly; therefore, it is important to identify subjects with risk factors for multiple falls. The objective of the present study was to determine the incidence of multiple falls and the risk factors. Among the 3,040 participants in the baseline study of the Research on Osteoarthritis/osteoporosis Against Disability (ROAD) study, 2,485 subjects (81.7%) participated in the follow-up study. Among the 2,485 subjects, 2,215 subjects (745 men and 1,470 women; mean age, 68.0 years) were analyzed. These subjects filled questionnaires regarding their falls between the baseline study and the follow-up study and questionnaires regarding their knee and lower back pain in the baseline study. Multiple falls was defined as 2 or more falls. They underwent radiography of the knee and the lumbar spine, and their physical abilities were measured in the baseline study. At the baseline, physical ability was estimated by measuring the grip strength and the walking speed at the usual pace. Knee osteoarthritis (OA) and lumbar spondylosis were defined as Kellgren/Lawrence grade ≥ 3 . The mean duration between the baseline and follow-up studies was 3.3 0.6 years. During this period, 261 subjects (11.8%; 84 men and 177 women) fell multiple times. A logistic regression analysis without adjustment showed that age (odds ratio [OR], 1.02; 95% confidence interval [CI], 1.01-1.03), grip strength (OR, 0.98; 95% CI, 0.97-1.00), walking speed [m/min] (OR, 0.98; 95% CI, 0.97-0.99), radiographic knee OA (OR, 1.86; 95% CI, 1.35-2.52), and knee pain (OR, 2.07; 95% CI, 1.56-2.73) were significantly associated with multiple falls, while radiographic lumbar spondylosis (OR, 0.93; 95% CI, 0.72-1.21) and lower back pain (OR, 1.21; 95% CI, 0.88-1.66) were not. Next, to determine the independent associations of each variable with multiple falls, a multiple logistic regression analysis was performed with age, gender, grip strength, walking speed, radiographic knee OA, and knee pain as independent variables. Walking speed [m/min] (OR, 0.98; 95% CI, 0.98-0.99) and knee pain (OR, 1.27; 95% CI, 1.08-1.48) were found to be independently associated with multiple falls. In conclusion, this longitudinal study

showed that lower walking speed at usual pace and knee pain were risk factors for multiple falls; these findings indicated that multiple falls may be prevented by walking as an exercise and by treating the knee pain.

Disclosures: Shigeyuki Muraki, None.

Lack of Evidence Defining Vitamin D Inadequacy as Less than 30 ng/ml of Serum 25(OH)D. Sena Hwang¹, Han Seok Choi², Kyoung Min Kim³, Kwang Joon Kim³, Yumie Rhee¹, Sung-Kil Lim¹. ¹Yonsei University College of Medicine, South Korea, ²Division of Endocrinology & Metabolism, Department of Internal Medicine Dongguk University Ilsan Hospital, South Korea, ³Institute of Endocrine Research, & Brain Korea 21 Project for Medical Sciences, South Korea

Background: It is well known that vitamin D is important for metabolism for various organs as well as bones. However, the Institute of Medicine (IOM) gave a skeptical response for maintaining serum 25(OH)D levels over 30 ng/mL because the current evidence does not support beneficial effects on skeletal and nonskeletal health. We want to determine the association of 25(OH)D and clinical disorders and the optimal level of serum 25(OH)D for skeletal and non-skeletal health. **Methods:** This is a cross-sectional analysis of vitamin D and clinical disorders in 10,562 volunteers (10 to 95 years, male 4759, female 5803) participated in KNHANES, and nationally representative survey to assess the health and nutritional status from 2008 to 2009. We grouped according to 25(OH)D level follows as 25(OH)D < 12 ng/mL for group 1, $12 \leq$ group 2 < 20 , $20 \leq$ group 3 < 30 , and ≥ 30 ng/dL for group 4. **Results:** Serum 25(OH)D was below 12 ng/mL in 14.8%, below 20 ng/mL in 60%, below 30 ng/mL in 91.7%, and above 30 ng/mL in 8.3%. In skeletal health analyzed by bone geometry, cross sectional area, cross sectional moment of inertia and cortical thickness in femoral neck were significantly increased with serum 25(OH)D and cortical buckling ratio was decreased with serum 25(OH)D over all age groups in males ($p < 0.05$). However, in females, it was significant only over 50 age groups. In addition, in males, BMD values in group 4 were higher than those in group 2 or 3 ($p < 0.01$). In females, it was significant only age group of over 20 years ($p < 0.05$). There were no significant differences in vertebra. In non-skeletal health, there were significant differences in HOMA-IR, lipid profile (total cholesterol, HDL-, LDL-Cholesterol, triglyceride) according to 25(OH)D groups. In concomitant diseases, the risk of pulmonary tuberculosis was increased in group 1 compared to group 4. Of interest, there were no significant differences in all factors of skeletal and non-skeletal health between 25(OH)D 20-30 ng/mL group and 25(OH)D ≥ 30 ng/mL group. **Conclusion:** We demonstrated vitamin D was important not only for skeletal but also non-skeletal health. However, maintaining serum 25(OH)D with 20-30 ng/mL may be appropriate for proper skeletal and non-skeletal health without any complications with excessive supplement of vitamin D.

Non-traumatic Fractures and the Treatment Care Gap in Individuals with Diabetes: the Canadian Multicentre Osteoporosis Study. Lisa-Ann Fraser¹, Jonathan Adachi², Alexandra Papaioannou³, Lehana Thabane³. ¹University of Western Ontario/McMaster University, Canada, ²St. Joseph's Hospital, Canada, ³McMaster University, Canada

Purpose: Individuals with diabetes have been found to be at increased risk of non-traumatic fracture. A fracture is strongly predictive of future fracture risk and therefore pharmacologic intervention is usually indicated. Diabetes is not a disease that has been classically associated with increased osteoporosis or fracture risk; therefore it is unclear if individuals with diabetes are being identified and treated for skeletal protection. We aimed to describe fracture prevalence and bisphosphonate use in men and women with insulin-dependent and non-insulin-dependent diabetes in a large population-based Canadian cohort study.

Methods: 7741 Canadian men and women over 50 years of age were examined, including 506 individuals with non-insulin-dependent diabetes and 98 with insulin-dependent diabetes. History of non-traumatic fracture was investigated and a logistic regression model was created to identify factors associated with bisphosphonate use at any time during a 10 year period of the CaMos study.

Results: Individuals with diabetes were more likely to have a history of fracture than non-diabetic CaMos participants (odds ratio [OR]=1.21, 95% confidence interval [CI] 1.00-1.46, $p=0.04$). Other factors that were found to be associated with a history of fracture ($p < 0.05$) were: femoral neck T-score (OR: 0.79), rheumatoid arthritis (OR: 1.34) family history of osteoporosis (OR: 1.26), female gender (OR: 1.11) and increased age (OR 1.01). Despite the association with increased fracture rates, individuals with diabetes were less likely to be on bisphosphonate therapy at any point over 10 years of CaMos compared to other CaMos subjects (OR: 0.58; 95% CI 0.46-0.75, $p < 0.001$). Increased femoral neck T-score was also associated with decreased bisphosphonate use (OR: 0.40; 95% CI 0.40-0.44, $p < 0.001$). Variables associated with increased bisphosphonate use included: rheumatoid arthritis (OR: 1.28, 95% CI 1.04-1.58, $p=0.02$), family history of osteoporosis (OR: 1.25, 95% CI 1.07-1.45, $p=0.004$), female gender (OR: 3.04, 95% CI 2.62-3.51, $p=0.003$), and history of non-traumatic fracture (OR: 1.20, 95% CI 1.06-1.36, $p=0.004$).

Conclusions: Despite having an increased prevalence of non-traumatic fractures, we found individuals with diabetes were less likely to be treated with a bisphosphonate than those without diabetes. These findings point to a care gap in the treatment of non-traumatic fractures in individuals with diabetes.

Disclosures: Lisa-Ann Fraser, None.

SU0381

Prediction of Fractures over 6 Years from FRAX® in Older Women: Recent Falls History as a Further Independent Risk Factor. Judith Finigan^{*}¹, Claus-C Glueer², Dieter Felsenberg³, David Reid⁴, Christian Roux⁵, Richard Eastell¹.

¹University of Sheffield, United Kingdom, ²Christian Albrechts Universitaet zu Kiel, Germany, ³Charite - Campus Benjamin Franklin, Germany, ⁴University of Aberdeen, United Kingdom, ⁵Hospital Cochin, France

FRAX®, the WHO Fracture Risk Assessment Tool, calculates the 10-year probability of osteoporotic or hip fracture from 11 risk factors and, optionally, femoral neck (FN) BMD. We aimed to examine associations between the FRAX-derived percentage probabilities of fracture and the 6-year incidence of any non-vertebral, major osteoporotic, or vertebral fracture in a postmenopausal population, and to investigate whether recent falls were an further risk factor.

Women over age 55 years were recruited at 5 European centres (the OPUS study). Medical and lifestyle data were obtained at baseline including any falls in the previous year. Non-vertebral fractures since baseline were self-reported and verified at 6-year follow-up. In addition, lateral spine radiographs were obtained at both visits for diagnosis of incident vertebral fractures. Subjects were only included in the analysis if they had complete data on FRAX risk factors and falls at baseline and incident fracture data and radiographs at follow up. FRAX probabilities were calculated individually, based on each subject's details, history and FN BMD. Multivariate logistic regression, with the calculated FRAX probabilities and falls history as co-variables, was used to calculate odds ratios of incident fracture.

The inclusion criteria were fulfilled by 1410 subjects, of whom 220 sustained an incident fracture at any site: 175 had a non-vertebral, 60 a vertebral and 129 a major osteoporotic fracture (vertebra, hip, wrist or humerus). In the year before baseline 402 women had one or more falls, of whom 90 had 3 or more. By stepwise multivariate regression the most significant FRAX probability scores for predicting fractures, those with FN BMD, were identified for each fracture category. Any recent fall was an additional independent predictor of non-vertebral fractures (adjusted OR 1.50 (1.07, 2.10)) but the number of falls was not. Conversely neither osteoporotic nor vertebral fractures were additionally predicted by a recent fall ($p > 0.05$) but women with 3 or more falls were at greater risk (adjusted ORs 2.29 (1.27, 4.11) and 3.15 (1.51, 6.56), $p < 0.01$).

We conclude that the 10-year percentage risk of osteoporotic fracture calculated by FRAX, including FN BMD, also predicts different categories of fracture over 6 years in postmenopausal women. Recent prior falls are a further risk factor for non-vertebral fractures but the risk of osteoporotic and vertebral fractures is increased only with multiple falls.

Disclosures: Judith Finigan, None.

Risk Factors for Vertebral Fractures in Frail, Long Term Care Residents. Mary Anne Ferchak, Megan Miller, Kimberly Zukowski, Carroll Lee^{*}, Subashan Perera, David Nace, Gail Fiorito, Neil Resnick, Susan Greenspan. University of Pittsburgh, USA

Background: Studies suggest a sideways fall, low hip bone mineral density, low BMI and poor mobility are associated with hip fracture in frail nursing home residents. However, little data are available on risk factors associated with vertebral fractures (VF) in this population.

Methods: To examine this question we assessed bone mineral density (hip or spine, DXA or heel ultrasound), calcium and vitamin D intake, Physical Performance Test (PPT), Physical Activities of Daily Living (PADL), Instrumental Activities of Daily Living (IADLs), Duke Comorbidity Index (DCI), mental status, falls history (in the last year) in 233 residents from long term care institutions on no medications for osteoporosis. Vertebral fractures included those reported as clinical vertebral fractures (medical record verified) or by DXA-derived Vertebral Fracture Assessment (moderate to severe fractures Genant classification).

Results: Mean age was 86.0 years. 30.5% of patients had a vertebral fracture, including 17.6% of patients who had an unknown, silent or moderate to severe vertebral fracture. Bone mineral density at the lateral spine or femoral neck was significantly lower, height shorter, and weight lower in patients with vertebral fracture compared to those without ($p < 0.05$, Table). The association with falls was marginally significant. Measures of heel ultrasound, calcium and vitamin D intake, PPT, PADL, IADL, DCI, mental status or osteoporosis diagnosis by BMD (T-score ≤ -2.5 at spine or hip) did not differ between the groups.

Conclusion: Low bone mineral density at the spine/hip, low body weight and history of falls are risk factors for vertebral fracture in residents of long term care. The association of bone mineral density and vertebral fracture in this cohort suggest that therapeutic intervention to improve bone mass should be pursued. Future studies are needed to examine which factors are associated with prospective changes in bone mineral density and incident vertebral fractures.

Variable	Vertebral fracture present	Vertebral fracture absent
N	71	162

Six Year Follow up in Patients with Previous Osteoporotic Fracture of Proximal Femur. Vaclav Vyskocil^{*}¹, Tomas Pavelka², Monika Honnerova³. ¹Center for Metabolic Bone Diseases, Czech Republic, ²Department of Orthopaedic Surgery, Czech Republic, ³Department of Bone Disease, Czech Republic

The authors observed 231 patients with low-trauma osteoporotic fractures, 87 in the area of proximal femur, 84 vertebral fractures and 60 fractures of distal forearm and proximal humerus, which had been treated in the Plzen University Hospital Clinic of Orthopedics and Traumatology in 2004. After hospital discharge densitometric measurement was performed and according to the results anti-osteoporotic pharmacotherapy was started. Bone mineral density (BMD) was measured in hip and spine.

In patients with spine injury was found significantly lower vertebral BMD, T-score -2.14 in area of L1-L4 and -1.6 in hip. The situation was opposite in patients with hip fractures: T-score -1.6 in L1-L4 and -2.02 in hip. In patients with fracture of proximal humerus and forearm was found less significant standard deviation from the norm T-score -1.3 in both areas. Average age of patients with fracture of distal forearm was 62, for vertebral fractures 67 and hip fractures 70. Relatively lower average age of patients with hip fractures was driven by the fact that those patients were able to come to densitometric measurement and all of them underwent surgical treatment of fracture. Treatment of distal forearm, proximal humerus and vertebral fractures was considering the patient age predominantly conservative.

Patients were treated despite the high fracture risk mostly by calcium and vitamin D. Only patients with lower BMD than -2.5 T score with low-trauma hip or vertebral fracture received an antiresorptive therapy at the specialized center. Although all patients were educated about the risk of another fracture, only 5% of them agreed to take the antiresorptive therapy. 15% of patients who refused the treatment suffered from another hip fracture contra-laterally within one year period and 35% within 3-year period after the first fracture.

After six years follow up of patients with the hip fracture (set of 87 patients), more than 43.7% of patients experienced contralateral fracture or other type of fracture. The authors also performed the monitoring of the same parameters in set of patients with vertebral fractures and distal forearm fractures and from the original densitometric measurements calculated FRAX index and they compare the risk of fracture with the actual incidence of fractures.

Disclosures: Vaclav Vyskocil, None.

Ten Year Probability of Fractures Estimation with the WHO Fracture Risk Assessment Algorithm in Subjects with Osteopenia Naive to Treatment in the Latin America Vertebral Osteoporosis Study (LAVOS) Population, Puerto Rico Site. Rafael Gonzalez^{*}¹, Leticia Hernandez¹, Lillian Haddock-Suarez². ¹University of Puerto Rico, School of Medicine, Puerto Rico, ²University of Puerto Rico School of Medicine, Puerto Rico

There is limited information in literature regarding the prevalence of osteopenia or osteoporosis risk factors in the Puerto Rican population. The Latin American Vertebral Osteoporosis Study (LAVOS) was the first population-based study of vertebral fractures in Puerto Rico. The prevalence of vertebral fractures was estimated to be 11.9%. In 2008, the National Osteoporosis Foundation (NOF) published a revised Clinical Guide for the Prevention and Treatment of Osteoporosis. Treatment in patients with osteopenia (T-score between -1.0 and -2.5) is recommended if the 10-year hip fracture probability is 3% or higher and/or if the 10-year major osteoporosis-related fracture probability is 20% or higher, based on the World Health Organization (WHO) FRAX® algorithm. The aim of this study was to determine the prevalence of osteopenia in the LAVOS population and of the risk factors used in the FRAX

algorithm, along with the proportion of subjects who were treatment candidates by the new NOF guide.

The prevalence of osteopenia and risk factors used in the new NOF FRAX-based Guide was estimated using data from 398 female subjects between 50-90 years old collected in LAVOS. Osteopenic subjects were identified according to the WHO definition, (T-score between -1.0 and -2.4). The proportion of postmenopausal women age 50+ years who are treatment candidates by the new NOF Guide was calculated as well as the prevalence of risk factors taken in consideration in the WHO FRAX algorithm. Subjects were sub-classified in 4 age strata as follows: (1) 50-59, (2) 60-69, (3) 70-79 and (4) 80+ years.

One hundred and seventy one (171) subjects were found to be osteopenic (42.96%). Ninety four (94) of these subjects were identified as osteopenic and naive to treatment, meeting inclusion criteria for our study. The prevalences of individual risk factors are shown in Table 1. After estimation of FRAX Score only 4 subjects (4.26%) met treatment criteria. Two subjects were 70-79 and 2 subjects older than 80 years old. No individuals met treatment criteria taking into consideration their 10 year major osteoporotic fracture probability.

Conclusion: Only 4 (4.26%) postmenopausal women were eligible for treatment according to their 10 year hip fracture probability and all were older than 70 yrs. These results are in accordance with previous studies showing that the new NOF FRAX-based Guide favors treatment in older women mostly based in their 10 yr probability of hip fracture.

Table 1. Prevalence of individual risk factors in the WHO FRAX algorithm in a sample of osteopenic and naive to treatment women in the Municipality of San Juan, Puerto Rico.

The Association Between Newer Anticonvulsants and Bone Mineral Density. Richard Lee^{*1}, Kenneth Lyles², Richard Sloane², Cathleen Colon-Emeric². ¹Duke University, USA, ²Duke University Medical Center, USA

Background: Newer anticonvulsant medications, such as levetiracetam, lamotrigine, and gabapentin, have been increasingly prescribed for the treatment of seizure disorders, neuropathic pain and mood disorders. Observational studies have reported an association between anticonvulsant use and reduced bone mineral density (BMD), but have largely been limited to traditional anticonvulsants, such as phenobarbital and phenytoin.

Objective: To examine the effect of newer anticonvulsant medications on BMD compared to traditional anticonvulsants.

Method: We performed a retrospective cohort study of patients at the Durham VA Medical Center. All patients who had a DXA between May 2006 and January 2010 were included. Cumulative exposure to anticonvulsant medications during the 10 years prior to DXA was determined from the computerized pharmacy record, including drug class, dose and duration. Patient demographics, comorbidities, and laboratory data were abstracted from the electronic medical record. Logistic regression modeling was used.

Results: There were 1779 BMD assessments within the study period. The most prescribed newer anticonvulsants were lamotrigine and gabapentin. Phenobarbital was the most prescribed traditional anticonvulsant. Use of newer anticonvulsants was associated with a lower risk of osteopenia or osteoporosis at the total hip or femoral neck (OR 0.72, 95% CI: 0.57 – 0.92) and lumbar spine (OR 0.74, 95% CI: 0.58 – 0.95). After adjustment for age, gender, BMI, and concurrent medications (including corticosteroids and bisphosphonates), the association between newer anticonvulsants and osteopenia or osteoporosis at the total hip or femoral neck was no longer statistically significant ($p = 0.08$). However, the association at the lumbar spine remained ($p = 0.02$).

Conclusion: Use of newer anticonvulsants, such as lamotrigine and gabapentin, is associated with a lower risk of osteoporosis or osteopenia by BMD at the lumbar spine.

The Importance of Morphometric Radiographic Vertebral Fracture Assessment for the Detection of Patients Who Need Pharmacological Treatment of Osteoporosis among Postmenopausal Diabetic Korean Women. Yong Jun Choi^{*1}, Seoung-Oh Yang², Chan Soo Shin³, Yoon-Sok Chung¹. ¹Ajou University School of Medicine, South Korea, ²Asia Cancer Center, South Korea, ³Department of Internal Medicine, Seoul National University College of Medicine, South Korea

Purpose: Vertebral fracture assessment (VFA) is important for identifying patients who need pharmacologic therapy for osteoporosis. However, many patients with VFs remain undiagnosed and untreated. This study evaluated the number of patients who would be candidates for osteoporosis treatment according to the National Osteoporosis Foundation (NOF) Clinician's Guidelines to the Prevention and Treatment of Osteoporosis, among postmenopausal diabetic Korean women with morphometric VFs, assumed to have no radiographic diagnosis of VFs.

Methods: A total of 873 postmenopausal type 2 diabetic women were enrolled. Lateral plain radiographs of the thoracolumbar spine, and total hip BMD were obtained. The FRAX[®] probability was computed using the algorithm available online

at <http://www.shef.ac.uk/FRAX> (South Korea version). The subjects were classified with and without VFs into candidates for osteoporosis treatment [Tx(+)] and not candidates for osteoporosis treatment [Tx(-)] according to the NOF pharmacologic treatment guidelines, regardless of the presence of VFs.

Results: Among the subjects with morphometric VFs, only 2% of the patients had previously diagnosed VFs by medical doctors. There were 33.6% of the patients with current back pain that had VFs. However, 73.6% of the patients with VFs were not included in the Tx(+) group, given the assumption of no radiographic diagnosis of VFs.

Conclusions: With regard to increased risk of VFs in postmenopausal Korean women with type 2 diabetes mellitus, radiographic VFA would be useful for the clinical identification of treatment for osteoporosis and fractures.

Figure. The number of women that were candidates for treatment [NOF Tx(+)] and not candidates for pharmacologic treatment [NOF Tx(-)] with [VF(+)] and without [VF(-)] vertebral fractures according to the National Osteoporosis Foundation (NOF) Guidelines: (A) After excluding the patients with a previous history of vertebral fractures (B) After excluding the patients with a previous history of vertebral fractures that were on pharmacological treatment for osteoporosis.

Utilization of osteoporosis Medications in Women With and Without Diabetes Mellitus. Nicole Wright*, Elizabeth Delzell, Paul Muntner, Jeffrey Curtis, April Carson, Monika Safford. University of Alabama at Birmingham, USA

Purpose: Individuals with diabetes mellitus (DM) have an increased fracture risk. They also have multiple medical problems that compete for physician attention, potentially resulting in sub-optimal use of osteoporosis medications. Using baseline data from the Reasons for Geographic And Racial Differences in Stroke (REGARDS) study, the objectives were to compare fracture risk and utilization of osteoporosis medications among women with and without DM.

Methods: REGARDS is a population-based nationwide cohort study of 30,239 Caucasian and African American adults age >45 years in the US. DM was defined by self-report of physician or other healthcare provider diagnosis. Women without DM included those who did not self-report and did not have a fasting glucose >126 mg/dL or non-fasting glucose ≥200 mg/dL. Fracture risk was calculated using the World Health Organization fracture assessment tool (FRAX), and women were considered at high fracture risk if hip FRAX scores were ≥3%, major osteoporotic FRAX scores were ≥20%, or if they reported having a previous fracture at 45 years of age or older. Logistic regression models were used to evaluate associations between DM and osteoporosis medication use among women with high fracture risk.

Results: This study included 14,679 women with a mean (SD) age of 64.3 (9.4) years, of which 45% were African American. At baseline, 3,148 (21.5 %) women had DM. The proportion of women at high fracture risk was substantial, but lower ($p < 0.001$) in women with DM (26.8%) than women without DM (35.6%). Among women with a high fracture risk ($n = 4,888$), only 21.0% without DM and 10.6% with DM used osteoporosis medications. Several socio-demographic and co-morbidity variables were associated with osteoporosis medication use, including: age, body mass index, race, income, education, smoking, insurance, self-reported health, steroid use, number of cardiovascular conditions, and number of prescriptions. In the high fracture risk group, women with DM were less likely than women without DM to be taking osteoporosis medications after adjusting for other factors related to osteoporosis medication use [adjusted Odds Ratio (95% CI) = 0.72 (0.53-0.98)].

Conclusion: Overall, only one in five women with high fracture risk in the REGARDS study received osteoporosis medications and only one in 10 women with DM did so. Interventions to improve osteoporosis awareness and treatment targeted at high risk women with DM may be warranted.

Vertebral Morphometry and its Heterogeneity Predict Lumbar Vertebral Fracture in Postmenopausal Women. The OFELY Study. Safaa Belghali, Jean-Paul Roux*, Elisabeth Sornay-Rendu, Roland Chapurlat, INSERM, UMR 1033, Université de Lyon, France

Vertebral morphometry is widely used to depict vertebral fracture but its utility for their prediction is poorly documented. The aim of our study was to analyze the vertebral morphometry and its heterogeneity in post menopausal women before incident vertebral fracture.

A case control study from the OFELY cohort was performed, including 29 postmenopausal women with incident lumbar vertebral fractures (mean age 71.9 years, mean time until fractures 9.4 years) age-matched with 57 controls without any incident fracture. Body height was not significantly different between groups. The distribution of vertebral fractures was: 7 (L4), 7 (L3), 5 (L2), 16 (L1), six women sustained more than one vertebral fracture. Digital scans were performed on lateral X-rays of lumbar spine (T12 to L4) at baseline with a spatial resolution of 0.26mm/pixel. From these radiographs, the following parameters were measured from six digitized points using Morpho Expert software (Explora Nova, la Rochelle, France): 1) the posterior, middle and anterior vertebral height, 2) the heterogeneity of heights evaluated by the coefficient of variation of these three values. All measurements were done by two observers, intra and inter observers reproducibility were excellent with an ICC of 0.99 and 0.97 respectively.

Mean vertebral heights were significantly lower in the fracture group vs the control one (33.43 vs 34.53mm; $p = 0.049$). The posterior heights did not differ between the two groups. Only the anterior and middle heights were significantly different between the two groups in L4 and L3 vertebrae. No significant differences were found in L1-L2 and T12. The mean heterogeneity of vertebral height was significantly greater in the fracture group (6 vs 5%; $p = 0.003$).

In summary, our study confirms the association between vertebral height and occurrence of fracture in postmenopausal women. The heterogeneity of vertebral heights seems to be a relevant variable associated with fracture, with a good reproducibility.

	Mean vertebral heights	Mean heterogeneity of heights (CV%)	L4			L3		
			ant. height	mid. Height	post. Height	ant. Height	mid. Height	post. Height
Fractures	33.43	6	35.89	33.56	34.17	36.21	32.71	35.89
Controls	34.53	5	36.75	34.68	34.93	37.11	34.07	36.43
p*	0.049	0.003	NS	0.02	NS	0.02	0.03	NS

Circulating Sclerostin Demonstrates a Circadian Rhythm in Young Healthy Men. Shankar Narayan H Santosh*, Frank Joseph², Amanda Hamilton³, Brian Durham⁴, Anna Robinson⁴, Jonathan Tang³, Jiten P Vora³, William D Fraser⁵. ¹Royal Liverpool University Hospital, GBR, ²Countess of Chester Hospital NHS Trust, United Kingdom, ³Royal Liverpool University Hospital, United Kingdom, ⁴University of Liverpool, United Kingdom, ⁵Department of Clinical Chemistry, University of Liverpool, United Kingdom

Introduction: Sclerostin is secreted predominantly by the osteocytes, and is a physiological inhibitor of bone formation. By binding to LRP5/6 receptor it inhibits the Wnt signalling pathway and limits bone formation. A cross-sectional study was undertaken to ascertain whether true endogenous sclerostin circadian rhythmicity exists in healthy individuals.

Subjects and Methods: 6 healthy young men with normal BMD were recruited. Blood samples were collected every hour. Samples were centrifuged immediately, and serum/plasma was separated to be frozen at -700C for later analysis. Sclerostin was measured by an enzyme linked immunoassay (Biomedica, Austria). All samples were assayed in duplicates. The inter and intra assay CV% being 12.3% and <5% respectively with a detection limit of 8.9pmol/L.

Statistical Analysis: Individual and population mean cosinor analysis was performed using CHRONOLAB 3.0 (Universidade de Vigo, Vigo, Spain), a software package for analyzing biological time series by least squares estimation. Circadian rhythm parameters evaluated were: 1) midline estimate statistic of rhythm (MESOR), rhythm-adjusted mean; 2) amplitude and 3) acrophase were measured. A p value for the rejection of the zero-amplitude (no rhythm) assumption is also determined for each individual series and for the group.

Results: Significant circadian rhythm was observed for sclerostin in the study population ($p = 0.028$). The mean sclerostin (MESOR) was 84.41.4pmol/L. Circulating sclerostin demonstrated a nocturnal peak (time of onset 0100h) with concentrations remaining above mean over 4 hours. A small but ill sustained increase is noted at 0700h which culminates in a steep descent to a trough (at 0800h) the levels remain low throughout the morning till midday (1200h). The maximum percentage increase in the sclerostin concentration between 0100h and 0700h [(value at each time point - 0100h value) / 0100h value x 100] was 19.7%.

Conclusion: These results confirm a definite circadian rhythm for circulating sclerostin. This is the first demonstration of a circadian rhythm for sclerostin secretion in young healthy men.

Take Two to Tango: Estrogen Deficiency and Increased Iron in Postmenopausal Osteoporosis. Qing Yang¹, Jinlong Jian¹, Florence Huang², Xi Huang^{*3}. ¹New York University Medical Center, USA, ²Bergen County Academy, USA, ³New York University School of Medicine, USA

Women during menopausal transition experience not only estrogen deficiency but also iron accumulation as a result of cessation of menstruation. Menopause initiates a rapid transit phase of bone loss at the early stage, which is reversible by hormone replacement therapy, and a subsequent slow phase of bone loss independent of estrogen deficiency. In the present study, we have investigated whether, in addition to estrogen deficiency, which promotes bone resorption, increased iron causes bone formation slowdown. We have found that hepcidin, a negative regulator of iron uptake, contains an estrogen responsive element. Estrogen deficiency by ovariectomy in mice initiates an increase in hepcidin, which temporarily causes an iron increase in the bone tissue because of iron excretion shutdown through its binding to ferroportin, an iron exporter. This estrogen deficiency-induced increase in iron in the bone could contribute to the early phase of bone loss. At the later stage, complete cessation of menstruation leads to a slow systemic increase in iron. We have found that iron inhibits alkaline phosphatase in osteoblast progenitor cells by enhancing hypoxia-inducible factor-2 α through an iron responsive element/iron regulatory protein system. Secondly, in the presence of iron, hemojuvelin (HJV), a co-receptor of bone morphogenetic proteins (BMP) receptors, is shed into the extracellular media. Solubilized HJV binds to BMPs and, thus, antagonizes the BMP signaling. Similar effects could be true with hemochromatosis Fe (HFE), another iron membrane protein. Taken together, our results suggest that iron accumulation is a previously ignored factor that could orchestrate the scenario of bone resorption outpacing bone formation with estrogen deficiency, leading to postmenopausal osteoporosis development.

Central IL-1 Signaling Regulates Bone Mass Via Parasympathetic Skeletal Innervation. Alon Bajayo^{*1}, Arik Bar², Adam Denes³, Marilyn Bachar², Vardit Kram², Malka Attar-Namdar², Alberta Zallone⁴, Raz Yirmiya², Itai Bab⁵. ¹Hebrew University Faculty of Dentistry, Israel, ²Hebrew University of Jerusalem, Israel, ³University of Manchester, United Kingdom, ⁴University of Bari Medical School, Italy, ⁵The Hebrew University, Israel

We have previously observed that central IL-1 stimulates bone mass accrual by favoring bone formation over bone resorption. This activity appears to oppose the adrenergic skeletal tone, which restrains bone formation and enhances bone resorption. Hence, we hypothesized that the central IL-1 signals are communicated to the skeleton by the parasympathetic nervous system (PSNS). Indeed, we show here osteoclastic nicotinic acetylcholine (ACh) receptors (nAChRs) consisting mainly of $\alpha 2$, $\beta 2$ and $\beta 4$ subunits, whereas osteoblasts express mainly muscular nAChRs subunits. Muscarinic ACh receptors were undetectable in either cell type. nAChR agonists inhibit bone resorption by inducing premature osteoclastogenesis and osteoclast apoptosis. The same agonists also stimulate osteoblast number. $\alpha 2$ subunit deficient mice have a markedly low bone mass phenotype due mainly to increased bone resorption. Additional parasympathetic components present in the skeleton are ACh as well as parasympathetic nerve fibers immunohistochemically positive for choline acetyltransferase and the vesicular ACh transporter (VAcHT). These fibers receive parasympathetic inputs from the central nervous system via the sacral intermediolateral cell column, shown by retrograde transneuronal tracing with a recombinant pseudorabies virus inoculated into the distal femoral metaphysis. The membrane bound and soluble ACh esterases (AChEs), the ACh degrading enzymes, are also present in bone cells. Taken together, these data establish the occurrence of skeletal parasympathetic innervation. PSNS activation by administering the peripheral AChE inhibitor pyridostigmine (PS) to mice during bone mass accrual leads to increased skeletal ACh content and a marked stimulation of bone mass consequent to decreased bone resorption. Mice with silenced central IL-1 signaling show high turnover low bone mass, almost complete inhibition of skeletal VAcHT expression and decreased ACh content, which cannot be rescued by PS. These findings demonstrate that during bone mass accrual central IL-1 signaling maintains a positive bone remodeling balance by controlling a skeletal parasympathetic tone.

FSH Correlates with Trabecular Bone Loss in Rats Transitioning to Ovarian Failure. Ashley Lukefahr¹, Jennifer B. Frye¹, Laura Wright², Janet Funk^{*3}. ¹University of Arizona, USA, ²The University of Arizona, USA, ³University of Arizona Health Sciences Center, USA

Elevated follicle-stimulating hormone (FSH) correlates with low trabecular bone mineral density (BMD) in women during the perimenopause, an estrogen-sufficient period. A similar estrogen-replete state with elevated FSH occurs in rats during persistent estrus, an acyclic period that precedes ovarian failure. To examine the hypothesis that elevated FSH can drive perimenopausal trabecular bone loss, trabecular bone was assessed prospectively (by serial DXA measurement of distal femoral and proximal tibial BMD) in female Sprague Dawley rats undergoing normal ovarian senescence or treated with VCD, an industrial chemical known to accelerate the natural process of ovarian follicular atresia. As anticipated, serum 17 β -estradiol levels remained unchanged during natural or VCD-induced persistent estrus. In control rats naturally transitioning to ovarian senescence, BMD of the proximal tibial and distal femoral were unchanged, relative to peak BMD attained at 5 months of age, during a 6-month period from age 14-20 months when serum FSH was elevated 3.5-fold relative to young cycling animals. Administration of VCD to 1-month old animals accelerated the onset (age 5 months) of increased FSH. FSH levels in these rats were dose-dependently increased by VCD and exceeded those documented in animals undergoing natural senescence, being 5 to 12-fold elevated as compared to young cycling animals. FSH elevations in these rats preceded significant 4-13% decreases in BMD as compared to age-matched controls. Overall, BMD was significantly decreased in VCD-treated groups whose average cumulative FSH exposure (area under the curve [AUC], age 2-12 months) was > 3.8-fold higher than age-matched controls. When assessed at multiple time points across the transition to ovarian failure in control and VCD-treated animals (age 2-13 months), FSH levels were significantly and inversely correlated with BMD ($r^2 = 0.19$, $p < 0.0002$). Inhibin A levels across the transition correlated inversely with FSH ($r^2 = 0.27$, $p < 0.0001$) but did not correlate with BMD unless normally cycling (2-month old) animals were excluded ($r^2 = 0.13$, $p < 0.006$). To our knowledge, these results provide the first in vivo evidence of a correlation between trabecular bone loss, elevated FSH and decreased inhibin in estrogen-replete rodents transitioning to ovarian failure, lending further support to the prevailing hypothesis that non-estrogenic hormonal changes drive trabecular bone loss during perimenopause.

Preliminary Evidence for Acute Post-Burn Bone Resorption in Sheep. Gordon Klein^{*1}, Minyi Hu², Liangjun Lin², Yi-Xian Qin², Cherry Croft³, Larry R Sumpter³, X Zhou³, H Qing⁴, Lynda Bonewald⁵.

¹University of Kentucky College of Medicine, USA, ²State University of New York at Stony Brook, USA, ³University of Kentucky, USA, ⁴University of Missouri Dental School, USA, ⁵University of Missouri - Kansas City, USA

Bone becomes adynamic by two weeks after severe burns in children. This occurs due to apoptosis of osteoblasts and, presumably, osteocytes caused by excessive endogenous glucocorticoid production and pro-inflammatory cytokines derived from the systemic inflammatory response that can cause osteoclastogenesis and acute bone resorption by stimulating the osteoblasts/osteocytes to produce RANK Ligand (RANKL). Thus it is possible that inflammatory cytokines and endogenous glucocorticoids together may be able to explain substantial resorptive bone loss by two weeks post-burn. If so we may be able to explain why acute administration of the bisphosphonate pamidronate is able to prevent significant post-burn bone loss. The aim of our study was to determine if osteoclasts are activated during this post-burn period. We obtained 1 cm² samples of iliac crest from six adult female cross-breed sheep weighing 30-40 kg. The specimens were fixated, dehydrated, and embedded in methylmethacrylate before being subjected to backscatter scanning electron microscopy (BS-SEM). When compared to specimens taken from uninjured sheep the burned sheep had less bone with enlarged osteocytic lacunae and substantial scalloping. The latter is considered a result of active bone resorption. To substantiate this finding TRAcP staining and osteoclast counts of two samples from each iliac crest section revealed an osteoclast count in the burned sample (n=1) that was 3.3 times higher in the burned specimen than in control specimens (n=3). To determine biomechanical properties, two trabecular bone cubes (average diameter 5x5x5 mm³) were cut from each sample using a low-speed diamond blade saw with continuous water irrigation. Compression testing was performed on a MTS Mini Bionix (MTS Corp, Minneapolis MN) axial load frame with Test Star II control software. Failure loading test was used to analyze the result of the mechanical testing, and compared to control samples (n=3), the experimental sample (n=1) showed a 28% decrease in elastic modulus (p<0.065). Thus we have preliminary evidence in sheep bones supporting acute resorption with attendant decrease in biomechanical stiffness acutely following burn injury. If further studies confirm these findings we have additional evidence supporting the early use of bisphosphonates to prevent post-burn bone loss.

Regulation of Parathyroid Hormone Secretion By Caffeine-Potential Impact on Osteoporosis. Ming Lu^{*}, Lars-Ove Farnebo, Robert Branstrom, Catharina Larsson. Karolinska Institutet, Sweden

Caffeine is a highly consumed psychoactive substance present in our daily drinks. Independent studies have reported associations between caffeine consumption, low bone mineral density and urinary calcium loss, as well as impaired bone development in vitro and in vivo. Besides calcium (Ca²⁺) and vitamin D, secretion of parathyroid hormone (PTH) is known as a critical regulator of bone remodeling. One study also observed a negative correlation between serum levels of intact PTH and coffee consumption, suggesting a potential association between caffeine and parathyroid gland function. However, the effect of caffeine on parathyroid hormone secretion in parathyroid cell has never been explored. In this study, we showed that 200µM and higher doses of caffeine inhibited intact PTH secretion in human parathyroid adenoma cells using perfusion technique. However, intracellular Ca²⁺ determined by Fura-2 was not affected by caffeine at any of the doses (50, 200, 500µM or 5mM). Protein expression of two main caffeine targets, adenosine receptors A1 and A2A, was demonstrated in human normal parathyroid and parathyroid adenomas. Measurements of intracellular cAMP showed decreased cAMP at 50µM caffeine, and gradually increased cAMP at higher concentrations. In conclusion, high doses of caffeine inhibit PTH secretion in human parathyroid cells independent of intracellular Ca²⁺ and cAMP level. The inhibition of PTH secretion caused by high doses of caffeine may contribute to bone loss in human.

Response Of Bone Turnover Biomarkers Following Ovariectomy In A Model Of Low Birth Weight In The Female Sprague-Dawley Rat. Thomas P Royals^{*}, Michael B Manigrasso¹, Norma B Ojeda², Michelle A Tucci³, Barbara T Alexander¹. ¹University of Mississippi School of Medicine, Department of Physiology, USA, ²University of Mississippi School of Medicine, Department of Pediatrics, USA, ³University of Mississippi School of Medicine, Department of Orthopedics, USA

Osteoporosis is the most common type of bone disease, with postmenopausal bone loss as the most prevalent cause. Ovariectomy (OVX) in the female Sprague-Dawley (SD) rat creates an ovarian hormone deficient animal model that mimics accelerated

bone loss observed in postmenopausal women. Low birth weight (LBW) also compromises adult bone structure and increases the risk of osteoporosis. Utilizing a model of LBW induced by placental insufficiency, the aim of this study was to test the hypothesis that bone loss due to estrogen deficiency would be exacerbated in female LBW or intrauterine growth restricted (IUGR) offspring as evaluated by serum bone remodeling biomarkers. Birth weight was significantly reduced in IUGR (n=10) compared to normal birth weight (NBW; n=12) offspring (5.11 ± 0.06g vs. 5.91 ± 0.09g respectively; p<0.05). At 12 weeks of age a subgroup of IUGR and control rats underwent OVX or SHAM OVX. Blood was collected at the day of surgery, day 0, and days 7, 14, 28, and 42 post OVX or SHAM OVX and three bone turnover biomarkers were evaluated: N-terminal propeptide of type I collagen (PINP), C-terminal telopeptide of type I collagen (CTX-1), and tartrate resistant acid phosphatase 5b (TRACP 5b). PINP, a bone formation marker, was increased in NBW OVX relative to IUGR OVX at days 7 and 14 post OVX. Whereas CTX-1, a marker of osteoclast activity, was increased in IUGR OVX relative to NBW OVX at 14 and 28 days post OVX. TRACP 5b, a marker of osteoclast number, was significantly reduced in both IUGR OVX and NBW OVX compared to their SHAM counterparts at all time points following ovariectomy. In addition the resorption index (RI), an indicator of mean osteoclast activity, CTX-1/TRACP 5b remained elevated above baseline in the IUGR OVX while their NBW counterparts had returned to baseline levels at 28 days post OVX. Thus, these data indicate that IUGR may lead to an increase in osteoclast activity and an increase in bone resorption following estrogen withdrawal compared to their NBW counterparts, thereby accelerating postmenopausal bone loss. Therefore low birth weight women not only have compromised adult bone structure and increased risk for osteoporosis, but their risk for postmenopausal osteoporosis may be further increased as well.

Effects of Various Bone Loss Factors on Bone Micro Architecture in Female Rats. Keiko Iwaki, Tomoko Hanaoka, Yasue Nishii, Hidetaka Imagita, Susumu Sakata, Akira Minematsu*. Kio University, Japan

There are various factors to cause bone loss. This study was investigated the effects of estrogen deficiency, immobilization and low calcium insufficiency on bone mineral density (BMD) and trabecular bone micro structure in female rats. Twenty-four Wistar female rats aged 10 week-old were divided into 4 groups randomly; sham-operated (SHAM), ovariectomy (OVX), sciatic denervation (DN) and low calcium intake (LC) groups. They were bred for 6 months and allowed at libitum feeding (standard laboratory diet; Ca 1.12g/100g or LC diet; Ca 1.18mg/100g) and drinking. After this experiment, all tibias of the rats were dissected out. Micro CT scanning was used to determine morphological indices of BMD and trabecular bone structure in the metaphysical region of the proximal tibia. This region spanned 2 mm, with the first slice starting from 1 mm under the growth plate. BMD and trabecular bone structure as bone volume fraction (BV/TV), trabecular thickness (Tb.Th), trabecular number (Tb.N), trabecular separation (Tb.Sp), trabecular width (Tb.W), connectivity density (Conn.D), trabecular bone pattern factor (Tb.Pf), the structural model index (SMI), and osteoporotic degree of marrow space (Vm) and trabecular (Vt) of bones were measured with bone analysis soft. This study was carried out in accordance with the Guide for Animal Experimentation and the Committee of Research Facilities of Laboratory Animal Science of Kio University. BMD of all groups decreased significantly compared with SHAM group (trabecular bone; range -12.3% to -16.8%, p<0.001, cortical bone; range -6.2% to -26.0%, p<0.0001), and decreased most in LC group. Though bone loss was occurred in OVX, DN and LC groups, bone micro structure parameters showed the different changes among these factors. Reduction of BV/TV was induced by decrease of BV in OVX group, but increase of TV in DN and LC groups (range -27.3% to -68.3%, p<0.0001). All micro structure parameters of OVX, DN and LC groups showed the negative changes compared with SHAM group. Tb.N, Tb.Sp, Tb.Pf, SMI, Vm and Vt of OVX group, Tb.Th, Tb.Sp, Tb.W, Tb.Pf, Vm and Vt of DN group, and Tb.N, Tb.Sp and Vm of LC group had significance to those of SHAM group. It was concluded that OVX, DN and LC occurred to decrease of BMD and increase of Tb.Sp, and the general factor like estrogen deficiency and lack of Ca affected Tb.N, and local factor like immobilization affected Tb.Th and Tb.W. The process of bone loss was different by its cause.

Influence of Vitamin D on Bone Micro-Structural and Biomechanical Properties in Patients with Hip Fracture. Cristina Miranda^{*1}, M^a Jose Montoya², Mercedes Giner³, M^a Angeles Vazquez², Ramon Perez-Cano¹.

¹University of Seville, Spain, ²Virgen Macarena Hospital, Spain, ³Virgen Macarena Hospital/Seville University, Spain

Introduction: Vitamin D is essential for muscle-skeletal health. Insufficient levels of 25(OH)D are associated with PTH and bone remodelling increase, bone mass decrease and mineralization defects.

Objective: The aim of this study was to evaluate serum levels of 25(OH)D, hormones with influence on bone metabolism (PTH and IGF-I), bone remodelling markers (β -CrossLaps and PINP), bone mass density (BMD) and bone micro-structural and biomechanical properties of femoral neck of patients with osteoporotic hip fracture that required hip arthroplasty (OP) compared to patients with osteoarthritis admitted for elective hip arthroplasty without osteoporotic fractures antecedents (OA).

M&M: We studied 29 OP patients and 14 OA patients, all of them over 50 years old. Hormones serum levels, bone remodelling markers (immunoassay, electrochemical-luminiscence), femur BMD (Hologic-Discover densitometre), microstructural (SkyScan 1172 computerized microtomography) and biomechanical (IGFA system, monoaxe compression essay) properties were measured. Ethical approval was obtained from the local Research Ethic Committee, as well as the informed consents from all the patients included in this study. Results were statistically analyzed with SPSS 17.0 software.

Results: OP patients showed 25(OH)D ($p = 0.02$) and femur BMD ($p = 0.029$) levels significantly lower than OA patients, but PTH ($p=0.029$) and β -CrossLaps ($p=0.04$) levels significantly higher. 25(OH)D levels were positively correlated with IGF-I ($r=0.338$, $p=0.044$) but negatively with β -CrossLaps ($r=-0.483$, $p=0.003$). PTH levels were negatively correlated with femur BMD ($r = -0.617$, $p=0.005$) and positively with trabecular separation ($r=0.530$, $p=0.006$). Patients with 25(OH)D levels lower than 20ng/mL (with comparable antropometrics parameters) showed significantly higher β -CrossLaps levels ($p=0.006$), lower IGF-I levels ($p=0.007$) and smaller trabecular thickness ($p=0.04$) than patients over 20ng/mL.

Conclusion: Both pathologies showed low vitamin D levels, especially in OP patients, high PTH and bone remodelling markers levels and decreased BMD levels. Patients with 25(OH)D levels lower than 20ng/mL showed high bone remodelling levels, low IGF-I levels and bone structural disorders (trabecular thickness), which may be related with an increased fracture risk.

MB Zemel theory postulated in 2004: "A high CaI would be a preventive factor for Ob/OW development". **Objective:** to evaluate the effect of feeding different Ca content diet on body composition, bone metabolism and insulin-resistance in rats that spontaneously develop Ob in adolescent state. Female IIMbb rats fed from pregnancy one of 3 isocaloric diets only varied in Ca content: 0.9g% (HG), 0.5g% (NG) and 0.2g% (LG). At weaning male offspring continued feeding the same mother diet till 50 days of age (Tf). Results (mean SD), groups HG, NG & LG, respectively are shown in the Table 1.

Different letters: $p<0.05$. LG increased BW by the increment in body fat. An inverse relationship between CaI and insulin resistance was observed. **Conclusions:** The low CaI not only affects bone metabolism but also body composition and insulin resistance in spontaneous obese rats. UBACyT091.

Dietary Iron Deficiency is Associated with Impaired Mineralization and Osteogenic Gene Expression in Weanling Sprague Dawley Rats. Edralin Lucas, MCKALE DAVIS, Yan Wang, Elizabeth Rendina, Stephen Clarke, Brenda Smith, Krista Shawron^{*}. Oklahoma State University, USA

Recent studies have demonstrated an intriguing connection between iron deficiency and negative alterations in BMD, leading to the speculation that iron plays a role in the regulation of normal bone metabolism. Due to these observations linking iron status and osteoporosis, examination of the mechanisms contributing to iron-dependent alterations in bone metabolism is warranted. Our objective was to explore the effects of iron deficiency on BMD and bone microarchitecture in the tibia and spine in an animal model of iron deficiency. Weanling Sprague Dawley rats were assigned to one of three groups for 35 days ($n=10-12$ /group): (1) iron deficient (ID; < 5 mg Fe/kg diet), (2) control (C; 50 mg Fe/kg diet) or (3) pair-fed (PF) the control diet to the level of intake as the ID group. BMD and microarchitecture were examined by DXA and microCT in both the tibia and spine. Total RNA was isolated from a metaphyseal region of the femur and used to synthesize cDNA to examine gene expression by qPCR.

Due to differences in food intake and body weight, only data for PF and ID are presented here. BMD of both the tibia and spine in ID animals was lower ($p<0.05$). Further examination of the tibia by microCT indicated that trabecular tissue was unaffected in response to iron deficiency, though cortical thickness was significantly decreased in ID animals ($p<0.05$). In contrast to the tibia, BV/TV, TbTh, and TbN were decreased in the spines of ID animals ($p<0.001$). To examine the extent to which alterations in osteogenic gene expression contributed to impaired microarchitecture in ID animals, RNA from the femur was extracted and used for gene expression analyses by qPCR. Osteocalcin, BMP-2, and Col1a1 expression was repressed in the ID group ($p<0.05$), suggesting an impairment in bone formation and mineralization in response to iron deficiency. Runx2 expression was repressed in ID animals ($p<0.05$) and associated with a decrease in osterix expression. The expression of genes related to osteoclast differentiation and activity, including CTSK, NFATc1, and TRAP were unaltered in response to iron deficiency. Thus, these data suggest that iron deficiency is associated with an impairment in osteoblast differentiation or function. Additional studies are currently in progress focused on examining the mechanisms through which iron deficiency impairs osteogenic gene expression and/or osteoblastogenesis.

The Effect of Weight Loss and Dietary Macronutrient Composition on Bone Mineral Density - Results of a Randomized Controlled Trial. Amir Tirosh¹, Vincent Carey¹, Frank Sacks¹, George Bray², Steven R. Smith², Meryl Leboff¹. ¹Brigham & Women's Hospital, USA, ²Pennington Biomedical Research Center of the Louisiana State University System, USA

Purpose: The effects of weight loss diets and different macronutrient compositions on bone mineral density (BMD) in overweight and obese individuals have not been fully elucidated, although there are concerns regarding the potential deleterious effects of low-carbohydrate high-proteins diet on BMD and fracture risk. **Methods:** The Preventing Overweight Using Novel Dietary Strategies (Pounds Lost), is a randomized controlled trial of 811 overweight and obese adults randomly assigned to 4 diets with targeted percentages of energy derived from fat, protein, and carbohydrates of: 20, 15, and 65%; 20, 25, and 55%; 40, 15, and 45%; and 40, 25, and 35%, respectively (N Engl J Med. 360:859, 2009). In 424 Pounds Lost participants (mean age 529 years, 57% females) from 2 centers (Boston and Baton Rouge). BMD was measured at the spine, total hip and femoral neck (FN) at baseline, 6, and 24 months of intervention using DXA machines (QDR 4500A, Hologic, Bedford MA). Reproducibility of the spine and femoral neck BMD were 1.21% and 1.74% respectively. **Results:** The overall average weight loss after 6 and 24 months of intervention was 6.9 and 6.1 kg, corresponding to a 7.9% and a 6.9% weight loss of the initial body weight, respectively. Retention rates were 78% and 56% at 6 and 24 months. There were no significant differences in the magnitude of weight loss among the 4 diet groups. Despite significant weight loss, the change from baseline in spine, total hip and FN BMDs at 6 months was 0.0005 (p=0.07), -0.001 (p<0.001), and -0.007 (p=0.016) gm/cm² and at 24 months was 0.005 (p=0.04), -0.014 (p<0.001), and -0.014 (p<0.001) gm/cm², respectively. In a multivariate model adjusted for age, sex, baseline BMD, diet group and baseline anthropometric measurements, for every 1% of body weight loss, there was a small but significant change in BMD of -0.00155 and -0.00121 gm/cm² at the total hip and FN (p<0.0001), with no change at the spine over 2 years. High protein diets were not associated with greater bone loss as compared with the low-protein groups. **Conclusions:** Dietary interventions to reduce weight loss can result in a small amount of bone loss, possibly related to the DXA measures or other mechanisms. This effect can become clinically significant with higher percentages of weight loss over time. All 4 interventions, including the low-carbohydrate-high-protein diets resulted in similar amounts of bone loss in this large, prospective randomized trial.

Bone Quality Is Negatively Affected by Glucocorticoid-induced Changes in the Geometry of Osteoclast Resorption Cavities. Jozef Vanderroost¹, Kent Soe², DITTE MARIE MERRILD², Jean-Marie Delaie³, Harry Van Lenthe⁴. ¹K.U.Leuven, Belgium, ²Vejle Hospital, University of Southern Denmark, Denmark, ³Vejle Hospital, CSFU-IRS, University of Southern Denmark, Denmark, ⁴Katholieke Universiteit Leuven, Belgium

Loss of bone strength and prevention of fractures is a major concern for clinicians dealing with bone pathologies, such as postmenopausal osteoporosis (PMOP) and glucocorticoid-induced osteoporosis (GIO). Unlike for PMOP, bone mineral density (BMD) is a poor predictor of fracture risk for GIO. We have recently found that glucocorticoid (GC) causes osteoclasts (OCs) to change their resorptive behavior, making large elongated resorption cavities instead of circular resorption cavities, without affecting the total eroded surface (S/Se et al. JBMR 2010). The aim of this study was to determine whether this change in resorptive behavior of OCs can explain the increase in fracture risk as seen in GIO.

The three-dimensional characteristics of resorption cavities generated in vitro by human OCs in the presence or absence of GC were recorded. The impact of GC-induced resorption on the mechanical properties of bone was modeled using the beam-shell finite element model of trabecular bone (Vanderroost et al. J Biomech 2011). Resorption cavities with a distribution of cavity dimensions taken from the in vitro measurements were added; the eroded surface was kept constant at 2% of the bone surface. Trabecular bone samples originated from 40 patients and three anatomical sites (4th lumbar vertebra, femoral neck and iliac crest) covering a wide range of trabecular bone properties. Uniaxial compression tests were used to quantify bone apparent stiffness as a measure of bone quality.

The model showed that, when compared to the control case, resorption cavities generated in the presence of GC, caused a statistically significant loss of stiffness (Table 1). The largest stiffness reduction was found for lumbar spine samples with mostly rod-like trabeculae, the lowest for femoral samples with mostly plate-like trabeculae (Table 1).

We conclude that the altered resorptive behavior of the OCs due to GC-exposure negatively affects bone stiffness and likely increases bone fracture risk independent of the extent of eroded surface. In vivo, this effect is likely to be stronger, because several OCs can resorb bone at the same cavity; hence, the excavation in vivo is likely to be deeper than the ones we observed in vitro after 72hrs of culture. Since deeper cavities can cause trabecular rupture or perforation, the expected stiffness loss in vivo is larger. These findings demonstrate that the dimensions of OC resorption cavities are one of the factors determining bone quality.

Stiffness loss (%)	Control	Glucocorticoids
4 th lumbar spine	0.315	0.336
Femoral head	0.084 ^a	0.111 ^a
Iliac crest	0.217 ^a	0.276 ^a
All data pooled	0.205 ^a	0.240 ^a

Age-Related Changes in Proximal Humerus Bone Health in White Males. Robyn Fuchs*, Sara Mantila Roosa, Andrea Hurd, Stuart Warden. Indiana University, USA

The proximal humerus is a common site for osteoporotic fracture during aging, accounting for up to 5% of fractures to the appendicular skeleton. While falls onto an outstretched hand are usually physically responsible for proximal humerus fractures, the ability of the underlying bone to resist applied loads must also play a role. Few studies have assessed proximal humerus bone health with aging. The aim of the current study was to explore age-related bone changes at the proximal humerus in men. A cross-sectional study design was used to assess peripheral quantitative computed tomography (pQCT)-derived bone properties of the proximal humerus in a cohort of 112 white males (age range = 30-85 yrs). A tomographic slice of the non-dominant upper extremity was acquired at 80% of humeral length proximal from its distal end-a location corresponding to the surgical neck of the humerus. Images were assessed for cortical (Ct.BMC) and trabecular (Tb.BMC) BMC, total (Tt.Ar), cortical (Ct.Ar) and medullary (Me.Ar) area, periosteal (Ps.Pm) and endosteal (Es.Pm) perimeter, cortical thickness (Ct.Th), and bone strength index for compression (BSI_c). BSI_c was calculated as the product of Tt.Ar and the square of total volumetric BMD. Data were plotted against age and linear regression lines assessed for their slope. Slopes were subsequently converted to percent change in the bone property per year. During aging, the proximal humerus expanded with Tt.Ar and Ps.Pm increasing at rates of 0.40%/yr and 0.19%/yr, respectively. However, Me.Ar (0.62%/yr) and Es.Pm (0.34%/yr) expanded at faster rates such that there was net loss of both Ct.BMC (-0.23%/yr) and Tb.BMC (-1.08%/yr). Also, the more rapid expansion of Me.Ar relative to Tt.Ar meant that Ct.Ar (-0.15%/yr) and Ct.Th (-0.34%/yr) both decreased with age. The net result of these mass and structural changes was progressive loss of bone strength with age, as indicated by a 0.44%/yr decline in BSI_c. These data provide a picture of bone changes at the proximal humerus during aging. They suggest that between age 30 and 80 yrs, approximately 54% and 11% of Tb.BMC and Ct.BMC at the proximal humerus is lost, respectively. They also suggest that compressive strength of the proximal humerus declines by 22% between age 30 and 80 years. These declines in proximal humerus bone health have implications for fracture risk at this location during aging.

Poor Bone Microarchitecture in Older Men with Low Muscle Mass and Grip Strength - The STRAMBO Study. Stephanie BLAIZOT¹, Stephanie Boutroy², Nicolas Vilaythiou³, Roland Chapurlat⁴, Pawel Szulc⁵. ¹INSERM UMR 1033, Université de Lyon, France, ²Columbia University Medical Center, USA, ³INSERM UMR1033, Université de Lyon & Hospices Civils de Lyon, France, ⁴E. Herriot Hospital, France, ⁵Hopital E. Herriot, Pavillon F, France

We have shown that low relative appendicular muscle mass (RASM, kg/m²) is associated with lower bone width in men (Szulc, JBMR, 2005). Our aim was to assess the association of bone microarchitecture with RASM and grip strength in 810 men aged ≥60 yr. Bone microarchitecture was assessed at the distal radius and tibia by high resolution peripheral QCT (XtremeCT Scanco). RASM was assessed by DXA. Statistical analyses were adjusted for age, height, fat mass, sex steroids, lifestyle factors and co-morbidities. At the distal radius and tibia, men in the lowest RASM quartile (Q1) had lower cross-sectional area (CSA), trabecular area and cortical thickness (Ct.Th) than men in the highest (Q4) quartile (6 to 11%, 0.33-0.64 SD, p<0.01-0.001, p_{trend}<0.05-0.001). At the distal tibia, they also had lower total and trabecular volumetric BMD (vBMD) and lower trabecular number (TbN) (Q1 vs Q4: 7 to 9%, 0.34-0.60 SD, p<0.05-0.005, p_{trend}<0.05) as well as more heterogeneous trabecular distribution (TbSpSD) (p<0.001). At the distal radius, men in the lowest quartile of grip strength had lower CSA, total and trabecular vBMD, TbN and Ct.Th than men in the highest quartile (4 to 10%, 0.29-0.45 SD, p<0.05-0.001, p_{trend}<0.05-0.005). They also had 8% higher TbSpSD (p_{trend}<0.005). After adjustment on arm muscle mass, differences remained significant for total and trabecular vBMD, TbN and TbSpSD. At the tibia, men in the lowest quartile of grip strength had lower total and cortical vBMD and lower Ct.Th (3 to 8%, 0.33 SD, p<0.05, p_{trend}<0.05). In multivariate models including both grip strength and arm muscle mass, total CSA and

trabecular area were associated with muscle mass ($r^2=3-7\%$, $p<0.001$), not grip strength. Cortical vBMD correlated with grip strength ($r^2=3\%$, $p<0.01$). Trabecular parameters were associated weakly with muscle mass ($r^2=1-3\%$) and grip strength ($r^2\leq 1\%$). Men having both low arm muscle mass and low grip strength (lowest tertiles) had 9% lower TbN (0.61 SD, $p<0.005$) and 5% higher TbSpSD (0.49 SD, $p<0.05$) than men in the highest tertiles of both variables.

In older men, low RASM and low grip strength are associated with poor cortical and trabecular microarchitecture. The associations remaining significant after adjustment for confounders including body size suggest direct association. Muscle mass and force are associated jointly and partly independently with bone microarchitecture, suggesting different mechanisms of linkage.

Bone Mineral Density and Skeletal Microarchitecture in Small-Fiber Polyneuropathy. Anne Louise Oaklander¹, Ruchit Kumbhani², Erica Siwila-Sackman², Heather Downs¹, Benjamin Leder³. ¹Department of Neurology, Massachusetts General Hospital, USA, ²Endocrine Unit, Massachusetts General Hospital, USA, ³Massachusetts General Hospital/Harvard Medical School, USA

Skeletal metabolism is regulated by both the central and peripheral nervous system in humans and animals. Most studies in this area have focused on the effects on the autonomic nervous system or damage to the large-diameter myelinated peripheral nerves, but almost all bone innervation is by small-diameter somatic and autonomic axons. Small-fiber polyneuropathy (SFPN) is a peripheral nerve disease that usually presents with burning pain in the distal lower extremity and has been associated with numerous underlying etiologies. Patients with SFPN can present with underlying local bone destruction but effects on skeletal health have not been systematically studied. To assess the skeletal effects of SFPN, we performed high-resolution peripheral quantitative computed tomography (HR-pQCT) of the distal tibia, DXA of the hip and spine, and measured serum CTX and PINP (BTMs) in 12 men with SFPN (age 30-60) and in 12 healthy, age-matched controls. The presence and severity of small-fiber losses was quantified using distal-leg skin biopsies immunolabeled against PGP9.5 and standard methods for clinical diagnosis. Subjects with DM, calcium regulatory disorders, hypogonadism, recent fracture, or using bone-active medications were excluded. Comparison between patients and their age-matched controls was performed by paired t-test. As shown below, mean (SD) density of epidermal nerve fibers was significantly lower in SFPN patients compared to controls whereas other clinical parameters were similar. Despite extensive peripheral nerve damage, tibial BMD, compartmental BMD, cortical thickness and trabecular microarchitecture (Tb.Th, Tb.N, Tb.Sp) did not significantly differ between groups. DXA-derived central BMD and BTMs were also similar (data not shown for trabecular microarchitecture and BTMs).

In summary, compared to healthy age-matched controls, men with SFPN have similar skeletal parameters both peripherally (tibia by HR-pQCT) and centrally (hip and spine by DXA). While this small study cannot exclude a modest influence of peripheral axonal damage on the skeleton, there does not appear to be a substantial or consistent skeletal phenotype in SFPN, even in the specific skeletal sites that correspond with the anatomical distribution of the axonal damage observed.

Bone Mineralization Is Not Different in Women With Long-Standing Type 2 Diabetes: A Microscopy Investigation with Quantitative Backscattered Electron Imaging (qBEI). Janet Pritchard¹, Cora Tomowich¹, Alexandra Papaioannou², Jonathan Adachi³, Stephanie Atkinson¹, Lora Giangregorio⁴, Karen Beattie¹, Justin DeBeer¹, Mitchell Winemaker¹, Victoria Avram¹, Henry Schwarcz¹. ¹McMaster University, Canada, ²Hamilton Health Sciences, Canada, ³St. Joseph's Hospital, Canada, ⁴University of Waterloo, Canada

Purpose: Adults with type 2 diabetes (T2D) are at greater risk of osteoporotic fracture, despite normal or elevated bone mineral density (BMD). Suppressed bone

turnover in these patients has been reported and may lead to hypermineralized bone, contributing to bone fragility. The purpose of this study was to replicate the bone mineral density distribution (BMDD) methodology developed by Roschger and colleagues (1), and to determine if BMDD is different in bone specimens from women with T2D compared to non-diabetic controls.

Methods: Using sections of fresh excised proximal femur from elective total hip replacement patients, we assessed BMDD in women >65 years who had T2D for more than 5 years, and women without T2D. A 5.0mm thick slice of bone was taken from the neck of the femur of the specimen, fixed in glutaraldehyde, embedded in epoxy, polished and coated with carbon. The sample was imaged using quantitative backscattered electron imaging (qBEI) with a scanning electron microscope (Vega, TESCAN USA), using previously described scanning parameters (1). Daily instrument variation was assessed using C, Al, MgO and enamel standards over 8 days, and the average %CV was 3.6%. Several regions of interest were randomly identified for each specimen and mean and standard deviation for BMDD variables (C_{MEAN}, C_{PEAK}, C_{LOW}, C_{WIDTH}) were derived using ImageJ (version 1.44o, NIH, USA)(1). This study was approved by Hamilton Health Sciences/FHS at McMaster University REB.

Results: These preliminary results include 3 specimens from women with T2D (mean age 74.0 years) and 2 specimens from controls (mean age 85.5 years). The average number of years since T2D diagnosis was 11.85.0 years. Women with T2D had a greater BMI (31.2 kg/m², versus 26.3 kg/m²). Analysis of bone specimens revealed that mean calcium concentration (C_{MEAN}) in samples from patients with T2D (22.30%wtCa) and controls (22.20%wtCa) were similar, however the C_{MEAN} for the control group was closer to the normative C_{MEAN} reported previously (22.20 wt %Ca)(2). Additional BMDD variables were also similar between groups.

Conclusions: Given the suppression of bone turnover in adults with T2D, as reported by others, mineralization characteristics, assessed using qBEI with SEM may have important implications related to the mechanisms acting to affect bone turnover in this high-fracture risk population.

Decreased Renal Function but not Liver Function Overpowers the Circulating Sclerostin Level. Se Hwa Kim¹, Hyeong Jin Kim¹, Soo Young Yoon², Sang Chol Lee², Sung-Kil Lim³, Yumie Rhee⁴. ¹Kwandong University College of Medicine, Myongji Hospital, South Korea, ²Department of Internal Medicine, College of Medicine, Kwandong University, Myongji Hospital, South Korea, ³Yonsei University College of Medicine, South Korea, ⁴Department of Internal Medicine, College of Medicine, Yonsei University, South Korea

BACKGROUND: Sclerostin is a Wnt inhibitor produced specifically by osteocytes and its circulating level is known to be negatively associated with estrogen and parathyroid hormone. However, basic relation to kidney or liver function with circulating sclerostin level is yet unrevealed. OBJECTIVE: The aim of the study was to compare serum sclerostin levels in Korean women and men to evaluate its relationship to age, gender, renal and liver function. METHODS: We conducted a cross-sectional observational study of 376 people from population based sampling of pre-(n=40) and post-menopausal women(n=176), and men(n=160). The patients with diabetes and hepatitis were included in these samples. We analyzed serum sclerostin levels by ELISA (Biomedica Co., Austria) and correlated with age, gender estimated GFR and liver function with Child-Pugh scores (CPS). RESULTS: 1) Gender difference: serum sclerostin level was definitely higher in males (105.98.6 pmol/L) vs females (60.45.6 pmol/L), we then analyzed gender-specifically hereafter. 2) In pre- and post-menopausal women, and men, sclerostin levels were positively associated with age ($r=0.22$ & $r=0.24$, respectively, $p<0.005$). There was a stronger relation between sclerostin level with renal function presented as serum creatinine (Cr) and estimated GFR, in both gender (Cr; $r=0.940$ and 0.875 , eGFR; $r=-0.623$ and -0.722 , respectively in females and males, $p<0.001$). Sclerostin level was dramatically increased in patients with CKD stage 3 and more (Fig). 3) The liver function measured by aspartate and alanine aminotransferase (AST/ALT) was only negatively related in females ($r=-0.220$ and -0.226 , $p<0.05$). Furthermore, we have assessed the sclerostin level according to CPS which better represents degree of chronic liver disease graded into A-C. The sclerostin level seemed to be higher in CPS class B-C, but after adjusting with Cr, there was no difference related to hepatic dysfunction. Decreased renal function was significantly associated with increased sclerostin level even after the adjustment for age, fasting glucose, and AST/ALT (standardized $\beta=-0.841$, $t=-12.8$, in females and $\beta=-0.864$, $t=-15.8$, in males, $p<0.0001$, respectively). CONCLUSIONS: Our findings suggest that serum sclerostin is higher in males and is metabolized mainly via kidney but not by liver. Therefore, in order to use or analyze the circulating sclerostin levels, the renal function should be considered as a main confounding factor.

Circulating sclerostin level according to CKD stage

Effects of Preoperative Renal Function on the Postoperative ADL of Patients with Osteoporotic Vertebral Collapse with Neurological Deficits. Masafumi Kashii¹, Ryoji Yamazaki², Tomoya Yamashita³, Takahito Fujimori¹, Yukitaka Nagamoto¹, Shinya Okuda², Takenori Oda², Tetsuo Ohwada³, Motoki Iwasaki², Hideki Yoshikawa¹. ¹Osaka University Graduate School of Medicine, Japan, ²Department of Orthopedic surgery, Osaka Rousai Hospital, Japan, ³Department of Orthopedic surgery, Kansai Rousai Hospital, Japan

Surgical treatment of osteoporotic vertebral collapse (OVC) with neurological deficits has some significant clinical challenges and problems because elder patients with extremely bone fragility often have serious medical comorbidities. The objective of this study is to minutely examine patients' background containing concurrent commodities and individual severity of osteoporosis in OVC patients with neurological deficits, and to investigate prognostic factors which affect postoperative patients' ADL.

We retrospectively reviewed 88 patients with OVC with neurological deficits who underwent three kinds of surgical procedures. Clinical results regarding neurological deficits and patient's ADL were assessed by the modified Frankel performance grade and the criteria of bedridden established by Ministry of Health, Labour and Welfare (J1-C2: eight-grade system), respectively. The prognostic factor of postoperative patients' ADL was examined using the univariate analysis and the multivariate analysis.

Improvement rate of neurological impairment and ADL was 60.2% and 55.0%, respectively. There were no significant differences in pain relief and improvement rate of neurological impairment and ADL among these three procedures. The multiple logistic regression analysis was performed using age, sex and two explanatory variables (the decrease of estimated glomerular filtration rate (eGFR) and high serum ALP) taken from the univariate analysis. Decrease of eGFR (OR=1.08; 95%CI, 1.03-1.13; p=0.0001) and high serum ALP level (OR=0.989; 95%CI, 0.979-0.997; p=0.0007) were the strong prognostic factors to predict deterioration of postoperative ADL in OVC patients with neurological deficits.

The majority of patients with poor postoperative ADL are in the condition with advanced-stage CKD with high bone turnover as well as bone fragility. It is important to fully recognize that osteoporosis is a systemic disorder and there is a hidden pathogenesis of osteoporosis such as CKD-MBD (Chronic Kidney Disease with Mineral and Bone Disorder). Decline of renal function and high serum ALP found in this study seems to be valuable markers to evaluate both patients' general health and severity of osteoporosis, when we choose the surgical procedure.

Estrogen Prevents TZDs-induced Apoptosis in Osteoblasts. Hui Sheng*. Shanghai, Fudan University, Peoples Republic of China

Thiazolidinediones (TZDs), as insulin sensitizers, are used in clinics for type 2 diabetes patients. Recent studies showed that TZDs exert bone damage, which is characterized by inhibiting bone formation. Our previous studies showed that TZDs induced osteoblasts apoptosis in vitro and in vivo models, indicating that osteoblasts apoptosis is one of the important mechanisms in this pathophysiology. Clinical data

showed older diabetic women are more susceptible to TZDs-induced bone loss, implying estrogen may have protective effects. This study aims to investigate the effects of estrogen on pioglitazone-induced osteoblasts apoptosis.

Primary rat calvaria osteoblasts and mice MC3T3-E1 osteoblasts were used and treated by 17 β -estradiol and pioglitazone hydrochloride (Pio). Osteoblasts apoptosis was tested by flow cytometry and Terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) assay. Glycogen synthase kinase 3 β (GSK3 β) was assayed by Western blot. siRNA for GSK3 β were used for underlying mechanism exploration.

Pio induced osteoblasts apoptosis in a dose-dependent manner, and the apoptosis rate increased from 4.5% in control group to 12.2%, 18.2%, 25.5%, in 5 μ M, 10 μ M and 20 μ M Pio- treated groups. Simultaneous treatment with Pio and 17 β -estradiol prevented osteoblasts apoptosis, the apoptosis rate decreased to 15%, 10.4%, and 6% after 17 β -estradiol treatment (0.001nM, 0.01nM, 0.1nM) in 10 μ M Pio group. Western blot results showed that Pio induced osteoblasts apoptosis with activation of GSK3 β , and 17 β -estradiol addition reduced the activity of GSK3 β . siRNA for GSK3 β could also improve Pio-induced osteoblasts apoptosis. The similar results were also confirmed in primary rat osteoblasts.

Estrogen could prevent Pio-induced osteoblasts apoptosis in vitro study. GSK3 β plays an important role in Pio-induced osteoblasts apoptosis. This study could at least partly explain the clinical observation that older diabetic women are more susceptible to TZDs-induced bone loss.

Aknowledgements This study was supported by Shanghai Pujiang Program (09PJ1410300), NSFC(30900698) and Ph.D. Programs Foundation of Ministry of Education of China(20090072120020).

SU0409

Osteocalcin and Residual β -Cell Function in Type 1 Diabetes. Annarita Maurizi, Rocky Strollo, Paolo Pozzilli, Nicola Napoli*. University Campus Biomedico, Italy

The skeleton is an important target of diabetes complications. The relationship between type 1 diabetes (T1D) and bone metabolism appears to be complex and the mechanisms leading to bone loss in T1D remain unclear. It is reported that not only poor glycemic control has negative effects on bone metabolism, but also the rate of bone turnover may in turn regulate glucose homeostasis.

Aim of the present study was the evaluation of the relationship between markers of bone formation [osteocalcin (OC), bone alkaline phosphatase (bALP)], bone mineral density (BMD) and body composition] and metabolic control in T1D patients. A total of 45 patients affected by T1D aged 18-50 years (29 males 16 females) and 37 age and gender-matched healthy subjects underwent assessment of biochemical bone formation markers (OC and bALP), BMD and measurement of body composition using dual energy X-ray absorptiometry. In T1D patients HbA1c, fasting C-peptide and daily insulin requirement (I.R.) were also evaluated. A two-sides paired T-test was used to assess differences between patients with T1D and controls. Pearson's correlation coefficients were used for assessing the association between two continuous variables. No differences were observed in OC and bALP levels between the two groups. T1D patients and controls showed also similar fat mass and BMD at all sites. In T1D patients fat distribution, expressed as abdominal fat/total fat ratio, was positively correlated with HbA1c levels ($r=0.5$, $p=0.032$) and with I.R. ($r=0.4$, $p=0.02$). Finally, a positive correlation between osteocalcin and fasting C-peptide was observed in T1D patients ($r=0.5$, $p<0.001$). In conclusion, patients affected by T1D show minor differences in body composition and no difference in BMD compared with normal subjects. The novel finding of a positive correlation between osteocalcin and residual C-peptide observed in T1D is consistent with experimental models, suggesting a direct effect of this osteoblast-derived protein on β -cell function

Disclosures: Nicola Napoli, None.

Serum Sclerostin Levels Correlate Positively with Bone Mineral Density at Multiple Skeletal Sites in Postmenopausal Women. Farayal Mirza*, Anne Kenny², Pamela Taxel¹, Joseph Lorenzo¹. ¹University of Connecticut Health Center, USA, ²University of Connecticut, USA

Sclerostin is a negative regulator of Wnt signaling and bone formation. We previously reported that serum estrogen levels inversely correlate with serum sclerostin levels in postmenopausal women. In this study, we examined the effect of aging on serum sclerostin levels and the relationship between serum sclerostin levels and bone mineral density (BMD) in postmenopausal women. We evaluated 100 postmenopausal women, 45 to 95 years of age, in a cross sectional study. Serum sclerostin levels were measured along with levels of estradiol (E2), estrone (E1), sex hormone binding globulin (SHBG) and serum and urine bone formation and resorption markers. Free estrogen index (FEI) was calculated as (E2+E1) (pmol/l)/SHBG. BMD was measured using dual x-ray absorptiometry in 88 subjects. Pearson product moment correlations were used to evaluate the relationships between age, serum sclerostin level and bone density.

Mean age of the subjects was 70.11 years. Mean body mass index (BMI) was 28.6. Mean serum sclerostin level was 48.20 ng/ml and mean FEI was 3.72 pmol/nmol. Serum sclerostin level correlated positively and significantly with age ($r = 0.316$, $p =$

0.001). However, although this relationship persisted after adjusting for FEI ($r = 0.315$, $p = 0.001$) it disappeared after adjusting for body mass index (BMI). In contrast, after adjusting for age, BMI, FEI and parathyroid hormone (PTH) levels, serum sclerostin correlated positively with BMD at the lumbar spine ($r = 0.386$, $p = 0.001$), mean total hip ($r = 0.437$, $p < 0.001$), mean trochanter ($r = 0.401$, $p < 0.001$), and total body BMD ($r = 0.461$, $p < 0.001$). There were no significant relationships between serum sclerostin levels and bone formation markers (bone specific alkaline phosphatase and osteocalcin, OC) or bone resorption markers (serum N-telopeptide, NTX). However, there was a trend for a negative relationship between serum sclerostin and the ratio of NTX to OC ($r = -0.224$, $p = 0.093$) after adjusting for age, BMI, FEI and PTH.

Our findings demonstrate that in multivariate analysis serum sclerostin levels correlate positively with bone density at multiple skeletal sites in postmenopausal women. We speculate that this association results from a relationship between serum sclerostin and bone turnover as reflected by the ratio of NTX to OC. Serum sclerostin levels are an easily obtainable independent marker of bone mass in postmenopausal women, which may have clinical utility.

The Associations of Serum Serotonin with Bone Traits Are Age- and Gender-specific. Qin Wang^{*1}, Leiting Xu², Decai Chen¹, Alen Markku³, Sulin Cheng². ¹Dept. Endocrinology of West China Hospital, Sichuan University, China, ²University of Jyväskylä, Finland, ³Department of Medical Rehabilitation, Oulu University Hospital & Institute of Health Sciences, University of Oulu, Finland

Objective: This study is aimed to investigate the associations between serum serotonin and bone traits at multiple sites in women and men.

Subjects and Methods: The study population of this report is a part of the CALEX-family study. In brief, 235 young women (mean age 18.3 yrs), 121 premenopausal (mean age 46.1 yrs) and 124 postmenopausal women (mean age 66.5 yrs), as well as 112 men under 60 yrs old (mean age 50.0 yrs) and 56 men over 60 yrs old (mean age 72.9 yrs) were included in this report. Body composition was assessed using DXA. Areal bone mineral density (aBMD) of whole body (WB), lumbar spine (L2-4), femoral neck (FN) and total femur (TF) were assessed by DXA. In addition, pQCT was used to assess bone mineral content (BMC), and total, cortical and trabecular volumetric bone mineral density (vBMD) at distal radius and tibial shaft. Fasting serum concentration of serotonin was determined using a competitive enzyme-linked immunosorbent assay.

Results: The serotonin concentration declined with advancing age both in females and males (all $p < 0.01$). Serotonin was negatively correlated with weight, BMI, lean and fat mass in women ($r = -0.22$ to -0.39 , all $p < 0.001$), but positively with height and lean mass in men (all $p < 0.01$). In young and premenopausal women, serotonin concentration was negatively correlated with aBMD of WB and L2-4 ($r = -0.21$ and -0.23 , respectively, all $p < 0.05$), but the statistical significance disappeared after adjusted for weight. Conversely, in postmenopausal women, serotonin was positively correlated with aBMD of WB, TF and FN, as well as with total BMC and vBMD of the distal radius ($r = 0.20$ to 0.30 , all $p < 0.05$). After adjusted for weight, the positive correlations remained or became even more pronounced. In men, no significant associations were found between serotonin and bone traits at multiple sites.

Conclusion: Serum concentration of serotonin was positively associated with bone traits only in postmenopausal women not in premenopausal women or men. The associations between serotonin and bone traits are gender- and age-specific.

Comparison of the Effect of Teriparatide in Japanese and Non-Japanese Patients with Osteoporosis - Bridging Strategy. Mika Tsujimoto, Kazunori Uenaka, Atsuko Iwata, Yoshihiro Higashiuchi, Hideaki Sowa^{*}. Lilly Research Laboratories Japan, Eli Lilly Japan K.K., Japan

Background/Objective: Teriparatide is an anabolic therapy for osteoporosis approved in the United States since 2002 and European Union since 2003. However, as with many other drugs, approval in Japan had lagged significantly at the time a phase 1 study was planned in Japan in 2003. A strategy for addressing the lag in drug approval by bridging data from large foreign studies with smaller domestic studies is described in the International Conference on Harmonization (ICH) E5 guideline. This bridging strategy was used to accelerate the new drug application, which led to Japan approval in 2010.

Methods: Analyses were made according to the ICH E5 guideline to support bridging between Japanese studies and the large Fracture Prevention Trial (ClinicalTrials.gov identifier: NCT00670501; FPT). We analyzed data from a single dosing study in healthy Japanese and Caucasian postmenopausal women (Phase 1, pharmacokinetics, Study identifier: GHCO; J-PK) as well as data from studies of 6 months (Phase 2, dose ranging, ClinicalTrials.gov identifier: NCT00191867; J-Ph2)

and 12 months (Phase 3, efficacy and safety, ClinicalTrials.gov identifier: NCT00433160; J-Ph3) randomized, placebo-controlled, once-daily treatment in Japanese patients with osteoporosis at high risk of fracture.

Results: In J-PK, apparent AUC and C_{max} were up to 40% greater in Japanese versus Caucasians; however body weight-adjusted values were comparable between populations. Age and time since menopause were similar in the FPT and Japanese studies, but bone mineral density (BMD) at lumbar spine (L1-L4) as well as body weight and proportion of smokers and drinkers were lower for Japanese at baseline. With teriparatide 20 µg/day, statistically significant increases in BMD compared with placebo were observed at 12 months in both FPT and J-Ph3. Furthermore, percent and actual changes in BMD were comparable between studies suggesting that Japanese and non-Japanese populations are similar in terms of BMD response. Dose-response at 6 months and changes in bone turnover markers were broadly comparable across populations. No novel safety signals were identified in Japanese subjects.

Conclusion: These results show that the teriparatide clinical data met ICH E5 criteria for bridging. Findings from foreign trials including the FPT, such as fracture prevention and bone microstructure improvement, can thus be extrapolated to anticipate response in Japanese subjects treated with teriparatide.

Evidence for Bone Reversal Properties of KoAct™, a Novel Dietary Supplement. Bahram Arjmandi^{*1}, Shirin Hooshmand¹, Jennifer Gu², Sara Campbell³. ¹Florida State University, USA, ²AIDP, Inc., USA, ³Rutgers University, USA

Menopause drastically increases the risk of osteoporosis, and although drug therapies are available, having an efficacious dietary supplement as an alternative to a prescription drug is highly desirable. Recent findings suggest that KoAct™, a calcium-collagen chelate, is highly effective in modulating bone mass in rat models of osteoporosis. Based on these findings, we hypothesize consumption of KoAct™ reverses bone loss in postmenopausal women with osteopenia as early as three months. We screened 90 women, 1 to 5 years postmenopausal, not on hormone replacement therapy or any other prescribed medication known to influence bone metabolism. Twenty qualified participants were randomly assigned to one of two treatment groups: 1) control and 2) KoAct™ as a dietary supplement intervention daily for three months. Control group received 500 mg of elemental calcium in the form of calcium carbonate, while the KoAct™ group received 5 g of KoAct™ which also contained 500 mg elemental calcium. Additionally both groups received 200 IU vitamin D daily. Bone mineral density of lumbar spine, forearm, hip, and whole body were assessed at baseline and the end of the study using dual-energy x-ray absorptiometry. Blood and urine samples were collected at baseline and after 3 months to assess bone biomarkers of bone metabolism. Physical activity recall and three-day food frequency questionnaire were completed at baseline and after 3 months to examine physical activity and dietary confounders as potential covariates. KoAct™ significantly increased BMD of total body in comparison to the control group (1% vs. baseline; p value = 0.021). In comparison with corresponding baseline values, KoAct™ tended to increase bone-specific alkaline phosphatase activity and decrease tartrate resistant acid phosphatase-5b after three months. These preliminary data suggested that KoAct™ enhances bone mass by increasing bone formation and suppressing bone resorption.

High Resolution Peripheral Quantitative Computed Tomography (HRpQCT) Detects Improved Trabecular Volumetric BMD and Microarchitecture in Premenopausal Women with Idiopathic Osteoporosis Treated with Teriparatide. Adi Cohen^{*1}, Stephanie Boutroy¹, Emily Stein², Xiaowei Liu², Joan Lappe³, Robert Recker³, David Dempster⁴, Hua Zhou⁵, Donald McMahon², Chiyuan Zhang⁴, Polly Chen⁴, Bin Zhou⁴, Ji Wang⁴, X. Edward Guo⁴, Elizabeth Shane². ¹Columbia University Medical Center, USA, ²Columbia University College of Physicians & Surgeons, USA, ³Creighton University Osteoporosis Research Center, USA, ⁴Columbia University, USA, ⁵Helen Hayes Hospital, USA

Idiopathic osteoporosis (IOP) in premenopausal (preM) women is a disorder of uncertain pathogenesis in which fragility fractures and/or low BMD occur in otherwise healthy women with intact gonadal function. Both HRpQCT and transiliac bone biopsy (Bx) revealed thinner cortices, fewer, thinner, more widely separated and heterogeneously distributed trabeculae, and reduced stiffness in women with IOP than controls. Although dynamic remodeling parameters were heterogeneous and did not differ between subjects and controls, subsets of women with IOP had low or high bone turnover assessed by bone formation rate/bone surface (BFR/BS). We hypothesized that teriparatide (TPTD), which directly increases osteoblast activity, would improve volumetric BMD (vBMD), bone microarchitecture and stiffness in women with IOP. Herein, we report interim results of an open-label pilot study of 22 preM women with IOP treated with TPTD 20 mcg SC daily. HRpQCT (Scanco Medical AG) of the distal radius (DR) and tibia (DT) was performed at baseline and 12-18 months in 18

women (age 415 yrs; 14 with fractures). Measurements were more variable at the DR than DT. Trabecular (Tb) vBMD increased significantly by 5.2% at the DR and 2.3% at the DT (Table), with larger increases in the inner than outer Tb compartment. Cortical (Ct) vBMD and thickness did not change at either site. At the DT, there were significant increases in Tb number and decreases in Tb separation and heterogeneity of the Tb network; similar directional changes at the DR were not significant. Stiffness (Tb elastic modulus) by FEA did not change significantly at either site. Changes in Tb and Ct vBMD did not correlate with %change in spine or hip BMD by DXA or baseline serum bone turnover markers. At the DR, %change in Tb vBMD correlated directly with baseline endocortical wall width (WWi) on transiliac Bx, a measure of osteoblast productivity ($r=0.502$; $p=0.04$). Percent change in DR Ct vBMD correlated directly with baseline cancellous osteoid width (OWi; $r=0.638$; $p=0.006$), as did DT CT vBMD with intracortical OWi ($r=0.484$; $p=0.049$). In conclusion, HRpQCT detected significant improvements in vBMD (DR and DT) and Tb microarchitecture (DT only) in preM women with IOP treated with TPTD. Baseline static parameters of osteoblast function (OWi, WWi) on transiliac Bx predicted responses in Tb and Ct vBMD, suggesting that osteoblast function is an important determinant of response to TPTD in preM women with IOP.

How to Predict a Suboptimal Response to Recombinant Parathyroid Hormone Treatment in Osteoporosis. Najia Siddique^{*1}, Martin Healy², Choon Guan Chan³, Nessa Fallon⁴, John Brown Walsh³, Miriam Catherine Casey³. ¹St James University Hospital, Ireland, ²central pathology lab, St.James Hospital, Ireland, ³Bone health services, St.James hospital, Ireland, ⁴osteoporosis & bone health clinic, St.James Hospital, Ireland

Introduction:

Recombinant PTH is an anabolic agent with a unique mechanism to increase bone mineral density and reduce fractures in postmenopausal women. However, little attention has been paid to what constitutes a poor response to rPTH treatment. Better understanding of indicators predicting response to it may lead to improved management and better clinical outcomes. This study therefore investigates the baseline characteristics of the patients who failed to respond to rPTH treatment despite being compliant to it.

Design: A retrospective study.

Methods:

Data on 234 patients with postmenopausal osteoporosis (mean age 68yrs) was collected, who were treated with PTH 1-34 for 18 months at Osteoporosis clinic in ST. JAMES Hospital, Dublin, Ireland. (60% were on bisphosphonates for ≥6 mths). Out of these, data on 160 patients who were compliant was selected for analysis. Patients were divided into two main groups as responders vs nonresponders. Patients with a <3% gain in BMD at lumbar spine or a new vertebral fracture at 18mth were considered as non responders to the treatment. A statistical comparison of the baseline characteristics and biochemical values at baseline, 3mths and 12 mths on rPTH was made between the groups using T-test and Wilcoxon rank sum test.

Results:

There was no significant difference in responders vs non responders for GFR, Serum PTH, Calcium, 25(OH)Vitamin D, Alk Phos and 24hr Urinary Ca at baseline, 3mth and 12mth on treatment. There was no significant difference in Bone markers including serum CTX, Osteocalcin and PINP at baseline. But a trend was observed towards a greater PINP rise in responders at 3mth. Two more significant findings are detailed below in Table 1.

Conclusion: This was a comprehensive study analysing a large population on rPTH to identify the predictors of a poor response to it. Of interest the non responders had significantly greater BMI vs responders. This group therefore could have poor dietary habits or metabolic syndrome however; this abstract doesn't investigate into it. Thus, Screening for lifestyle, dietary habits and metabolic syndrome could refine the selection of patients for rPTH treatment for Osteoporosis. This data analysis also identified a lesser PINP rise at 3mths as compared to the responder group. Therefore, PINP measurement at 3 months could somehow predict who is going to respond and vice versa. Very little else predicts response to this treatment especially when this analysis is independent of 25 (OH) vitamin D levels.

Table1.

	Responders Median and CI	Non-responders Median and CI	p-value
BMD at baseline	0.70 (0.64, 0.78)	0.80 (0.74, 0.89)	0.0003
BMD gain	12.4 (7.8, 18.3)	0.84 (-1.08, 1.92)	<0.001
BMI	20.5 (15.0, 26.8)	29.2 (21.1, 32.9)	0.005

Baseline BMI, BMD and BMD gain at 18mths

Once Yearly Zoledronic Acid After 18 months of Parathyroid Hormone (1-84) for Severe Osteoporosis. Marco Invernizzi^{*1}, Stefano Carda², Alessio Baricich², Maurizio Bevilacqua³, Carlo Cisarì². ¹University of Eastern Piedmont, Novara, Italy, ²Department of Clinical & Experimental Medicine, University of Eastern Piedmont "A. Avogadro", Italy, ³Endocrinology & Diabetes Unit, Department of Medicine, Luigi Sacco Hospital (Vialba)-University of Milan, Italy

INTRODUCTION: Since the use of full-length parathyroid hormone (PTH1-84) as a treatment for severe osteoporosis is limited to 18 months, important questions remain regarding management strategy after this treatment.

Previous studies investigate the use of alendronate after 1 year of PTH1-84 alone, showing further gains in Bone Mineral Density (BMD). However these gains in BMD were lost if PTH1-84 was not followed by an antiresorptive agent. At present time evidences about antiresorptive therapies other than alendronate after PTH1-84 are lacking.

AIM: to determine whether once yearly 5mg of intravenous zoledronic acid (ZOL) can maintain or increase gains in BMD at hip site after 18 months of therapy with PTH1-84.

METHODS: 18 severe osteoporotic postmenopausal women who had received PTH1-84 monotherapy (100 µg daily) for 18 months were treated with 5mg zoledronic acid two months after having ended PTH1-84 therapy. BMD at femoral neck and total hip were assessed with the use of dual-energy x-ray absorptiometry at baseline, after 18 months of treatment and 1 year after zoledronic acid infusion. Bone biochemical turnover markers (serum CTX, OC and B-ALP) were assessed at baseline, every 6 month during PTH treatment and 1 year after zoledronic acid infusion. Tolerability was evaluated by adverse experience (AE) reporting.

RESULTS: At femoral neck BMD increased by 6.4% (2.2% after PTH1-84 and 4.4% after ZOL respectively) and an analogue improvement was observed at total hip. After PTH1-84 treatment there were significant increases at 6, 12 and 18 months of OC (+232.5%, +212.5%, +190% respectively), serum CTX (+151%, +236%, +244%) and B-ALP (+131%, +210%, +198%; $p<0.01$ for all vs. basal). On the other hand, after zoledronic acid infusion we observed a decrease in OC (-58%), serum CTX (-70.4%) and B-ALP (-30.6%). None of the patients experienced severe adverse events during PTH1-84 treatment, while 7 (38.8%) of patients experienced a self-limiting acute phase reaction after ZOL.

CONCLUSIONS:

Our data show that after 18 months of PTH1-84, ZOL is a safe and effective option to not only to maintain but also to increase BMD at the hip site. These results have clinical implications for therapeutic choices after the discontinuation of PTH1-84.

PTH (1-84) Acutely and Transiently Augments Vasodilation in the Bone Vasculature and Diminishes Osteoclast Activity in Rats. Rhonda Prisby^{*}, Jeremiah Campbell, Thomas Menezes. University of Texas at Arlington, USA

Intermittent parathyroid hormone (PTH) administration augments bone mass and is a treatment for osteoporosis. In addition, 15 days of PTH enhanced vasodilation of the femoral principal nutrient artery (PNA), the primary conduit for blood flow to long bones. Adequate circulation to bone is requisite for normal growth, remodeling and repair, yet the acute response of the bone vascular system to PTH remains unknown. The purpose of the study was to determine which system, vascular or skeletal, is foremost affected by PTH. **METHODS:** Male Wistar rats (3-4 mon) were administered 100 µg/kg of PTH 1-84 and sacrificed at 1H (n=6) and 4H (n=8). A control (CON; n=7) group received PBS. Right PNAs were dissected and cannulated to assess endothelium-dependent (acetylcholine [ACh]: 10⁻⁹ – 10⁻⁴ M) and endothelium-independent (sodium nitroprusside [SNP]: 10⁻¹⁰ – 10⁻⁴ M) vasodilation. Right femora were analyzed by bone histomorphometry to determine bone microarchitectural (i.e., bone volume to total volume ratio [BV/TV; %], trabecular thickness [Tb.Th; µm], trabecular number [Tb.N/mm], and trabecular separation [Tb.S; µm]) and bone static (i.e., osteoid surface to bone surface [OS/BS; %], osteoblast surface to bone surface [Ob.S/BS, %], osteoclast surface to bone surface [Oc.S/BS; %], osteoclast number per total bone area [N.Oc/TA/mm], and osteoclast number per bone perimeter [Oc.N/BPm/mm]) properties. **RESULTS:** Endothelium-dependent vasodilation was augmented by 41% 1H subsequent to PTH, which normalized to

CON values by 4H. No differences among groups exist in endothelium-independent vasodilation to SNP. As expected, bone microarchitectural properties were similar among groups. Data indicate no change in Ob.S/BS; however, PTH diminished Oc.S/BS by 48% and 62% at 1H and 4H, respectively, vs. CON. In addition, N.Oc/Tar was also significantly reduced vs. CON. CONCLUSIONS: A single dose of PTH 1-84 acutely (1H) augmented endothelium-dependent vasodilation of the femoral PNA. Intriguingly, these early modifications in bone vasomotor function were associated with reduced osteoclast activity; i.e., bone resorbing cells. Acute effects of PTH (1H and 4H) were not evident in osteoblast activity. Currently, the question as to which system is first modified by PTH remains to be resolved. Future studies (i.e., an earlier time point of analysis) and determination of bone perfusion are requisite to answer this question.

Treatment with PTH 1-84 in Male Patients with Severe Osteoporosis - Results from a Prospective 24 month Open-Label Trial. Christian Muschitz¹, Judith Haschka^{*2}, Roland Kocijan², Astrid Fahrleitner-Pammer³, Guenther Nirnberger⁴, Angela Trubrich⁵, Christina Bittighofer⁵, Heinrich Resch⁶. ¹St. Vincent's Hospital, Austria, ²St. Vincent Hospital Vienna, Austria, ³Medical University Graz, Austria, ⁴Bioconsult Ltd, Austria, ⁵The VINFORCE Study Group - St. Vincent Hospital - Medical Department II, Austria, ⁶Medical University Vienna, Austria

Purpose: Osteoporosis in men is an important and often underestimated problem. Generally accepted is the administration of antiresorptives which influence bone metabolism by reducing bone resorption and increasing bone mineral density (BMD). Usually Anabolic treatment by Parathyroid hormone (PTH) is reimbursed when new osteoporotic fractures occur during antiresorptive treatment, in glucocorticoid induced osteoporosis (GIOP) and in patients with low BMD and multiple clinical risk factors (CRF).

Methods: We prospectively assigned 26 men (mean age 63.3 14.3 ys) to daily subcutaneous injections of 100µg of PTH 1-84 for 24 months. All pts received daily supplementation of 1000mg calcium and 800IU vitamin D. Mean T-score was -3.24 0.92 at L1-L4 and -2.31 0.94 at hip. 81% had prevalent fractures including vertebral fractures (20 pts, mean 3 1.8), non vertebral fractures (11 pts) and hip fractures (5 pts). 6 pts had long term steroid medication (9.3 5.3 ys). 20 pts had prior antiresorptive treatment (6.3 2.6 ys) and 6 were treatment naive (low BMD, ≥ 2 CRFs).

Primary objectives were the gain of BMD at lumbar spine and hip and the changes of bone turnover markers (PINP, S-CTX). Secondary objectives were reduction of new osteoporotic fractures and the evaluation of safety and tolerability.

Patients had BMD measurements (DXA), X-ray of spine, assessment of PINP, S-CTX at baseline and at months 6, 12, 18 and 24. A visual analogue scale (VAS) was assessed for general health.

Results: The increase of lumbar BMD at month 12 was 6.51% and at month 24 finally 13.98%, at femoral neck from 1.17% and 8.5% and at total hip 1.5% and 7.72% compared to baseline (P<0.0001 for all). PINP rapidly increased up to 421% at month 12 and remained till to the end of the observation period; S-CTX increased between 181% and 322% (maximum 347% at month 12) [P<0.001 for all].

One patient (GIOP) had a new morphometric vertebral fracture and one patient sustained a hip fracture after a major trauma (accident).

PTH 1-84 was generally well tolerated. VAS score declined from 7.5 to 3.2 (P<0.05).

Conclusions: Our data suggest that PTH 1-84 rapidly increases BMD at different skeletal sites regardless of prior long-term treatment with bisphosphonates or steroid medication. The bisphosphonate induced suppression of the bone turnover does not seem to reduce the anabolic effect of PTH in male patients with severe osteoporosis

Atypical Diaphyseal Femoral Fractures Associated With Bisphosphonate Use and Severe Curved Femur: A Case Series. Satoshi Sasaki^{*1}, Yuji Kasukawa², Yoichi Shimada², Michio Hongo², Naohisa Miyakoshi². ¹Yuri-kumiai General Hospital, Japan, ²Akita University Graduate School of Medicine, Japan

Purpose: Recent reports have raised concerns about atypical subtrochanteric and diaphyseal femoral fractures after long-term bisphosphonate treatment, which may be associated with severely suppressed bone turnover (SSBT). However, diaphyseal femoral fractures without bisphosphonate treatment have also been reported in patients with severely curved femur, which are not rare in the elderly. The purpose of this study was therefore to investigate associations between occurrence of such fractures, bisphosphonate use, and curvature of the femur.

Methods: Nine consecutive elderly patients treated for atypical diaphyseal femoral fractures between 2005 and 2010 were retrospectively reviewed. Three patients sustained bilateral fractures. Eight patients were administered bisphosphonates and

one patient was administered raloxifene. Duration of osteoporosis treatment, type of fractures, surgical procedure, and curvature of opposite femur were evaluated.

Results: The mean duration of drug administration was 3.6 years. All fractures showed similar X-ray patterns of simple transverse fracture with medial spike. Nine femurs showed thickening of the femoral cortex. One case was treated with locking plate fixation, while the other cases were operated with intramedullary nails (9 antegrade nails, 2 retrograde nails). One femur treated with retrograde nail showed delayed bone union. Femoral curvature tended to show larger values in cases without cortical thickening than those with cortical thickening, however, it was not significant.

Conclusions: Our experience suggests that 2 types of atypical diaphyseal femoral fracture should be considered in the elderly: fracture resulting SSBT and showing thickening of the femoral cortex; and pathological fracture due to malalignment of the femur without cortical thickening.

Disclosures: Satoshi Sasaki, None.

Atypical Femoral Fractures: From the Pain without Fracture to the Fracture without Pain. Enrique Casado^{*}, Ivonne Vazquez, Marta Larrosa, MarÚa GarcÚa-Manrique, Jose Antonio Gonzalez, Jordi Gratacos. University Institute Parc TaulÚ, Spain

Purpose: To describe the clinical and radiological features of patients with atypical femoral fractures diagnosed in the last three years at the Hospital of Sabadell (Barcelona, Spain).

Methods: Descriptive study. All consecutive patients admitted to the Orthopedics Department, Hospital of Sabadell (reference population 400,000) from January 2008 to December 2010 were reviewed. After the confirmation of an atypical fracture of the femur (major features) the patient clinical chart was reviewed, collecting some data about patient demographics, osteoporosis treatment and phospho-calcium metabolism parameters on admission.

Results: Eight atypical fractures of the femur in six patients were registered. All patients were female. Mean age 76.710.1 years (range 60-91). In all cases the fracture was located in the femoral shaft. In two patients the fracture was bilateral and in four patients unilateral (2 right, 2 left). Six out of eight fractures were transverse and two were oblique. Two patients had no previous symptoms and four patients had previous limb pain (lasting 1-8 months). All patients except one were receiving bisphosphonates: alendronate (2 patients), ibandronate (2 patients), risedronate (1 patient). Patients under risedronate and ibandronate had previously received other bisphosphonates for more than 7 years. The time of treatment with bisphosphonates in each patient ranged between 3 and 12 years. Five patients (83%) had hypovitaminosis D (25 (OH)D <25 ng/ml), with a mean of 25(OH)D of 185.4 ng/ml. The only patient with normal vitamin D levels was receiving chronic treatment with glucocorticoids for pulmonary fibrosis.

Conclusions: Atypical fractures of the femur in our series were located in the diaphysis and occurred in women over 60 years with hypovitaminosis D and treated with bisphosphonates for more than 3 years. The clinical presentation of these fractures was variable: some patients had an incomplete fracture with previous limb pain and other patients had a complete fracture without any previous symptoms.

Bone Safety of a Novel Delayed-release Risedronate 35 mg Once-a-Week Assessed by Bone Histology and Histomorphometry. Robert Recker^{*1}, Ivo Valter², Katre Maasalu³, Clelia Magaril⁴, Zulema Man⁵, Jose Ruben Zanchetta⁶, Carlos Mautalen⁷, Kadri-Liina Vahula⁸, Paul Miller⁹, Dietrich Wenderoth¹⁰, Michael McClung¹¹. ¹Creighton University Osteoporosis Research Center, USA, ²Center for Clinical & Basic Research, Estonia, ³OCRC, Tartu University Hospital, Estonia, ⁴IMAI-Research, Argentina, ⁵Centro Medico TIEMPO, Argentina, ⁶Instituto de Investigaciones Metabolicas (IDIM), Argentina, ⁷Centro de OsteopatÚas Medicas, Argentina, ⁸KLV Medical Office, Estonia, ⁹Colorado Center for Bone Research, USA, ¹⁰Warner Chilcott Deutschland GmbH, Germany, ¹¹Oregon Osteoporosis Center, USA

Bisphosphonates (BPs) are the standard of care for postmenopausal osteoporosis. The dosing instructions of oral BPs per their approved labels require that they be taken on an empty stomach at least 30 to 60 minutes before the first food or drink or other medications. The 2-year efficacy and safety results of a novel delayed-release (DR) formulation of risedronate 35 mg once-a-week (OaW) that can be taken with or without breakfast are available. The results of the bone histology and histomorphometry of the corresponding study are presented.

The primary objective of this randomized, double blind, active controlled study was to determine the non-inferiority, based on the percent change in lumbar spine BMD from baseline to Endpoint/Week 52, of risedronate 35 mg OaW DR taken before or after breakfast compared to 5 mg daily immediate release (IR), in 923 randomized postmenopausal (PM) women, at least 50 years of age, with a lumbar spine or total hip BMD T-score < -2.5 or a T-score < -2.0 with at least one prevalent vertebral fracture. 722 of the 923 randomized subjects completed 2 years of treatment. 45 subjects (risedronate 35 mg OaW DR following breakfast (FB) n=15/307, risedronate 35 mg OaW DR at least 30 minutes before breakfast (BB) n=12/308, risedronate 5 mg IR daily n=18/307) consented to undergo a single transiliac bone biopsy at Week 104. Bone biopsy samples were examined by qualitative histology and quantitative histomorphometry.

After 2 years of treatment, no histological abnormalities were observed in any of the risedronate-treated groups and double tetracycline label was detected in all 45 biopsies. Results for key bone turnover parameters were similar across treated groups, indicating comparable remodeling activities as well as bone mineralization parameters showing that mineralization was not impaired by the 35 mg DR formulation. The histomorphometric results seen with 5 mg IR daily in this study are consistent with the results seen in previous 5 mg IR studies in subjects with PMO.

Overall 35 mg Risedronate DR weekly regimens preserve normal bone quality and maintain bone remodeling and mineralization at a level similar to the 5 mg IR daily regimen and within the normal pre-and post-menopausal range.

Osteocalcin (OC) knock-out mice have increased fat mass and insulin resistance, and are more likely to develop diabetes (DM) on a high fat diet. Antiresorptive therapies reduce circulating levels of total OC by 40-50%. Reductions in under-carboxylated OC have been shown with alendronate. To test whether these therapies increase the risk of weight gain, glucose intolerance or DM, we used data from randomized placebo-controlled trials, the Fracture Intervention Trial (FIT) of alendronate (ALN), the Health Outcomes and Reduced Incidence with Zoledronic Acid (ZOL) Once Yearly (HORIZON) trial, and the Fracture Reduction Evaluation of Denosumab (DMAB) in Osteoporosis every 6 months (FREEDOM) trial. Analyses excluded women with probable baseline DM or with unknown status, based on self-report, DM medication use, or an elevated fasting glucose (FG)(>126 mg/dl) or non-fasting glucose (>200 mg/dl). Incident DM was identified based on adverse events, new use of DM medication, or at least 2 elevated glucose results. Changes in weight and FG were compared with linear mixed models. The rate of incident DM was compared with proportional hazards (FIT, FREEDOM) or logistic regression (HORIZON) models. In FIT 6459 postmenopausal women with femoral neck (FN) T-score < -1.6 received daily ALN or placebo (PBO) for up to 4 years; 308 were excluded. Weight (N=6151) and serum glucose (N=1073) were measured annually. In HORIZON 7736 postmenopausal women with osteoporosis based on FN T-score and/or baseline vertebral fracture received a once-yearly infusion of ZOL or PBO for up to 3 years; 623 were excluded. Weight (N=7113) and FG (N=5213) were measured annually. In FREEDOM 7762 postmenopausal women with T-score < -2.5 received DMAB or PBO every 6 mos for up to 3 years; 686 were excluded. Weight (N=7076) was measured annually. FG (N=7048) was measured at baseline, 1-mo, 6-mos, and every 6 mos thereafter. ALN and DMAB, but not ZOL, were associated with less weight loss than PBO but differences were modest (Table). FG changes and the rate of incident DM did not differ between any therapy and PBO. Gain in total bone with antiresorptive therapy may account for some, but not all, of the differences in weight change, a finding that warrants further investigation. We found no change in fasting glucose or diabetes incidence with antiresorptive therapy in postmenopausal women. Lowering OC with antiresorptive therapy does not appear to have a clinically important effect on glucose homeostasis.

Table. Effects of antiresorptive therapies on glucose metabolism after 3-4 years

	ALN	PBO	ZOL	PBO	DMAB	PBO
Mean weight change (kg)	0.26*	-0.06	-0.35	-0.50	-0.13*	-0.44
Mean FG change (mg/dl)	3.41	3.87	0.71	0.52	1.83	1.74
	69	72	68	75	66	78
Incident DM (N(%))	(2.3%)	(2.4%)	(2.0%)	(2.1%)	(1.9%)	(2.2%)
Incident DM (RR (95% CI) for TMT vs PBO)	0.96 (0.69, 1.33)		0.91 (0.65, 1.27)		0.85 (0.61, 1.17)

Effects of Combination therapy (Alendronate with Alfacalcidol) on Osteoporotic Fractures for Postmenopausal Japanese Women: The Japanese Osteoporosis Intervention Trial (JOINT) - 02. Hiroaki Ohta¹, Masataka Shiraki², Toshitaka Nakamura³, Masao Fukunaga⁴, Takayuki Hosoi⁵, Yukari Uemura⁶, Tatsuhiko Kuroda⁷, Nobuaki Miyakawa⁷, Yasuo Ohashi⁶, Hajime Orimo⁸.
¹Tokyo Women's Medical University Sanno Medical Center, Japan, ²Research Institute & Practice for Involuntary Diseases, Japan, ³University of Occupational & Environmental Health, Japan, ⁴Kawasaki Medical School, Japan, ⁵National Center for Geriatrics & Gerontology, Japan, ⁶Department of Biostatistics, School of Public Health, The University of Tokyo, Japan, ⁷Public Health Research Foundation, Japan, ⁸Japan Osteoporosis Foundation, Japan

Objectives The Japanese Osteoporosis Intervention Trial (JOINT) - 02 was conducted a randomized controlled trial to clarify the efficacy and safety of alendronate with alfacalcidol versus alendronate alone in a clinical practice. Eligible patients were postmenopausal women with severe osteoporosis who were aged 70 years or older and had several risk factors for incident fractures. The primary endpoint was prevention of incident fractures, and the anti-fracture efficacy was evaluated in relation to the baseline serum level of 25-hydroxycholecalciferol [25(OH)D]. Research design and methods A total of 2164 patients were randomized to alendronate with alfacalcidol (combination therapy group) or alendronate alone (monotherapy group). The efficacy was evaluated for 2022 patients (combination therapy group, 995; monotherapy group, 1027) and the safety 2053 patients (1019 and 1034, respectively). Results The combination therapy group had a significantly reduced risk of vertebral fractures after the first 6 months (HR, 0.53; 95% CI, 0.28 to 0.99). In subgroup analyses, the combination therapy group was superior in the strata of number of prevalent vertebral fractures of ≥ 2 (HR, 0.51; 95% CI, 0.32 to 0.84) and grade 3 of prevalent vertebral fractures (HR, 0.55; 95% CI, 0.38 to 0.94). The rate of non-vertebral weight-bearing bone fractures, which mainly consisted of proximal femur fractures, was significantly lower in the combination therapy group than in the monotherapy group during the follow-up period (HR, 0.31; 95% CI, 0.10 to 0.96). A lower baseline 25(OH)D level was associated with a higher incidence of non-vertebral weight-bearing bone fractures (HR, 3.34; 95% CI, 1.21 to 9.25) after adjustment for age, prevalent vertebral fractures and BMD despite alendronate use. Although one patient given the combination therapy had mild hypercalcemia, serious hypercalcemia and unknown adverse events were not encountered in either group. Conclusions In conclusion, combination therapy of alendronate with alfacalcidol was more effective for fracture prevention, especially for non-vertebral weight-bearing bone sites, than alendronate alone in elderly osteoporosis patients with multiple risks. Alendronate combined with alfacalcidol in a promising treatment for postmenopausal osteoporosis.

Effects of Monthly Risedronate with Cholecalciferol on 25-hydroxyvitamin D Level and Bone Markers in Korean Patients with Osteoporosis. Sung-hwan Moon¹, HYOUNG MOO PARK², Chan Soo Shin³, Ho-Yeon Chung⁴, Yoon-Sok Chung⁵, Byung-koo Yoon⁶, Jae-Suk Chang⁷, Moo-Il Kang⁸, Jin-Young Park⁹, Hyun-Koo Yoon¹⁰.
¹Yonsei University, South Korea, ²CHUNG-ANG UNIV. OB&GYN, Republic of Korea, ³Department of Internal Medicine, Seoul National University College of Medicine, South Korea, ⁴Kyung Hee University, South Korea, ⁵Ajou University School of Medicine, South Korea, ⁶Sungkyunkwan University, South Korea, ⁷Ulsan University, Asan Medical Center, South Korea, ⁸Seoul St. Mary's Hospital, South Korea, ⁹Konkuk University, South Korea, ¹⁰Cheil General Hospital & Women's Healthcare Center, South Korea

Introduction: We performed a randomized, double-blind, prospective, 16-week clinical trial to evaluate the efficacy and safety of monthly risedronate with and without cholecalciferol on 25-hydroxyvitamin D [25(OH)D] levels and bone markers in Korean patients with osteoporosis.

Methods We randomly assigned 150 adults with osteoporosis to one of two treatment groups: RSD+ (monthly risedronate 150 mg and cholecalciferol 30,000 IU combined in a single pill, n=74) or RSD (monthly risedronate 150 mg alone, n=76). We measured serum levels of 25(OH)D, parathyroid hormone (PTH), and bone markers and performed muscle function tests, at baseline and after 16 weeks of treatment.

Results: After 16 weeks of treatment, mean serum 25(OH)D increased significantly from 17.8 to 24.3 ng/mL in the RSD+ group and declined significantly from 18.1 to 15.8 ng/mL in the RSD group. The RSD+ groups had significant decreases in serum PTH from 46 to 36.7 pg/mL during the study, but the RSD group showed increasing tendency of PTH from 38 to 40.6 pg/mL. In both groups, serum bone-specific alkaline

phosphatase (BSAP) and C-terminal telopeptide (CTX) declined rapidly and significantly during the treatment; there were no significant differences between groups. There was also no significant difference between groups in lower-extremity function tests. The overall incidence of clinical adverse events was not significantly different between groups.

Conclusion In patients with osteoporosis, a once-monthly pill of risendronate and cholecalciferol provided equivalent anti-resorptive efficacy to risendronate alone in terms of bone turnover and improved 25(OH)D level over a 16-week treatment period without significant adverse events.

Efficacy of Intravenous Ibandronate in Postmenopausal Women with an Inadequate Response to Oral Bisphosphonate. Ha Young Kim^{*1}, Sung Jin Bae², Beom-Jun Kim², Seung Hun Lee³, Jung-Min Koh², Ghi Su Kim³.

¹Wonkwang University Sanbon Hospital, South Korea, ²Asan Medical Center, South Korea, ³Asan Medical Center, University of Ulsan College of Medicine, South Korea

Objective: Oral bisphosphonate (BP) therapy is a mainstay for treatment of post-menopausal osteoporosis. However, it has been reported that the number of inadequate responders to oral BP is up to 25% in treated post-menopausal women. The mechanism behind inadequate responses to oral BP have to be detailed and clarified. In this study, we evaluated the efficacy of intravenous BP using biochemical bone turnover markers in post-menopausal women with an inadequate response to oral BP.

Material and Methods: We measured serum C-telopeptide (CTX) levels after 6 months of therapy in 172 post-menopausal women who have received uninterrupted oral BP therapy (Alendronate, 10mg/day and 70mg/week; Risedronate, 5mg/day and 35mg/week; Ibandronate, 150mg/month) for at least 3 months. Inadequate responders were defined as patients who did not show more than a 51% reduction of serum CTX compared with pre-treated levels or whose serum CTX did not fall to below the pre-menopausal mean level. Identified inadequate responders were classified into two groups: Continuous Oral BP Treatment and Change to IV Ibandronate Treatment. After 3 months and 12 months of treatment, we measured serum CTX levels.

Result: At the baseline, there was no significant difference in age, years since menopause, height and weight between the alendronate treatment group (n=88) and the risedronate treatment group (n=84). We identified 28 inadequate responders (16.3%; 11(12.5%) in the alendronate group and 17 (20.2%) in the risedronate group. The alendronate group showed a higher tendency in therapeutic response ($P=0.169$). Among the subjects who were changed to IV ibandronate therapy (n=13), serum CTX levels measured 7 days after the second injection (0.191 0.110 ng/mL) and again just prior to the fifth injection (0.274 0.159 ng/mL) showed a significant decrease compared to pre-treatment levels (0.450 0.134 ng/mL) ($P < 0.001$ and $P = 0.004$, respectively).

Conclusion: Inadequate response to oral BP may result from decreased absorption in the intestine and/or binding with food-containing materials. Therefore, the change to intravenous BP could be a good alternative for inadequate responders.

Lessons Learned From Setting Up a Community Based IV Bisphosphonate Service. Eamonn Brankin^{*1}, Robin Munro², Wendy Feeney², Margaret Yates², Paul Mitchell³, John Hinnie⁴, Andrew Gallagher⁵, Janet Horner¹, Stephen Gallacher⁶. ¹NHS Lanarkshire, United Kingdom, ²NHS Lanarkshire Osteoporosis Service, United Kingdom, ³University of Derby, United Kingdom, ⁴South Glasgow Osteoporosis Service, United Kingdom, ⁵Victoria Infirmary, United Kingdom, ⁶Southern General Hospital, United Kingdom

In 2010 we presented set up of an IV bisphosphonate infusion service. We now share lessons learned to aid colleagues wishing to follow suit. During the process the financial situation within the NHS changed resulting in significant service implementation delay. Historically, various services – rheumatology, orthopaedics, care of the elderly and family medicine each treated patients in isolation. We aimed to progress to a unified service. Lessons learned: -Establish a unified drug budget. Lack of a drug budget was our biggest hurdle -Enlist senior NHS pharmacist help at outset. -To achieve NHS funding approval a protocol must be submitted to budget holders very early in the process -Sourcing Vitamin D was difficult requiring additional approval as an unlicensed use -Many patients in care homes have mental health/consent issues. This causes delay in treatment -For financial reasons funding approval for the use of zoledronic acid was restricted to hip fracture patients initially. Limiting treatment numbers improves chances of initial funding approval -A significant number of patients died shortly post fracture. As such it is beneficial to delay IV treatment for a period of time post fracture -Developing a patient identification system is essential -Inconsistencies with data retrieval from IT systems causes issues. -Access to past medical/drug histories is variable. Access to the NHS emergency care summary across primary/secondary care would be optimal. Some care homes are

reluctant to release notes -Care home staff may be too busy to help staff assess patients and some patients with more severe dementia did not tolerate cannulation -Setting up the service required close networking with care homes, care home liaison and mental health staff, pharmacy, falls/elderly care teams. The patient pathway improved as other services are now aware of how to access the service -Timing issues – political and financial, are important as is mentoring/training of nurses in IV cannulation and drug administration -It is optimal to have an IT system which records patient consultations. Working between primary/secondary care makes careful choice of an appropriate IT system essential, but again takes time -Liaison with medical physics is essential. Lightweight ambulatory infusion pumps are optimal for community use. This may not fit with corporate purchasing policy. Pumps have to be 'fit for purpose' as patients with dementia may not be able to sit for the duration of the infusion

Osteoporosis Treatment Patterns Among Medicare Beneficiaries. Huifeng Yun^{*1}, Jeffrey Curtis¹, Robert Matthews¹, Meredith Kilgore², Michael Morrissey¹, Nicole Wright¹, Kenneth Saag¹, David Becker¹, Elizabeth Delzell¹. ¹University of Alabama at Birmingham, USA, ²University of Alabama At Birmingham School of Public Health, USA

Background: Low adherence to bisphosphonates (BPs) is associated with increased fracture risk. Standard measures of adherence, which often classify patients as non-persistent (i.e., discontinuing) if they switch to other osteoporosis (OP) treatments or restart therapy at a later time, may underestimate adherence and hinder identification of factors associated with discontinuation.

Objectives: To identify OP medication discontinuation and switching patterns among Medicare beneficiaries and factors associated with discontinuation.

Method: We used a 5% sample of Medicare beneficiaries with at least 30 months of fee-for-service and part D drug coverage from 2006 through 2008. We identified a cohort of new BP users who initiated treatment after a 12 month baseline period with no BP prescriptions filled. We classified medication status at the end of 18 months of follow-up as: continued same BP drug without a treatment gap (≥ 90 days after end of days' supply), discontinued all OP drugs (≥ 90 days with no subsequent prescription for an OP med), restarted same drug after a gap, switched to another BP or non-BP drug without a gap, or switched to another drug with a gap. We used multinomial logistic regression to identify factors associated with medication status at the end of follow-up.

Results: Among 5,069 new BP users, after 18 months of follow-up, 35.5% continued the same BP, 37.0% completely discontinued, 15.3% restarted the same drug after a gap ≥ 90 days, and 12.1% switched to another BP or non-BP drug, either with (3.9%) or without (8.2%) a gap. With non-persistence defined as total discontinuation, having a gap in BP therapy ≥ 90 days or switching, 64.4% of patients would have been considered non-persistent. Lower income, more comorbidity, and no DXA during baseline were significantly associated with total discontinuation of BPs within 18 months.

Conclusion: Among new BP users, switching between BPs, switching out of the BP treatment class, and having treatment gaps are common. Discontinuation and switching patterns should be considered in order to characterize adherence more accurately in future OP studies.

SU0428

Relationship Between Change in Total Hip BMD in Response to Zoledronic Acid 5 mg and Pre-treatment Change in Total Hip BMD: the HORIZON-PFT Extension Study. Richard Eastell^{*1}, Lisa Palermo², Steven Boonen³, Felicia Cosman⁴, Ian Reid⁵, Steven Cummings⁶, Dennis Black². ¹University of Sheffield, United Kingdom, ²University of California, San Francisco, USA, ³Center for Metabolic Bone Disease & Division of Geriatric Medicine, Belgium, ⁴Helen Hayes Hospital, USA, ⁵University of Auckland, New Zealand, ⁶San Francisco Coordinating Center, USA

Several studies have shown the high bone turnover is associated with 1) greater rates of bone loss and 2) greater BMD response to anti-resorptive therapy in postmenopausal osteoporosis. However, it is not known whether greater rates of bone loss prior to therapy are associated with greater BMD response to anti-resorptive therapy. In the HORIZON-PFT Extension study, one group of women who were randomized to receive placebo for 3 years (years 1, 2 and 3), were then all treated with Zoledronic Acid 5 mg annually for up to three injections (years 4, 5 and 6, P3Z3 Study) (n=1223). We measured total hip BMD at baseline, 1, 2 and 3 years on placebo and at 4.5 and 6 years on zoledronic acid. BMD was measured by DXA and total PINP by automated immunoassay analyser. The PINP was measured at 3, 4.5 and 6

years, but results were excluded if patients had a fracture in the past year (PINP increases for up to a year following a fracture). Also, by design not all subjects were followed for as long as 6 years, so this analysis will focus on the results at 4.5 years.

The change in total hip BMD in years 0-3 was related to the change in total hip BMD on zoledronic acid at 4.5 years ($r = -0.39$, $P < 0.0001$). Thus, those with greater loss during years 0-3 had greater gain during years 3-4.5. In order to test whether this last result was robust, we repeated the analysis with hip BMD at 6 years ($r = -0.24$, $P < 0.0001$) and we repeated the analysis with change in hip BMD at 2 years ($r = -0.09$, $P < 0.01$). The change in total hip BMD in years 0-3 on placebo was related to the serum PINP at the end of the 3-year period ($r = -0.24$, $P < 0.0001$). The change in total hip BMD on zoledronic acid from year 3 to 4.5 was related to the serum PINP at the end of the 3-year period ($r = 0.26$, $P < 0.0001$). We conclude that BMD response to zoledronic acid is greater in postmenopausal women who had larger loss prior to treatment. The likely mechanism for this association is that higher bone turnover is associated with both greater BMD response to zoledronic acid and greater bone loss on placebo.

SU0429

The Effect of One Year Bi-monthly Ibandronate on Bone Mineral Density and Bone Turn Over Marker in Korean Postmenopausal Women. Young Goo Shin*. Wonju College of Medicine, South Korea

Background: Osteoporosis is the condition of fragile bone, which is easy to fracture with minor trauma. Bisphosphonates are widely prescribed worldwide, today. Among these bisphosphonates, the oral monthly ibandronate is the least frequent dosing in postmenopausal osteoporosis, approved by USA-FDA. But, in Korea, the HIRA (public health assurance) cover the drug cost with only 6 month during one year and only in patients just T-score less than -3.0 regardless the kinds of drugs for osteoporosis. So, in Korea, physician should prescribe the drugs for osteoporosis by the above guideline or the other 6 months-prescribing should be done without public health assurance coverage. So, I review the efficacy of ibandronate with the change BMD and bone marker during one year treatment between monthly and bi-monthly dosing.

Methods: About 200 patients were enrolled. The patients were divided to 2 groups, monthly dosing and bi-monthly dosing. Patients were tested for L2-4 spine BMD, femur neck BMD, total hip BMD, serum osteocalcin and CTx at baseline and 1 year after dosing.

Results: The patients for monthly dosing were 78 and for bimonthly dosing were 48. The age was older with monthly (62.5 vs 59.5, $p = 0.031$). The basal BMD (g/cm²) were significant higher with bi-monthly; L2-4 (0.860 vs 0.967), femur neck (0.720 vs 0.797), total hip (0.762 vs 0.861).

With monthly dosing, there were significant increasing BMD at all site and decreasing bone marker after ibandronate treatment by paired t-test. The BMD (g/cm²) was increased as follows: L2-4 0.860 to 0.899, femur neck 0.720 to 0.744, total hip 0.762 to 0.789. The osteocalcin (ng/ml) 27.12 decreased to 14.89, and the CTx (ng/ml) 0.74 decreased to 0.23.

With bi-monthly dosing, the BMD was only significant increasing in lumbar spine BMD, and the others also have tendency to increase but not significant by paired t-test. The changes of BMD (g/cm²) as follows: L2-4 0.967 to 1.011, femur neck 0.797 to 0.803, total hip 0.861 to 0.865. The changes of bone markers also significant decrease in this group by paired t-test. The osteocalcin (ng/ml) 24.6 decreased to 18.05, and the CTx (ng/ml) 0.61 decreased to 0.32.

But these significant changes were disappeared with repeated measured ANOVA, adjusted with age, height and weight.

Conclusion: The ibandronate therapy was effective to Korean postmenopausal women in both groups, monthly or bi-monthly dosing. And there was not differ between the 2 dosing treatments.

Limitation of this study: There was some selection bias because the patients were not conditioned. So, I had tendency to prescribe the drug monthly to weaker bone, bi-monthly to relative strong bone.

Table 1. Basal characteristics in both groups

	Monthly (n=78)	Bi-monthly (n=48)	p
Age (years)	62.55 ± 7.72	59.50 ± 7.90	0.031*
Height (cm)	151.29 ± 6.44	152.43 ± 6.16	0.261

Weekly Alendronate Versus a Single Infusion of Zoledronic Acid: Effects on Bone Turnover Markers, Areal and Volumetric BMD and Bone Microarchitecture During the First Year After Heart or Liver Transplantation. Adi Cohen*¹, Emily Stein², Stephanie Boutry¹, Donald McMahon², Chiyuan Zhang³, Polly Chen³, Kavita Pandit¹, Donna Mancini¹, Robert Brown¹, Susan Restaino¹, Elizabeth Shane². ¹Columbia University Medical Center, USA, ²Columbia University College of Physicians & Surgeons, USA, ³Columbia University, USA

Bone loss and vertebral fractures occur during the first year after heart (HTX) or liver (LTX) transplant. Alendronate (ALN) prevents bone loss in HTX recipients and 3 month (3M) infusions of zoledronic acid (ZA) prevent bone loss in LTX recipients. We conducted a 12M, double-masked, active comparator, non-inferiority trial in 84 HTX or LTX recipients randomized to ALN 70 mg/week or a single infusion of ZA 5 mg, both initiated 258 days post-TX. We compared 12M change in serum C-telopeptide (CTx), BMD at the lumbar spine (LS), femoral neck (FN) and total hip (TH) by DXA, and in a subset, volumetric BMD (vBMD) and microarchitecture at the radius (RAD) and tibia (TIB) by HRpQCT. A nonrandomized reference group (REF, n=25; T score ≥ -1.5) was also enrolled. In the REF group, CTx fell by 21% ($p = \text{NS}$). BMD fell by 1.71.1% (SD; $p = 0.12$) at the LS, 2.00.8% ($p = 0.01$) at the TH and 1.91.0% ($p = 0.07$) at the FN. TIB trabecular (Tb) vBMD fell by 2.17.0% ($p = 0.04$) and Tb number (Tb.N) fell by 3.513.4% ($p = 0.07$), with no significant changes at the RAD. Cortical (Ct) parameters were stable. By 2M, CTx declined significantly more ($p < 0.05$) in the ZA (-69%); 0.656 to 0.201 pg/ml; $p < 0.02$) than the ALN group (-35%); 0.554 to 0.360 pg/ml; $p < 0.13$) and remained lower all year. 12M LS aBMD increased in the ZA group (1.80.7%; $p = 0.03$) with no change in the ALN group (-0.30.7%; $p = 0.9$). TH and FN aBMD did not change in either group. When HTX and LTX recipients were analyzed together, no DXA or HRpQCT parameter differed between ALN and ZA groups. However, HTX recipients randomized to ALN had more LS bone loss than those randomized to ZA (-2.80.9 vs +1.30.9%; $p = 0.013$). In LTX recipients randomized to ALN, RAD Tb vBMD fell by -3.88.0% ($p = 0.01$) and Tb.N fell by -8.716.1% ($p = 0.03$); neither measure changed in the ZA group (between-groups $p < 0.04$). In HTX recipients, TIB Ct thickness declined by -1.54.5% in the ALN group ($p = 0.09$), with no change in the ZA group (+0.44.0%, $p = \text{NS}$). In summary, ZA suppresses CTx more than ALN after HTX or LTX. There was no LS, FN or TH bone loss in HTX/LTX recipients treated with either drug. However, ZA provided greater protection than ALN for LS aBMD in HTX recipients and RAD Tb vBMD and Tb.N in LTX recipients. We conclude that a single infusion of ZA provides more suppression of CTx and is non-inferior to weekly ALN in preventing bone loss during the first 12M after HTX/LTX.

Bisphosphonate Prescribing, Persistence and Cumulative Exposure in Ontario, Canada. Andrea Burden^{*1}, J. Michael Paterson², Daniel Solomon³, Muhammad Mamdani¹, David N. Juurlink¹, Suzanne Cadarette¹. ¹University of Toronto, Canada, ²Institute for Clinical Evaluative Sciences, Canada, ³Harvard Medical School, USA

Purpose:

To describe bisphosphonate prescribing, persistence and cumulative exposure among seniors in Ontario, Canada.

Method:

We used Ontario Drug Benefit pharmacy claims to identify residents aged ≥ 66 years who initiated oral bisphosphonate therapy between April 1996 and March 2009. The first date of bisphosphonate dispensing was considered the index date. Persistence with therapy was defined as continuous treatment with no interruption exceeding 60 days. We examined persistence with therapy and the number of extended gaps (>60 days) between prescriptions over time periods ranging from one to nine years. We also identified the proportion of patients filling only a single prescription and switching to a different bisphosphonate, and calculated the median days of exposure irrespective of gaps in therapy.

Results:

451,113 eligible new bisphosphonate users were identified: mean age=75.6 years (SD=6.9), 84% female, and median follow-up length=4.7 years. Persistence with therapy declined from 63% at one year to 46% at two years and 12% at nine years. Among those with at least five years of follow-up (n=213,029), 61% had one or more extended gaps in bisphosphonate therapy. Overall, 10% of patients filled only a single prescription, 37% switched to a different bisphosphonate and the median exposure was 2.2 years.

Conclusion:

Less than half of patients persisted with bisphosphonate therapy for two years and interruptions in therapy were common, with most patients experiencing two or more >60 day gaps in therapy. Interventions are needed to improve persistence with bisphosphonate therapy and reduce the frequency of gaps in treatment.

Disclosures: Andrea Burden, None.

Case Study: Osteoporosis in Cosenza (Clabria, Italy). Alfonso Reda^{*1}, Claudia Carbone², Luisa Gallo², Maria Gabriella Bartoletti³, Brunella Piro⁴. ¹Italy, ²Servizio Farmaceutico Territoriale, Italy, ³Centro Riabilitazione Biolife, Italy, ⁴Ufficio di Farmacovigilanza Servizio Farmaceutico, Italy

Introduction. The osteoporosis is a disease characterized by underdiagnosis and undertreatment. We want to see if it is true in our referring population. **Method.** We have considered the population from the district of Cosenza in Calabria (Italy). The whole population is 291'086, the women are 149'246 (51.3%) and the men are 141'790 (48.7%). Particularly the women above 50 years hold are 89'994 (60.3%). We have considered two years 2009 – 2010 and all the patients treated with an active drug for osteoporosis (sold in chemistry). Teriparatide, parathyroid hormone, raloxifene, alendronyc acid (only with colcalciferole), ibandronic acid, ricedronic acid, strontium ranelate. **Results.** All treated women are above 50 years hold and they are 11094 (12.33 % of the women above 50 years hold). 84 (0.75% of the treated women above 50 years hold) women took the teriparatide. Two women took parathyroid hormone (0.018% of the women treated above 50 years hold). We have to say that the prescription of teriparatide, parathyroid hormone, is under a restrictive criteria. 317 women took raloxifene (2.86% of the treated women above 50 years hold). 4610 (41.55 % of the treated women above 50 years hold) women took alendronyc acid (only with colcalciferole). 1082 (9.75 % of the treated women above 50 years hold) women took ibandronic acid. 2649 (23.87% of the treated women above 50 years hold) women took ricedronic acid. 2350 (21.18 % of the treated women above 50 years hold) women took strontium ranelate. **Conclusions.** Our observation confirms the underdiagnosis and undertreatment of the osteoporosis. This is one of the greatest problem of Italian health system.

Disclosures: Alfonso Reda, None.

Comparative Analysis of Clinical Outcomes in Patients with Osteoporotic Vertebral Compression Fractures (OVCF); Conservative Treatment Vs Balloon Kyphoplasty. Seong-Hwang Moon¹, Seung Woo Suh², Hwan Mo Lee¹, Si Young Park^{*3}, Jae Young Hong². ¹Yonsei University College of Medicine, South Korea, ²Korea University, College of Medicine, South Korea, ³Korea University, Medical College, South Korea

Introduction

Almost OVCF can be treated conservatively. Recently Kyphoplasty has become a common treatment for painful osteoporotic compression fractures. It has shown numerous benefits including early pain control and height restoration of vertebral body. In spite of simple procedure, numerous complications related to kyphoplasty have been reported. Moreover there is limited evidence to support its superiority.

Methods

Prospectively, we assigned 259 patients who had one or two acute painful OVCF confirmed by MRI. All patients were treated conservatively in initial three weeks. Kyphoplasty was performed in 98 patients who complained sustained back pain and disability in spite of conservative treatment for initial 3 weeks. Participant were stratified according to age, sex, level, number of fractures, BMD, BMI, collapse rates and past history of spine fractures. Pain score using VAS and Oswestry disability index were assessed at 1 week and at 1,3,6 and 12 months.

Results

A total of 259 patients were enrolled and 238 (89 of 98 in Kyphoplasty group, and 149 of 161 in conservative treatment group) completed the 1 year follow up. About 62% of patients were treated successfully with conservative treatment. Risk factors of failure of 3 weeks conservative treatment were older age (over 80), severe osteoporosis (less than -3.0 of t-score), overweight (over 25 of BMI) and larger collapse rates (over 35%). There were significant reductions in VAS and ODI score in both groups at each follow up assessment. At 1 month, better clinical results were assessed in Kyphoplasty group. However, there were not significant differences in outcome measures between two groups at 3,6,12 months. 13 subsequent compression fractures (8 in Kyphoplasty group, 5 in conservative treatment group) occurred during the 1 year follow up period.

Conclusion

Both treatments of OVCF showed successful clinical results at 1 year follow up period. Kyphoplasty showed better outcomes in only 1st month. At the result, in case of the patient with OVCF has no risk factors for failure of conservative treatment, Kyphoplasty might not be indicated. Trial of conservative treatment for 3 weeks will be beneficial.

Compliance with Intravenous Zoledronate in Elderly Patients with Osteoporosis. Young-Kyun Lee^{*1}, Yong-Chan Ha², Deog-Yoon Kim³, Jae-Suk Chang⁴, Hyun-Koo Yoon⁵, Kyung-Hoi Koo¹. ¹Seoul National University Bundang Hospital, South Korea, ²Chung-Ang University Hospital, South Korea, ³Kyung Hee University Hospital, South Korea, ⁴Ulsan University, Asan Medical Center, South Korea, ⁵Cheil General Hospital & Women's Healthcare Center, South Korea

Purpose; Although bisphosphonate is effective for the prevention and treatment of osteoporosis, this therapy obviously work only when patients with osteoporosis take it with good compliance. Intravenous zoledronate, which is administrated annually, has shown the good efficacy of osteoporosis therapy and has ensured its effectiveness for one year. On the contrary to poor compliance with oral bisphosphonate, annual administration of zoledronate seems to overcome the weak point of oral bisphosphonate. However, there is little information available concerning compliance with intravenous zoledronate for osteoporosis in the usual care setting. The aim of this study was to assess intravenous zoledronate compliance after the first administration, and to evaluate the factors contributing to compliance with zoledronate.

Methods; A questionnaire survey about the second administration of zoledronate was performed in 259 patients, whom the first intravenous zoledronate had been administered between January 2009 and December 2009, at the second visit. The questionnaire asked whether the patients were administered zoledronate or not, and why they refused the second injection in non-compliance patients.

Results; One hundred thirty six patients revisited our outpatient clinic at the second year, and the second administration was performed on 89 patients (34.4%, 89/259). Of 79 patients completed the questionnaire, thirteen patients refused the second administration and wanted to exchange into oral bisphosphonate. A post-infusion syndrome was the reason why the six patients out of thirteen (46.2%, 6/13) refused the second administration (46.2%, 6/13).

Conclusion; Although it is guaranteed that the effect of annual intravenous administration of zoledronate will last for a year, the compliance to the second administration was only a third, which was comparable with oral bisphosphonate after a year. The post-infusion syndrome was the factor contributing compliance with intravenous zoledronate in real setting.

Does FRAX® change Treatment Decision in Patients visiting a German University Hospital?. Susanne Rendl¹, Peter Schneider^{*2}. ¹University Clinic Würzburg, Germany, ²Clinic for Nuclear Medicine, Germany

Purpose: FRAX derived 10-years fracture probability incorporates femur neck BMD as risk factor modulating a small range of the fracture probability forecast, thus giving BMD a minor weight as compared with T-score definition alone. We wanted to see whether or not FRAX influenced our treatment recommendations for use of level Ia or Ib agents in clinical routine.

Methods: 100 consecutive patients (26 men, age 65.18.2, 74 women, age 62.311.4) were scanned within 6 weeks using DXA at both hips and the spine (GE Prodigy) and pQCT at the distal radius (Stratec XCT2000). Risk factors were assessed and entered in compliance with FRAX risk factor definition. The lower of the dual femur neck density values was entered. Treatment decision was met using propriety software to project the calculated probabilities on the decision diagram [1] (fig.1). The decision was "yes" if one of the probabilities for general osteoporotic or hip fracture exceeded the threshold. FRAX based neck T-score was compared with German (D) normal data base T-scores for radius, spine and neck. Correlations were determined, $p < 0.05$ was considered significant.

Results: Correlations for the T-scores $\text{neck}_{\text{FRAX}}/\text{neck}_D$ were $r=0.96$, for the T-scores $\text{spine}_D/\text{neck}_D$ $r=0.49$, and, for T-scores $\text{radius}_D/\text{neck}_D$ $r=0.60$, all significant. The mean FRAX derived T-Score was 0.12 lower (not signif.) than the D. Percentages of treatment candidates according to a T-score threshold of ≤ -2.5 or to the FRAX risk assessment tool are shown in fig.2. The correlation between the neck T-score $\text{neck}_{\text{FRAX}}$ and the FRAX_{risks} derived treatment decision (yes/no) was weak ($r=0.38$, $p < 0.01$). The $\text{neck}_{\text{FRAX}}$ T-score correlated with the probability for major osteoporotic fractures by $r=0.62$ ($p < 0.01$). 3% of the patients with a $\text{neck}_D \leq -2.4$ and 16% with a $\text{neck}_D > -2.5$ received a treatment recommendation. For the FRAX-derived neck T-score it was the same rate, but included different individuals (T-Score range: $-0.5 \dots -3.4$, $r=0.95$) due to the impact of their risk profile.

Conclusion: FRAX as a very useful tool is leading to different treatment decisions as compared with a solely T-score based decision. However, it provides a more convincing justification, which is far less dependent on known systematic DXA errors, particularly evident in spine DXA.

Osteoporosis Medication Prescribing in British Columbia and Ontario: Impact of Public Drug Coverage. Suzanne Cadarette^{*1}, Diana Baek¹, Nadia Gunraj², Greg Carney³, Michael Paterson², Colin Dormuth³. ¹University of Toronto, Canada, ²Institute for Clinical Evaluative Sciences, Canada, ³University of British Columbia, Canada

Background: Approved therapies for treating osteoporosis in Canada include bisphosphonates, calcitonin, denosumab, raloxifene and teriparatide. However, significant variation in public drug access to these medications exists across Canada. We sought to compare patterns of osteoporosis medication prescribing between British Columbia (BC) and Ontario.

Methods: Using dispensing data from BC (PharmaNet) and Ontario (Ontario Drug Benefits), we identified all new users of osteoporosis medications aged 66 or more years from 1995/96-2008/09. We summarized the number of new users by fiscal year, sex and index drug for each province. BC data were also stratified as provincial PharmaCare accepted or not.

Results: We identified 578,254 ($n=122,653$ BC) eligible new users. Overall patterns of prescribing were similar between provinces: 1) most received an oral bisphosphonate (94% BC and 99% in Ontario); 2) etidronate prescribing declined after 2001/02, reaching a low of 41% in BC and 10% in Ontario in 2008/09; and 3) the proportion of males treated increased over time, from 8% of new users in 1995/96, to 25% of new users in 2008/09. We note differences in access to second-generation bisphosphonates (alendronate or risendronate) in BC when stratified by whether or not drugs were covered by BC PharmaCare; $<2\%$ (PharmaCare) versus 79% (non-PharmaCare) of medications dispensed were for second-generation bisphosphonates.

Conclusions: Oral bisphosphonates are the primary drugs used to treat osteoporosis in Canada. Prescribing practices changed over time as newer medications came to market, yet access to second-generation bisphosphonates through BC PharmaCare was limited. Implications of differential access to oral bisphosphonates warrants further study.

Osteoporosis Telephonic Intervention to Improve Medication Adherence (OPTIMA): A Large Pragmatic Randomized Controlled Trial. Daniel Solomon^{*1}, Maura Iversen², Jerry Avorn², Timothy Gleeson², Alan Brookhart³, Amanda Patrick², Laura Rekedal², William Shrank², Joyce Liu², Elena Losina², Jeffrey Katz². ¹Harvard Medical School, USA, ²Brigham & Women's Hospital, USA, ³University of North Carolina, USA

Purpose: Multiple studies have demonstrated poor adherence with medications prescribed for chronic illnesses, including osteoporosis. Few interventions have been proven to improve adherence. We conducted a randomized controlled trial of telephone counseling based on motivational interviewing to improve medication adherence for osteoporosis.

Methods: We collaborated with a pharmacy benefit program for Medicare beneficiaries in one US state and invited persons newly prescribed a medication for osteoporosis to participate. Consenting persons were randomized to either a one-year program of telephone-based counseling ($n = 1,046$) using a motivational interviewing framework or a control group ($n = 1,041$) that received intermittent mailed educational materials. Medication adherence was the primary outcome and was

measured as the median (interquartile range, IQR) medication possession ratio (MPR), calculated as the ratio of days with filled prescriptions to total days of follow-up. The median MPR was compared across treatment arms.

Results: The groups were well balanced at baseline, with a mean age of 78 years; 94% were female. In an intention-to-treat analysis, median adherence was 48.8% (IQR 6.9, 87.9) in the intervention arm and 40.6% (1.5, 86.0) in the control arm ($P = 0.074$ by Kruskal-Wallis test) (see Table). The completer analysis showed similar effects ($P = 0.019$). Subjects 65-74 years old had a larger intervention effect than those 75 or over (P for interaction = 0.045). There were no differences in self-reported fractures.

Conclusions: A telephonic motivational interviewing intervention provided improvement in osteoporosis medication adherence that did not reach statistical significance. Such counseling-based programs may be a useful tool to improve adherence to medications for chronic conditions.

Post Fracture Osteoporosis Treatment Program, is it Efficient? Elena Segal^{*1}, Marina Nodelman¹, Doron Norman¹, Michael Soudry¹, Daniela Militianu¹, Sophia Ish-Shalom². ¹Rambam Health Care Campus, Israel, ²Rambam Health Care Campus, Technion Faculty of Medicine, Israel

Low trauma events are common in the elderly. Patients with fragility fractures have a fivefold risk for further osteoporotic fractures. Orthopedic care usually does not include initiation of fracture prevention treatment.

Patients/methods: Fractures Prevention Program (FPP) was initiated in Rambam Health Care Campus in March 2009. All patients (pts) with fragility fractures were referred from the Department of Orthopedic Surgery to the Bone and Mineral Metabolism Unit for fracture prevention treatment (consult during hospitalization and outpatient clinic after discharge).

Results: 900 pts, aged 50-107 (75.1811.7), 247 (27.4%) men, 653 (72.6%) women. There were 593 (66%) hip fractures, 60 (7%) vertebral fractures, 247 (27%) other fractures (humerus, wrist, tibia, fibula); 155 (17%) pts had previous fragility fractures.

All hip radiographs were retrospectively assessed by a bone radiologist; 5 (0.8%) met the atypical fractures criteria. All were treated with alendronate for 2-9 years. They were not diagnosed during hospitalization.

Prior to hospitalization 156 pts (17.3%) received a fracture prevention treatment: 152 (23.2%) women [134 (88.2%) oral bisphosphonates; 10 (6.5%) – raloxifene, 5 (3.3%) – teriparatide]; 4 (1.6%) men – alendronate. 250Hd serum level prior to hospitalization was available for 239 (26.5%) pts. Mean 250Hd was 26.514.7 (4-118) ng/ml; in 85 (35.6%) pts 250Hd ≤ 20 ng/ml, 25 (10.5%) 250Hd ≤ 10 ng/ml.

154 (17.1%) pts [23 (9.3%) men, 131 (20.1%) women] adhered to the FPP. 98 (63.6%) pts had

femoral (neck and midshaft) fractures, 56 (36.4%) – other fractures. 746 (82.9%) pts stayed out of the FPP: 52 (10.6%) women continued, 1 (0.3%) man started the treatment in the community. 693 (92.8%) pts refused to join the FPP and remain untreated, 18 (2.4%) died. 207 (23%) pts are currently treated, including 53 in the community: 80 (38.6%) receive alendronate, 46 (22.2%) – risendronate, 5 (2.4%) – raloxifene, 32 (15.4%) – zoledronate, 28 (13.5%) – teriparatide, 16 (7.7%) – calcium and vitamin D prior to starting bisphosphonate. Four patients with atypical fractures were switched to teriparatide, 1 – refused.

Conclusion: Majority of elderly pts remain untreated after fragility fractures. Hospital based FPP increased by 8% the rate of post fracture treatment. Diagnosis of atypical fractures deserves special clinical and radiologic attention during hospitalization.

SU0439

Psychometric Properties of the Osteoporosis-Specific Morisky Medication Adherence Scale (OS-MMAS) in Postmenopausal Women With Osteoporosis (OP) Treated with Bisphosphonates (BP). Kristi Reynolds^{*1}, Hema Viswanathan², Cynthia O'Malley², Paul Muntner³, Teresa Harrison¹, T. Craig Cheatham⁴, Jin-Wen Hsu¹, Deborah Gold⁵, Stuart Silverman⁶, Andreas Grauer⁷, Donald Morisky⁸. ¹Kaiser Permanente Southern California, USA, ²Amgen Inc., USA, ³University of Alabama at Birmingham, USA, ⁴Kaiser Permanente Pharmacy Analytic Services, USA, ⁵Duke University Medical Center, USA, ⁶Cedars-Sinai/UCLA, USA, ⁷Amgen Health Center, USA, ⁸University of California, Los Angeles, USA

Purpose: Low adherence to BPs in women with OP is common and can lead to poor outcomes. The objective of this study was to examine the psychometric properties of the recently developed OS-MMAS in postmenopausal women newly prescribed BPs.

Methods: This was a cross-sectional survey of women aged ≥ 55 yrs with OP who were newly initiated on daily or weekly BPs between 5/15/10 and 8/15/10 and enrolled in Kaiser Permanente Southern California (KPSC). KPSC is a large integrated healthcare delivery system with over 3.2 million members. Eligible women were randomly selected and mailed a self-administered survey that included: the 8-item OS-MMAS, Self-Efficacy for Appropriate Medication Use Scale (SEAMS), Beliefs about Medicines Questionnaire (BMQ), Treatment Satisfaction Questionnaire for Medicines (TSQM), Gastrointestinal Symptom Rating Scale (GSRs), 12-item Short Form Health Survey (SF12), and clinical and sociodemographic questions. OS-MMAS scores range from 0 to 8; higher scores indicate better medication adherence. Test-retest reliability was assessed using a subset of respondents surveyed within 7 to 21 days of the initial survey. Women reporting discontinuation of BP therapy were excluded. Reliability was assessed using Cronbach's α and intraclass correlation coefficients (ICCs). Convergent validity was assessed using correlations between OS-MMAS and related measures with Bonferroni adjustment, and confirmatory factor analysis (CFA).

Results: Of 195 respondents, 150 were included. The mean (SD) age was 71 (9) years; 61% were white, and 30% had a prior fracture. Overall, 31%, 33% and 36% had low (<6), medium (6 to <8) and high (8) OS-MMAS scores, respectively. The OS-MMAS had high internal consistency (Cronbach's $\alpha = 0.79$) and demonstrated good test-retest reliability with a weighted Kappa statistic of 0.61 (95% CI, 0.48-0.75) and an ICC of 0.77 (95% CI, 0.58-0.84). The directionality of correlations was consistent with our expectations. Convergent validity was supported by significant correlations with the SEAMS, BMQ necessity and TSQM scores. No significant correlations were found between OS-MMAS and BMQ concerns, GSRs, and SF-12. In CFA, validity was supported by measurement of a single underlying factor of medication adherence.

Conclusion: The OS-MMAS showed strong psychometric properties among women newly prescribed BPs. Further evaluation of validity based on pharmacy data is ongoing to evaluate the utility of the tool in the clinic setting.

Measures	Correlation With the 8-Item OS-MMAS	P-value

Reduced BMD and Osteoporosis in Men Treated for Hypogonadism. Mario Rui Mascarenhas¹, Ana Paula Barbosa², Antonio Gouveia de Oliveira³, Ana Gonçaves⁴, Vera Simoes⁵, David Santos Pinto⁶, M Bicho⁷, Isabel do Carmo⁸. ¹Faculdade de Medicina Lisboa, Portugal, ²Endocrinology University Clinic & Metabolism & Endocrinology Center, Genetics Laboratory (FMUL), CEDML - Endocrinology, Diabetes & Metabolism Clinic, Lda., Endocrinology, Diabetes & Metabolism Department, Santa Maria Hospital, CHLN-EPE, Portugal, ³Biostatistics Department, FCMUNL, Portugal, ⁴Endocrinology, Diabetes & Metabolism Department, Santa Maria Hospital, CHLN-EPE, Romania, ⁵Metabolism & Endocrinology Center, Genetics Laboratory (FMUL), CEDML - Endocrinology, Diabetes & Metabolism Clinic, Lda., Portugal, ⁶CEDML - Endocrinology, Diabetes & Metabolism Clinic, Lda., Portugal, ⁷Metabolism & Endocrinology Center, Genetics Laboratory (FMUL), Portugal, ⁸Endocrinology, Diabetes & Metabolism Department, Santa Maria Hospital, CHLN-EPE, Portugal

OBJECTIVE

To study the impact of the therapy of male hypogonadism in patients with low bone mineral density (BMD) and osteoporosis.

MATERIALS AND METHODS

A group of 26 non-treated hypogonadal men (17 with hypogonadotropic hypogonadism, 7 with hypergonadotropic hypogonadism and 2 with eugonadotropic hypogonadism) were evaluated with DXA scans before and during therapy for the disease: these exams were repeated after starting treatment, between 1-8 years: mean 3.1 (2.3) years (treated hypogonadal men group).

The BMD at the lumbar spine and at the hip (femoral neck and total) as well as the total body fat and lean masses were accessed by using the QDR Discovery-W densitometer (Hologic Inc.). The weight, height and BMI were also determined. Blood was collected for measurement of the LH, FSH, PRL, estradiol and total testosterone levels in the peripheral blood.

Descriptive, Anova and regression analysis statistical tests were used; statistical significance was considered for $P < 0.05$.

RESULTS

The mean BMD, T-scores and Z-scores were lower at the lumbar spine in the no treated male hypogonadism group as compared with the treated hypogonadism group, but the mean BMD, T-scores and Z-scores at the total hip were similar between the groups. The bone mass qualification is in Table 1.

TABLE1. Prevalence of normal BMD, reduced BMD and osteoporosis in the no treated and treated male hypogonadism groups.

A small increment was detected in the mean total body lean mass during hypogonadism treatment ($P > 0.05$) as well as a decrease in the mean total body fat mass ($P > 0.05$).

CONCLUSIONS

The data of this study may suggest that a late therapy of male hypogonadism may influence the weak response at the cortical bone. However, the increase in the cortical BMD to hypogonadism treatment may be higher in men with initial low BMD at the lumbar spine and at the femoral neck.

The increment of the BMD was greater in men with the lowest total testosterone levels.

Finally, it remains unclear whether the low BMD of hypogonadal men can be restored to normal, after a long-term androgen or the etiological therapy of the male hypogonadism.

However, other associated measures, to increase bone mass, may have clinical indication in order to reduce the early osteoporosis development risk.

TABLE1. Prevalence of normal BMD, reduced BMD and osteoporosis in the no treated and treated male hypogonadism groups.

Groups:	NO TREATED HYPOGONADISM n = 26 (100%)	TREATED HYPOGONADISM n = 26 (100%)
BMD		
Normal	6 (23.1%)	8 (30.8%)
Reduced	12 (46.1%)	11 (42.3%)
Osteoporosis	8 (30.8%)	7 (26.9%)

The Efficacy of Bazedoxifene in Postmenopausal Women is Independent from Kidney Function. Rene Rizzoli¹, Silvano Adami², Amy Levine³, Santosh Sutradhar⁴, Arkadi Chines⁴. ¹University Hospital, Switzerland, ²University of Verona, Italy, ³Pfizer, USA, ⁴Pfizer Inc, USA

Purpose: Two global, randomized, double-blind, placebo- (PBO) and active-controlled phase 3 studies (2-year prevention [N = 1583] and 3-year treatment [N = 7492]) have shown that bazedoxifene (BZA) is safe and effective for prevention and treatment of osteoporosis in postmenopausal women. We investigated whether kidney function, which generally worsens with age, influences the effects of BZA. The efficacy

of BZA was evaluated in relation to baseline glomerular filtration rate (GFR) in women enrolled in these studies.

Methods: Data for the BZA 20- and 40-mg and PBO groups from both studies were integrated, and bone turnover markers (osteocalcin and C-telopeptide [CTx]) and bone mineral density (BMD) were assessed. In the treatment study, the incidence of fractures was assessed for all fractures (morphometric vertebral and clinical) for the 2 BZA doses combined because of the small number of events. GFR was estimated by the Modification of Diet in Renal Disease Study equation. Women were categorized by GFR in mL/min per 1.73 m²: normal (GFR ≥ 90 ; n = 1477), mild impairment (60 \leq GFR < 90 ; n = 4617), or moderate/severe impairment (GFR < 60 ; n = 549).

Results: Across all renal subgroups, BZA 20 and 40 mg reduced osteocalcin (median percent change from baseline; -34.7% to -41.5%) and CTx (-42.8% to -49.6%) at Month 12 versus PBO (-18.7% to -20.4%; $P < 0.0001$ and -23.4% to -24.9%; $P < 0.0001$, respectively). Improvements in lumbar spine BMD (mean percent change from baseline) at Month 24 were greater for BZA 20 mg (1.4%-1.8%) and BZA 40 mg (1.6%-2.1%) versus PBO (0%-0.1%; $P < 0.0001$) for the normal and mild renal impairment subgroups; a similar trend was observed in the moderate/severe renal impairment subgroup but the increases with BZA versus PBO were not statistically significant. Changes in total hip BMD from baseline to Month 24 were greater for BZA 20 mg (0.8%-1.1%) and BZA 40 mg (0.9%-1.1%) versus PBO (-0.3%; $P < 0.0001$) in the normal and mild renal impairment subgroups, as well as for BZA 40 mg (1.1%) versus PBO (-0.3%; $P < 0.001$) in the moderate/severe renal impairment subgroup. The effect of BZA treatment on all fractures did not appear to be affected by kidney function, as evidenced by overall consistent trends (hazard ratios < 1) across GFR categories and no treatment by GFR interaction ($P = 0.766$).

Conclusion: Kidney function did not appear to affect the efficacy of BZA on bone turnover, BMD, and fractures in postmenopausal women.

Adherence to Osteoporosis Medications in Men: A Systematic Review of the Literature. Robyn VonMaltzahn¹, Heather Wiewer¹, Seema Patel¹, Nicole Yurgin². ¹HERON Evidence Development Ltd, United Kingdom, ²Amgen Inc, USA

Male osteoporosis is recognized as a growing but under-managed problem. Adherence to therapy is important in understanding real-life effectiveness and how this may be improved. We conducted a systematic review to identify information on adherence to osteoporotic medication in men, including typical adherence rates, and the factors and consequences associated with adherence. MEDLINE and Embase were searched using keywords and MeSH terms from 1998-2010 and recent conference proceedings (2008-2010) were also screened. Studies were included if they were in English and reported osteoporosis related adherence data from actual clinical practice for male populations.

Fourteen studies were identified which reported male-specific information. Of these, eight studies reported adherence rates specific to men, indicating a paucity of research in this population. Disparate methods of measurement and reporting were used, hindering comparison between results. Medication Possession Ratios (MPRs) were calculated from insurance database records in four studies. One US study reported MPRs at one year ranging between 70% [for monthly bisphosphonates (BPs)] and 41% (for daily BPs). Another US study reported more than 40% of men were non-adherent (MPR $< 80\%$) to alendronate (ALN) at one year. Persistence with newly prescribed medication was reported to be as low as 54% for weekly oral ALN after one year of treatment in a study from Germany. In a small study of men in the UK who were prescribed teriparatide injections, persistence was reported to be as high as 77% after one year. Where reported, results were conflicting with regard to gender differences in adherence. No significant association between adherence and risk of fracture was shown in one 2-year study in men treated with ALN but the number of fractures may have been too small to reliably demonstrate lack of association. In the same study, adherent men (MPR $\geq 80\%$) showed a significantly greater increase in lumbar spine bone mineral density compared with those who were non-adherent.

Where available for males, adherence and persistence estimates varied widely, perhaps due to differences in methodology, geography, and/or treatments. Nevertheless, the available studies indicate that a substantial number of male osteoporotic patients do not optimally use currently prescribed osteoporotic medications. Further research is needed to characterize adherence in men and to identify the impact of adherence on fracture risk in men.

SU0443

Medication Adherence in Patients on Osteoporosis Therapy: Physician Perceptions Versus Patient Behavior. Qian Cai¹, Jeffrey Curtis², Sally Wade³, Hema Viswanathan⁴, Jeff White⁵, Akhila Balasubramanian⁴, Joel Kallich⁴, John Adams⁶, Brad Stolshek⁴. ¹HealthCore, Inc, USA, ²University of Alabama at Birmingham, USA, ³Wade Otucomes Research & Consulting, USA, ⁴Amgen Inc., USA, ⁵Wellpoint, USA, ⁶RAND Corporation, USA

Purpose

Adherence to osteoporosis medication regimens is a key determinant of clinical benefit (fracture risk reduction). This study compares physicians' estimates of medication possession ratios (MPR) for their patients with MPR calculated from pharmacy claims for those same patients.

Methods

Administrative claims data from a large, U.S. commercial health plan were used to identify females, \geq age 45, with \geq 1 osteoporosis pharmacy claim between 1/1/2005 and 8/31/2008, and continuous coverage for \geq 12 months before and after first (index) medication claim in the study period. Patients with pre-index Paget's disease or malignant neoplasm, and those in a skilled nursing facility or on combination therapy at index were excluded. Prescribing physicians treating \geq 5 study patients were invited to complete a 26-item IRB-approved online or paper survey covering physician characteristics, estimated adherence levels for their patient panel, and patient management approaches. Claims-based MPR was calculated for the 12-month post-index period for each patient. Physicians were classified as optimistic (overestimated % of their patients achieving MPR \geq 0.8 by \geq 10%) or non-optimistic based on absolute differences. Logistic regression was used to assess physician characteristics associated with optimism.

Results

The analysis included survey data from 376 of the 2184 invited physicians (62% female; 58% age 45-60 years; 55% with $>$ 20 years in practice; 35% in academic setting) and claims data for 2748 patients [mean age (SD) of 62.0 (10.6) years]. On average, physicians estimated 67% of patients to have MPR \geq 0.8, yet only 40% of their eligible patients had claims-based MPR \geq 0.8. Optimistic physicians (n=277, 74%) estimated 70% of patients to have MPR \geq 0.8; yet, only 32% of their patients had claims-based MPR \geq 0.8. On average, non-optimistic physicians (n=99, 26%) underestimated the percent of patients with MPR \geq 0.8 by 8 percentage points (54% vs. 62%). Physicians in academic settings were more likely to be optimistic than community-based physicians (OR 1.69, 95% CI: 1.01, 2.85).

Conclusion

Physicians treating postmenopausal osteoporosis patients in a commercial health plan tended to overestimate the proportion of patients in their practices who had MPR \geq 0.8 for osteoporosis medications. Overestimating adherence may impede physicians' ability to support patients' efforts to adhere to medication regimens.

Womens Attitudes toward Screening for Osteoporosis (Risk-stratified Osteoporosis Strategy Evaluation). Mette Rothmann^{*1}, Lotte Huniche², Jette Ammentorp³, Kim Brixen⁴, Anne Pernille Hermann⁵. ¹Denmark, ²Institute of Public Health, University of Southern Denmark, Denmark, ³Institute of Regional Health Services Research, University of Southern Denmark, Denmark, ⁴Institute for Clinical Research, Denmark, ⁵Department of Endocrinology, Odense University Hospital, Institute of Regional Health Services Research, University of Southern Denmark, Denmark

Purpose: A large-scale trial on risk-stratified screening for osteoporosis in the Region of Southern Denmark has been initiated to test if risk-stratified screening in women aged 65-80 years is effective with respect to preventing fractures. Before a screening program is to be implemented WHO recommends that ethics and psychological issues and participant's perspective are investigated. The aim of this study was to investigate womens perspectives on the actual screening program.

Methods: In order to obtain in depth and nuanced insight into womens attitudes toward screening for osteoporosis, qualitative interviews were carried out. Data were generated using focus group interviews (4 groups, n=15) and in-depth interviews (n=3). To ensure group dynamics the focus groups were divided with respect to age (65-72 and 73-80). The focus group discussions were facilitated by photos, statements and participants' comments. Both focus groups and in-depth interviews were semi-structured.

Result: Generally, the women were positive about screening for osteoporosis. Attitudes toward screening were influenced by age, experiences with illness, and knowledge on osteoporosis. Screening was perceived as an opportunity to take care of personal health. In general, women did not find screening for osteoporosis ethically

and psychologically problematic due to disease severity. In contrast, reasons for non-attendance were lack of relevance due to a healthy life situation, confidence in bodily experiences of illness and a resistance to be medicalised. A screening program seems to entail a number of issues important in women's everyday lives such as; to be sick or healthy, to be at risk, and knowledge on osteoporosis.

Conclusions: Knowledge on women's attitudes and perspectives on the actual screening program is important to the evaluation of the program according to WHO recommendations. Generally the women display acceptance of the screening program. No major ethical issues or psychological consequences were detected. However, awareness of fracture risk was described as affecting everyday life such as physical activity. A minority of the women question the relevance and usefulness of screening affecting the willingness to participate in the program. Significantly, non-attendance was described as a deliberate decision based on personal considerations. This contrasts widespread assumptions of non-attendance as caused by lack of knowledge or disregard of general health recommendations.

Baseline Fracture Probabilities Using the WHO FRAX® Tool in a Phase 3 Study of a Novel Oral Recombinant Salmon Calcitonin. John Kanis¹, Helena Johansson¹, Christine Buben², James Gilligan², David Krause^{*2}. ¹WHO Collaborating Centre for Metabolic Bone Diseases, United Kingdom, ²Tarsa Therapeutics, USA

BACKGROUND: The WHO FRAX® tool is a population based model designed to evaluate fracture risk of individual patients (pts). It is based on individual pt models that integrate the risks associated with clinical risk factors as well as bone mineral density (BMD) at the femoral neck. ORACAL is a recently completed phase 3 trial of a novel oral recombinant salmon calcitonin. The objective of this study was to determine fracture probabilities at baseline of women recruited to this trial, using FRAX. **METHODS:** In this multinational, randomized, active and placebo controlled trial, 565 postmenopausal women with osteoporosis were randomized 4:3:2 to oral calcitonin tablets and placebo nasal spray, nasal calcitonin spray and placebo tablets, or placebo tablets and nasal spray. The intended treatment exposure was for 48 weeks. Replicate DXA scans were obtained at baseline, Week 24 and Week 48; images were read centrally by blinded readers. The study was undertaken at multiple sites in the US, UK, Bulgaria, Poland, Hungary and South Africa. Demographic and risk factor data were provided by the sponsor to a central database for purposes of risk calculation. The data were anonymised and blinded to treatment allocation. For each pt the 10 year probability of a major osteoporotic fracture (clinical spine, hip, forearm and humerus) was calculated with and without BMD for the country chosen. Version 3.1 of the FRAX models was used. **RESULTS:** The mean age/BMI was 66.5y/25.7 kg/m². The mean probability of a major fracture was 11.9% and, for a hip fracture was 3.2% when BMD was used in the FRAX model. The overall effect of excluding information on BMD was to increase hip fracture risk slightly; however, the addition of BMD to the FRAX model increased the estimated hip fracture probability up to the age of 70 years. At the age 70-89 years, the hip fracture probability calculated with BMD was lower than that calculated without BMD. Most pts were Caucasian. Very high risk was demonstrated for US Caucasian pts (N=69). High risk was represented by the Bulgaria, Poland, South Africa (Caucasian), UK, US (Black) and US (Asian) pts (N=434). Moderate risk was represented by pts in Hungary (N=54). Fracture probabilities increased progressively with age. **CONCLUSIONS:** Although not an entrance criterion, the WHO FRAX tool confirmed that ORACAL enrolled a multinational population of postmenopausal women at high risk of fracture.

SU0446

Bone Loss Caused by Anticonvulsants: BMD Improvement Using Strontium Ranelate. Ilenia Pepe^{*1}, Giuseppin Campisi¹, F Scozzari¹, Nicola Napoli², Giovambattista Rini³, Gaetana Di Fede¹. ¹University of Palermo, Italy, ²University Campus Biomedico, Italy, ³Department of Clinical Medicine, Italy

Certain anticonvulsants may cause bone loss, mostly phenytoin, phenobarbital, carbamazepine, and primidone. It has been reported that bone loss nearly doubled in those receiving anti-epileptic drugs, compared to the general population.

These antiepileptic drug are all potent inducers of CYP-450 isoenzymes, leading to rapid metabolism of vitamin D, and possibly, estrogen. anti-epileptic drugs are also associated with decreased fractional calcium absorption, secondary hyperparathyroidism, and increased bone turnover.

Clinical cases: from 2008 to 2009 we have observed 4 patients attending to the Bone Health Program at University of Palermo (3 females and 1 male, age 54.24.3) treated from 2 to 5 years with anticonvulsants. Their serum biochemistry showed a typical osteomalacia pattern: 25(OH)vitamin D 10.41.2 ng/ml, Ca 8.20.4 mg/dl, PTH 1552.1 ng/ml. BMD measured by DEXA was in the osteoporosis range in all four patients (<-2.5 SD at lumbar spine, femoral neck and total femur). Patients were treated for

6 months with calcitriol (1 mcg/day), calcium (1000 mg/day) and strontium ranelate 2g/day.

At a six months clinical control, vitamin D, Ca and PTH were in the normal range and we observed also a slight BMD increase at lumbar spine (+2%), femoral neck (+1.5%) and total femur (+2%).

Conclusions, the National Institute for Health and Clinical Excellence in UK, recommend a strict monitoring of vitamin D, PTH and calcium serum levels. However, Vitamin D and calcium supplementation should be taken in consideration in order to avoid osteomalacia. In this preliminary study we showed for the first time that strontium ranelate treatment may be helpful together with calcitriol and calcium supplementation to revert anticonvulsants related bone loss. Patients healed quickly and without side effects.

Delayed Healing of a Sub-Prosthetic Fracture of the Femoral Shaft after Prolonged Alendronate Therapy: Treatment with Teriparatide. Emanuela Raimondo¹, Marco Massarotti², Carlo Eugenio Zaolino³, Andrea Fossali³, Luca Pietrogrande^{*4}. ¹A.O. San Paolo, Italy, ²IRCCS Humanitas Clinical Institute, Italy, ³Università Statale degli Studi di Milano, Italy, ⁴Università degli Studi di Milano, Italy

Background. Many recent reports describe cases of atypical femoral fractures of the proximal femur without efficient trauma associated with long-term therapy with alendronate. It is not yet clear the dimension of the problem and the pathophysiological bases, nor the way of treatment of these fractures.

Methods. We report a case of a 68-year-old woman that after 12 years of therapy with alendronate, for a low energy hip fracture treated with total hip arthroplasty (THA), incurred in a transverse fracture of the femoral diaphysis just below the tip of the stem after a very low energy trauma. The fracture was correctly treated with plating, but 6 months after surgical treatment there was the rupture of the plate for non-union. The fracture was fixed again with an LCP plate and a strut bone-graft with cerclages.

After 18 months there still was pain in the fracture site during weight-bearing and the radiographic appearance showed an atrophic non-union of the fracture. The bone turnover markers shown a very low remodelling rate. A treatment with teriparatide (1-34 PTH) was started and after 18 months the fracture was healed at the clinical, radiographic and bone scan evaluation.

Discussion. The minimal energy that caused the fracture and its radiographic appearance are similar to that present in described low bone turnover atypical subtrochanteric femoral fractures. The difficult healing, despite a correct surgical treatment, suggest a role of the low bone turnover.

Conclusions.

Fractures in bones with a severe suppression of the turnover are an emerging challenge to the orthopaedic surgeons, only the association of an anabolic therapy with a correct surgical treatment of these fractures seems to guarantee a success, as already reported. The routinely use of PTH in these kind of fracture is recommended.

SU0448

Effects of Folic Acid and B Vitamin Supplementation on Fracture Risk in Women: Results of a Large Randomized Trial. Douglas Bauer^{*1}, JoAnn Manson², Li-Yung Lui³, Deborah Kado⁴, William G. Christen⁵, Ara Sarkissian⁵, Margarette Haubourg⁵, Steven Cummings⁶, Katie Stone⁷. ¹University of California, San Francisco, USA, ²Harvard Medical School, USA, ³California Pacific Medical Center Research Institute, USA, ⁴University of California, Los Angeles, USA, ⁵Harvard University, USA, ⁶San Francisco Coordinating Center, USA, ⁷California Pacific Medical Center-Research Institute, USA

Elevated homocysteine and low vitamin B12 levels are associated with a greater risk of fracture in some but not all observational studies. The skeletal benefits of vitamin supplementation to lower homocysteine and increase B12 levels are unknown. To address this question we collected fracture outcomes in a large cardiovascular endpoint trial of vitamin supplementation.

We retrospectively reviewed and adjudicated fracture outcomes among 5442 women over age 42 with existing cardiovascular disease or 3 or more risk factors enrolled in the Women's Antioxidant and Folic Acid Cardiovascular Study (WAFACS). Participants were randomized to either the combination of daily folic acid (2.5 mg), vitamin B6 (50 mg) and vitamin B12 (1 mg) or matching placebo, and followed for an average of 7.0 yrs. After completion of study follow-up but before unblinding, participants were queried about the occurrence of clinical fractures during the trial. Radiographic reports or other clinical documentation for each reported fracture were reviewed centrally without knowledge of treatment assignment; women with inadequate fracture documentation were excluded. Following an intention-to-treat analysis, we assessed the effect of vitamin therapy vs. placebo on fracture risk

using Cox models. Subgroup analyses defined by age, B vitamin supplement use, and hormone therapy use were also done.

The vitamin and placebo groups were well matched at baseline with regards to age (62.6 vs. 62.5), postmenopausal status (91.3% vs. 91.5), previous fracture (37.1% vs. 37.5) and estrogen replacement (51.8% vs. 51.8%). 80% of women reported >66% compliance during the trial. Of the 1229 women reporting fractures, adequate documentation was available for 597, and 349 women had confirmed non-spine fractures (including 22 hip and 67 wrist fractures). The risk of any non-spine fracture was similar among those randomized to vitamins or placebo (RH=1.08, 95% CI: 0.88, 1.34), as were rates of hip (RH=0.99, CI: 0.43, 2.29) and wrist fracture (RH=1.30, CI: 0.80, 2.11). Non-spine fracture results were similar among those who were 100% compliant (RH=1.05, CI: 0.82, 1.35) and among baseline subgroups defined above (interaction p values>0.05).

We conclude that in this large double-blinded randomized trial of women with existing cardiovascular disease or multiple risk factors, the combination of daily folic acid, B6 and B12 treatment had no significant effect on non-spine fracture risk.

Effects of Vitamin K or Bisphosphonate on Serum Undercarboxylated Osteocalcin In Osteoporosis Patients. Hiroshi Yonezu^{*}. Department of orthopaedic surgery, Mitoyo General Hospital, Japan

(INTRODUCTION) Undercarboxylated osteocalcin (ucOC) is a marker of vitamin K deficiency in bone formation, and an increased ucOC level is a predictor of hip fracture. On the other hand, ucOC is reportedly affected by bone turnover, and bisphosphonate or steroid administration may reduce the serum ucOC level. In this study we evaluated the effect of vitamin K or bisphosphonate administration on serum ucOC levels.

(PATIENTS AND METHODS) We measured serum ucOC levels in 321 patients with osteoporosis (average age 76.4 years). Fifty-seven patients had been taking vitamin D, 31 bisphosphonate, 19 bisphosphonate + vitamin D, and 15 vitamin D + vitamin K. These treatments had been taken for at least 6 months. One hundred ninety-nine patients had received no therapy for osteoporosis. Patients whose serum ucOC level was above the normal range (upper limit 4.5 ng/ml) were prescribed additional vitamin K or bisphosphonate for 6 months.

(RESULTS) The average serum ucOC level was 6.966.31 ng/ml. The serum ucOC level exceeded the upper limit of normal in 57.0% of our patients, but was low those who had taken vitamin K or bisphosphonate. There was a significant correlation between the ucOC level and NTX. There was no significant difference in lumbar BMD between patients with normal and abnormal ucOC levels. The serum ucOC level normalized in 64.6% of patients after receiving additional vitamin K medication, but was high in those with high bone turnover. The serum ucOC level normalized in 31.9% of patients after receiving additional bisphosphonate medication. Vitamin K reduced the serum ucOC level, but did not alter bone turnover or lumbar BMD. On the other hand, bisphosphonate reduced the serum ucOC level, via decreased bone turnover and increased lumbar BMD.

(DISCUSSION) It has been reported that vitamin K treatment reduces ucOC but does not alter bone turn over, density or geometry in healthy postmenopausal women. On the other hand, the effect of bisphosphonate on the serum ucOC level is controversial. It was recently reported that bisphosphonate may interfere with vitamin K activation in bone cells. However, whether bisphosphonate treatment decreases the carboxylation of osteocalcin is uncertain. Further study is needed to resolve this issue.

(CONCLUSION) Our results support the suggestion that vitamin K decreases the ucOC level when taken as a supplement to treat vitamin K deficiency, and that bisphosphonate decreases the serum ucOC level by decreasing bone turnover.

Long-term Effects of Angiotensin Converting Enzyme Inhibitor (ACEI) on Femur Neck BMD of Men in the Health Aging and Body Composition Study. Nahid Rianon^{*1}, Claudia Pedroza², Melissa Garcia³, Ann Schwartz⁴, Frances Tykavsky⁵, Jane Cauley⁶, Brendan Lee⁷, Tamara Harris⁸. ¹UTHealth The University of Texas Medical School at Houston, USA, ²UT Houston Medical School, USA, ³NIA/NIH, USA, ⁴University of California, San Francisco, USA, ⁵University of Tennessee, Memphis, USA, ⁶University of Pittsburgh Graduate School of Public Health, USA, ⁷Baylor College of Medicine & Howard Hughes Medical Institute, USA, ⁸Intramural Research Program, National Institute on Aging, USA

Background: A large proportion of older adults in the U.S. are under antihypertensive treatment. Animal studies indicate that antihypertensive medications affecting the renin-angiotensin system (RAS) may have positive effects on bone. Preliminary data from the Health Aging and Body Composition (Health ABC) study showed a positive cross-sectional association in men between femur neck bone mineral density (FNeckBMD) and RAS related medications, e.g., angiotensin converting enzyme inhibitors (ACEI). In this study we investigate if long-term use of ACEI can reduce risk for age-related bone loss in older men.

Methods: We used regression analysis to examine associations between year 10 FNckBMD and long-term (4 years) ACEI use in 913 men of the Health ABC study. Long-term ACEI use was defined as ACEI medications used at both years 5 and 10 examinations. Models were adjusted for year 5 report of age, weight, height, race, exercise and current smoking, HTN and diabetes mellitus (defined as self-reported and/or medication use), and use of steroid, calcium and vitamin D supplements. In addition, we controlled for thiazide and bone promoting medication (BoneMeds) use for 4 years. We also investigated associations between annual percent change in FNckBMD from year 5 to year 10 and long-term ACEI use in the same men using a similar regression model.

Results: Mean (standard deviation) age for men at year 10 was 833 (range 78-89) years. About 23% of men were using ACEI at both Year 5 and Year 10. Mean year-10 FNckBMD was 0.780.15 gm/cm² for ACEI users and was 0.750.14 for non ACEI users. Average annual bone loss among ACEI users and non-users were 3.035% and 2.736%, in order. The year-10 FNckBMD among men with long-term ACEI use was 0.039 gm/cm² higher (95% confidence interval: 0.004 to 0.074, $p < 0.05$) than those not using ACEI. However, there was no significant association between annual percent change of FNckBMD and ACEI use in these men. BoneMeds use was a significant predictor of year-10 FNckBMD in both models ($p < 0.05$).

Conclusions: Long-term (4 years) ACEI use was associated with FNckBMD in older men in the Health ABC study at Year 10 but not with change between Year 5 and Year 10. Very small percent change in FNckBMD or a smaller effect of ACEI than BoneMeds and a small sample size may have impacted our results.

Disclosures: Nahid Rianon, None.

Prevention of Hip Fractures with a Multifactorial Educational Program in Elderly Finnish Women: A Population-Based, Long-Term Controlled Clinical Trial. Tuula Pekkarinen^{*1}, Eliisa Loyttyniemi², Matti Valimäki³. ¹Peijas Hospital, Finland, ²Turku University, Finland, ³Helsinki University Central Hospital, Finland

Non-pharmacological approaches to reduce osteoporotic fracture risk are of great importance both economically and individually.

We assessed effectiveness of a multifactorial educational program in prevention of osteoporotic hip fractures among community-dwelling elderly women. Inclusion criteria were female gender, age 60-70 years and living in Uusimaa region in southern Finland. A random sample of women with these criteria was drawn from the population register.

A total of 2178 women (52% of the cohort) were recruited between 1996 and 2000 and randomized in intervention group (IG, n=1004) and control group (CG, n=1174). The intervention started with a one-week period at a rehabilitation center followed by two one-day sessions during the ten-year follow-up and included counseling on physical activity, balance training, nutrition, hip protectors, home hazards and medications and illnesses related with falls. The CG received usual information through media and health care system. At baseline and at years 2, 5, 8 and 10 both groups filled in a questionnaire regarding factors related to osteoporosis (e.g. current medication, life-style and fractures). All fractures during the study were confirmed from a radiologists report. A hip fracture was the primary end-point of the study.

At baseline mean age was 65.3 (SD 3.1) years in the IG and 65.3 (SD 3.1) in the CG ($p = 0.62$), and mean BMI 26.9 kg/m² (SD 4.5) and 26.1 (SD 4.1), $p < 0.0001$ respectively. At baseline subjects in the IG reported having sustained more often major fractures (23% vs 19%, $p = 0.03$) and falls within 3 months (13% vs 12%, $p = 0.04$), used more often vitamin D (55% vs 49%, $p = 0.003$) and calcium supplementation (47% vs 39%, $p < 0.0001$) than subjects in the CG. Dietary calcium intake was greater, mean 827mg (SD 469) in the IG vs 787mg (SD 464) in the CG, $p = 0.03$. At baseline estrogen use did not differ between the groups, but smoking was more common in the CG (current+ ex-smokers 30% vs 27% in IG, $p = 0.04$). Together 218 women died during the follow-up, 89 (9%) in the IG and 129 (11%) in the CG, $p = 0.12$. During the ten year follow-up, 6 women (0.6%) in the IG sustained hip fracture vs 18 women (1.5%) in the CG, $p = 0.04$.

As compared with usual care, this multifactorial educational program appears to be a viable option to prevent osteoporotic hip fractures among elderly women.

The Effect of Vitamins K on Bone Density and Fractures in Postmenopausal Women: Should There Be More Studies? Olga Gajic-Veljanoski^{*1}, George Tomlinson², Ahmed M. Bayoumi³, Zoe Agnidis¹, Angela Cheung¹. ¹University Health Network, Canada, ²University of Toronto & University Health Network, Toronto, Canada, ³University of Toronto & St. Michael's Hospital, Toronto, Canada

Studies in different populations have shown variable effects of vitamins K2 and K1 on bone mineral density (BMD) and fractures. We performed a systematic review to examine the clinical effectiveness of vitamins K on BMD and fractures in postmenopausal women and to determine whether future studies are worthwhile.

We systematically searched electronic databases (Medline, EMBASE, CINAHL, AMED, International Pharmaceutical Abstracts:1950- March 2011) and bibliographies, screened 4749 and reviewed 130 potentially eligible studies. We included

randomized-controlled trials (RCTs) assessing the effects of vitamins K2 or K1 on the lumbar spine (LS), total hip (TH) and femoral neck (FN) BMDs or on the risk of clinical, vertebral and non-vertebral fractures in postmenopausal women. Two reviewers used the Cochrane Risk of Bias tool to assess the methodological quality of 19 relevant RCTs. Bayesian random-effects meta-analyses were used to synthesize the evidence from trials comparing vitamin K2 (0.36mg/d-1 RCT, 45mg/d-11 RCTs, 5647 women), vitamin K1 (0.08-5mg/d, 6 RCTs, 1133 women) or both (1 and 45mg/d, 1 RCT, 381 women) against control treatments. The outcomes were mean difference (MD) (difference in the mean % change) for BMD, population odds ratio (OR) for fractures and posterior probabilities of benefit (MD > 0 or OR < 1) in favor of vitamins K in current and future studies.

Vitamin K2 increased LS BMD by 1.59% (95% Credible Interval (CrI): 0.31, 2.93). The probability of any increase in LS BMD was 99.1% in current and 84.3% in future studies. Vitamin K2 did not change TH and FN BMDs (the probabilities of benefit: 25.4% and 57.3% in current and 31.9% and 56.5% in future studies for TH and FN BMDs, respectively). Vitamin K1 had no effect on LS (MD: -0.17%, 95%CrI: -0.81, 0.49), TH or FN BMDs. The probabilities of benefit of vitamin K1 on LS, TH and FN BMDs were 28.7%, 71.2% and 63.3% in current and 35.6%, 69.3% and 57.1% in future studies, respectively. Vitamin K2 was not associated with significant reductions of clinical (current OR: 0.61, 95%CrI: 0.18, 1.41; future OR: 0.55, 95%CrI: 0.04, 5.35), vertebral and non-vertebral fractures, but the probabilities of benefit were 89.9-93.6% in current and 71.6- 78.1% in future studies.

In conclusion, we found moderate-to-high probabilities of beneficial effect in favor of vitamins K2 and K1 on BMD and fractures in postmenopausal women. Further trials are required to determine the effect of vitamins K on fractures.

Acute Bone Marker Responses to Whole-Body Vibration and Resistance Exercise in Young Women. Debra Bemben^{*}, Vanessa Sherk, Carmen Chrisman, Kaelin Young, Jessica Smith, Harshvardhan Singh, Michael Bemben. University of Oklahoma, USA

Whole-body vibration (WBV) is a type of mechanical stimulus that has been shown to acutely increase anabolic hormone responses; however, its acute effects on bone metabolic markers have not been determined. The purpose of this study was to examine bone marker responses to single bouts of high intensity resistance exercise (RE) and high intensity resistance exercise combined with WBV (WBV + RE) in women ages 20-30 years. Subjects (n=10) were not resistance trained, and they were taking oral contraceptives to control for menstrual phase variations in bone marker levels. We used a randomized, cross-over repeated measures design as subjects performed both conditions in random order 2 weeks apart. The RE session involved 6 isotonic exercises 3 sets of 10 repetitions at 80% of maximal strength. The WBV + RE session exposed subjects to 5 minutes of vibration (5 1 minute repetitions, 20 Hz, 1mm amplitude separated by 1 minute of rest) standing barefoot on a vibration platform (Vibraflex, Orthometrics, Inc.) with knees bent at 30 degrees. After a 3 minute rest, subjects then performed the RE protocol. All sessions were in the morning and fasting blood samples were obtained before, immediately post WBV, immediately post RE, and 30 minutes post RE. Bone-specific alkaline phosphatase (Bone ALP), tartrate-resistant acid phosphatase (TRAP5b), and C-terminal Telopeptides of Type I collagen (CTX) were measured using commercial ELISA kits. Bone ALP did not have significant condition or time effects, nor did it change from the pre vibration to post vibration time points. In contrast, bone resorption markers showed significant acute responses. TRAP5b significantly ($p < 0.05$) increased from the pre to post vibration time points, then decreased from immediately post RE to 30 minutes post RE for both conditions. Correcting the TRAP5b concentrations for plasma volume changes eliminated these significant responses. There was a significant ($p < 0.05$) condition \times time interaction effect for CTX, which decreased from pre to post vibration and from pre to 30 minutes post exercise only for the WBV + RE condition. Plasma volume corrections did not alter these responses. Also, the WBV + RE condition showed a greater relative decrease in CTX levels than RE (-12.6 4.7% and -1.13 3.5%, respectively). In conclusion, a low amplitude whole-body vibration exposure was associated with an acute decrease in CTX levels not elicited with resistance exercise alone in young women.

Disclosures: Debra Bemben, None.

Balloon-Sacroplasty on Patients with Osteoporotic Fatigue Fractures. Reimer Andresen^{*1}, Sebastian Radmer², Peter Kamusella³, Christian Wissgott³, Jan Banzer⁴, Hans-Christof Schober⁵. ¹Westkustenklinikum Heide, Germany, ²Zentrum für Bewegungsheilkunde, Berlin, Germany, ³Westkustenklinikum Heide Westkustenklinikum Heide, Germany, ⁴Charité Universitätsmedizin Berlin, Germany, ⁵Klinikum Sudstadt Rostock, Germany

Introduction:

In patients with calcipenic osteopathy, fatigue fractures of the Os sacrum are relatively common and are typically accompanied by strong, disabling pain. The aim of our study was to verify the feasibility and safety of Sacroplasty by using a balloon catheter as well as the outcome of pain after the intervention.

Material and Methods:

25 patients (20 women with an average age of 72.6 years, 5 men with an average age of 68.4 years) were diagnosed in a CT to have an Os sacrum fracture, in 12 women the fracture was unilateral, in the remaining patients bilateral. As a manifestation from an extant bone reconstruction process, all patients, through MRT strong T2 weighted images, were found to have distinctive oedema. In QCT results, all patients were found to have strong demineralisation of the vertebrae column with results from max 63mg/dl to min 13mg/dl, clinically, extreme pain is significant. On all patients, a CT controlled balloon sacroplasty was performed. During the intervention, the patient is in a ventral position, to enable the cement to be dispensed in a longitudinal angle to the fracture, and the balloon catheter is directed through a hollow needle in the Os sacrum either from the caudal to the cranial or from the craniodorsal to the caudoventral. The balloon catheter was accordingly deflated 1-3 times along the fracture in the appropriate direction, thus causing a cavity that was then filled with PMMA-cement under low pressure. A control-CT as well as a conventional X-ray was then carried out. The pain intensity was defined by means of VAS before the intervention, on the second day, after 6 and 12 months.

Results:

The balloon-sacroplasty enabled a good technical performance on every patient. The control-CT and the X-Ray control of the Os sacrum showed an adequate distribution of the cement, a cement leakage was not detected. Before the operation, the average pain encountered was according to the VAS 8.3. On the second postoperative day, a considerable reduction with an average of 2.7 was reported, this was still stable with an average of 2.5 after 6 and 12 months.

Discussion:

The Balloon-Sacroplasty is an effective treatment method for immediate pain relief and remobilisation in patients with fatigue fractures of the Os sacrum. Different approaches as well as the utilisation of a balloon enables preferably large cement streams in the longitudinal direction of the fracture in the Os sacrum.

Development of a Comorbidity Index Using the FREEDOM Trial in Women With Postmenopausal Osteoporosis. Stuart Silverman^{*1}, Andrea Wang², Hema Viswanathan², Yu-Ching Yang², Cesar Libanati³, Michelle Geller², Luanda Graetz⁴, Andreas Grauer⁵, David Macarios², Michael Nevitt⁶, Dennis Revicki⁷, Ethel Siris⁸, Steven Boonen⁹. ¹Cedars-Sinai/UCLA, USA, ²Amgen Inc., USA, ³Amgen Inc, USA, ⁴University of Southern California, USA, ⁵Amgen Health Center, USA, ⁶University of California, San Francisco, USA, ⁷United BioSource Corporation, USA, ⁸Columbia University College of Physicians & Surgeons, USA, ⁹Center for Metabolic Bone Disease & Division of Geriatric Medicine, Belgium

Purpose: Comorbidities are often important for adjusting for risk of outcomes in clinical trials, especially in pooled analyses using clinical trial data. Existing comorbidity indices offer little assistance in this regard as they are not designed for use with data commonly collected in a clinical trial. We developed a comorbidity index by adapting and applying two published algorithms to subjects' medical history from the FREEDOM trial (Cummings, NJEM 2009) in postmenopausal women with osteoporosis.

Methods: The FREEDOM trial enrolled women aged 60 to 90 years with a total hip or lumbar spine DXA T-score ≤ -2.5 and not ≤ -4.0 at either site. Comorbidity indices were calculated using methods described by Wolfe et al. (Wolfe, J Rheumatol 2010) and Sangha et al. (Sangha, Arthritis Rheum 2003). Here, we present results based on the method by Wolfe et al. as it allowed for weighting and inclusion of previous fractures. The index included pulmonary and cardiovascular conditions, hypertension, diabetes, previous fractures, depression, gastrointestinal ulcer or disorders, and cancer. The range for the index is 0 to 9, with higher scores indicating greater comorbidity. Four clinicians independently reviewed subjects' medical history data using MedDRA preferred terms corresponding to specific comorbid condition categories. In cases where there was lack of agreement, discrepancies were adjudicated by a fifth clinician who facilitated a panel discussion to reach consensus. Spearman correlations between the index and subject characteristics expected to be associated with comorbidities were examined.

Results: A total of 7,808 subjects were included; 60% of subjects had either zero or one comorbidity. The mean modified Wolfe comorbidity index was 1.4 (SD: 1.3) for all subjects. The comorbidity index distribution was as follows: 0, 29.2% of the population; 1, 29.9%; 2, 23.5%; 3, 10.8%; 4, 4.5%; 5, 1.7%; and ≥ 6 , 0.3%. The correlation between the indices using the two methods was 0.9. Correlations between the modified Wolfe comorbidity index and baseline characteristics are shown in the table.

Conclusions: The Wolfe et al. algorithm may be adapted for clinical trial data to assess comorbidities. As expected, the index was found to be significantly correlated with variables including the number of medications and impaired health status at baseline. This comorbidity index allows for the categorization and understanding of co-morbid conditions in clinical trial populations.

Baseline Characteristics	Correlation With the Modified Wolfe Comorbidity Index	P-value
Number of medications	0.54	< 0.0001
Osteoporosis Assessment Questionnaire (OPAQ) physical function	-0.28	< 0.0001
OPAQ emotional status	-0.28	< 0.0001
EQ-5D Visual Analog Scale score	-0.28	< 0.0001
OPAQ back pain	-0.22	< 0.0001
Body mass index (kg/m ²)	0.16	< 0.0001
Age (years)	0.16	< 0.0001

Table 1

Effects of Maitake Mushroom VitaminD₂ Supplementation on Serum vitamin D Level and Bone Metabolic Markers in Postmenopausal Women. Noriaki Yamamoto^{*}. Niigata rehabilitation hospital, Japan

Background: Maitake is a kind of mushroom contains a large amount of vitamin D₂.

The purpose of this study is to determine the effects of oral intake of Maitake mushroom supplementation in postmenopausal women for 1 year.

Methods: We conducted an open-label study with 31 postmenopausal women. All subjects take Maitake mushroom supplementation (Ichimasa kamaboko Co.,Ltd) containing 1600IU of vitamin D₂ everyday for 6 months. After 6 months of this study, all subjects were divided into 2 subgroup. Group A, 17 women continued to take supplementation for another 6 months and Group B, 14 women stop the supplementation. Serum Ca and bone metabolic markers (urinary NTX, serum BAP, 25OHD) were assessed at beginning, 6, and 12 months of this study.

Results: Comparing to the baseline, 6 months supplementation of Maitake mushroom significantly increased serum 25OHD level from 21.26 ng/mL to 31.14 ng/mL ($p < 0.01$). Another 6 months of treatment, 25OHD level was maintained 31.34 ng/mL ($p < 0.01$) in group A until 12 months of this study. However 25OHD level went down to 21.56 ng/mL after 6 months from the cessation of supplementation, in group B.

The serum BAP, Ca, and urinary NTX/Cre, level showed no significant changes during this study.

Conclusion: Improvement in 25OHD level in postmenopausal women was achieved by receiving Maitake mushroom supplementation which containing 1600IU of vitamin D₂ without adverse events.

Evaluation of a 1,25D-Dihydroxy Vitamin D Assay on the IDS-iSYS Automated System. Sybil Bergmann^{*1}, Michael Gardner², Chris Roffe², Chris Fox², Zoltan Seres², David Laurie². ¹TUD UKD Institute of Clinical Chemistry & Laboratory Medicine, Germany, ²Immunodiagnostic Systems Limited, United Kingdom

1,25-dihydroxyvitamin D (1,25D) is one of the major regulators of calcium metabolism. Measurement of 1,25D is used in conjunction with 25-hydroxyvitamin D (25D) and parathyroid hormone (PTH) in the differential diagnosis of various bone diseases. However, 1,25D circulates at very low (pg/mL) concentrations compared to 25D (ng/mL) and both are bound to the vitamin D binding protein. Specific and accurate measurement of 1,25D is thus difficult requiring some sort of sample extraction (immunoextraction or C18) and immunoassay.

As a result 1,25D assays currently available to laboratories are manual RIA or EIA versions which are time consuming relative to the number of samples that can be processed. To our knowledge no semi or fully automated 1,25D assays exist.

A new 1,25D assay was evaluated where 1,25D was extracted from delipidated samples by the current IDS immunoextraction technology and reconstituted samples were run directly on the IDS-iSYS system. Sample 1,25D competed with 1,25D-Acridinium (1,25D-ACR) for a limited amount of biotinylated polyclonal anti-1,25D antibody sites. Bound complexes were captured by use of streptavidin-coated magnetic particles. Following washing and addition of Trigger reagents, bound 1,25D-ACR was measured in a luminometer where signal generated was inversely proportional to the 1,25D concentration in the sample. Total time to first result (immunoextraction and immunoassay) was 4hr 30min.

The 1,25D assay had an assay range of 5 to 415pg/mL. Analytical sensitivity (mean -2SD of 'A' calibrator, n=20) was 6.4pg/mL. Intra-assay precision was 12%, 7% and 7% for samples at 22, 76 and 317pg/mL, (n=20). Inter-assay precision was 11 to 16% (samples 17 to 318pg/mL, n=8). An excellent correlation (n=55) with a slope of 1.29, intercept 0.9pg/mL and an R² of 0.86 was demonstrated to the commercially available IDS RIA.

These are the first laboratory results from a semi-automated 1,25D assay. The combination of immunoextraction and the IDS-iSYS system will allow laboratories to accurately analyse larger numbers of samples per day. With an expanded assay range,

excellent precision and good correlation to current methods the IDS-iSYS 1,25D assay will be a valuable tool in clinical laboratories for the accurate measurement of 1,25D in human sera or plasma.

Vitamin D Deficiency and Repletion: Effect of Ethnicity and BMI. Amer Budayr*¹, Joan Lo², Rita Hui², Ashley Coates², Moxie Stratton-Loeffler², Malini Chandra², Jerome Minkoff². ¹Permanent Medical Group, USA, ²Kaiser Permanente, USA

While the optimal level of vitamin D (25-OH-D) continues to be debated, the prevalence of vitamin D deficiency in adults is very high. We examined trends in use of prescription strength vitamin D (receipt of ergocalciferol 50,000 IU) and testing (25-OH-D) in the setting of a large integrated health care delivery system over an interval of 4 years (2007-2010). With the increased public awareness and ongoing physician education efforts over the period of the study, we wanted to examine the quantitative impact of this "epidemic" on the utilization of pharmacy and laboratory services. The broader goal of this study was aimed at examining optimal regimens of vitamin D replacement and the effect of demographic and clinical characteristics on the rate of successful vit D repletion.

METHODS: We ascertained the number of patients with new vitamin D prescriptions for each year, excluding patients with Vitamin D prescription in the prior 12 months. Among these patients, we examined the frequency of Vitamin D repeat testing between 6-52 weeks after receiving the first prescription. The rate of successful repletion was defined by a 25-OH-D level of 30 ng/ml or higher in the repeat testing.

RESULTS: We identified a total of 110,220 (76% female, mean age 59 +/- 16 years) patients initiating pharmacologic vitamin D during the study period. Across the 4 years of study, the number of patients with new prescriptions for vitamin D increased 6-fold from 6893 in 2007 to 42,858 in 2010. For the first prescription, 75% received a total of 0.45 – 0.60 M IU. We found an initial 69 % rate of repeat testing. The rate of successful repletion was in obese individuals and those of African American race.

CONCLUSION: We observed increasing population trends in the treatment of Vitamin D deficiency within a large integrated health care delivery system that parallel efforts to increase awareness of Vitamin D deficiency among healthcare providers and patients. Race/ethnicity and body mass index may be associated with differential rates of successful repletion. A significant proportion of patients may require additional therapy to achieve optimal levels of Vitamin D during follow-up testing.

Vitamin D Status does not Affect Bone Mineral Density Response to Raloxifene with Co-administration of Alfacalcidol. Itsuo Gorai*¹, Yasuhisa Iwaoki². ¹Sanikukai Hori Hospital, Japan, ²Department of Obstetrics & Gynecology, JA Yoshida General Hospital, Japan

Purpose: The persistent increase in PTH caused by vitamin D insufficiency reduces bone density response to anti-resorptive agents in postmenopausal women with osteoporosis. Vitamin D status at initiation of therapy did not affect bone mineral density (BMD)'s response to both alendronate and raloxifene with co-administration of cholecalciferol and calcium. We tried to assess whether vitamin D status at randomization could modify the subsequent BMD response to raloxifene with co-administration of alfacalcidol in postmenopausal Japanese women with osteoporosis or osteopenia (<-2.0 SD). **Method:** A total of 169 subjects (64.76.9 yrs) were randomly assigned to groups receiving 60 mg raloxifene (R), or 1 µg alfacalcidol (D), or a combination of both (R+D) for 2 yrs. Serum 25(OH)D was measured at randomization. We compared the groups using a Turkey-Kramer test for changes in L- and TH-BMD and calcium metabolism when significant differences were found using one-way ANOVA. The parameters in each group were analyzed by means of paired-t tests. **Result:** Baseline 25(OH)D was 23.7 ng/ml and 67.6% had vitamin D insufficiency (I) [20ng/ml<25(OH)D<32ng/ml] and 24.2% had vitamin D deficiency (D) (≤20ng/ml). I-PTH was 38.7pg/ml and 6.3% had asymptomatic hyperparathyroidism (i-PTH>65pg/ml). In the D+R group there was a significant increase in L-BMD (+4.6% at 1 yr and +5.8% at 2 yrs, P<0.0001), and the increase was significant compared with that in the R-group (vs. +2.6% at 2 yrs, P<0.05). In both R- and R+D groups there were no significant differences in the background characteristics except for corrected serum Ca of the R+D groups (I>D) between each vitamin D category. We found no significant differences in the changes in L-BMD at 2 yrs between I and D categories in both R- and R+D groups (4.0% vs. 1.8%, 5.6% vs. 5.9%, respectively). In each vitamin D category, there were no significant differences in the backgrounds between the R- and the R+D groups. Irrespective of vitamin D status, i-PTH showed an increase in the R-group and a decrease in the R+D group. In I category supplementation of alfacalcidol to raloxifene showed non-significant increases in L-BMD at 6, 12 and 18 months (4.4%, 5.0% and 4.9%) and a significant increase at 24 months (5.9%, P=0.0095) compared to the raloxifene alone group (1.6%, 2.3%, 2.8% and 1.8%, respectively). **Conclusion:** Vitamin D status at randomization did not

affect the subsequent BMD response to raloxifene with co-administration of alfacalcidol.

Inhibition Of Gut Serotonin Synthesis Normalizes Bone Mass In Lrp5-Deficient Mice And Other Models Of Osteoporosis. Hiroyuki Inose¹, Bin Zhou², Vijay Yadav², X Guo², Gerard Karsenty², Patricia Ducy*². ¹Tokyo Medical & Dental University, Japan, ²Columbia University, USA

A proof-of-concept study recently showed that decreasing synthesis of gut serotonin through the use of a small molecule inhibitor of Tph1 could prevent and treat ovariectomy-induced osteoporosis in rodents. Since the role of gut-derived serotonin in the control of bone formation arose from the study of Lrp5-deficient mice it was important to verify the usefulness of this treatment in these mutant mice as well as in other models of osteoporosis. To address the first question we compared the efficacy of the small inhibitor of Tph1 to LiCl. While both drugs could normalize bone formation parameters we noted that LiCl also increased significantly bone resorption parameters, an unwanted effect in the treatment of osteoporosis. Next, we showed that Tph1 inhibition could cure ovariectomy-induced osteoporosis in one year-old mice. We noted also that the anabolic effect of Tph1 inhibition persisted up to 6 weeks after the arrest of the treatment in mice. Lastly, we gathered evidence that Tph1 inhibition could work well in concert with an anti-resorptive agent to increase bone mass in ovariectomized mice. Taken collectively these data underscore the potential therapeutic importance of the inhibition of gut serotonin synthesis for the treatment of osteoporosis.

Development of an Osteopenic Bone Fracture Model. Kellie Brune*¹, Hong Liu¹, Christopher Bull¹, Jeffrey Wolos², Rachel Reams¹. ¹Covance Laboratories, Inc., USA, ²Scientific Consultant, USA

The purpose of developing this osteopenic rat fracture model was to provide an early (as short as 42 days) and longitudinal assessment tool for osteopenic bone regeneration. An in-house computer analysis program for computed tomography (CT) images was designed to specifically analyze the healing process at the fracture site.

A total of 36 virgin Sprague Dawley rats were ovariectomized at 6 months of age. Following ovariectomy, a 2 month window was allowed for bone loss to occur. 8 – 10 weeks post ovariectomy, an external fixator was secured in place on both femurs using stainless steel screws. Each femur was then cut transversely (mid-diaphysis) using a micro saw blade. After the surgery, the rats were divided into three groups: two groups treated with 5 or 30 mcg/kg/day parathyroid hormone (PTH), and a vehicle treated group. 3D images were collected at selected time points using Volumetric Computed Tomography (VCT). The VCT image gray level at each voxel within a 5 mm thick stack at the osteotomy site was quantified and converted as callus BMD (bone mineral density). The region of interest in each slice in the stack was then determined by an elastic wrapping algorithm. Statistical density distributions of callus BMD for each group were extracted at Days 7, 42, 63 and 84. Quantitative measures that reflect bone regeneration quality based on these distributions were given as Total Mineral, Mean Intensity, High Density Fraction and Total Mineral above 815 BMD.

Data from this 12 week validation study demonstrated a constant increase of bone regeneration across all three groups. The regeneration as indicated by our VCT measurements was statistically significantly stronger in the 30 mcg/kg/day group than in the 5 mcg/kg/day group which in turn was significantly stronger than the vehicle group. These statistically significant, dose-responsive alterations were noted as early as Day 42. In addition, Total Mineral above 815 BMD at Day 42 correlated well to the biomechanical strength measured at Day 84 (Pearson CC=0.7512 with p<0.0001). Our data support the utility of this model as an early and longitudinal assessment of bone regeneration that provides data that are complementary to, or potential a replacement for, traditional endpoints such as mechanical strength or histopathology. This model provides a robust higher-throughput screening tool to compare the pharmacological efficacy between benchmark compounds such as PTH, and other agents.

Effect of PTH 1-84 on the Remodeling, Microstructure and Bone Mass In Male Orchidectomized Rats. Marta MartÍN-Fernandez^{*1}, Manuel DÚaz-Curiel², David Guede³, Jose Ramon Caeiro⁴, Concha de la Piedra¹, Elena Martínez⁵. ¹Bioquímica Investigacion, Instituto de Investigacion Sanitaria Fundacion Jimenez DÚaz, Spain, ²Internal Medicine, Instituto de Investigacion Sanitaria Fundacion Jimenez DÚaz, Spain, ³Trabeculae, Parque Tecnológico de Galicia, Spain, ⁴Cirugía ortopedica y Traumatología, Complejo Hospital Universitario de Santiago de Compostela, Spain, ⁵Director Medico, Spain

Androgenic depletion due to hypogonadism affects bone metabolism, causing osteopenia. Although its utility in the treatment of postmenopausal osteoporosis has been established, there is limited evidence on the effect of PTH 1-84 in male osteoporosis.

Purpose: To study the effect of PTH 1-84 in an experimental model of orchidectomized male rats, measuring the changes in bone mineral density (BMD), remodeling markers and bone microstructure.

Material and Methods: 4 groups of 10 6-month-old male Wistar rats. SHAM: n=10, simulated intervention; OQX: n=10, orchidectomized; OQX+PTH1: n=10, orchidectomized and treated with PTH 10 mcg/Kg; OQX+PTH2: n=10 orchidectomized and treated with PTH 50 mcg/Kg. The treatment was started 3 months after orchidectomy, and was maintained for 3 months. After sacrifice, BGP, FTR 5b and beta-CTX bone remodeling markers, BMD of the lumbar spine and femur, and a femoral microstructure analysis by microCT scan were measured.

Results: A statistically significant reduction in vertebral and femoral BMD was evidenced in the OQX group versus the SHAM group, which partially reverted with the low dose of PTH, and completely reverted with the high dose. A significant increase of the CTX/FTR ratio was seen in the OQX group versus the SHAM group, which was maintained in the treated groups. The level of BGP did not show any changes in the OQX group, although a significant dose/response increase was seen in the treated groups. A relative reduction of BV/TV was seen in the OQX group, a decrease in the number of trabeculae and an increase in their separation. PTH treatment (both doses) restored baseline values of BV/TV, partially reducing separation and increasing trabecular number with the low dose, completely restoring both parameters with the high dose. Trabecular pattern factor increased in OQX, it was restored with the low PTH dose, and it became lower than in the SHAM group with the high dose. The structure model index (SMI) experienced a significant reduction in the high-dose group, compared to the OQX rats.

Conclusions: In an animal model of osteoporosis by androgenic deprivation, treatment with PTH 1-84 has shown to have a bone-forming effect, reflected by an increase in bone formation markers, and increased lumbar and femoral BMD and a partial or total recovery of microstructural parameters.

Increased Alveolar Bone Mass in Sclerostin Knockout Mice. Min Liu^{*1}, Xianglong Han², Pam Kurimoto¹, Jerry Feng², Paul Dechow², Hua Zhu Ke¹. ¹Amgen Inc., USA, ²Baylor College of Dentistry, Texas A & M Health Science Center, USA

It has been postulated that osteoporosis and oral bone loss are associated among the elderly, although the evidence for this relationship is mostly preliminary. During development, most long bones develop endochondrally, whereas bones of the skull and face generally develop through intramembranous ossification. Sclerostin (Scl), acting through antagonizing BMP and Wnt signaling, is a potent inhibitor of bone formation. Sclerostin knockout (SOST KO) mice show a high bone mass phenotype in various skeletal regions (eg, vertebrae and long bones). In the current study, we analyzed the jaw bone phenotype of SOST KO mice. Methods included radiography, quantitative μ CT, mechanical testing, and histological analysis.

We first investigated the expression pattern of Scl in the periodontium of young and adult wildtype (WT) mice. Strong Scl expression was observed in WT mandibular odontoblasts, osteocytes and cementoblasts, although there were no significant differences in TRAP staining and osteocyte apoptosis between WT and SOST KO mice. Radiography and μ CT assessment revealed that 10-month old WT mice had age-related mandibular bone loss while aged-matched SOST KO mice did not; the mandible bone in SOST KOs was well-preserved, even in 24-month-old mice. Quantitative μ CT analyses showed that increases in bone volume fraction (BVF) in SOST KO mice varied regionally in the mandible. Compared to WT, SOST KO mice had increases of 18%, 12.5% and 4% in alveolar bone, condylar head, and condylar neck BVF respectively, which was correlated with variations in WT BVF among regions; areas with lower BVF showed greater increases in BVF and bone density. In line with elevated bone mass, mechanical testing showed significantly stronger mandibular bone in SOST KO mice (+61%, $p < 0.02$) than WT mice. The increase in total alveolar bone volume in SOST KO mice coincided with osteon formation, which does not normally exist in small animals. Lastly, in spite of the high bone mass phenotype in the mandible, teeth developed normally in the SOST KOs.

In conclusion, SOST KO mice preserved mandibular bone at old ages and had higher alveolar bone mass and stronger mandibles compared with WT mice. The overall increase in bone strength in the mandible suggests a systemic effect, while the relative regional differences in jaw bone mass increases suggest local mechanical effects.

Inhibition of Sclerostin by Monoclonal Antibody Enhances Bone Healing in a Rat Osteotomy Model. Yi-Xin He^{*1}, Zhong Liu¹, Tao Tang¹, Li-Zhen Zheng¹, Chi-Wai Man¹, Chao-Yang Li², Ge Zhang¹, Hua-Zhu Ke², Ling Qin¹. ¹The Chinese University of Hong Kong, Hong Kong, ²Amgen Inc., USA

Sclerostin is a negative regulator of bone formation and treatment with a sclerostin monoclonal antibody (Scl-Ab) results in increased bone formation, bone mass and bone strength in animal models of bone loss and fracture repair. The objective of this study was to investigate the effects of systemic administration of Scl-Ab on fracture repair in an open fracture model in rat femur. Sixty 6-month-old SD rats were randomly divided into Scl-Ab groups and vehicle groups after a transverse osteotomy performed at the mid-shaft of the right femur. One day post-surgery, rats were treated with Scl-Ab (s.c. injection, 25 mg/kg, 2 times per week) or vehicle for 3 or 6 weeks. The fractured femora were dissected for microCT scanning, mechanical testing, histology and angiography. MicroCT showed that the Scl-Ab groups had significantly higher callus volume fraction and BMD in both 3 and 6 weeks (Figure 1A) post-fracture compared to vehicle groups. Four-point bending testing showed significantly higher ultimate load (+98%) in Scl-Ab group than vehicle group with stiffness and energy to failure also trending higher in the Scl-Ab group at 6 weeks post fracture (Figure 1B). The increased callus bone volume fraction and fractured femoral bending strength with Scl-Ab treatment suggest that enhanced bone repair was achieved by inhibiting sclerostin. H&E staining showed more granulation tissues at 3 weeks and more woven bone at 6 weeks in the Scl-Ab treated calluses than in vehicle treated calluses. Fracture repair is complex, involving a coordinated sequence of biological processes that includes angiogenesis. Consistent with the enhanced fracture repair, we also observed an increase in callus vascularization (microCT based angiography) at the 3 week time point in the Scl-Ab treated animals as compared to vehicle treated animals (Figure 1C). Our data, showing enhanced fracture repair in rat osteotomy model support the potential of systemic Scl-Ab administration to enhance open fracture healing in patients.

Vitamin K₂ Improves Renal Function and Increases Femoral Bone Strength in Rats with Renal Insufficiency. Jun Iwamoto^{*1}, Azusa Seki², Hideo Matsumoto¹. ¹Keio University School of Medicine, Japan, ²Hamri Co., Ltd, Japan

Renal insufficiency induces cortical bone loss in rats. The purpose of the present study was to examine the effects of vitamin K₂ on renal function and cortical bone

mass and bone strength in rats with renal insufficiency. Thirty male Sprague-Dawley rats, 8 weeks of age, were randomized by the stratified weight method into the following three treatment groups of 10 rats each: sham-operation (control), 5/6 nephrectomy (NX), and 5/6 NX + vitamin K₂ administration (30 mg/kg, 5 days/week, orally). Nine days after the surgery, serum and urine samples were collected to assess renal function and the treatment was initiated next day. After 6 weeks of treatment, the serum and urine samples, femora, and tibiae were obtained. Renal function was re-evaluated, bone histomorphometric analysis was performed on the tibial diaphysis, the length and wet weight of the femur were measured, and the bone mineral density (BMD) and mechanical strength of the femoral diaphysis were determined by peripheral quantitative computed tomography and three-point bending test, respectively. NX did not only induce renal dysfunction as indicated by the increased serum creatinine and urea nitrogen levels and the decreased creatinine clearance, but also decreased the femoral wet weight and femoral diaphyseal BMD without significantly affecting the femoral length, tibial diaphyseal cortical and marrow areas, and femoral diaphyseal bone strength. Vitamin K₂ improved renal function parameters, but did not significantly influence the femoral length, femoral wet weight, and femoral diaphyseal BMD. However, vitamin K₂ decreased the marrow area of the tibial diaphysis and increased the stiffness of the femoral diaphysis. These findings suggest that vitamin K₂ appears to improve renal function and increase bone strength without improving BMD in the cortical bone of rats with renal insufficiency.

Alendronate Systemic Administration: Effects on Bone and Mineralized Dental Structures. Marilia Lucisano¹, Raquel Silva^{*2}, Roberto Silva³, Raquel Gerlach¹, Paulo Nelson-Filho¹, Ricardo Battaglini⁴, Monica Serra¹, Leslie Morse⁵, Lea Silva¹. ¹School of Dentistry of Ribeirao Preto - University of Sao Paulo, Brazil, ²School of Dentistry of Ribeirao Preto - University of Sao Paulo, Brazil, ³School of Pharmaceutical Sciences of Ribeirao Preto - University of Sao Paulo, Brazil, ⁴The Forsyth Institute, USA, ⁵Harvard Medical School, USA

The objective of this study was to evaluate the effect of the systemic use of sodium alendronate in rats *in vivo*. Forty-five Wistar rats aged 36-42 days and weighing 200-230 g were assigned to two groups: experimental (n= 25) and control (n= 20). The experimental group received two weekly doses of 1 mg/kg of chemically pure sodium alendronate, while the animals of the control group received distilled water. After 60 days, the animals were sacrificed, the maxillary incisors were extracted and the tibias were removed. We determined bone mineral density, by radiographic optical densitometry and dual-energy x-ray absorptiometry (DXA); the mineralized dental structures of murine incisors, by analysis of infrared (IR) spectrometry, fluorescence spectroscopy, cross-sectional microhardness (CSMH), scanning electron microscopy (SEM) and polarized light microscopy (PLM). The results were subjected to statistical analysis by the Kruskal-Wallis non-parametric test, using the SAS (Statistical Analysis System) software for Windows version 9.1.3 (significance level of 5%). The experimental group presented higher mineral bone density (p<0.05) than the control group, by radiographic optical densitometry and DXA. The chemical analysis by IR spectrometry and fluorescence spectroscopy revealed the presence of alendronate in the mineralized dental structure of the specimens of the experimental group, with a percentage of incorporation of 0.0018% per tooth. The results of enamel and dentin CSMH did not show statistically significant difference between the experimental and control groups (p>0.05). There were no significant morphological differences among the specimens of the groups by SEM and PLM. Based on the obtained results, it may be concluded that the treatment with sodium alendronate caused an increase in the mineral bone density of the proximal tibial metaphysis, and that alendronate was incorporated in the mineralized dental structures without causing significant effects in the enamel and dentin microhardness and morphology of rat incisors.

Disclosures: Raquel Silva, None.

Is Alendronate Effective in Improving Material Properties of Frail Cortical Bone in Inactive Model Rats? Mitsutoshi Suto¹, Kouji Naruse¹, Kentaro Uchida¹, Kaori Suto¹, Ken Urabe¹, Moritoshi Itoman², Yuko Mikuni-Takagaki^{*3}. ¹Department of Orthopedic Surgery, Kitasato University School of Medicine, Japan, ²Kyushu Rosai Hospital, Japan, ³Kanagawa Dental College & Graduate School of Dentistry, Japan

Age, hormones, diseases, medications, and physical activity all affect the bones of elderly people, some of whom suffer from osteoporosis. Bisphosphonates are now widely prescribed to treat osteoporosis, and they are effective. However, new evidence suggests that people who take bisphosphonates may be at greater risk of a subtrochanteric or proximal diaphyseal femur fractures from a low-energy event. With a new inactive rat model, (J Bone Miner Metab, in press), we studied the effect of alendronate (ALN) to answer key questions related to these atypical fractures. At 40 weeks female Wistar rats underwent surgery, either an ovariectomy (OVX) or a sham operation, and were then kept for 5 weeks. For the next 13 weeks, we forced some rats inactive by housing them in cages that allow free access to water and food but do not permit the rats to rise up or walk. Dissected femur were analyzed by ?CT,

pQCT, confocal Raman microspectroscopy, and three point bending test. Our results show that alendronate effectively prevents cortical bone loss in osteoporotic OVX rats but not in inactive rats. Results of pQCT also showed that a geometry parameter, cross sectional moment of inertia, CSMI, of Inactive+ALN is smaller than that of Walking (Sham). Matrix parameters such as Amide I and Amide III showed that Inactive rat cortical bone has significantly lower intensity values than those of Walking and OVX+ALN rats and that values of Inactive rats and Inactive+ALN rats are not significantly different. Mineral parameters such as PO43- ?4 also showed a significant difference between OVX+ALN and Inactive rats. Both mineral and matrix are deficient in the cortical bone of inactive rat, and ALN does not seem to restore the deficiency. Measurements of bone strength showed that the breaking force of both Inactive and Inactive+ALN rat femur is significantly smaller than that of WalkingALN and OVX+ALN rats, and that ultimate force of Inactive+ALN rat femur is significantly smaller than that of OVX+ALN rat. ALN may have made these parameters of cortical bone in the inactive rats worse. Association of atypical fractures with the physical inactivity of patients treated with bisphosphonates may be worth examining.

First-In-Human Study of Transdermal Salmon Calcitonin - Pharmacokinetics and Pharmacodynamics. Yael Kenan^{*1}, Efrat Kochba², Galit Levin³, Keren Greenfeld-Barsky², Keren Mevorat², Hagit Sacks², Hana Gadasi², Yael Leshem², Francis Berenbaum⁴, Virginia Kraus⁵. ¹TRANSPhARMA MEDICAL LTD., Israel, ²TransPharma Medical, Israel, ³Transpharma Medical, Israel, ⁴Saint-Antoine hospital, AP-HP, France, ⁵Duke University Medical Center, USA

Salmon calcitonin (sCT) has been shown to reduce the bone resorption and cartilage degradation associated with osteoarthritis. TransPharma Medical has developed a transdermal (TD) delivery system of synthetic sCT to alleviate the discomfort of subcutaneous (SC) injections and to improve reliability of delivery, patients' acceptance and compliance. The system creates MicroChannels in the upper skin layers, allowing rapid diffusion of the peptide from a subsequently-applied drug patch into the inner skin and systemic circulation (Ish Shalom et al., ASBMR2010). The aim of this phase I study was to assess safety, tolerability, pharmacokinetics (PK; serum sCT), and pharmacodynamics (PD; CTX-I, CTX-II/cr) of ascending doses of TD sCT in an open-label, cross-over, single-center study in 20 healthy postmenopausal women age 45-75 y. CTX-I and CTX-II are biomarkers for bone resorption and cartilage degradation, respectively. In Part A, 12 women received sCT SC 100 IU (Salco; Genmedix.Ltd) and sCT TD 300 µg. In Part B, 14 women (including 6 from part A) received sCT SC 100 IU (Mialcalcin; Novartis) and 60, 100, 150 µg sCT TD. There was a wash-out period of 1 week after each dose. PK and PD were evaluated from samples collected postdose for up to 24 h in Part A and up to 7 days in Part B. Evaluation of the daily biological variability of CTX biomarkers was assessed for 24 h predose. Skin and general safety assessments were performed. TD delivery of sCT was safe and tolerable; there were no clinically significant differences across study groups in adverse events. Cmax of TD sCT was delayed compared to SC. A dose-response in Cmax was observed for TD 60, 100 and 150 µg sCT; relative bioavailability ranged from 18 to 25%. In Parts A & B, the changes from predose to maximal reduction in CTX-I and CTX-II were similar between TD and SC delivery of sCT; these reductions in biomarkers were significantly greater than those observed with diurnal variation. Biomarker data also demonstrated a comparable PD profile between TD and SC for all doses in the relative percent change from predose to 12 h postdose (Table), and 24 h and 7 days postdose (data not shown). In conclusion, this first-in-human, dose-range finding study of transdermal sCT demonstrated significant reductions in markers of bone resorption and cartilage degradation that were comparable to subcutaneously administered sCT. Delivery of both TD and SC sCT was well-tolerated.

Table. Relative percent change from predose to 12 hour postdose for serum CTX-I and urine CTX-II by salmon calcitonin delivered transdermally (TD) or by subcutaneous (SC) injection.

	Serum CTX-I (ng/ml)	Urine CTX-II (ng/ml-mmol Cr)
Part A		
TD 2x150 µg	-95.1 (-96.0, -91.1) (n=12)	-79.2 (-84.4, -68.2) (n=12)
SC 100 IU	-80.2 (-84.6, -71.6) (n=12)	-66.0 (-78.6, -28.2) (n=12)
Part B		
Control*	-19.6 (-26.6, -10.3) (n=14)	-28.8 (-46.2, -14.1) (n=14)
TD 60 µg	-90.2 (-94.4, -80.9) (n=14)	-74.1 (-79.5, -55.0) (n=14)
TD 100 µg	-93.3 (-98.7, -79.6) (n=12)	-72.9 (-77.9, -48.6) (n=12)
TD 150 µg	-93.8 (-96.7, -86.8) (n=11)	-72.5 (-83.8, -49.5) (n=11)
SC 100 IU	-93.4 (-95.4, -92.3) (n=11)	-59.2 (-73.7, -53.3) (n=11)

Data presented as median % change from predose, (95% CIs),

Non-nuclear ERα Signaling Prevents Oxidative Stress and the Loss of Bone, but not the Loss of Uterine Weight, in OVX Mice. Shoshana M. Bartell^{1,*}, Li Han¹, Srividhya Iyer¹, Aaron Warren¹, Randal S. Shelton¹, Robert W. Bradsher¹, Sung H. Kim², Benita S. Katzenellenbogen², Ken L. Chambliss³, Philip W. Shaul³, John A. Katzenellenbogen², Paula K. Roberson¹, Robert S. Weinstein¹, Charles A. O'Brien¹, Robert L. Jilka¹, Maria Jose S. Almeida¹, Stavros C. Manolagas¹. ¹Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA, ²University of Illinois, USA, ³University of Texas Southwestern Medical Center, USA

Sex steroid deficiency in mice, similar to aging, increases the generation of reactive oxygen species (ROS) and the activity of p66shc, an isoform of the growth factor adapter Shc that amplifies ROS production in the mitochondria. Moreover, the adverse effects of the acute loss of ovarian function on bone can be prevented by antioxidants. Conversely, estrogens decrease ROS and p66Shc activation, antagonize ROS-induced osteoblast apoptosis, and attenuate the pro-survival effects of RANKL on osteoclasts also via anti-oxidant mechanisms. These effects of estrogens are fully preserved in a mouse model bearing an estrogen receptor (ER) α knock-in mutation that prevents binding to DNA. In addition, a 17 β -estradiol (E2) dendrimer conjugate (EDC) that is not capable of stimulating the nuclear-initiated actions of ER is as potent as E2 in attenuating p66shc phosphorylation and osteoblast apoptosis, as well as promoting osteoclast apoptosis in vitro. Prompted by these observations and the demonstration that ER α non-nuclear signaling induced by the EDC promotes cardiovascular protection, but not uterine or breast cancer growth in mice (Chambliss et al, JCI 2010), we have examined here the effects of this compound on the skeleton of ovariectomized (OVX) mice. For these experiments, 17 week-old C57BL/6 female mice were OVX or sham-operated and implanted with mini-pumps delivering vehicle, a dendrimer control (DC), or equimolar concentrations of E2 or the EDC for 6 weeks. The EDC prevented the OVX-induced oxidative stress (as determined by ROS and glutathione levels in the bone marrow and p66shc phosphorylation in vertebral bone) to the same extent as E2; was as potent as E2 in preventing bone loss at the spine (DEXA); and significantly attenuated loss of cortical bone as determined in the vertebrae or femur (micro-CT). Further, EDC was as potent as E2 in preventing the OVX-induced increase in both osteoclast and osteoblast progenitors, as assayed by the number of bone marrow-derived TRAP-positive cells and CFU-OB, respectively. In sharp contrast, the OVX-induced decrease in uterine weight was fully restored by E2 but was unaltered by the EDC. DC- and vehicle-treated OVX mice were indistinguishable in all these measures. These results demonstrate unequivocally that at least several effects of estrogens on bone, including their anti-oxidant properties, are mediated by a mechanism distinct from their classical genotropic action on reproductive organs.

Effects of Low Intensity Pulsed Ultrasound on OVX Induced Bone Mass Decrease in Mice. Yoshitsugu Kojima¹, Takayuki Watanabe¹, Hiroki Yazawa¹, Hiroyoshi Nishi², Nobuo Izumo², Yoshihiro Nishimura^{1,*}. ¹Nippon Sigmax Co., Ltd., Japan, ²Yokohama College of Pharmacy, Japan

Low intensity pulsed ultrasound (LIPUS) has been widely used for bone fracture healing. Effects of LIPUS on bone fracture site have been revealed recently. Yet mechanism of LIPUS on osteoporosis is less well understood. The aim of this study is to test the effects of LIPUS on bone loss model of OVX model mouse. ICR mice, 14-week-old, were ovariectomized or sham operated. Ovariectomized mice were divided into ultrasound exposed group and unexposed group. LIPUS was exposed for 20min/day, and 5day/week at 2MHz, duty 20%. Bone density and bone mineral content (BMC) were measured with LCT-100Lite, Hitachi Aloka Medical, Ltd, on pre-exposed, one month and two month after beginning of LIPUS exposure. At three month, all mice were sacrificed. Tibia, ovary and serum were collected. The bone density and BMC of right tibia were measured. Sera were used for ELISA of osteopontin (OPN) and TRAP. At three month ovary weight was significantly decreased to 15% of sham group on both OVX and LIPUS exposed groups. Bone density was significantly decreased on OVX mouse against sham mouse at 1, 2 and 3 month after OVX operation. BMC was significantly decreased on OVX group against sham group at 1 and 2 month. However, BMC was not showed significant difference on LIPUS group. Moreover, at 3 month, BMC of LIPUS group was significantly higher than that of OVX group. OPN expression level in serum was significantly increased on LIPUS group. On the other hand, TRAP level was decreased on both LIPUS and OVX groups against sham group. In this study, the effects of LIPUS on BMC were indicated. The results of ELISA suggested the effect of LIPUS on osteoblastic cells. Our next step is to elucidate the mechanism of osteogenic responses by LIPUS with western blot and real-time PCR.

Interaction of Calcium Intake and Vitamin D Status throughout Young Adulthood and OVX-Induced Estrogen Deficiency on Bone and Calcium Metabolism. Clara Park^{*}, James Fleet, George McCabe, Connie Weaver, Purdue University, USA

Calcium (Ca) intake and vitamin D (VD) status may affect the progression of bone loss through menopause in women. We investigated this in female Sprague Dawley rats. Initially weanling rats were fed a diet with 0.4% Ca and 100 IU VD/kg diet for 5 wks in a UV-free environment, targeting the average Ca and VD status of US adolescents. Bones were labeled with ⁴⁵Ca and 24-hour urine collections were done weekly thereafter to assess bone loss. At 8 wks of age, rats were fed diets containing either 0.2 % or 1.0 % Ca and 50, 100, or 1000 IU VD/kg diet (14-16 rats/treatment diet, 2 x 3 factorial design). Ovariectomy (OVX) was performed at 12 wks of age. Rats were sacrificed at 7 mo of age and tibias and femurs were excised. Urinary ⁴⁵Ca excretion was measured by liquid scintillation, 4-day metabolic Ca balance (at 3 mo post-OVX or older) and bone Ca content were determined by atomic absorption spectrometry and inductively coupled plasma optical emission spectrometry, bone length and width by digital calipers, bone density by underwater weighing, bone structure by μ CT, and bone strength by 3-point bone breaking. One-way or 2-way ANOVA was used to analyze the data. Urinary ⁴⁵Ca increased after OVX in all rats, but rats on the 1.0 % Ca diet excreted less starting 4 wks after OVX, regardless of VD intake. VD improved net Ca absorption in rats fed 0.2 % but not 1.0 % Ca. A Ca x VD interaction affected Ca content in tibia but not femur. In tibia, Ca content was highest in the 1.0 % Ca + 100 IU VD/kg diet group, however, no diet effect was observed for bone length, width, density, or bone strength. In the femur, higher VD intakes increased bone width and improved mechanical strength (higher energy to failure). Ca intake increased tibia trabecular (Tb) number and reduced Tb spacing, while higher VD reduced Tb spacing. No diet effect was seen in cortical bone. We conclude that high Ca intake prevents bone turnover after OVX regardless of VD status, but VD can increase Ca absorption at low Ca intakes. Increased VD intake affects bone width and strength only in the femur. In the tibia, Ca and VD interact on bone Ca content, but Ca and VD promote trabecular bone independently. Thus Ca metabolism and bone health during estrogen deficiency is affected by the habitual input of Ca and VD during later growth and adulthood through the individual and interactive effects of these nutrients.

Effects of Parathyroid Hormone, Alendronate and Their Combination Regimen on Bone Mass and Turnover in Ovariectomized Cathepsin K Null Mice. Michael Gentile^{*1}, Carlyle Horrell¹, Maureen Pickarski¹, Le Thi Duong². ¹Merck & Co., Inc., USA, ²Merck Research Laboratories, USA

Cathepsin K (CatK) is a cysteine proteinase highly expressed in osteoclasts and plays a major role in bone resorption. Inhibition of CatK prevents bone loss while preserving bone formation in ovariectomized (OVX) mice, rabbits and monkeys. Treatment with the CatK inhibitor odanacatib has been shown to increase bone mineral density (BMD) at the spine and hip in postmenopausal osteoporosis. Parathyroid hormone (PTH) is the currently approved osteoanabolic agent for the treatment of osteoporosis. The goal of this study is to compare efficacy of hPTH1-34 (40µg/kg, daily, 5x week), ALN (0.3mg/kg, wkly) and their combined effects in OVX-wild type (WT) vs. -KO mice. Treatment of skeletal mature OVX-mice (surgery at age 12 weeks) was initiated at 3-months post surgery for 12-weeks total. *In vivo* DEXA was performed at baseline, 6 and 12 weeks during treatment, and calcein was administered 7 and 2 days prior to necropsy. Although whole body BMD of KO is significantly higher than WT at baseline, OVX resulted in significant lumbar vertebrae (LV) bone loss in WT by 12.0% (p<0.001, one way ANOVA, Fisher's PLSD) and KO by 10.9% (p<0.001) versus the respective Sham-OVX. Lumbar vertebra (LV4-6) and whole femur (WF) were evaluated *ex vivo* for BMD and dynamic histomorphometry. In OVX-WT mice, PTH and ALN increased LVBMD (p<0.001) by 13.3% and 24.0%; and WF BMD (p<0.001) by 14.8% and 18.5%, respectively vs. vehicle. In OVX-KO, PTH and ALN increased LVBMD (p<0.001) by 19.2% and 23.0%; and WF BMD (p<0.001) by 28.3% and 11.6%, respectively. Interestingly, combination of PTH and ALN additionally increased LVBMD (p<0.001) by 42.2 % and WFBMD by 29.6 % in OVX-WT and increased LVBMD (p<0.001) by 51.9 % and WFBMD by 35.0 % in OVX-KO with total BMD gains in KO significantly higher than that in WT. From dynamic histomorphometry, bone formation rate (BFR) in Sham and OVX-KO is ~3-4 fold higher than that in Sham and OVX-WT. While ALN treatment alone diminished overall bone turnover and BFR, PTH increased trabecular BFR in both OVX-WT and -KO. In combination with PTH, ALN partially reduced PTH induced gains in BFR in both OVX-WT, and -KO with the KO groups displaying increased BFR relative to WT in all treatment regimens. Taken together, the combination regimen of PTH and ALN resulted in higher gains of bone mass with less suppression of bone formation in response to estrogen deficiency in CatK KO as compared to that in wild type mice.

Efficacy of ONO-5334, a Cathepsin K Inhibitor, on Bone Mineral Density, Geometry and Bone Strength in the Radius in Ovariectomized Cynomolgus Monkeys. Satoshi Nishiwaka*, Hiroyuki Yamada, Yasutomo Nakanishi, Akiko Kunishige, Yasuaki Hashimoto, Hiroshi Mori, Yasuo Ochi, Masafumi Sugitani, Kazuhito Kawabata. Ono Pharmaceutical Co., Ltd., Japan

ONO-5334 is a small molecule and an orally-active inhibitor of cathepsin K, which plays an important role in osteoclast-mediated bone resorption. We have previously reported that ONO-5334 increased areal BMD in the radius as well as the lumbar vertebra in ovariectomized (OVX) monkeys ¹⁾. In this study, we evaluated the efficacy of ONO-5334 on trabecular and cortical bone, and bone strength in the radius.

Female cynomolgus monkeys were assigned to one of the following 6 groups (20 animals/group): sham operated, OVX control treated with vehicle, ONO-5334 1.2, 6 or 30 mg/kg, or alendronate (ALN) 0.05 mg/kg. ONO-5334 was orally administered once daily from the day following OVX surgery for 16 months. ALN was administered i.v. once every 2 weeks. After necropsy, distal and mid radius (5 and 50% of total radius length from the distal end, respectively) were scanned using pQCT to measure volumetric BMD (vBMD) and geometric parameters, followed by a 3-point bend test at the mid radius.

In the distal radius, OVX caused a significant decrease in trabecular vBMD (p<0.01), but there were no changes in integral and cortical vBMD and geometric parameters such as cortical thickness, periosteal and endosteal perimeter compared to the sham group. ONO-5334 at 6 and 30 mg/kg significantly increased integral vBMD (41, 48% resp.) and cortical vBMD (23, 22% resp.), and cortical thickness (51, 59%), vs the OVX control group (all p<0.01). ONO-5334 at 6 and 30 mg/kg significantly decreased endosteal perimeter (p<0.01 vs OVX), but did not affect periosteal perimeter. ONO-5334 at 30 mg/kg increased trabecular vBMD over sham level (p<0.01 vs OVX). In the mid radius, OVX induced a significant decrease in cortical vBMD (p<0.01 vs sham), but there were no changes in geometric parameters. All ONO-5334 doses significantly increased cortical vBMD and thickness (except for cortical thickness of 1.2 mg/kg) (p<0.05 vs OVX). Periosteal and endosteal perimeters were not affected by ONO-5334. Bone strength (maximum load) at the mid radius decreased due to OVX (p<0.05 vs sham), and significantly increased by ONO-5334 at 6 and 30 mg/kg (p<0.05 vs OVX). ALN did not affect any pQCT parameters or bone strength in the radius.

In summary, ONO-5334 increases BMD by affecting cortical bone predominantly as well as trabecular bone in the radius. In addition, ONO-5334 has a positive effect on bone strength in the mid radius, where cortical bone predominates.

MIV-711, a Potent and Selective Oral Once Daily Cathepsin K Inhibitor, Reduces Markers of Bone Resorption While Maintaining Carboxylated and Undercarboxylated Osteocalcin Levels in Dogs Subjected to Partial Medial Meniscectomy, an Experimental Model of Osteoarthritis. Erik Lindstrom¹, Lotta Vrang¹, Susanne Sedig¹, Ylva Terelius¹, Kristina Wikstrom¹, Britt-Louise Sahlberg², Timothy Chambers³, Don Mau⁴, Alison Bende⁵, Urszula Grabowska^{*6}. ¹Medivir AB, Sweden, ²Medivir, Sweden, ³St. George's Hospital Medical School, United Kingdom, ⁴Pre-Clinical Research Services, USA, ⁵Bolder Biopath, USA, ⁶Medivir, United Kingdom

Background and Aims

Cathepsin K, produced by osteoclasts, degrades type I collagen in bone and cathepsin K inhibitors act as anti-bone resorptives. Although agents are now available that suppress bone loss, anti-resorptive treatment typically suppresses bone formation, and thus prevents the replacement of lost bone. We have recently evaluated MIV-711, a potent and selective cathepsin K inhibitor, in an experimental dog model of osteoarthritis (OA) on markers of bone resorption and bone formation.

Methods

Female beagle dogs, subjected to partial medial meniscectomy, were treated with either vehicle (n=15) or MIV-711 (n=15) at 30 µmol/kg once daily (q.d.) starting the day before surgery. Treatment continued for 28 days after surgery followed by necropsy on day 29. Plasma and urinary samples were collected at various time points during the experiment and at necropsy. Biomarkers were measured using commercially available ELISA kits.

Results

MIV-711 reduced CTX-I levels (marker of bone resorption) in plasma (max effect: 46-67%, effect at trough: 30-37%) and in urine (79-86%) compared to baseline. CTX-I levels did not change in response to vehicle. The plasma levels of undercarboxylated and carboxylated osteocalcin (a marker of bone formation) did not differ between vehicle and MIV-711-treated groups at sacrifice.

Conclusions

In summary, markers of bone resorption in OA dogs were reduced by the selective cathepsin K inhibitor MIV-711 compared to vehicle while the bone formation markers measured did not differ from vehicle despite the prominent inhibition of bone resorption. Taken together, these data suggest MIV-711 may be beneficial not only for osteoporosis but also for OA.

Pre-operative Intermittent Administration of Human Parathyroid Hormone Enhances Bone Union at the Site of Cancellous Bone Osteotomy in Ovariectomized Rats. Hiroyuki Tsuchie*, Naohisa Miyakoshi, Yuji Kasukawa, Hiroshi Aonuma, Toyohito Segawa, Daisuke Kudo, Yoichi Shimada. Akita University Graduate School of Medicine, Japan

Purpose: Surgery for osteoporotic fracture occasionally requires several days of pretreatment to control various complications. If postoperative bone union is promoted by intermittent administration of PTH during this preoperative waiting period, the duration of post-operative bed rest may be decreased. Therefore, we evaluated the effects of preoperative PTH treatment on bone union and its mechanism of cancellous bone fracture. Method: Seven-month-old female Sprague-Dawley rats underwent ovariectomy (OVX) followed by osteotomy of the proximal tibia four weeks after OVX, then the tibiae were fixed with wire one week after osteotomy. Animals were divided into the following 6 groups (n=10-11 in each group at different time points) according to the method of human PTH administration (hPTH, 30 µg/kg body weight) or vehicle (3 times a week) before and after wiring: (1) pre-operative vehicle-treated control group (V); (2) pre-operative PTH-treated control group (P); (3) pre- and post-operative vehicle-treated group (V-V); (4) pre-operative vehicle- and post-operative PTH-treated group (V-P); (5) pre-operative PTH- and post-operative vehicle-treated group (P-V); and (6) pre- and post-operative PTH-treated group (P-P). Tibiae from the V-V, V-P, P-V, and P-P groups were harvested 2 or 4 weeks after osteotomy. Decalcified hematoxylin/eosin stained sections were used to evaluate bone union, bone volume per tissue volume (BV/TV), osteoid surface (OS/BS) and eroded surface (ES/BS). Alcian blue/hematoxylin stained sections were used to evaluate cartilage volume. Sections immunostained with PCNA, Sox9 or Runx2 were used to evaluate cell differentiation and proliferation. Result: PTH treatment significantly increased BV/TV and OS/BS, and decreased ES/BS. At 1 and 2 weeks after osteotomy, the percentages of bone union in P, P-V and P-P groups were significantly greater than these in the V, V-V and V-P (P<0.05, respectively). Cartilage volume in the P group was significantly greater than that in the V group (P<0.01). P-P group showed significantly increased percentages of cell positive for PCNA (p<0.05) and Runx2 (p<0.01), but not Sox9, compared to the V-V group at 4 and 2 weeks after osteotomy, respectively. Conclusions: Pre-operative intermittent administration of hPTH enhances bone union by promoting cartilage formation and cell differentiation to osteoblast, but not by promoting cell proliferation.

Strontium Ranelate Rebalances Adipogenesis and Osteoblastogenesis and Attenuates Bone Loss in Senescent Osteopenic Mice through NFATc/Maf and Wnt Signalling. Zuzana Saidak¹, Eric Hay², Caroline Marty¹, Alain Barbara¹, Pierre Marie^{*3}. ¹Inserm U606 & University Paris Diderot, France, ²INSERM 4606, France, ³INSERM Unit 606 & University Paris Diderot, France

Age-related bone loss is associated with a continuous decrease in bone forming activity associated with a preferential differentiation of mesenchymal stromal cells (MSC) into adipocytes. We previously showed that the anti-osteoporotic drug strontium ranelate (SrRan) activates osteoblastic cell replication, differentiation and survival through Wnt/NFATc signaling activation. Here, we investigated whether SrRan controls MSC adipogenic differentiation *in vitro* and *in vivo*. We showed that SrRan (3 mM) increased Runx2 expression and osteogenesis and decreased PPARgamma2 expression and adipogenesis in murine C3H10T1/2 and human primary MSC, indicating that SrRan regulates adipocyte/osteoblast differentiation. We then tested the effect of SrRan in senescent osteopenic SAMP6 mice which exhibit decreased osteoblastogenesis and increased adipogenesis. SAMP6 mice were administered with SrRan 5 days per week for 10 weeks at a dose-level (1800 mg/kg) providing serum Sr level equivalent to the known clinical exposition in osteoporotic treated women. DEXA and microCT analyses showed that SrRan increased tibial bone volume, trabecular thickness and number and decreased trabecular separation, resulting in higher connective density (+38%, $P < 0.05$) compared to control mice. Histomorphometric analysis confirmed that SrRan increased femoral bone volume (+38 %, $P < 0.01$) as a result of increased bone formation rate (+45%, $P < 0.001$) and decreased TRAP+ osteoclast surface and number (-31%, $P < 0.05$). Remarkably, SrRan decreased adipocyte volume (-43%, $P < 0.05$) and size (-55 %, $P < 0.05$) in the bone marrow compared to control mice. Gene expression analysis of the mice bone marrow stroma showed that SrRan increased Wnt5a mRNA level by 2-fold compared to control mice. Furthermore, SrRan increased bone marrow stroma expression of Maf, a NFATc-regulated transcription factor controlling the bifurcation between osteoblasts or adipocytes. The results show that SrRan has the potential to act on the switch between adipocyte and osteoblast differentiation of mesenchymal stromal cells *in vivo*, and suggest the implication of Wnt and NFATc/Maf signaling cascade in this effect. Restoration of the balance between osteogenesis and adipogenesis by SrRan resulted in attenuation of bone loss and improved bone microarchitecture in senescent osteopenic mice.

Elcalcitol (ED-71) Increases Bone Formation and Strength of Cortical Bone in Osteoporotic Mouse Model. Sadaoki Sakai^{*}, Koichi Endo, Keisuke Tanaka, Masahiko Mihara. Chugai Pharmaceutical Co., Ltd., Japan

The primary aim of osteoporosis treatment is to reduce bone fracture. A phase III clinical trial showed that in osteoporotic patients with sufficient vitamin D supply, elcalcitol (ED-71; a 2β-hydroxypropyloxy derivative of 1α,25(OH)₂D₃) was superior to alfacalcidol in decreasing bone resorption and reducing incidence of vertebral and non-vertebral fractures, such as wrist fractures, with safety equivalent to that of alfacalcidol (ASBMR2010, #1248). The aim of the current study was to investigate the mechanisms of ED-71 on the recovery of cancellous and cortical bone. For this purpose, we induced osteoporosis in mice by injecting them with GST-RANKL, a fusion protein of glutathione S-transferase and the extracellular domain of human receptor activator of NF-κB ligand. Two i.p. injections of GST-RANKL (each 1 mg/kg, 24h intervals) significantly reduced distal femur cancellous bone volume/tissue volume (BV/TV). Mice were given ED-71 (0.05 μg/kg, p.o.) once daily for 11 days from 3 days after the first GST-RANKL injection. On the day after the last ED-71 administration we assessed the structure, morphology, and midshaft strength of the femur. Micro-CT analysis revealed that ED-71 recovered BV/TV of both distal cancellous and midshaft cortical bone and also increased midshaft cortical thickness and strength. Morphological analysis revealed that ED-71 decreased Osteoclast surface/bone surface (Oc.S/BS) but did not change mineralizing surface/bone surface (MS/BS) or bone formation rate (BFR) of cancellous bone. However, ED-71 increased MS/BS of both periosteal and endosteal cortical bone. As a consequence of these alterations in morphology, cortical thickness and midshaft strength were increased. In summary, ED-71 treatment recovered femur BV/TV of both distal cancellous and midshaft cortical bone in GST-RANKL-induced osteoporotic mice. The morphological analyses revealed some differences in the mechanisms of ED-71 with respect to cancellous and cortical bone. In cancellous bone, ED-71 reduced bone resorption, whereas in cortical bone, ED-71 upregulated bone formation, thereby elevating cortical thickness and bone strength. This action of ED-71 on cortical bone might be one mechanism behind the reduction of non-vertebral fractures observed in osteoporotic patients treated with ED-71.

Impact of Allosteric Modulators of the Extracellular Calcium-Sensing Receptor on Human Calcitonin-Secreting C-cells. Hee Chang Mun^{*1}, Arthur Cristopoulos², Arthur Conigrave¹. ¹University of Sydney, Australia, ²Monash University, Australia

The extracellular Ca²⁺-sensing receptors (CaR) is a class C G-protein coupled receptor that plays a central role in calcium homeostasis by regulating parathyroid hormone (PTH) and calcitonin (CT) secretion. We previously demonstrated that L-amino acids (1) and γ-Glutamyl peptides (2) allosterically activate the CaR in CaR-expressing HEK-293 cells and normal human parathyroid cells. In normal parathyroid cells, L-Phenylalanine (L-Phe) and S-methylglutathione (SMG) activate intracellular Ca²⁺ mobilization and suppress PTH secretion. In the current study, we have investigated the impact of CaR activation by positive allosteric modulators including L-Phe, SMG, cinacalcet as well as the calcilytic NPS 2143 on intracellular Ca²⁺ mobilization and CT secretion from human calcitonin-secreting TT cells. TT cells were cultured in F12-K nutrient medium with 10% FBS in the presence of 100 ng mL⁻¹ human interleukin-1 beta (hIL-1β) for 48 h (3). For the analysis of intracellular Ca²⁺ mobilization, TT cells were cultured on coverslips, loaded with the Ca²⁺-sensitive dye fura-2 AM (5 μM; 1.5 h) and then analyzed for sensitivity to elevated Ca²⁺ concentration or allosteric modulators. For analysis of CT secretion, TT cells were cultured in 24-well plates with hIL-1β as above and then incubated with extracellular Ca²⁺ (0.5 to 1.5 mM) in the presence of allosteric modulators for various times (0 – 20 min). In fura-2 loaded cells, allosteric modulators (10 mM L-Phe, 30 μM SMG and 10 μM cinacalcet) enhanced intracellular Ca²⁺ mobilization in the presence of extracellular Ca²⁺ (2.0 mM) and these effects were suppressed by 20 μM NPS 2143. In experiments on CT release, we also observed enhanced sensitivity to elevated Ca²⁺ concentration in the presence of L-Phe, SMG and cinacalcet and a threshold Ca²⁺ concentration was identified at around 1.0 mM. In addition, CT secretion was suppressed in response to all these modulators by 20 μM NPS 2143. We find that positive allosteric modulators of the CaR promote intracellular Ca²⁺ mobilization and CT secretion from CT-secreting cells and that these effects are suppressed by the calcilytic NPS 2143.

Bone Mineral Values And Sex Hormones Related To Maturity In Adolescent Females. Rita Gruodyte^{*1}, Jaak Jurimae², Toivo Jurimae², Adam Baxter-Jones¹. ¹University of Saskatchewan, Canada, ²University of Tartu, Estonia

Although the role of estradiol in bone health is well established, relatively little is known with regards to the role of progesterone. The aim of this study was to evaluate the relationships of estradiol and progesterone with bone mineral density (BMD) and content (BMC) in adolescent females. In a cross-sectional sample of healthy 13-15-year-old girls (n=202), total body (TB) BMC (g) and BMD (g/cm²) as well as at femoral neck (FN) and lumbar spine (L2-L4) (LS) BMD were measured using DXA. Venous blood samples were drawn after an overnight fasting to determine the concentration of estradiol and progesterone. Years from Peak Height Velocity (PHV) was used as an indicator of biological age and was estimated using anthropometric equation parameters. Maturity groups (early, average and late maturing) were developed using a tertile split based on predicted age at PHV (APHV). When subdivided by maturity, early maturers TB BMC was inversely correlated to estradiol ($r = -0.27$; $p < 0.05$), although after adjusting for Body Mass Index (BMI), these associations disappeared ($p > 0.05$). In the average maturing group, significant correlations ($r = 0.33$, $p < 0.05$) were found between TB BMD and estradiol, whereas progesterone correlated with the TB BMC ($r = 0.32$, $p < 0.05$) and FN BMD ($r = 0.40$, $p < 0.01$). Partial correlation analysis, while controlling for BMI, confirmed these associations. In the late maturers no relationships were observed between bone parameters and sex hormones. Stepwise multiple regression analysis indicated that, in average maturers only, estradiol alone explained 8.7% and 9.1% of the total variance at TB and LS BMD, respectively. Accordingly, progesterone explained 10% and 15.6% of the total variance at TB BMC and FN BMD, respectively. Estradiol and progesterone together explained 24.5% of the total variance at the FN BMD in the average maturing group only. In conclusion positive influences of estradiol and progesterone to bone mineral variables appear to be maturity dependant.

Estrogens Attenuate Osteocyte Apoptosis via Activation of the NO/cGMP/ PKG Pathway. Nisha Marathe^{*}, Hema Rangaswami, Gerry Boss, Renate Pilz. UCSD, USA

Estrogens exert a positive effect on bone health through both genomic and extra-genomic effects. They protect osteoblasts and osteocytes from apoptosis via binding to a membrane-bound estrogen receptor and rapidly activating protein kinase B (Akt)

and the mitogen-activated protein kinases Erk-1/2. Estradiol has also been shown to rapidly increase intracellular nitric oxide (NO) and cGMP concentrations. We recently found NO/cGMP-dependent activation of Src and Erk-1/2 in mechanically-stimulated osteoblasts; therefore, we explored the role of the NO/cGMP signaling pathway in estrogen regulation of osteocyte survival.

To study the anti-apoptotic effects of estrogens, we examined etoposide-induced cell death in MLO-Y4 osteocyte-like cells by trypan blue staining, caspase-3 cleavage, and TUNEL assays. Apoptosis was completely prevented when cells were treated with estradiol, and we found that this protective effect was mimicked when cells were pre-treated with the membrane-permeable cGMP analog 8-CPT-cGMP. Pharmacological inhibition of NO synthase, soluble guanylate cyclase, or cGMP-dependent protein kinases (PKGs) reversed the anti-apoptotic effects of estradiol, supporting a requirement for NO/cGMP/PKG signaling downstream of estrogen. siRNA-mediated knock-down and viral reconstitution of individual PKG isoforms demonstrated that the anti-apoptotic effects of estradiol and cGMP were mediated by PKG I α and PKG II. We found that Akt and Erk-1/2 activation by estradiol required PKG II, and that cGMP mimicked the effects of estradiol on Akt and Erk, including induction of Erk nuclear translocation. Osteocyte apoptosis is regulated by interaction of the death-promoting protein BAD with the anti-apoptotic protein Bcl-2. The ability of BAD to interact with Bcl-2 and induce apoptosis is negatively regulated by BAD phosphorylation on Ser¹³⁶ and Ser¹⁵⁵, with Akt phosphorylating BAD on Ser¹³⁶. We found that cGMP increased BAD Ser¹⁵⁵ phosphorylation in intact osteocytes, and that PKG I phosphorylated this site in vitro. Experiments with phosphorylation-deficient BAD mutants demonstrated that the anti-apoptotic effects of cGMP and estradiol required BAD phosphorylation on Ser¹³⁶ and Ser¹⁵⁵.

In conclusion, estradiol protects osteocytes against apoptosis by activating the NO/cGMP/PKG cascade; PKG II is required for estradiol-induced activation of Erk and Akt, and PKG I α contributes to pro-survival signaling by directly phosphorylating BAD.

Flaxseed, Alone or Combined with Low-Dose Estrogen Therapy Has No Adverse Effect on Uterus Health in Ovariectomized Rats. Sandra Sacco^{*1}, Jessica J.M. Jiang², Lilian U. Thompson², Wendy Ward². ¹University of Toronto, Switzerland, ²University of Toronto, Canada

Background: The risk of adverse events associated with the use of standard-dose hormone therapy (conjugated equine estrogen + medroxyprogesterone acetate) may be reduced by using low-dose transdermal estrogen monotherapy (LD). Thus, LD may be appropriate for use by postmenopausal women with an intact uterus. Previously, we showed using ovariectomized (OVX) rats that flaxseed (FS), rich in phytoestrogen lignan and n-3 polyunsaturated fatty acids, protects against bone loss and deterioration of bone microarchitecture and strength at the lumbar vertebrae when combined with LD compared to either treatment alone. However, their combined effects on uterine tissue are unknown.

Objective: To determine the effects of FS combined with LD on markers of uterine health in OVX rats.

Study Design: 3 weeks following ovariectomy or SHAM surgery, 3-month-old female Sprague-Dawley rats (OVX, n=48; SHAM, n=12) were randomized to: 1) SHAM, 2) OVX, 3) OVX+FS, 4) OVX+LD or 5) OVX+FS+LD. Ground FS was added to the AIN-93M diet (100g/kg diet), and LD was delivered using a subcutaneous implant to deliver 0.42 μ g 17 β -estradiol/kg body weight per day, mimicking LD in postmenopausal women. After 12 weeks, uterus wet weight was determined and histological analyses of the luminal epithelium were performed to determine morphological characteristics and cell proliferation.

Results: As expected, SHAM had a significantly higher relative uterus weight (p<0.001) compared to all other groups. However, no significant differences in uterus weight were observed among OVX groups. Qualitative analyses demonstrated that luminal epithelia in the OVX group were flattened or cuboidal cells organized in a single layer while FS, LD and FS+LD treatments resulted in a single layer of elongated luminal epithelia that were columnar in shape. SHAM resulted in higher cell proliferation (p<0.05) of the luminal epithelium compared to the OVX, FS, LD and FS+LD groups. No other differences in cell proliferation were observed.

Conclusion: FS, alone and in combination with LD, does not affect uterine weight and cell proliferation at the luminal epithelium in the OVX rat model of postmenopausal osteoporosis. The observation that FS, alone and combined with LD, induces a small estrogen-like effect on the morphology of the luminal epithelium which is lower in magnitude to SHAM, suggests that FS both alone and combined with LD are not significant modulators of uterine carcinoma risk in this OVX rat model.

Gender-Specific Effects of Estrogen and Androgen on Gene Expression in Human Monocyte-Derived Osteoclasts. Jun Wang¹, Paula Stern^{*2}. ¹Northwestern University, USA, ²Northwestern University Medical School, USA

Estrogen and androgen are both critical for the maintenance of bone, but the target cells, mechanisms and responses could be sex-specific. To compare sex-specific actions of estrogen and androgen on osteoclasts, human peripheral blood mononuclear precursor cells from adult Caucasian males (n=3) and females (n=3) were differentiated into osteoclasts and then treated for 24 hr with 10 nM 17 β -estradiol or testosterone. Gene expression was studied with a custom designed qPCR-based array containing 94 target genes related to bone and hormone action. In untreated osteoclasts, only 4 genes showed significant gender differences, with the largest difference being a 776-fold greater expression of the tumor necrosis factor family member APO2L in the cells from the male donors. Treatment with 17 β -estradiol significantly affected 12 genes in osteoclasts from females and 6 genes in osteoclasts from males. Fifteen of the 18 genes responsive to 17 β -estradiol were different in the cells from the two sexes, and 2 of the genes affected by 17 β -estradiol in both sexes were regulated oppositely in the male and female-derived cells. Among the genes most highly stimulated (greater than 100-fold) by 17 β -estradiol in the cells from the female donors were integrin alpha 1, osteonectin, caspase 2 and Fas ligand. None of these genes was significantly stimulated by 17 β -estradiol in the cells from the male donors. Fas was the most highly stimulated gene (greater than 2000-fold) by 17 β -estradiol in the cells from the male donors only. Testosterone treatment significantly affected 6 genes in osteoclasts from females and 2 genes in osteoclasts from males; all except one were different in the two sexes. Among the genes most highly stimulated (greater than 100-fold) by testosterone in the cells from the female donors only were transforming growth factor beta 3, phosphatase and tensin homolog (PTEN), and intercellular adhesion molecule 1 (ICAM1). The findings indicate that although osteoclasts from both sexes respond to both 17 β -estradiol and testosterone, the cells from the two sexes respond differently to each of the hormones. The apoptotic effects may be mediated differently. The results also suggest that there are aromatase-independent effects of testosterone on the osteoclasts that are not mimicked by 17 β -estradiol. An understanding of the sex-selective skeletal responses to other stimuli including therapeutic agents could lead to more personalized and efficacious therapy.

Reduced Bone Mass and Muscle Strength in Male 5 α -Reductase Type 1 Inactivated Mice. Sara Windahl¹, Klara Sjogren^{*2}, Niklas Andersson³, Anna Borjesson¹, Charlotte Swanson², Johan Svensson², Sofia Moverare Skrtic⁴, Marie Lagerquist⁵, Claes Ohlsson⁶. ¹Center for Bone & Arthritis Research, Sahlgrenska Academy, Sweden, ²Centre for Bone & Arthritis Research, Sweden, ³Sahlgrenska University Hospital, Sweden, ⁴Center for Bone & Arthritis Research at the Sahlgrenska Academy, Sweden, ⁵Center for Bone & Arthritis Research, Sweden, ⁶Center for Bone Research At the Sahlgrenska Academy, Sweden

Androgens are important regulators of bone mass but the relative importance of testosterone (T) versus dihydrotestosterone (DHT) for the activation of the androgen receptor (AR) in bone is unknown. 5 α -reductase is responsible for the irreversible conversion of T to the more potent AR activator DHT. There are two well established isoenzymes of 5 α -reductase (type 1 and type 2), encoded by separate genes (*Srd5a1* and *Srd5a2*). 5 α -reductase type 2 is predominantly expressed in male reproductive tissues whereas 5 α -reductase type 1 is highly expressed in liver and moderately expressed in several other tissues including bone. The aim of the present study was to investigate the role of 5 α -reductase type 1 for bone mass and muscle using *Srd5a1*-/- mice.

Four-month-old male *Srd5a1*-/- mice had reduced trabecular bone mineral density (-36%, p<0.05) and cortical bone mineral content (-15%, p<0.05) but unchanged serum androgen levels compared with wild type (WT) mice. The cortical bone dimensions were reduced in the male *Srd5a1*-/- mice as a result of a reduced cortical periosteal circumference compared with WT mice. T treatment increased the cortical periosteal circumference (p<0.05) in orchidectomized WT mice but not in orchidectomized *Srd5a1*-/- mice. Male *Srd5a1*-/- mice demonstrated a reduced forelimb muscle grip strength compared with WT mice (p<0.05). Female *Srd5a1*-/- mice had slightly increased cortical bone mass associated with elevated circulating levels of androgens.

In conclusion, 5 α -reductase type 1 inactivated male mice have reduced bone mass and forelimb muscle grip strength and we propose that these effects are due to the lack of 5 α -reductase type 1 expression in bone and muscle. In contrast, the increased cortical bone mass in female *Srd5a1*-/- mice, is an indirect effect mediated by elevated circulating androgen levels.

24,25(OH)₂ Vitamin D Levels Are Elevated in Dialysis Patients. Marta Christov^{*1}, Nigel Clarke², Richard Reitz², Julia Wenger¹, Ravi Thadhani¹, Harald Jueppner¹. ¹Massachusetts General Hospital, USA, ²Quest Diagnostics, Inc., Nichols Institute, USA

25(OH) vitamin D (25D) deficiency is common in patients with chronic kidney disease (CKD) and in patients treated with dialysis, and this deficiency may contribute to the adverse outcomes observed in these cohorts. In addition, in these groups of patients increased FGF23 levels are thought to inhibit the renal 1- α hydroxylase and stimulate the 24-hydroxylase thus contributing to diminished 1,25(OH)₂ vitamin D (1,25D) levels and to the development of secondary hyperparathyroidism. Recent data suggest the presence of increased amounts of the vitamin D catabolic enzyme 24 hydroxylase (CYP24) in the kidney of humans and animals with CKD, which may contribute to both 25D deficiency (by direct modification and subsequent metabolism into inactive analogs) as well as 1,25D deficiency (by "siphoning off" of the precursor 25D and direct modification of 1,25D). The absolute levels of 24,25(OH)₂ vitamin D (24,25D) in the CKD/dialysis population, and thus the level of 24-hydroxylase activity, are unknown. Using a novel mass spectrometry approach, we measured 24,25D levels in the circulation of 120 individuals with no known renal dysfunction and 60 patients initiating hemodialysis. In the controls, 24,25D levels were correlated with 25D status, i.e. individuals with lower total 25D levels had lower 24,25D levels. For example, the mean 24,25D level in individuals with 25D levels <20 ng/mL was 1.270.3 ng/mL (meanSEM), while in individuals with 25D levels >30 ng/mL it was 6.10.56 ng/mL (meanSEM). In the dialysis population the ratio of 24,25D to 25D levels was significantly elevated; patients with baseline 25D levels <20 ng/mL had an increased 24,25D level of 9.01.26 ng/mL (meanSEM), at times rising above the absolute 25D level in individual patients. 24,25D levels correlated positively with 25D, calcium and albumin. Treatment with an active vitamin D analog did not increase 24,25D levels and neither did the dialysis procedure itself. Given that FGF23 is a strong inducer of the 24-hydroxylase, studies to assess the correlation between 24,25D and FGF23 levels are ongoing. In summary, 24,25D levels in dialysis patients are increased compared with those in the control population, which may reflect increased 24-hydroxylase activity and contribute to 25D deficiency.

An Immunoassay for Free 25 Hydroxy Vitamin D. Mike Martens^{*1}, Frans Rosmalen², Leon Swinkels¹, Erik Harbers³, George Parsons⁴. ¹Future Diagnostics, The Netherlands, ²Future Diagnostics BV, The Netherlands, ³Future Diagnostics, Netherlands, ⁴Parsons Group LLC, USA

The objective of this study was to develop an immunoassay for free 25 Hydroxy Vitamin D [25(OH)VitD]. Binding proteins for 25 Hydroxy Vitamin D₂ and D₃ are altered by some of the same factors that control thyroid hormone binding protein levels. Pregnancy and oral contraceptive use increase both thyroid and 25(OH)VitD binding proteins and the corresponding total analyte concentrations may give misleading results. Liver disease decreases both thyroid and 25 (OH)VitD binding protein levels and total 25(OH)VitD. Total 25(OH)VitD levels may underestimate vitamin levels. End stage renal disease and dialysis also represent interesting challenges for measurement of free versus total 25(OH)VitD.

Binding protein levels may play an important role in 25(OH)VitD bioavailability, and current assays destroy that information with sample pretreatment steps before the actual assay begins.

Our novel Free 25(OH)VitD assay captures information on both the total 25(OH)VitD levels and the serum binding protein status in a simple, easily automatable format. Antibodies reactive with 25(OH)VitD are immobilized on traditional solid phases such as microtiter wells or superparamagnetic particles. Standards, controls and patient samples are exposed to these antibodies in a simple buffer and allowed to react. Free 25(OH)VitD is captured on the antibody and accumulated during a 90-minute incubation. The solid phase is then washed and a labeled analog of 25(OH)VitD is allowed to react with the remaining antibody in a second incubation. This incubation is followed by another wash and quantitation of the signal, which is inversely proportional to the level of free 25(OH)VitD in the sample. The assay was calibrated against a symmetric dialysis method.

Measurements of free 25(OH)VitD in samples from third trimester pregnancy confirmed a significantly higher total 25(OH)VitD than in controls. The free 25(OH)VitD in these subjects was comparable or even lower than in controls.

We have developed a free 25(OH)VitD assay capable of determining the actual Vitamin D status in critical patient groups.

SU0486

Immunoassay for 25 hydroxy vitamin D. Leon Swinkels^{*1}, Antwan Maas², Mike Martens¹, Frans Rosmalen³. ¹Future Diagnostics, The Netherlands, ²Future Diagnostics, Netherlands, ³Future Diagnostics BV, The Netherlands

The objective of this study was to develop an immunoassay for 25(OH)Vitamin D [25(OH)VitD]. About 85% of the circulating 25(OH)VitD is bound to Vitamin D binding Protein (DBP) with a relatively high affinity. The accuracy of 25(OH) Vitamin D measurement in serum by immunoassay depends among others on the efficiency of the release of endogenous 25(OH)Vit D from DBP.

There are several approaches to eliminate the effect of DBP in the assay for 25 (OH)Vit D. Organic solvents may be used to solubilize and separate 25(OH)Vit D from its binding protein. For this purpose ethanol can be used, but this method requires centrifugation of the denatured protein and therefore is not suitable for automation. Methods that do not require a separation step, may rely on competitive displacement using compounds such as Anilino Sulfonic Acid (ANS), or on displacement of bound 25(OH)Vit D by lowering the pH.

We propose an alternative method for the release of 25(OH)Vit D based on fluoro-alkyl surfactants. We used an antibody that recognized 25(OH)Vit D₂ as well as 25 (OH)Vit D₃.

The surfactant effectively releases 25(OH)Vit D from DBP. The efficacy of the release was compared with the efficiency of displacement using a combination of methanol and ANS. The displacement was monitored using 3H-25(OH)Vit D. The apparent residual binding was less using the fluoro-alkyl surfactant than with methanol/ANS.

The results of the assay using the alternative release composition were compared with the results obtained by LCMS. A good correlation was observed (r=0.945, n=40, range 6-60 ng/ml).

We conclude that this alternative release approach is an effective, easily automatable method for the assay of 25(OH)Vit D.

Mechanisms Involved in Altered Calcium Homeostasis in the Klotho Knockout Mouse. Leila J. Mady^{*1}, Puneet Dhawan², Angela Porta³, Makoto Kuro-o⁴, Sylvia Christakos¹. ¹University of Medicine & Dentistry & New Jersey - New Jersey Medical School, USA, ²UMDNJ, USA, ³Kean University, USA, ⁴The University of Texas Southwestern Medical Center at Dallas, USA

Klotho is a multifunctional protein and cofactor for FGF23 involved in phosphate and calcium homeostasis. A premature aging phenotype has been described in klotho deficient mice. Klotho knock out (KO) mice have increased serum calcium, renal 1 α (OH)ase and serum 1,25(OH)₂D₃ and decreased serum PTH. In klotho KO mice upregulation of 24(OH)ase by 1,25(OH)₂D₃ is significantly reduced by 6 weeks of age. To understand the mechanisms of the premature aging phenotype we examined genes and transcription factors involved in calcium homeostasis and the activity of VDR and VDR coactivators by in vivo ChIP. Since studies from our lab indicate that CARM1 [a methyltransferase that methylates histone 3 at arginine 17 (H3R17)] is a coactivator with VDR of 24(OH)ase transcription and ChIP-seq analysis identified 1,25(OH)₂D₃ dependent genome wide co-occurrence of VDR binding and H3R17 methylation in kidney cells, in vivo ChIP assays were done examining VDR binding and H3R17 methylation in response to 1,25(OH)₂D₃. In vivo ChIP revealed a significant 2-4 fold decrease in VDR binding and H3R17 methylation at the 1,25 (OH)₂D₃ regulatory regions of the 24(OH)ase gene in kidney of 6 week old klotho KO mice compared to WT mice and aging 50 week old mice respectively, suggesting that in kidney prolonged exposure to high levels of 1,25(OH)₂D₃ results in desensitization to 1,25(OH)₂D₃. In klotho KO mice we also found a significant decrease in renal C/EBP β (3 fold compared to WT). Since C/EBP β is a transcription factor that inhibits 1 α (OH)ase transcription, our findings suggest that decreased renal C/EBP β is one factor involved in the increase in 1 α (OH)ase in klotho KO mice. In klotho KO mice intestine there is an induction of TRPV6 and calbindin-D_{9k} and an increase in intestinal calcium absorption. Calbindin-D_{9k} is increased in all regions of the intestine (6-46 fold compared to WT; highest induction in ileum, cecum and colon). In vivo ChIP in the klotho KO mouse intestine indicates enhanced binding of cdx2 at the cdx2 regulatory regions in the calbindin-D_{9k} gene. In the aging 50 week old mouse there is a marked decline in calbindin and in intestinal calcium absorption. These findings, which indicate that the mechanisms involved in the phenotype of klotho KO mice are in contrast to changes observed in aging mice, highlight the importance of klotho in the regulation of calcium homeostasis and provide new insight into molecular mechanisms related to the phenotype of the klotho KO mouse.

Multiple Sclerosis and Chronic Diseases Is More Frequent in Young Adults Born in Summer Versus Winter – An Effect of Vitamin D Status?. Susanna Streyms Thomsen*, Lars Rejnmark, Leif Mosekilde, Peter Vestergaard. Aarhus University Hospital, Denmark

Background: Development of diseases such as type 1 diabetes mellitus (T1D), infections and multiple sclerosis (MS) is believed to result from the interaction between imprinting of genes and environmental factors, including vitamin D status at the time of conception, intrauterine growth or time of birth. Vitamin D status is among other factors dependent on maternal exposure to sunlight and therefore dependent on season of the year.

Hypothesis: Occurrence of later diseases such as T1D, infection and MS is influenced by time of gestation or time of birth.

Aim: To investigate relations between T1D, infections, MS and season of gestation and intrauterine growth in people living in Denmark.

Design: Cohort studies in Denmark using 3 birth cohorts followed until December 31, 2009.

Material and Methods: Data were obtained from 1) all children born in 1940 (n=72.839), 2) all children born in 1977 (n=89.570) and 3) all children born in 1996 (n=74.015). Information on death and migrations were obtained from the central person register along with all contacts to hospitals (1977-2009) which were obtained from the National Hospital Discharge Register. The main exposure variable was month of birth (subdivided into: summer, i.e. April-September and winter, i.e. October-March) and the main outcome variable was occurrence of T1DM, occurrence of MS, or hospitalization due to infections.

Statistical analyses were done using one sided Fishers Exact test and Kaplan-Meier survival plots using IBM SPSS version 19.

Results: There were no associations between T1D or infection in terms of time of birth in any of the three birth cohorts. There was an association between MS and time of birth, as 60.2% (n=62) with the diagnosis of MS was born in summertime and 39.8% (n=41) were born in wintertime (p=0.046) in the 1977 cohort. Fig. 1 shows the Kaplan-Meier survival curve, diseases of free survival. However, no association between time of birth and MS was present in the 1940 cohort. In the 1996 cohort, too few cases of MS were present for analysis.

Conclusion: MS in subjects less than 35 years of age may be related to season of birth and thus maternal vitamin D exposure. In subjects older than 35 years (the 1940 cohort, which was followed from 1977 and onwards) the effect of season could not be confirmed. Decreased exposure to sun in the winter time leading to low vitamin D levels during pregnancy is a possible explanation and this needs further research.

Novel Mechanism of Negative Regulation of 1,25-Dihydroxyvitamin D₃ Induced 24(OH)ase Transcription: Epigenetic Modification Involving Cross-talk Between Protein Arginine Methyltransferase 5 and the SWI/SNF Complex. Sneha Joshi*¹, Tanya Seth², Puneet Dhawan³, Said Sif⁴, Sylvia Christakos². ¹UMDNJ-NJMS, USA, ²University of Medicine & Dentistry & New Jersey - New Jersey Medical School, USA, ³UMDNJ, USA, ⁴Ohio State University, USA

The mammalian SWI/SNF chromatin remodeling complex facilitates gene transcription by remodeling chromatin using the energy of ATP hydrolysis. Each SWI/SNF contains two homologous ATPases, BRG-1 and BRM. Recent studies have indicated an interplay between histone modifying enzymes and chromatin remodeling factors. Among the histone modifying enzymes are the protein arginine methyltransferases (PRMTs) which have been implicated in transcriptional activation or repression. Little is known however about the role of SWI/SNF and PRMTs in vitamin D receptor (VDR) mediated transcription. Using SW13 and C33A cells, which are deficient in BRM and BRG-1, we found that 1,25(OH)₂D₃ induction of 24(OH)ase transcription is markedly reduced (6 – 10 fold), suggesting that the SWI/SNF complex is an important component of VDR mediated transcription. Activation of transcription was restored in these cells preferentially by BRG-1. In UMR osteoblastic cells the N-terminal region of BRG-1 (BRG-1-N), that acts as a dominant negative inhibitor, inhibits 1,25(OH)₂D₃ induction of 24(OH)ase expression 2 fold as indicated by Western blot analysis. Mutant BRG-1 also inhibits C/EBPβ enhancement of VDR mediated 24(OH)ase transcription and expression. Immunoprecipitation assays indicate that BRG-1 associates with C/EBPβ. Chromatin immunoprecipitation assays show that C/EBPβ and BRG-1 bind simultaneously to the 24(OH)ase promoter. BRG-1 enhancement of VDR mediated transcription is not observed using a 24(OH)ase promoter construct with the C/EBP site mutated. Here we further show that PRMT5, a type II PRMT that dimethylates histone 3 at arginine 8 (H3R8) and histone 4 at arginine 3 (H4R3) inhibits BRG-1 and C/EBPβ enhancement of 1,25(OH)₂D₃ induced 24(OH)ase transcription. In the presence of PRMT5 (100ng) the 3 fold enhancement of VDR mediated 24(OH)ase transcription observed in the presence of BRG-1 and the 5 fold enhancement in the presence of both BRG-1 and C/EBPβ (100ng each) are inhibited. 1,25(OH)₂D₃ induction of 24(OH)ase transcription is also inhibited (2 fold) by PRMT5 (p<0.05 transcriptional activation in the presence or absence of PRMT5). Using a catalytically inactive PRMT5 (methylation of H3 and H4 is lost) negative regulation of 24(OH)ase transcription is not observed. ChIP assays show that PRMT5 associates with BRG-1 at the C/EBP site. These studies define epigenetic events linked to a novel mechanism of negative regulation of VDR mediated transcription.

Role of TAF12 in the Increased VDR Activity in Paget's Disease of Bone. Jumpei Teramachi¹, Huiling Cao¹, Jolene Windle², G. David Roodman³, Noriyo Kurihara¹. ¹University of Pittsburgh & The Center for Bone Biology at UPMC, USA, ²Virginia Commonwealth University, USA, ³University of Pittsburgh, The Center for Bone Biology at UPMC, & VA Pittsburgh Healthcare System, USA

We reported that osteoclast precursors (OCL-P) from Paget's (PD) patients expressing measles virus nucleocapsid protein (MVNP) are hypersensitive to 1,25-(OH)₂D₃ (1,25-D₃) and form OCLs at physiologic rather than pharmacologic levels of 1,25-D₃. The increased 1,25-D₃ sensitivity was mediated by TAF12, a coactivator of VDR, which is expressed at higher levels in PD OCL than normals. These results suggest TAF12 plays an important role in the abnormal OCL activity in PD. We then generated transgenic mice in which TAF12 expression is targeted to the OCL lineage (TAF12 mice). OCL-P from TAF12 mice formed OCL at very low levels of 1,25-D₃, and had a similar responsiveness to RANKL as wild type (WT) mice. However, TAF12-OCL-P did not form hyper-multinucleated OCL characteristic of PD. In contrast, inhibition of TAF12 with a specific TAF12 antisense construct decreased OCL formation and OCL-P sensitivity to 1,25-D₃ in PD bone marrow samples. Thus, TAF12 plays an important role in induction of the 1,25-D₃ hypersensitivity of OCL-P from PD patients. However, the molecular mechanisms underlying both 1,25-D₃'s effects on OCL formation and the contribution of TAF12 to these effects in both normals and PD patients are undefined. Therefore, we performed ChIP analysis, using an anti-TAF12 antibody, and demonstrated TAF12 binds the 24-hydroxylase (Cyp24a1) promoter, which contains two functional VDREs in the presence of 1,25-D₃. Since TAF12 in kidney cells directly interacts with ATF7 and potentiates ATF7-induced transcriptional activation of ATF7-driven genes, we determined if TAF12 is a functional partner of ATF7 in OCL-P. Interestingly, ATF7 was also increased in OCL-P from mice expressing MVNP in their OCL. ATF7 expression was detected in OCL-P lysates from MVNP mice and was not further increased by 1,25-D₃. Expression of TAF4 was not affected by MVNP. Immunoprecipitation of lysates from either WT or MVNP expressing OCL-P with an anti-TAF12 antibody and blotting with an anti-ATF7 antibody or vice versa revealed that TAF12 and ATF7 physically interact in OCL-P. Importantly, TAF12-dependent ATF7-regulated transcriptional activation was inhibited by TAF4, which binds both ATF7 and TAF12. We also showed that knockdown of ATF7 decreased Cyp24 sensitivity to 1,25-D₃ as well as TAF12 levels in MVNP-expressing cells. These results show that

ATF7 interacts with TAF12 and may be involved in the upregulation of TAF12 and the hypersensitivity of OCL-P to 1,25-D₃ in PD.

Serum 25OHD Changes Following High Rates of Sun Exposure in Young Subjects with Pigmented Skin Living in the Tropics. Estela Carvalho¹, Amanda Melo¹, Lara Voss¹, Daniele Fontan², Narriane Holanda³, Francisco Bandeira^{*4}. ¹Agamenon Magalhaes Hospital, Brazil, ²Brazil, ³Agamenon Magalhaes Hospital, Bra, ⁴UPE, Brazil

Objective: To Evaluate the changes in serum 25OHD levels after prolonged (from 6-10 am) sunlight exposure :in 10 healthy subjects (7 females and 3 males, mean age 33.7.4 years, body mass index(BMI) 23.7. 3.32 kg/m², with a exposed body surface area of 73.8. 22.7%, mean of PTH levels 47.9933.69, mean of calcium levels 9.520.43, mean of albumin levels 4.210.24, mean of creatinine levels 0.790.17) who were evaluated on beaches along the coast of Recife(8°S). Regarding the skin phototype(Fitzpatrick classification), 80% had type 3 or more. **Methods:** Anthropometric data and information on skin phototype and sun exposure x fraction of body surface area exposed (BSA) were collected and, serum 25OHD was measured before and after sunlight exposure without sunscreen. **Results:** The mean estimated irradiance at the 4h period was 4.0602.107 watts/m². Mean serum 25OHD increased from 22.595.45 ng/ml to 24.396.60 ng/ml(p<0.05) at the end of 4h period; and to 25.80 5.81 ng/ml one week after sun exposure(NS). **Conclusion:** Although statistically significant, the changes in serum 25OHD levels were minimal in absolute terms (mean of 3ng/ml) for the very large amount of UV received. Considering the harmful effects of this amount of sun exposure on skin health, our data demonstrated that oral vitamin D supplementation may be a preferable approach to achieve optimal serum 25OHD concentration.

The Efficacy of High-Dose Oral Vitamin D₃ Administered Once a Year: Is the Increased Risk of Falls Attributable To Changes in Muscle Strength? Kerrie Sanders^{*1}, Amanda L Stuart¹, Elizabeth J Williamson¹, Julie A Simpson¹, Mark Kotowicz², Geoffrey Nicholson³. ¹University of Melbourne, Australia, ²Barwon Health, Australia, ³The University of Queensland, Australia

We have previously reported an increased rate of falls and fractures in a RCT using a single annual dose of 500,000IU cholecalciferol administered orally to 2,256 older women in fall or winter for 3 to 5 years¹. The increased rate of falling in the vitamin D group was higher in the first 3 months following dosing (p=0.017) suggesting an adverse mechanism in the immediate post-dose period. Serial biochemistry and physical assessments were done on a sub-study of 97 randomly selected participants. Serum 25-hydroxyvitamin D (25D) was measured using DiaSorin immunoassay. Muscle strength was measured at the hip flexion, quadriceps and hip abduction using a NicholasTM Manual Muscle Tester and is reported at 3-month post dose, ≥2 years after recruitment. The peak force (kg) required to break an isometric muscle contraction was measured as the examiner applied force against the participant. For each participant 3 trials were performed and averaged for each muscle group.

The median baseline serum 25D was 49nmol/L. The vitamin D group, 1-, 3- and 12-month median post dose levels were 124, 93 and 62nmol/L, respectively. Our post-hoc analysis used a linear regression model for hip flexion strength at 3-months post-dose and included age, baseline strength and change in 25D as covariates. The analysis was stratified by whether or not the change in 25D was more than 150% of the baseline serum 25D. For the group with smaller increases in 25D (<150%), increases in 25D were associated with progressively increased hip flexion strength whereas the group with larger increases in 25D (>150%) were associated with decreasing strength (estimated mean change in hip flexion strength associated with a 10 nmol/L unit increase in 25D = 0.38 kg {95% CI: 0.1, 0.7} vs -0.26 kg {95% CI: -0.6, 0.06}; Group<150% vs Group>150% increase in 25D, respectively). There was heterogeneity of the two effects (p=0.003). For quadriceps and hip abduction, the direction of effects in the two strata followed similar patterns, but the p-values for heterogeneity were not significant.

These findings suggest a threshold effect of vitamin D status and are consistent with a U-shaped association reported between frailty status and 25D levels². Analysis of muscle biomarkers and vitamin D metabolites will further progress our understanding of a mechanism underlying the occurrence of increased falls following annual high-dose vitamin D supplementation.

The Vitamin D Analog Eldecalcitol (ED-71) Is a Potent Regulator of Intestinal Phosphate Absorption and NaPi-IIb. Alex Brown^{*1}, Cynthia Ritter². ¹Washington University in St. Louis School of Medicine, USA, ²Washington University School of Medicine, USA

The vitamin D analog eldecalcitol [1α,25-dihydroxy-2β-(3-hydroxypropyloxy) vitamin D3] has been developed for treatment of osteoporosis. We have previously reported that this analog has greater potency than calcitriol, the natural vitamin D hormone, on intestinal calcium and phosphate (Pi) absorption. In the present study, we further investigated the actions of eldecalcitol on Pi absorption and induction of the intestinal sodium/phosphate cotransporters. Vitamin D-deficient rats were treated orally with 0, 20, 50 or 150 pmol of eldecalcitol or calcitriol q.o.d. for 12 days. Serum phosphate levels rose slightly, but not significantly, with eldecalcitol, while they were unchanged by calcitriol. Duodenal Pi absorption, measured by the in situ loop method, was increased maximally by 8-fold increase with the 20 pmol dose of eldecalcitol, while none of the doses of calcitriol were effective. This action of eldecalcitol was attributable to a dramatic 24-fold induction of NaPi-IIb (SLC34A2) mRNA in the duodenum; Pit-1 (SLC20A1) and Pit-2 (SLC20A2) mRNA levels were not increased. An additional experiment with a shorter treatment period confirmed the induction of NaPi-IIb mRNA in the duodenum and jejunum, but not the ileum, while calcitriol was ineffective in all segments. Surprisingly, lung NaPi-IIb was not increased by eldecalcitol, despite its co-expression with the VDR in alveolar type II cells. These studies indicated that chronic oral administration of eldecalcitol potentially stimulates intestinal Pi absorption via induction of NaPi-IIb. Further investigation of the mechanism for the induction, and cell specificity, is underway.

The Association Between Mortality and Vitamin D Levels is U-shaped: A Study from the Primary Health Care, Denmark. Darshana Durup^{*1}, Henrik J Jørgensen², Peter Schwarz³, Anne-Marie Heegaard¹, Bent Lind⁴. ¹Faculty of Pharmaceutical Sciences, University of Copenhagen, Denmark, ²Department of Clinical Biochemistry, Bispebjerg Hospital, Denmark, ³Glostrup Hospital, Denmark, ⁴Copenhagen General Practitioners Laboratory, Denmark

Aim

The aim of this investigation was 1) to determine the prevalence of vitamin D deficiency and secondary hyperparathyroidism (SHPT); 2) to investigate the association of mortality with the levels of 25-hydroxyvitamin D (25(OH)D), calcium and parathyroid hormone (PTH) in the primary health care

Methods

Vitamin D results from 247,546 subjects referred from the general practitioners in the Copenhagen area (population 1.1 mill) and s-PTH (n=34,990) and s-calcium (n=111,524) results from the subjects were included in the study. Blood samples were collected from 2004 to 2010. The 3-year mortality associated with SHPT was studied by Kaplan-Meier analysis. The association between 3-year mortality and 25-hydroxy vitamin D, calcium and PTH serum levels was graphed and the odds ratios were calculated. The study protocol was approved by the Danish Data Protection Agency

Results

The prevalence of vitamin D deficiency, based on serum 25-hydroxyvitamin D (s-25(OH)D), were as follows; s-25(OH)D < 50 nmol/L: 53.3 %; s-25(OH)D < 25 nmol/L: 20.5 %; and s-25(OH)D < 12.5 nmol/L: 5.4 %. Mean age was 50.8 (females) and 51.4 years (males). 11.08% suffered from SHPT (n=29,939). Analysis of mortality as a function of serum 25(OH)D, calcium (s-calcium) and PTH (s-PTH) levels showed a U-shaped association for all three parameters. The lowest mortality was observed in subjects with s-25(OH)D ranging 60-70 nM. When compared to the overall mortality at the 60 nM s-25(OH)D level, the odds ratios were 1.78 for 25(OH)D levels ≤10nM and 1.86 for levels ≥140 nM. The corresponding numbers for subjects above 60 years of age (n=91,195) were 2.82 and 2.22, respectively. When compared to the overall mortality at the 4 pM serum PTH level, odds ratios were 2.62 for serum PTH levels ≤1 pM and 7.32 for levels ≥14 pM. When compared to the overall mortality at the 2.4 mM serum calcium level, odds ratios were 18.75 for levels ≤2 mM and 4.63 for levels ≥2.7 mM

Conclusion

In the general population vitamin D deficiency was not only prevalent (53.3%), but also severe; 11.2 % of the vitamin D deficient subjects also suffered from SHPT. Both high and low serum levels of 25(OH)D, calcium and PTH were associated with increased mortality. Attention must be paid to this U-shaped correlation.

Further investigations specifically aimed at elucidating causal relationships between s-25(OH)D and mortality and morbidity are needed to make recommendations more evidence-based.

Vitamin D Binding Protein and Monocyte Responsivity to 25-hydroxyvitamin D and 1,25-Dihydroxyvitamin D: Analysis by Mathematical Modeling. Rene Chun^{*}¹, Brad Peercy², Arthur Sherman³, John Adams⁴, Martin Hewison⁵.
¹Orthopedic Hospital Research Center UCLA, USA, ²Dept. Mathematics & Statistics, University of Maryland at Baltimore County, USA, ³NIDDK - LBM - Math Cell Modelling Section, USA, ⁴University of California, Los Angeles, USA, ⁵UCLA, USA

Studies *in vitro* have shown that vitamin D can regulate many biological activities. However, the relevance of these activities is unclear because binding of both 25-hydroxyvitamin D (25OHD) and 1,25-dihydroxyvitamin D (1,25(OH)₂D) to the serum vitamin D binding protein (DBP) will be greater *in vivo* than in cell culture. We hypothesize that DBP is a key determinant of the tissue bioavailability of 25OHD and its subsequent metabolism to 1,25(OH)₂D by the enzyme 1 α -hydroxylase (CYP27B1). DBP exists in allelic forms (GC1F, GC1S, GC2) that circulate at different levels (GC1F>GC1S>GC2) and exhibit differing affinities for vitamin D metabolites (GC1F>GC1S>GC2). To predict the impact of DBP level/genotype on biological activity *in vivo*, we developed a 'steady state' mathematical model to estimate levels of free 25OHD and 1,25(OH)₂D under different DBP conditions. Results with this model show that in 100% serum with 50 nM 25OHD and 100 pM 1,25(OH)₂D, <0.05 nM 25OHD (0.1%) and <1.5 pM 1,25(OH)₂D (1.5%) are 'free'. Levels of free 25OHD and 1,25(OH)₂D increase 3-fold from GC1F/1F to GC2/2 given the same total ligand concentrations. To explore the biological impact of DBP, a 'dynamic' mathematical model was generated incorporating localized CYP27B1 activity and binding of 1,25(OH)₂D to the vitamin D receptor (VDR). This model was based on published biochemical data and *in vitro* data for 25OHD/1,25(OH)₂D-mediated induction of the antibacterial cathelicidin gene product (CAMP) in human monocytes. Using this model, we predicted the induction of CAMP expression *in vivo* under various activation parameters relative to DBP levels and genotype. Induction of CAMP was minimal in unactivated conditions. However, enhanced expression of VDR (5-fold) and CYP27B1 (10-fold) supported 25OHD-mediated induction of CAMP (greater than 5-fold). Intracellular metabolism of 25OHD to 1,25(OH)₂D (opposed to exogenous 1,25(OH)₂D) was the most viable mode for vitamin D-mediated induction of CAMP *in vivo*. As with the 'steady state' model, the 'dynamic' model predicted *in vivo* induction of CAMP by 25OHD would be lower for high affinity forms of DBP (e.g. GC1F). These new models underline the importance of DBP as a determinant of vitamin D 'status.' In particular, DBP affinity data have implications for circulating 25OHD and 1,25(OH)₂D levels and subsequent vitamin D supplementation strategies in patients with specific DBP genotypes.

Analyses of Gene Expression in hMSC Indicate Age-Associated Loss of Self-Regeneration and Function. Peggy Benisch^{*1}, Sonke Frey², Lothar Seefried¹, Ludger Klein-Hitpass³, Moustapha Kassem⁴, Regina Ebert⁵, Franz Jakob¹. ¹University of Würzburg, Orthopedic Center for Musculoskeletal Research, Germany, ²Hospital University Würzburg, Department of Trauma-, Hand-, Plastic- & Reconstructive Surgery, Germany, ³Hospital University Essen, Institute of Cell Biology, Germany, ⁴Odense University Hospital, Denmark, ⁵University of Würzburg, Orthopedic Center for Musculoskeletal Research, Germany

Mesenchymal stem cells represent the basis of bone formation, because as multipotent cells they can differentiate into many cell types important for bone homeostasis, e.g. osteoblasts. During aging an imbalance between bone formation and bone resorption occurs, which results in reduced bone mass. It is still unclear whether MSC biology is directly involved in reduced bone formation associated with age or osteoporosis, e.g. by accumulating malfunctions or by entering replicative senescence.

In this study, age-associated changes in gene expression of human MSC (hMSC) were determined by performing microarray hybridizations and data analyses with SAM. RNA of hMSC isolated from patients of old age (+ 80 years) was compared to control hMSC from patients of younger age (45-57 years). Moreover, the gene expression patterns of *in vitro* aged, senescent hMSC was compared to the pattern of hMSC from patients of old age to perform a comparison between *ex-vivo* and *in vivo* aging. Human MSC of patients diagnosed with primary osteoporosis were also examined because osteoporosis is a polygenetic disease of aged bone.

Systems biology based interpretation of the microarray data revealed that senescent hMSC, *in vivo* aged hMSC as well as hMSC from patients with osteoporosis showed deficiency in proliferation, differentiation capacity and migration despite the fact that all three hMSC populations exhibited only few similarities in gene expression pattern. Genes that were lower expressed (42 in total) in all three different hMSC populations were linked to chromosome condensation and DNA repair.

Furthermore, in hMSC from patients with osteoporosis we detected genes responsible for enhanced osteoclastogenesis (CSF1, COX2, ANGPTL4) and promising candidates for osteoporosis with respect to inhibition of osteogenesis. SOST as an inhibitor for WNT signaling, as well as MAB21L2 as an inhibitor for BMP signaling were higher expressed in those cells.

In summary, our findings suggest that *in vivo* aging does not necessarily result in senescent stem cells, because the aging of an organism is a multicellular process, which is influenced by many other factors, e.g. accumulation of mutations and tumor defense. Furthermore reduced bone formation in osteoporosis could be connected to autoinhibition of the stem cells, as well as reduced differentiation capacity and migration. We can hypothesize that hMSC serve less efficiently as a regenerative source for osteogenesis in aged-associated bone loss.

Borage and Fish Oils Lifelong Supplementations Decrease Inflammation and Improve Bone Health in a Murine Model of Senile Osteoporosis. Fabien Wauquier^{*1}, Laurent Leotoing², Claire Philippe², Elisabeth Miot Noiraull³, Veronique Coxam⁴, Yohann Wittrant⁵. ¹INRA, UMR 1019, UNH, CRNH Auvergne, F-63009 Clermont-Ferrand, France, France, ²INRA, France, ³INSERM, France, ⁴INRA Theix, France, ⁵Institut National de la Recherche Agronomique, France

Fats are prevalent in western diets; they have known deleterious effects on muscle insulin resistance and may contribute to bone loss. However, relationships between fatty acids and locomotor system dysfunctions in elderly population remain controversial. The aim of this study was to analyze the impact of fatty acid quality on the age related evolution of the locomotor system and to understand which aging mechanisms are involved. In order to analyze age related complications, the SAMP8 mouse strain was chosen as a progeria model as compared to the SAMR1 control strain. Then, two months old mice were divided in different groups and subjected to the following diets : (1) standard "growth" diet - (2) "sunflower" diet (high $\omega 6/\omega 3$ ratio) - (3) "borage" diet (high γ -linolenic acid) - (4) "fish" diet (high in long chain $\omega 3$). Mice were fed *ad libitum* through the whole protocol. At 12 months old, mice were sacrificed and tissues were harvested for bone studies, fat and muscle mass measures, inflammation parameters and bone cells markers expression. We demonstrated for the first time that borage and fish diets restored inflammation and bone parameters using an original model of senile osteoporosis that mimics clinical features of aging in humans. Therefore, our study strongly encourages nutritional approaches as relevant and promising strategies for preventing aged-related locomotor dysfunctions.

Botulinum Toxin Type A Does Not Directly Affect Bone Cell Viability or Differentiation. Susan Grimston^{*}, Marcus Watkins, Roberto Civitelli. Washington University in St. Louis School of Medicine, USA

Botulinum toxin Type A (BtxA) has been used recently to model disuse bone loss, as a single intramuscular injection of BtxA results in muscle paralysis rapidly followed by profound bone loss, attended by sharply increased osteoclast number and bone resorption. However, it can be argued that the BtxA-induced bone loss might be attributed in part to a direct effect of BtxA on bone cells. We tested this hypothesis in macrophages derived from bone marrow of mouse tibiae and femora (as an osteoclast model), and in the MC3T3 osteoblastic cell line. For osteoclast differentiation, non-adherent bone marrow cells, which include macrophages, were cultured in the presence of M-CSF and Rankl to promote osteoclast differentiation. Osteoclasts were visible after 4-5 days in culture as TRAP+ multinucleated cells. Osteoblast like MC3T3 cells were cultured in α -MEM without ascorbic acid. Both osteoblast and osteoclast cultures were incubated with BtxA for 24 hours at concentrations ranging from 12.5mU/100 μ l to 200mU/100 μ l. Cell viability, assessed by the MTT method, was not affected by BtxA in either MC3T3 (93.0225.1% to 135.5428.5% of non-treated control cultures) or macrophage/osteoclast cultures (82.5414.52% to 119.6132.22% of control). By contrast, 10 μ M tamoxifen caused osteoclast cell death and 10% EtOH caused MC3T3 cell death, 1.282.2% and 3.271.2% viability of control, respectively. Importantly we detected no effects of BtxA at any concentrations on the number of TRAP positive cells. Furthermore, exposure of macrophage cultures to BtxA during differentiation into osteoclasts showed no effect of treatment on either osteoclast differentiation or cell viability (83.028.7% to 127.1710.18% of controls); and BtxA did not promote osteoclast differentiation in the absence of Rankl. These data demonstrate that BtxA does not affect bone cell viability at concentrations used in mice *in vivo*, and does not affect the differentiation of macrophages into osteoclasts. Therefore it is unlikely that a direct effect of BtxA on osteoclast viability or differentiation may explain the sharp increase in endocortical bone resorption, osteoclast activation and bone loss occurring after intramuscular BtxA injection in mice. Bone loss in this model is more likely due to local muscle paralysis and its resulting decreased force production. The BtxA model of bone loss is therefore an effective tool for modeling disuse osteoporosis.

Muscle Strength and its Relationship to Inflammation Markers and Antioxidants Intake in Elderly Women. Patr cia Genaro^{*1}, Marcelo Pinheiro², Ligia Martini³, Vera Szejnfeld⁴. ¹Universidade Federal de Sao Paulo, Brazil, ²Sao Paulo Federal University/ Unifesp/ Escola Paulista De Medicina, Brazil, ³University of Sao Paulo, Brazil, ⁴UNIFESP/EPM, Brazil

Inflammation markers are associated with physical decline and this association may point to a role of inflammation in age-related decline in muscle mass and strength. On the other hand, diet plays an important function by contributing to muscle protein turnover and an antioxidant system as well. The aim of the present study is to evaluate the relationship between muscle mass and strength, antioxidant intake and inflammatory markers in elderly women. This cross-sectional study comprised 177 free-living elderly, mean age 71.2 years old (5.1). Dietary intakes were assessed by three-day dietary records. The Nutrition Data System software (Minneapolis, MN) was used to evaluate nutrient intakes (vitamin C, vitamin E, selenium and zinc). Body composition was measured in all participants using dual-energy X-ray absorptiometry (DXA, Lunar). Grip strength assessed by dynamometer (Jamar[®]) was used as a measure of muscle strength. Inflammation markers measured in 12h fasting blood samples included interleukin-6 (IL-6), C-reactive protein and tumor necrosis factor-alpha (TNF- α). Skeletal muscle mass was significantly higher in women who were in the last tertile of muscle strength, compared with women who were in the first tertile [14.7 kg (1.9) vs 13.0 kg (1.9), p=0.000] respectively. There was no significant difference between antioxidants intake among tertiles of muscle strength. Muscle strength was negatively correlated with IL-6 (r = - 0.201; p=0.007). In addition, this cytokine appears to contribute negatively to the muscular strength regardless of age, muscle mass, fat mass, physical activity, smoking, consumption of protein and calcium and vitamin D supplementation (r²=0.271; p=0.000). In conclusion, there was no association between antioxidant intake and muscle strength. On the other hand, interleukin-6 appears to contribute negatively to muscle strength in elderly women.

Skeletal Muscle Cells Secrete Factor(s) Protecting Bone Cells from Glucocorticoid Induced Cell Death. Katharina Jaehn^{*1}, Leticia Brotto¹, Nuria Lara¹, Chenglin Mo¹, Mark Johnson², Marco Brotto¹, Lynda Bonewald¹. ¹University of Missouri - Kansas City, USA, ²University of Missouri, Kansas City Dental School, USA

Prolonged glucocorticoid (GC) management of inflammatory diseases is the leading cause for secondary osteoporosis potentially through osteoblast and osteocyte cell death. As we have recently shown that muscle cells produce factors that enhance osteocyte responsiveness to mechanical loading and that mechanical loading of MLO-Y4 osteocyte cells blocks GC induced cell death, we hypothesized that muscle factors may also play a role in the protective effects of loading on bone cell viability. Dexamethasone (dex) treated MC3T3 osteoblast, MLO-Y4 osteocyte, and primary isolated osteocyte-enriched cells from 7 day-old mice were used to assess the effect of conditioned media (CM) derived from C2C12 myotubes or from *ex vivo* contracted extensor digitorum longus (EDL) or soleus muscle from 4 month-old mice. Both the trypan blue exclusion for cell death and nuclear fragmentation assay for apoptosis were used. C2C12 myotube CM, but not undifferentiated C2C12 myoblast CM prevented dex-induced cell death and apoptosis in MC3T3, MLO-Y4, and primary osteocyte cells. The effect of C2C12 myotube CM media was effective down to 0.1% and the active factor(s) were found to be smaller than 10kD, stable to freezing and heating, destroyed by UV, extractable in ethyl acetate under both neutral and acidic conditions and volatile.

EDL is composed mainly of fast-twitch, glycolytic, type IIB/IIx, fatigable muscle fibers that are lost with aging while the soleus muscle represents a muscle composed of slow-twitch, oxidative, type I/IIa, fatigue resistant fibers that are less affected by age. Primary EDL and soleus muscle CM prevented dex induced MLO-Y4 cell death. The CM derived from the EDL muscle contracted under high frequency of 80Hz was more potent in prevention of dex-induced osteocyte death than CM from soleus muscle (app. 10 fold), and more potent than CM produced during low frequency contraction of 1Hz (app. 10 fold). This would suggest that type II fibers are superior to type I fibers in protecting and maintaining osteocyte viability.

We conclude that muscle cells naturally secrete factor(s) that prevent apoptosis in osteoblasts and osteocytes stressed by glucocorticoid exposure. Identification of this factor could have far reaching consequences for the prevention of glucocorticoid induced secondary osteoporosis.

Assessment of Muscle Mass Changes and Nerve Conduction Velocity in the Rat Orchidectomy Model. NANCY DOYLE^{*1}, Aurore Varela², Elisabeth Lesage², Solomon Haile¹, Joseph Arezzo³, Susan Y. Smith², Hitoshi Saito⁴. ¹CHARLES RIVER, Canada, ²Charles River Laboratories, Canada, ³Albert Einstein College of Medicine, Departments of Neuroscience & Neurology, USA, ⁴Chugai Pharmaceutical Company, Limited, Japan

Androgens may indirectly affect musculoskeletal homeostasis through interaction with body growth, body composition and the GH-IGF-I axis. The purpose of this study was to evaluate the effects of orchidectomy (ORX) and subsequent testosterone depletion on muscle and peripheral nerve conduction velocity in mature Sprague-Dawley rats over a 3-month period.

Six-month-old male rats were randomly assigned to 2 groups by body weight (BW). Ten rats underwent either ORX or Sham operation and were observed for 13 weeks after surgery. Bone densitometry and fat/lean analysis by pQCT was measured at 0, 6 and 13 weeks. pQCT scans were obtained at the proximal tibia metaphysis and diaphysis. Body weights and food consumption were measured weekly and muscle weights were recorded at necropsy. In addition, conduction velocity was recorded in the mixed caudal nerve, the sensory digital nerve, and the distal motor branches of the tibial nerve innervating plantar muscles of the foot at 0, 6 and 12 weeks.

Following surgery, food consumption of ORX rats was lower than Shams by up to 10% between Weeks 5 and 13, which resulted in lower body weight gains and a reduced body weight of 5% at the end of the study. This was associated with decreases in muscle area (measured by pQCT), relative to Shams of 6% and 13% at Weeks 6 and 13, respectively, with no significant changes in muscle density or fat area. Paired muscle weights measured at necropsy were also consistent with these observations, showing trends for lower gastrocnemius and extensor digitorum longus weights by 4.5% and 4.0% respectively, for ORX rats compared to Shams. The induced changes in muscle were not associated with slowing of either sensory or motor nerve conduction velocity.

The ORX rat is an established model for the evaluation of the effects of experimental treatments on bone mass; the present study indicates that this model can also be valuable in tracing direct effects of compounds on muscle mass which are independent of peripheral neuropathy.

Characterization of Bone Status in a Premature Aging Mouse Model. Sergio Portal^{*1}, Rashed Manassra², Daniel Lozano³, Alicia Acitores⁴, Monica De la Fuente², Pedro Esbrit⁵. ¹Spain, ²Dpto. de Fisiología Animal (Fisiología Animal II), UCM, Spain, ³Instituto de Investigación Sanitaria-Fundación Jiménez Dúaz, Spain, ⁴Laboratorio de Metabolismo Nutrición y Hormonas, Instituto de Investigación Sanitaria-Fundación Jiménez Dúaz, Spain, ⁵FUNDACION JIMENEZ DIAZ, Spain

Bone frailty and subsequent bone fractures are associated with aging-related osteopenia. Research in this field uses animal models as source of information. However, animal aging and frailty models are usually difficult to obtain. Here, we describe the bone status of a premature aging mouse (PAM) model that spontaneously develops from normal female ICR-CD1 mice. These mice take longer to explore a T-shaped maze; they have high anxiety levels and similar neurochemical parameters than those of aging mice, a decreased immune function and a lower life span. Adult PAM (292 weeks), old PAM (722 weeks), and their NoPAM counterparts (n=6 per age/type) were analyzed. After assessing bone densitometry (by PIXImus), mice were euthanized, long bones were extracted for Q-PCR (femur), western blot analysis (tibia), and histomorphometry (femur) studies. At sacrifice, body weight decreased in old NoPAM (p<0.05); whereas glycemia increased in both old NoPAM and PAM (p<0.05). With aging, the % fat in total body, and in tissue surrounding vertebrae (L1-L4) and long bones significantly increased only in NoPAM (p<0.05). Adult PAM showed higher BMD and BMC values than NoPAM in the tibiae (p<0.05). Consistently, % BV/TV showed a trend to be higher, related to significantly (p<0.05) higher Tb.N. and lower (p<0.05) Tb.Sp., in adult PAM mice. Runx2 expression was significantly downregulated with aging in both types of mice studied (p<0.05). There were no significant changes in the OPG/RANKL system with age in these mice. A significant increase in the adipogenic markers PPAR γ and Ap2 and in the oxidative stress marker FOXO-1 gene expression occurred in adult PAM and in both old groups; in contrast, exploring the expression of genes related with the Wnt-pathway, we found that Cyclin-D1 (final target gene) expression was significantly downregulated in these mice. A significant downregulation in Dkk-1 (inhibitor) was observed in both types of old mice (p<0.05). β -catenin protein levels were similar in both types of adult mice, but dramatically decreased in the long bones with age in both groups. Meanwhile, sclerostin was decreased in both PAM groups. In conclusion, these results support the notion that PAM might be a useful model for bone frailty studies, including exploring the role of oxidative stress in the mechanisms of age-related osteopenia.

MO0008

Community-dwelling Female Fallers Have Lower Leg Muscle Density, and Similar Forearm Muscle Density and Distal Radius Bone Parameters Relative to Non-fallers: Evidence from the Saskatoon CaMos Cohort. Andrew Frank^{*1}, Jonathan Farthing², Philip Chilibeck², W.P. Olszynski³, Saija Kontulainen⁴. ¹The University of Saskatchewan, Canada, ²College of Kinesiology, University of Saskatchewan, Canada, ³Midtown Medical Center (#103), Canada, ⁴University of Saskatchewan, Canada

Falls result in an estimated 1.7 million distal radius fractures globally, and muscle function is a major contributing factor to fall incidence. Low muscle density reflects higher muscle adiposity, which is associated with poor lower extremity performance, the development of mobility impairments, frailty, bone fragility and fracture. These associations may relate to falls, yet no studies have compared muscle density and distal radius bone parameters between community-dwelling fallers and non-fallers. Our primary objective was to determine whether peripheral quantitative computed tomography (pQCT)-derived lower leg and forearm muscle density and cross-sectional area (MCSA) differ between community-dwelling elderly women grouped as fallers (one or more falls in the past year) and non-fallers. Additionally we sought to determine whether pQCT derived distal radius total bone mineral content (ToC), density (ToD), area (ToA), compression bone strength index (BSIc), and trabecular bone content (TrC), density (TrD) and area (TrA) differ between the two groups. Women (N=140), age 60 or older (mean 74.2 SD 7.8y) were recruited from a random sample of community-dwelling residents. pQCT scans of the 66% non-dominant lower leg and 65% forearm were acquired to determine muscle density and MCSA. The 4% distal radius was scanned to obtain ToC, ToD, ToA, BSIc TrC, TrD and TrA. Basic functional mobility (Timed Up and Go Test [TUG]), and handgrip strength were also measured. All variables were screened for violations of normality and equality of variance. Independent t-tests, Mann-Whitney U tests, and analyses of covariance were used to compare (P<0.05) variables between groups. The lower leg muscle density of Fallers (n=36) was 3.2% lower (P=0.044, mean rank difference of -15.3) than non-fallers (n=99). Forearm MCSA was 5.3% higher (P=0.038, mean rank difference of 15.9) in fallers (n=36) than non-fallers (n=100). Age, height, weight, body mass index, TUG, handgrip strength, forearm muscle density, and all radius bone parameters (adjusted for forearm MCSA) did not differ between fallers and non-fallers. Differences in muscle density appear to be localized to the lower extremity and may serve as a physiological marker in the assessment of lower leg muscular health and fall risk in community-dwelling elderly women. The clinically relevant distal radius bones appear to be similar between community-dwelling female fallers and non-fallers.

Development of an Immunoassay for the Quantitative Determination of Myostatin (GDF-8). Karl Florian Wintgens*, Corinna Berger, Stanka Stoeva, Franz Paul Armbruster. Immundiagnostik AG, Germany

The TGF-beta superfamily member Myostatin, also known as Growth Differentiation Factor-8 (GDF-8), is an important regulator of muscle mass. Myostatin inhibits muscle growth and promotes muscle protein degradation in mammals and other vertebrates. In many conditions associated with muscle loss, such as old age, prolonged bed rest, liver cirrhosis, uremia, cancer, and HIV infection, Myostatin levels are increased.

The aim of this study was to develop an immunoassay for the quantitative detection of human Myostatin. For this purpose, recombinant human Myostatin was expressed in HEK293-EBNA cells and used to immunize rabbits. The resulting polyclonal rabbit antiserum was characterized by Western Blot and immunohistochemistry. The antiserum detects all subunits of Myostatin, the propeptide, the c-terminal mature protein as well as the protein dimer. In sections of human skeletal muscle, Myostatin can be visualized around the myonuclei and near the cell borders.

A competitive enzyme immunoassay (EIA) was established using the polyclonal anti-Myostatin antibody. The Myostatin EIA does not cross-react with GDF-11, Myoglobin, Follistatin or Follistatin-related gene protein. The limit of detection is 0.273 ng/ml as determined by repeated measurements of a blank sample. The mean coefficient of variation was determined to be < 10 % for intraassay variance and 15 % for interassay variance. Using the Myostatin EIA a reference range was established in a healthy population subdivided according to age and gender. To our knowledge, this is the first commercially available Myostatin immunoassay. It is a suitable tool for the sensitive and precise quantification of Myostatin.

Forearm Muscle and Cortical Bone Predict Fracture Load. Jenny Zhao*¹, Ruchun Dai¹, Zhehao Dai¹, Jon Jacobson¹, Harry Genant², Peter Augat³, Yebin Jiang¹. ¹Osteoporosis & Arthritis Lab, University of Michigan, USA, ²University of California, USA, ³Biomechanics Research Laboratory, Germany

Investigation of muscle and bone interaction is of considerable research interest. The largest loads applied to bones during daily activities come from the muscles. We investigated the relationships between muscle and bone and used an in vitro fracture model to identify how bone and muscle predicted fracture load.

Cross-sectional area (CA) of cortical bone and muscles, cross-sectional moments of inertia (CSMIs) of the cortical bone were determined from MR images of 20 fresh human cadaveric forearms that were also evaluated using a peripheral quantitative CT (pQCT) scanner at 15% of the length of the forearm. The specimens were randomly assigned to different loading patterns with wrist either in a neutral position or extended/dorsiflexion 45 adjusted between the axes of the radius and the third metacarpal confirmed on radiographs. The load to fracture was applied at a displacement rate of 75 mm/second, mimicking an impact from a fall.

There was no significant difference in the maximum load between dorsiflexion (23881685 N) and neutral position (27821104 N). The pressure sensitive films showed focal pressure concentration in the center of the radiocarpal joint in neutral upright loading configuration, and in an equally distributed pressure pattern across the radiocarpal joint in extended-wrist situation. Correlations (r^2) were 0.61 ($p < 0.0001$) between MRI muscle CA and cortical bone CA, and 0.52 ($p < 0.0001$) between MRI muscle CA and pQCT BMC at the 15% site. Correlations (r^2) between MRI and pQCT at the 15% site were 0.89 and 0.90 ($p < 0.0001$) for polar CSMI and CA, respectively. The fracture load could be predicted by MRI cortical CA, MRI muscle CA, and pQCT cortical BMC at the 15% site with r^2 of 0.85, 0.57, and 0.84 ($p < 0.0001$), respectively. Similar strong correlations with the fracture load were found after adjustment for bone size.

The muscle and bone are significantly associated. The properties of cortical bone and the muscle in the distal radius contribute significantly to its biomechanical competence and predict strength and risk of forearm fractures. Rather than directly influencing fracture load, the different loading configurations influenced the load transfer pattern from the carpal bones into the radius.

Disclosures: Jenny Zhao, None.

pQCT Measures of Bone and Muscle Are Independently Associated With Falls in Women – A Principal Components Analysis of Morphometric Measures. Andy Kin On Wong*¹, Aakash Bhargava¹, Karen Beattie¹, Christopher Gordon¹, Laura Pickard¹, Colin Webber², Alexandra Papaioannou², Jonathan Adachi³. ¹McMaster University, Canada, ²Hamilton Health Sciences, Canada, ³St. Joseph's Hospital, Canada

Individuals who fall lack muscle strength, which may also affect bone. Objective: To determine the association between fallers and morphometric measures of bone and muscle using peripheral quantitative computed tomography (pQCT).

Methods: Women ≥ 50 years of age completed grip strength, timed 'up-and-go' (TUG) tests, and responded to a questionnaire on self-reported falls in the last year, and duration of vitamin D supplementation. pQCT scans were obtained at the 66% site of the tibia with a single slice thickness of 2.3–0.5 mm. Muscle was segmented from bone to yield measures of bone and muscle macrostructure, density as well as bone mechanical parameters using manufacturer software. Principal components analysis (PCA) was performed using Varimax transformation to extract components (PC) explaining the largest percent of variance in bone variables above an Eigenvalue cutoff of 1.0. Binary logistic regression determined the relationship between 1-year prevalence of falls and each of bone PC's, individual bone and muscle parameters. Regression models were adjusted for anthropometrics, physical function and duration of vitamin D use, as shown in Table 2. Odds ratios per standard deviation increase in variables were reported with 95% confidence intervals (CI). Regression model fit was ascertained by Hosmer-Lemeshow tests. Receiver-operator characteristics (ROC) analyses for falls was examined for the same variables reporting areas under the curve (AUC) tested against 0.50.

Results: Of 49 women (mean age: 74.56 \pm 8.4 years; BMI: 26.5 \pm 4.2 kg/m²), 14 (28.6%) fell at least once. PCA identified 7 pQCT bone PC's explaining 93.51% of variance in 60 variables. Only PC1-PC3 providing component loading correlations larger than 0.80 were further analyzed (Table 1). Combined, muscle and bone volumetric density showed reduced odds for falls (0.846 (0.726, 0.987)), not significant after accounting for covariates. Only a larger PC2 was associated with reduced odds for falls by as much as 90% after accounting for covariates (Table 2). pQCT PC2 exhibited a significant AUC of 0.714 (95% CI: 0.547, 0.881) with 71.4% sensitivity and 72.2% specificity for falls discrimination.

Conclusions: pQCT bone characteristics associated with peri- and endosteal geometry, marrow area and mass at the mid-tibia (PC2) were independent discriminants of falls in women. Combined with smaller muscle area and density, poor mid-tibial bone geometry is associated with fallers.

Table 1. Principal components of pQCT-derived bone macrostructural measures at the 66% tibia. Extraction of 7 PC's with significant variance explanation (Eigenvalues (EV) > 1.0) and with 3 PC's containing variables with component loading correlation coefficients > 0.80. Subscripts: P = polar.

PC	EV	% of Variance Explained	Cumulative % of Variance	Variables with Component Loading Correlations (R) > 0.80
1	21.32	38.08	38.08	Moments of inertia _{xx} (cortical, total), bending resistance _{xx} (cortical), bone mineral content (cortical, total)
2	14.72	26.29	64.36	Endosteal and periosteal circumference, marrow area and mass
3	4.57	8.17	72.53	Density-weighted moment of inertia _{yy}
4	3.94	7.03	79.56	N/A
5	3.67	6.55	86.11	N/A
6	2.27	4.05	90.16	N/A
7	1.87	3.35	93.51	N/A

Table 2. Odds for falls in women explained by pQCT bone measures. Principal component 2 for pQCT bone parameters was examined for an association with falls and was further examined in conjunction with muscle area and density (Models 4-9), adjusting for anthropometrics (age, BMI), duration of vitamin (Vit) D use and physical function (maximum grip strength (GSM_{max}), timed 'up-and-go' (TUG) time).

Model	Covariates	OR	Lower CI	Upper CI	P-value
	None	0.444	0.209	0.942	0.034
Model1	Age, BMI	0.327	0.111	0.961	0.042
Model2	Model1+GSM _{max} , TUG Time	0.092	0.010	0.858	0.036
Model3	Model2+Duration Vit D use	0.104	0.012	0.931	0.043
Model4	Model1+Muscle area	0.328 ^a	0.110	0.980	0.046
Model5	Model1+Muscle density	0.184	0.043	0.791	0.023

Retest Reliability of Muscle Function Testing in Older Adults. Bjoern Buehring^{*1}, Ellen Fidler¹, Diane Krueger¹, Neil Binkley². ¹University of Wisconsin, Madison, USA, ²University of Wisconsin, USA

Background: Sarcopenia is a risk factor for falls and fractures. As muscle performance (strength and power) predicts disability, morbidity and mortality better than muscle mass, it is appropriate that a recent consensus definition of sarcopenia included measuring both mass and function. Clinical trials of sarcopenia prevention/treatment require sensitive quantitative tools to evaluate muscle function. Jumping mechanography (JM) may be one such tool. However, it is necessary to evaluate whether muscle performance as measured by JM in older adults is reproducible over time and correlates with classical functional assessment tools. Thus, the purposes of this study was to evaluate reproducibility of JM parameters over time and correlate these measures with current functional tests.

Methods: Community dwelling individuals age 70 and older who volunteered and met inclusion/exclusion criteria performed a battery of muscle function tests including the short physical performance battery (SPPB), grip strength, and JM. JM uses maximal counter-movement jumps performed on a force plate. With this methodology, force is recorded and body weight corrected peak power and jump height are calculated. To examine reliability over time, these measures were performed at a screening visit, a baseline visit a few days later and at 2 weeks and 3 months. Intraclass correlation (ICC) and coefficient of variation (CV) were used to examine retest reliability.

Results: 49 females and 48 males (average age of 80.6, range 70 – 95) with and without osteoporosis and sarcopenia participated. Muscle function testing was generally well tolerated; no participant sustained a JM related injury. Jump power, jump height and grip strength had excellent ICCs (0.94, 0.89, and 0.95 respectively) CV was 6.8% for jump power, 13.5% for jump height and 13.6% for grip strength. ICC and CV for SPPB components varied among tests (ICC: 0.37 for total balance score to 0.81 for repeated chair rise time, CV: 9.5% for gait time to 23.4% for total balance score).

Conclusion: JM appears to have an excellent retest reliability in older adults with and without sarcopenia. No apparent learning effect was observed. In this study JM was comparable to grip strength and possibly better than measures included in the SPPB. JM is a promising tool for muscle power assessment in older adults and likely comparable to classical function assessment tools for longitudinal interventional studies.

The Association Between Serum 25-Hydroxyvitamin D and Obesity and Sarcopenia in Elderly Men. Vidmantas Alekna^{*}, Asta Mastaviciute, Marija Tamulaitiene. Vilnius University, Lithuania

Background: A combination of excess weight and reduced muscle mass, and strength is called as sarcopenic-obesity. There are not sufficient data about vitamin D status in sarcopenic-obesity.

Purpose: The aim of this study was to investigate serum 25-hydroxyvitamin D in obese, sarcopenic and sarcopenic-obese elderly men.

Methods: Subjects for this cross-sectional study were 58 men aged 60 years and more. Exclusion criteria were conditions and current use of any medication known to affect muscle and lipid metabolism, or taking vitamin D supplements. DXA was used to measure fat mass, body fat percentage, and lean mass (iDXA, GE Lunar). Sarcopenia was defined as condition when appendicular skeletal muscle mass divided by stature squared was $<7.26 \text{ kg/m}^2$ and gait speed was $<0.8 \text{ m/s}$. Obesity was based on the relative fat mass and was defined as percentage of body fat greater than 27% and BMI greater than 30 kg/m^2 . In case of the combination of sarcopenia and obesity subjects were classified as sarcopenic-obese. Serum levels of 25-hydroxyvitamin D were measured by automated immunoassay (Cobas E411, Roche Diagnostics).

Results: Of all men investigated 35 subjects were obese, 15 - sarcopenic and 8 men were defined as sarcopenic-obese. The mean 25-hydroxyvitamin D was $15.485.8 \text{ ng/ml}$ in obese subjects, $11.36.24 \text{ ng/ml}$ in sarcopenic, and $9.084.17 \text{ ng/ml}$ in sarcopenic-obese men. Using one-way ANOVA test statistically significant 25-hydroxyvitamin D status difference was found between body composition groups investigated ($p=0.036$). Post hoc analysis revealed the statistically significant difference of serum 25-hydroxyvitamin D between obese and sarcopenic men as well as between obese and sarcopenic-obese groups ($p=0.04$ and $p=0.02$, respectively). There was weak correlation of 25-hydroxyvitamin D with obesity ($r=0.215$, $p=0.004$).

Conclusions: Serum 25-hydroxyvitamin D is associated with obesity in men. The lowest serum 25-hydroxyvitamin D was found in sarcopenic-obese men. Larger cohorts of subjects studied are needed to clarify the significance of our finding.

Bone Micro-Architecture, Muscle Strength, and Undercarboxylated Osteocalcin in Middle-Aged Men. Itamar Levinger^{*1}, Roger Zebaze², Ali Ghasem-Zadeh², George Jerums³, David Hare³, Steve Selig⁴, Ego Seeman². ¹Victoria University, Australia, ²Austin Health, University of Melbourne, Australia, ³Austin Health, Australia, ⁴Deakin University, Australia

Background: Serum undercarboxylated osteocalcin (unOC) has been shown to play a role in energy metabolism in mice. There is also a growing number of correlative evidence to suggest that unOC play a role in glycaemic control in humans. Remodelling is surface dependent – there must be a surface for remodelling to be initiated upon before matrix can be remodelled. We tested the hypothesis that bone assembled with a larger surface/tissue volume configuration (therefore high porosity, lower volumetric bone density, vBMD) will be associated with higher serum unOC. We also tested whether muscle strength is negatively correlated with bone porosity.

Methods: We examined the associations between bone micro-architecture in the distal tibia and distal radius, by using high-resolution peripheral quantitative computed tomography (HR-pQCT) and serum unOC and muscle strength, in 29 middle-aged men (age 52.9 ± 1.3 yrs BMI $=32.00.9 \text{ kg-m}^2$ mean SEM). Correlations between bone measures and serum unOC and muscle strength were adjusted for age and BMI.

Results: unOC correlated with porosity of the entire tibia ($r=0.59$, $p=0.001$) and radius ($r=0.52$, $p=0.005$), and so correlated negatively with total vBMD of the entire tibia ($r=-0.56$, $p=0.002$) and radius ($r=-0.49$, $p=0.008$). unOC was also correlated with cortical porosity in the tibia and radius ($r=0.57$, $p=0.001$ and $r=0.60$, $p=0.001$, respectively). Muscle strength correlated negatively with porosity of the tibia ($r=-0.36$, $p=0.04$) and directly with total vBMD of the tibia ($r=0.42$, $p=0.019$) and radius ($r=0.35$, $p=0.046$).

Conclusion: Increased bone porosity is associated with higher serum unOC while higher bone density is associated with lower serum unOC in middle-aged man. Serum unOC is surface dependent. Greater muscle strength is associated with lower bone porosity and so higher vBMD. Interventions aimed to increase muscle strength may have favourable effects on bone quality in ageing man.

Reambulation After Disuse Causes Differential Age-Dependent Responses in Bone Strength and Bone Formation in Trabecular and Cortical Bone. Tristan Fowler^{*1}, Thomas Williams¹, Nisreen Akel¹, William Hogue¹, Frances Swain¹, Esther Dupont-Versteegden², Larry Suva¹, Dana Gaddy¹. ¹University of Arkansas for Medical Sciences, USA, ²University of Kentucky, USA

We and others have demonstrated the deleterious effects of age and disuse on trabecular bone mass and strength. The goal of the present study was to investigate the effects of disuse on cortical bone geometry and strength, the capacity for bone restoration by reambulation (RE), and the impact of age on these skeletal changes. Using the well established hindlimb suspension (HS) model of musculoskeletal disuse, male rats 6 mo. and 32 mo. of age were assigned to control groups, HS for 14 days, and HS + RE for either 7 or 14 days. To determine if HS and/or RE effects were the result of changes in bone formation, rats were injected with calcein and Alizarin red and tibiae were analyzed via dynamic histomorphometry to determine bone formation rate (BFR) and mineral apposition rate (MAR) in both trabecular and cortical bone compartments. Femoral cortical bone strength was determined by three-point bending. Load-displacement curves were recorded and analyzed yielding measurements of stiffness, load at yield, peak load, load at failure, total displacement, energy to yield, and energy to failure. MicroCT analysis revealed no significant differences in cortical bone geometry by HS or RE in the tibial mid-shaft within any age group. Dynamic histomorphometry in the cortex revealed that HS reduced both endosteal and periosteal BFR and MAR in both the 6 and 32 mo. old rats. Neither 7 nor 14 days of RE affected the HS-induced decreases in dynamic cortical bone formation indices. These cortical results contrast with the findings in trabecular bone where MAR and BFR were completely restored with 7 days of RE in 6 mo. rats, and 14 days of RE in 32 mo. old rats. The cortical histomorphometry results paralleled mechanical testing data that demonstrated 32 mo. old bones had decreased stiffness and peak load not restored by RE. In 6 month old rats, HS caused a decrease in stiffness, but no change in peak load, or energy to yield or failure. The decrease in stiffness was restored by RE. Collectively, these findings demonstrate that HS compromises cortical bone strength in both 6 and 32 mo. old rats, and that skeletal recovery by RE is age-dependent. Unlike aged trabecular bone that has delayed bone formation recovery potential, aged cortical bone had no recovery potential. These findings suggest that ambulation in the elderly may selectively protect trabecular bone while having a more limited benefit for the protection of cortical bone.

Yoga Spinal Flexion Positions and Vertebral Compression Fracture in Osteopenia of Spine. Mehrsheed Sinaki^{*1}, Bart L Clarke¹, Elisabeth Preisinger², Vahab Fatourehchi¹. ¹Mayo Clinic, USA, ²Univ Vienna, Austria

Abstract: That yoga has a positive effect on balance, posture, flexibility, and quality of life is well-known. The objective of this report is to raise awareness of the effect of strenuous yoga flexion poses on the osteopenic (OP) spine. Flexibility of the spine achieved with yoga in older individuals can be an affliction rather than a blessing. Back strengthening exercises are important to reduce bone loss related vertebral compression fractures (fx) (VCF's). We previously reported on subjects with known osteoporosis who developed VCF's after spine flexion exercises (SFE's), and recommended that SFE's not to be prescribed in patients with osteoporosis of the spine.

We report 3 cases of healthy individuals with low bone mass, yoga-induced pain and/or fx.

Patient #1: An 87 y/o healthy woman with osteopenia developed severe back pain while performing strenuous spine flexion exercises during yoga with instructor supervision. Spine x-rays: L2 VCF and mild anterior wedging of several thoracic vertebrae. BMD Spine: T score -1.4; hips R/L : -1.2/-1.6.

Patient #2: A 61 y/o woman with osteopenia developed severe back pain while performing strenuous SFE's during yoga poses. Spine x-rays: VCF of superior end plate of T4. BMD Spine: T score -1.8.

Patient #3: A 70 y/o woman with osteopenia and degenerative joint disease of the cervical spine developed severe neck and back pain after performing common yoga spinal flexion position exercises. BMD: T Score: Spine -1.3; BMD hips:-1/-0.9. Spine x-rays: Advanced osteopenia. Degenerative cervical spondylosis, most significant at C4-7. Degenerative changes in the thoracic spine with anterior wedging of T8 and T9.

SUMMARY: OP is characterized by low bone mass, loss of bone microstructure and ↑ fx risk. OP musculoskeletal rehabilitation is a non-pharmacologic approach to reduce vertebral fx. Although exercise has been shown to be an effective method for improving BMD and ↓ fx risk, our subjects developed VCF's, neck and back pain while engaged in Yoga exercises. This suggests that factors other than bone mass should be considered for exercise counseling in patients with OP. The ↑ torque pressure applied to vertebral bodies during SFE's may be one such risk and requires consideration.

CONCLUSION: Although exercise is effective and important in the treatment of OP, fx risk assessment in individuals with bone loss performing SFE's and other high impact exercises is an important clinical consideration.

Bone Densitometry Evaluations in Juvenile Dogs. Rana Samadfam^{*1}, Maria Adamo², Aurore Varela¹, Keith Robinson², Susan Y. Smith¹. ¹Charles River Laboratories, Canada, ²Charles River, Canada

Effects on skeletal development and mineralization during neonatal and juvenile periods could have long lasting consequences later in adult life. The aim of this study was to establish procedures to evaluate the effects of drugs on skeletal development and density in non-clinical pediatric studies in beagle dog pups, the primary non-rodent species used in post-natal and juvenile studies. The techniques evaluated included radiography, DXA and pQCT. These imaging techniques were performed repeatedly on the same animals, from neonatal pups to juvenile animals of several months of age. DXA provided measurements for area, bone mineral content (BMC) and bone mineral density (BMD) of large areas of the skeletal system. pQCT provided volumetric measurements of area, BMC and BMD of the total slice, trabecular and cortical bone as well as geometry parameters. Radiograph images were used to assess skeletal abnormalities and epiphyseal closure during growth. These images were also used to measure length of the femur, tibia and lumbar spine. Beagle pups were scanned at weeks 1, 2, 3, 4, 5, 13, 17, 20 and/or 26 postpartum. Reproducible data were obtained for in vivo DXA scanning of the whole body, lumbar spine and whole right femur of weanling pups. Due to low bone density, manual bone mapping was required at 4 weeks and occasionally at 13 weeks of age. At 4 weeks, pQCT was performed at the radius proximal metaphysis and diaphysis. A single scan was acquired at the diaphysis using 40% of the bone length. The metaphysis scans were acquired at 18% of the total bone length. Changes in skeletal morphology during growth necessitated adjustment of slice positioning at the metaphysis over the course of the study. Increases in bone length measured by radiology were consistent with increases in body weight and increases in area parameters (DXA and pQCT). The results of these investigations indicate that radiography, DXA and pQCT provide reproducible and repeated non-invasive measurements of skeletal growth in vivo in skeletally immature dog pups at axial and appendicular sites. These data, combined with routine histology, provide a comprehensive assessment of the developing skeleton supporting use of these end-points in this model in drug development.

In Vivo and Ex Vivo Measurements of Post Natal Skeletal Development in Rodents Non-Clinical Reproductive Toxicology and Pediatric Studies. Aurore Varela^{*1}, Maria Adamo², Jacquelin Jolette³, Luc Chouinard⁴, Rana Samadfam¹, Keith Robinson², Susan Y. Smith¹. ¹Charles River Laboratories, Canada, ²Charles River, Canada, ³Charles River Laboratories, Preclinical Services Montreal, Canada, ⁴Charles River Laboratories, PCS Montreal, Canada

The aim of this work was to establish procedures to evaluate the effects of drugs on skeletal development in non-clinical pediatric studies in rats, the primary rodent species used in post-natal and juvenile studies. The techniques evaluated included radiography, DXA, pQCT, histology and histomorphometry. Sprague-Dawley pups starting at 7-day old were used.

Radiographs were taken under anesthesia to measure the femur, tibia and lumbar spine (L1-L6) lengths. Positioning and anatomical landmarks selected were reliable for repeat measurements of the same animal with coefficient of variation (CV%), not exceeding 1.7% at 14 days of age. CV% between age groups ranged from 0.7 to 4.7% across all sites evaluated and were similar for males and females at 14, 21, 28 and 35 days old. Bone length increased at each site with age, consistently with longitudinal bone growth. The details of the radiographs allowed evaluation of skeletal abnormalities including those of the physis. Peripheral QCT was performed in vivo as early as 7 days post-partum at the tibial proximal metaphysis and diaphysis. DXA scanning of the whole body, lumbar spine (L1-L4) and of the whole right femur of weanling rats (28 and 35 days of age) was performed using manual bone mapping. These imaging techniques were performed repeatedly on the same animals, from neonatal pups to juvenile animals of several months of age. pQCT provided information on the trabecular and cortical bone compartments and bone geometry. For pQCT, reproducible data was acquired using single or multiple scan slices set at 15% of the total bone length for females and 13% in males. Changes in skeletal morphology during growth, for animals more than 7 weeks of age, necessitated adjustment of slice positioning during the study. Histology provided cellular and microscopic architecture information. Histomorphometry measurements, including growth plate thickness in 35 day old rats, was used to evaluate effects of drug upon the cartilaginous scaffold and its mineralization, and to provide structural and dynamic bone turnover variables.

These results indicate that radiography, DXA and pQCT provide reproducible and repeated non-invasive measurements of skeletal growth in vivo in skeletally immature rats at axial and appendicular sites. These data, combined with histology and histomorphometry ex vivo evaluations, provide a comprehensive assessment of the developing skeleton supporting use of these end-points for drug development.

Increasing Incidence of Nutritional Rickets in Olmsted County, Minnesota, since 1970. Tom Thacher^{*1}, Philip Fischer¹, Peter Tebben², Ravinder Singh¹, Stephen Cha¹, Barbara Yawn³. ¹Mayo Clinic, USA, ²Mercy Health, USA, ³Olmsted Medical Center, USA

Background: Concern has been expressed regarding the persistence and possibly increasing incidence of nutritional rickets in the United States. It is unclear if the incidence is related to an increased prevalence of vitamin D deficiency or an artifact of increased 25(OH)D measurements or rising immigrant population. The aim of this study was to determine if the incidence of nutritional rickets has increased.

Methods: We identified all children (<18 years) residing in Olmsted County, MN between 1970 and 2009 with diagnostic codes of rickets, vitamin D deficiency, hypovitaminosis D, rachitis, osteomalacia, genu varum, genu valgum, craniotabes, hypocalcemia, hypocalcemic seizure, and tetany in the Rochester Epidemiology Project databases. Data abstraction was performed to select subjects with X-ray confirmation of rickets. Nutritional rickets was defined as X-ray evidence of rickets without evidence of inherited, genetic, or other secondary causes of rickets.

Results: Of 778 children with eligible diagnostic codes, 25 had radiographic evidence of rickets, and 17 were attributed to nutritional rickets. Fifteen (88%) were aged 6-24 months, 13 (76%) were black or non-Caucasian. Clinical presentation included poor growth (12), leg deformity (8), motor delay (5), leg pain (3), weakness (3), and hypocalcemia or tetany (2). Of the 13 who had 25(OH)D measurements, 5 (38%) had vitamin D deficiency (≤12 ng/ml). In consecutive 10-year intervals from 1970 to 2009, the mean incidence rates of nutritional rickets in children under 3 years of age were 0, 2.2, 3.7, and 24.1 per 100,000, respectively (P=0.003).

Conclusion: The incidence of nutritional rickets has increased significantly during the past four decades in Olmsted County, MN, and not all cases can be attributed to vitamin D deficiency.

Disclosures: Tom Thacher, None.

Age-Related Changes in Cortical Bone Geometry in the Human Tibial Diaphysis: A Whole-Bone Perspective. Zachariah Hubbell¹, James Gosman¹, Colin Shaw², Timothy Ryan². ¹The Ohio State University, USA, ²Pennsylvania State University, USA

Previous research has revealed distinct developmental trajectories for trabecular and cortical bone structures in the long bones of humans. Mature configuration of trabecular microarchitecture is achieved by late childhood, while development of cortical bone geometry extends into late adolescence. The purpose of this research is to test the hypothesis that the ontogenetic pattern of change in cortical cross sectional geometry from the whole-bone diaphyseal perspective is age- and anatomical site-specific. Tibiae ranging developmentally from neonatal to skeletally mature were obtained from the Norris Farms no. 36 skeletal series, a collection of skeletons recovered from an Oneota Native American cemetery dating to approximately A.D. 1300. Whole tibiae underwent high resolution x-ray CT scanning at the Penn State Center for Quantitative Imaging with resolutions ranging from 0.013 to 0.094 mm depending on specimen size. Cortical bone cross-sectional geometric properties were calculated for entire tibial diaphyses using the BoneJ plugin for ImageJ. From these results, Imax/Imin ratios (a measure of cross-sectional shape) were calculated for each CT slice (between 983 and 2277 slices per bone) for the whole diaphysis of each tibia and were then plotted against percent diaphyseal length (Figure 1). For each tibia, average values of Imax/Imin were calculated for five regions of the diaphysis of equal length (Region 1 being most distal, Region 5 being most proximal); these averages were correlated with age. Correlation results and associated p-values are presented as a table in Figure 2. The distribution of Imax/Imin values indicate that in general, cross-sectional shape follows a trend of decreasing 'roundness' with increasing age, especially toward the proximal end of the diaphysis (represented by Region 4, 60% to 80% of diaphyseal length). These changes in shape correspond to patterns of site-specific bone accretion that likely reflect combined genetic patterning, linear growth, and mechanical/locomotor influences. Notably, Imax/Imin values in Region 4 appear to increase markedly for individuals age 9 years and older, while remaining relatively homogeneous for individuals age 5 years and younger. Further investigation of this age-related anatomical divergence may elucidate the regional significance of diaphyseal cortical bone accrual during growth as well as the potential factors that influence the shift toward mature cortical bone structural configuration.

Figure 1. Age-specific Imax/Imin values by percent tibial diaphysis.

Age (yrs)	Imax/Imin Averages				
	Region 1	Region 2	Region 3	Region 4	Region 5
0.63	1.33	1.35	1.41	1.26	1.15
3	1.22	1.27	1.31	1.36	1.45
5	1.36	1.54	1.59	1.48	1.45
9	1.46	1.81	1.96	2.02	2.12
15.5	1.23	1.61	1.72	1.94	2.26
19.5	1.56	2.08	2.13	2.33	2.11
Pearson's Correlation	0.483	0.848	0.841	0.94	0.885
P-value	0.056	0.058	0.059	0.057	0.058

Note: Reported p-values are likely influenced by small initial sample size and may reach significance after analyzing a larger number of specimens.

Figure 2. Average values of Imax/Imin and age correlations for each region of the tibial diaphysis.

MO0021

A Comparison of Trabecular Bone Microstructure at the Distal Radius and Distal Tibia Between Healthy Weight and Overweight Adolescents: An HR-pQCT Study. Christa Hoy¹, Lindsay Nettlefold¹, Sarah Moore¹, Sojung Kim¹, Meghan Donaldson², Heather Macdonald¹, Heather McKay¹. ¹University of British Columbia, Canada, ²San Francisco Coordinating Center, USA

Obesity prevalence has increased drastically in recent years and is known to be associated with many chronic conditions. Although overweight children have greater bone mass than their healthy weight peers, they sustain more fractures. Thus, there is a need to better understand the relation between overweight status and three-dimensional properties of bone microstructure that influence bone strength. We aimed to examine this relation in this cross-sectional study using high-resolution pQCT (HR-pQCT) in adolescent boys and girls in the Healthy Bones Study cohort. We categorized boys (n=100; 17.41.6yrs) and girls (n=84; 17.81.8yrs) into body mass index (BMI) groups using the CDC BMI for age curves (Overweight (OW) \geq 85th percentile, 14 boys, 15 girls; Healthy Weight (HW) < 85th percentile, 86 boys, 69 girls). We used HR-pQCT and standard protocols to assess the non-dominant distal radius (7% site) and left distal tibia (8% site). Bone outcomes for tibia and radius were: trabecular number (Tb.N, 1/mm), trabecular thickness (Tb.Th, mm), trabecular bone volume to tissue volume (BV/TV, %) and trabecular separation (Tb.Sp, mm). We used multiple regression to evaluate the variance in trabecular bone microstructure explained by weight status after adjusting for age (yrs), ethnicity (Asian vs. Caucasian), physical activity (min/day) and radius or tibia length (mm). For girls, OW was not a significant predictor of trabecular bone microstructure at either site. However, in boys OW was a significant positive predictor of BV/TV ($p < 0.01$, 13.7% greater than HW) and Tb.N ($p < 0.05$, 9.3% greater than HW) and negative predictor of Tb.Sp ($p < 0.01$, 11.9% less than HW) at the distal radius. At the distal tibia in boys, weight status was a positive predictor of Tb.N ($p < 0.01$, 15.2% greater than HW) and negative predictor of Tb.Th ($p < 0.05$, 7.5% less than HW) and Tb.Sp ($p < 0.01$, 15.7% less than HW). Thus, an apparent paradox exists where OW positively influences BV/TV and Tb.N in boys; however, trabeculae are thinner at the distal tibia suggesting a negative effect of excess body weight on bone microstructure. Further research with a larger cohort over a longer time period is needed to clarify these sex-specific relations and their implications.

Table 1. Descriptives for healthy weight (HW) and overweight (OW) boys and girls and bone microstructure variables as measured by HR-pQCT at the distal radius and tibia.

Variable	Boys		Girls	
	HW (n=86)	OW (n=14)	HW (n=69)	OW (n=15)
Age (yrs)	17.4 (1.6)	17.3 (1.6)	17.8 (1.8)	17.8 (1.8)
Tibia length (mm)	420 (25)	431 (36)	381 (23)	390 (29)
Radius length (mm)	265 (15)	262 (15)	257 (13)	261 (16)
Physical activity (min/day)	80.5 (11.8)	53.6 (39.1)	81.4 (42.1)	33.3 (35.3)
Ethnicity (% Asian/Caucasian)	(48/52)	(5/9)	(53/16)	(4/11)
Radius BV/TV (%)	15.7 (3.3)	17.7 (2.5)	13.3 (2.8)	13.7 (2.6)
Radius Tb.N (1/mm)	1.93 (0.25)	2.04 (0.14)	1.85 (0.27)	1.88 (0.19)
Radius Tb.Th (mm)	0.054 (0.014)	0.056 (0.015)	0.054 (0.012)	0.053 (0.009)
Radius Tb.Sp (mm)	0.444 (0.073)	0.397 (0.036)	0.474 (0.095)	0.464 (0.047)
Tibia BV/TV (%)	17.2 (2.5)	19.0 (2.3)	16.1 (2.9)	16.8 (3.1)
Tibia Tb.N (1/mm)	1.86 (0.26)	2.15 (0.25)	1.75 (0.26)	1.82 (0.22)
Tibia Tb.Th (mm)	0.050 (0.011)	0.055 (0.012)	0.050 (0.014)	0.048 (0.011)
Tibia Tb.Sp (mm)	0.458 (0.055)	0.398 (0.047)	0.491 (0.061)	0.419 (0.041)

Data are Mean (SD); means are unadjusted.

Accumulation of Bone Marrow Adipose Tissue in Childhood May Adversely Affect Skeletal Strength. Krista Casazza¹, Lynae Hanks¹, Harry Hu². ¹UAB, USA, ²USC, USA

Although appositional relationship between body fat and bone mineral content (BMC) in the pediatric population is often reported, obesity is overrepresented in childhood fracture cases thus challenging a beneficial contribution of adiposity to bone health. Further, whereas, insulin resistant children tend to have higher bone mass compared with the general population, they paradoxically remain unprotected from fractures. Assessment of the bone marrow compartment particularly during growth and development represents a viable avenue in which to explore the allocation of resources between fat and bone as it is here that undifferentiated cells capable of multiple lineages (i.e. osteoblasts, adipocytes) meet their fate. The objective of this study was to evaluate the association between bone marrow adipose tissue (BMAT) and BMC in growing children and to determine the extent to which total body adiposity and insulin may influence this relationship. Ninety-five pre-pubertal children age 4-10 years ($\mu = 6.8 \pm 0.2$) participated. BMC and total body mass were assessed by DXA, bone marrow adipose tissue by MRI and fasting insulin by venipuncture. A positive relationship between BMAT and BMC was observed ($p < 0.001$); however, inclusion of total body fat or fasting insulin attenuated the relationship ($p = 0.19$, 0.58 , respectively). Stratification by percent fat cut-points (25% for boys, 30% for girls), revealed greater BMAT, BMC and insulin among those with greater adiposity. However, a differential contribution of adiposity to the

BMAT-BMC relationship was observed such that among children with normal adiposity the relationship was not significant ($p=0.37$) whereas, among those with excess adiposity BMAT was inversely associated with BMC ($p=0.03$) and the relationship was at least in part mediated by insulin. Accumulation of BMAT may adversely affects skeletal strength and the effect may be exacerbated in children with excess adiposity and impaired insulin dynamics. Revelation of factors contributing to bone integrity within the bone marrow cavity during childhood is a key determinant in body composition trajectory over the life course with numerous health implications.

Bone Biomarkers and Mineral Biochemistries in Early Pubertal Black and White Adolescent Boys and Girls. Kathleen Hill¹, Berdine Martin², Emma Laing³, Stuart Warden⁴, George McCabe², Richard Lewis³, Connie Weaver², Munro Peacock⁵. ¹Indiana University School of Medicine, USA, ²Purdue University, USA, ³The University of Georgia, USA, ⁴Indiana University, USA, ⁵Indiana University Medical Center, USA

Purpose: To describe mineral biochemistries and bone metabolism biomarkers in healthy early pubertal adolescents and to determine differences in these measures among blacks, whites, boys, and girls. **Methods:** Baseline fasting blood and urine from 247 healthy early pubertal (Tanner stage 2-3) US adolescents (black girls $n = 55$, black boys $n = 51$, white girls $n = 64$, white boys $n = 77$) participating in a randomized controlled trial of vitamin D supplementation were measured for serum osteocalcin (OC), bone alkaline phosphatase (BAP), parathyroid hormone (PTH), calcium (Ca), phosphate (Pi), creatinine (Cr) and urine Ca, Pi, Cr, and N-telopeptide cross-links (NTx). Differences in these variables among blacks, whites, boys, and girls were analyzed using ANOVA with SAS 9.2 (Cary, NC) and significance set at $\alpha = 0.05$. Pearson correlations were used to assess associations among variables. Variables were inspected for normal distribution and transformed when appropriate. **Results:** OC was higher in blacks than whites (37 vs. 30 ng/mL), and did not differ between boys and girls. NTx was lower in blacks than whites (529 vs. 613 nM/mM) and higher in girls than boys (600 vs. 556 nM BCE/mM Cr). BAP was higher in black girls than white girls (235 vs. 201 U/L). Serum Pi was higher in blacks than whites (5.2 vs. 5.0 mg/dL), serum Ca was higher in black boys than white boys (9.9 vs. 9.8 mg/dL) and there were no sex differences in serum Ca or Pi. Serum Cr was higher in blacks than whites (0.67 vs. 0.62 mg/dL) and in boys than girls (0.66 vs. 0.62 mg/dL). Urine Ca/Cr mg ratio was higher in whites than blacks (0.07 vs. 0.04) and was higher in black boys than black girls (0.05 vs. 0.03). Urine Pi/Cr mg ratio was higher in whites than blacks (3.69 vs. 3.17) but there was no sex difference. Positive correlations existed among OC, BAP and NTx. Additionally, serum PTH and Pi were positively associated with bone turnover, serum PTH was negatively associated with urine Ca/Cr, and urine Ca/Cr and P/Cr were negatively correlated with bone turnover. **Conclusions:** Black children had different mean values for bone turnover markers compared with whites, but the direction of the difference varied by marker, and bone turnover markers were most strongly associated with serum Pi. Blacks had lower urinary calcium excretion than whites, which was most strongly associated with serum PTH.

MO0024

Influence of Bone Age and Diet-induced Weight Loss on Bone Mineral Density in Prepubertal Obese Children. Guillermo Martinez Diaz-Guerra¹, Gabriel Martos², Sonsoles Guadalix³, Jesus Argente², Federico Hawkins⁴. ¹University Hospital 12 Octubre, Spain, ²Hospital Infantil Universitario Nino Jesus, Spain, ³University Hospital 12 de Octubre, Spain, ⁴Hospital Universitario, Spain

Background: The effects of obesity and weight loss after caloric restriction in bone mass of young obese children have been insufficiently studied to date.

The aims of this study were: 1) To compare the standardized spine BMD (LS-BMD) of a group of obese children according to both their chronological (CA) and their bone age (BA). 2) To evaluate the effect of diet-induced weight loss on BMD in childhood obesity.

Patients and Methods: Prospective study in 25 prepubertal obese children (19 boys/6 girls; mean age 8.71.5 years; mean BMI 4.71.3 SDS). BA was estimated according Greulich & Pyle method at baseline. Spine BMD (L1-L4) measurements and body composition analysis were performed at baseline and 12 months (Hologic QDR 4500) after reducing their BMI in more than 1.5 SDS. Therapeutic plan included caloric restriction, self-registered physical activity and behavioural management.

Results: BA was significantly higher than CA in obese children (9.5 2.0 vs 8.7 1.5 years; $p < 0.001$). Standardized LS BMD was significantly higher if referred to CA (2.04 1.24 SDS) than to BA (1.32 1.27 SDS; $p < 0.001$). According to CA, 56% of patients had high bone mass (defined as BMD > 2 SDS) whereas according to BA, 28% had high bone mass.

Weight loss determined a reduction of the raw (41.4 2.9 vs. 36.6 4.4%) and standardized (3.9 0.7 vs. 2.9 0.8 SDS) percentage of body fat (both $p < 0.001$). In contrast, a significant increase in LS BMD (0.714 0.070 vs. 0.764 0.099 g/cm²; $p < 0.001$) was observed without changes in standardized LS BMD (2.0 1.2 vs. 2.3 1.5 SDS).

Conclusions 1) Obese prepubertal children show an advance in skeletal development. 2) Referral of BMD to CA overestimates bone mass in these children. 3) Properly controlled weight reduction does not alter BMD acquisition in prepubertal obese children.

Disclosures: Guillermo Martinez Diaz-Guerra, None.

MO0025

Insulin Inhibits Cortical Bone Development Independently of Body Composition: Findings From a Cross Sectional Analysis of pQCT Parameters in Adolescents. Adrian Sayers¹, Debbie Lawlor¹, Naveed Sattar², J.H. Tobias³. ¹University of Bristol, United Kingdom, ²University of Glasgow, United Kingdom, ³Avon Orthopaedic Centre, United Kingdom

Background / Aim: Hyperinsulinaemia may be a risk factor for low bone mineral density, possibly reflecting a lipotoxic effect of intra-muscular fat deposition on bone. We aimed to determine if insulin is related to bone development, and if so whether this effect is independent or mediated by changes in body composition including intra-muscular fat deposition.

Methods: A total of 2784 boys and girls (mean age 15.5 years) from the Avon Longitudinal Study of Parents and Children participated in the study. Blood samples were taken after an overnight or minimal 8-hour fast and insulin levels were measured using a Mercodia ELISA which does not cross-react with pro-insulin. Periosteal circumference and cortical bone mineral density was measured at the 50% tibial site using peripheral quantitative computed tomography. Subcutaneous fat area, muscle density (inversely related to intramuscular fat), and muscle cross sectional area (MCSA) were also calculated.

Results: Insulin was positively associated with PC in minimally adjusted (age/sex) analyses [β 0.015 (95%CI:0.003,0.027), $P=0.015$] (β = change per 50% increase in insulin), but there was an inverse association following further adjustment for height, MSCA, subcutaneous fat and muscle density [β -0.013 (95%CI:-0.022,-0.003), $P=0.008$]. Insulin was inversely related to BMD_C in both minimal and more completely adjusted analyses [β -0.018 (95%CI:-0.030,-0.006), $P<0.0001$, more completely adjusted model].

Path analyses revealed inverse associations between insulin and PC via a direct path [β -0.012 (95%CI:-0.022,-0.003), $P=0.01$], and an indirect path through muscle density [β -0.002 (95%CI:-0.004,-0.001), $P=0.0004$]. Positive indirect associations were also seen between insulin and PC via subcutaneous fat [β 0.013 (95%CI:0.009,0.016), $P<0.0001$] and MCSA [β 0.015 (95%CI:0.010,0.020), $P<0.0001$].

Conclusions: The relationship between insulin and PC via intramuscular fat provides evidence of a lipotoxic effect on bone. However, an inverse association between insulin and bone parameters persisted after adjusting for body composition, suggesting insulin also acts to inhibit bone development via a direct pathway yet to be elucidated.

Disclosures: Adrian Sayers, None.

MO0026

Skeletal Muscle Fat Content is Inversely Associated with Bone Strength in Young Girls. Joshua Farr¹, Janet Funk², Zhao Chen³, Jeffrey Lisse⁴, Robert Blew⁵, Vinson Lee⁵, Monica Laudermilk⁵, Timothy Lohman⁴, Scott Going⁴. ¹Mayo Clinic, USA, ²University of Arizona Health Sciences Center, USA, ³University of Arizona College of Public Health, USA, ⁴University of Arizona, USA, ⁵The University of Arizona, USA

Childhood obesity is an established risk factor for insulin resistance and type 2 diabetes mellitus. Its influence on bone development, however, remains controversial, and may depend on the regional pattern of fat deposition. Consequently, we examined associations of regional fat compartments (calf and thigh) with weight-bearing bone parameters in girls. Data from 444 girls aged 9–12 years from the “Jump-In: Building Better Bones” study were analyzed. Peripheral quantitative computed tomography (pQCT) was used to assess volumetric bone mineral density (vBMD, mg/cm³), bone geometry, and indices of bone strength at metaphyseal and diaphyseal sites of the femur and tibia along with subcutaneous adipose tissue (SAT, mm²) and muscle density (mg/cm³), an index of skeletal muscle fat content. As expected, SAT was positively correlated with total body fat mass ($r = 0.87-0.89$, $p < 0.001$) and muscle density was inversely correlated with total body fat mass ($r = -0.24$ to -0.28 , $p < 0.001$), supporting that pQCT provides useful measures of regional adiposity. Multiple linear regression with muscle density, SAT, muscle cross-sectional area, bone length, maturity offset, and ethnicity as independent variables gave significant associations between muscle density and trabecular vBMD ($\beta = 0.11-0.26$, $p < 0.05$) and bone strength index ($\beta = 0.13-0.19$, $p < 0.001$) at metaphyseal regions of the femur and tibia. In contrast, associations between muscle density and trabecular area at metaphyseal regions of the femur and tibia were non-significant ($p > 0.05$). Positive associations were observed between muscle density and cortical vBMD ($\beta = 0.08-0.17$) and area ($\beta = 0.06-0.08$) at diaphyseal regions of the femur and tibia, whereas associations between muscle density and endosteal and periosteal circumferences at diaphyseal regions of femur and tibia were lower and non-significant (all p values > 0.05). In addition, significant associations were observed between muscle density and strength-strain index ($\beta = 0.06-0.09$, $p < 0.01$) at diaphyseal regions of the femur and tibia, whereas associations between SAT and bone parameters were non-significant at all skeletal sites (all p values > 0.05), except metaphyseal bone strength index of the tibia ($\beta = 0.09$, $p = 0.029$). In conclusion, our results suggest that excess skeletal

muscle fat content of the calf and thigh may be detrimental to the development of weight-bearing bones in young girls.

Disclosures: Joshua Farr, None.

MO0027

Lumbar Bone Mineral Density (BMD) in Children with Duchenne Muscular Dystrophy Treated with Corticosteroids. Cristina Tau^{*1}, Gisela Viterbo², Soledad Monges³, Juliana Castagneto¹. ¹Metabolismo Calcico, Endocrinolog  a, Hospital de Pediatria Garrahan, Argentina, ²Endocrinolog  a, Hospital de Pediatria Garrahan, Argentina, ³Neurolog  a, Hospital de Pediatria Garrahan, Argentina

Reduced mobility and glucocorticoids as adjunctive therapy may cause osteoporosis and fractures in children with Duchenne muscular dystrophy (DMD). We analyzed the BMD in 16 boys with DMD treated with deflazacort or methylprednisone, age, time of immobilization, treatment duration, and cumulative dose of corticosteroids therapy. Lumbar L2-L4 BMD was measured by dual-energy X-ray absorptiometry (Lunar, Prodigy). Mean age was (SD) 11.53 years (range, 6.3-18.2). All children received deflazacort (0.9mg/kg/day, n=10) or methylprednisone (0.75mg/kg/day, n=6) during 3.82.1 years (range, 0.75-7), with vitamin D (300 to 2400 IU), and calcium supplement (0.25 to 1 g/day). Calcium intake by dairy products was 594221 mg/day. Serum calcium (Ca), phosphate (P), alkaline phosphatase (AP), PTH, and urinary calcium and D-Pyridoline/creatinine (uD-Pyr) were measured. Weight (Z-Score) was -0.151.16 (-1.70 to 2.65), height was -1.690.95 (n:9; -2.7 to -0.08). Eight patients were wheelchair-bound (mean age: 13.42.6 years), and the mean age for walking incapacity was 10.9+/-1.5 years. Time of their immobilization was 2.32.2 years. Two patients had long bone fractures, seven patients had vertebral crush fractures (two of them could walk). The cumulative corticosteroids dose was 28,520.3 g (range, 6.3-68.4). Mean BMD Z-score was -2.51.6 ranging from -5.9 to -0.4. BMD Z-score was <-2 in nine patients (56%), and between -1 and -2 in four patients (25%). BMD-Z-score was inversely correlated with age (p<0.000), time of immobilization (p<0.02), and duration of corticosteroid therapy (p<0.001). BMD-Z-score was also inversely correlated with cumulative dose of corticosteroids both in patients receiving deflazacort and those receiving methylprednisone (p<0.000). Patients with vertebral crush fractures had lower BMD (Z-score: -3.781.26, p<0.006). The number of fractures was positively correlated with cumulative corticosteroids dose. Ca, P, AP and PTH were within the normal range. Urinary calcium was increased in six patients (four were wheelchair-bound) and four other patients had increased uD-Pyr (three of them were immobilized). In summary, severe osteoporosis was found in children with DMD. Lowest BMD was correlated with treatment duration, cumulative corticosteroids dose, and time of immobilization.

Disclosures: Cristina Tau, None.

MO0028

Idiopathic Infantile Hypercalcemia. Stepan Kutilek^{*1}, Sylva Skalova², Josef Gut³, Milan Bayer². ¹Pardubice Hospital; Faculty of Health Studies; University of Pardubice, Czech Republic, ²Department of Paediatrics in Hradec Kralove, Faculty of Medicine in Hradec Kralove, Charles University in Prague, Czech Republic, ³Dept. of Pediatrics, Ceska Lipa Hospital, Czech Republic

Idiopathic infantile hypercalcemia (IIH) is a rare cause of hypercalcemia in the first year of life. IIH has an estimated incidence of approximately 1 in 47,000 live births. We present three patients with IIH, where other causes of hypercalcemia were clearly ruled out. In two girls aged 1.5 and 5 months, the S-Ca peaked to 5.2 and 4.3 mmol/L, respectively. Hypercalcaemia resolved after furosemide and glucocorticoid application. In the third patient, a 5-months old boy, S-Ca reached 5 mmol/L, and two doses of intravenous pamidronate were necessary due to poor effect of steroids and furosemide.

IIH was originally described during a period of high-dose vitamin D fortification in England in the 1950s. The diagnosis of IIH can be established only after the exclusion of other conditions that cause hypercalcemia in the first year of life, such as Williams syndrome, benign familial hypocalciuric hypercalcemia, severe neonatal hyperparathyroidism, Janssensmetaphyseal dysplasia, primary hyperparathyroidism, vitamin D intoxication, granulomatous diseases, thyroid disease, malignancy. Identification of the gene for Williams syndrome (WS) now allows a clear separation of IIH from WS. The inheritance and pathogenesis of IIH remains largely unknown, with only sporadic cases reported to date. Familial occurrence has been also documented. IIH presents between the ages of 3 and 7 months with nonspecific signs and symptoms such as lethargy, thirst, hypotonia, poor feeding, failure to thrive, dehydration, constipation and respiratory distress, all due to hypercalcemia. Hypercalciuria with nephrocalcinosis is also common finding in IIH. Only limited published data exist on the natural history of IIH, with case reports suggesting that hypercalcaemia spontaneously resolves when the child is approximately 12 months of age. Treatment consists of furosemide (given only after rehydration), glucocorticoids, and eventually calcitonin. The application of pamidronate in our patient is a first report of such treatment in IIH, as until now pamidronate has not been used in IIH, but only in one patient with WS. In conclusion, IIH is a rare condition of uncertain pathogenesis and natural history. Appropriate treatment improves outcome of patients with IIH.

Mechanical-Tactile Stimulation Increases Tibial Bone Strength in Preterm Infants. Laurie Moyer-Mileur¹, Hillarie Slater¹, Kimberly Neff¹, Joanna Beachy¹, Sandra Smith¹, Chelsea Evans¹, Brett Barrett¹, Shannon Haley^{*2}. ¹University of Utah, USA, ²University of Utah School of Medicine, USA

Preterm delivery (<37 wks post-menstrual age) is associated with suboptimal bone mass. Preterm infants experience numerous stressful events. Stress decreases insulin-like growth factor-I and in turn, osteoblast number and bone mass. We have reported improved stress response in preterm infants who received mechanical-tactile stimulation (MTS) consisting of kinesthetic movement and tactile stimulation. We hypothesized that twice daily MTS would increase bone formation and bone strength in preterm infants. Furthermore, we predicted that increased bone formation and bone strength would be associated with improved stress response and circulating IGF-1 levels. Preterm, AGA infants (29-32 wks, 10th-90th%ile) were randomly assigned to MTS (N=15) or Control (N=17). Twice daily, 20 min sessions of DMT were provided by a licensed massage therapist, 6 d/wk, for up to 4 wks. Control infants received the same care without MTS treatment. Treatment was masked to parents, health care providers, and study personnel. Baseline and weekly measures were collected for tibia speed of sound (tSOS, m/sec), a surrogate for bone strength, by quantitative ultrasound (Sunlight8000); serum IGF-1; urine markers of bone resorption (pyridinium crosslinks) and urine levels of osteocalcin (Glu-OC). Data are reported comparing changes from baseline to Day 15 on study by repeated measures with gender, weight gain, and corrected age a cofactors. Infant characteristics at birth and study entry as well as energy/nutrient intake were similar between MTS and Control. MTS intervention maintained tSOS values and prevented the decrease in tSOS observed in Control infants (p<0.001). MTS infants also experienced greater increases in serum IGF-1 as well as urine osteocalcin (Glu-OC; P<0.05). The markers of bone resorption, urinary deoxypyridinoline and pyridinoline, were not significantly different between groups. MTS improves bone strength in premature infants by attenuating the decrease that normally follows preterm birth. Further, MTS increased circulating IGF-1 levels as well as urinary osteocalcin (Glu-OC). Taken together, we speculate that MTS improves bone mineralization.

Transmission of a Floor-based Vibration Stimulus Across the Tibia and Femur in Children with Osteogenesis Imperfecta. Christopher Modlesky^{*1}, Marcus Spera¹, Kurt Manal¹, Brianne Mulrooney¹, Lauren Davey², Erica Hartman¹, Michael Bober². ¹University of Delaware, USA, ²A.I. DuPont Hospital for Children, USA

Purpose: There is evidence that a high-frequency, low-magnitude vibration (HLV) treatment administered daily increases bone mass and improves bone structure. It is plausible that the effect of the treatment is dictated by the degree to which the HLV stimulus reaches a bone site. The aim of this pilot study was to determine the degree to which an HLV signal emitted by a floor-based platform transmits across the tibia and femur of children with osteogenesis imperfecta (OI), a group that is very susceptible to fracture.

Methods: Seven children with mild OI (Type 1; 5-10 y) were randomly assigned to stand on a platform that emits an HLV (0.3 g, 30 Hz; n = 4; Juvent Medical, Inc, Somerset, NJ) or a platform that makes a similar sound but does not emit an HLV (n = 3). Tri-axial accelerometers (CXL10GP3; Crossbow, Technology, Inc, San Jose, CA) were placed on the medial aspect of the distal tibia (D tibia), the lateral condyle of the distal femur (D femur), the greater trochanter of the proximal femur (P femur) and on the platform. Accelerations were assessed for 30 seconds while the platform was off and for 30 seconds while the platform was on.

Results: Relative to the platform, acceleration transmission (mean SD) was 95 10% at the D tibia, 74 10% at D femur and 34 7% at P femur (see Figure). On the other hand, no notable differences were observed at any site in the placebo group.

Conclusions: The findings suggest that of the bone sites evaluated in the tibia and femur, the maximum effect of a floor-based HLV treatment should be at the distal tibia.

Active Shape Modelling of Bilateral Knee Osteoarthritis in the Osteoarthritis Initiative. Jennifer Gregory, Richard Aspden, David Reid, Rebecca J Barr, Fiona Saunders*. University of Aberdeen, United Kingdom

Purpose: To determine the changes in osteoarthritis (OA) by active appearance modelling (AAM) of a bilateral model of the knees.

Dataset: The male participants of Image group B from the Osteoarthritis Initiative (OAI) were selected. They were matched to suitable controls by age, height and weight after previous selection for beam angle (10 2.5).

Methods: This model was based on an active shape model of a single knee used in previous studies. A template of 186 points was constructed using a single image from the OAI image set using AAM software to describe the shape of the knees. The coordinates of the points were found semi-automatically in all images and principal components analysis (PCA) was used to reduce these variables to a small number of independent variables (modes). Here we describe the correlation between various measured parameters such as joint space narrowing and joint alignment in relation to shape and appearance mode 1. Correlations were carried out using Pearson's correlation in SPSS v18.0.

Results: Table 1 shows that the Image B cohort and the controls were well matched using the height and weight parameters ($p = 0.914$ and $p = 0.980$ respectively); however the age matching was less successful due to non-Gaussian distribution.

Correlations show that hip-knee angle, medial joint space narrowing and joint alignment were highly correlated to mode 1 in both shape and appearance (table 2). This was clearly shown by the model, as large changes in the distance between the knees were observed, with the joint alignment measurement and hip knee angle also being tied in with these observations. Medial joint space narrowing was also associated with these parameters. Osteophytes, a typical radiographic indicator of osteoarthritis were found not to be correlated until higher modes of shape and appearance variation (table 2). Other parameters such as symptomatic OA were found to be correlated with higher modes of change in shape and appearance. In addition to the shape changes described above, appearance mode 1 also showed sclerosis where there was evidence of joint space narrowing.

Conclusions: The data shows that the new bilateral knee model shown here is a strong model which correlates common anatomical features of OA such as joint space narrowing with changes in shape and appearance.

Table 1: Characteristics of Image B modelling cohort and matched controls

Variable	Image B cohort	Matched Controls	p value
Age	64 (52-72)	63 (52-71)	0.275†
Height (mm)	1771.3 ± 68.5	1772.5 ± 68.0	0.914
Weight (kg)	94.8 ± 13.7	94.7 ± 13.6	0.980
BMI	30.2 ± 3.7	30.1 ± 3.8	0.942
Beam Angle [degrees]	10.9 ± 2.4	11.11 ± 1.1	0.686

Analysed using paired t test except †Wilcoxon Signed Rank Test, mean ± SD except age which is median and interquartile range

Table 2: Correlation with selected OA parameters in mode 1

Variable	Shape mode 1 correlation (p value)	Appearance mode 1 correlation (p value)
Hip-knee angle (right)	0.558 (0.01)	0.565 (0.01)
Hip-knee angle (left)	0.507 (0.01)	0.523 (0.01)
Medial Joint space narrowing (right)	-0.348 (0.01)	-0.332 (0.01)

Are Raman Spectroscopic and MicroCT Compositional Measurements Commensurate?. Gurjit Mandair^{*1}, Jason P. Long², Jessica Lopez¹, Steven A. Goldstein², Michael D. Morris¹. ¹University of Michigan, Department of Chemistry, USA, ²University of Michigan, Orthopaedic Research Labs, USA

Purpose: This study examines whether bone tissue composition as measured by Raman spectroscopic mapping is commensurate with volumetric bone mineral density (vBMD) as measured by micro-computed tomography (microCT). **Methods:** Tibiae from a skeletally-mature, female beagle were obtained and the proximal metaphyses were removed for analysis. Specimens were dehydrated and embedded in polymethylmethacrylate. Distal and proximal cortical surfaces were mapped using Raman spectroscopy (six Raman maps per cortical bone type). MicroCT-scans were acquired (29 µm voxel size) and vBMD (mg/cc) values calculated at the same locations (ROI depths of 175 microns and 1.5 mm). Mean mineral-to-matrix (M/M) and carbonate-to-mineral (C/M) ratios were calculated from the pixel histograms of the corresponding Raman maps. Full-width at half-maximum (FWHM) of the Gaussian-fitted compositional histograms were used as measures of bone mineral heterogeneity. Similar data were obtained for cancellous bone along the proximal metaphyses (30 Raman maps). Correlations between Raman compositional parameters and vBMD, including FWHM were investigated. **Results:** By using 1.5 mm deep ROIs, moderate correlations were observed between distal vBMD and M/M ratios ($R^2 = 0.61$), the latter performed slightly better when compared to proximal bone ($R^2 = 0.43$). Correlations between vBMD and C/M for distal and proximal bone were moderate but improved significantly when the distal and proximal datasets were pooled together ($R^2 = 0.82$, $p \leq 0.001$). From FWHM studies, the strongest correlation was found between distal C/M and FWHM ($R^2 = 0.95$) and a partial correlation between distal M/M and FWHM ($R^2 = 0.41$). Raman analyses showed that cortical and cancellous bone composition along the proximal metaphyses were identical in terms of M/M ratios ($p \geq 0.8$) and C/M ratios ($p \geq 0.15$). In ongoing studies, we have observed similar moderate correlations in human specimens. **Conclusions:** As expected only moderate linear correlations between Raman compositional parameters and vBMD were found. Raman compositional parameters include information that is not directly related to calcium content. A better approach is to consider the techniques complementary measures of bone mineral content because Raman spectroscopy reports directly on ion substitutions within the mineral crystallites, while vBMD does not. Non-linear correlative methods may work better and these approaches are currently under development.

Biomechanical Role of Collagen Cross-Links in Bone Strength: Finite Element Study. Abdelwahed Barkaoui^{*1}, Ridha Hamblé¹, Awad Bettamer². ¹PRISME Institute, EA4229, University of Orleans, France, ²L'Université d'Orleans, France

Collagen cross-linking, a major post-translational modification of collagen, plays important roles in biomechanical features of bone. The aim of this work is to use a 3D FE model of collagen microfibril and to investigate the important roles of cross-links in the expression of bone strength and its capacity to absorb energy. Studies in vitro and in vivo have reported that increases in cross-linking are associated with enhancement of some mechanical properties (strength and stiffness) and reductions of others (energy absorption). These experimental data are limited in their ability to define individual biomechanical effects of cross-linking. In the present work the study of the effect of cross-links is more realistic that's because the proposed FE model succeed to combines the collagen, mineral and cross-links furthermore been able to varying the mechanical properties of each phase and to visualize their influence on corresponding properties of the collagen microfibril. FE model of microfibril with symmetric and periodic boundary conditions is considered here, with an array of five TC cross-linked together, the all is put into a mineral matrix. A parametric study was performed in order to investigate the influence of varying number of cross-links on the mechanical behaviour of the microfibril. This Finite element model was coupled to a UMAT to calculate the equivalent proprieties of microfibrils. From a FE point of view, spring elements can be used to model connections between two different regions to couple a force with a relative displacement representing the elasticity of the physical connecting constituents. In this study results were obtained under tensile loading with symmetric and periodic boundary conditions. These results show that the number of cross-links has a most influence on the increase in the elastic and failure properties, at constant Young's modulus, if the number of cross-link N increase the bone material will be more stronger, however when $N > 20$ fracture stress does not depend on the cross-link number and it remains at plateau value, same observation has been also found by M.J.Buehler in his molecular multi-scale study. Where it is found that fracture stress depend on the cross-link density β only when $\beta < 25$. This plateau can be explained by the fact that whenever the number of cross link increases their stiffness increases up a threshold value hence the behaviour of all collagen-cross-links becomes insensitive to the number N.

MO0034

Bone Mineral Density (BMD) and Microarchitecture Assessment by Trabecular Bone Score (TBS) at the Spine in Patients with Rheumatoid Arthritis (RA) and Systemic Sclerosis (SSc). Eugenie Koumakis^{*1}, Emese Toth¹, Marine Meunier¹, Emilie Maury², Andre Kahan¹, Yannick Allanore¹, Catherine Cormier³. ¹Rheumatology Department A, Cochin Hospital, APHP, Paris Descartes University, France, ²Service De Rhumatologie A, AP-HP Groupe Hospitalier Cochin - Saint Vincent De Pa, France, ³AP-HP Groupe Hospitalier Cochin, France

RA is a frequent chronic inflammatory rheumatic disease, and a frequent cause of secondary osteoporosis, due to a chronic inflammatory state and long-term glucocorticoid therapy (GC). In SSc, the risk of osteoporosis may be less important because of milder inflammation and fewer patients receiving glucocorticoids. The aims of our study were to examine BMD and bone microarchitecture by TBS in female patients with RA and SSc, to assess their associations with GC use and prevalent fractures and to compare these parameters between these 2 populations and with a control population of same age and sex.

Cross-sectional study of 82 female RA and 38 female SSc patients with mean age of 62.69.3 and 61.10.1 years, mean BMI of 24.44.4 and 26.53.7kg/m², mean disease duration of 17.613.2 and 9.78.6 years, mean CRP of 14.319.7 and 8.69.1mg/l, respectively. In the combined RA and SSc population (n=120), 104 were receiving GC (mean total dose of 3354626117mg in RA and 862111524mg in SSc). 35.3% of RA patients and 36.8% of SSc patients had a history of fracture. BMD and TBS were assessed at AP Spine (L1-L4) with DXA Prodigy (GE-Lunar) and TBS iNsight® (Med-Imaps).

In the combined RA and SSc population, TBS and BMD were significantly lower in patients with a history of fracture (n=43) than in non fractured patients (p=0.006 and p=0.03 respectively). 16 out of these 43 fractured patients had a spine and/or hip BMD in the osteopenia zone (T-score between -1 and -2.5), and TBS was below 1.35 (threshold defining microarchitectural alteration in studies of postmenopausal women) in 11/16 (68.8%) patients. In RA and SSc patients receiving more than 5mg/day of GC (n=55) TBS and BMD were significantly lower than in controls (p=0.007 and p=0.04 respectively), whereas there was no difference with patients receiving less than 5mg/day. Among SSc and RA patients with GC, SSc patients tended to have lower TBS than RA patients (not significant) despite lower total GC dose (p=0.01), higher BMI (p=0.03), and no difference in CRP between the 2 groups.

Microarchitecture assessment by TBS helped to differentiate between patients with and without fractures and between patients with GC and controls. TBS detected 68.8% of fractured patients in the osteopenia zone on BMD. TBS tended to be lower in SSc than in RA suggesting that in SSc there may be additional risk factors for osteoporosis other than glucocorticoid therapy and systemic inflammation, such as vascular alterations and fibrosis.

Changes in Osteocyte Density in Postmenopausal Women with Prodromal Bone Deterioration (PBD) in Femoral Shaft after Long Term Bisphosphonate Therapy. D. Sudhaker Rao, Shijing Qiu*, Saroj Palnitkar. Henry Ford Hospital, USA

In recent years, there is growing concern about atypical femoral fractures in patients on long-term bisphosphonate (BP) therapy. Such atypical fracture is often preceded by the presence of sub-periosteal new bone and fissure fracture line(s) in lateral femoral cortex, which we refer to as prodromal bone deterioration (PBD). We have previously demonstrated that bone fragility was increased in postmenopausal women with lower osteocyte density. In this study, we investigated whether the PBD resulting from long-term BP treatment is associated with compromised osteocyte integrity.

Trans-iliac bone biopsies were obtained from 4 age matched normal postmenopausal women and 4 postmenopausal PBD patients who had received >5 years of BP treatment. From toluidine blue stained sections, we measured numbers of osteocytes (Ot.N), empty lacunae (EL.N) and total lacunae (Tt.L.N) in osteonal and interstitial areas in cortical bone. Table 1 shows the differences in osteocyte-related variables between PBD patients and normal women. In both osteons and interstitial bone, the densities of osteocytes and total lacunae as well as the percentage of osteocyte occupied lacunae were significantly decreased in PBD patients, whereas the increase in empty lacunar density in PBD patients was seen only in osteons.

The results suggest that patients with PBD (or atypical fracture) have lower osteocyte density. Moreover, the severely suppressed bone turnover induced by long term BP therapy may exacerbate osteocyte deficit. The loss of osteocytes integrity would interfere with microdamage repair, increasing bone fragility and the risk of fracture.

MO0036

Chinese Women Have Greater Cortical Bone Density at the Hip Compared to White Women. Marcella Walker^{*1}, Isra Saeed², Donald McMahon¹, Julia Udesky¹, George Liu³, Thomas Lang², John Bilezikian⁴. ¹Columbia University, USA, ²University of California, San Francisco, USA, ³New York Downtown Hospital, USA, ⁴Columbia University College of Physicians & Surgeons, USA

Chinese women have lower rates of hip and forearm fracture than white women despite lower areal bone density (aBMD) by dual x-ray absorptiometry (DXA). We recently reported higher cortical bone density as well as greater trabecular and cortical thickness, but smaller bone area at the forearm and tibia as measured by high resolution peripheral quantitative computed tomography in Chinese (CH) compared to white women. Premenopausal, but not postmenopausal Chinese women, also had higher trabecular bone density compared to white women. It is unclear whether the differences in skeletal structure observed at peripheral sites are relevant to the central skeleton (lumbar spine and hip). This study was designed to assess this question by comparing racial differences at the lumbar spine (LS) and hip by quantitative computed tomography (QCT). Bone size and volumetric density (vBMD) in pre (PreM; n=83) and postmenopausal (PostM; n=50) CH and white women were determined by QCT. L1-L2 measures included vertebral cross-sectional area (VBSCA) and mid vertebra integral (INT) and trabecular (Tb) vBMD. QCT hip measures included INT, Tb and cortical (Ct) vBMD at the femoral neck (FN) and total hip (TH), FN cross-sectional area (FNCS) and the ratio of tissue volume in Ct regions to total tissue volume within the periosteal boundaries (C/I), a measure of Ct thickness. Age did not differ in either the preM or postM groups: PreM CH 354 vs. white 344yrs and PostM CH 612 vs. white 623 yrs. aBMD by DXA did not differ at the LS or TH in either the PreM or PostM groups. At the LS, VBSCA was smaller in CH compared to white women among PostM but not PreM women. There were no racial differences in INT or Tb vBMD in either age group at the LS. At the hip, FNCS was lower in CH than in white women: 6.5% lower (p=0.02) in preM CH and 8.2% lower (p=0.008) in postM Chinese. Cortical vBMD was 3.6% greater at the TH (p=0.02) in preM CH vs. white women, but there were no differences in Ct vBMD at the FN. Among PostM women, Ct vBMD was 4% greater in CH compared to white women at both the FN (p=0.04) and TH (p=0.03). There were no differences in INT or Tb vBMD or C/I at any hip site in either age group. Similar to the peripheral skeleton, we observed smaller bone size but greater cortical BMD at the hip in Chinese versus white women. The denser cortical compartment in Chinese versus white women may provide greater bone strength and therefore a lower risk of fracture despite smaller bone size.

Differentiation of Treatment Effects of Odanacatib from Alendronate in Ovariectomized Rhesus Monkeys Using Voxel Based Morphometry of Quantitative Computed Tomography Images. Sangeetha Somayajula^{*1}, Seetha R. Kummari², Todd Bredbenner³, Belma Dogdas⁴, John Szumiloski⁵, Mona L Purcell⁶, Paul McCracken⁷, DON WILLIAMS⁸, Le Thi Duong⁷, Sherri L Motzel⁹, Antonio Cabal¹⁰. ¹USA, ²Case Western Reserve University, USA, ³Southwest Research Institute, USA, ⁴Informatics -IT, Merck Research Laboratories, USA, ⁵Biometrics Research, Merck Research Laboratories, USA, ⁶Imaging, Merck Research Laboratories, USA, ⁷Merck Research Laboratories, USA, ⁸MERCK, USA, ⁹Lab Animal Resources, Merck Research Laboratories, USA, ¹⁰Merck & Co., Inc., USA

Preclinical evaluation of disease burden and treatment efficacy is critical to the development of new therapies for osteoporosis. Quantitative computed tomography (QCT) is a clinically translatable in vivo imaging modality that produces three-dimensional (3D) images of volumetric bone mineral density (vBMD). This enables localization of longitudinal changes in vBMD at each voxel using voxel based morphometry (VBM). Here, VBM was used to evaluate the local effects of odanacatib (ODN) and alendronate (ALN) in comparison to Vehicle (VEH) in ovariectomized (OVX) rhesus monkey. QCT data were obtained (spatial resolution 500 µm) for three groups (n=16 each) of OVX animals treated with VEH, 2 mg/kg ODN daily, and 15 µg/kg twice weekly ALN. Longitudinal QCT measurements were made at 0, 6, 9, 12, and 18 months post-treatment. Femurs were semi-automatically segmented from QCT images, and a statistical shape and density model was generated from all the subjects at each time point, leading to corresponding tetrahedral meshes describing proximal femur geometry with vBMD values assigned at each node of the mesh. In this corresponding representation, the longitudinal change of vBMD at each node is tracked, and the spatial distribution of density changes for each treatment group was obtained. Longitudinal changes in femoral neck vBMD are shown in Fig 1. We also performed a paired t-test (p=0.05, false discovery rate threshold 0.05) between baseline and 18 months for each group to find the nodes that have a significant increase in vBMD compared to baseline. The total number of nodes that showed significant increase was 782 for ODN, 475 for ALN, and 0 for VEH group (Fig.2). The distribution of distances of the interior significant nodes from the surface nodes is shown in Figure 3. While ALN had a nearly uniform distribution of significant nodes up to about 4 mm from the surface, ODN showed an approximately Rayleigh distribution with a peak around 2.5 mm (average cortical thickness is 2.2 mm). We

verified that this distribution is different from that obtained by a random sampling of interior nodes, confirming that the difference is due to treatment effect, and not by chance. This work shows that ODN is efficacious in increasing vBMD (femoral neck vBMD and number of significant nodes), and that the effect of ODN is more cortical compared to ALN. These findings are supported by data from other modalities and anatomic locations.

Figure1: Model means and relative standard errors of QCT femoral neck vBMD

Figure 3: Histogram of distances of significant internal nodes from surface nodes

Figure 2: Nodes showing significant increase in BMD from baseline to 18 months

MO0038

Hip Fracture in Older Women: Association with the Femoral Strength as Assessed by Finite Element Analysis of Qct Scans. Lang Yang*, Will J M Udall, Eugene V McCloskey, Richard Eastell. University of Sheffield, United Kingdom

Bone fractures only when loaded beyond its strength. Although conventional BMD by DXA predicts hip fracture well, it is not a specific measure of the bone strength. The purpose of this study was to determine the association of femoral strength, as estimated by finite element (FE) analysis of QCT scans, with hip fracture in comparison to femoral neck (FN) and total hip (TH) BMD.

We recruited 50 postmenopausal women (55-89 yrs) who had sustained hip fractures (37 intracapsular (IC) and 13 extracapsular (EC)) due to low-energy trauma. QCT scans were performed within 3 months of the fracture. For each fracture case a postmenopausal women, matched by age (5 yrs), weight (5 kg) and height (5 cm) was recruited as a control.

We performed linear-elastic FE analysis to simulate a sideways fall. The elastic modulus and yield stress of elements were calculated from the element vBMD. Femoral strength was defined as the impact force that caused the von Mises stress in a volume of at least 125 mm³ that's made up of contiguous elements to exceed the element yield stress. Odds ratio (OR) of hip fracture for one standard deviation change was derived from conditional logistic regression and area under the curve (AUC) from analysis of receiver operating characteristics. Significance level was chosen at $p < 0.05$.

As expected, the fracture group had lower FN BMD (0.568 SD 0.100 v. 0.659 SD 0.105 g/cm²), TH BMD (0.693 SD 0.136 v. 0.803 SD 0.125 g/cm²) and strength (2702 SD 746 v. 3664 SD 812 N) than the controls. The strength was highly correlated to the FN and TH BMDs ($r = 0.64$ & 0.72 , $p < 0.0001$). The hip BMDs and strength were significantly associated with hip fracture (see Table). Strength alone discriminated hip fracture significantly better than TH BMD. Bivariate logistic regression showed that strength was associated independently with hip fracture and significant larger AUCs than that of TH BMD were obtained by combining BMDs and strength.

In conclusion, femoral strength derived from the FE analysis of QCT scans has the potential to discriminate hip fracture better than BMD alone.

	OR (95% CI)	AUC (95% CI)
Univariate logistic regression		
FN BMD	4.3 (1.9, 9.5)	0.73 (0.63, 0.82)
TH BMD	5.5 (2.2, 13.9)	0.72 (0.62, 0.82)
Strength	5.1 (2.2, 11.6)	0.82 (0.73, 0.90) ^a
Bivariate logistic regression		
1. FN BMD	2.6 (1.1, 6.5)	0.81 (0.72, 0.89) ^{ab}
Strength	4.1 (1.6, 10.3)	
2. TH BMD	2.4 (0.8, 6.9)	0.79 (0.70, 0.88) ^b
Strength	3.6 (1.4, 9.1)	

Note: AUC with subscript a and b were significantly larger than that of FN and TH BMDs at $p < 0.05$, respectively.

MO0039

Insulin resistance, Diabetes, and Composite Indices of Femoral Neck Strength: Findings from The Hip Strength Across the Menopausal Transition Study. Shinya Ishii¹, Jane Cauley², Preethi Srikanthan³, Carolyn Crandall³, Mei-Hua Huang⁴, Michelle Danielson⁵, Gail Greendale³, Arun Karlamangla³. ¹UCLA, VA, USA, ²University of Pittsburgh Graduate School of Public Health, USA, ³University of California, Los Angeles, USA, ⁴UCLA, USA, ⁵University of Pittsburgh, USA

Diabetes mellitus (DM) has been associated with increased fracture risk, despite being associated with higher areal bone mineral density (aBMD). We hypothesized that this disparity is, at least partly, due to DM associations with bone size (which affects bone strength) and body size (which determines the forces on bone during a fall), and that composite indices of femoral neck strength, which integrate dual energy x-ray absorptiometry (DXA) derived aBMD, femoral neck width (FNW) and femoral neck axis length (FNAL) with body weight and height, and are inversely associated with hip fracture risk, would be lower in diabetic and pre-diabetic women than in women with neither condition. We also hypothesized that the strength indices would be inversely related to insulin resistance, the primary pathology in type 2 diabetes.

We analyzed data from 1887 women (from 4 ethnic groups: Caucasian, African American, Chinese and Japanese) from the baseline visit of the Study of Women's Health Across the Nation (SWAN), when participants were in either pre- or early peri menopause. Composite indices for femoral neck strength in different failure modes were created as $aBMD \times FNW / \text{weight}$ for compression strength index (CSI), $aBMD \times (FNW)^2 / FNAL$ for bending strength index (BSI), and $aBMD \times FNW \times FNAL / \text{height} \times \text{weight}$ for impact strength index (ISI). Women were categorized into DM (n=81), pre-diabetes (n=291), and normal groups (n=1515) based on fasting glucose

measurements, self-report of DM, and review of medications. Homeostasis model assessment of insulin resistance (HOMA-IR) was calculated from fasting values of glucose and insulin, and log-transformed for analysis. Multiple linear regression models were used to adjust for age, race/ethnicity, menopausal stage, body mass index (BMI), smoking status, and study site.

Areal BMD was higher and yet all three composite strength indices were lower in women with DM and pre-diabetes than in women who were normal (Table). There were graded inverse relationships between HOMA-IR and all three strength indices in LOESS plots; these inverse relationships persisted after adjusting for covariates in linear regression. (Table).

Relative to the loads they bear, diabetic women have lower femoral neck strength, consistent with their documented higher rates of fracture. Insulin resistance appears to play an important role in the reduction in bone strength in diabetes.

Measuring Apparent Trabecular Structure with the Stratec pQCT: A Comparison with HR-pQCT. Deena Lala^{*1}, Angela Cheung², Kayla Hummel¹, Dean Inglis³, Christopher Gordon³, Lora Giangregorio¹. ¹University of Waterloo, Canada, ²University Health Network, Canada, ³McMaster University, Canada

Background/Objective: Peripheral quantitative computed tomography (pQCT) is used to assess bone density and cortical bone structure. Previous work suggests that the Stratec pQCT can be used to estimate apparent trabecular structure, but it is unknown how this technique compares to comparatively newer methods with improved spatial resolution such as high-resolution pQCT (HR-pQCT). We examined the accuracy of pQCT-based measurements of cortical thickness, density and apparent trabecular structure at the ultra-distal tibia, using HR-pQCT as a gold standard.

Methods: Fifteen dry human tibia specimens were immersed in saline in a sealed cylinder and scanned 22.5mm from the distal tibia plateau using pQCT (one slice; thickness: 2.2mm; pixel size 0.2mm x 0.2mm; Stratec XCT2000), and HR-pQCT (simultaneous acquisition of 110 slices; thickness: 9.02mm; isometric voxel size 82µm; Scanco XtremeCT). Pearson correlations were used to examine relationships between the techniques for apparent trabecular structure variables (average hole size, H_A ; trabecular spacing, TbSp; bone volume to total volume, BV/TV; trabecular volumetric bone mineral density, TDen; trabecular area, TbA; total area, TotA) and cortical thickness (CTH) and density (CDen). pQCT measures of H_A , BV/TV, TbSp, were assessed using custom developed software, while Stratec software was used to obtain TDen, TbA, TotA, and CDen, and CTH was obtained using both. H_A was compared to TbSp to establish convergent validity. Bland-Altman analyses were performed to qualitatively investigate measurement bias between pQCT and HRpQCT. All analyses were performed using SAS 9.2.

Results: All variables were well correlated ($r^2=0.50-0.98$, Table 1). pQCT estimates of H_A , TbSp, BV/TV, TDen, TbA, CTH (custom), CDen, and TotA were overestimated, while CTH (Stratec) was underestimated compared to HRpQCT (Table 1). Additionally, as values of H_A , BV/TV, TotA increased, the difference in methods increased, however as values of CTH (Stratec) increased, the difference in methods decreased. There were no proportional differences for TbSp, TbA, CDen, CTH (custom software), and TDen.

Conclusion: pQCT-based measurements of cortical thickness, density and apparent trabecular structure at the ultra-distal tibia were well correlated with HR-pQCT estimates. pQCT yielded higher values for H_A , TbSp, BV/TV, TDen, TbA, CTH (custom), CDen, TotA, and lower values for CTH (Stratec).

Morphometric Assessment of Vertebral Fracture Risk in Postmenopausal Women using Vertebral Shape Models and Discriminative Shape Alignment. Alessandro Crimi¹, Marco Loog², Marleen de Bruijne³, Mads Nielsen⁴, Martin Lillholm^{*5}. ¹Nordic Bioscience & University of Copenhagen, Denmark, ²Delft University of Technology, Netherlands, ³University Medical Center Rotterdam, Netherlands, ⁴University of Copenhagen, Denmark, ⁵Synarc Imaging Technologies, Denmark

Purpose

The FRAX index summarizes osteoporosis risk factors, such as, prevalent vertebral fractures and BMD into a 10-year risk of major osteoporotic fractures. Vertebral deformities below accepted fracture thresholds are, however, not normally considered. This work investigated to which extent vertebral pre-fracture morphometric changes offer risk segregation in addition to standard OP risk factors.

Methods

A case group of 19 postmenopausal women was selected as the subset of an epidemiological study population (PERF) that had no vertebral fractures at baseline and developed at least one incident fracture in the lumbar region (T12-L4) by follow-up (6.3 years). 91 controls that remained fracture free throughout were matched to the case group based on BMD, BMI, age, and other standard OP risk factors. Lateral radiographs were acquired at baseline and follow-up. Vertebral fracture status was assessed, using Genant's semi-quantitative method, by an experienced radiologist. Subsequently, the corner and mid-points of the two vertebral end-plates were annotated for each lumbar vertebra using a computer-program.

A shape model was trained on the spine/vertebral shapes represented by the lumbar height points using Discriminative Shape alignment (DSA) and each shape represented using 2-4 eigenmodes. The ability to separate cases from controls at baseline was tested using a linear classifier. The performance was estimated using unbiased cross-validation. The inter-annotator reproducibility was assessed through repeat annotations by two trained x-ray technicians.

Results

Based on the ROC-curves for separation of cases and controls at baseline, results are reported as the area under the curve (AUC) and a Delong p-value indicating significance of performance relative to chance. The AUC for the radiologist was AUC = 0.73, $p=0.01$. For the two repeat annotations, the values were AUC=0.70, $p=0.02$ and AUC=0.70, $p=0.01$ respectively, yielding an inter-annotator CV of 2.4%.

Conclusion

For groups matched for standard OP risk factors, the suggested methodology was able to segregate lumbar fracture risk using pre-fracture vertebral deformities measured at baseline. The inter-annotator reproducibility between radiologist and technicians was good. Inclusion criteria for OP clinical trials, such as, BMD and prevalent vertebral fractures could be supplemented by a morphometric measure of fracture risk and potentially improve statistical power or reduce required samples sizes.

MO0042

Nanoindentation Shows Significantly Increased E, H and Viscosity for Sclerotic Bone Healing Response, Corresponding well with Micro-CT and pQCT Results. Xiuli Chen^{*1}, Yong Hoow Chan², Sungyun Park², James Goh³, Shamal Das De³, Richie Soong⁴, Taeyong Lee¹. ¹National University of Singapore, Singapore, ²Division of Bioengineering, National University of Singapore, Singapore, ³Department of Orthopaedic Surgery, National University Hospital, Singapore, ⁴Department of Pathology, National University of Singapore, Singapore

Purpose

Sclerotic bone formation, which was found in some rodent bones with osteolytic W256 mammary carcinoma cells induced, is similar to the development of lytic lesions into sclerotic for benign tumors. The aim of this study is to quantify changes in bone

micro-mechanical, micro-structural and materials properties of localized sclerotic healing response.

Methods

28 female SD rats were inoculated with W256 cells in the left femur, 5 mm away from distal metaphysis. 9 SD rats were sham operated in the left femur. Localized sclerotic bone formation away from surgical site was observed from histological evaluation at 10, 30, 50 day time points. At 50 day, femurs were harvested and subjected to microCT, pQCT scanning. Following that, the bones were embedded in epoxy, polished and rehydrated for nano-indentation. A Berkovich tip was used to indent on the bone using CSM (Continuous Stiffness Measurement) mode at 45Hz. Forty indentations were made per bone specimen and creep test was carried out at maximum load of 6.3mN for 400s. Viscosity (η) was evaluated using Voigt model.

Results

Histological observation of localized woven bone formation was concurred in pQCT images (Figure 1). Significant increases in BMD % change (Figure 2A), cortical density % change, BMC % change (compared to intact RF) were observed as compared to sham groups ($p < 0.05$). Similarly, nanoindentation results showed significant increases in elastic modulus (E) (Figure 2B), hardness (H) and viscosity (η) (Figure 2C) in sclerotic cortical bone in the same ROI as compared to the normal bone. This is not unexpected since increase in mineralization (as indicated from increases in BMC and BMD) increases E. In sclerotic bone, significant Pearson correlation was also found between h and H ($R = 0.540$, $p = 0.009$) and a weaker correlation between h and E ($R = 0.414$, $p = 0.055$). These results correspond well with previous study [2], where there were positive relationships of h with E and H .

Conclusions

Nanoindentation was able to quantify localized mechanical property changes for sclerotic healing response, which complemented micro-structural and material property changes monitored by microCT and pQCT. Similar sclerotic bone formation found in other benign tumor cases can change the local mechanical properties of bone with increase in E , H and h . This study helps to demonstrate the use of nanoindentation for the study of diseased bone and localized drug effect.

Physical Exercise Programs in a Female Rat Model: What Is the Most Osteogenic? Priscilla C. AVELINE*, Eric LESPESSAILLES, Claude-Laurent BENHAMOU, Gael Rochefort, INSERM U658, France

Physical exercise is a well-recognized intervention to adapt the skeleton and to increase bone density and bone mass by changing bone architectural, remodeling and mechanical properties. Exercise triggers an osteogenic response increasing bone strength. The aim of this study was to determine in a female rat population what is the best physical exercise to improve bone quality.

In this study, four different exercise groups were studied: fall impact 30 cm (F30), fall impact 45 cm (F45), fall impact 60 cm (F60), a treadmill (T) group and a sedentary group. Each group included 10 female Wistar rats, 8 weeks old at baseline. Animals were subjected to 10 impacts per day from different heights, 5 days a week or run on a treadmill: 1h a day, 5 days a week during 8 weeks. Bone mineral density (BMD) and content (BMC) (whole body and left femurs) were measured by DXA (Hologic Discovery) at different time of the study (week 0, week 4 and week 8). Morphological properties of the trabecular bone from tibias, femurs and L2 to L4 vertebrae were analyzed by micro-computerized tomography (Skyscan 1072) and mechanical properties were recorded.

BMD and BMC on whole body and left femurs increased all groups versus baseline but differences between groups were not significant. In terms of bone mass (BV/TV), the F45 and F60 groups had significantly higher values than the 5 groups, while the F30 and T groups had no higher values than the 5 groups. The profile was

similar concerning Tb.N, Tb.Th, while Tb.Sp, Tb.Pf and SMI were significantly lower in the F45 and F60 groups. For mechanical properties, F45 were significantly superior to the other groups concerning the Young modulus.

These data suggest that the treadmill exercise and the impact 30 cm (with this specific intensity) are not beneficial on bone status, while impacts from 45 and 60 cm appear the most osteogenic, and impact 45 cm gives the best mechanical results.

μ CT results on the percent of bone volume (BV/TV) from femurs, tibias and vertebrae after different physical exercises, compared to sedentary.

Fall impact 45 cm (F45) or fall impact 60 cm (F60) were significantly (*) increased compared to control (C), fall impact 30 cm (F30) or treadmill (T). These results showed that the impact 45cm and 60cm exercises induced a higher rise of bone volume than the other exercise. Physical exercise had also different effect on bone sites.

Pre- and Post-Menopausal Differences in Bone Density, Microstructure, and Mechanical Competence in Chinese-American and Caucasian Women. Xiaowei Liu^{*1}, Marcella Walker², Emily Stein¹, Bin Zhou², Julia Udesky², George Liu³, Donald McMahon¹, Elizabeth Shane¹, John Bilezikian¹, X Guo². ¹Columbia University College of Physicians & Surgeons, USA, ²Columbia University, USA, ³New York Downtown Hospital, USA

Despite lower areal BMD (aBMD) by DXA, Chinese-American (CH) women have fewer fractures than Caucasian (CA) women. We applied individual trabeculae segmentation (ITS) and finite element analysis to high-resolution peripheral QCT images of the distal radius (DR) in pre- (PreM; n=95) and post-menopausal (PostM; n=97) CH and CA women to quantify trabecular (Tb) plate- and rod-microarchitecture and bone stiffness.

Age did not differ between PreM groups (CH 367 vs. CA 357 yrs) but was lower in PostM CH (CH 612 vs. CA 643 yrs). Height and weight were lower in the CH vs. CA groups (PreM: CH 162cm 57kg vs. CA 165cm 63kg; PostM: CH 157cm 58kg vs. CA 163 cm 66kg, $p < 0.05$). aBMD did not differ at the spine, hip or 1/3 radius in either age group. At DR, PreM CH had 14% greater Tb vBMD (Dtrab), 65% higher Tb plate vs. rod ratio (P-R Ratio), 46% higher plate bone volume fraction (pBV/TV), and 23% greater plate-plate junction density (P-P Junc.D, indicating intactness of Tb network) compared to PreM CA women ($p < 0.001$). Despite smaller bone size (-9%, $p = 0.03$), greater cortical thickness and vBMD (Ct.Th & Dcort, 18% & 4%, $p < 0.001$) and more Tb plates led to 14% greater whole bone stiffness ($p < 0.05$) in PreM CH vs. CA women. In contrast, PostM CH had similar Dtrab, pBV/TV, and P-P Junc.D, yet 38% higher P-R Ratio ($p = 0.01$) compared to PostM CA women. Despite smaller bone size (-10%, $p = 0.008$), PostM CH women had greater Ct.Th & Dcort (18% & 6%, $p < 0.01$) and relatively intact Tb plate, resulting in similar bone stiffness compared to CA women.

The aBMD at each site, and Ct.Th and Dcort at DR were significantly lower in PostM vs. PreM, and the PreM-PostM differences were similar between CH and CA women. Whole bone stiffness, Dtrab, and Tb plate parameters were also significantly lower in PostM vs. PreM women. Moreover, the PreM-PostM differences in Dtrab and pBV/TV were significantly greater ($p < 0.05$) in CH and the differences in stiffness, P-R ratio, and P-P Junc.D tended to be greater in CH vs. CA women ($p = 0.06$, Table 1).

The data show greater microstructural advantages in both Ct and Tb bone in PreM CH women. However, differences between the PreM-PostM groups suggest greater loss in plate-like Tb bone in PostM CH women. Nevertheless, advantages such as thicker cortices and more plate-like Tb bone remain in PostM CH. The results provide greater insight into the microstructural advantages of the CH vs. CA skeleton in both pre- and postmenopausal states.

PostM vs. PreM	CH (%)	CA (%)	p-value (PreM-PostM differences in CH vs. CA)

Pyridoxamine and Sorbinil Do Not Prevent Bone Mechanical and Tissue Deterioration in a Rat Model of Type 2 Diabetes. Maxime Gallant^{*1}, Kathleen Hill¹, Benjamin Rowland¹, Matthew Allen¹, Richard G. Peterson², David Burr¹. ¹Indiana University School of Medicine, USA, ²PreClinOmics Inc., USA

Type 2 diabetes mellitus (T2DM) is metabolic disorder characterized by high blood glucose levels and insulin resistance. The hyperglycemia in T2DM causes an increase in advanced glycation end products which are known to negatively affect bone tissue, resulting in a more brittle bone phenotype. We hypothesized that pharmacologically interfering in the glucose and fructose-induced glycation pathways with the vitamin B6 vitamer pyridoxamine (PM) or the aldose reductase inhibitor sorbinil (Sorb), respectively, would prevent bone tissue deterioration in a rat model of T2DM.

Fifteen week-old Zucker Diabetic Sprague-Dawley (ZDSD) and control CD rats were fed a high-fat diet (Purina 55CA) for 3 wks to induce T2DM and were treated with PM (100 mg/kg, s.c.), Sorb (65 mg/kg, p.o.) or respective vehicles for 15 wks. A baseline group of both strains was analyzed at 15 wks of age, before the diet-induced initiation of T2DM. Bones were analyzed post-mortem for changes in density, architecture, and mechanical properties. Blood chemistries were also performed. Two-way ANOVAs were performed to look at strain and diet effect between the baseline and control animals, and strain and treatment between the controls, PM and Sorb groups.

At baseline, the ZDSD and CD rats had similar BMD, BV/TV and vertebral mechanical and tissue properties. However, the ZDSD had significantly stronger and stiffer femurs but lower energy absorption capacity compared to CD controls. These differences in whole bone mechanical properties remained after correction for differences in geometry indicating the differences exist at the tissue level.

The high-fat diet induced T2DM in ZDSD rats but not CD rats, as expected, and significantly decreased BMD, bone mechanical and material properties at both the femur and vertebra compared to the control CD rats.

Treatment with pyridoxamine had no beneficial effect on any bone parameter and in some cases reduced properties compared to untreated controls (e.g. decreased vertebral strength). Sorbinil increased femur toughness, but only in CD rats; no beneficial effect of sorbinil was observed in ZDSD rats.

These results show that pyridoxamine does not positively affect bone properties in a rat model of T2DM or in control rats. Sorbinil had some positive effects on bone, but seemed to be effective only in control CD rats. The rapid onset of T2DM in the ZDSD rat model may reduce the potential therapeutic window available to improve bone mechanical properties.

Quantitative Bone Micro-Architecture in Young Adults Using Multi-Detector CT Imaging and Volumetric Topological Analysis – A Feasibility Study. Punam K. Saha^{*}, Yinxiao Liu, Cynthia Pauley, Trudy Burns, James Turner, Steven Levy. University of Iowa, USA

Background: Adult bone diseases, especially osteoporosis, lead to increased risk of fracture associated with substantial morbidity, mortality, and financial costs. Clinically, osteoporosis is defined by low bone mineral density (BMD). However, evidence suggests trabecular bone (TB) micro-architecture is an important determinant of bone strength and fracture risk. Multi-detector CT (MDCT) shows promise for peripheral TB imaging at an acceptable radiation dose that avoids invasive bone biopsies with conventional histomorphometry. Volumetric topological analysis (VTA), developed in our laboratory, assesses topology of individual trabeculae on

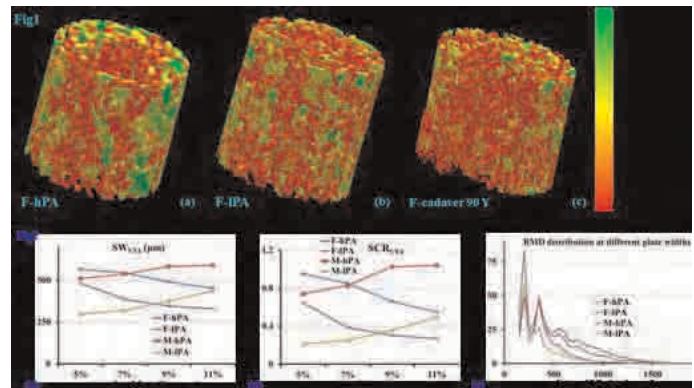

the continuum between a perfect plate and a perfect rod (Fig1), and provides a unique measurement of BMD distribution at different TB plate widths (Fig2). We conducted a feasibility study of TB micro-architecture in young adults using MDCT and VTA.

Methods: Four age-similar (18-23Y) volunteers – 1 male/1 female each with high/low physical-activity (PA) (hPA/iPA) participated. MDCT scans of the distal tibia were acquired on a 128 slice Siemens Flash scanner at 120kV, 200mAs, pitch: 1.0, slice thickness: 0.3mm and scan length: 10cm (total effective dose:17 mrem \approx 20 days of environmental radiation). An INTableTM Calibration Phantom was used to calibrate CT Hounsfield units into BMD (mg/cc).

Results: Fig1 compares color-coded TB plate/rod classification for the female volunteers with high (F-hPA) and low (F-lPA) PA to a 90Y female cadaver specimen. The TB core of F-hPA has more plates (green). The cadaver has significantly fewer plates and more rods (red). Fig2 summarizes the surface-width (SWVTA) (2a), surface-to-curve-ratio (SCRVTa) (2b) and BMD distribution (2c) at different plate widths over 5-11% of tibial length from the distal endplate. Volunteers with hPA show higher architectural parameters (SWVTA, SCRVTa). PA level is a less meaningful predictor of BMD distribution over more rod-like trabeculae (<500 μ m), but is more strongly associated with the plate width range 500-1000 μ m (2c). The rate of change of TB geometry along the tibial axis is gender-dependent.

Conclusion: MDCT with VTA detected effects of PA in vivo and is suited for longitudinal and cross-sectional clinical studies related to bone diseases.

MO0047

Recent Hip Fracture Does Not Account for Polar and Radial Distribution of Cortical Density At Tibial Mid-Diaphysis. Ari Heinonen^{*1}, Timo Rantalainen², Johanna Koskinen³, Marja Arkela-Kautiainen⁴, Mauri Kallinen⁴, Sarianna Sipilä³. ¹Department of Health Sciences, University of Jyväskylä, Fin, ²Department of Mechanical Engineering, Lappeenranta University of Technology & Neuromuscular Research Center, Department of Biology of Physical Activity, University of Jyväskylä, Finland, ³Gerontology Research Centre, Department of Health Sciences, University of Jyväskylä, Finland, ⁴Central Finland Central Hospital, Finland

It is well established that cortical volumetric density (vBMD, mg/cm³) varies around the bone cross-section as well as along the axial length of the bone. Changes in vBMD distribution have been attributed to growth and aging, whereas it is unclear whether lower limb vBMD distribution is modulated by recent hip fracture. This study evaluated the tibial side-to-side differences in polar and radial vBMD distributions as well as differences in vBMD (mg/cm³), cortical area (CoA, mm²) and density weighted section modulus (SSI, mm³) among 68 hip fracture patients (mean age: 79.7 years, height: 161.9 cm, weight: 66.1 kg). 78% of the participants were women and 9% current smokers. The majority (80%) of fractures occurred as the consequence of a fall. The participants had sustained a femoral neck or trochanteric fracture 6 to 16 weeks earlier. Bone cross-sections at the tibial mid-diaphysis were assessed with peripheral quantitative computed tomography (pQCT). Polar and radial vBMD distributions were analyzed in 36 sectors and 3 divisions, respectively. The innermost and outermost layers of pixels were excluded from the analysis to avoid partial volume effect (Fig. 1). The side-to-side differences (fractured vs. non-fractured side) in the tibial vBMD (-0.34.3 %), CoA (-0.85.6 %) and SSI (-1.08.9 %) were not statistically significant. No significant differences were observed in polar vBMD distribution (MANOVA, P = 0.787) or in radial vBMD division (P = 0.758) between the fractured and non-fractured side (Fig.1). In conclusion, a recent proximal femoral fracture has no effect on polar and radial cortical density distributions or bone mineral mass and strength in the tibial bone. This suggests that previously reported bone mass and geometry decline after hip fracture is caused by the disuse following the injury.

Reference Point Indentation: A new paradigm for characterization of visco-elastic materials. Alexander Proctor*, Davis Brimer. Active Life Scientific, Inc., USA

Reference Point Indentation (RPI) is an emerging microindentation technology with novel translational research capabilities, including both ex vivo and in vivo measurement of Bone Material Strength (BMS). Here we characterize the performance of an improved RPI instrument optimized for pre-clinical bone research (BioDent, Active Life Scientific, Inc., Santa Barbara, CA). The improved BioDent is a load-controlled RPI with cyclical indentation capabilities. The novel arrangement of a Test Probe and a Reference Point enable quantitative measurements of mechanical properties at a local site on the bone without the need for a rigid load frame. The instrument can indent a material at forces ranging from 2.0N to 12.0N at frequencies ranging from 0.1Hz to 5.0Hz. Each measurement may consist of up to 100 cyclical indentations at the same location. For this study a calibration phantom, poly-methyl methacrylate (PMMA), was measured using various combinations of input parameters. PMMA is often used as a calibration phantom because it exhibits similar mechanical properties to bone during indentation testing. To characterize the performance of BioDent, 20 different indentation forces were selected that evenly span the operating range of the instrument (2.0N-12.0N) and 6 different indentation frequencies were selected that evenly span the operating range (0.1Hz-5.0Hz). Each of these measurements consisted of 10, 50, or 100 indentations cycles. A total of 360 measurements were made on PMMA. For each combination of input parameters, measured outputs were tabulated and evaluated for consistency and reproducibility. Additionally, performance characteristics were calculated during each measurement (force resolution, distance resolution, and compliance). For each combination of input parameters BioDent showed an average variation of less than 10-15% between each measurement. Maximum force varies by less than 10% for all indentation forces. Based on these results, it is clear that the improved RPI instrument, optimized for pre-clinical bone research, can consistently and quantitatively measure material strength of visco-elastic materials.

MO0049

Regional Variation in Cortical Microarchitecture of the Distal Radius and Tibia. Galateia Kazakia¹, Gregory Bernstein², Miki Sode³, Andrew Burghardt¹, Sharmila Majumdar¹. ¹University of California, San Francisco, USA, ²University of California, USA, ³University of California San Francisco & Berkeley, USA

Cortical structure is vital to the mechanical integrity of long bones, and can be influenced by age, disease, and therapeutic intervention. Quantification of cortical structure parameters is critical to fracture risk prediction in the context of these effects, but conventional analysis techniques obscure potentially important regional parameter variations. Therefore, the objective of this study was to characterize spatial variability in cortical microstructure and geometry at the distal radius and tibia. High resolution peripheral QCT images were acquired from 142 healthy individuals (50 M 92 F, 20-78 y). Periosteal and endosteal boundaries and haversian porosity within the cortical compartment were identified using an automated segmentation technique. Cortical thickness (Ct.Th), porosity (Ct.Po), pore diameter (Po.Dm), and heterogeneity of pore size (Po.Dm SD) were calculated by direct 3D methods. Four regions were defined based on anatomic axes. Regional variations were examined with respect to global means, and compared between male/female and young/elderly subjects. At

both the radius and tibia, substantial regional variation was found. Overall in the radius, Ct.Po varied from +38% (medial) to -39% (anterior). Radius Po.Dm and Po.Dm SD followed the same pattern, with increased and more heterogeneous pore size at the medial quadrant, and reduced and less heterogeneous pore size at the anterior quadrant. Radius Ct.Th varied +10% (posterior) to -18% (lateral). At the radius, age differences were most pronounced in the lateral quadrant, where Ct.Po was 357% higher in elderly (65-78) vs young (20-29) women (1.5x the global mean difference). Age related increases in Po.Dm and Po.Dm SD were also most pronounced in the lateral quadrant of the radius. Overall in the tibia, Ct.Po varied from +18% (posterior) to -30% (anterior). Tibia Ct.Th varied +9% (lateral) to -5% (posterior). At the tibia, age differences were most pronounced in the anterior quadrant, where Ct.Po was 443% higher in elderly vs young women (1.5x the global mean difference). In elderly women, both the radius and tibia displayed the highest Ct.Po within the quadrant adjacent to the secondary bone: the lateral quadrant in the tibia, the medial (ulnar) quadrant in the radius. These data illustrate that substantial regional variation exists in cortical microstructure. Investigation of regional changes in addition to global trends may lead to more sensitive analysis of age-related skeletal changes.

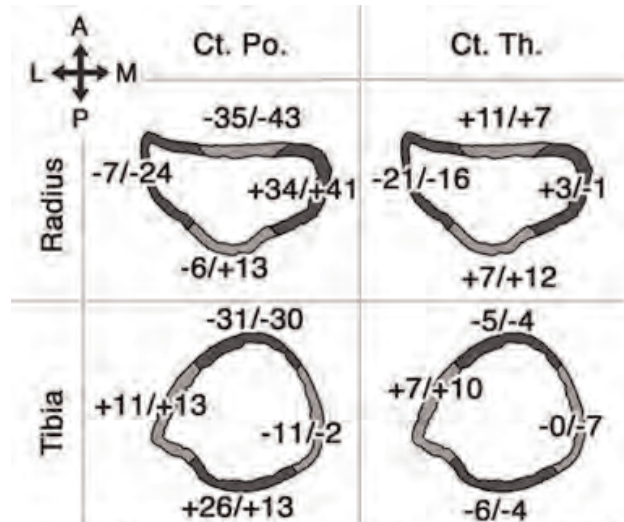

Figure: Regional variation in cortical porosity (Ct.Po) and thickness (Ct.Th) expressed as mean % difference from the global mean for males/females.

Risedronate Improves Bone Architecture and Strength Faster Than Alendronate in Ovariectomized Rats on a Low Calcium Diet. Tetsuo Yano¹, Mei Yamada¹, Tomoyuki Konda¹, Makoto Shiozaki¹, Daisuke Inoue². ¹Ajinomoto Pharmaceuticals Co., LTD, Japan, ²Teikyo University Chiba Medical Center, Japan

Background/Aim: Several studies have suggested that clinical dose of risedronate (RIS) is less potent in suppressing bone turnover and in increasing bone mineral density (BMD) than alendronate (ALN). Nevertheless, RIS does reduce bone fracture risk as potently as ALN from the early phase of treatment. Such differences in clinical efficacy between bisphosphonates may arise from unique pharmacological properties of each compound, but the mechanism remains unclear. In the present study, we tested a hypothesis that RIS improves bone quality, especially bone architecture, faster than alendronate, using ovariectomized (OVX) rats.

Methods: Female Sprague Dawley (SD) rats at 24 weeks of age were divided into sham-operated and ovariectomized groups and fed a low calcium (0.05%) diet under paired feeding. Three months after surgery, OVX rats were divided into five groups (vehicle, RIS (3.5, 17.5 µg/kg/week s.c.) and ALN (7, 35 µg/kg/week s.c.)) based on serum parameters of bone turnover, such as NTx and ALP. Six or eight weeks after treatment, the rats were sacrificed and bone architecture and strength of the left femur were evaluated using micro-CT and a three-point-bending biomechanical testing apparatus, respectively.

Result: Trabecular BMD (-47% at 8 weeks), trabecular number and trabecular thickness were significantly decreased in OVX rats, compared with the sham-operated group. Similarly, cortical BMD, cortical bone area (Ct.Ar, -9% at 6 weeks) and cortical thickness (Ct.Th) were also decreased in OVX rats. RIS significantly improved Ct.Ar (+8%) and Ct.Th (+9%) at 6 weeks. In contrast, ALN only caused a significant improvement in Ct.Ar (+8% at 6 weeks) with the higher dose. At 8 weeks, both RIS and ALN significantly increased trabecular BMD (+46%) compared to the vehicle controls. Bone strength using three-point bending method showed a good and significant overall correlation with Ct.Ar and Ct.Th. In bone strength test, only RIS, but not ALN, significantly improved maximum load at 6 weeks, consistent with the better improvement in the cortical architecture by RIS.

Conclusion: Consistent with our hypothesis, in a relatively early phase of treatment in OVX rats on a low calcium diet, RIS showed a superior effect on cortical bone architecture and strength to ALN. These results further suggest that RIS has a relatively predominant effect on bone quality compared to ALN.

Skeletal Fragility and Hip Geometry: The Fracture Is "Behind the Angle".

Monica Celi^{*1}, Irene Cerocchi², Alessandro Scialdoni³, Luca Saturnino³, Umberto Tarantino⁴. ¹University of Rome Tor Vergata, Italy, ²Università Di Roma Tor Vergata, Italy, ³University of Tor Vergata, Italy, ⁴Azienda Ospedaliera PTV, Italy

Aim: To assess how differences in the proximal femur geometry (PFG) can influence hip fracture risk.

Methods: We studied 224 postmenopausal women aged 50 – 95 years who had sustained a fragility fracture and who resulted osteoporotic either at the proximal femur or at the lumbar spine or both. Bone Mineral Density (BMD) was evaluated by Dual X-Ray absorptiometry (Lunar i-DXA, GE Healthcare) and in addition to the conventional densitometry measurements, structural variables were determined using the Hip Strength Analysis program, including hip axis length (HAL), neck-shaft angle (NSA) and the femur strength index (FSI) calculated as the ratio of estimated compressive yield strength of the femoral neck to the expected compressive stress of a fall on the greater trochanter. Patients were divided into two groups based on fracture site (hip fracture group, n=112; non-hip fracture group n=112). Non-hip fracture included vertebral, humeral, wrist and ankle fractures due to low-energy trauma. Age, height, weight, Body Mass Index (BMI), femoral neck BMD and structural variables were compared between the two groups using t test.

Results: femoral neck BMD and PFG parameters (i.e. NSA, HAL and FSI) were different when groups were compared by t test. Differences regarding age and anthropometric parameters were not statistically significant. We found that patients in the hip fracture group had longer HAL than the non-hip fracture group (mean value 103.7 mm vs 101.4 mm, $p < 0.05$) and wider NSA (mean value 126.3 vs 123.2, $p < 0.01$). Significant differences were also found in the hip fracture group between patients with lateral fractures and patients with medial fractures. In particular, HAL resulted greater in the medial fracture group with respect to subjects with a lateral fracture (mean value 105.2 mm vs 99.3 mm, $p < 0.01$). Moreover, medial fracture patients were generally taller than those with a lateral fracture (mean body height 159.8 cm vs 156.44 cm, $p < 0.05$).

Conclusions: These data indicate that differences in PFG parameters might have a role in predisposing to hip fracture instead of non-hip fracture following low-energy trauma in women of the same age. PFG and anthropometric parameters seem to also influence hip fracture type (lateral or medial).

Statistical Power in Measures of Microscopic Tissue Damage in Cancellous Bone. Katherine Ehler^{*1}, Ralph G. O'Brien², Christopher Hernandez¹.

¹Cornell University, USA, ²Case Western Reserve University, USA

The accumulation of microscopic cracks and other microscopic damage has been implicated as a characteristic of bone that may influence whole bone strength and resistance to fracture. While there have been a number of studies of naturally-occurring and experimentally generated microscopic tissue damage in cancellous bone, most reports show high variability as indicated by coefficient of variation (SD/ Mean, typically 50-100%). High measurement variability limits the ability to detect differences between groups. Variability in measures of microscopic tissue damage is caused by both sampling methodology (stereology, number of sections, amount of specimen, etc.) as well as biological variability among specimens. Here we present a statistical model to express how sampling methodology influences measures of microscopic tissue damage and statistical power. A statistical model using a Poisson distribution to simulate microscopic tissue damage events (individual cracks or regions of diffuse damage) was generated. The model used the results from published measures of microscopic tissue damage (DV/BV, Cr.Dn) achieved with 2D histology/ stereology or 3D approaches (lead uranyl acetate staining). The statistical model suggests that when using stereology, error in measures within the sample can be minimized by examining a cross-sectional area equivalent to 2 or more slices of an 8 mm diameter cancellous bone core. Specimen bone volume fraction and the mean amount of microscopic tissue damage present in the specimen have only a minor influence on this measurement error. The amount of variance found when using stereology is typically large, however, and is estimated to require 67 specimens/group to detect a 30% difference between groups with a power of 0.80. In contrast, 3D measures of microscopic tissue damage (as demonstrated using lead uranyl acetate staining or fluorescence-based serial milling) do not have as much measurement error because they examine the entire specimen and hence are estimated to require only 6 specimens/group to achieve the same statistical power for the situation above (Fig. 1). Stereology-based measures of microscopic tissue damage in cancellous bone are highly variable and require very large sample sizes to detect all but the most drastic differences between study groups. Three-dimensional measures of microdamage have the potential to detect more subtle differences between groups.

The Correlation Between Bone Mineral Density Values With Insertion Torque of Pedicle Screws In Posterior Lumbar Pedicle Screw Fixation. Jae Hyup Lee^{*1}, Young-Ho Shin², Ji-Ho Lee², Jae Woo Park², Hye Soo Lee².

¹Seoul National University, College of Medicine, South Korea,

²Department of Orthopedic Surgery, Seoul National University College of Medicine, SMG-SNU Boramae Medical Center, South Korea

In a pedicle screw fixation, the degree of osseointegration between a screw and the bone is an essential factor for the stability and fusion. The purpose of this study was to predict the initial fixation force of a pedicle screw prior to the surgery, to identify the correlation between the BMD and the torque during a pedicle screw fixation and to clarify the predictable torque depending on the BMD. A total of 181 patients enrolled prospectively from November of 2006 to December of 2009; received the posterior lumbar instrumentation using a pedicle screw by a single surgeon; and intraoperatively had an insertion torque of pedicle screw measured by digital torque gauge. Conventional 6.5mm diameter by 40 to 45mm length pedicle screw was placed. In regard to the maximal insertion torque, an analysis was performed using Pearson's correlation coefficient for the BMD at the corresponding surgical vertebrae, mean BMD at the lumbar vertebrae and mean BMD in the proximal femur. A simple regression analysis was also performed to evaluate the correlation between the BMD and the predicted insertion torque generated during a pedicle screw fixation. In regard to the insertion torque during a pedicle screw fixation, there was a positive correlation with the BMD at the surgical vertebrae ($r=0.49$), T-value at the surgical vertebrae ($r=0.52$), mean BMD in the lumbar vertebrae ($r=0.32$), mean T-value in the lumbar vertebrae ($r=0.50$), mean BMD in the proximal femur ($r=0.45$) and mean T-value in the proximal femur ($r=0.42$). In patients with osteoporosis, the insertion torque had positive correlations with the BMD in the lumbar vertebrae. The insertion torque was significantly lower in patients with osteoporosis and those with osteopenia as compared with normal patients. Besides, a regression analysis formula for the insertion torque (kgf·cm) was found to be $-1.3 + 16.1 \times$ (the BMD at the surgical vertebrae) and $9.6 + 7.87 \times$ (mean BMD in the lumbar vertebrae). The BMD therefore be used in predicting the accurate degree of a pedicle screw fixation. Because there is a positive correlation between the BMD and the fixation force of a pedicle screw, however, it can therefore be inferred that the assessment of BMD would be useful in determining the fixation of device and the number of fusion segments in patients who are suspected to have osteoporosis and indicated in a pedicle screw fixation.

MO0054

The Effect of Advanced Glycation Endproducts on Cortical Bone Mechanical Properties. Sibi Sutti¹, Christopher Tranquada², Marc Grynpas¹, Thomas Willett^{*3}. ¹Samuel Lunenfeld Research Institute, Canada, ²University of Toronto, Canada, ³Mount Sinai Hospital, Canada

Advanced glycation endproduct (AGE) accumulation in bone may contribute to skeletal fragility in aging, diabetes, and various other diseases and conditions. Recent literature suggests that AGEs may deteriorate cortical bone toughness and post-yield properties. Fatigue resistance of cortical bone is more physiologically meaningful and more sensitive to changes in bone collagen. The effect of AGEs on cortical bone fatigue has not been studied.

Objective: Determine the sensitivity of cortical bone fatigue resistance to AGEs using a controlled in vitro model where only the collagen is modified through AGE formation.

Objective A: Test phosphate buffered saline (PBS) vs. simulated body fluid (SBF) to determine which best maintains bone properties during incubation.

Hypothesis A: SBF will maintain the mineral phase and mechanical properties better than PBS.

Objective B: Test the effect of in vitro AGE accumulation on bone mechanical properties and fatigue resistance.

Hypothesis B: AGE accumulation will reduce bone toughness and fatigue resistance.

Matched triplet beams corresponding to ASTM D790 were cut from 10 steer metatarsi; one was a non-incubated control (kept at -20°C), and two were incubated in either SBF 0.6M ribose or PBS 0.6M ribose at 37°C for 14 days. Ribose causes AGE formation. BMD was measured with DEXA. Static three-point bending failure tests were performed to test the incubation buffers and the effect of AGE accumulation. AGE contents were measured using HPLC. Fatigue testing of specimens (10 triplets) incubated in SBF 0.6M ribose and matched non-incubated controls was performed under both low-cycle and high-cycle conditions in three-point bending.

PBS incubation led to BMD loss (3-4%) and variations in mechanical properties whereas SBF incubation maintained BMD, reduced variation and eliminated detectable differences in mechanical properties between non-incubated controls and incubated controls. The post-yield toughness of the SBF+ribose specimens was 21% lower than non-incubated controls and incubated controls, supported by decreased damage fraction and increased secant modulus at failure. We were unable to confirm an effect of AGEs on fatigue resistance in this model.

SBF is a better buffer for long-term incubation of bone specimens. Static tests performed on cortical bone beams incubated in SBF+ribose suggest that AGEs may deteriorate bone toughness. On the other hand, our fatigue data has not confirmed an effect on fatigue resistance.

MO0055

Validation of a Novel Microindenter for Bone Material Strength Measurement. Robert Guerri Fernandez^{*1}, Adolfo Diez-Perez², Xavier Nogues³, Daniel Prieto-alhambra³, Leonardo Mellibovsky⁴, Daniel Bridges⁵, Connor Randall⁶, Paul Hansma⁷. ¹Fundacio IMIM, Spain, ²Autonomous University of Barcelona, Spain, ³Institut Municipal D'Investigacio Medica, Spain, ⁴Internal Medicine / Infectious Diseases, Hospital del Mar, IMIM, Spain, ⁵University of California Santa Barbara, USA, ⁶UCSB, USA, ⁷University of California, Santa Barbara, USA

Fracture has been the only direct measurement of bone strength in clinics. Reference Point Indentation (RPI) provides an in vivo method for assessing bone material properties (1). A new handheld pocket-size RPI instrument (Osteoprobe®) (2) measures bone's resistance to fractures caused by impacts. Here we report the first validation study.

Methods: we carried out a case-control study including a consecutive sample of hip fracture cases and controls who accepted to participate. Measurements are made at the tibial midshaft after local anesthesia. The instrument applies impacts of 18N with a rise time of order 1 msec to a sharpened probe that has been inserted through the skin and soft tissue into the bone surface with a first force of 11N. Test time is about 2 minutes and painless. We perform 5 indentations for the patient and then 5 indentations into a PMMA calibration phantom (PMMA). The raw data obtained from the test is the indentation distance increase from the impact. The Bone Material Strength (BMS) a normalized parameter, is defined as 100 times the ratio of the average indentation distance increase from the impact into the calibration PMMA phantom divided by the indentation distance increase from the impact into the bone.

To compare BMS in cases and controls adjusted for age differences we used multivariate logistic regression.

Results: 21 cases (age 826) and 12 controls without fractures (age 778) were assessed. Age-adjusted analysis was performed using univariate logistic regression.

The BMS was significantly lower for the fracture vs. no fracture cases (795 vs. 916), which stood for adjustment for age (OR per increase in one Standard Deviation of BMS 18.42[1.5to226.26];p=0.023)(see Figure).

These results are consistent with the previous results with a cyclic-loading microindentation instrument (1,2). This new RPI instrument uses impacts and test conditions that mimics the trauma conditions for fractures and it is simple and convenient since it is handheld and gives just one, normalized, measurement that may provide a direct measurement of bone material propensity to fracture. We conclude that BMS determined from impact microindentation testing discriminates between fracture and no fracture cases. Bone material properties measured by microindentation may be highly relevant to measure fracture risk in the clinical setting. (1) JBMR 2010; 25:1877; (2) Active Life Scientific, Santa Barbara, CA.

MO0056

Volumetric Bone Mineral Density Estimation using a 3D Reconstruction Method from Dual-energy X-ray Absorptiometry. Tristan Whitmarsh¹, Ludovic Humbert², Luis Del Rio^{*3}, Alejandro Frangi⁴. ¹Universitat Pompeu Fabra, Spain, ²Ph, Spain, ³Cetir Centre Medical, Spain, ⁴PhD, Spain

Volumetric BMD (vBMD) has been shown to be strongly related to bone strength and osteoporotic hip fracture. This can be estimated for the femoral neck from Dual-energy X-ray absorptiometry (DXA) by using the projected area as: $vBMD = BMC/A^2$ where BMC is the bone mineral content and A the projected area on the DXA image. However, such approximation cannot be used for other critical locations, such as the trochanteric and adjacent shaft region. An accurate quantification of the vBMD can be obtained from Quantitative Computed Tomography (QCT), however, this modality subjects the patient to a high radiation dose and is not as widely available as DXA central devices.

In this work an estimation of the vBMD from a DXA image is presented by using a 3D reconstruction method. The reconstruction method uses a 3D statistical model, constructed from a dataset of QCT scans which describes the statistical variations in shape and BMD distribution. The 3D statistical model is registered onto the 2D DXA image of the patient so that the projection of the model matches the DXA image. The result of this reconstruction process is a patient specific volumetric reconstruction of the BMD distribution onto which the vBMD can then be extracted for specific regions.

Reconstructions were subsequently obtained from the DXA images of 30 patients (15 male and 15 females with an average age of 5013 years). The vBMD of the femoral neck and the trochanteric region was extracted from the reconstructions and the vBMD in the corresponding regions of the QCT scans of the same subjects were considered the ground truth. The linear correlation with the ground truth vBMD then indicates the vBMD estimation accuracy. For the trochanteric and shaft region, our method achieved a strong correlation with a correlation coefficient of 0.94 and 0.93 and a Mean Average Error (MAE) of 15.3 and 21.8mg/cm³ respectively. In addition, the proposed method resulted in a MAE of 17.2mg/cm³ and a correlation coefficient of 0.92 for the femoral neck region whereas the vBMD, estimated using the projected area, resulted in a correlation coefficient of 0.91.

These results indicate that our proposed method accurately estimates the vBMD of the trochanteric, shaft and femoral neck region from DXA. This potentially allows for an improved fracture risk estimation while maintaining DXA as the current standard modality.

Changes in the 3D Osteocyte Lacunar Network Induced by Estrogen Withdrawal and Pharmaceutical Treatment of Osteoporosis as Detected by Synchrotron Micro-CT. Steven Tommasini¹, Andrea Trinward¹, Alvin Acerbo², Lisa Miller³, Stefan Judex¹. ¹Stony Brook University, USA, ²Brookhaven National Laboratory, USA, ³Brookhaven National Laboratory, USA

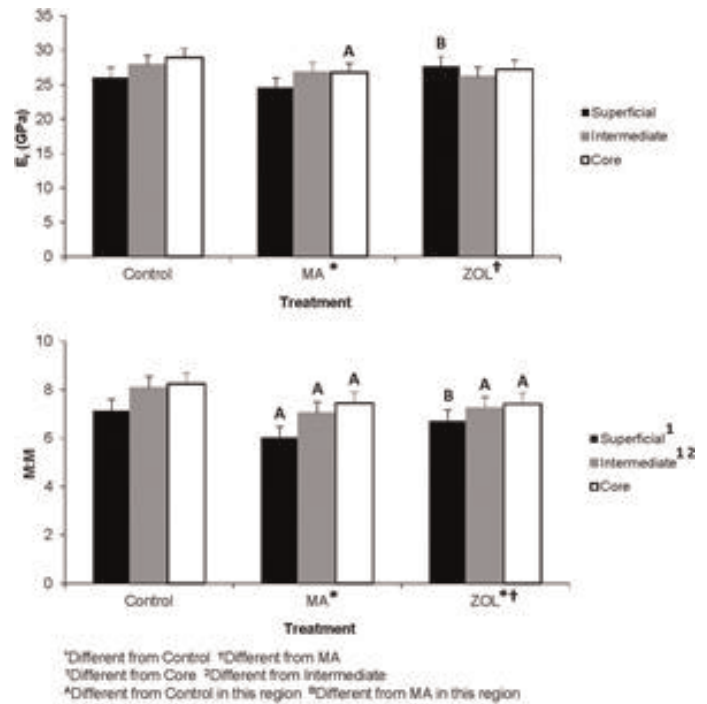

Osteocyte lacunar size may increase in rodents that were either ovariectomized (OVX) or treated with parathyroid hormone (PTH). As this evidence was largely limited to 2D methods, the aim of this study was to quantify changes in the 3D osteocyte-lacunar network induced by estrogen withdrawal and 2 different osteoporosis treatments. Unlike 2D measurements, this data collected via synchrotron radiation-based μ CT (0.75 μ m resolution) can describe the size and 3D spatial distribution of a large number of osteocyte lacunae within cortical bone. Six-month old female Sprague-Dawley rats were separated (n=6/group) into 1) age-matched control, 2) untreated OVX, 3) OVX treated with PTH, or 4) OVX treated with Alendronate (ALN). Intracortical microporosity of the medial quadrant of the femoral diaphysis was quantified at endosteal, intracortical, and periosteal regions of the samples, allowing the quantification of osteocyte lacunae that were formed primarily before and after the start of treatment. Average osteocyte lacunar volume (Lc.V) of untreated OVX rats was significantly greater ($p<0.01$) in the periosteal region compared to endosteal and intracortical regions indicating that, in bone formed after estrogen withdrawal, there was an increase in osteocyte lacunar size. However, Lc.V in bone formed after the start of both treatments was similar to controls. The number of lacunae per bone volume was significantly higher in the periosteal region for ALN and PTH treatments compared to age-matched controls and untreated OVX ($p<0.05$) suggesting that bone formed on the periosteal surface after the start of treatment had more osteocytes per bone volume. Thus, activity of osteoblasts was different compared to before treatment. There also was a significant increase in the size and number of small pores in the intracortical region for PTH compared to controls, but not for ALN. This is consistent with previous reports. Additionally, small porosities may be related to improved bone strength with PTH treatment, as smaller osteocyte lacunae may be better able to absorb shear forces than larger lacunae. Together, these changes may not only directly influence the mechanical properties of bone tissue, but also may affect the osteocyte's role as mechanosensors. Further associations of this data with detailed spatial mechanical and chemical matrix data will improve our understanding of the relationship between osteoporosis treatments, osteocyte biology, and bone quality.

MO0058

Gradients in Mineralization and Nanomechanical Properties Across Trabeculae are Altered with Zoledronate Treatment in an Ovine Model of Osteoporosis. Jayme Burket¹, Jennifer MacLeay², Shefford Baker¹, Adele Boskey³, Marjolien Van Der Meulen¹. ¹Cornell University, USA, ²Hill's Pet Nutrition, Inc., USA, ³Hospital For Special Surgery, USA

Trabeculae from healthy human bone show gradients in tissue stiffness from edge to center paralleling gradients in mineralization. Increased turnover with osteoporosis decreases tissue mineralization and may affect mineral properties and their tissue distribution. Ovine metabolic acidosis (MA), unlike OVX, increases turnover and produces similar mineral changes as human osteoporosis, allowing us to examine disease and treatment effects on cancellous tissue composition and mechanical properties. Cancellous bone was obtained from distal femora of skeletally mature ewes. Controls (CONT) were fed a normal diet for 12 months (n=5); treatment groups were fed a diet to induce MA for 6 months and then treated with either Zoledronate (ZOL, n=6) or vehicle (n=6) while maintaining the diet for another 6 months. Reduced modulus (E_r) and hardness (H) were assessed with nanoindentation along lines spanning the width of 3 trabeculae/sample, with indents placed at the center of lamellae (n=10-17/trabecula). Mineral:matrix (M:M), carbonate:phosphate (C:P) and crystallinity (XST) were characterized by Raman spectroscopy at indent locations. Effects of treatment, region (superficial, intermediate, or core of trabecula), and their interaction were tested by multifactor, nested ANOVAs with Tukey post-hoc. Relative to CONT, MA decreased M:M in all regions (mean -13%); with ZOL, only core regions had lower M:M, and the positive mineralization gradient from superficial to core tissue was reduced (MA Δ 10% vs. CONT Δ 16%). E_r followed mineralization, decreasing in all regions with MA (-6% vs. CONT), and increasing only in superficial regions with ZOL (+13% vs. MA). ZOL restored E_r to CONT levels in all regions, but the gradient from superficial to core of trabeculae was not recovered. H was similar to E_r . C:P increased in core regions with MA (+6% vs. CONT) and increased in all regions with ZOL (+6% vs. CONT). XST increased in all regions with MA and ZOL (+8% vs. CONT). Changes in tissue mineralization with MA in sheep were similar to those of high-turnover osteoporosis in humans. ZOL restored mineralization levels, stiffness, and hardness but did not recover gradients present in healthy tissue and mineral crystal properties were altered. The role of gradients in trabeculae is unknown. Restoring tissue stiffness at the periphery of trabeculae may be most critical to resist bending and buckling loads, two dominant failure modes of trabeculae within cancellous bone.

Mechanical Property and Tissue Mineral Density Differences Among Severely Suppressed Bone Turnover (SSBT) Patients, Osteoporotic Patients, and Normal Subjects. Crystal Tjhia¹, Clarita Odvina², Sudhaker Rao³, Susan Stover¹, Xiang Wang¹, David Fyhrie¹. ¹University of California Davis, USA, ²University of Texas Southwestern Medical Center, Dallas, USA, ³Henry Ford Hospital, USA

We hypothesized that tissue-level mechanical properties and mineralization of the iliac crest would differ among 1) a subset of osteoporotic patients with atypical fractures and severely suppressed bone turnover associated with long-term bisphosphonate use (SSBT), 2) age-matched, bisphosphonate-naïve osteoporotic patients with vertebral fracture, 3) age-matched normals and 4) younger normals. Large differences in tissue-level mechanical properties or mineralization among these groups could help explain the occurrence of fracture in the 2 patient groups. Elastic modulus, hardness and tissue mineral densities of cortical and trabecular bone regions of 55 iliac crest biopsies were measured using nanoindentation and quantitative backscattered electron microscopy. Twelve SSBT patients (SSBT group), 11 untreated osteoporotic patients with vertebral fracture (Osteoporotic group), 12 age-matched subjects without fracture (Older Normal group), and 20 younger subjects without fracture (Younger Normal group) were examined (Table 1). Elastic modulus, hardness, and mineral density of trabecular bone were different among the groups ($p<0.05$, Fig. 1). The SSBT group had harder trabecular bone compared to the other three groups and stiffer trabecular bone compared to the osteoporotic and younger normal groups. SSBT trabecular bone was more highly mineralized than that of the older normals and osteoporotics. Among the osteoporotics, younger normals and older normals, trabecular bone mechanical properties were not different from each other, and trabecular bone mineral density was only slightly higher in younger normals than older normals and osteoporotics. Cortical bone mechanical properties and mineralization were not different among groups. The largest difference in mechanical properties or mineralization was that SSBT trabecular bone was 17.8% harder than that of younger normals. In contrast, the differences in bone formation rate (BFR; previously measured) among the groups were much greater, with the osteoporotic, younger normal and older normal groups having greater BFR than the SSBT group by 5400%, 4400% and 4800%, respectively. The differences in mechanical properties and mineral densities were consistent with differences in BFR, but the magnitudes of the mechanical property and mineral density differences were small. We conclude that differences in tissue mechanical and mineral properties among the groups are consistent with normal aging and differences in BFR.

MO0061

The Decrease in Cortical Bone Volumetric Mineral Density Induced by Teriparatide in Postmenopausal Osteoporotic Women is Associated With an Increase in Cortical Porosity as Assessed by High Resolution Peripheral Computerized Tomography (HR-pQCT). Cesar Bogado^{*1}, Fernando Silveira¹, David Dempster², Hua Zhou³, Ursula Masiukiewicz⁴, Cecilia Fosse⁴, Jose Ruben Zanchetta¹. ¹Instituto de Investigaciones Metabolicas (IDIM), Argentina, ²Columbia University, USA, ³Helen Hayes Hospital, USA, ⁴Pfizer, Inc., USA

We have previously reported that daily injections of 20 µg teriparatide for 12 months in a group of 20 postmenopausal women with osteoporosis resulted in a decrease in cortical vBMD at the distal radius and tibia, as assessed by HR-pQCT (1).

To test the hypothesis that the decrease in vBMD was related to an increase in cortical porosity, HR-pQCT scans of the distal tibia obtained during our previous study were analyzed using an automated segmentation technique developed to identify the periosteal and endosteal margins and detect intracortical pore space morphologically consistent with Haversian canals (2). Cortical bone vBMD and porosity (Co. Po) were measured at baseline and month 3, 6 and 12 following teriparatide administration. Bone turnover rate was estimated measuring serum CTX and PINP.

Percent changes over time are depicted in Table1. The changes in cortical vBMD were almost identical to those obtained in our previous study using the standard analysis technique (1). Co.Po significantly increases at month 6 and continues to increase subsequently. This increase in cortical porosity is in agreement with the findings in paired iliac crest bone biopsies obtained in 11 of these patients, showing a 68.3% (95% CI 7.77, 162.70; p= 0.026) increase in cortical porosity area at month 12, compared to baseline. The increase in Co.Po at month 6 is coincident with the increase in overall bone turnover rate, indicated by the significant rise in serum CTX levels, after a period of bone formation stimulation reflected by the serum PINP changes at month 3. There was a strong linear negative correlation (R-squared= 0.46; p= 0.0013) between the changes in vBMD and Co.Po at month 12. That correlation was maintained after adjusting for baseline vBMD (R-squared 0.45; p= 0.0016).

In conclusion, our results suggest that the decrease in cortical vBMD induced by teriparatide is related to an increase in cortical porosity and that those changes in porosity can be estimated by non-invasive imaging techniques like HR-pQCT.

Integrated Finite Element Modeling of Upper Femur Behavior With Ageing: From Cellular Activities Toward Fracture. Ridha Hamblil^{*1}, Abdelwahed Barkaoui², Romain Rieger¹, Eric Lespessailles³, Claude Laurent Benhamou⁴, Awad Bettamer⁵. ¹PRISME Institute, France, ²PRISME Institute, EA4229, University of Orleans, France, ³Centre Hospitalier Regional, France, ⁴INSERM Orleans-France, France, ⁵L'Universite d'Orleans, France

Introduction: Bone models offer the opportunity to simulate bone behaviour (remodeling, resistance, fracture, ...). Current works focused either on bone mechanical induced reactions or biological cells activities in a given bone site without considering the synergic interactions between mechanical stimulus and the biological machinery of bone cells. We have developed a finite element model integrating coupled mechanical and biological aspects in order to simulate the upper femur behaviour starting from a remodeling cycle (under cyclic load and frequency for a given period of time) followed by a fracture prediction (under a monotonic excessive load) to predict the maximum force at fracture and the fracture pattern of the femur. **Material and Method:** The initial 3D geometry model (standardized femur model

Group	N	Age	Mean Age (SD)	Bone formation rate [µm ³ /µm ² /yr]
Younger Normal	20	20-40	31.6 (5.6)	13.5 (6.9)
Older Normal	12	49-74	63.8 (8.5)	14.8 (13.7)
Osteoporotic	11	53-76	65.5 (7.7)	16.7 (19.4)
SSBT	12	49-77	64.1 (9.3)	0.3 (0.4)

Prediction Of Mechanical Bone Strength From In Vivo Bone Density And Biomarkers In A Rat Experiment - An Individual Model Using Automatic Learning. Joseph Zarka^{*1}, Eric Lespessailles², Su Hua Leow¹, ZAHRA ACHIOU³, Claude Laurent Benhamou⁴. ¹JZ SARL, France, ²Centre Hospitalier Regional, France, ³INSERM, France, ⁴INSERM Orleans-France, France

We have previously analyzed the combined effects on bone tissue of zoledronic acid (Z) and physical activity (PA) in an ovariectomized (OVX) rat model. Although the treadmill running exercise was shown to preserve the bone strength, the combined effects of Z and PA did not produce any additive effect. In the present study we aimed to explore the ability of an Automatic Learning software (SEA of Ecole Polytechnique, CADLM, France) to predict bone biomechanical properties from body composition, bone density measurements and bone biomarkers obtained in vivo.

The study included 5 groups of 12 female rats (6 months old at baseline): 1) sham, 2) OVX, 3) OVX + PA, 4) OVX + Z, 5) OVX + Z + PA. Body weight, lean body mass, fat mass, whole body mineral content and density were measured by DXA before sacrifice, such as biomarkers of bone remodelling: serum osteocalcin and collagen cross links (CTX). We have extracted from the database each rat separately and treated all the parameters on the whole group. The criteria to be predicted are the Young's Modulus, the ultimate force and stress to failure. Ten cases have been randomly excluded from the study group and the predictive model has been retested in this sub-group.

As every software of Automatic Learning, the results with the SEA software are expressed by the quantification of errors obtained by the model. The maximum relative errors were evaluated at 8% for the ultimate force, 8% for the stress at failure and 20% for the Young's Modulus.

These data suggest that it seems possible to estimate bone biomechanical properties from in vivo non invasive measurements like DXA and bone biomarkers by this software of automatic learning working. All this work is produced on an individual basis, suggesting an interest in "personalized" prediction of the bone status. This model is currently tested with another group of rats.

Disclosures: Joseph Zarka, None.

from <http://www.biomedtown.org>) has been implemented with the averaged properties of a 75 yrs femur. Local material properties was assigned (BV/TV, elastic modulus, strain at fracture, biological cells activities parameters). The remodeling process is simulated based on the reaction of the osteoblasts-osteoclasts-osteocytes balance. Formation and resorption of bone are respectively performed by the osteoblasts and the osteoclasts. The BMUs behaviour has been incorporated into the finite element model based on previously published validated models. The 3D femur model has been submitted to two cycles (one and two years period) of remodeling process under cyclic loading with low (2000 N) and high (3400 N) physical activities applied at angle of 20 from the vertical. The frequency was fixed at 6000 cycles/day in both cases. At the end of every remodeling cycle, fracture FE simulation were performed to assess the fracture conditions (force and fracture profile) in relation with the remodeling-predicted bone adaptation. Results: Our predicted results show that the maximum fracture force and fracture profile of the upper femur depends mainly on the remodeling process conditions (amplitude of the remodeling force and duration). Indeed, The predicted maximum fracture forces corresponding to the different cases was: Low force-1 yr remodeling : F= 4000N, Low force-2 yrs remodeling : F= 3400N, High force-1 yr remodeling : F= 4400N, High force-2 yrs remodeling : F= 5200N. The proposed unified remodeling-to-fracture model can be applied to study the effects of remodeling factors (force, frequency, cells activities) on the strength of human femur.

Positive Association Between Circulating Sclerostin and Bone Mass in Chronic Spinal Cord Injury: Evidence Against Sclerostin as a Target to Treat Chronic Disuse Osteoporosis. Leslie Morse^{*1}, Supreetha Sudhakar², Valery Danilack³, Carlos Tun⁴, Antonio Lazzari⁵, David Gagnon⁶, Eric Garshick⁷, Ricardo Battaglini⁸. ¹Department of Physical Medicine & Rehabilitation, Harvard Medical School, Spaulding Rehabilitation Hospital, USA, ²Spaulding Rehabilitation Hospital, USA, ³Programs in Research at VA Boston, USA, ⁴Rehabilitation Medicine Service, USA, ⁵Primary Care Section, VA Boston Healthcare System & Boston University School of Medicine, USA, ⁶VA Cooperative Studies Program, VA Boston Healthcare System, Department of Biostatistics, Boston University School of Public Health, USA, ⁷Pulmonary & Critical Care Medicine Section, Medical Service, VA Boston Healthcare System, Channing Laboratory, Department of Medicine, Brigham & Women's Hospital, Harvard Medical School, USA, ⁸The Forsyth Institute, USA

Spinal cord injury (SCI) results in profound bone loss due to muscle paralysis and the inability to ambulate. Sclerostin, a Wnt signaling pathway antagonist produced by osteocytes, is a potent inhibitor of bone formation. Short-term studies in rodent models have demonstrated increased sclerostin in response to mechanical unloading that is reversed with reloading. These studies suggest that complete spinal cord injury, a condition resulting in mechanical unloading of the paralyzed lower extremities, will be associated with high sclerostin levels. We assessed the relationship between circulating sclerostin and bone density in 39 subjects with chronic SCI and 10 without SCI. We found that greater total limb bone mineral content was significantly associated with greater circulating levels of sclerostin. Sclerostin levels were reduced, not elevated, in subjects unable to walk due to SCI compared to persons who walked regularly. The ability to walk regularly, not injury severity, was also significantly associated with greater bone density at SCI-specific, sublesional skeletal sites (distal femur and proximal tibia). These findings suggest that circulating sclerostin is a biomarker of osteoporosis severity, not a mediator of ongoing bone loss, in long-term, chronic paraplegia. This is in contrast to the acute sclerostin-mediated bone loss demonstrated in animal models of mechanical unloading where high sclerostin levels suppress bone formation. As these data indicate important differences in the relationship between mechanical unloading, sclerostin, and bone mineral content in chronic SCI compared to short-term rodent models, it is likely that sclerostin is not a good therapeutic target to treat chronic SCI-induced osteoporosis.

Extracellular High Glucose Levels Modulate Bone Cell Mechanotransduction. Mia Thi^{*}, David C. Spray, Sylvia O. Suadicani. Albert Einstein College of Medicine, USA

Although it has been shown that patients with insulin dependent diabetes mellitus (IDDM; Type 1 diabetes) display higher bone loss and increased risk for osteoporosis and related bone fractures, the underlying mechanisms are still not well understood. Given that the maintenance of skeletal integrity in response to daily physical activity relies on the regulation of the bone forming cells, osteoblasts, and the primary load sensing cells, osteocytes, we hypothesized that bone loss in diabetes is due to compromised ability of bone cells to perceive and respond to mechanical loading as a result of changes in structure of bone cells pericellular matrix (PCM) and altered expression of specific purinergic receptors (P2Rs) and pannexin1 (Panx1) channels. To simulate in vitro the extracellular glucose levels to which bone cells are exposed in

healthy vs. diabetic bones, we cultured MOB-C (osteoblastic cells) and MLO-Y4 (osteocytic cells) for 10 days in α -MEM containing 100 mg/dL (5.5 mM) and 450 mg/dL (25 mM) glucose. Cells were subjected to oscillatory fluid shear stress [FSS - low level unidirectional mean flow ($\tau = 0.5$ dyne/cm²) superimposed with a sinusoidal oscillating flow ($\tau = 10$ dyne/cm²) at 1 Hz] in a parallel plate flow chamber with a closed flow loop. We observed that high glucose (HG) exposure altered the thickness of PCM determined by heparan sulfate proteoglycan immunolabeling in both MOB-C and MLO-Y4 cells. While P2Y₁R expression remained the same, HG exposure differentially regulated the expression of P2Y₂R, P2Y₄R and P2X₇R subtypes and Panx1 in MLO-Y4 and MOB-C. The P2X₇R and Panx1 in MLO-Y4 was substantially downregulated in HG while the P2Y₂R and P2Y₄R in MOB-C were significantly upregulated. Moreover, FSS-induced ATP release under control conditions was substantially reduced after HG exposure in both MLO-Y4 and MOB-C. Likewise, FSS-induced Ca²⁺ transients in both cell types were also lower in HG compared to control condition. These findings indicate that HG-induced thickening of bone PCM and altered P2R and Panx1 expression impairs proper sensing and transduction of physiological FSS, which ultimately impairs the adaptive response of osteocytes/osteoblasts to mechanical loading.

Fluid Shear Modulates COX2 mRNA Expression but not Mineralization during Oscillatory Motions. Gunes Uzer^{*1}, Sarah Manske¹, Ete Meilin Chan¹, Yi-Xian Qin², Clinton Rubin², Stefan Judex¹. ¹Stony Brook University, USA, ²State University of New York at Stony Brook, USA

When applied at high frequencies, bone can sense and respond to mechanical signals of extremely small magnitude. During the application of low-level vibrations, cell populations within the bone are likely subjected not only to acceleratory motions but also to fluid shear as a result of fluid-cell interactions. Here, we tested whether COX2 mRNA expression and the level of calcification is modulated by the magnitude of vibration induced fluid shear. To this end, we developed a combined cell culture/analytical model in which finite element (FE) modeling determined peak fluid shear stresses acting on a monolayer of cells during high-frequency oscillations. Fluid shear was modulated both in vitro as well as analytically by increasing the acceleration magnitude and/or increasing the viscosity of the fluid via the addition of dextran. Osteoblast-like MC3T3-E1 cells were vibrated at 0.15g or 1g peak accelerations at 60Hz for 30min/day in mediums with dextran concentrations of 0%, 3%, 6% or 9% for 1, 7, or 14 days (n=3-4, each). Increase of dextran concentration from 0% to 9% resulted in a 4.5-fold increase in estimated fluid shear. Similarly, increasing acceleration from 0.15g to 1g increased fluid shear 6.7-fold. COX2 mRNA expression was determined by RT-PCR at day 1 and calcification levels were determined at days 14 and 21. Compared to controls, cells subjected to 1g peak acceleration elicited greater increases in COX2 expression than cells subjected to 0.15g. The only group in which COX2 levels were not up-regulated was the 0.15g, 0% dextran group (45% down-regulated compared to controls). Increasing fluid shear via dextran or acceleration magnitude resulted in a logarithmic increase of COX2 expression ($R^2=0.8$). Differences in COX2 expression as a function of fluid shear were not mirrored by calcification data obtained after either one or two weeks of vibration. Vibration exposure at 0.15g or 1g vibration equally increased ($p<0.05$) calcification compared to non-vibrated controls, independent of the viscosity level of the medium. This data suggests that cells are able to respond to very low levels of fluid shear (0.02Pa – 0.08Pa) when exposed to an oscillatory frequency of 60Hz. That the non-linear increase in COX2 mRNA with fluid shear was not matched by a similar relation between fluid shear and calcification suggests that fluid shear does not regulate the level of vibration-induced mineralization.

Microscale Fluid-Flow Analysis in Osteocyte Canaliculi Using High-Resolution Image-Based Models. Hiroshi Kamioka^{*1}, Yoshitaka Kameo², Yuichi Imai³, Astrid Bakker⁴, Rommel Bacabac⁵, Takashi Yamashiro³, Taiji Adachi⁶, Jenneke Klein-Nulend⁷. ¹Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sc, Japan, ²Department of Mechanical Engineering, Graduate School of Engineering, Osaka Prefecture University, Japan, ³Department of Orthodontics, Okayama University Graduate School of Medicine, Dentistry, & Pharmaceutical Sciences, Japan, ⁴Department of Oral Cell Biology, ACTA-University of Amsterdam & VU University Amsterdam, Research Institute MOVE, Netherlands, ⁵Medical Biophysics group, University of San Carlos, Philippines, ⁶Department of Biomechanics, Research Center for Nano Medical Engineering, Institute for Frontier Medical Sciences, Japan, ⁷ACTA-VU University Amsterdam Dept Oral Cell Biology (Rm # 11N-63), The Netherlands

A number of fascinating studies suggest that osteocytes play a key role in the regulation of bone mass and structure by mechanical stimuli, thereby designating osteocytes as important mediators of bone fracture resistance. It is generally thought that mechanical loading-induced matrix strains cause a flow of interstitial fluid over the osteocyte processes, but how this fluid flow subsequently activates the osteocyte is still a matter of much debate. Several theories exist, but their value of these theories is somewhat limited since they are not based on actual three-dimensional (3D) morphologies of the osteocyte canaliculi, while microscopic fluid flow analysis using detailed morphological data of the osteocyte canaliculi in the bone matrix is essential for the quantitative estimation of the fluid-induced shear stress acting on the cell processes. In the current study we aimed to construct a realistic 3D model of the pericellular space between the osteocyte cell membrane and the canalicular wall for microscale flow analysis. We observed detailed structures of both osteocyte cell processes and canaliculi. Furthermore, using the 3D image-based model of a single canaliculus, fluid dynamics was numerically analyzed using the Lattice Boltzmann method. We found that the microscopic surface asperity of the osteocytic processes and canalicular wall strongly influenced the flow profiles, demonstrating the applicability of high-resolution image-based models for quantitative flow analysis in the canaliculus. Our simulation assumed the steady-state Newtonian flow in a canaliculus at 602 nm in length. However, whether this assumption holds at micro-scale fluid flow as well as the estimation of the influence of the fluid mechanical properties and the boundary conditions on the shear stress acting on the surface of cell processes needs further discussion. This study was partially supported by the Nanotechnology Network Project at the Research Center for Ultrahigh Voltage Electron Microscopy, Osaka University, from the Ministry of Education, Culture, Sports, Science and Technology (MEXT) of Japan.

MO0068

Molecular Factors Involved in the Early Response of Bone and Skeletal Muscle to Mechanical Unloading. Maria Squire^{*1}, Jason Stankiewicz², Melissa Monaghan³, Anil Dhundale⁴, Stefan Judex⁵. ¹Department of Biology, The University of Scranton, USA, ²Biochemistry Program, The University of Scranton, USA, ³OSI Pharmaceuticals, LLC, USA, ⁴LIHTI & SBU Business Incubators, Stony Brook University, USA, ⁵Biomedical Engineering Department, Stony Brook University, USA

Bone and skeletal muscle are mechanosensitive tissues, remodeling their structures to accommodate to changes in their mechanical loading environments. In rodents, hindlimb unloading significantly decreases the quantity of bone and skeletal muscle within as little as 2 weeks. Functional relationships between bone and muscle have been proposed, but whether their initial molecular responses to altered mechanical loading are similar or distinct is largely unknown. In this study, we examined gene expression in bone and muscle following short-term hindlimb unloading. Total RNA was extracted from the whole proximal tibia and soleus of adult (4 mo) female F1 crossbred (BALB/cByJ x C3H/HeJ) mice following 4 d of normal cage activity (control) or hindlimb unloading (n=5 each). Reference samples were hybridized with either a control or unloaded sample onto custom oligonucleotide arrays (n=5 per group) containing 16,442 ESTs (70mer oligos) from the Operon mouse genome library (v2). Following normalization and filtering, 164 (tibia) and 115 (soleus) differentially regulated genes were identified (p<0.05), with only 3 genes common to both lists. Of the three genes affected in both tissues, one was a transcription factor (transcription factor AP-4 (Tfap4)) and another was a known modulator of transcription factor activity (protein inhibitor of activated STAT 2 (Pias2)). Both were significantly up-regulated in bone (64% and 38%) and muscle (68% and 52%). Classification of the differentially regulated genes in bone revealed that unloading down-regulated mRNA levels of runt-related transcription factor 2 (Runx2a, -38%) and a number of extracellular matrix genes including collagen type I α 1 (-30%) and biglycan (-45%). qPCR analyses confirmed the down-regulation of biglycan (-49%) as well as the down-regulation of asporin (-41%) and decorin (-41%), all of which belong to class I small leucine rich proteoglycans. In skeletal muscle, the gene encoding for MAD homolog 7 (Drosophila) (SMAD7), a protein with a known role in skeletal muscle cell differentiation, was down-regulated by 57% following unloading and qPCR studies are ongoing to validate this finding. Taken

together, the results suggest that although there may be some overlap in the molecular mechanisms that mediate the early response of bone and skeletal muscle to mechanical unloading, most of the genes are tissue-specific.

The Effect of Vibratory Forces on the Rate of The Tooth Movement in Rats. Zana Kalajzic^{*1}, Elizabeth Blake¹, Achint Utreja¹, Manshan Xu¹, Jing Chen¹, Flavio Uribe¹, Ravindra Nanda¹, Douglas Adams¹, Sunil Wadhwa². ¹University of Connecticut Health Center, USA, ²University of Connecticut, USA

Orthodontic tooth movement requires external orthodontic forces to be converted to cellular signals that result in coordinated removal of bone by osteoclasts (compression side), and the formation of new bone by osteoblasts (tension side). Recently, vibratory forces have been shown to increase the rate of tooth movement in rodent models. The objective of this study was to examine potential mechanisms behind this action. Seven week old Sprague Dawley female rats were used in this study. The animals were divided into three groups. The control group (A) received only the orthodontic spring which was activated from the left maxillary first molar to the maxillary left incisor. The experimental group (B) received the spring and additional occlusal vibratory stimulation of 0.4 N compression at 30Hz for 10 minutes twice a week. The third group (C) received the vibratory stimulation only. The duration of the experiments was 2 weeks. The amount of tooth movement and alveolar bone parameters were measured using microCT analysis. Dissected maxillae were processed for paraffin and frozen embedding. Sagittal sections were stained for TRAP, Von Kossa and immunostained for TUNNEL. Vibratory forces significantly decreased the amount of tooth movement (50%) in the experimental group B compared to the control group A. We did not notice any changes in osteoclast number, localization or mineralization of the PDL between those 2 groups. Vibration alone in group C did not cause any change of osteoclast number and their localization nor any change in bone parameters: total volume, bone volume and tissue density. However, the number of apoptotic cells within the PDL was higher in the experimental group B than in control groups A and C. Future studies will need to address the possible role of PDL cell apoptosis in the tooth movement.

MO0070

TNF α Partly Controls Fluid Pressure Induced Osteolysis. Anna Fahlgren^{*1}, Denis Nam¹, Goran Andersson². ¹Hospital for Special Surgery, USA, ²Karolinska Institute, Sweden

In contrast to the well-understood pathway by which implant-derived particles induce bone resorption, little is known about the recently-described process in which loosening is generated as a result of force-induced mechanical stimulus at the bone-implant interface (Fahlgren et al, 2010). Specifically, there is no knowledge as to what cells or signaling pathways couple mechanical stimuli to bone resorption in context of loosening. We showed previously that pressure-induced osteoclast activation was associated with lower levels of inflammatory cytokines compared to particle-induced osteolysis. Thus, mRNA expression of TNF α (0,330.07 versus 0,470,16) and RANKL (3,72,3 versus 11,49,6) was significantly lower after fluid pressure compared to wear particles. Never the less, we found the same number of osteoclasts per unit area in both models. These findings suggest that in both circumstances levels of TNF α are sufficient to induce maximal osteoclastogenesis in the presence of priming levels of RANKL (Lam et al, 2003). To test this hypothesis we used our established model of pressure-induced bone loss in rats in the absence of wear particles. To block TNF α function we administered Enbrel 4mg/kg (TNF α Ra) (n=9), or saline (n=8), every third day, starting 2 days prior to initiation of the pressure stimuli. As a positive control similar groups of experimental or control animals were given dexamethasone 2mg/kg (n=10), to suppress activation of the innate immune system. Our primary readout was the number of cathepsin K positive osteoclasts. Five days of pressurization resulted in suppression of Cathepsin K positive osteoclast by both dexamethasone (64%) and Enbrel (50%) (Figure 1). These results suggest that a) pressure induced osteolysis is mediated only in part of TNF α , and b) additional inflammatory cytokines are required for osteoclast activation.

Figure 1. Inhibition of pressure induced osteoclast activation by dexamethasone (Dexa) and Enbrel (TNFaRa) treatment.

MO0071

Bone Geometry and Strength is Preserved in Adults Following Bariatric Surgery. Lesley Scibora^{*1}, Sayeed Ikramuddin¹, Henry Buchwald¹, Thomas Beck², Moira Petit¹. ¹University of Minnesota, USA, ²Quantum Medical Metrics, LLC, USA

Bone loss is an accepted consequence of bariatric surgery based on areal bone mineral density outcomes. No known studies have prospectively explored the effects of bariatric surgery on bone strength indices in morbidly obese adults using peripheral quantitative computed tomography. Purpose: To describe changes in tibial and radial bone geometry, volumetric density, and estimates of bone strength from baseline (pre-surgery) to 12 months following bariatric surgery in morbidly obese adults. Methods: Bone geometry and strength were assessed by peripheral quantitative computed tomography (pQCT) in 10 obese (mean BMI 49.4 (SD 5.6) kg/m²; mean age 42.3 (SD 15.5) years) adults. Total volumetric bone mineral density (ToD, mg/mm³), total bone area (ToA, mm²), and bone compressive strength (bone strength index (BSI)) were assessed at the distal (4%) sites of the tibia and radius. ToA and cortical bone area (CoA, mm²), cortical volumetric density (CoD, mg/mm³), cortical thickness (CoTh, mm), and bone bending strength (polar strength strain index (SSIp), mm³) were measured at the midshaft sites of the tibia (66%) and radius (50%). Air displacement plethysmography was used to assess body composition (fat mass and fat-free mass (kg)). Results: On average, at 12 months following bariatric surgery body weight decreased 23% ($p < 0.01$), reducing BMI to 38.5 (SD 9.9) kg/m². Weight loss was primarily fat mass (-38.5%, $p < 0.01$), rather than fat-free mass (-5.7%, $p < 0.05$). The fat mass to fat-free mass loss ratio at 3, 6, and 12 months was 4.7:1, 7.5:1, and 7:1, respectively. After 12 months, changes in bone parameters were marginal (<1.0%) at radius (50%) and tibia (66%) midshaft sites, with non-significant increases in BSI at the distal radius (+1.7%) and tibia (+2.5%). Conclusions: Morbidly obese adults who underwent bariatric surgery experienced rapid and substantial weight loss, primarily due to fat mass loss, compared to a small reduction of fat-free mass. However, participants did not suffer short-term deleterious effects on estimates of bone strength at either weight-bearing or non weight-bearing sites. Our results contrast with DXA-based studies that demonstrated reductions up to 14% at hip sites, but not at the radius. Although participants remained obese, they lost little fat-free mass; this may have preserved bone strength. Future studies should examine longer-term effects of bariatric surgical procedures on bone geometry and strength.

Disclosures: Lesley Scibora, None.

MO0072

Effect of Carbohydrate Feeding on the Bone Metabolic Response to Exhaustive Running. Craig Sale^{*1}, Julie Greeves², Thomas Jones³, Ian Varley¹, Ruth Hobson¹, John Dutton⁴, William Fraser⁵. ¹Nottingham Trent University, United Kingdom, ²HQ Army Recruiting & Training Division, United Kingdom, ³Northumbria University, United Kingdom, ⁴University of Liverpool, United Kingdom, ⁵University of East Anglia, United Kingdom

There is a proposed link between carbohydrate (CHO) feeding and bone metabolism at rest, which suggests a potential strategy to attenuate the increase in bone resorption often shown following strenuous exercise (Scott et al. 2010, *JCEM*, 95, 3918-25). We examined the bone metabolic response to CHO ingestion during exhaustive running.

Ten healthy males (mean SD, age 23.2 y, height 1.75 ± 0.08 m, body mass 72.93 ± 7.54 kg, body fat percentage 14.2% and $\text{VO}_{2\text{max}}$ 55.49 ± 6.53 ml·kg⁻¹·min⁻¹) completed two repeated measures, counterbalanced 7 d trials involving a bout of 120 min of running at 70% $\text{VO}_{2\text{max}}$, once with CHO feeding at the start and every 20 minutes of exercise (total glucose ingestion was 102.10 ± 10.56 g) and once with a matched placebo (P). From days 1 to 3, participants refrained from exercise and maintained dietary control. On day 4, venous blood was withdrawn prior to exercise, with subsequent samples being withdrawn immediately post-exercise and after 60 and 120 min of recovery. Participants also provided blood samples at rest on three follow-up days (5, 6 and 7). Markers of bone resorption (β -CTX) and bone formation (PINP), osteoprotegerin (OPG), parathyroid hormone (PTH), glucose and lactate were measured. Bone marker data were analysed using area under the curve (AUC) and paired samples t-tests, with other data being analysed using two-way ANOVA.

CHO feeding resulted in a significantly increased plasma glucose concentration at the cessation of exercise ($P \leq 0.001$) and reduced lactate concentrations across the trial period ($P \leq 0.05$). In P, β -CTX concentrations were increased to ~120% of baseline on days 5 to 7. With CHO feeding, these increases in β -CTX were abolished (~100% of baseline on days 5 to 7). The AUC for β -CTX, calculated from baseline and follow-up day data only, was significantly lower in CHO than in P ($P \leq 0.05$). CHO feeding had no significant effect on AUC for PINP or on PTH and OPG concentrations at any time point.

CHO feeding attenuated the increase in bone resorption observed with strenuous running, suggesting a strategy for reducing the negative effect of repeated exhaustive exercise on bone. However, CHO feeding had no significant effect on bone formation. The effect of CHO feeding on bone resorption was not explained by changes in either OPG or PTH.

This work was sponsored by the UK Ministry of Defence (Army).

Heterogeneity in Mechanosensitivity Among Canadian Postmenopausal Women With and Without Fractures. Celeste Hamilton^{*1}, Thomas Beck², Alia Khaled³, Sophie Jamal⁴, Jonathan Adachi⁵, Jacques Brown⁶, Kenneth S. Davison⁷. ¹Women's College Hospital/University of Toronto, Canada, ²Quantum Medical Metrics, LLC, USA, ³Department of Electrical & Computer Engineering, Johns Hopkins University, USA, ⁴The University of Toronto, Canada, ⁵St. Joseph's Hospital, Canada, ⁶Laval University, Canada, ⁷Department of Medicine, Laval University, Canada

The function of bone's adaptation to mechanical load is to adjust the amount and distribution of bone tissue, such that strains experienced within the bone are kept within certain physiological limits. Genetic differences may cause heterogeneity in load response (mechanosensitivity), such that equivalent loads would generate higher or lower strains depending on load sensitivity. Individuals who are less sensitive to load stimuli should therefore require higher strains to generate an adaptive response and should consequently have weaker bones and be more susceptible to fracture. The purpose of the current study was to determine if stresses (proportional to strains) at the femoral neck under equivalent physiologic loads were higher in postmenopausal women with a history of fractures than in women without fractures. We studied 2922 postmenopausal women who participated in the Canadian Multicentre Osteoporosis Study (CaMos) and who had available Hip Structure Analysis (HSA) data from dual energy x-ray absorptiometry (DXA) scans. Women were categorized into 3 groups based on the number of self-reported fractures at baseline (no fractures, 1-2 fractures and 3 or more fractures). We computed stress (megapascals=MPa) at the infero-medial margin of the femoral neck in a one-legged stance mode using a 2-D engineering beam analysis incorporating dimensions and geometry from DXA scans using the HSA method. We used general linear models (SAS 9.1) after first evaluating significant confounding effects of parameters in Table 1 to determine associations between stance stress and the number of reported fractures based on fracture groupings. Women with 1-2 fractures had higher stress than women with no fractures (10.892.39 vs. 10.622.11 MPa; $p=0.0028$) and women with 3 or more fractures had higher stress than women with 1-2 fractures (11.422.35 vs. 10.892.39 MPa; $p=0.0162$). Because the infero-medial margin of the femoral neck is a site that is normally loaded under compression during upright walking, where the cortex is relatively well preserved with age, these findings are consistent with the theory that individuals who fracture may be more likely to have an underlying genetic difference causing decreased mechanosensitivity. This has important clinical implications in terms of treatment selection, as those with compromised mechanosensitivity may respond best to metabolic agents which would increase their response to load stimuli.

Table 1. Subject characteristics by fracture group.

Variable	No fractures (n=1683)	Fracture Group 1-2 fractures (n=1114)	3 or more fractures (n=125)
		Mean(SD)	
Age (years)	65.2 (9.1)	66.2 (9.3)	68.8 (9.3)
Weight (kg)	68.5 (13.4)	69.5 (13.3)	69.6 (13.7)
Years since menopause	18.5 (10.3)	20.3 (10.3)	23.0 (10.8)

Increased Microcracks and Nanoindentation Modulus in the Subchondral Region of the Femoral Head Following Ischemic Necrosis. Olumide Aruwajoye¹, Mihir Patel², Matthew Allen³, Pranesh Aswath², Harry Kim⁴. ¹Texas Scottish Rite Hospital, USA, ²University of Texas at Arlington, USA, ³Indiana University School of Medicine, USA, ⁴Scottish Rite Hospital for Children, USA

Ischemic necrosis (IN) of the immature femoral head initially produces subchondral fracture and subsequent femoral head deformity. Interestingly, even before bone resorption or repair occurs, a decrease in the indentation stiffness of the femoral head and its bony components has been reported. Furthermore, increased mineralization of the necrotic bone has been found suggesting that the material properties of the bone are altered following IN. We hypothesize that the increased mineralization of the necrotic bone leads to increased subchondral brittleness and an increase in the microdamage, resulting in the compromise of the mechanical properties of the subchondral region following IN. The purpose of this investigation was to determine the nanoindentation properties and to assess the presence of microcracks in the subchondral region 2 weeks post IN induction in a well established piglet model of IN. This model has been shown to develop a subchondral fracture and femoral head deformity resembling juvenile femoral head osteonecrosis. Five animals were used for the nanoindentation and microcrack assessments. The left femoral head of each animal was used as a normal control, while the right side had a surgical IN induction by ligating the femoral neck vessels with a ligature. Two 2 mm sections were obtained from each femoral head for the assessments. Measurements included crack length and number, with calculations of crack density, crack surface density, hardness, and reduced modulus. A bony area of the subchondral region was randomly selected for nanoindentation. On average, 44 indentations per 3600 μm^2 were obtained. Nanoindentation for the normal side showed a modulus of 12.23.6 GPa and corresponding hardness of 456187 MPa, while the ischemic side showed a significant increase in the modulus and hardness, 17.16.5 GPa and 626310 MPa, respectively ($p < 0.001$). Crack density in the ischemic side (mean 3.2 cracks/ mm^2) was significantly higher compared to the normal side (mean 0.27 cracks/ mm^2) in the subchondral region ($p < 0.001$). Taken together, these results suggest that IN of the immature femoral head increases the brittleness of the subchondral trabecular bone and makes it more susceptible to microcracks. We postulate that continued loading of the hip joint when there is a lack of bone cells to repair the microcracks due to IN leads to an accumulation of the microcracks and subsequent subchondral fracture.

MO0075

Low Intensity Pulsed Ultrasound as Targeted Therapy towards Bone Loss. Sardar Uddin¹, Yi-Xian Qin². ¹Stony Brook University, USA, ²State University of New York at Stony Brook, USA

Osteoporosis and microgravity has been known to cause adverse effect on bone quality leading to decrease in bone mass density (BMD) in load-bearing bones (Lang T.F et al 2006). Therapeutic approaches using drugs and different growth factors have been considered to maintain bone mass with limitations of high costs and difficulty to maintain over longer periods of time besides the systematic effects of such treatments (Hughes-Fulford M. 2002). To reverse the adverse effects on bone physiology, it is important to provide cells with physical stimulus which can maintain essential mechanical signal for cells to counter the bone loss. Ultrasound generated local acoustic pressure vibrations can be readily applied *in vivo* for human therapeutics as a non-invasive modality and more target specific treatment related loading profiles. The objective of this study was then to evaluate the systematic effects of low intensity pulsed ultrasound (LIPUS) on a disused bone model.

C5BL/6 mice were hind limb suspended for 4 weeks. Animals were distributed into 5 groups, Age-Match(AM), Non-Suspended Sham(NS), Non-Suspended-LIPUS

(NU), Suspended Sham (SS) and Suspended - LIPUS(SU). NU and SU animals' tibia were exposed to LIPUS at 30mW/cm² for 20min/day for 5 days/week.

After 4 weeks of loading animals were euthanized and tibia were collected. Bone quality was assessed using mCT with resolution of 12mm. MicroCT data showed significant increase in bone mineral density (mmHg/cc, $p = 0.02$), Trabecular Thickness (mm, $p = 0.05$) and Bone surface/volume (mm²/mm³, $p = 0.05$) (Table 1). Analyses of right (non LIPUS treated) and left (LIPUS treated) tibia of NU don't show any changes. Right tibia of SU mice doesn't show any anabolic effects of LIPUS exposure as observed in left tibia (Fig 1).

LIPUS anabolic effects are localized and show no systematic effects suggesting LIPUS treatment as localized noninvasive therapy inhibited bone loss induced by disuse. Further work includes on-going histomorphometry and molecular analyses to understand the mechanotransductive pathways activated by LIPUS stimulation.

Fig 1: LIPUS as localized bone loss therapy.

Short Term Physical Activity May Induce Changes In Bone Density And Geometry Even After Bone Maturation In Talented Female Athletes. Beatrice FERRY¹, Eric Lespessailles², Gaele Ducher³, Martine DUCLOS⁴, Pierre ROCHCONGAR⁵, Geraldine NAUGHTON⁶, Daniel Courteix⁷. ¹Clermont Universite, Universite Blaise Pascal, EA 3533, Laboratoire de Biologie des Activites Physiques et Sportives, BP 10448, F-63000; ²Universite de Limoges, Faculte des Sciences et Techniques, Departement STAPS, F-87060 LIMOGES, France, ³Centre Hospitalier Regional, France, ⁴Penn State University, USA, ⁵Service de Medecine du Sport et des Explorations Fonctionnelles, France, ⁶Unite de biologie et medecine du sport, CHU Pontchaillou, France, ⁷Centre of Physical Activity Across the Lifespan Australian Catholic University, Australia, ⁸Universite Clermont Ferrand Laboratoire De Biologie Des APS, France

The benefits of exercise on bone geometry and density are linked to the history and modalities of sports participation. The period of late adolescence, characterized either by a minimal increase or a plateau in bone maturation has not been plainly investigated. The aim of the present study was to assess changes in hip structural parameters and bone mineral density, in high level adolescent soccer and swimmers.

Fifty-eight girls swimmers (SWIM: n=26, aged 15.9 ± 2 years) or soccer players (SOC: n=32, aged 16.2 ± 0.7 years) were investigated before and after an 8-month training season. Fifteen non active age-matched adolescents were enrolled at baseline to serve as a reference group. Body composition and areal bone mineral density were measured at the total body, lumbar spine and total hip by DXA. Indices of bone geometry were extracted from DXA scans using the hip structure analysis (HSA) method. Anatomical (cross sectional area-CSA, endocortical diameter-ED and periosteal diameter-WIDTH) and mechanical parameters (CSMI, Z and buckling ratio-BR) were analyzed. A one way ANOVA with repeated measures was performed.

After eight month of training, SOC increased their density at all traditional bone sites whereas SWIM did not. The SOC's changes are associated with an increase of whole body lean mass. At the neck and total hip, SWIM kept their baseline low Z-score values and SOC remained above the normal. The most important changes in HSA parameters were observed at the femoral shaft. When comparing the T-score to the control group at this section, SWIM who were normal for ED and WIDTH and below for CSA, did not change after the season. For the SOC group who started

already above the average range, CSA and WIDTH still improve during this period. The T-score showed an improvement of CSMI and Z at FS section for SOC ($p < 0.001$), without any change in the SWIM group. Remarkably SWIM had improved the T-score of BR ($p < 0.005$) while SOC did not.

A season of training for sport characterized by impact (SOC) is associated with bone geometry improvement in late adolescent female despite expectations that this period of growth represents a plateau in bone maturation. This study adds to the existing literature describing intensive swimming practice as lacking an osteogenic effect when assessed by DXA. Weight bearing physical activity can be an important contributor to bone strength at the end of adolescence, as observed during childhood.

Disclosures: Beatrice FERRY, None.

MO0077

β -Adrenergic Receptor Antagonist Suppresses Occlusal Force Unloading-Induced Alveolar Bone Loss in Rats. Yasuhiro Shimizu^{*1}, Jun Hosomichi², Sawa Kaneko¹, Takashi Ono¹. ¹Orthodontic Science, Department of Orofacial Development & Function, Division of Oral Health Science, Graduate School, Tokyo Medical & Dental University, Japan, ²Department of Orthodontics & Pediatric Dentistry, School of Dentistry, University of Michigan, Orthodontic Science, Department of Orofacial Development & Function, Division of Oral Health Science, Graduate School, Tokyo Medical & Dental University, USA

Mechanical stress to bone plays a crucial role in the maintenance of bone homeostasis, and prolonged lack of mechanical stimuli leads to disuse osteoporosis. Unloading of occlusal force upon alveolar bone, occlusal hypofunction, suppresses the formation of bone and results in atrophic changes of alveolar bone. Sympathetic nervous system controls bone resorption by increasing production of RANKL, via β -adrenergic receptors in leptin-dependent neuronal regulation of bone formation. Sympathetic nervous system mediates unloading-induced bone loss by reduction in osteoblastic cell activity and enhancement of osteoclastic cell activity. Therefore, we hypothesized that the modulation of sympathetic nervous system via β -adrenergic receptors is involved in the metabolism of the alveolar bone. We focused on the effect of sympathetic nervous tone on occlusal force unloading-induced alveolar bone loss in rats using a non-selective β -adrenergic receptor antagonist.

Twenty-four 5-week-old male Wistar rats were randomly divided into 4 groups; Group C was an untreated group, Group H was an occlusal hypofunction group, Group B was a group administered a non-selective β -adrenergic receptor antagonist, propranolol hydrochloride, and rats in Group HB received water with the same dose of propranolol as in Group B under the hypofunctional condition in the molar area. Occlusal hypofunction in the molar area was produced by attaching appliances to rat maxillary and mandibular incisors. In addition, propranolol was administered orally to rats in drinking water to pharmacologically suppress sympathetic nervous activity. After 1 week, alveolar bones were examined by micro-CT, histomorphometry and histology to determine their trabecular bone phenotypes and histological changes.

The marrow spaces of the interdental alveolar bone of rat mandibular first molars (M1) increased in Group H but not in Group C, while these decreased in Group HB. Bone volume/tissue volume, trabecular thickness and trabecular number for interdental alveolar bone of M1 in Group H were significantly lower than those in Group C, whereas those in Group HB remained as high as those in Group C. The number of TRAP-positive cells in Group H increased compared to that in Group C, whereas it significantly decreased in Group HB. Findings from our study suggest that β -adrenergic receptors in the sympathetic nervous system are the target of occlusal force unloading-induced alveolar bone loss.

Collagen Enzymatic Cross-links Deficiency and Bone Quality. Delphine Farlay^{*1}, Marie-Eve DUCLOS², Evelyne Ginevys³, Cindy BERTHOLON¹, Stephanie VIGUET-CARRIN¹, Thierry ROGER⁴, Daniel HARTMANN⁵, Roland Chapurlat⁶, Helene Follet⁷, Georges Boivin⁸. ¹INSERM, UMR1033; Universite De Lyon, France, ²Universite de Lyon, UPSP 2007-03-135 RTI2B, VetAgroSup, France, ³Universite De Lyon, France, ⁴VetAgroSup, France, ⁵Universite de Lyon, UPSP 2007-03-135 RTI2B, France, ⁶E. Herriot Hospital, France, ⁷INSERM, UMR1033 ; Universite De Lyon, Fra, ⁸INSERM, UMR 1033 ; Universite de Lyon, France

A collagen enzymatic cross-link (ECL) deficiency, such as pyridinium ECL, alters the mechanical properties of bone organic matrix. However, the influence of such a deficiency on mineral characteristics is not well documented. Our hypothesis was that a decrease in pyridinium ECL modifies the arrangement of collagen fibers and consequently disrupts the mineral characteristics of bone mineral. To investigate the relationship between ECL and mineral phase, a model of lathyritic rats was designed. This model consists to inhibit the lysyl oxidase, enzyme catalyzing the ECL formation, by using a lathyrogen agent such as α -aminopropionitrile (α APN). Twenty Wistar rats (28 day-old) received either 666 mg/kg/day of α APN (LATH) or vehicle (CTL) twice daily during 30 days. After sacrifice, left tibia and radii were embedded in

PMMA for histomorphometry and Fourier Transform Infrared Microspectroscopy (FTIRM). By the latter, mineral maturity (age of mineral, 1030/1110 cm⁻¹ area ratio), crystallinity index (crystal size/strains, FWHM 604 cm⁻¹) were measured. Right tibia and radii were frozen at -20°C for biochemical dosage (HPLC) of ECL, pyridinoline (PYD) and desoxypyridinoline (DPD). Histomorphometry and FTIRM were performed on radii in which the decrease of ECL was higher than in tibia. Non-parametric tests (U Mann-Whitney) were performed. Results: a significant body weight loss was observed in all LATH animals, after the 14th day of injection, compared to CTL rats. In LATH rats, significant decreases of both ECL and collagen synthesis were observed compared to CTL. Moreover, a significant decrease of BV/TV, an increase in growth plate thickness and cortical porosity were observed. Cortical thickness was not modified. Mineral maturity and crystallinity index were unchanged in LATH animals. In conclusion, an ECL deficiency does not affect the quality of bone mineral phase.

Polarization Control of Raman Spectroscopy Optimizes Measures of Bone Quality. Alexander Makowski^{*1}, Chetan Patil¹, Lacey Gorocho¹, Anita Mahadevan-Jansen¹, Jeffry Nyman². ¹Vanderbilt University, USA, ²Vanderbilt University Medical Center, USA

Interest in the concurrent assessment of both mineral and collagen phases of bone composition and matrix organization has led to novel techniques that modulate laser polarization while conducting Raman Spectroscopy (RS). Since bone is inherently birefringent, polarization will affect the light path through the tissue and hence the Raman spectra. Moreover, polarization bias from RS system components could affect measurements of mineral to collagen ratios, crystallinity, and carbonate substitution. We modulated source and collection polarization in a commercial instrument to test the hypothesis that matching the polarization behavior of individual Raman peaks would isolate the quantification of organization from the quantification of compositional properties while minimizing variance in traditional Raman properties of bone.

To demonstrate the effect of polarization on compositional differences between osteonal and interstitial bone, we collected spectra from multiple osteons and neighboring interstitial sites of a transverse section of human cortical bone (medial quadrant of the femur mid-shaft) before and after 90 degree sample rotation. To analyze sensitivity of spectral components to the light orientation, spectra were collected on the same sample and similar tissue sites after adding an excitation arm (isolator) and a collection arm (analyzer) polarizers. With a fixed sample orientation at each site, spectra were collected at analyzer rotation angles of 0:180 degrees per 15.

Bone rotation studies revealed lower coefficients of variation for the collagen marker Proline than the traditional Amide I, and it yielded more consistent measures of osteonal-interstitial tissue differences in mineral to collagen ratio, regardless of bone orientation. Exploring underlying causes, sinusoidal modeling of the peak intensities vs. polarization angle revealed that the established quantity ν_1 Phosphate/Amide I contains a bias in bone orientation relative to laser polarization, making it suitable for structural analysis, while the alternative ν_1 Phosphate/Proline corrects for polarization bias, and thus can assess composition independent of polarization angle (Fig.1). These results support differential optimization of RS quantities for analysis of structure or composition. Careful consideration of polarization bias for instrumentation and experimental protocols can prevent spurious correlation, ensuring Raman provides meaningful insight into bone's resistance to fracture.

Fig1. Peak intensity vs. polarization shows bias (Amide I, left) and correction (Proline, right)

Calcified Cartilage in Mature Rat Cortical Bone. Fiona Linnea Bach-Gansmo¹, Jesper Thomsen², Annemarie Bruel², Henrik Birkedal^{*1}.¹Aarhus University, Denmark, ²University of Aarhus, Denmark

Bone remodeling of cortical bone in humans involves Haversian remodeling. However, this mode of remodeling is very scarce in rodents such as rats [1, 2]. Indeed, why Haversian remodeling is used in some animals but not in others remains an unresolved question.

Using backscatter electron imaging, we found islands of brighter contrast, reflecting a higher degree of mineralization, in the center of mid-femoral rat cortical bone. The islands typically had rounded borders, often concave with an osteocyte located nearby, in a manner suggesting that the island had not been turned into bone, when an osteoblast matured into the osteocyte. This observation suggested that these islands could be remnant calcified cartilage. This hypothesis was confirmed by toluidine blue staining and by immuno-labelling against collagen type II. The degree of mineralization was mapped by qBEI [3], which clearly established that these areas were more highly mineralized than the surrounding tissue. This was further confirmed by energy dispersive X-ray analysis mapping. The mechanical properties of the cartilage islands were probed by nanoindentation using an indentation protocol similar to the one in [4]. As expected from the higher degree of mineralization, both the indentation modulus and hardness were significantly higher in the calcified cartilage than in surrounding bone.

The islands were elongated in the longitudinal direction of the femur. Our present observations explain previous biochemical results showing that collagen type II is present in rat cortical bone [5].

We suggest that the cartilage islands are leftovers from the bone formation process. As such they represent archaic mineralized tissue that is unlikely to sense and react appropriately to microcracks etc. Further work is needed in order to establish, whether their presence leads to reduced mechanical performance. We speculate that avoiding their presence may be an additional reason for Haversian remodeling in larger animals.

Thermodynamic Properties and Characterization of Proteoliposomes Rich in Microdomains Carrying Alkaline Phosphatase. Mayte Bolean^{*1}, Ana Maria Simao¹, Bruno Favarin¹, Jose Luis Millan², Pietro Ciancaglini³.¹Department of Chemistry, FFCLRP-USP, Brazil, ²Sanford-Burnham Medical Research Institute, USA, ³FFCLRP-USP, Brazil

Tissue-nonspecific alkaline phosphatase (TNAP) is associated to the plasma membrane via a GPI-anchor and plays a key role in the biomineralization process. In plasma membranes, most GPI-anchored proteins are associated with "lipid rafts", ordered microdomains enriched in sphingolipids, glycosphingolipids and cholesterol. In order to better understand the role of lipids present in rafts and their interactions with GPI-anchored proteins, the insertion of TNAP into different lipid raft models was studied using dipalmitoylphosphatidylcholine (DPPC), cholesterol (Chol), sphingomyelin (SM) and ganglioside (GM1). The membrane models studied were binary systems (9:1 molar ratio) containing DPPC:Chol, DPPC:SM and DPPC:GM1; ternary systems (8:1:1 molar ratio) containing DPPC:Chol:SM, DPPC:Chol:GM1 and DPPC:SM:GM1 and finally, a quaternary system (7:1:1:1 molar ratio) containing DPPC:Chol:SM:GM1. Calorimetry analysis of the liposomes and proteoliposomes revealed lateral phase segregation only in the presence of cholesterol, with the formation of cholesterol-rich microdomains centered above T_c=41.5°C. The presence of GM1 and SM into DPPC-liposomes influenced mainly ΔH and Δt_{1/2} values. The gradual increase in the complexity of the systems decreased the activity of the enzyme incorporated. The presence of the enzyme also fluidifies the systems, as seen by the intense reduction in ΔH values, but do not alter T_c values significantly. The study of these microdomains will contribute to our understanding of the interactions between the lipids present in MVs and GPI-anchored TNAP.

MO0082

Vascular Endothelial Cells Produce Factors that Promote Osteogenic Differentiation of MSCs but Inhibit Mineral Deposition and Terminal Osteocyte Differentiation. Jennifer Fitch¹, James Birkhead², Elle Nugent², Louis Gerstenfeld^{*1}. ¹Boston University School of Medicine, USA, ²Pervasis Therapeutics, USA

Skeletal development after injury or surgery is co-dependent on vascularization. While this co-dependency is often thought of in terms of the skeletal tissue's need for appropriate nutrition and oxygen, vascular morphogenesis also provides the structural template around which the Haversian and trabecular bone units develop. These phenomena suggest that development and mineralization of skeletal tissue is tightly coordinated with vascular ingrowth. In order to define the nature of the signals between skeletal and vascular tissues, human endothelial cells (EC) embedded in a collagen carrier were co-cultured in transwell culture chambers with murine bone marrow stromal cells (MSCs). After a six day selection for the adherent MSCs, the cells were grown in a 50/50 MSC/EC culture media mixture supplemented with osteogenic levels of ascorbate and beta-glycerophosphate. Co-cultures were either grown for up to 15 days continuously in the presence of ECs or only for 6 days after initial selection. Continuous co-culture prevented mineral nodule formation but enhanced osteogenic differentiation based on the induction of osteonin and elevated osteocalcin and RankL mRNA expression compared to control no co-culture. Co-culture for only six days and assay of the cultures after an additional 12 or 15 days of growth showed that shorter co-culture periods delayed nodule formation but after additional time nodule formation caught up to control cultures. Assay of osteogenic differentiation (OC, BSP and RANKL) showed statistically significant increases in expression at 12 days, while assay of genes associated with terminal osteocyte differentiation (DMP1, Phex and FGF23) that are known to control mineral deposition showed delayed onset for the expression of DMP1 and Phex but enhanced the expression of FGF23. At 15 days both DMP1 and Phex were expressed at statistically higher levels than control cultures while FGF23 levels were decreased well below those seen in either the control or day 12 cultures. The decreased expression of FGF23 that is known to inhibit mineral deposition and elevated expression of DMP1 and Phex that promote matrix mineralization suggest a mechanism for the delay in mineralization related to the control of phosphate metabolism. The data suggest that factors produced by EC will promote early osteogenic differentiation but prevent premature mineralization during the period when newly formed blood vessels are growing into the developing bone tissue.

***Pknox2* Is Identified as a Regulator for Ulna and Deltoid Tuberosity Formation During Limb Development.** Wenrong ZHOU^{*1}, Zhu Huang², Haixia Zhao², Jingjing Cao³, Wan Yong², Jun Yang⁴, Gang Ma², Ruijiang Zhou³, Xizhi Guo². ¹Shanghai JiaoTong University, Peoples Republic of China, ²Shanghai Jiao Tong University, Peoples Republic of China, ³Bio-X Center, Shanghai Jiao Tong University, China, 200240, China, ⁴Shanghai Jiao Tong University, China

Pknox2 encodes a homeodomain-containing transcription factor as a member of Pknox subfamily of TALE (Three Amino acid Loop Extension) family. Its expression was confined in presumptive zuegopod and partial stylopod domain in murine limb at E10.5 or E11.5; after E12.5 it was specifically expressed at joint region of limb bud. To analysis the *Pknox2* function in vivo, we ectopically activated *Pknox2* expression in chondrocyte or osteoblast through generating *Col2a1-Pknox2* and *Col1a1-Pknox2* transgenic mice. The *Col2a1-Pknox2* transgenic embryos displayed a twisted radius and disorganized ulna with missing olecranon at the elbow joint in forelimb, while the hind limb was relatively normal. Histochemistry analysis showed that chondrocyte differentiation and osteogenesis program was exclusively abrogated in the ulna of *Col2a1-Pknox2* mutant at 15.5. Interestingly, ectopic ossified nodals on the first lumbar was also detected, indicating an alteration of the axial formula. In addition, *Col1a1-Pknox2* transgenic mice exhibited relatively normal skeletons except with loss of deltoid tuberosity. Preliminary data also suggested a potential modulation of Hox10/11 protein family and Wnt/ β -catenin signaling by *Pknox2* in regulating ulna identity and deltoid tuberosity development. More evidence is coming out to elucidate the mechanism of *Pknox2* in limb development.

Activation of IGF- β Signaling Regulates Joint and Tendon Marker Expressions in Isolated Joint Developing TGF- β Type II Receptor Expressing Cells. Tieshi Li^{*1}, Lara Longobardi¹, Froilan Granero-Molto¹, Timothy Myers², Ying Li¹, Douglas Mortlock³, Anna Spagnoli¹. ¹University of North Carolina at Chapel Hill, USA, ²University of North Carolina, USA, ³Vanderbilt University Medical Center, USA

TGF- β type II receptor (*Tgfr2*) signaling plays an essential role in joint and tendon development as indicated by the lack of these skeletal elements in the *Tgfr2*^{PRX-1KO} mouse, in which the *Tgfr2* is conditionally inactivated in developing limbs. (Spagnoli A et al, J Cell Biol, 2007; Schweitzer R et al, Development, 2009). In our previous studies we also showed the specific expressing domains of Tgfr2 within the developing limbs. (T. Li et al, ASBMR-2010). This study is to investigate the gene expression profile in embryonic limb mesenchymal Tgbr2 expressing cells and whether those cells provide signaling for joint and tendon marker expression. We isolated Tgfr2 expressing cells (1-2%) from developing (E13.5 and E14.5) limb mesenchyme digits of *Tgfr2*- β -Gal-GFP-Bac, a GFP-LacZ reporter mouse for Tgbr2 expression, of via GFP FACS sorting and treated isolated cells with TGF- β . Statistical significance was set at $p < 0.05$. qRT-PCR measurements showed that Tgfr2 positive cells compared to negative cells express more tendon markers such as Scleraxis (SCX) and Notch1 as a stem cell related gene, but less Collagen I and Collagen II. Comparing gene expression in E13.5 Tgfr2 positive cells vs E14.5 we found that joint marker genes such as GDF5, Sulf-1 and Gli3 increased with time. These results are consistent with our previous immunohistochemistry studies in which we showed the co-localization of Tgfr2 with these markers in developing joints (T. Li et al; ASBMR-2010). When placed in cultures, Tgfr2 expressing cells failed to form micromasses. Activation of Tgfr2 signaling in Tgfr2 expressing cells with Tgfb1 treatment (10 ng/ml; for 16 hours), when compared with untreated cells, up-regulated tendon-related gene expressions such as SCX and Tenomodulin as well as joint and stem cell markers such as GDF5, Noggin, Sulf-1, Notch1 while down-regulated collagen I, collagen II, Wnt9a, Gli3 and Tbx5. We further evaluated in Tgbr2 expressing cells, the expression patterns of genes related to mesenchyme stem cells. We found that 100% of Tgfr2 expressing cells express CD29; while around 20-30% express CD44, CD166, CD73 and CD105. Our studies provide evidence that the joint developing Tgfr2 expressing cells can be isolated, express joint and tendon markers and such expression is regulated by the activation of the TGF β signaling.

Delayed Bone Fracture Healing In Mice Due to Tamoxifen-induced Knockout of IGF1R Gene In Chondrocyte. Zhiqiang Cheng^{*1}, Hanson Ho², Fuqing Song², Alfred Li³, Christian Santa Maria², Yongmei Wang⁴, Michael You³, Chialing Tu³, Daniel Bikle⁵, Wenhan Chang¹. ¹University of California, San Francisco, USA, ²VAMC, UCSF, USA, ³VAMC, UCSF, USA, ⁴Endocrine Unit, University of California, San Francisco/VA Medical Center, USA, ⁵Endocrine Research Unit, Division of Endocrinology UCSF, USA

Fracture healing is delayed in mice due to tamoxifen-inducible knockout IGF1R gene in the chondrocyte. Z. Cheng, H. Ho, F. Song, Alfred Li, Christian Y. Santa Maria, C. Tu, D. Bikle, W. Chang. Endocrine Research Unit, Department of Veterans Affairs Medical Center, NCIRE, University of California, San Francisco, CA, USA. Many studies showed that IGF1R is important in the normal endochondral bone formation in the growth plate during development, starting from embryonic stages. Specific deletion of IGF1R in chondrocytes showed cell hypoproliferation, delayed differentiation and shortened hypertrophic zone. Although the majority of fracture heal is endochondral ossification parallel those that take place in growth plate, the process is more complex in fracture healing. To assess the role of IGF1R in this process, we fractured the chondrocyte-specific knockout of IGF1R mice by using three-point bending. Since cartilage-specific IGF1R Knockout mice died shortly after birth, we generated Tamoxifen-inducible expression of Cre under the control of the type II collagen promoter. We injected Tamoxifen one day before fracture at the age of 3 months, keeping injection for 6 days. We investigated the callus of these mice, 4 Wild Type (WT) vs. 3 Knockout (KO), after non-fixed tibia fracture over 10 days by using gene expression analyses and by bone histomorphometry. Callus gene expression confirmed IGF1R expression is significantly reduced in KO mice with the higher level of IGF1. It showed the early differentiation marker—Agg and Col (II) were increased in KO mice compared to WT, the late terminally differentiation marker—OPN is decreased in KO mice, but Col(X) is increased in KO. The osteoblast marker—Clo(I) and OCN were different between two group. Histomorphometric analysis demonstrated that there were a moderate increased on BV/TV (22.4% vs. 18.5%, +21% $p=0.062$). A significant increase in WT were seen on total callus volume (TV) (8.6% vs. 5.2%, +65.4% $p=0.0009$), terminal differentiative chondrocytes volume (TDCV/CV) (56.2% vs. 48.0%, +17.1% $p=0.014$) and new bone thickness (BTh) (10.9% vs. 9.7%, +12.4% $p=0.016$). The cartilage volume in the callus (CV) was decreased in WT compare to KO (20.4% vs. 34.4%, -68.6% $p=0.0012$). The increased CV, but reduced hypertrophic chondrocytes as well as decreased BV/TV in the callus of the IGF1R KO mice indicated that the deletion of IGF1R in cartilage could extended the process of chondrocytes maturation from the resting phase to the terminal differentiation, and lead to delayed ossification, eventually reduced new bone formation. This study revealed that the conditional knockout IGF1R in the chondrocyte exerts impaired fracture healing of mice. It implicated the IGF1R also playing a key roles during the endochondral bone formation of fracture repair process, just like its function in normal bone development.

Developing GFP Reporters for Assessing Lineage Progression Within Articular and Fibroarticular Tissues. Sumit Yadav^{*}, Xi Jiang, Jianping Huang, Peter Maye, Ivo Kalajzic, David Rowe. University of Connecticut Health Center, USA

Mapping the early cellular response to cartilage injury has been difficult to construct because stages of lineage progression are not well defined. We are utilizing GFP reporters that are active in different types of cartilaginous tissues and have found significant differences in expression between fibrocartilage, articular cartilage and growth plate cartilage. While Col2A1 and Col10A1 reporters show activity in the expected cellular locations in the three tissue types, other reporters appear to have unique patterns of expression. A Dkk3-GFP reporter was active in the superficial pre-chondrocytic articular cells of fibrocartilage (temporal mandibular joint, TMJ) and articular cartilage. Also common to both tissues are the synovial lining cells that express lubricin GFP, while deeper cells within the cartilage matrix that are tenascin C GFP positive. Articular cartilage cells of young animals express GDF5-GFP in the groove of Ranvier, and Dlk1-GFP in the superficial cells along the lateral articular surface prior to the more central location of Dkk3 cells. In contrast, TMJ shows reporter expression of osterix, BSP and Col1A1 after Dkk3 activation and prior to the onset of Col2A1 expression. None of these pre-chondrocytic reporters are observed in growth plate chondrocytes. Most striking is the activity of a SMAA-CreERT2 driver, which demonstrates that the mature cells within the fibrocartilage develop from a SMAA progenitor, a lineage that is not observed in articular or growth plate chondrocytes. A pathway of lineage progression of SMAA \rightarrow Dkk3 \rightarrow Col3.6/BSP \rightarrow Col2A1 \rightarrow Col10A1 is observed in all fibrochondrocytic tissues including the TMJ, intervertebral disc and endplate, sternum, multiple tendon/ligament entheses and fracture callus. These reporters have proven useful in developing conditions for maintaining chondrocyte differentiation in primary culture, particularly under low oxygen culture conditions, and for isolating subpopulations of cells either directly from articular surfaces or primary culture for microarray characterization based on their GFP expression. As more molecular and cellular detail is assembled to validate the meaning of these reporters within the context of cartilage biology, a better

understanding of the signals that control lineage progression will emerge, and reporter mice can be assembled to better map the consequence of injury, repair or degeneration to articular and fibrocartilagenous tissues.

Essential Role of the Runx2-Cbf- β Transcription Complex for Endochondral Bone Formation. Kyung-eun Lim¹, Jung-eun Kim², Ichiro Taniuchi³, Na-rae Park^{*1}, Suk-Chul Bae⁴, Je-Yong Choi⁵. ¹Department of Biochemistry & Cell Biology, Skeletal Diseases Genome Research Center, School of Medicine, WCU Program, Cell & Matrix Research Institute, Kyungpook National University, South Korea, ²Depat. of Molecular Medicine, Kyungpook National University School of Medicine, South Korea, ³Laboratory for Transcriptional Regulation, RIKEN Research Center for Allergy & Immunology, Japan, ⁴Department of Biochemistry, School of Medicine, Institute for Tumor Research, Chungbuk National University, South Korea, ⁵Kyungpook National University, School of Medicine, South Korea

Endochondral bone formation requires expression of Runx2 in prehypertrophic and hypertrophic chondrocytes. Core binding factor- β (Cbf- β) is a partner protein of Runx family transcription factor. Here, we showed that chondrocyte-specific deficiency of Cbf- β inhibited endochondral bone formation. Cbf- β /fl mice died immediately after birth. However, Cbf- β /+ mice showed no difference in longevity and skeletal tissues compared with wild type mice. From embryonic days 15.5 (E15.5) to birth, Cbf- β /fl mice showed delayed chondrocyte maturation and decreased Runx2 expression in chondrocytes compared with wild type. Besides, Runx2 protein levels from primary chondrocyte (E15.5), mouse embryonic fibroblast (E12.5), and mesenchymal cell (E11.5) in Cbf- β /fl mice were dramatically reduced without change of its mRNA levels. These findings indicate that Cbf- β is essential for Runx2 mediated endochondral bone formation by regulating Runx2 protein stability.

Expression of Ift88, a Cilia Component Gene, is Under Temporal Regulation Along with the Differentiation of Chondrocytic Cell Line ATDC5. Makiri Kawasaki^{*1}, Tetsuya Nakamoto¹, Takuya Notomi², Tadayoshi Hayata³, Yoichi Ezura⁴, Masaki Noda¹. ¹Tokyo Medical & Dental University, Japan, ²GCOE, Tokyo Medical & Dental University, Japan, ³Medical Research Institute, Tokyo Medical & Dental University, Japan, ⁴Tokyo Medical & Dental University, Medical Research Institute, Japan

Primary cilium, a non-motile, microtubule-based structure which protrudes from the cell surface, is observed in most of the eukaryotic cells. Now it is revealing that this organelle has a role as a mechanosensor and it is involved in multiple signaling pathways, however the function of primary cilia in chondrocytes is scarcely known. Intraflagellar transport (IFT) is required for the cilia assembly and Ift88/Tg737 is one of the IFT particles moving anterogradely along the cilium. It has been shown that the deletion of Ift88/Tg737 causes loss of cilia. In this research, we examined whether or not Ift88 is expressed in the mouse chondrocytic cell line ATDC5 and its expression is regulated along with the differentiation of ATDC5. After 10 days in culture, ATDC5 cells started to form nodules and expressed chondrocyte specific extracellular matrix. During this period, Ift88 expression was dramatically increased four-fold compared to day 7 of culture. The Ift 88 expression peaked on day 14 and the level of its expression was maintained up to day 17. This expression pattern of Ift88 was corresponding to that of type 2 collagen. In the meanwhile, Runx2 and OSX expression were also increased on day 10 three-fold and two-fold, respectively. However these two genes showed a decreasing tendency in expression after day 14 of culture. These results indicate that Ift88 expression is regulated along with chondrocyte differentiation.

MO0089

Neurofibromin Is Required for Normal Endochondral Ossification. Koichiro Ono^{*1}, Weixi Wang², Jean Ndong³, Heather Eleanor³, Xiangli Yang², Florent Elefteriou². ¹Center for Bone Biology, USA, ²Vanderbilt University, USA, ³Vanderbilt University Medical Center, USA

Most genetically linked human skeletal abnormalities are caused by dysregulation of endochondral ossification. Studies of achondroplasia have focused on FGFR3 signal transduction pathways, including signaling through STAT1 and ERK. Mutations in Nf1, the gene encoding the RAS GTPase protein neurofibromin, cause constitutive ERK activation. Neurofibromin is expressed by pre-hypertrophic and hypertrophic chondrocytes, as determined by immunohistochemical analysis. Based on these observations, we hypothesized that proper regulation of endochondral

ossification may require neurofibromin. To address the role of Nf1 in this process, we generated Nf1 conditional knockout mice lacking Nf1 in chondrocytes, using the mouse type2 collagen promoter-cre mice (Nf1col2^{-/-} mice). Histological analyses showed that although growth plate develops normally till E15.5, the hypertrophic zone in Nf1col2^{-/-} mice become progressively shorter than WT littermates afterwards. Nf1col2^{-/-} mice are born with a normal body but their growth is impaired postnatally, leading to a 50% size reduction by 5 weeks of age. This growth phenotype starts to develop when primary ossification centers appear, leading us to hypothesize that lack of Nf1 in chondrocytes mainly impairs the formation of primary ossification centers rather than chondrocyte proliferation or differentiation. To support this notion, in vivo BrdU incorporation and in situ hybridization assays did not reveal significant changes in chondrocyte proliferation or expression of Indian hedgehog (Ihh), a critical determinant of chondrocyte proliferation in the growth plate of Nf1col2^{-/-} pups. In addition, blood vessel invasion of primary ossification centers was not affected by lack of Nf1. On the other hand, qPCR analyses using both chondrocyte micromass cultures and growth plate cartilage from WT and Nf1col2^{-/-} mice showed a significant increase in Opn and Rankl expression in mutant chondrocytes, suggesting that Nf1 inhibits early osteoclastogenesis. Supporting this data, TRAP staining indicated that osteoclast number at the osteochondral border in Nf1col2^{-/-} newborns was significantly increased. In addition, WT splenocytes plated on primary chondrocytes from Nf1col2^{-/-} mice formed more osteoclasts than WT splenocytes plated on WT chondrocytes. These results collectively indicate that neurofibromin function in chondrocyte is required for proper longitudinal growth and inhibits osteoclast differentiation at the osteochondral border.

Sirt6 Regulates Chondrocyte Proliferation and Differentiation during Endochondral Ossification. Jinying Piao^{*1}, Hiroki Ochi², Kunikazu Tsuji³, Daisuke Koga⁴, Atsushi Okawa⁴, Sadao Morita¹, Shu Takeda², Yoshinori Asou⁴. ¹Department of Rehabilitation Medicine, Graduate School, Tokyo Medical & Dental University, Japan, ²Section of Nephrology, Endocrinology & Metabolism, Department of Internal Medicine, School of Medicine, Keio University, Japan, ³Section of Orthopedic Surgery, Division of Bio-Matrix, Graduate School, Tokyo Medical & Dental University, Japan, ⁴Department of Orthopaedics Surgery, Tokyo Medical & Dental University, Japan

Members of the sirtuin (SIRT) family of NAD-dependent deacetylases promote longevity in multiple organisms. Deficiency of mammalian Sirt6 leads to growth retardation, shortened life span (die around p24) and an aging-like phenotype in mice. SIRT6^{-/-} mice fail to thrive and exhibit osteopenia, with 30% reduction in bone mineral density and lordokyphosis at 3.5 weeks of age. However, the roles of Sirt6 in bone and cartilage metabolism are unclear. The aim of this study is to investigate the Sirt6 signal pathway in the maintenance of cartilage. For this purpose, histological evaluation was performed in Sirt6^{-/-} mice and WT littermates. Sirt6 was expressed in articular chondrocyte and growth plate chondrocyte. At birth, the length of tibiae and femur was 10-20% shorter in Sirt6^{-/-} compared to wild-type littermates. In the growth plate (GP), PCNA expression was reduced in Sirt6^{-/-} mice. The number of TUNEL positive cells was comparative between Sirt6^{-/-} and littermate at this stage. At two weeks after birth, growth retardation was apparent in Sirt6^{-/-}, with reduced proliferating zone in GP, delayed formation of secondary ossification center and decreased primary spongiosa. Col2 mRNA expression was reduced in Sirt6^{-/-} primary chondrocyte, indicating chondrocyte differentiation was retarded by Sirt6 deficiency. Sirt6^{-/-} mice is reported to exhibit severe metabolic defects with precipitous drops in serum glucose and IGF-1 levels. Thus, to evaluate the involvement of exogenous glucose and IGF-1 in the prevention of chondrocyte differentiation, Sirt6 was knocked-down by siRNA in primary chondrocyte and chondrocyte-like cell line ATDC5. Real time PCR analysis revealed the expression of chondrocyte marker genes, including Col2, Col10 and aggrecan, were reduced in vitro. Interestingly, autologous IGF-1 expression in chondrocyte was not affected by Sirt6 deficiency. Our data indicate that Sirt6 controls cell growth and differentiation in embryonic and postnatal chondrocytes.

TGF- β -induced SnoN Prevents BMP Signaling and Hypertrophic Conversion of Chondrocytes. Ichiro Kawamura^{*}, Yasuhiro Ishidou, Katsuyuki Imamura, Masahiro Yokouchi, Seturo Komiya, Shingo Maeda. Graduate School of Medical & Dental Sciences, Kagoshima University, Japan

(Objective)

Loss of TGF- β signaling in mice leads to the promoted hypertrophic differentiation of articular chondrocytes, which process is suggested to be an important step in progression of osteoarthritis (OA). However, the molecular mechanisms of which TGF- β inhibits chondrocyte maturation remain unclear. We screened for target genes downstream of TGF- β signaling to inhibit chondrocyte hypertrophy.

(Methods)

To assess the impact of endogenous TGF- β signaling in chondrocyte maturation, we treated ATDC5 cells with a TGF- β type I receptor inhibitor compound SB431542, and induced differentiation with BMP-2. Maturation of chondrocytes was evaluated by real-time reverse transcription polymerase chain reaction (RT-PCR) and ALP staining. The function of the purified gene was studied by stable overexpression and siRNA-knockdown approaches.

(Results)

BMP-induced expression of Col10a1 gene, a specific marker for hypertrophic chondrocytes, was further up-regulated dramatically, upon treatment with SB431542. Although the phosphorylation (activated status) of BMP-Smads-1/5/8 was not influenced by SB431542 application, expression of Id1 gene, the direct target of BMP Smads, was enhanced by SB431542. Thus, BMP signaling seemed to be inhibited by TGF- β signaling at the level beneath the phosphorylation process of BMP-Smads. We studied expression profile of candidates for BMP signal-inhibitors, and found that SnoN was the only gene which expression was induced upon TGF- β treatment, while was inhibited by SB431542 application. Importantly, knock down of SnoN resulted in enhanced maturation of ATDC5, and overexpression of SnoN suppressed it. Finally, the immunohistochemistry revealed that the expression of SnoN was positive only in prehypertrophic zone of mouse growth plate. In human OA cartilage, SnoN was detected around degenerated hypertrophic chondrocytes of moderate OA cartilages. However, SnoN was absent in severe-grade OA cartilages.

(Conclusion)

Our results suggest that SnoN suppresses hypertrophic transition of chondrocytes, as an effector of TGF- β signaling, to prevent the progression of OA.

The Critical Role of the Epidermal Growth Factor Receptor in Endochondral Ossification. Xianrong Zhang^{*1}, Valerie Siclari², Shenghui Lan³, Ji Zhu¹, Frank Beier⁴, Ling Qin². ¹University of Pennsylvania, School of Medicine, USA, ²University of Pennsylvania, USA, ³Union Hospital, Tongji Medical College, Huazhong University of Science & Technology, China, ⁴University of Western Ontario, Canada

Loss of epidermal growth factor receptor (EGFR) activity in mice alters growth plate development, impairs endochondral ossification, and retards growth. However, the detailed mechanism by which EGFR regulates endochondral bone formation is unknown. Here, we used an EGFR-specific small molecule inhibitor, gefitinib, in a rat model to study long bone growth. Administration of this inhibitor into 1-month-old rats by oral gavage for 7 days produced profound defects in long bone growth plate cartilage characterized by epiphyseal growth plate thickening, massive accumulation of hypertrophic chondrocytes, and decreased hypertrophic cartilage mineralization. Immunostaining demonstrated that growth plate chondrocytes express EGFR but endothelial cells and osteoclasts have low to no expression. BrdU labeling and mRNA expression analysis of chondrocyte differentiation markers revealed that gefitinib did not alter chondrocyte proliferation or differentiation in the growth plate. H&E staining did not identify any overt difference in the number, location, orientation, or morphology of blood vessels underneath the growth plate in gefitinib-treated rats. However, we observed a 50% decrease in the number of TRAP+ cells at the chondro-osseous junction, but not in the primary spongiosa, in gefitinib-treated rats. This decrease in osteoclast number was due to attenuated RANKL expression in the growth plate. Moreover, gefitinib treatment inhibited the expression of matrix metalloproteinases (MMP9 and 13), increased the amount of collagen fibrils, and decreased degraded extracellular matrix products in the growth plate. In vitro, TGF α , an EGFR ligand, strongly stimulated RANKL, MMP9 and MMP13 expression and suppressed OPG expression in primary chondrocytes. Furthermore, chondrocyte-specific EGFR-deficient mice exhibited a similar phenotype as gefitinib-treated rats with enlarged hypertrophic zones in the growth plate, indicating that chondrogenic EGFR expression is responsible for normal growth plate development. Together, our data demonstrate that EGFR signaling supports osteoclastogenesis at the chondro-osseous junction and promotes chondrogenic expression of MMPs in the growth plate. Therefore, we conclude that EGFR signaling plays an essential role in the remodeling of growth plate cartilage extracellular matrix into bone during endochondral ossification.

The Differentiation Capacity of the Mesenchymal Stem Cells into Intervertebral Disc Under the Hypoxia Condition. Hwan-Mo Lee¹, Seong-Hwang Moon², Young-Mi Kang^{*1}. ¹Yonsei university, South Korea, ²Yonsei University College of Medicine, South Korea

INTRODUCTION

Human mesenchymal stem cells (hMSCs) from the bone marrow represent a potential source of pluripotent cells for autogenous bone tissue engineering. Aggrecan is since this major extracellular matrix which permits the intervertebral disc (IVD) to withstand compressive loads. GLUT-1 expression is also stimulated in a variety of cells under hypoxic condition, a response that is mediated by the transcription factor HIF-1 α . Among various phenotypes, HIF-1 α and glucose transporter-1 (GLUT-1)

proved to be phenotypical signature of nucleus pulposus. Therefore, the objective of this study is to evaluate possibility that hMSCs induce the IVD in hypoxia condition.

MATERIALS AND METHODS

Human bone marrows were collected during surgery from patients (age range 45-67 years) with lumbar spinal stenosis. hMSCs were purified by density gradient centrifugation in Ficoll/Hypaque and maintained in the condition medium until one passage. The hMSCs were seeded in collagen type I sponge at a cell density of 5×10^5 cell per each one for protein and RNA isolation in hypoxia condition (1% O₂, 5% CO₂, 37 °C) and normal condition (5% CO₂, 37 °C) for three days. Human disc cells were used as a control. For expression of HIF-1 α and GLUT-1 at the mRNA and protein level, RT-PCR and western blot were performed according to the manufacturing protocol.

RESULTS AND DISCUSSION

The expression of aggrecan mRNA was increased in hypoxia condition as comparing with normal condition. Also the expression of GLUT-1 mRNA on the MSCs is higher than on the disc cells. Hypoxic condition on the MSCs rendered increase in aggrecan and GLUT-1 mRNA expression, which also provide phenotypical stabilization under the hypoxic condition. Furthermore, expression of GLUT at protein level was increased comparing with others. Glucose is needed both for glycolytic metabolism and the synthesis of glycoproteins and glycosaminoglycans. The uptake of glucose by disc cells is a fundamental process that has been neglected in most studies of IVD metabolism. Our study suggests that the MSCs can be differentiated into IVD although further work is required to confirm this observation.

Understanding the Mechanisms of Radius and Ulna Deformation in Neonatal Chk β Mutant Mice. Zhuo (Bill) Li^{*}. University of Alberta, Canada

Choline kinase (CK) has two isoforms: Chk α and Chk β . CK is the first enzyme in Kennedy pathway to make phosphatidylcholine and it converts choline to phosphocholine. Inactivation of Chk α in mice results in embryonic lethality, whereas Chk β mutant mice display hindlimb muscular dystrophy and neonatal forelimb bone deformation. Previous study has been demonstrated that impaired phosphatidylcholine biosynthesis contributes to hindlimb muscular dystrophy phenotype, but the mechanisms for neonatal forelimb bone deformation are still unknown. To understand the mechanisms of bone deformation phenotype, we characterized the major long bones of forelimb and hindlimb both at embryonic and neonatal stages by various histology techniques. We found that the deformation is only specific to radius and ulna. While humerus and femur in mutant mice still maintain relative normal growth plate structure, radius, ulna and tibia have bone developmental and growth plate defect. In details, at embryonic stage, we found that in mutant mice radius, ulna and tibia have delayed formation of primary ossification center, which is accompanied by premature chondrocyte hypertrophy leading to increased hypertrophic zone and decreased proliferation zone. In addition, we also found that in mutant mice radius and ulna display unorganized proliferative columns and abnormal cell morphology at distal end of growth plate but tibia doesn't. At neonatal stage, radius and ulna in mutant mice are much shorter and totally lose the proliferation zone at the distal end growth plate and they still suffer from enlarged hypertrophic zone and decreased proliferation zone at proximal end. In mutant mice tibia at neonatal stage is also much shorter and continues to show increased hypertrophic zone and reduced proliferation zone at both proximal and distal ends of the growth plate, but it maintains relative good growth plate structure and normal cell morphology at both ends. In conclusion, our study shows that (1) Chk β deficiency affects the development of distal limb long bones including radius, ulna and tibia (2) that the cartilage and growth plate defect observed in mutant mice radius and ulna could be the main cause for their structure deformation (3) and that the less severe growth plate defect observed in mutant mice tibia compared to radius and ulna may explain why deformation only occurs in radius and ulna but not tibia.

Annexin a5 Expression Regulates Periodontal Tissue and Cementum Formation. Akemi Shimada^{*1}, Koichiro Komatsu¹, Kazuhisa Nakashima¹, Norio Amizuka², Bent Brachvogel³, Akira Nifuji¹.
¹Tsurumi University School of Dental Medicine, Japan, ²Hokkaido University School of Dentistry, Japan, ³Universitat Zu Koln, Germany

Objectives: Periodontal ligament connects tooth cementum and alveolar bone to maintain and support teeth in situ and preserve tissue homeostasis. The progenitor cells for periodontal tissues and their molecular markers have not yet been identified. Pericytes have been suggested to be progenitor cells for periodontal tissues and one molecule that is specifically expressed in the pericytes is annexin A5 (Anxa5). In this study, we examined whether Anxa5 is expressed in progenitor cells in periodontal tissues and functions in their homeostasis by using anxa5 knockout /LacZ knock-in mice.

Methods: We used Anxa5 knockout /LacZ knock-in mice which contain a LacZ (β -galactosidase) reporter gene fused in-frame with the Anxa5 gene. The maxillae dissected from the Anxa5-LacZ^{+/+}, Anxa5-LacZ^{+/-}, and Anxa5-LacZ^{-/-} mice at 1, 4, 7, and 8 weeks of age were fixed and subjected to LacZ histochemistry and immunohistochemistry using anti-annexin A5 antibody. The morphology of the first molar and its periodontal tissues were analyzed by micro computed tomography (micro CT) and histology.

Results: At the 1 week old of age, LacZ gene expression was detected around the area forming tooth roots. After tooth eruption at 4 to 8 weeks of age, LacZ gene expression was detected in all over the periodontal ligament, specifically intensive in the periodontal ligament around the root apices and cervical areas. Intensive LacZ gene expression was also observed in the cementoblast at the root apices, periosteal cells of the alveolar bone, and putative pericytes around the blood vessels in the periodontal ligament. Immunohistochemistry using anti-annexin A5 antibody showed consistent results with LacZ histochemistry. The histological and micro CT analyses showed that smaller amount of cementum formation at the mesial root apex was observed in the Anxa5^{-/-} mice than in the wild mice. In addition, the width of periodontal ligament of Anxa5^{-/-} mice was significantly narrower than that of wild mice ($p < 0.001$).

Conclusion: These results suggest that Anxa5 is expressed in the periodontal tissue cells including pericytes and functions for periodontal tissues and cementum formation.

Novel Genes Critical for Bone Formation. Yunxia (Yesha) Lundberg^{*1}, Mohammed Akhter², Liping Yang¹, Hui Zhang¹, Hua Yang¹, Xing Zhao¹, Yinfang Xu¹, Yan Zhang¹. ¹Boys Town National Research Hospital, USA, ²Creighton University, USA

We have identified novel genes (identity to be revealed at the ASBMR meeting due to possible patent application) that critically affect bone formation. Examination of respective knockout and functional null mutant mice for these genes shows morphological and histological abnormalities in bone. Detailed micro-CT analyses of trabecular bone at the distal femur have been done using 16 μ m scan resolution (1.5 mm region of interest proximal to the growth plate). Compared to that in wildtype mice (n=11), trabecular bone in mutant mice (n=9-10) show significant reductions in many parameters including apparent volumetric mineral density (App-vBMD), bone connectivity/density (ConD), bone volume over total volume (BV/TV), and trabecular bone number (TrabN), with a concomitant increase in trabecular spacing (TrabSp). Preliminary histological and molecular studies suggest that the bone abnormalities likely arise from altered numbers of osteoblasts and osteoclasts, and that these genes may function through inter-linking and overlapping mechanisms.

Disclosures: Yunxia (Yesha) Lundberg, None.

Pax9, a Transcription Factor That Is Expressed in Ligament Cells Derived From Ligamentum Flavum of Patients with Lumbar Spinal Canal Stenosis. Ken Watanabe^{*}, Yoshihito Sakai, Shumpei Niida, Atsushi Harada. National Center for Geriatrics & Gerontology, Japan

Lumbar spinal canal stenosis, a condition that spinal canal narrows causing compression of the nerves, is seen more in and reduces activity of daily living of elderly. Although the etiology has not been clarified yet, it has been suggested that the stenosis is caused by congenital narrow canal and acquired hypertrophy of ligamentum flavum. Molecular and cellular mechanism underlying hypertrophy of ligamentum flavum is not yet to be elucidated. To determine the molecular basis of ligamentum flavum cells, gene expression profiling was performed. The primary ligament (LF) cells were prepared from the ligament flavum removed from the surgery of the patients by collagenase treatment. For the control, human osteoblasts (hOST), mesenchymal stem cells (hMSC), and skin fibroblasts (MJ90) were used. RNA was

isolated from the cells from 3 patients diagnosed as lumbar spinal canal stenosis, as well as the control cells, and the gene expression was analyzed by microarray technique. Scleraxis (SCX) and Mohawk (MKX), genes known to be expressed in ligaments and tendons, were extracted as genes encoding transcription factors predominantly expressed in the LF cells. In addition to these genes, PAX9, ME0X2, and TP63 were identified. To determine the function of the transcription factors, the genes were introduced in 10T1/2. Whereas mock-transfected 10T1/2 cells deposited lipid droplets in the 2 wk culture, the deposition was significantly suppressed in MKX-, ME0X2-, PAX9-, and ETV4-transfected cells. The cell accumulation was observed in the PAX9-transfected cells, suggesting that the proliferation was upregulated. This observation was supported by BrdU incorporation assay. Since HDAC9 was extracted as a gene expressed in LF cells, the expression of Hdac9 was determined in the transfected cells. Hdac9 was specifically upregulated in PAX9-transfected cells but not in others. HDAC9 encodes a type II histone deacetylase and its activity was inhibited by HDAC inhibitors, such as sodium butyrate (SB) and Trichostatin A (TSA). TSA, as well as SB, significantly reduced the proliferation both of the cells in a dose-dependent manner. Thus, PAX9-induced proliferation may be mediated by upregulation of HDAC activity at least in part. Since, in some cases, ligament cells were focally accumulated in hypertrophied ligamentum flavum in the patients, the PAX9-HDAC9 pathway may be participated in the hypertrophy of ligamentum flavum.

Phenotypic Analysis of Transgenic Mice Overexpressing Mx1 in Oral Bones. Ibtisam Senussi^{*1}, Ariane Berald², Sylvie Babajko³. ¹Inserm U872, France, ²University Paris-Diderot, France, ³INSERM, France

Homeobox gene Mx1 encodes for a transcription factor widely expressed during embryogenesis and postnatal development involved in epithelio-mesenchymal interactions. Thus, Mx1 is particularly important in limb and tooth development, and could control progenitor cells and terminal differentiation of mineralized tissue forming cells like osteoblasts and odontoblasts. Mutations in this gene in humans are associated to cleft palate and/or tooth agenesis. Similar phenotype is observed in mice presenting an invalidation of Mx1 gene. As null mutant mice died at birth, it is difficult to study the role of Mx1 in vivo. Thus, we decided to generate a transgenic mouse line with Mx1 expression targeted in mineral matrix secreting cells by 2.3 Kb collagen 1 alpha 1 promoter.

Histological analysis of the mandibles at one day after birth showed an accumulation of bone in Mx1 transgenic (Mx1 Tg) mice compared to wild types. The greatest differences were observed in bone surrounding the incisor and the molars. Osteoblast and osteoclast metabolism was analyzed by TRAP (tartrate-resistant acid phosphatase) activity and collagen 1 alpha 1 ISH (in situ hybridization) respectively. Both of them showed an increased number of labelled cells in Mx1 Tg mice reflecting active bone remodeling.

Analysis of caspase-3 expression associated to apoptosis was carried out by IHC (Immunohistochemistry) using a specific antibody directed against caspase-3. Our results showed stronger staining and ten times more caspase-3 expressing osteoblasts in transgenic mice compared to wild-type mice. This could explain the fact that it was not possible to evidence Mx1 over-expression by RT-Q-PCR.

These results are in accordance with Mx1 function that probably increases the pool of progenitor cells. In addition, increased Mx1 expression is associated with high bone remodeling.

These results could be interesting for gene or cell therapy for bone reconstruction using Mx1

MO0099

Skeletal Phenotyping of Chibby Knockout Mice. David Komatsu^{*1}, Joshua J. Hinkle², Mohanlall Narine², Feng-Qian Li³, Ken-Ichi Takemaru³, Michael Hadjiargyrou⁴. ¹Stony Brook University, Dept. of Orthopaedics, USA, ²Stony Brook University, Dept. of Biomedical Engineering, USA, ³Stony Brook University, Dept. of Pharmacology, USA, ⁴State University of New York at Stony Brook, USA

Chibby (Cby) is a highly conserved 14 kDa protein that both antagonizes canonical Wnt/ β -catenin signaling and facilitates the formation of motile and primary cilia. Mice with global Cby deletion (Cby^{-/-}) are undistinguishable from wild-type (Cby^{+/+}) littermates at birth, but by post-natal day (P) 14 develop anemia, reductions in subcutaneous fat, and runting. By P25 the majority of Cby^{-/-} mice die, for unknown reasons, and survivors develop chronic sinusitis and remain runted. This study examined the skeletal phenotype of a cohort of Cby^{-/-} mice that survived into adulthood (N=5) and were sacrificed at 3 months, and compared these mice to a group of age-matched Cby^{+/+} controls (N=5). MicroCT analyses revealed that Cby^{-/-} femurs were 16% shorter than those from Cby^{+/+} mice. Consistent with reduced length, cortical and periosteal areas were reduced by 33 and 21% in Cby^{-/-} mice, respectively. Similarly, Cby^{-/-} mice had reductions of 61% in bone volume (BV), 23% in total volume (TV), 49% in BV/TV, 17% in trabecular thickness, and 38% in connectivity density, concomitant with a 23% increase in trabecular spacing. H&E staining revealed thinner cortices, fewer trabeculae, and smaller growth plates in

Cby^{-/-} tibiae, as well as a reduction in the number of hypertrophic chondrocytes. IHC staining of Cby^{+/+} tibiae with Cby antibodies showed positive staining of osteocytes within the cortices, and lower intensity diffuse staining within the growth plates that could not be resolved to specific cell types. Quantitative RT-PCR analysis of osteocalcin (OC) showed it to be up-regulated ~3-fold in Cby^{-/-} samples. Given the smaller size of Cby^{-/-} mice, the findings of shorter femora with thinner cortices and less trabecular bone were fully expected. However, while histological observations of smaller tibiae in Cby^{-/-} mice are consistent with smaller bones, the reduction in hypertrophic chondrocytes suggests that Cby may also have direct effects on skeletal development. The increase in OC expression in Cby^{-/-} mice provides further evidence that Cby directly affects the skeleton. As OC expression is down-regulated by Wnt signaling, these data are consistent with the function of Cby as a Wnt antagonist, but difficult to reconcile with the low bone mass phenotype of these mice. In order to clarify these issues, we are in the process of analyzing newborn Cby^{-/-} mice, as well as adult Cby^{+/+} mice, which are not runted. The further characterization of these mice is expected to provide new insights into the role of not only Wnt signaling, but also the role of cilia in skeletal development and homeostasis.

Trps1 Plays Distinct Roles in the Development and Function of Mineralizing Tissues. Dobrawa Napierala^{*1}, Brian Dawson², Terry Bertin³, Chad Shaw³, Anne Poliard⁴, Odile Kellerman⁵, Brendan Lee⁶. ¹University of Alabama at Birmingham School of Dentistry, USA, ²Baylor College of Medicine, Howard Hughes Medical Institute, USA, ³Baylor College of Medicine, USA, ⁴Faculte de Chirurgie Dentaire, et UMR-S 747, Universite Paris Descartes, France, ⁵INSERM, Universite Rene Descartes, France, ⁶Baylor College of Medicine & Howard Hughes Medical Institute, USA

The transcription factor Trps1 is highly expressed in developing cells destined to produce mineralizing matrix. Interestingly, the onset of mineralization coincides with diminished Trps1 expression, which suggests that Trps1 is involved in maturation of these cells, but may negatively affect the function of mature cells. Previously we have demonstrated that deficiency of Trps1 in mice results in advanced mineralization of perichondrium due to insufficient repression of the Runx2 transcription factor. Our recent studies of Trps1 transgenic mice specifically expressing Trps1 in osteoblasts and odontoblasts revealed severe impairment of dentin mineralization. Thus the *in vivo* data suggest that Trps1 acts as a repressor of mineralization. To understand the role of Trps1 in differentiation and function of cells producing mineralized matrix, and to identify genes regulated by Trps1 in these cells we used the 17H1A11 preodontoblastic cell line, a cellular model of mineralization. We generated both Trps1-deficient and Trps1-overexpressing 17H1A11 cell lines. Effects of Trps1 on the mineralization of the generated cell lines were evaluated by alkaline phosphatase, von Kossa and alizarin red staining. As predicted, based on our previous *in vivo* data, delayed mineralization of Trps1-overexpressing cells was observed when compared to control cells. Interestingly, 17H1A11 Trps1-deficient cells lose their characteristic alkaline phosphatase activity and ability to mineralize. Global gene expression studies using the Affimetrix Mouse Exon 1.0 ST Array were performed to identify genes regulated by Trps1 in 17H1A11 cells. These analyses identified genes involved in several signaling pathways as well as components of the extracellular matrix. Genes with a previously demonstrated function in mineralization were also identified. In conclusion, our studies demonstrate that while Trps1 represses mineralization, it is required for the terminal differentiation of cells destined to produce mineralizing matrix, and it executes this function by regulating genes involved in mineralization.

Absence of P2X7 Nucleotide Receptors Leads to Abnormal Fat Distribution in Mice. Kim Beaucage^{*}, Andrew Xiao, Matthew Grol, David Holdsworth, Stephen Sims, Mark Darling, S. Jeffrey Dixon. The University of Western Ontario, Canada

Extracellular nucleotides such as ATP signal through two subfamilies of P2 nucleotide receptors – P2Y (G protein-coupled receptors) and P2X (ATP-gated nonselective cation channels) – in many cell types. The P2X7 receptor is expressed by both osteoblasts and osteoclasts. In this regard, mice lacking P2X7 exhibit reduced bone formation and excessive bone resorption. We have shown previously that deletion of the P2X7 receptor results in downregulation of osteogenic markers and upregulation of adipogenic markers in calvarial cell cultures, indicating that P2X7 may regulate bone and fat lineage determination from a common mesenchymal progenitor. Given these effects of P2X7, our purpose was to assess whether the skeletal changes observed in mice lacking this receptor are associated with altered adipose tissue distribution and lipid accumulation *in vivo*. Two, 6, 9 and 12-month-old, male wild-type (WT; P2rx7^{+/+}) and P2X7 knockout (KO; P2rx7^{-/-}) mice (n=10) were fasted for 6 hours, sacrificed and weighed. Blood samples were obtained by cardiac puncture. Selected tissues were weighed and prepared for histological analyses. KO mice exhibited a significantly greater overall body weight than WT at 9 months of age. In this regard, epididymal fat pad weight in KO mice was also significantly greater at 9 months, consistent with a role for P2X7 in regulation of metabolism and adipose tissue development. Morphometric analysis revealed no

significant difference in the size of epididymal fat pad cells, consistent with adipocyte hyperplasia rather than hypertrophy. Histological examination revealed increased accumulation of lipid droplets and/or increased numbers of adipocytes in several tissues in 9 and 12-month-old KO mice, including kidneys and several exocrine glands, but not liver, heart or skeletal muscle. Specifically, extraorbital lacrimal glands and pancreas from KO mice exhibited a greater number of adipocytes in perivascular, periductal and acinar regions. Lipid accumulations were also apparent in the renal tubular epithelium and acini of the submandibular salivary gland. Blood plasma analyses revealed diminished total cholesterol levels and greater triglyceride levels in 9-month-old KO compared to WT mice, reflecting disrupted lipid metabolism. Taken together, these data indicate that P2X7 regulates systemic adipose distribution and metabolism, and are consistent with an inhibitory effect of the P2X7 receptor on fat lineage determination and adipogenesis.

Alkaline pH Increases Phosphate Production by Proteoliposomes Carrying Alkaline Phosphatase and Nucleotide Pyrophosphatase/ Phosphodiesterase-1. Ana Maria Simao^{*1}, Mayte Bolean², Jose Luis Millan³, Marc Hoylaerts⁴, Pietro Ciancaglini². ¹University of Sao Paulo - USP, Brazil, ²FFCLRP-USP, Brazil, ³Sanford-Burnham Medical Research Institute, USA, ⁴Center for Molecular & Vascular Biology, University of Leuven, Belgium

Endochondral calcification is mediated by chondrocyte- and osteoblast-derived matrix vesicles (MVs). The primary function of tissue-nonspecific alkaline phosphatase (TNAP) is to degrade extracellular inorganic pyrophosphate (ePPi), a mineralization inhibitor produced by nucleotide pyrophosphatase/ phosphodiesterase-1 (NPP1), thus restricting the concentration of ePPi to maintain a Pi/PPi ratio permissive for normal bone mineralization. In this study, either TNAP, recombinant NPP1 or both together were reconstituted in dipalmitoylphosphatidylcholine (DPPC) liposomes as previously standardized¹, as an osteoblast-derived MVs biomimetic, and the hydrolysis of ATP, ADP, AMP and PPi by these proteoliposomes was studied at pH 9, by measuring the amount of inorganic phosphate (Pi) liberated as a function of time¹, since it has been shown that the pH may play a regulatory role during the mineralization process. Hydrolyzed ATP and ADP nucleotide intermediates were separated and quantified by HPLC¹. All substrates were hydrolyzed by TNAP, NPP1- and TNAP plus NPP1-containing proteoliposomes. NPP1 plus TNAP additively hydrolyzed the substrates, but TNAP appeared more active in adenosine formation than NPP1. Cooperative effects were observed for all substrates studied and the catalytic efficiencies were higher for TNAP-containing proteoliposomes. Affinity constants were lower for NPP1-containing proteoliposomes, except for ADP. Also, at pH 9, catalytic efficiencies were higher for ATP and PPi hydrolysis when compared with physiologic pH1, for both TNAP- and NPP1-proteoliposomes. Therefore, the reconstitution of TNAP and NPP1 into proteoliposome membranes generates a phospholipid microenvironment that enables the complementary hydrolysis of natural phospho-substrates and their intermediates at pH 9, leading to very efficient phosphate accumulation in the immediate microenvironment of the phospholipid membrane surface. More detailed studies of those catalytic processes at different pH will allow us to understand the fine regulatory role that changes in pH may play during the mineralization process by modulating both the microenvironment composition and Pi production by the proteins involved in this process.

Bone Regeneration Potential of Polypropylene Fumarate Scaffolds Coated with Osteoconductive Agents. Theresa Hefferan^{*1}, M. Brett Runge¹, Mahrokh Dadsetan¹, James Herrick¹, Donna Jewison¹, Glenda Evans², Viviane Luangphakdy³, Kentaro Shinohara³, Hui Pan³, George Muschler⁴, Michael Yaszemski¹. ¹Mayo Clinic College of Medicine, USA, ²Mayo Clinic, USA, ³Cleveland Clinic, USA, ⁴Cleveland Clinic Foundation, USA

Traumatic injury and surgical resection can result in large segmental bone defects for which there are limited options for reconstruction and bone regeneration. In order to expand the treatment options, our laboratory has developed a biocompatible, biodegradable synthetic bone substitute - polypropylene fumarate (PPF). PPF is a polyester polymer with mechanical properties similar to bone and a slow rate of degradation. The objective of this study was to assess the bone regenerative capacity of PPF scaffolds with an osteoconductive coating in a canine femoral multi-defect model. A Viper Si2 stereolithography system was used to fabricate 3-dimensional porous PPF scaffold cylinders with an overall size of 9.9 mm diameter x 15 mm height. The pores were 1mm x 1mm channels, separated by 500 um walls. To promote bone regeneration, the scaffolds were coated by spray deposition with either hydroxyapatite (HA) or tri-calcium phosphate (TCP). The canine femoral multi-defect model was used to assess bone regeneration and the scaffolds were harvested after 4 weeks. Bone regeneration was assessed by micro-CT scanning and quantitative histology. First, the scaffolds were fixed and scanned using a GE Locus micro-CT scanner at 45 micron resolution and subsequently processed for histology. After embedding the scaffolds in methyl methacrylate, they were sectioned at 5 microns and stained. A modified

Goldner trichrome stain was used to delineate mineralized bone and osteoid formation within the scaffold. The Goldner stained slides were scanned using a NanoZoomer Digital Pathology System (Hamamatsu) and the slides were analyzed using the software package IHC Score (Bacus Labs) to measure bone growth into the implant, cellular matrix, and residual polymer. The results are reported as a percentage of the total area for the residual scaffolds, and as a percentage of the pore area in the scaffold for the bone and cell matrix. After 4 weeks, 58.8% + 6.9% (PPF-HA) and 62.2% + 2.4% (PPF-TCP) of the total area contained scaffold. The scaffold pores were filled with 25.1% + 1% (PPF-HA) and 29.2% + 12.8% (PPF-TCP) bone; and 74.9% + 1% (PPF-HA), 70.8% + 12.8% (PPF-TCP) cellular matrix. New bone was formed along scaffold surfaces, while the scaffold pores in the pericortical region were nearly completely filled with new bone. This short-term study in a large animal model demonstrates the bone regenerative potential for porous PPF scaffolds coated with the osteoconductive agents HA or TCP.

CD59 - A Novel Role in Bone Homeostasis. Anja Bloom¹, Carole Elford¹, Robert J van 't Hof², B Paul Morgan¹, Bronwen AJ Evans¹, Daniel Aeschlimann¹, Anwen S Williams¹. ¹Cardiff University, United Kingdom, ²University of Edinburgh, United Kingdom

The complement (C) system has crucial functions in host defence; regulating the inflammatory response, mammalian development, tissue repair, angiogenesis, liver regeneration and neurone refinement. Novel data by Tu et al. recently described a role for C-components in osteoclastogenesis (OC-genesis). CD59a is a regulator of the terminal C pathway in mice; the purpose of the study was to investigate the importance of CD59a in bone homeostasis. Methodology: Femurs and spines were collected from 8-10 week old wild-type (WT) and CD59a deficient (CD59a^{-/-}) mice. Bone architecture and bone resorption parameters were analysed by μ CT and Aniline blue/TRAP staining respectively (n= 12 per group). For mechanistic studies, bone marrow cells from WT (n=8) and CD59a^{-/-} (n=6) mice were cultured in osteoclast (OC) differentiation medium for 7 days, and the OC stained and counted. The chemokine mKc was quantified in OC assay supernatants by ELISA. Results: In male mice femoral length was increased in CD59a^{-/-} versus WT mice (4%, p<0.05). Cortical bone volume was increased (26%, p<0.01) whilst BMD was reduced (7%, p<0.01) in CD59a^{-/-} versus WT. Trabecular bone analysis of the distal femur showed increased BV/TV (90%, p<0.005), Tb.Th (18%, p<0.005) and Tb.N (57%, p<0.005) in CD59a^{-/-} over WT. In vitro, OC-genesis was increased by 29% (p<0.05) and mKc levels were elevated by 283% (p<0.001) in CD59a^{-/-} over WT. Finally, sections of distal femurs were analysed for OC numbers and resorption surfaces by histomorphometry. OC/BS (77%, p<0.05) and OC.S/BS (71%, p<0.01) were increased in the trabecular bone of CD59a^{-/-} over WT mice. In female mice, there was no difference in femoral length; no histomorphometric changes and no difference in OC-genesis (CD59a^{-/-} versus WT). Conclusions: Changes in bone histomorphometry related to CD59a gene deletion are gender specific. Our study identifies CD59a as a potentially important regulator of OCs which is necessary for maintaining healthy bone in young adult male mice. More studies are necessary to establish whether CD59 is an important homeostatic regulator in bone in humans. Since aberrant CD59 expression has been noted in human arthritic joints, CD59 could also augment adverse bone pathology in diseases such as rheumatoid arthritis and osteoarthritis.

Dental Pulp Cells Exhibit High Performance as a Biomaterial for Bone Formation Through Expression of Annexin A8. Yuko Nakamichi¹, Takahiro Hagihara¹, Midori Nakamura¹, Asayo Imaoka², Yoshimitsu Abiko², Hiroshi Nakamura¹, Naoyuki Takahashi¹, Nobuyuki Udagawa¹. ¹Matsumoto Dental University, Japan, ²Nihon University, Japan

Dental pulp cells are considered to be a promising tool for the regeneration of hard tissues, due to their multipotency. The goal of the present study is to establish a simple method of regenerating hard tissues using dental pulp cells. Toward this end, we characterized dental pulp cells in comparison with osteoblasts and explored the mechanisms of calcification. The survival of cultured dental pulp cells completely depended on cell density. The densely cultured dental pulp cells exhibited 60-times stronger ALP activity than osteoblasts. Dental pulp cells remarkably induced extracellular matrix (ECM) calcification even in the absence of exogenous BMP-2, or in the presence of a pan-BMP antagonist, Noggin. On the other hand, ECM calcification in osteoblast culture was completely suppressed by the addition of Noggin. A Genechip analysis showed the overall gene expression in dental pulp cells to be similar to that in osteoblasts, though dental pulp cells expressed higher levels of BMPs, annexin A8 (a Ca channel), and solute carrier protein 20a2 (Slc20a2) (a Pi transporter) than osteoblasts. Furthermore, dental pulp cells exhibited extremely lower expression levels of ectonucleotide phosphodiesterase/pyrophosphatase-1 (ENPP-1) and matrix Gla protein (MGP), calcification inhibitors. These results may explain why ECM calcification in dental pulp cell culture was not suppressed by the pan-BMP antagonist Noggin. Overexpression of either annexin A8 or Slc20a2 in osteoblasts induced ECM calcification even in the absence of exogenous BMPs. Especially, the effect of annexin A8 was dominant. In contrast, knockdown of either

annexin A8 or Slc20a2 using siRNAs suppressed ECM calcification in dental pulp cell culture. Finally, we examined the ability of the cultured dental pulp cells to form hard tissues. We transplanted three-dimensional culture of dental pulp cells with denatured type I collagen sponges (GelfoamTM) and semi-solid type I collagen (Cellmatrix Type I-ATM) into immunocompromised mice. At 8 weeks after transplantation, the grafts generated bone in which hematopoiesis was carried out. Taken together, these results suggest that transplanted dental pulp cells exert bone regenerative activity through the expression of annexin A8.

Effect of AMD3100 on MSC Mobilization and Bone Regeneration in the Mouse. Margaret McNulty^{*}, Kent W. Christopherson, Robin R. Frank, Amarjit Viridi, D. Rick Sumner. Rush University Medical Center, USA

Enhancement of intramembranous bone repair is likely to improve the long-term success of distraction osteogenesis, joint replacement, and rigid fracture fixation. Mobilized adult stem cells have great potential for regenerative medicine and represent an important strategy for enhancing bone repair. Stem cells can be mobilized from the bone marrow to the peripheral blood using drugs that affect the CXCR4/SDF-1 axis, including AMD3100, a direct antagonist of CXCR4. The purpose of this study was to examine the effect of AMD3100 treatment on bone regeneration following marrow ablation in mice. Ten week old female C57/Bl6 mice received a single injection of AMD3100 (5mg/kg; n=7) or saline (n=8) and were sacrificed one hour after injection. Peripheral blood (PB) was collected for CFU-F assays immediately after sacrifice. Cells from all mice in each group were pooled, and 0.5X10⁶ cells were plated in triplicate at 37°C, 5%CO₂, 5%O₂, 100% humidity for 7 days. In addition, a second group of 11-week old female C57/Bl6 mice underwent femoral bone marrow ablation surgery in the left femur (n=57). These mice received a single injection of AMD3100 (5mg/kg) or saline 3 hours after surgery and were sacrificed after 7, 14, or 21 days (n=9-10/group). Trabecular bone volume (BV), total volume (TV), and BV/TV were assayed by μ CT in the distal 50% of the femur, 0.5mm proximal to the growth plate. A significant increase in WBCs in the PB was found in AMD3100 treated mice one hour after injection (p=0.004). The average number of CFU-F colonies increased in the PB of the AMD3100 mice (196.5 CFU/mL) compared to saline treated mice (4.8 CFU/mL). BV was significantly elevated in the ablated femurs of AMD3100 treated mice compared to saline injected mice at 7 days post-surgery (p=0.022), however BV/TV was not significantly different (p=0.063). BV and BV/TV were also elevated in the AMD3100 treated mice at 21 days, but neither of these differences were significant (p=0.052 and p=0.090, respectively). This study shows that AMD3100 is capable of mobilizing MSCs to the peripheral blood, and has the potential to improve bone regeneration at early time points following femoral bone marrow ablation in the mouse.

MO0107

Loss of Prolyl-3-Hydroxylation at Position 986 of Type I Collagen in Transgenic Mice Has A Negative Effect on Bone Mass and Structure. Ingo Grafe¹, Dustin Baldrige¹, Erica Homan¹, Terry Bertin¹, Yuqing Chen¹, Mary-Ann Weis², Dobrawa Napierala¹, Tao Yang¹, Brian Dawson¹, Caressa Lietman¹, Elda Munivez¹, Shan Chen¹, Monica Grover¹, Ming-Ming Jiang¹, David Eyre², Brendan Lee¹. ¹Department of Molecular & Human Genetics, Baylor College of Medicine, USA, ²Department of Orthopaedics & Sports Medicine, University of Washington, USA

Purpose

Cartilage associated protein (CRTAP) is required for prolyl-3-hydroxylation (3-Hyp) at position 986 of the triple helical domain of fibrillar collagens *in vivo*. It has been shown that loss of CRTAP results in recessive Osteogenesis Imperfecta (OI), but it is unclear if the concomitant loss of 3-Hyp directly contributes to the bone phenotype. Therefore, this study investigates if loss of 3-Hyp at position 986 of the α 1(I) collagen chain has a negative impact on bone tissue through use of a transgenic mouse model.

Methods

Transgenic mice with overexpression of mutated *Colla1* gene in bone have been generated. Specifically, a point mutation was introduced in the *Colla1* DNA, resulting in a proline to alanine change at position 986. Alanine cannot be 3-hydroxylated and as it is the second most common amino acid in the X-position of the collagen Gly-X-Y triplet, the P986A substitution is predicted not to disrupt folding or stability of the collagen triple helix. The P986A *Colla1* gene is expressed in transgenic mice (P986A-Tg) under control of the osteoblast specific 2.3kb *Colla1* promoter. Similarly, transgenic mice with overexpression of the wildtype *Colla1* gene were generated as controls (Control-Tg). Expression levels of *Colla1* mRNA were quantified by RT-PCR and 6 week old female P986A-Tg and Control-Tg mice with similar expression were chosen for further studies.

Results

In bone of P986A-Tg mice, mass spectrometry confirmed a 20% expression of the alanine form of total α 1(I) collagen chains. As compared to non-transgenic littermates the P986-Tg mice had a 8% reduced weight (p<0.05). MicroCT analysis of vertebral body L4 demonstrated a reduced BV/TV (-11.1%;p<0.05), reduced trabecular number

(-9.6%; $p<0.05$), increased trabecular separation (+14.2%; $p<0.05$) and a slightly reduced BMD (-8.3%; $p=0.054$). No significant differences regarding these parameters were observed in Control-Tg mice compared to non-transgenic littermates.

Conclusion

Our results indicate that bone specific expression of $\alpha 1(I)$ collagen chains lacking 3-Hyp at position 986 affects bone mass and structure in a dominant negative manner. This suggests that 3-Hyp is required for the formation of normal bone and that loss of 3-Hyp, at least in part, may contribute to the OI phenotype related to loss of function of Crtap.

MO0108

Peripheral Nerve Regulation of Early Heterotopic Ossification. Elizabeth Salisbury*, Eric Rodenberg, Corinne Sonnet, ZaWaunya Lazard, John Hipp, Francis Gannon, Tegv Vadakkan, Mary Dickinson, Elizabeth Olmsted-Davis, Alan Davis. Baylor College of Medicine, USA

Heterotopic ossification (HO), or bone formation in nonskeletal sites, is often the result of traumatic injury. The release of BMP2 (bone morphogenetic protein 2) upon injury has been linked to this process. Here we examine the role of the peripheral nerves in HO. As BMP2 has been shown to stimulate release of the neuro-inflammatory molecules substance P (SP) and calcitonin gene-related peptide (CGRP) from peripheral, sensory neurons, we examined this process in our cell-based gene therapy model of HO. Isolation of proteins from mouse hind limb tissues after injection of AdBMP2 transduced cells reveals an increase in expression of SP and CGRP. Animals lacking functional sensory neurons (TRPV1 $-/-$) display impaired release of SP and CGRP, and microCT shows the resultant HO in these animals is significantly inhibited. One major outcome of neuroinflammation is the recruitment of mast cells. Toluidine blue staining reveals an increase in the number of mast cells after induction of HO that appear to localize to the peripheral nerve structures, presumably for nerve tissue remodeling. If mast cell degranulation is blocked using cromolyn, heterotopic bone volume is substantially reduced. Immunohistochemistry also reveals expression of the stem cell markers nanog and Klf4, as well as the osteoblast marker osterix, within the peripheral nerves of these tissues. The data suggests that BMP2 can act on sensory neurons to induce neuroinflammation, resulting in nerve remodeling and the release of osteogenic stem cells from the nerve. Intriguingly, mast cell degranulation also induces the rapid and transient production of brown adipose, which plays a key role in bone patterning. Degranulating mast cells release serotonin locally, which, in this model, induces sympathetic signaling and the rapid increase of both $\beta 3$ -adrenergic receptor and uncoupling protein 1 (UCP1) gene expression. Immunofluorescence reveals expression of the brown adipose marker UCP1 associated with the peripheral nerve upon BMP2 induction. Blocking mast cell degranulation with cromolyn appears to block local sympathetic signaling, as UCP1 gene expression is no longer elevated in the tissues undergoing bone formation. Together, these data support the hypothesis that BMP2 induced heterotopic bone formation is mediated by peripheral nerve signaling. Further, mast cells appear to play a crucial role in the process through both nerve remodeling and activation of sympathetic signaling.

PHOSPHO1 Overexpression Promotes Extracellular Matrix Mineralization in Osteoblast Cultures. Carmen Huesa¹, Manisha Yadav², Elaine Seawright³, Tina Moreira⁴, Jose Luis Millan⁴, Colin Farquharson⁵. ¹Roslin institute/University of Edinburgh, United Kingdom, ²Burnham Institute for Medical Research, USA, ³Roslin Institute, University of Edinburgh, United Kingdom, ⁴Sanford-Burnham Medical Research Institute, USA, ⁵Roslin Institute, University of Edinburgh, United Kingdom

During the process of bone formation, osteoblasts mineralize their extracellular matrix (ECM) by promoting the initial formation of crystalline hydroxyapatite inside matrix vesicles. Bone alkaline phosphatase (TNAP) is important for ECM mineralization yet TNAP null (*Akp2*^{-/-}) mice are born with a normal mineralized skeleton. The phosphatase, PHOSPHO1, is highly expressed by osteoblasts and chondrocytes and its developmental expression profile coincides with the initial stages of mineralization. Membrane phospholipids, phosphatidylethanolamine (P-Etn) and phosphatidylcholine (P-Cho) have been identified as putative substrates for PHOSPHO1. The skeleton of *Phospho1*^{-/-} mice is characterized by osteoidosis, which results in altered material and mechanical properties, greenstick fractures and scoliosis. In this study we examined the effects of PHOSPHO1 overexpression in osteoblast-like cells in the presence of various substrates to further characterize the function of this phosphatase in the mineralization process. Two subclones of the MC3T3-E1 cell line previously characterized as mineralizing (clone 14) and non-mineralizing (clone 24) were used. Over a 21-day culture, ECM mineralization by clone 14 was first noted at day 11 when beta-glycerol phosphate (BGP) and P-Cho were substrates. No mineralization was noted with P-Etn. ECM mineralization of clone 24 was less than that noted in clone 14 and was first noted at day 11 (BGP), 14 (P-Cho) and 21 (P-Etn). Clone 14 expressed 10 times more PHOSPHO1 protein than

clone 24, which may explain the greater ECM mineralization noted in clone 14. A lentiviral vector was constructed to induce the overexpression of mouse recombinant PHOSPHO1. An empty vector was used as control. PHOSPHO1 overexpression in clone 14 resulted in a 20% increase in PHOSPHO1 protein levels and no alteration in ECM mineralization at day 14 in the presence of BGP, P-Etn or P-Cho. PHOSPHO1 overexpression in clone 24 showed an 80% increase in PHOSPHO1 expression when compared to the control cells and a 10-fold increase in mineralization with BGP, P-Etn and P-Cho as substrate. These data highlight the importance of PHOSPHO1 in the control of osteoblast ECM mineralization. Work on primary osteoblasts from wild type, *Phospho1*^{-/-}, and *Akp2*^{-/-} mice, is in progress to uncover the mechanisms of action of this phosphatase and its functional interaction with TNAP.

Sexual Dimorphisms in Bone Mineral Density in Sprague-Dawley Rats from 8 to 20 Weeks of Age. Jason DeGuire*, Hope Weiler. McGill University, Canada

Peak bone mass is said to be achieved by 12 wk of age in rodents, but sexual dimorphisms according to bone site are unclear. Therefore, the objective of this study was to serially measure bone mineral density (BMD) in growing healthy rats from sexual maturity to middle-age. Sixty Sprague-Dawley rats (30 male, 30 female) were fed an AIN-93 diet from weaning and measured at 8, 12 and 20 wk of age for whole body, lumbar spine vertebrae (L4) and femur using dual-energy x-ray absorptiometry and analyzed with small animal software (QDR 4500A, Hologic Inc). Mixed model repeated measures ANOVA was used to test for sex and time effects with post hoc Tukey testing and significance set at $P<0.05$. Male (8 wk: 308, 12 wk: 465, 20 wk: 615 g) and female (8 wk: 208, 12 wk: 269, 20 wk: 323 g) rats were of normal body weight. For all BMD measurements, a sex by time interaction was observed. Whole body and lumbar spine BMD increased significantly at each time point ($P<0.0001$; Table 1), but was not different between sexes until week 16 ($P<0.0001$). However, femur BMD in females increased significantly from 8 to 12 wk ($P<0.0001$), but was not different at 12 and 20 wk whereas in males, BMD increased at each time ($P<0.0001$). At 8 wk, sex differences were not detected for femur BMD, but were evident at both 12 and 20 wk ($P<0.0001$). These data suggest that peak bone mass is not consistently reached by 12 wk of age in male and female rats and that age at attainment of peak bone mass is likely site specific as is the case for humans.

Table 1: Estimated mean bone mineral density \pm SE (g/cm³) at 8, 12 and 20 weeks of age.

Age (wk)	Sex	Whole Body	Lumbar Spine	Femur
8	Male	0.120 \pm 0.001 ^a	0.194 \pm 0.003 ^a	0.280 \pm 0.006 ^a
	Female	0.122 \pm 0.001 ^a	0.230 \pm 0.003 ^b	0.272 \pm 0.006 ^b

Whitetail Deer Antlerogenic Progenitor Cells Show Robust Mineralization in a Murine Ossicle Growth Model. Ethan Daley¹, Amy Koh-Paige¹, Laurie McCauley², Steven Goldstein³. ¹University of Michigan, USA, ²University of Michigan, School of Dentistry, USA, ³University of Michigan Orthopedic Research Labs, USA

The deer's annual cycle of antler regeneration is unique among mammals and enabled by some of the highest bone formation and resorption rates in nature. This cycle is driven by antlerogenic progenitor cells (APCs) residing in niches in the permanent pedicle and antler tip. How APCs conform to models of mesenchymal stromal (MSC) cell behavior and how they differ from other bone-forming, cervid MSCs is poorly understood. Here, we present the initial results of an ongoing *in vitro* and *in vivo* functional characterization of APCs and cervid marrow-derived MSCs (cmMSCs).

In vitro assays: Two mature whitetail stags (*Odocoileus virginianus*) were acquired during the rapid growth phase of antler regeneration. APCs were harvested from the antler reserve mesenchyme and perichondrium and cmMSCs from the phalanx medullary canal. Adherent cells were cultured using standard methods and frozen. Animal-matched cmMSCs and perichondrial APCs were thawed and the viability (>90%) measured. Cell number was measured over 264 hours using a fluorescent nuclear dye and CFU-F assays were used to estimate clonogenicity.

In vivo assays: cmMSCs and perichondrial APCs, as well as murine MSCs harvested from C57/BL6 mice (for method validation) were seeded onto 17 gelatin scaffolds (97500-1x10⁶ cells/scaffold) and implanted subcutaneously in 4 athymic mice (6 BL6-seeded scaffolds, 2 APC, 9 cmMSC.) At 4 and 6 weeks, ossicles were analyzed

using micro-computed tomography. Four week ossicles were paraffin-embedded, sectioned and stained for manual cell counts.

Results: cmMSCs colony counts and cell numbers at most plating densities were greater than those of paired APCs. However, APC-seeded ossicles had greater cellularity in both cortical and interior regions than paired cmMSCs. APC-seeded ossicles also had similar bone mineral content and bone/tissue volume as BL6 ossicles, despite seeding densities 1/5-2/3 that of the latter. CmMSC-seeded scaffolds showed comparatively low BMC and BV/TV, even at 6 weeks.

Conclusions: Implanted APCs gave rise to more mineralized ossicles compared to matched cervid MSCs. While APCs *in vitro* were less proliferative and colony-forming than cmMSCs, APCs *in vivo* formed more cellular ossicles. The latter could be due to rapid APC proliferation in the presence of unidentified factors available in a corporal but not *in vitro* environment. Or, perhaps APCs themselves secrete factors more conducive to host cell homing and/or proliferation.

DMP1 Does Not Function As A Co-transcriptional Factor. Baozhi Yuan¹, Shuxian Lin², Zhengguo Cao³, Ying Liu³, Yongbo Lu⁴, Marc Drezner⁵, Jian Feng⁶, Qi Zhang², Tian Gao³. ¹University of Wisconsin, Madison, USA, ²Baylor College of Dentistry, USA, ³Baylor College of Dentistry, Texas A&M Health Science Center, USA, ⁴University of Missouri, Kansas City, USA, ⁵University of Wisconsin, USA, ⁶Texas A&M Health Science Center, USA

DMP1 plays a key role in the differentiation of osteoblasts into osteocytes. The identification of DMP1 mutations in humans has led to the discovery of autosomal recessive hypophosphatemic rickets. Currently, there are two hypotheses: 1) DMP1 is a matrix protein that functions via MAP kinase signaling (JBMR 2010); and 2) DMP1 acts as co-transcriptional factor (JBC, 2002). This study was designed to test whether DMP1 could function as a transcription factor both *in vivo* and *in vitro*. First we generated two Adenovirus CMV constructs: natural form of DMP1, containing a signal peptide that directs the extracellular transport of DMP1; and nlsDMP1 transgene, in which the signaling peptide is replaced with a Nucleus Localization Signal peptide that directs DMP1 into the nucleus only. Both Ad-CMV-construction increased expressions of BSP and ALP with no apparent difference when infected into the MC3T3 osteoblast cell line. Next, these constructs were driven by a 3.6 kb rat Col 1 α 1 promoter for generations of transgenic lines separately. Three to five independent lines were generated from each transgene. Immunohistochemistry assay showed that the natural DMP1 was expressed in bone matrix but not in the nucleus; and that the nlsDMP1 was expressed in osteoblast/osteocyte nucleus only. Different analyzing methods, including X-ray, μ CT, histology and immunohistochemistry, showed that none of the transgene displayed an apparent phenotype in the WT background. Interestingly, the natural DMP1 fully rescued the Dmp1-KO phenotype when crossed into the Dmp1 KO knockout background, including biochemistry parameters (FGF23, Pi), rickets and osteomalacia in 2 independent-rescue-lines. In contrast, the nlsDMP1 failed to rescue the Dmp1-KO phenotype. **CONCLUSIONS:** No rescue of Dmp1-KO mice by the targeted re-expression of the nlsDMP1 in osteoblast-osteocyte supports the concept that DMP1 is not a co-transcription factor but an extracellular matrix protein.

Both Ad-CMV-construction increased expressions of BSP and ALP

Immunohistochemistry assay showed the expression of natural DMP1 and nlsDMP1

Thrombospondin-2 Promotes Collagen Fiber Assembly and Stability in the Osteoblast-Derived Extracellular Matrix. Andrea Alford*, Anita Reddy. University of Michigan, USA

Our published data suggest that thrombospondin-2 (TSP2) RNAi affects collagen in the extracellular matrix (ECM) of MC-3T3-E1 cells. We have extended these observations by examining the effects of a total genetic absence of TSP2 on levels and distribution of type I collagen in primary marrow stromal cells (MSC) undergoing osteoblastic differentiation. We harvested MSC from the long bones of 8-week old male TSP2-null and wild-type (WT) littermates and cultured them under osteogenic conditions. After 9 days, conditioned medium and 0.5 M acetic acid-soluble matrix fractions were collected and collagen was quantified using a Sirius red dye-binding assay. DNA was quantified in parallel wells by UV spectrophotometry. Our data suggest that WT cells secrete more total collagen than TSP2-null cells, and that it is distributed differently between the medium and matrix compartments in the two cell-types. While the conditioned medium of WT MSC contains more collagen than that of TSP2-null cells (10.1 \pm 0.53 vs. 5.6 \pm 0.045 ng per μ g DNA in WT vs TSP2-null cultures, respectively; $p < 0.001$), collagen levels in the acid-soluble matrix are similar (1.4 \pm 0.1 vs 1.2 \pm 0.1 ng per μ g DNA in WT and TSP2-null cultures, respectively; $p = 0.057$). Relative levels of mature fibrillar collagen in the acid-insoluble matrix were estimated by heat-denaturing it to gelatin. On a per DNA basis, the acid-insoluble matrix of WT cells contained about twice as much collagen as that of TSP2-null cells (1.0 \pm 0.15 and 0.48 \pm 0.046 for WT and TSP2-null cultures, respectively; $p < 0.05$). After 30 days, WT cells had accumulated a collagen-rich acid insoluble matrix, whereas the TSP2-null cultures still displayed relatively low levels (1.0 \pm 0.12 and 0.19 \pm 0.08 for WT and TSP2-null cultures, respectively; $p < 0.0001$). We conducted western blot analysis of conditioned medium using an antibody that recognizes pro- α 1(I)-collagen, as well as the pro-peptide processed forms. Our preliminary data show that

type I pro-collagen appears in the medium sooner in WT than in TSP2-null cultures, but that removal of the pro-peptides from type I pro-collagen occurs in both cell types. Together, our data suggest that TSP2 may promote the synthesis or secretion of collagen, as well as facilitate its proper assembly into fibrils during the initial stages of osteoblast differentiation, and that TSP2 may also affect the stability of matrix collagen fibers in the mature, mineralizing matrix.

Conditional Loss of MT-MMP Activity in Perivascular Tissues Leads to Disruption of Skeletal Growth. Joanne Shi*, Susan Yamada, Emily Purcell, Pamela Robey, Kenn Holmbeck. National Institute of Dental & Craniofacial Research, USA

Purpose: Multipotent skeletal progenitor cells residing in the bone marrow proper (including the subset associated with marrow vasculature) express membrane-type matrix metalloproteinases (MT-MMPs). We have previously shown that universal loss of MT-MMP activity in adulthood leads to severe perturbation of the skeletal homeostasis with dramatic bone loss and exuberant osteoclast activity, fibrosis, joint erosion and arthritis. MT-MMPs are expressed in a wide variety of cells in the skeleton and the contribution of specific skeletal cell populations to the development of disease is therefore difficult to assess. To work around this obstacle, we have employed a strategy of cell-specific ablation of MT-MMP activity. Here we investigate the role of MT-MMP activity in a subset of vascular-associated cells expressing these proteases.

Methods: A mouse strain carrying a floxed conditional null allele for MT1-MMP was crossed to mice expressing Cre-recombinase under the control of the SM22a promoter to excise of the MT1-MMP gene in perivascular cells.

Results: We demonstrate that selective ablation of MT1-MMP in the SM22a-expressing subset of cells caused significant diminution of skeletal bone content in both the craniofacial and appendicular skeleton. In the skull, fibrosis of the sutures was pronounced and the bone of the cranial vault was thin with overt endosteal fibrosis. In long bones, SM22a-specific loss of MT1-MMP led to substantial loss of trabecular bone, diminished cortical thickness and atrophy of the epiphyseal growth plate.

Conclusion: The specific loss of MT-MMP activity in cells associated with the vasculature led to overt reduction of bone content in mice. We propose based on these observations that the peri-vascular environment is a significant repository of skeletal progenitor cells with potential to populate several tissues of the skeleton including the craniofacial bone, sutures and cartilages. In summary, our data provide compelling evidence that vascular-associated multipotent progenitor cells contribute substantially to skeletal development.

MO0115

Chronic MAPK Inhibition in Hyp Mice Rescues Disordered Vitamin D Metabolism and Skeletal Mineralization Defect. Martin Zhang¹, Daniel Ranch², Anthony Portale¹, Farzana Perwad^{*3}. ¹University of California, San Francisco, USA, ²Univ. Texas Health Science Center, San Antonio, USA, ³University of California San Francisco, USA

The X-linked hypophosphatemic (Hyp) mouse carries a loss-of-function mutation in the *PheX* gene, which results in hypophosphatemia due to renal phosphate (Pi) wasting, inappropriately suppressed 1,25(OH)₂D production, and rachitic bone disease. Increased circulating fibroblast growth factor-23 (FGF-23) is responsible for the disordered metabolism of Pi and 1,25(OH)₂D. We previously showed in Hyp mice that activation of the mitogen-activated protein kinase (MAPK) signaling pathway mediates FGF-23-induced suppression of renal Pi reabsorption and 1,25(OH)₂D synthesis, and this suppression is reversed when MAPK signaling is acutely inhibited. In the present study, we tested the hypothesis that chronic MAPK inhibition in Hyp mice can reverse their metabolic derangements and rachitic bone disease. Hyp mice were fed the MAPK inhibitor, PD0325901 (PD901) (7.5 mg/kg) or vehicle orally, 5 days/week for 4 weeks. After 4 weeks of treatment, weight gain was greater than in vehicle-treated mice (2.4±0.2 vs 0.5±0.2 gm, mean ± SEM, P<0.05). In Hyp mice, PD901 induced 15-fold and 2-fold increases in renal 1α-hydroxylase mRNA and protein abundance, respectively (P<0.05) and thereby higher serum 1,25(OH)₂D levels (115±13 vs 70±16 pg/ml, P<0.05), compared to values in vehicle-treated Hyp mice. With PD901, serum Pi levels (5.1±0.5 vs 3±0.2 mg/dl, P<0.05) and Npt2a brush-border membrane protein abundance (P<0.05) were higher than in vehicle-treated mice. Hyp mice typically develop rachitic bone disease characterized by shortened long bones, increased unmineralized osteoid volume, widened epiphyses, and disrupted growth plates. In the PD901-treated Hyp compared to vehicle-treated Hyp mice: Histomorphometric analysis of distal femur showed significant mineralization of cortical and trabecular bone, lower osteoid volume (24.3±2.3 vs 73.7±3.7%), and lower osteoid thickness (7.8±1.6 vs 18.42±2.6 μm (P<0.05); microCT analysis showed a substantial increase in cortical bone volume (0.31±0.005 vs 0.27±0.003 %, p<0.05), cortical thickness (0.11 ±0.003 vs 0.09±0.002μm, P<0.5) and

femur length (11.79±0.15 vs 11.21 ±0.36 mm, P=0.2). These findings provide evidence that in Hyp mice, activation of the MAPK pathway is critical for FGF23-mediated suppression of renal Pi reabsorption and 1,25(OH)₂D production, and chronic MAPK inhibition reverses disordered Pi and 1,25(OH)₂D metabolism and significantly improves the rachitic bone disease.

Dietary Phosphate Intake Modulates Phenotype of a Mouse Model of Familial Tumoral Calcinosis. Shoji Ichikawa*, Amie K. Gray, Anthony M. Austin, Leah R. Padgett, Michael Econs. Indiana University School of Medicine, USA

Mutations in the *GALNT3* gene cause familial tumoral calcinosis characterized by ectopic calcifications due to hyperphosphatemia and hyperostosis-hyperphosphatemia syndrome presenting with recurrent swelling of the long bones. We recently developed *Galnt3* knockout mice, which had hyperphosphatemia with increased bone mineral density (BMD) and infertility in males. To test the effect of dietary phosphate intake on their phenotype, *Galnt3* knockout mice were fed various phosphate diets: 0.1% (low), 0.3% (low normal), 0.6% (normal), and 1.65% (high). Serums were analyzed for calcium, phosphorus, alkaline phosphatase, creatinine, blood urine nitrogen, and a phosphaturic hormone, fibroblast growth factor 23 (Fgf23). Femurs were evaluated by dual-energy X-ray absorptiometry. On all four phosphate diets, *Galnt3* knockout mice had consistently higher phosphorus levels and lower alkaline phosphatase and intact Fgf23 concentrations than littermate controls. The low phosphate diet normalized serum phosphorus, alkaline phosphatase, and areal BMD in *Galnt3* knockout mice. However, normophosphatemia failed to correct male infertility in *Galnt3* knockout mice. The high phosphate diet did not increase serum phosphorus concentration due to compensatory increase in intact Fgf23 levels. However, increased phosphate intake induced the development of large ectopic calcifications, reminiscent of tumoral calcinosis in humans. In conclusion, the low phosphate diet normalizes biochemical and skeletal phenotypes of *Galnt3* knockout mice, indicating that dietary phosphate restriction can be an effective therapy for tumoral calcinosis. In contrast, the high phosphate diet brings out a more severe phenotype in *Galnt3* knockout mice, making them an excellent animal model of tumoral calcinosis.

MO0117

Evaluation of a New Automated Chemiluminescence Immunoassay for FGF23. Yuichiro Shimizu*, Seiji Fukumoto, Toshiro Fujita. University of Tokyo Hospital, Japan

Fibroblast growth factor 23 (FGF23) is a hormone regulating phosphate and vitamin D metabolism. Excess and deficient FGF23 actions result in several kinds of hypophosphatemic rickets/osteomalacia and familial hyperphosphatemic tumoral calcinosis, respectively. We have previously established an enzyme-linked immunosorbent assay (ELISA) for full-length active FGF23. Using this assay, we have shown that hypophosphatemia with FGF23 levels of more than 30 pg/ml indicates the disease caused by excess actions of FGF23. However, this ELISA has a rather narrow assay range (3 to 800 pg/ml). In addition, it was pointed out that the assay performance of this ELISA was not satisfactory when automatic washing machine was used. Therefore, we have evaluated the basic performance and clinical utility of a newly developed automated chemiluminescence immunoassay for FGF23. This assay uses the same monoclonal antibodies for FGF23 as the previous ELISA and a fully automated chemiluminescence system (CL-JACK, Kyowa Medex, Japan). The assay requires 10 µl of serum or plasma samples and needs 20 minutes for the first result. The detection limit using 2 standard deviations of blank sample was 1 pg/ml and the good linearity was proven up to 15,000 pg/ml. The coefficient of variations using samples with FGF23 levels of 10 to 2500 pg/ml were less than 5%. When FGF23 levels in more than 200 samples from hypophosphatemic patients with various cases were measured by this assay and the previous ELISA, there was a good correlation with R^2 of more than 0.9. In addition, when these samples were divided into two groups with FGF23 levels of higher or lower than 30 pg/ml, there was no discrepancy in the discrimination of samples using these two assays. These results indicate that this new chemiluminescence immunoassay for FGF23 has a wider assay range and a lower detection limit than those of the previous ELISA. This assay also showed good repeatability, requires less amount of samples and shorter time to get the first result. Therefore, this assay seems to be ideal for both clinical use and clinical studies especially measuring many samples with high FGF23 levels.

Disclosures: Yuichiro Shimizu, None.

MO0118

Fibroblast Growth Factor 23 (FGF23) Alters Gene Expression of Isolated Cardiac Ventricular Muscle. Michael Wacker*, Vladimir Tchikrizov², Jaime Mannix², Chad Touchberry², Jason Stubbs³, Lynda Bonewald². ¹University of Missouri-Kansas City School of Medicine, USA, ²University of Missouri - Kansas City, USA, ³University of Kansas Medical Center, USA

Fibroblast growth factor 23 (FGF23) is a hormone primarily released by osteocytes in bone that regulates phosphate and vitamin D metabolism to create a bone-kidney-gut axis. Recent observational studies in humans suggest circulating FGF23 levels to be independently and positively associated with cardiac morbidity and mortality, but the mechanisms responsible remain unclear. FGF23 levels are markedly elevated in patients with several inherited forms of hypophosphatemic rickets and in patients with chronic kidney disease (CKD), yet it is unclear if FGF23 directly contributes to changes in cardiac function. To begin to determine if FGF23 has a direct effect, heart weight to body weight ratios (HW/BW) of two animal models with high serum FGF23 levels were analyzed and the independent effects of recombinant FGF23 on isolated wild-type cardiac muscle strips were examined. The *Dmp1* null mouse model which has high serum FGF23 due to disruption of *Dmp1* expression in osteocytes had a 17% increase in HW/BW compared to wild-type at 24 weeks of age (n=5-6). The *Col4a3* null mouse, a murine model of human Alport disease that develops progressive proteinuric kidney disease and exhibits high levels of serum FGF23, demonstrated a 22% increase in HW/BW compared to wild-type at 10 weeks of age (n=4-5). In order to determine if FGF23 could have a direct receptor-mediated effect on cardiac muscle to induce hypertrophy, we performed quantitative RT-PCR analysis of right ventricular RNA for FGF receptor 1 (FGFR1) and the co-receptor *klf10*. We observed FGFR1 mRNA to be expressed at 6.7 1.0 cycles greater than the β -actin housekeeping gene in all 4 control strips. For *klf10*, mRNA was detectable in 2 of 4 control strips with expression at 15.6 0.2 cycles higher than β -actin. In addition, right ventricular muscle strips were treated for 24 hrs with 900 pg/ml FGF23 or vehicle. Gene expression levels of atrial natriuretic peptide (ANP) and brain natriuretic peptide (BNP), markers of cardiac hypertrophy, were found to be increased 18 and 6 fold respectively from vehicle levels (n=4). In summary, our data indicate that two distinct mouse models exhibiting FGF23 overexpression demonstrate cardiac hypertrophy. Furthermore, treatment of isolated mouse cardiac muscle with FGF23 causes a significant increase in ANP and BNP gene expression. These data provide support for the hypothesis that FGF23 may be a direct contributor to the development of cardiac hypertrophy.

MO0119

Absence of the Mid-region, Nuclear Localization Sequence, and C-terminus of PTHrP Alters the Osteogenic, Adipogenic, Chondrogenic, and Myogenic Differentiation of Murine Bone Marrow Stromal Cells. Blake Hildreth*, Krista M. Hernon, Brandlyn N. Marlow, John Leong, Thomas Rosol, Ramiro Toribio. The Ohio State University, USA

Since the roles of the mid-region, nuclear localization sequence (NLS), and C-terminus of parathyroid hormone-related protein (PTHrP) in the differentiation of bone marrow stromal cells (BMSC) is currently unknown, we investigated the effects of deletion of these regions on their multi-lineage differentiation. It is established that the N-terminal domain promotes bone and cartilage differentiation from BMSC, while concurrently inhibiting adipogenesis. However, little information exists regarding the role of PTHrP in myogenesis. BMSC were isolated from mice lacking the mid-region, NLS, and C-terminus of PTHrP (*Pthrp*^{Δ1/Δ}) and wild-type (control) littermates. Cells were grown in differentiation media both in monolayer (osteo-, adipo-, and myogenesis) and in pellet cultures (chondrogenesis) for 24 days. Secreted biomarkers were analyzed every 6 days and compared with a 2-way RM-ANOVA. Lineage-specific mRNA at day 12 and 24, and histochemical/morphological indices at day 24 were measured and compared with an unpaired t-test at $P < 0.05$. *Pthrp*^{Δ1/Δ} BMSC had greater alkaline phosphatase (ALP) activity ($P < 0.0001$). However, *Pthrp*^{Δ1/Δ} BMSC ultimately had reduced osteoblast maturation, demonstrated by decreased mineralization and osteocalcin secretion at day 24 ($P = 0.016$ and 0.029). Similarly, *Pthrp*^{Δ1/Δ} BMSC-derived cartilage pellets were smaller ($P < 0.0001$) and expressed greater *Ihh* ($P = 0.035$) but less *Sox9* at day 24 ($P = 0.042$). Although *Pthrp*^{Δ1/Δ} BMSC produced greater numbers of adipocytes ($P = 0.023$) with increased *Pparγ* expression at day 24 ($P = 0.087$), both genotypes had similar adipogenic gene expression profiles. Interestingly, *Pthrp*^{Δ1/Δ} BMSC produced a larger number of myocytes ($P < 0.0001$) and expressed more *desmin* and *myogenin* at day 24 ($P = 0.002$ and 0.031). In conclusion, regions distinct from the N-terminus influence BMSC differentiation. Increased ALP and *Ihh* by *Pthrp*^{Δ1/Δ} BMSC, but less bone and cartilage formation, indicates that the mid-region, NLS, and C-terminus inhibit proliferation, but promote osteoblast and chondrocyte maturation. This is the first time that these regions of PTHrP have been implicated in regulating adipocyte and myocyte formation, and they complement the inhibitory function of the N-terminus. Similarities in adipogenic gene expression profiles, despite a greater number of *Pthrp*^{Δ1/Δ} BMSC-derived adipocytes, suggest alterations in energy metabolism, which may contribute to the perinatal lethality in *Pthrp*^{Δ1/Δ} mice.

Acute Decline in Serum Sclerostin in Response to PTH Infusion in Healthy Men. Elaine Yu^{*1}, Ruchit Kumbhani², Erica Siwila-Sackman², Benjamin Leder³. ¹Massachusetts General Hospital, USA, ²MGH Endocrine Unit, USA, ³Massachusetts General Hospital/Harvard Medical School, USA

Background: Animal models suggest that the osteoblast-stimulating actions of parathyroid hormone (PTH) are mediated by acute suppression of sclerostin, an inhibitor of the anabolic Wnt pathway. Conflicting data exist on the effect of intermittent subcutaneous PTH therapy on serum sclerostin, but the immediate physiologic changes in serum sclerostin in response to acute PTH administration have not been reported in human studies.

Objective: We sought to determine the physiologic effects of acute PTH infusion on serum sclerostin and bone turnover markers in healthy adult men.

Methods: 53 healthy adult men underwent an 18-hour intravenous infusion of hPTH(1-34) at a dose of 0.55 U/kg-h. Serum levels of ionized calcium, sclerostin, and markers of bone formation (osteocalcin, PINP) and bone resorption (CTX, NTX) were obtained at 0, 6, 12, and 18 hours.

Results: Serum ionized calcium, CTX and NTX increased, and OC and PINP fell linearly throughout the PTH infusion ($p < 0.01$ for all). Average (SEM) sclerostin levels declined from 936 (65) pg/ml to 813 (63) pg/ml at 6 hours ($p < 0.01$) and remained stably suppressed for the duration of the PTH infusion. We did not observe any significant correlations between change in sclerostin and change in bone turnover markers.

Conclusion: Serum sclerostin declined in response to acute PTH infusion within 6 hours in healthy adult men. The early plateau in sclerostin suppression by PTH contrasts with the linear changes seen in bone turnover markers, and may indicate that maximal stimulation of the Wnt pathway is achieved quickly after exposure to PTH. This finding might partially explain the opposing effects of intermittent and continuous PTH.

Change in Sclerostin during PTH infusion

MO0121

Greater Increase in Urinary Calcium in Response to 1,25(OH)₂D₃ in Genetic Hypercalciuric Stone-Forming Rats than in Controls. Kevin Frick^{*1}, John Asplin², Christopher Culbertson¹, Daniel Asplin², Nancy Kreiger¹, David Bushinsky¹. ¹University of Rochester, USA, ²Litholink Corporation, USA

Genetic hypercalciuric stone-forming (GHS) rats, selectively bred to maximize urine (U) calcium (Ca) excretion, demonstrate increased intestinal Ca absorption, increased bone resorption and reduced renal tubular Ca reabsorption, all leading to a marked increase in UCa compared to control Sprague-Dawley rats and all form kidney stones. The GHS rats express an increased number of vitamin D receptors (VDR) at these sites of disordered Ca transport. To determine if the excess VDR is biologically active, we fed GHS rats a Ca replete diet (1.2% Ca) and injected 1,25(OH)₂D₃ (1,25D, 25 ng/d) or vehicle (veh) for 9 d. With 1,25D, UCa in SD increased from 1.70.3 mg/d to 24.41.2 mg/d and in GHS from 10.50.7 to 41.90.7 and PTH was suppressed to undetectable levels in both groups (all groups n=8, mean SEM, all comparisons $p < 0.01$). To determine if GHS rats would continue to have an augmented increase in UCa in the absence of 1,25D induced intestinal Ca absorption, GHS and SD rats were fed a low Ca diet (0.02%) and again injected with 1,25D or veh for 9 d. With 1,25D, UCa in SD increased from 1.30.1 mg/d to 9.40.9 mg/d and in GHS from 4.70.3 to 21.50.9 and PTH was again suppressed in both groups (all groups n=8, all comparisons $p < 0.02$). In both studies the marked increase in UCa with 1,25D in GHS, which exceeded the increase in SD, indicates that the enhanced number of

VDR in GHS results in greater biological response to administered 1,25D. To help understand the greater increase in UCa in response to 1,25D in GHS than SD, we measured RNA expression of a number of components of renal tubular Ca transport in the low Ca diet study. We found that expression of the distal luminal renal Ca transporter TRPV5 and the transcellular Ca transport protein calbindin D_{28k} were both elevated by 1,25D in SD but not GHS rats. These findings indicate the potential for less renal tubular Ca reabsorption in GHS than SD resulting in greater hypercalciuria. Thus, the increased VDR found in the GHS rats is biologically active and results in a greater increase in UCa as compared to SD rats. In the absence of appreciable dietary Ca, the greater UCa in the GHS rats compared to SD may be secondary to a decrease in distal renal tubular Ca reabsorption mediated by TRPV5.

High Prevalence of Vitamin D Deficiency Among Pregnant Women at Term and Their Neonates in Thessaloniki, Northern Greece. Gkastaris Konstantinos, Karras Spiros, Papadopoulos Foteini^{*}. Panagia General Hospital, Thessaloniki, Greece

Introduction: Maternal vitamin D status is integral to fetal development. There are few data from Greece, a country with abundant sunshine, regarding the prevalence of vitamin D deficiency in pregnancy. Our aim was to assess vitamin D status of women at term and their neonates in a region of Northern Greece.

Methods: Maternal serum and cord blood levels of calcium (Ca), 25-hydroxyvitamin D (25-OH-D), alkaline phosphatase (ALP), phosphorus (P) and parathyroid hormone (PTH) were studied in 60 mother-newborn pairs at term. The study was conducted between February 2010 - March 2011. Dietary habits and skin phototype (Fitzpatrick's classification) were studied.

Results: Mean level of maternal serum 25(OH) D was 10.11 (6.2-21.2) ng/ml, significantly lower ($P < 0.001$ -paired samples test) than that of cord blood 14.2 (9.5-23.8) ng/ml. Maternal serum 25-OH-D correlated positively with cord blood 25-OH-D ($r = 0.79$, $P < 0.001$) (Spearman's correlation). According criteria defining vitamin D deficiency, 82.3% of mothers and 62.5% of neonates were vitamin D deficient, respectively. Umbilical venous blood P was significantly ($P < 0.001$) higher than maternal blood levels [5.2 (3.8-5.9) vs. 3.6 (2.9-3.8) mg/dl], while umbilical PTH levels were significantly lower ($P < 0.001$) than maternal levels [4.5 (2.5-7.1) vs. 22.19 (6.5-36.2) pg/ml]. No differences were found between maternal and cord blood Ca and ALP levels ($p = 0.710$). The intake of Ca and vitamin D was uniformly low [283103 mg/d and 4824 IU/d], respectively. Mothers who delivered during winter and spring had lower 25-OH-D levels ($P < 0.001$), than those who delivered in summer and autumn [8.9 (5.1-11.1) vs. 9.6 (5.8-15.4)]. Finally, women with fair phototype had higher 25-OH-D ($P < 0.001$) than women with darker phototypes.

Conclusion: We observed a high prevalence of hypovitaminosis D among pregnant women and their newborns in Northern Greece. Further public health intervention and vitamin D supplementation is needed to improve maternal and neonatal vitamin D status.

Intermittent PTH Therapy is Anabolic in the Temporomandibular Joint in Young Growing Mice. Yosuke Kamiya^{*1}, Jing Chen¹, Manshan Xu¹, Achint Utreja¹, Kyeong Lee¹, Hector Aguila¹, Carol Pilbeam¹, Sunil Wadhwa². ¹University of Connecticut Health Center, USA, ²University of Connecticut, USA

Intermittent PTH treatment is a common therapy for the treatment of osteoporosis and unlike other osteoporosis therapies is able to cause an anabolic response in the periosteum. The temporomandibular joint is composed of the mandibular condyle, the articular portion of the temporal bone and a disc that are covered by fibrocartilage. Unlike other joints, the cartilage of the mandibular condyle is derived from periosteum. Therefore, the goal of this study was to examine if similar to bone, intermittent PTH therapy is anabolic in the temporomandibular joint (TMJ). Intermittent PTH (80µg/kg) or vehicle was injected to young mice (6-7 weeks old male C57BL/6) for 14 days. Gene expression of chondrocyte maturation markers, proliferation and condylar cartilage thickness was evaluated in the mandibular condyle from both treatment groups. In young growing mice, intermittent PTH therapy caused a significant increase in the mandibular condylar cartilage thickness, no changes in proliferation and a trend for increased Collagen type 2 expression ($p = .10$) compared to the vehicle treated group. Intermittent PTH treatment caused increased condylar cartilage thickness in young growing mice. Future studies are needed in order to evaluate the effects of intermittent PTH treatment in the temporomandibular joint in adult non-growing mice.

Parathyroid Hormone-Vitamin D Relationship is Mediated by Weight Status. Lynae Hanks^{*1}, Krista Casazza², Ambika Ashraf¹, Timothy Mark Beasley¹, Jessica Alvarez¹, Jose Fernandez¹. ¹University of Alabama at Birmingham, USA, ²UAB, USA

Obesity has been associated with low levels of 25-hydroxy vitamin D (25OHD) and high levels of parathyroid hormone (PTH), two antagonistic hormones intricately involved in skeletal health. Whereas, PTH secretion increases to adapt to higher rate of bone formation associated with growth, fat as the main reservoir of vitamin D may affect 25OHD bioavailability thereby perturbing the PTH-25OHD relationship. This has particular relevance during in females as they approach reproductive maturity as it is then that peak bone mass is attained. The aim of this study was to identify the 25OHD nadir resulting in PTH stimulation by weight status. One-hundred normal (n=60) and overweight (n=40) females ages 5-15 years were included. Despite similar 25OHD levels, the relationship between D and PTH differed by weight status (controlling for reproductive maturity). Loess regression analysis indicated 27.2ng/dL (p=0.002) as the level of 25OHD necessary to stimulate PTH secretion in normal weight girls, whereas 14.4ng/dL was the level identified in overweight girls (although the trend and the post-threshold relationship in the overweight group was not significant). This data suggests a weight-dependence in inflection point; or more specifically, that the vitamin D decrement to stimulate PTH secretion is likely of lower magnitude in normal weight girls. This can have profound implications in terms of skeletal health during this sensitive period of development.

Parathyroidectomy Improves Bone Geometry and Microarchitecture in Female Patients with Primary Hyperparathyroidism. A 1-year Prospective, Controlled Study using High Resolution Peripheral Quantitative Computed Tomography. Stinus Hansen^{*1}, Ellen M Hauge², Jens Erik Beck Jensen³, Kim Brixen⁴. ¹Dept. of Endocrinology, Odense University Hospital, Denmark, ²Department of Rheumatology, Aarhus University Hospital, Denmark, ³Osteoporosis Research Clinic, Hvidovre University Hospital, Denmark, ⁴Institute of Clinical Research, University of Southern Denmark, Denmark

Objective.

Following parathyroidectomy (PTX), bone mineral density (BMD) increases in patients with primary hyperparathyroidism (PHPT), yet information is scarce concerning changes in bone structure following normalization of parathyroid hormone levels post-surgery. In this 1-year prospective, controlled study high resolution peripheral quantitative computed tomography (HR-pQCT) was used to evaluate alterations of bone geometry, volumetric BMD (vBMD) and trabecular microarchitecture in female patients with PHPT before and one year after PTX, compared to age- and sex-matched healthy control subjects.

Subjects and Methods

At baseline and after one year of follow up, 26 women with PHPT, in whom PTX was successful (median age 62, range 44-75 years), and 31 female controls (median age 63, range 40-76 years), recruited by random sampling from the background population, were studied using HR-pQCT (Scanco Medical) of the distal radius and tibia providing 82 µm isotropic voxel size images. Changes from baseline to follow-up were assessed with a two group mean comparison t-test of delta values.

Results

Results are shown in Table 1. The two groups were comparable regarding age, height, weight and menopausal status (not shown). At one year, cortical (Ct.) area, Ct. thickness and Ct. vBMD increased in radius in patients (0.09%, 0.68% and 0.50%, respectively) opposed to decreases in controls (-3.35%, -2.64% and -0.76%, respectively) (all p<0.01). A similar pattern was observed in tibia with increases in patients (Ct. area 2.87%, Ct. thickness 10.51%, Ct. vBMD 0.80%) contrasting decreases in controls (-0.30%, -1.10%, -0.43%, respectively) (all p<0.05). Trabecular (Tb.) bone changes were only observed in radius. In patients, Tb. vBMD and Tb. bone volume per tissue volume (BV/TV) increased (2.01% and 1.44%, respectively) along with decreased Tb. spacing (3.97%). In controls, Tb. vBMD and Tb. BV/TV decreased (-0.37% and -0.64%, respectively) whereas Tb. spacing increased (1.53%) (all p<0.01). No significant differences were found for Tb. number or Tb. thickness or any trabecular parameter in tibia.

Conclusion

In patients with PHPT, normalization of PTH levels induces significant alterations of cortical bone in both radius and tibia, reversing or alleviating age-related changes observed in controls. In radius, trabecular bone volumetric BMD increased while trabecular spacing decreased. These changes suggest that bone strength increases.

Phospholipase C Signaling through the PTH/PTHrP Receptor Is Required for Serum Phosphate Homeostasis but not for Serum 1,25(OH)2D3. Jun Guo^{*1}, Hiroko Segawa², Lige Song¹, Minlin Liu¹, F. Richard Bringham¹, Ken-Ichi Miyamoto³, Henry Kronenberg¹, Harald Jueppner¹. ¹Massachusetts General Hospital, USA, ²University of Tokushima Graduate School, Japan, ³Tokushima University School of Medicine, Japan

Parathyroid hormone (PTH) regulates phosphate (Pi) homeostasis by reducing renal Pi reabsorption. To determine which second messengers mediate this action in vivo the effect of continuous PTH infusion was assessed in wild-type (Wt) and in DD mice expressing a mutant PTH/PTHrP receptor (PPR) that activates adenyl cyclase normally but cannot activate phospholipase C (PLC). Mice at 7 wk of age were infused (s.c.) with vehicle or hPTH(1-34) (40 µg/kg/day) for 8 days. Blood and urine were collected before and 1, 2, 4, and 8 days after infusion. PTH infusion caused a persistent decrease in serum Pi (by 50%) in Wt mice, whereas DD mice exhibited lowered serum Pi only transiently for the first 2 days before returning to the basal level. Fractional excretion index of Pi (FEi-Pi) was increased initially in Wt and DD mice, but did not persist in DD mice. To determine the roles of NaPi2a (2a) and NaPi2c (2c), the proximal tubule phosphate transporters, in mediating the PTH actions in Wt and DD mice, mice that are null for each transporter in either Wt or DD background were tested. PTH infusion caused a persistent decrease in serum Pi in Wt/2c-/- mice, which was similar to the response in Wt mice. Interestingly, the PTH effect was less pronounced in DD/2c-/- mice than in DD mice. From lower baseline levels, in Wt/2a-/- mice PTH infusion led to a further persistent decrease in serum Pi. The Pi lowering effect of PTH observed in Wt/2a-/- mice was somewhat attenuated in DD/2a-/- mice. In mice null for 2a and 2c, continuous PTH had no effect on serum Pi or FEi-Pi. PTH administration led to an almost 2-fold increase in serum 1,25(OH)2D3 in both Wt and DD mice with or without 2a or 2c. However, continuous PTH administration had no effect on the already elevated serum 1,25(OH)2D3 levels in Wt or DD mice lacking both transporters. PTH infusion increased serum FGF23 (C-Term ELISA kit) in sera collected after 8 days of infusion by 50% in all groups of mice. In addition, PTH infusion dramatically elevated blood ionized calcium in all groups of mice regardless of basal levels. Our data indicate that the PPR/PLC signaling pathway contributes to PTH-dependent regulation of Pi homeostasis, but not to the regulation of 1,25(OH)2D3, FGF23, and blood calcium levels. Both 2a and 2c are essential targets of PTH action on Pi homeostasis.

PTH Activates BMP Signaling by Inducing Endocytosis of BMP Extracellular Antagonists. Bing Yu^{*1}, Xiaoli Zhao², Chaozhe Yang³, William Lu², Mei Wan⁴, Xu Cao¹. ¹Johns Hopkins University, USA, ²Department of Orthopaedics & Traumatology, The University of Hong Kong, China, ³Department of Orthopaedic Surgery, The Johns Hopkins University, USA, ⁴Johns Hopkins University School of Medicine, USA

More than 20 members in the BMP subfamily transduce their signals using the same BMP receptors. The activity and specificity of different BMPs are achieved by various extracellular antagonists that regulate their binding to their receptors. PTH

has been shown to induce Smad1 phosphorylation effectively, suggesting that PTH regulate the activities of BMP extracellular antagonists. We found that PTH stimulated the level of phosphorylated Smad1 (p-Smad1) in osteoblastic cells on the bone surface of 8-wk old mice in 30 min after single dose injection. Moreover, PTH increased p-Smad1+ MSCs from 12.1% to 81.2% at 30 min in vivo. PTH also stimulated BMP-2-induced phosphorylation of p38, another downstream target of BMP signaling pathway. Importantly, noggin abrogated the PTH-induced phosphorylation of Smad1, indicating PTH activates Smad1 signaling through regulation of extracellular BMP antagonists. PTH lost its effect on Smad1 phosphorylation in PTH1R-/- OC59 cells. These data demonstrate that PTH activation of BMP signaling is PTH1R-dependent and extracellular BMP antagonist noggin negatively regulates the activation.

We therefore examined whether PTH increases the access of BMP ligands to their receptors with 125I labeled BMP2. PTH stimulated 125I-BMP2 cell surface binding in a dose- and time-dependent manner. When PTH-induced PTH1R endocytosis was blocked by knockdown of β -arrestin using siRNA, PTH-elevated phosphorylation of both Smad1 and ERK1/2 was inhibited. Moreover, chlorpromazine, an endocytosis inhibitor, also inhibited the PTH-enhanced phosphorylation of Smad1. We further examined how PTH-induced endocytosis stimulates phosphorylation of Smad1. LRP6 binds to noggin and sclerostin, the antagonists of BMPs, and they form a complex, indicating that LRP6 may organize an extracellular network of BMP antagonists that prevent access of BMPs to BMP receptors. Indeed, deletion of endogenous LRP6 in the MSCs isolated from floxed LRP6 mice by adenovirus-mediated Cre expression elevated PTH-stimulated Smad1 phosphorylation. Furthermore, PTH induces endocytosis of LRP6 in disruption of the antagonist inhibition, but does not induce endocytosis of BMP receptor (BMPRII). As a result, PTH increased the exposure of BMPRII significantly in a cell surface protein biotinylation assay. Collectively, our data demonstrate that PTH stimulates phosphorylation of Smad1 by increase of binding of BMPs to their receptors to induce osteoblast differentiation of MSCs.

Regulation of Renal Sodium-Dependent Phosphate Co-Transporters During Lipopolysaccharide-Induced Acute Inflammation. Shoko Ikeda^{*1}, Hironori Yamamoto¹, Mina Kozai¹, Masashi Masuda¹, Sarasa Tanaka¹, Otoki Nakahashi¹, Hiroko Segawa², Yutaka Taketani¹, Ken-Ichi Miyamoto², Eiji Takeda¹. ¹Dept. Clinical Nutrition, University of Tokushima, Japan, ²Dept. Molecular Nutrition, University of Tokushima, Japan

Type II sodium-dependent phosphate (NaPi) co-transporters Npt2a and Npt2c play a critical role in renal Pi homeostasis, and their brush border membrane (BBM) expression is down-regulated by parathyroid hormone (PTH) and fibroblast growth factor 23 (FGF23). Sepsis is the systemic inflammatory response syndrome (SIRS) that occurs during severe infection and is often associated with electrolyte disorder. Indeed, it has been reported that endotoxin induces plasma PTH levels, hypocalciuria and hyperphosphaturia. However, the mechanism of regulation of Pi homeostasis during acute inflammation is still unclear. In this study, we investigated the regulation of renal Pi metabolism and its mechanism under the acute systemic inflammation using lipopolysaccharide (LPS; E.coli 055:B5) treated animals.

C57BL/6J mice in 3hr after LPS (2-20mg/kg, i.p.) challenge indicated dose-dependently increase the levels of plasma Pi and PTH and urinary Pi excretion, in contrast, urinary Ca excretion was significantly decreased. However, C3H/HeJ mice carrying a Toll-like receptor 4 mutation did not show these changes by LPS. We also observed LPS stimulated PTH levels in a time-dependent manner but plasma FGF23 levels were transiently-increased at 3 hr. Western blot analysis using kidney BBM demonstrated that renal expression of Npt2a but not Npt2c was down-regulated at 3 hr after LPS injection. Furthermore, TNF- α treatment also increased plasma PTH levels and decreased renal BBM Npt2a protein levels. Surprisingly, parathyroidectomized (PTX) rats had impaired LPS responsiveness of urinary Pi excretion and renal Npt2a expression. However, plasma FGF23 levels were significantly increased in both sham and PTX rats after 3 hr of LPS treatment. These results suggest that the alteration of Pi homeostasis during LPS-induced acute inflammation is mediated the down-regulation of renal Npt2a gene expression by PTH.

MO0129

The Immediate PTH Anabolic Action on Bone Marrow Mesenchymal Progenitor Cells. Valerie Siclari^{*1}, Ji Zhu², Fei Liu¹, Abhishek Chandra¹, Ling Qin¹. ¹University of Pennsylvania, USA, ²University of Pennsylvania, School of Medicine, USA

Intermittent injection of parathyroid hormone (PTH 1-34) is an effective anabolic treatment for osteoporosis. Long-term, it dramatically increases trabecular bone mass but the exact mechanism, especially its early action on bone, is not completely understood. Recently, we established a novel method to isolate mesenchymal progenitors (MP) from trabecular bone marrow (BM) and identified a rapid effect of PTH on these cells. The current method to isolate MPs from rodents is to culture BM flushed from long bones. However, histology revealed that it only released BM from the cortical mid-shaft but not BM entrapped within the trabecular bone. To obtain trabecular MPs, long bones were cleaned of soft tissue and periosteum.

Cortical BM was flushed out of the bone and then the bones were cut in half, washed, and digested in collagenase/trypsin solution to release the trabecular BM cells. In vitro, these cells generated both alkaline phosphatase (AKP)⁺ and ⁺ colonies and could differentiate into osteoblasts and adipocytes, suggesting that they include mesenchymal stem cells and osteoprogenitors. The frequency of MPs from trabecular BM was about 3-fold more than that from cortical BM. Interestingly, a single PTH1-34 injection (80 ug/kg) in rats increased the number of trabecular MPs 1.9-, 2.2-, and 3.0-fold after 2, 4, and 24 hrs, respectively. A similar effect was observed in mice. PTH1-34 treatment increased CFU-AKP⁺ colony diameter, suggesting that PTH stimulates the proliferative ability of trabecular AKP⁺ MPs. PTH1-31 (activating PKA pathway), but not 3-34 (activating PKC pathway), produced similar effects. Continuous PTH1-34 (40 ug/kg/day), which leads to bone loss, did not have any effect on the trabecular MPs. Bone resorption was not required for the PTH-induced increase in the number of trabecular MPs. Enhanced proliferation alone cannot explain why PTH increases trabecular MP numbers within 2-4 hrs. Chemotaxis assays demonstrated that conditioned media (CM) from PTH-treated osteoblasts resulted in a 2-fold increase in the migration of MP cells compared to CM from vehicle-treated cells but PTH alone had no effect on the migration. This suggests that PTH stimulates osteoblasts to secrete chemotactic factors which subsequently induce MP migration toward the trabecular bone. In summary, our studies identify an early step in anabolic PTH action on bone in which PTH rapidly stimulates MP proliferation and migration.

Treatment of Non-healing Fractures with Parathyroid -hormone (1-34). Thomas Westphal¹, Dirk Ganzer², Kathrin Baessgen¹, Guido Schroeder¹, Hans-Christof Schober^{*3}. ¹Klinikum Sudstadt, Germany, ²Dietrich Bonhoeffer Klinikum, Germany, ³Klinikum Sudstadt RostockKlinik Fur Innere Medizin I, Germany

Introduction: Non-healing fractures remains a major challenge in orthopaedic surgery. Numerous surgical interventions and the disability of the patients are causing high individual and economic burden. Case reports have shown some effectiveness of Teriparatid 1- 34 (Forsteo®) in non - unions and delayed healing of bone fracture .

In the study presented, we aimed to induce fracture healing and to improve the clinical situation by short term treatment with rhPTH 1-34.

Methods: 8 patients: age 49 - 74 y; gender: 4 male, 4 female, fracture site: femur (1x), proximal tibia (3x) and pilon -tibial (4x), time duration of non -unions: 9 - 32 months.

Number of surgical interventions: 2 - 7 times with autogenous bone grafting. X-ray: before, 3 and 6 months after treatment; Laboratory testing: Calcium, Phosphorus, alkaline phosphatase, bone specific alkaline phosphatase, Vitamin D, tartrate resistant alkaline phosphatase 5b before and after 3 weeks of treatment.

Treatment: 2 months rh PTH 1- 34 (Forsteo®) 20µg subcutaneously once daily.

Results: In all cases except one a fracture healing could be observed. Radiological signs of fracture healing were usually detected after 3 months. Calcium levels did not increase. Changes in the markers of bone turnover were inconsistent.

Conclusion: 2 months administration of 20 µg recombinant parathyroid hormone 1 - 34 seems to induce stable consolidation of the bone in non-unions and delayed healing of bone fractures despite inconsistent changes in bone turnover markers. Therefore PTH could be an alternative option in the treatment of non healing fractures of long bones.

Disclosures: Hans-Christof Schober, None.

Bone Loss in the B-ABLE Clinical Cohort of Women Completing Aromatase Inhibitor 2-year therapy after Tamoxifen: Patterns and Determinants. Daniel Prieto-alhambra^{*1}, Sonia Servitja², Laia Garrigos², Elisa Torres³, Maria Martinez-Garcia², Joan Albanell², Adolfo Diez-Perez⁴, Ignasi Tusquets², Xavier Nogues⁴. ¹Institut Municipal D'Investigacio Medica, Spain, ²Medical Oncology Department, Breast Cancer Unit. Molecular Therapeutics & Biomarkers in Breast Cancer, Cancer Research Program, IMIM-Hospital del Mar, Autonomous University of Barcelona, Barcelona, Spain, ³Department of Internal Medicine, URFOA IMIM-Hospital, RETICEF(Red Tematica de Investigacion Cooperativa en Envejecimiento y Fragilidad), Instituto Carlos III, Barcelona, Spain del Mar, Parc de Salut Mar, Autonomous University of Barcelona, Spain, ⁴Department of Internal Medicine, URFOA IMIM-Hospital del Mar, Parc de Salut Mar, Autonomous University of Barcelona, RETICEF(Red Tematica de Investigacion Cooperativa en Envejecimiento y Fragilidad), Instituto Carlos III, Barcelona, Spain, Spain

PURPOSE Aromatase inhibitors (AI) are first-line agents in hormone-positive early breast cancer. Data on AI-related bone loss is scarce, and comes mostly from randomised clinical trials. We aimed to quantify and to determine the predictors of bone loss after a pre-specified 2-year AI therapy, in the B-ABLE prospective clinical cohort.

METHODS We recruited in our hospital (Oncology and Bone Metabolism Units, Parc de Salut Mar, Barcelona (Spain)) a consecutive sample of women eligible to switch from tamoxifen to AI therapy. BMD was measured at baseline and yearly using DXA. Serum 25-hydroxy-vitamin D levels (25(OH)D) were assessed at baseline, 3 months and 1-year. Patients started on Exemestane or Letrozole according to current guidelines. Participants with osteoporosis or a T-score <-2.0 with fracture risk factors were started on bisphosphonates. All received daily vitamin D3 (800 IU) with calcium, and women with baseline 25(OH)D<30 ng/ml received additional 8,000 IU D3 weekly. Paired T-test was used to quantify bone loss. Multivariate regression models were fitted to determine predictors of bone loss (adjusted for BMI, radio and chemotherapy, baseline 25(OH)D and age). All the analyses were stratified on bisphosphonate use (BPU).

RESULTS To date 85 participants have completed the pre-specified 2-year AI therapy: 56(65.9%) Exemestane, 29 (34.1%) Letrozole. Bisphosphonates were given to 31(36.5%). Bisphosphonate non-users (BPNU) experienced a significant bone loss vs. baseline throughout the 2-years follow-up (3.36% [95%CI 2.00% to 4.71%; p<0.001], which occurred mainly in the first year: 2.37% [1.19% to 3.56%; p<0.001]. BPU showed non-significant bone loss: 0.14% [-2.10% to 2.38%;p=0.70]. (see Fig 1) Type of AI was predictive of bone loss at year 1 (adjusted beta (ab) for letrozole vs exemestane 2.74, p=0.011) but not at year 2. Serum 25(OH)D levels at month 3 were predictive of bone loss both at years 1 and 2: ab per 10ng/ml -0.69 (p=0.003) and -0.49 (p=0.043) respectively. Years since menopause predicted 2-year bone loss: ab per year -0.54 (p<0.001).

CONCLUSIONS Bisphosphonate non-users experience a significant decline in BMD, which is highest in the first year of AI therapy. BPU prevents this. Vitamin D repletion reduces bone loss in BPNU.

BMD at baseline and after 2 years on AI therapy: bisphosphonate users and non-users.

CT-based Rigidity Analysis Affects Treatment of Patients with Appendicular Metastasis. Ara Nazarian^{*1}, Vahid Entezari¹, Robert Turcotte², Megan Anderson¹, Albert Aboulafia³, Patrick Lin⁴, Edward Cheng⁵, Richard Terek⁶, Mark Gebhardt¹, Timothy Damron⁷, Brian Snyder⁸. ¹Beth Israel Deaconess Medical Center, USA, ²McGill Medical Centre, Canada, ³Sinai Hospital, USA, ⁴MDACC, USA, ⁵UMN, USA, ⁶RI hospital, USA, ⁷State University of New York Upstate Medical University, USA, ⁸Children's Hospital Boston/Harvard Medical School, USA

INTRODUCTION: Clinicians make subjective assessments regarding fracture risk using clinical and radiographic guidelines that are sensitive but poorly specific. We have developed and validated a CT-based method to monitor the fracture risk associated with metastatic lesions. This study aims to evaluate whether patient's treatment based on clinical and radiographic guidelines was changed by CT-based Structural Rigidity Analysis (CTRA).

PATIENTS AND METHODS: Patients with uni/bilateral metastasis to appendicular skeleton were enrolled prospectively into the study. Biplanar radiographs and transaxial CT scans (with hydroxyapatite phantom) of involved bones were obtained on all patients. The orthopedic oncologist was asked to select a treatment (observation, chemotherapy, radiation, surgical stabilization, intercalary allograft and/or prosthetic replacement) based on the fracture risk assessment using Mirels score and then again after CTRA.

RESULTS: 86 patients (male/female= 0.86, Age =60.3 ±14.4) with metastasis to appendicular skeleton were enrolled into the study. Lung, breast, multiple myeloma,

kidney and prostate were major sources of metastasis. There were total of 100 lesions of the femur, humerus, acetabulum and clavicle which 62% were lytic, 28% were mixed and the rest was blastic in nature. The median total Mirels score for the lesions was 9 (range:7-12). Considering the full range of treatments options, CTRA would have changed the initial treatment plan in 26% (n=21) of the times. Based on the Mirels criteria alone (Score <9), 68% of lesions (n=55) were at high risk for fracture. According to physicians' initial judgment, 44% of these lesions (n=36) needed surgical fixation, while CTRA alone recommended surgery in 40% (n=33) of lesions.

DISCUSSION: The results suggest that more than 25% of the clinical treatment recommendations would potentially be altered by use of CTRA. Treatment plans were similar in cases where there was either marked bony destruction or minimal bone involvement.

Disclosures: Ara Nazarian, None.

Curcuminoids Decrease Osteolytic Breast Cancer Bone Metastases Separate from Effects on Tumor Cell Growth. Laura Wright^{*1}, Theresa Guise², Khalid Mohammad², Janet Funk³. ¹The University of Arizona, USA, ²Indiana University, USA, ³University of Arizona Health Sciences Center, USA

Curcuminoids are polyphenolic compounds isolated from the rhizome of turmeric (*Curcuma longa* L.), a botanical commonly used in Ayurvedic medicine. We previously found that curcuminoid-containing turmeric extracts inhibited osteoclast-mediated bone resorption in a translational model of rheumatoid arthritis and prevented rheumatoid synovocyte expression of parathyroid hormone-related protein (PTHrP), a bone-resorptive peptide in rheumatic joints. Because PTHrP is also a critical breast cancer-derived mediator of lytic bone metastases, curcuminoid effects on osteolytic breast cancer bone metastases were tested. Four-week old female nude mice (n = 11/group) were inoculated with MDA-MB-231 cells (1 x 10⁵) into the left cardiac ventricle and treated ip every other day with a curcuminoid-enriched extract (25 mg curcuminoids/kg/dose) or vehicle. Evidence of lytic bone lesions in the hind limbs was evaluated prospectively for 3 weeks by x-ray. Curcuminoid-treated mice had significantly less osteolytic bone lesion area compared to vehicle-treated mice (2.0 ±1.0 mm² vs. 11.1 ±2.1 mm²; p < 0.05). In a separate study, four-week old female nude mice were inoculated with MDA-MB-231 cells (1 x 10⁶) into the left mammary fat pad. Using an identical dosing regime, orthotopic tumor volume was not significantly reduced by curcuminoid treatment relative to vehicle-treated mice (500 ±85 mm³ vs. 769 ±120 mm³; p > 0.05) in four-week old female nude mice (n = 7/group). *In vitro*, when MDA-MB-231 cells were pre-treated with curcuminoids (0.3-10 mg/ml) and stimulated with TGF-β (5 ng/ml) for 24 hours, PTHrP secretion, as measured by radioimmunoassay, was inhibited by curcuminoids (IC₅₀ = 2.1 mg/ml) independent of effects on cell proliferation and survival. These initial data suggest that curcuminoids may decrease lytic bone metastases in breast cancer through inhibition of breast cancer cell expression of PTHrP.

Effect of Exercise on Bone Strength, Body Composition and Physical Performance in Breast Cancer Patients- A 12-month RCT. Riku Nikander^{*1}, Harri Sievanen², Katriina Ojala³, Pirkko-Liisa Kellokumpu-Lehtinen⁴, Tiina Palva⁵, Carl Blomqvist⁶, Riitta Luoto³, Tiina Saarto⁶. ¹Metropolia University of Applied Sciences, Helsinki, Finland, Finland, ²UKK Institute, Finland, ³UKK Institute for Health Promotion Research, Finland, ⁴Tampere University Hospital, Finland, ⁵Pirkanmaa Cancer Society, Finland, ⁶Helsinki University Central Hospital, Finland

Breast cancer is the most common malignant disease of women in Western countries. This 12-month randomized controlled examiner-blinded trial aimed to explore whether vigorous aerobic exercise could facilitate survivors' recovery from breast cancer by enhancing their body composition, physical performance and bone strength.

A total of 86 patients were randomly assigned into the training or control group after the adjuvant chemo- and/ or radiotherapy. Body composition and bone traits were assessed by DXA and pQCT. Physical performance was also assessed. Training effects on outcome variables were estimated by ANCOVA.

While bone loss occurred in both groups, bone strength was better maintained among the trainees. At the femoral neck, the distribution of trainees' bone mass

remained unchanged in contrast to controls who lost bone from their upper region of the femoral neck (2%, $p < 0.05$). In addition, the total cross-sectional area and bone structural strength improved 1% and 2% compared to controls among the postmenopausal trainees at the tibial diaphysis ($p < 0.05$). Small positive training effects of physical performance were observed in agility (between-group difference 3%, $p < 0.05$).

In conclusion, a 12-month vigorous aerobic exercise training regimen helped to maintain bone structural strength and slightly improved physical performance of breast cancer patients.

Osteocyte-derived FGF23 Stimulates Klotho-Positive Prostate Cancer Cells.

Pierrick Fournier^{*1}, Erik Imel², Daniel Edwards¹, James Knight¹, Noah Hahn¹, John Chirgwin¹. ¹Indiana University, USA, ²Indiana University School of Medicine, USA

Prostate cancers metastasize to bone more frequently than other solid tumors, often causing osteoblastic responses via local interactions with the bone microenvironment. Bone is the sole source of fibroblast growth factor 23, an endocrine hormone that acts on kidney cells expressing its receptor (klotho+FGFR1) to increase the transcription factor EGR1 and alter metabolism of vitamin D. This pathway normally controls kidney handling of phosphate. Expression of klotho by other tumor types has been reported, suggesting FGF23 might act on bone-metastatic prostate cancers.

Eight human prostate cancer lines tested all expressed mRNAs for klotho & FGFR1iic. DU145 cells, which cause bone lesions in nude mice, were treated with 100ng/ml recombinant human FGF23 and analyzed by real-time PCR ($n=3$). EGR1 mRNA increased 3 X at 1hr ($p < 0.0001$) and returned to baseline after 2 hrs. Expression of mRNAs encoding the vitamin D-inactivating 24-hydroxylase, CYP24A1 and TRPV6 Ca channel increased 2X at 2 hrs ($p < 0.05$) and returned to baseline by 4 hrs. Two other early-response genes, CTGF & Cyr61, were significantly increased by FGF23. Parallel results were seen with C4-2B cells, where treatment with 100ng/ml FGF23 for 6 days increased cell number by 40% ($p < 0.05$) in the face of growth-inhibiting concentrations of 1,25-dihydroxyvitamin D3. This response was not seen with MDA-MB-231 breast cancer cells, which have very low klotho expression. FGF23/klotho signaling may contribute to tumor growth in bone through targets downstream of EGR1, such as Cyp24A1 & TRPV6, which regulate prostate cancer responsiveness to 1,25-dihydroxyvitamin D3.

Following case reports of altered FGF23 concentrations in patients with prostate cancer, we measured circulating intact FGF23 in bisphosphonate-naïve prostate cancer patients: 27 with bone metastases, and 12 without. Serum FGF23 concentrations did not differ between groups: 32.5 19.1 in the bone metastasis group and 39.0 20.7 in the group without bone metastases ($p=0.35$).

The data suggest that a local FGF23/klotho/EGR-1 axis may be active in prostate cancer bone metastases, where signaling could alter tumor growth and vitamin D resistance. FGF23 binding to klotho on prostate cancer cells may provide a novel target for therapeutic intervention against bone metastases.

Runx2 ChIP-seq. Gillian Little*, Ben Berman, Sanjeev Baniwal, Gerhard Coetzee, Baruch Frenkel. University of Southern California, USA

Runx2 plays important roles in both bone and cancer biology. In bone, it controls both osteoblastogenesis and osteoblast-driven osteoclastogenesis. In cancer, attention has increasingly moved to the role of Runx2 in bone metastasis. Runx2 is subjected to multiple negative feedback mechanisms, whereby its expression and activity are inhibited in response to its own activation. These self-limiting mechanisms impede the detection of Runx2 DNA-binding and stimulation of target genes in living cells that are not synchronized for Runx2 activation. To overcome this experimental impediment, we transduced mesenchymal stem cells, primary osteoblasts, breast cancer and prostate cancer cells with lentiviruses encoding Doxycycline (Dox)-inducible Runx2. Dox treatment resulted in synchronous activation of Runx2 and robust stimulation of target genes. In C4-2B prostate cancer cells, Dox treatment resulted in expression of Runx2 to levels seen in more aggressive metastatic cells such as PC3, reaching a steady state at 12h. Despite this, Runx2 chromatin immunoprecipitation (ChIP) assays at known Runx2-occupied regions (R2ORs) demonstrated cyclical recruitment of Runx2 with a periodicity of about 4h (Figure 1). We selected the 20h time point to capture what is to our knowledge the first true genome-wide Runx2 DNA-binding landscape in living cells. Massively parallel sequencing of the Runx2 ChIP (ChIP-seq) revealed 5,413 robust and highly significant R2ORs, many of which were located close to genes we identified by expression microarray analysis as differentially regulated by Runx2 in C4-2B cells. These include known R2ORs near the *CSF2* and *KLK2* genes, and novel regions including those near *WNT4*, *TCF7L2*, *LRP6*, *GSK3B*, *WISP1*, *WIF1*, *DKK2*, *TGFB2*, *TGFBR3*, *IGF2R*, *DLX1*, *BMP6*, *FGF13*, *PIP* and *RUNX1* genes (see Figure 2 for examples). Less than 5% of R2ORs were within 2kb of a transcription start site and more than 90% were located within introns or intergenic regions, suggesting Runx2 likely occupies predominantly enhancer and not promoter regions. Functional annotation analysis of R2ORs revealed significant enrichment in cell motility and migration pathways and motif analysis using several methods revealed RUNX as the strongest of several very highly

enriched motifs within R2ORs. High throughput characterization of Runx2 genomic occupancy and activation of target genes will open new avenues in understanding the role of this transcription factor in both cancer and bone biology.

Runx2 Controls a Positive Feedback Loop between Androgen Signaling and Prolactin-induced Protein (PIP) in promoting T47D Cell Proliferation.

Sanjeev Baniwal*, Gillian Little, Nyam-Osor Chimgé, Baruch Frenkel. University of Southern California, USA

PIP is a small polypeptide expressed by advanced breast and prostate cancer (BCa, PCa) cells. However, both the regulation of PIP expression and its function in cancer cells are poorly understood. Using breast and prostate cancer cells, we found that Runx2, a pro-metastatic transcription factor, functionally interacts with the Androgen Receptor (AR) to regulate PIP expression. In C4-2B/Rx2^{dox} and LNCaP/Rx2^{dox} PCa cells, Doxycycline (Dox)-induced Runx2 synergized with AR to promote PIP expression. In T47D BCa cells, which express endogenous Runx2 and PIP, basal as well as hormone stimulated PIP expression was abrogated by shRNA-mediated Runx2 knockdown. Chromatin immunoprecipitation (ChIP) assays showed that Runx2 and AR occupied an enhancer element located ~11kb upstream of the PIP open reading frame, and that Runx2 facilitated AR recruitment to the enhancer. Dox-induced PIP knockdown using shRNA arrested proliferation that was driven by either a mixture of serum growth factors or dihydrotestosterone (DHT) alone. PIP knockdown compromised DHT-stimulated expression of multiple AR target genes including PSA, FKBP5, FASN, and SGK1. The inhibition of AR activity due to loss of PIP was attributable at least in part to abrogation of its nuclear translocation. Our data suggest that Runx2 controls a positive feedback loop between androgen signaling and PIP in promoting carcinogenesis. PIP may explain at least in part the oncogenic properties of AR and Runx2, and pharmacological inhibition of PIP may offer a novel therapeutic approach for the treatment of a subset of prostate and breast cancer

patients.

Runx2 Regulates PIP

MO0138

The Vitamin D Receptor has a Ligand-Independent Role in Human Breast Cancer Cell Growth. Trupti Trivedi¹, Yu Zheng¹, Li Laine Ooi¹, Colette Fong-Yee¹, Colin Dunstan², Markus Seibel¹, Dr. Hong Zhou¹. ¹Bone Research Program, ANZAC Research Institute, The University of Sydney, Australia, ²University of Sydney, Australia

We have previously reported that vitamin D deficiency promotes human breast cancer growth in murine bone. While this effect seems to be mediated mainly through the bone micro-environment, vitamin D and the vitamin D receptor (VDR) may also have direct actions on cancer growth in bone. The current study aimed to define the role of the VDR in human breast cancer growth *in vitro* and *in vivo*.

Using stable shRNA expression, VDR expression was knocked down by 85% and 80% in MDA-MB-231 (MDA-VDRshRNA) and MCF-7 (MCF7-VDRshRNA) cells, respectively. Non-target (NT) cells served as controls. The induction of CYP24 mRNA expression by 1,25(OH)2D3, normally seen in VDR expressing cells, was completely abrogated in VDR-knock-down cells, indicating effective disruption of VDR signaling.

Compared to untreated NT cells, treatment of MDA-NT and MCF7-NT cells with 10⁻⁸ M 1,25(OH)2D3 significantly reduced cell growth by 37% and 48%, resp., and induced a 2 to 3-fold increase in apoptosis. Surprisingly, MDA-VDRshRNA and MCF7-VDRshRNA cells also exhibited reduced growth rates (-40% & -53%, resp.) and increased apoptosis (6 to 7-fold) compared to the corresponding NT cells cultured in ligand free conditions. Treatment of either knockdown cell line with 1,25(OH)2D3 treatment had no effect on growth or apoptosis. In MDA-VDRshRNA cells, the reduced cell growth was associated with decreased β -catenin protein and its target gene, cyclin D1, when compared to MDA-NT cells.

To investigate tumor growth *in vivo*, MDA-VDRshRNA and NT cells were xenografted orthotopically into the mammary fat pad of nude mice. Again, VDR knockdown significantly reduced tumor growth from day 12 onwards. At day 33 post implantation, tumour weight was reduced by 40% and apoptosis was significantly increased in VDRshRNA compared to NT tumours ($p < 0.05$). Similarly when MDA-NT and VDRshRNA cells were implanted into the tibiae of nude mice, lytic lesion size at endpoint (day 21) was significantly smaller in mice implanted with VDRshNA than with NT cells ($p < 0.05$).

We conclude that the VDR has ligand-independent functions in regulating breast cancer cell growth which contrast its ligand-dependent, anti-proliferative and pro-apoptotic effects. It appears that the ligand-independent actions of the VDR are mediated through the β -catenin signalling pathway.

MO0139

Treatment with Interleukin 6 Receptor Antibodies Inhibits Prostate Cancer Growth in a Murine Model of Bone Metastasis. Dennis Basel¹, Yu Zheng², Julian Kelly¹, Frank Buttgerit³, Robert L Sutherland⁴, Colin Dunstan⁵, Dr. Hong Zhou⁶, Markus Seibel⁶. ¹ANZAC Research Institute, the University of Sydney, Australia, ²Bone Research Program, ANZAC Research Institute, The University of Sydney, Australia, ³Department of Rheumatology & Clinical Immunology, Charite University Medicine (CCM), Germany, ⁴Cancer Research Program, Garvan Institute of Medical Research, Australia, ⁵University of Sydney, Australia, ⁶Bone Research Program, ANZAC Research Institute, The University of Sydney, Australia

In patients with metastatic prostate cancer, high circulating interleukin-6 (IL-6) levels have been associated with disease progression and poor prognosis. In human prostate cancer cells, expression of IL-6 has been linked to a more aggressive phenotype and progression of hormone refractory prostate cancer. We previously demonstrated a correlation between increasing or decreasing bone resorption activity and corresponding changes in metastatic tumor IL-6 expression and tumor growth in

murine models of breast and prostate cancer. These data indicate that IL-6 may play a role in metastatic cancer growth in bone. In the present study, we investigated the effect of the IL-6 on human prostate cancer growth *in vitro* and *in vivo*.

In vitro studies: Treatment of the human prostate cancer cell line, PC3, with RANKL up-regulated IL-6 mRNA expression 2-fold within 4 hrs. Interestingly, treatment of PC3 cells with IL-6, in turn, increased RANK expression 2-fold, and PTHrP expression 4-fold. The effects of IL-6 on RANKL expression were blocked by treatment of PC3 cells with the anti-human IL-6 receptor (IL-6R) antibody, tocilizumab (Tmab). These data suggest that RANKL, IL-6 and RANK (or PTHrP) may form a "feed-forward" loop that promotes cancer growth in bone.

In vivo studies: PC3 cells were implanted intra-tibially into five week-old BALB/c nu/nu male mice. Mice were then randomized into 2 groups (n= 8 each), receiving either Tmab (50mg/kg/3d) or vehicle. Zoledronic acid (ZA) was co-administered at a dose of 100 μ g/kg every 3 days in a subset of mice (n=8) to determine the contribution of the bone microenvironment to tumor growth. Tibiae were monitored by X-ray imaging on days 17, 24 and 30 (sacrifice). Compared to controls, treatment with Tmab significantly inhibited radiographic osteolysis from d17 onwards (d17: 0.110.04 vs. 0.370.10 mm²; d24: 0.440.13 vs. 0.900.14 mm²; d30: 0.800.24 vs. 1.460.22 mm², $p < 0.05$). Co-treatment with ZA completely prevented osteolysis.

As tumor-derived IL-6 increased tumor cell RANK expression, and bone-derived RANKL increased tumor cell IL-6 expression, the inhibitory effects of Tmab on tumor growth may be due to the interruption of a "feed-forward" loop between tumor and bone cells which involves RANKL, IL-6 and RANK (or PTHrP). Our data indicate that IL-6 plays an important role in the metastatic growth of prostate cancer cells in bone and may be a potential therapeutic target in prostate cancer bone metastasis.

TWIST WR/Runx Domain Synergizes NF- κ B Activity and Promotes Cellular Invasiveness through IL-8 Production. Karen Aboody¹, Shan Li², Raquel Raices³, Stephen Kendall⁴, GINA LOWE⁵, Carlotta Glackin⁶. ¹City of Hope Medical Center, USA, ²Beckman Research Institute Graduate School, USA, ³Stem Cell Technologies, USA, ⁴Fluidigm, USA, ⁵CITY OF HOPE/BECKMAN RESEARCH INSTITUTE, USA, ⁶Beckman Research Institute at City of Hope, USA

Metastasis is the major cause of mortality among cancer patients. One potential mechanism of metastatic spread centers the concept of epithelial-to-mesenchymal transition (EMT). In adenocarcinomas, EMT describes the processes that differentiated cells lose epithelial features, acquire mesenchymal properties and attain the ability to invade the basement membrane, leading to dissemination of cancer cells. More recently, tumor cells undergoing EMT were also reported to display stem cell-like phenotype, which relates EMT to the cellular potential of tumor relapse and metastatic re-growth. Multiple EMT regulators identified to date are primarily based on their ability to repress E-cadherin expression, a hallmark of EMT. Many of these regulators have a role in early morphogenesis, such as Zeb2, Snail and the master regulator of mesenchymal lineages, Twist, emphasizing the important role of EMT in the pathology of metastasis.

Here we describe the unique property of the C-terminal WR/Runx domain of Twist in mediating NF- κ B activation and breast cancer cell invasion through the expression of interleukin 8 (IL8). We discovered that IL8 production is induced by Twist expression in a cis-binding independent mechanism. In this mechanism, Twist activates the IL8 promoter by stimulating and synergizing NF- κ B transcriptional activity through interactions of NF- κ B subunit RELA with the WR protein binding domain. Activated NF- κ B exhibits enhanced IL8 promoter binding affinity, leading to increased IL8 cytokine production. Finally, we demonstrate that the IL8 autocrine pathway in breast cells increases cellular invasiveness by promoting production and activation of metalloproteinases. Given the important roles of NF- κ B in cancer progression, as well as the many significant functions of IL8 in angiogenesis, chemotaxis, proliferation and invasion, Twist-expressing cells can indirectly activate and synergize a series of complex biological responses through the WR domain among cancer cells, in addition to the immune and circulatory system, thereby triggering cancer cell dissemination.

In order to test the therapeutic role of Twist inhibition of IL-8 in metastasis, Soluble Twist Inhibitors (STIs) are being evaluated as novel therapeutics to selectively reduce tumor cell invasion, allowing progression toward a normal differentiated or apoptotic phenotype. The impact of STIs as novel therapeutics may serve as proof-of-principle for reducing aggressive tumor metastases *in vivo*.

MO0141

VEGFR3 Expression in Human Breast Cancers and Effects of VEGFR3 Antibody in a Mouse Model of Metastatic Breast Cancer. Yoshikazu Morita¹, Lei Shu², Kristina Subik², Ping Tang², Brendan Boyce², Lianping Xing¹. ¹University of Rochester, USA, ²University of Rochester Medical Center, USA

VEGF-mediated angiogenesis plays an important role in cancer development and metastasis. The VEGF family contains multiple members, including VEGF-A, B, C,

and D. VEGF-C and D are growth factors for lymphatic endothelium and signal through VEGFR3, a receptor specific for VEGF-C and D. Breast cancer cells and osteoclasts express high levels of VEGF-C, which could have a role in bone metastasis. However, the VEGF-C/VEGFR3 system has not been investigated in breast cancer bone metastasis. Here, we examined VEGFR3 expression using immunohistochemistry in a tissue microarray containing cores from breast cancer and normal breast tissue from 116 patient samples. We found that most breast cancer samples (70%; 84/116 cases) are VEGFR3 positive, while normal breast tissue is mainly negative (87%, 96/110 cases). VEGFR3 expression correlated positively with estrogen receptor (ER+ or ER+/PR- (progesterone receptor) expression status, tumor type, and lymph node metastasis compared to VEGFR3 negative tumors, i.e. ER+: 56% vs 26%; ER+/PR-: 73% vs 27%; infiltrating ductal carcinoma: 74% vs 26%; lymph node metastasis: 87% vs 13%. Furthermore, VEGFR3 positive staining correlated with tumor size (<1 cm: 26% positive vs 74%, 1-2 cm: 81% vs 19%, >2cm: 80% vs 20% in VEGFR3-negative tumors). To examine the effect of VEGFR3 blockade on breast cancer bone metastasis, we injected MDA-MB-231 cells, which express high levels of VEGF-C, into the left vehicle of nude mice. The mice were given VEGFR3 neutralizing antibody (VEGFR3 NA) (0.8mg/mouse, twice a week, ip) for 4 weeks, a regime that inhibits lymphangiogenesis around inflamed joints of TNF transgenic mice. We found that mice that given VEGFR3 NA were healthier and heavier (body weight: 21+2g vs 19+1) than mice given IgG control. They also had a lower death rate than the IgG-treated mice (# dead: 1/9 vs 4/6). However, X-ray and histology indicated that VEGFR3 NA did not affect the number and size of bone metastases or bone volume in recipient mice. In summary, 1) most breast cancers express VEGFR3; 2) VEGFR3 expression is positively associated with ER status, tumor size and lymph node metastases; 3) VEGFR3 blockade improves the general health and survival of tumor-bearing mice. Thus, VEGFR3 is a potential prognostic indicator for breast cancer, and further studies are warranted to determine how VEGFR3 blockade improves survival of tumor-bearing mice if it reduces bone metastases in combination with other anti-cancer treatments.

Vertebral Fractures and Trabecular Microstructure in Men with Prostate Cancer on Androgen Deprivation Therapy. Julie Wagner*, Karen Vujevich, Megan Miller, Subashan Perera, Joel Nelson, Neil Resnick, Susan Greenspan. University of Pittsburgh, USA

Background: Although bone mineral density (BMD) assessed by conventional dual energy x-ray absorptiometry (DXA) is the gold standard to determine fracture risk, BMD does not assess for vertebral fractures (VF). High resolution microMRI (HR-MRI) assesses bone microarchitecture and may provide additional information in men with VF. Androgen deprivation therapy (ADT), a common treatment for prostate cancer, is associated with bone loss and fractures.

Methods: To determine if identification of VF increased the diagnosis of osteoporosis beyond BMD and if HR-MRI demonstrated skeletal deterioration in men with VF, we enrolled 137 men ≥ 60 years with nonmetastatic prostate cancer on ADT for ≥ 6 months. BMD of the spine and hip were assessed by DXA. Vertebral fracture assessment (VFA) by DXA was confirmed with conventional lateral x-ray and classified by Genant criteria (mild, moderate, severe VF). HR-MRI of the wrist included bone volume to total volume (BV/TV), surface density (trabecular plates), surface/curve ratio (plates/rods) and erosion index (higher depicts deterioration).

Results: Silent (unknown) VF were found in 37% of men. The duration of ADT was associated with lower BMD at the spine ($r = -0.21$), total hip ($r = -0.20$), and 1/3 distal radius ($r = -0.32$, all $p < 0.05$). 7% of total participants were classified as having osteoporosis by BMD. 37% of men without osteoporosis by BMD had VF identified by VFA and conventional x-rays. This suggests that 82% of patients with clinically defined osteoporosis would have been misclassified by BMD alone. By ANOVA comparison across VF grades, the BV/TV was lower, surface density was lower and erosion index was higher in men with moderate-severe VF compared to lesser grades (Table, all $p < 0.05$). Conventional BMD at the spine, hip and 1/3 distal radius were also significantly lower ($p < 0.05$) in men with the more severe grade of VF ($p < 0.05$). Indices of HR-MRI were associated with BMD at the ultra distal radius ($r = 0.46-0.65$, $p < 0.01$), total hip ($r = 0.34-0.49$, $p < 0.01$) and some with spine ($r = 0.22-0.37$, $p < 0.05$).

Conclusions: ADT for men with prostate cancer is associated with silent VF in 37% of men. Measurement of BMD alone leads to misclassifications of osteoporosis which can be avoided by assessment for VF. HR-MRI provides a novel technique to assess the deterioration of structural integrity in men with VF and adds additional information to conventional BMD.

10 Years of Balloon Kyphoplasty in Malignant Vertebral Body Lesions - Critical Analysis of Benefits and Complications. Dr. Max Markmiller*. Klinikum Kempten, Germany

Purpose of the study: Affection of the spine by metastases threatens the patients with pain, loss of mobility and neurologic defects. Treatment options have to meet concerns of the short term prognosis, the limited operability and should allow quick mobilisation and short hospital stay. An answer is the minimally-invasive percutaneous augmentation of the vertebra by CT – guided dilatation and injection of bone cement (methylmethacrylate). Benefits are immediate mobilization after the procedure, minimized surgical trauma and no need of an additional orthosis. Cement leakage rates are increased compared to kyphoplasty procedures of osteoporotic fractures, but no oncologic patient required a surgical revision.

Methods: The patients were documented prospectively by ASA – Score, Karnovsky – Index, Visual Analog Scale (VAS) and Oswestry Disability Index (ODI). Percutaneous kyphoplasty was guided with CT and combined with fluoroscopy. All patients were aftertreated functionally with early mobilisation. Epidural tumor involvement was no contraindication.

Results: From 05/2000 to 05/2011 out of 1117 kyphoplasties 115 patients with metastatic lesions were treated. The localisation favorites the thoracolumbar junction. The subjective evaluation using the VAS showed a decrease of the pain level of 60 % in 80% of the patients. All patients were mobile without orthosis after the procedure. The clinical and radiological followups after 6 and 12 months confirmed the good results in the ODI however 24 patients had died in between. Radiologically, all survivors showed an unaltered mechanical sufficient bone cement material. The complication rate is on the lower limit of the literature, but increased compared to kyphoplasty procedures of osteoporotic fractures. Complications refer to paravasations of the bone cement (40 patients, 35 %): eight patients showed temporary radiculopathy, 31 patients with intervertebral, vascular or paravertebral paravasation stayed asymptomatic. 9 patients showed epidural paravasation without neurological impairment, no oncologic patient required surgical revision.

Conclusion: Percutaneous kyphoplasty is an excellent method of palliation for pain relief and mobility in oncologic patients with cancer metastases of the spine.

MO0144

A New Murine Model of Medulloblastoma Bone Metastasis. Jessica Grunda*, James Mobley, Gregory Clines. University of Alabama at Birmingham, USA

Purpose: Medulloblastoma is the most commonly diagnosed pediatric primary brain neoplasm, comprising 20 to 25% of all childhood CNS tumors. Approximately 13% of these patients will develop extra-neural brain metastases, of which bone is the most prevalent site of metastasis (84%), followed by bone marrow (27%), lymph nodes (15%), lung (6%), and liver (6%). Although recent meta-analyses indicate that these extra-CNS metastases significantly diminish patient survival, response to therapy and quality of life, no studies exist investigating mechanisms underlying medulloblastoma extra-neural metastasis or treatment, highlighting the critical need for research in this area. The purpose of the herein described study was to generate and characterize murine models of medulloblastoma bone metastasis, which would greatly facilitate the elucidation of new treatment strategies.

Methods: The human DAOY and D283 Med medulloblastoma cell lines were inoculated into the intratibial space of athymic nude mice. Development of bone metastases and tumor burden were monitored through radiographic imaging and quantified by computerized image analysis. Total bone area, tumor area, osteoclast and osteoblast cell numbers of bone lesions and control bone were assessed through

histomorphometric analysis. Potential molecular pathways involved in bone metastasis were explored.

Results: Lytic and mixed lytic / blastic lesions were radiographically detected in mice 30 and 34 days post Daoy and D283 Med tumor cell injection respectively. Histomorphometric analysis of various bone parameters confirmed these observed bone phenotypes. Subsequent molecular analysis of bone lesions and *in vitro* medulloblastoma cell cultures identified several signaling pathways potentially driving the development of medulloblastoma skeletal metastases and bone remodeling.

Conclusions: The new mouse models of medulloblastoma osseous metastasis described herein are a critical first step in the investigation of mechanisms driving the extra-neural metastasis of medulloblastoma to the bone. Results from this and future studies utilizing these models should aid in the development of tumor-specific bone metastases treatments. Furthermore, findings may also facilitate the development of novel therapies targeting bone metastases from other types of cancers as well, such as prostate, breast and lung.

BTK Mediates SDF-1-Induced Migration of Myeloma Cells and Osteoclast Precursors, Osteoclastogenesis and Myeloma Cell Clonogenicity. RAKESH BAM*, Angela Pennisi, Upparahalli Sathisha, Xin Li, Sharmin Khan, Yuping Wang, Wen Ling, Bart Barlogie, John Shaughnessy, Shmuel Yaccoby. University of Arkansas for Medical Sciences, USA

Multiple myeloma (MM) cells typically grow in bone, recruit osteoclast precursors and induce their differentiation in areas adjacent to tumor foci. Bruton's tyrosine kinase (BTK), a nonreceptor tyrosine kinase of the TEC family, is preferentially expressed in the hematopoietic cells and known to regulate B-lymphocyte function, osteoclastogenesis and induction of chemotaxis by SDF-1. The aims of the study were to evaluate expression of BTK in MM cells and osteoclast precursors, determine its role in migration of these cells towards SDF-1, osteoclast differentiation, and clonogenicity of myeloma cells. Our clinical microarray data indicate that primary MM cells express BTK and that relative to normal plasma cells, BTK expression is upregulated in myeloma cells molecularly classified in the CD-1, CD-2, HY, LB and MF subtypes. Expression of BTK at the RNA and proteins levels in MM cells and osteoclast precursors was validated using qRT-PCR and Western Blot. SDF-1 (30 nM) induced migration of MM cells (n=5) by >2.5 folds, an effect that was significantly inhibited by the small molecule BTK inhibitor, LFM-A13 (25-50 μ M). Using FACSARIA flow cytometry we found that CXCR4-positive, but not CXCR4-negative, sorted myeloma cells express BTK, indicating that BTK expression is restricted to a subset of MM cells and that CXCR4 and BTK signaling are linked. LFM-A13 or siRNA against BTK inhibited clonogenic potential of myeloma cell lines using a 2-week methylcellulose assay. LFM-A13 reduced migration of osteoclast precursors towards SDF-1 and dose dependently (10-40 μ M) inhibited formation of multinucleated osteoclasts in cultures supplemented with RANKL and M-CSF. *In vivo*, SCID-rab mice were engrafted with BTK-expressing MM cells. Upon establishment of MM growth as assessed by measurement of circulating human immunoglobulins, hosts were intraperitoneally treated with 40 mg/kg LFM-A13 or vehicle (10 mice/group) twice a day for 3 weeks. Whereas in the control group bone mineral density (BMD) of the implanted bone was reduced by 154% from pretreatment levels, it remained unchanged in the LFM-A13 treated hosts (p<0.01). LFM-A13 prevented induction of osteolytic lesions and reduced the number of osteoclasts in myelomatous bones. At the end of the experiment, tumor burden was insignificantly lower in hosts treated with the LFM-A13. We conclude that BTK plays critical role in MM cell homing and clonogenicity, and in homing and differentiation of osteoclast precursors.

Functional Inhibition of Osteoblastic Cells in an In Vivo Mouse Model of Myeloid Leukemia. Benjamin Frisch*¹, John Ashton², Lianping Xing³, Michael Becker², Craig Jordan², Laura Calvi¹. ¹University of Rochester School of Medicine, USA, ²University of Rochester School of Medicine & Dentistry, USA, ³University of Rochester, USA

The mechanisms by which leukemic cells shape their bone microenvironment have currently been evaluated only in xenograft or irradiated models where non-hematopoietic cells are abnormal. Normal osteoblastic cells play a crucial role in hematopoiesis, thus we hypothesized that leukemia-dependent disruption of osteoblastic cells may contribute to impairment of normal hematopoiesis in acute leukemias. To define effects of leukemic cells on the bone microenvironment we employed an immunocompetent syngeneic murine model of acute myeloid leukemia in which leukemia develops in WT C57/B6 mice within 10 days. Leukemic mice had significant trabecular and cortical bone loss by micro-CT analysis (0.23 \pm 0.13 \pm 0.01 tibia trabecular BV/TV Normal(N) vs Leukemic(L) p<0.001 n=5 mice/group). In leukemic mice TRAP+ osteoclastic cells were mildly increased at day 6 but decreased at day 10 (d6: 50.8 \pm 3.6 vs 64.4 \pm 3.2; d10: 33.8 \pm 4.7 cells/ histological section N vs L p<0.05 n=5 mice/group) however the resorption marker CTX did not change. Treatment with zoledronic acid rescued leukemia-induced trabecular but not cortical bone loss (0.24 \pm 0.02 vs 0.10 \pm 0.01 cortical BV/TV N vs L p<0.001 n=4 mice/group)

and disease course was unaffected. Leukemic mice had severe reduction in osteocalcin (OC) mRNA in non-hematopoietic CD45- marrow cells (1290 \pm 124.7 vs 440.1 \pm 34 relative expression N vs L p<0.001 n=5 mice/group) even at early time points when the leukemia was only detectable in the marrow. Osteoprogenitor cells were also decreased (5.8 \pm 1.2 vs 0.9 \pm 0.3 CFU-OBs/1x10⁶ marrow cells N vs L p=0.005 n=7-10 mice/group). Immuno-staining indicated decreased endosteal-lining Osteopontin+ cells in leukemic mice. Leukemic mice had severe systemic decrease in OC levels (92.6 \pm 11.6 vs 25.9 \pm 4.4 ng/ml N vs L p<0.0001 n=8-12 mice/group). CCL-3 mRNA was increased 16 fold in CD45+ marrow cells from leukemic mice compared to normal controls (p<0.005 n=5 mice/group). CCL-3 was reported to increase osteoclastogenesis, inhibit osteoblastic function, and downregulate OC expression in multiple myeloma. We are currently investigating if CCL3 mediates the leukemia-dependent osteoblastic inhibition. These data demonstrate the impact of leukemic cells on the marrow microenvironment particularly osteoblasts. Therapeutic mitigation of leukemia-induced osteoblastic dysfunction may represent a novel approach to promote normal hematopoiesis in patients with myeloid neoplasms.

Localized Tumor Growth in Bone: Quantification of Tumor Burden, Bone Destruction, and Weight Bearing. Subba Chintalacheruvu*¹, Jeffrey Wolos², Elizabeth Misener¹, Christopher Bull¹, Li Li¹, Kellie Brune¹. ¹Covance Laboratories, Inc., USA, ²Scientific Consultant, USA

Metastatic bone disease is common in patients with multiple myeloma, breast, prostate, and lung cancer, and is a frequent cause of morbidity in advanced cancer patients. Metastatic bone tumors destroy bone and cause severe bone remodeling, leading to structural weakening and bone fractures in a large percentage of patients, and often resulting in severe bone pain.

We have implemented multiple imaging modalities to examine tumor growth, bone erosion, and pain in a nude rat model. A surgical defect was created in the tibia, exposing the marrow cavity. Luciferase-expressing MDA-MB-231 mammary tumor cells were injected into the exposed bone cavity. Rats inoculated with tumor cells were treated with either doxorubicin (3 mg/kg/week, iv) or risendronate (80 μ g/kg/day, ip). Animals were monitored weekly for tumor burden by optical imaging and for bone erosion by CT. In addition to clinical observations, pain in weight bearing paws was measured by an incapacitance machine. Compared to controls, rats treated with doxorubicin demonstrated a significant decrease in luminescence, indicating tumor growth inhibition (bone protection). Decreased luminescence correlated with sparing of the bone as measured by CT. In contrast, risendronate had limited effect on tumor growth, but preserved bone integrity. In both treatments, protection of bone was associated with normalization of weight bearing. This finding supports the premise that pain in metastatic bone cancer is due to bone loss (destruction) and remodeling. Weight-bearing data correlated directly with clinical observations. This model, leveraging multiple imaging modalities, enables longitudinal and quantitative assessment of tumor growth, bone loss, remodeling and weight-bearing in test animals and therefore provides a sensitive and robust screening tool to evaluate compounds for anti-tumor, bone-sparing and pain amelioration effects.

Longitudinal Monitoring of Osteolytic Bone Tumors with Integrated Optical-MicroCT Imaging. Jeff Meganck*, Ning Zhang, Heng Xu, Ed Lim, Stanley Liang, Victor Ninov, Jay Whalen, Chainey Kuo, Tammy Troy, Qing Feng, JaeBeom Kim, Brad Rice. Caliper Life Sciences, USA

Tumor metastases in the vicinity of bone tissue may cause osteolytic lesions and further exacerbate the pathological condition. Longitudinal *in vivo* bioluminescence imaging studies are commonly applied to detect the onset of metastases and monitor tumor burden over time due to the high sensitivity and simplicity of these methods. MicroCT has also been extensively used to monitor the bone loss that occurs with osteolytic lesions; these methods are accurate as long as the radiation dose is managed to minimize the impact on tumor biology. Because these two modalities monitor the pathological process from different perspectives, but need to be interpreted together, the purpose of this study is to explore the utility of a new integrated optical-MicroCT system to simultaneously track metastasis and osteolytic lesion development with the human mammary tumor MDA-MB231-luc2 cell line.

Systemic tumor metastases were established via intracardiac injection of MDA-MB231-luc2 cells into Nu/Nu mice. Injections were confirmed at Day 0 via bioluminescence imaging. Bioluminescence and MicroCT images were sequentially acquired at 1week intervals until animal death (4-8 weeks). For all bioluminescence images, acquisition occurred approximately 10 minutes after an intraperitoneal injection of luciferin. To visualize an overlay of the two images and simplify interpretation, a correction was applied to the optical images to account for inherent distortion in the lens used to acquire the optical images. Next, the MicroCT image was registered with the photograph. Finally, the skin surface of the mouse is extracted and input into 3D diffuse optical tomography algorithms to reconstruct the 3D optical signal. Preliminary data indicate that the 3D bioluminescence signal can be accurately overlaid with the MicroCT image. In addition, quantification of the bioluminescence signal shows increases that are consistent with exponential cell growth. Quantifying bone volume in the distal femur of the MicroCT image indicates a decrease in bone volume that

happens simultaneously with this increased cellular growth. This study established the utility of multimodality optical/microCT imaging within a single system for quantifying tumor metastases and bone degeneration in a complex pathological setting.

Partial Weightbearing for 21-Days and Low Dose High Energy Radiation Results In Cancellous and Cortical Bone Loss. Brandon Macias^{*1}, Florence Lima¹, Yasaman Shirazi-Fard¹, David Cunningham¹, Evelyn Yuen¹, Kaleigh Camp¹, Michael Wiggs¹, James D Fluckey¹, Elizabeth S Greene¹, Matthew Allen², Leslie A Braby¹, Harry Hogan¹, Susan Bloomfield¹. ¹Texas A&M University, USA, ²Indiana University School of Medicine, USA

Astronauts on exploration missions, such as to the moon, may experience whole body radiation doses of ~1.0 Gy per mission. No data exist testing radiation effects in combination with Lunar gravity levels of weightbearing (WB) which approximate 1/6th those of Earth. We hypothesized modeled galactic cosmic radiation during simulated Lunar gravity (G/6) would exacerbate bone loss seen during G/6 without radiation exposure. Female BALB/cByJ mice (4-mo-old, n=9/group) were randomly assigned to cage control (1G), 1/6th gravity (G/6), or 1/6th gravity+radiation (G/6+R) for a 21-d partial WB suspension protocol. Both 1G and G/6 mice were exposed to ²⁸Si (300MeV/u) under one of three conditions: 0.5Gy (Day-0), 0.17Gy (Day-0) or fractionated 0.5Gy dose (0.17Gy on Days 0, 2 and 7). Femoral cancellous architecture and cortical geometry were assessed by microCT; bone formation rate (BFR), mineral apposition rate (MAR) and mineralizing surface (MS/BS) were quantified by dynamic histomorphometry. Load to failure of the femoral neck (FN) was measured using an Instron 3345. Relative to the 1G group, distal femur BV/TV and Tb.N were significantly lower in the 1G+0.5Gy (-14%, -14%, respectively) and G/6+0.5Gy (-26%, -15%, respectively) groups at day 21. Cortical cross-sectional thickness, cross-sectional bone area, and polar moment of inertia were significantly lower in the G/6 groups compared to the 1G groups. Endocortical and periosteal bone formation rates were both lower in G/6 groups, with and without radiation exposure. FN load to failure, in 1G and G/6 groups receiving a single 0.17Gy dose were significantly lower (-33% and -17%, respectively) vs. SHAM controls. Interestingly, there was an intermediate decrement of load to failure in both the single and fractionated 0.5Gy 1G groups (-17% and -16%, respectively); however, the 0.5Gy single or fractionated ²⁸Si dose groups during G/6 show a higher load to failure (29% and 33%, respectively) vs. SHAM controls. Serum TRAP5b was significantly higher in all G/6 groups compared to 1G controls; no independent effect of ²⁸Si exposure was detected on this marker of osteoclast number. In support of our hypothesis, low dose high energy radiation exposure during partial WB conditions exacerbates cancellous bone loss. However, the higher load to failure of FN in partial WB mice receiving 0.5Gy exposures suggests that bone loss may not be consistent in all metaphyseal bone sites or may not accurately predict changes in bone strength.

RANK Ligand Regulation of Autophagy in Oral Squamous Cell Carcinoma Tumor Cells. Yuvaraj Sambandam^{*1}, Kumaran Sundaram², William Ries¹, Sakamuri Reddy². ¹Medical University of South Carolina, USA, ²Charles P. Darby Children's Research Institute, USA

Head and neck squamous cell carcinomas (HNSCC) are the most common malignant neoplasm estimated to be greater than 40,000 cases annually in the US. Oral squamous cell carcinoma (OSCC), which contributes to >40% of all HNSCC, is associated with mucosal surfaces of the oral cavity and oropharynx. We recently reported OSCC tumor invasion of bone and osteolysis in mice. Autophagy is a cellular self-consumption process for degradation of damaged/ dysfunctional cellular organelles, protein aggregates and plays an important role in malignant tumor progression and resistance to anti-cancer therapies. We showed OSCC cells express high levels of RANK ligand (RANKL), a potent osteolytic factor; however a functional role for RANKL in autophagy is unknown. We demonstrated RANK expression in OSCC tumor cells by confocal and histochemical analysis. Formation of autophagosomes involves autophagy proteins (Atg) and conversion of cytoplasmic microtubule-associated protein 1 light chain 3 (LC3-I) into the membrane form of LC3-II. We identified high levels of LC3-II expression in OSCC tumor cells (SCC-1, SCC-12 & SCC-14a) compared to normal human epithelial (RWPE-1) cells. Further, we showed increased levels of LC3-II and Atg5 expression in OSCC tumor specimens from human subjects and OSCC tumors on calvaria from athymic mice by immunohistochemistry. Interestingly, Western blot analysis of total cell lysates obtained from OSCC cells stimulated with RANKL (0-100 ng/ml) for 24 h demonstrated a dose dependent increase in LC3-II and RANKL expression which indicates an autoregulation of RANKL expression and autophagosome formation in OSCC cells. Thus our results implicate a novel function for RANK-RANKL signaling that may play an important role in autophagy modulation of OSCC tumor progression/osteolysis.

RNA-Dependent Protein Kinase is Essential for 2-Methoxyestradiol-Induced Autophagy in Osteosarcoma Cells. Caihong Yang, Kristen Shogren, Ribu Goyal, Michael Yaszemski, Avudaiappan Maran^{*}. Mayo Clinic College of Medicine, USA

Autophagy is a multi-step process that leads to sequestration and degradation of organelles and macromolecules within lysosomes. Autophagy, which regulates cell death in normal and pathophysiological conditions, has been implicated in tumor suppressor pathways. Osteosarcoma is the most common primary malignant bone tumor that affects children and young adults. Surgical resection and adjunctive chemotherapy are widely used in the treatment of osteosarcoma. Although surgery and chemotherapy have improved survival in the last decades, many patients diagnosed with osteosarcoma develop metastatic diseases. The anti-tumor compound 2-Methoxyestradiol (2-ME) triggers cell death through the induction of apoptosis in osteosarcoma cells, but not in normal osteoblasts. The goal of this study is to investigate whether autophagy plays a role in the anti-tumor effects of 2-ME in osteosarcoma cells. Our analysis of osteosarcoma cells using transmission electron microscopy shows that 2-ME treatment leads to the accumulation of autophagosomes. The results also show that 2-ME induces the conversion of the microtubule-associated protein LC3-I to LC3-II, a biochemical marker of autophagy that is correlated with the formation of autophagosomes. Furthermore, 2-ME does not induce accumulation of autophagosomes in osteosarcoma cells that stably express the dominant negative mutant RNA-dependent protein kinase (PKR) protein and are resistant to the anti-proliferative and anti-tumor effects of 2-ME. Thus, our study shows that 2-ME treatment induces autophagy in a PKR-dependent manner in human osteosarcoma cells, and that the induction of autophagy could lead to anti-tumor pathways in 2-ME-treated osteosarcoma cells. Taken together, these results demonstrate that treatment strategies that increase PKR expression and positively control autophagy could be useful in clinically controlling osteosarcoma growth in patients.

Selective Targeting of the Ubiquitin Ligase Cbl Reduces Receptor Tyrosine Kinases Signaling and Osteosarcoma Tumorigenesis. Nicolas Severe^{*1}, François-Xavier Dieudonne¹, Caroline Marty¹, Olivia Fromiguet¹, Pierre Marie². ¹INSERM U606 & University Paris Diderot, France, ²INSERM Unit 606 & University Paris Diderot, France

Receptor tyrosine kinases (RTKs) are cell surface transmembrane proteins responsible for intracellular signal transduction. Over-expression of RTKs are often associated to human cancers, resulting in tumor cell growth and metastasis. Although RTKs represent pivotal targets in approaches of cancer therapy, strategies using anti-RTKs are not optimally efficient in clinics. Ubiquitin ligase-dependent degradation downregulation of RTKs is a critical step for modulating their activity. We previously showed that the ubiquitin ligase c-Cbl positively controls mesenchymal cell differentiation into osteoblasts via negative regulation of RTKs. In this study, we hypothesized that genetic manipulation of c-Cbl might reduce RTK signaling and tumorigenesis in osteosarcoma cells. Western blot analyses showed that c-Cbl and Cbl-b were inversely expressed in various human and murine osteosarcoma cells, in line with the basal expression of RTKs in these cells. We overexpressed c-Cbl in human (U2OS) and murine (K7M2) osteosarcoma cells with wild type (WT) c-Cbl. c-Cbl overexpression slightly (50 %) reduced cell replication and markedly (80 %) induced cell apoptosis in both U2OS and K7M2 cells in vitro, as shown by BrdU, MTT, caspases activity and TUNEL analysis. These effects were associated with c-Cbl-induced downregulation of RTKs, indicating that selective targeting of Cbl can reduce RTK-dependent osteosarcoma cell growth and survival. Additionally, c-Cbl overexpression reduced U2OS cell migration and invasion, as shown by conventional assays. To investigate whether the negative effect of c-Cbl overexpression on cancer cells may translate in reduced tumorigenesis in vivo, murine K7M2 osteosarcoma cells were transduced with c-Cbl or control vector and transplanted intramuscularly in BALB/C mice. Analysis of tumor size showed that c-Cbl overexpression in K7M2 cells reduced tumor growth by 50 % after 3 weeks compared to control tumors (P<0.05). Overall, the results provide the first demonstration that targeted overexpression of c-Cbl in osteosarcoma cells reduces RTK expression, inhibits cell growth, promotes cell apoptosis and reduces cell migration and invasion in vitro. In vivo, this effect translates into reduced tumorigenesis in this aggressive type of cancer. This study provides the proof-of-concept that selective targeting of the ubiquitin ligase Cbl reduces RTK signalling and osteosarcoma tumorigenesis.

Serum 25-hydroxyvitamin D and Nuclear Grade in Patients with Ductal Carcinoma In Situ. Mercedes Gacad^{*1}, Nancy Greep¹, Deborah Cunningham¹, Jaime Shamoni², Myung-Shin Sim¹, Dave Hoon¹, Armando Giuliano¹, Frederick Singer¹. ¹John Wayne Cancer Institute, USA, ²Saint John's Health Center, USA

Epidemiologic studies suggest that vitamin D deficiency may play a role in the development and clinical course of invasive breast cancer. In this pilot study we examine the possibility that vitamin D deficiency may be a factor in the expression of ductal carcinoma in situ (DCIS), a non-obligate precursor of invasive breast carcinoma. We have evaluated serum 25-hydroxyvitamin D levels and tumor characteristics in 64 patients who had surgery for (DCIS). After informed consent blood was taken from patients prior to surgery between 2000 and 2010. The sera were stored at -80 degrees centigrade and subsequently evaluated in a batch assay at Heartland Assays utilizing the DiaSorin Liaison Assay. The mean serum 25-hydroxyvitamin D +/- SD was 26.5 +/- 11.5 ng/ml with a range of 4.2 - 66.7 ng/ml. While there is controversy in defining vitamin D sufficiency, we classified levels of <20 ng/ml as deficient, 20-30 ng/ml as insufficient and >30 ng/ml as sufficient. In the 64 patients 27% were classified as vitamin D deficient, 44% as insufficient and 29% as sufficient. Nuclear grade has been used to classify and predict the clinical course of DCIS. The nuclear grade of the patients lesions were classified as low, intermediate, or high. Using Student's T test we compared mean serum 25-hydroxyvitamin D levels in patients who had low grade to patients with intermediate and high grade nuclear scores and found that the low nuclear grade patients had higher serum 25-hydroxyvitamin D levels (n=11; mean +/- SD= 32.9 +/- 14.7 ng/ml) than intermediate grade patients (n=13; mean +/- SD= 24.0 +/- 9.7, p= 0.09) and high grade patients (n=40; Mean +/- SD= 25.5 +/- 10.7; p= 0.07) although the differences were not quite significant. An increase in sample size of the intermediate and high nuclear grade patients may provide stronger evidence of the effect of vitamin D deficiency on DCIS. Further analyses including Ki67 seem warranted to help determine whether vitamin D deficiency has an impact on cell replication in patients with DCIS

Disclosures: Mercedes Gacad, None.

Single Cytotoxic Agents Directly Cause Bone Loss due to Increased Osteoclastogenesis: Implications for Preventing Bone Loss in Cancer Patients. Julie Quach^{*1}, Maria Askmyr¹, Tanja Jovic¹, Kirby White¹, Emma Baker¹, Nicole Walsh², Louise Purton¹. ¹St. Vincent's Institute, Australia, ²St Vincent's Institute of Medical Research, Australia

Purpose: Reduced bone mass is one of the most common side effects occurring in long-term survivors of cancer therapies. Aside from osteolytic lesions occurring in response to some cancers, the bone loss is most commonly attributed to the use of corticosteroids as part of the anti-cancer (cytotoxic) treatment regime. In this study we sought to determine 1) the effects that common cytotoxic therapies have on bone in the absence of corticosteroids and 2) whether zoledronic acid (ZOL) could protect against cytotoxic therapy-induced bone loss. **Methods:** We treated cohorts of eight-week old male mice with three different cytotoxic therapies: 1) lethal total body irradiation (TBI); 2) lethal TBI with bone marrow transplantation (BMT) or 3) a single dose (150mg/kg) of the chemotherapy agent, 5-fluorouracil (5-FU). In a separate study we also investigated the effects of a single dose of ZOL (10µg/kg) injected 3 days prior to BMT. Bone parameters were compared to those of non-treated age-matched littermate controls. **Results:** All three cytotoxic treatments caused rapid, irreversible loss of trabecular bone compared to controls as assessed by µCT and histomorphometry (Figure A). In all three therapies this bone loss correlated with significant increases in the numbers and size of osteoclasts at 4 to 7 days post-treatment, and elevated osteoclast activity as shown by significantly increased levels of serum carboxy-terminal collagen-1. Increased mRNA expression of inflammatory cytokines, including TNFα, IL-1β and IL-6, was observed in F480+CD11b+ macrophages purified from BM after cytotoxic therapies by fluorescence-activated cell sorting (FACS). These inflammatory cytokines preceded elevated expression of RANK in osteoclast precursors and increased RANKL expression in FACS-purified osteoblastic cells (1). Treatment of mice with a single dose of ZOL prevented the bone loss that occurred in the BMT mouse model (Figure B). **Conclusions:** Bone loss occurs in response to a range of cytotoxic therapies independent of corticosteroid use. This is likely due to inflammation occurring in response to cytotoxic therapies, which in turn causes increased osteoclastogenesis. Furthermore, a single dose of ZOL prevented the bone loss observed after BMT. Collectively these studies suggest that blocking osteoclast activity prior to commencing cytotoxic therapies may prevent the long-term bone loss that occurs in cancer patients.

The Role of VEGF in the Progression of Human Osteosarcoma. Paul Daft^{*1}, Jennifer Paige-Robinson², Majd Zayzafoon³. ¹The University of Alabama At Birmingham, USA, ²University of Alabama-Birmingham, USA, ³University of Alabama at Birmingham, USA

Osteosarcoma is the most common primary bone tumor found in children and young adults. These malignant tumors are characterized by the production of tumor osteoid, and demonstrate aggressive local and distant metastasis. Angiogenesis is a complex process by which new blood vessels arise from the pre-existing vasculature. Most tumor types overexpress Vascular Endothelial Growth Factor (VEGF), directly correlating with regions of angiogenesis. We previously demonstrated the ability of Ca2+/Calmodulin kinase two alpha (CaMKIIα) to regulate the growth and metastasis of osteosarcoma in vivo. In order to determine whether the observed effects of CaMKIIα were due to its ability to regulate VEGF, expression we examined the role of VEGF in the growth of osteosarcoma. Here we show that the levels of VEGF gene expression are positively correlated with the in vitro growth and motility of different osteosarcoma cell lines. A two-fold increase in VEGF mRNA expression was observed in the more aggressive osteosarcoma cells when compared to the less aggressive cells. VEGF protein levels were measured using Enzyme-Linked Immunosorbent Assay, demonstrating a four-fold increase in VEGF protein secretion in the highly aggressive 143B cell line when compared to the less aggressive MG-63 cell line. Conditioned media from 143B cells resulted in increased tube formation in an endothelial cell tube formation assay when compared to MG-63 cells. In order to examine whether CaMKIIα regulates VEGF expression and secretion, we genetically inhibited CaMKIIα with shRNA, and pharmacologically with KN-93. Both MG-63 and 143B CaMKIIα deficient cells resulted in an 80% decrease of both VEGF gene expression and protein levels of its main transcription factor, hypoxia inducible factor one alpha (HIF-1α). In order to identify the signaling pathways by which VEGF controls the growth of osteosarcoma, we treated 143B cells with the VEGF inhibitor, CBO-P11. VEGF inhibition resulted in decreased survival of 143B cells, demonstrated by an 80% reduction in the levels of the phosphorylated pro-survival protein Akt (P-AKT), while increased cellular apoptosis was shown by an increase in the pro-apoptotic cleaved caspase-3. Taken together our data suggest that the ability of CaMKIIα to control VEGF expression and secretion may be critical for the growth of human osteosarcoma.

The Skeletal Effects of the Tyrosine Kinase Inhibitor Nilotinib. Susannah O'Sullivan^{*}, Jian-Ming Lin, Maureen Watson, Karen Callon, Dorit Naot, Pak Cheung Tong, Anne Horne, Opetia Aati, Fran Porteous, Greg Gamble, Jillian Cornish, Peter Browett, Andrew Grey. University of Auckland, New Zealand

Nilotinib is a tyrosine kinase inhibitor (TKI) developed to manage imatinib-resistance in patients with chronic myeloid leukaemia (CML). It inhibits similar molecular targets to imatinib, but is a significantly more potent inhibitor of Bcr-Abl. Nilotinib exhibits off-target effects in other tissues, and of relevance to bone metabolism, hypophosphataemia has been reported in up to 30% of patients receiving nilotinib. We have assessed the effects of nilotinib on bone cells in vitro and on bone metabolism in patients receiving nilotinib for treatment of CML. We firstly investigated the effects of nilotinib on proliferating and differentiating osteoblastic cells, and on osteoclastogenesis in murine bone marrow cultures and RAW264.7 cells. Nilotinib potently inhibited osteoblast proliferation (0.01-1µM), through inhibition of the platelet-derived growth factor (PDGFR). There was a biphasic effect on osteoblast differentiation such that it was reduced by lower concentrations of nilotinib (0.1-0.5µM), with no effect at higher concentrations (1µM). Nilotinib also potently inhibited osteoclastogenesis, predominantly by stromal-cell dependent mechanisms. Thus, nilotinib decreased osteoclast development in murine bone marrow cultures, but did not affect osteoclastogenesis in RAW264.7 cells. Nilotinib treatment of osteoblastic cells increased expression and secretion of OPG and decreased expression of RANKL. In 10 patients receiving nilotinib, levels of bone

turnover markers were in the low-normal range, despite secondary hyperparathyroidism, findings that are similar to those in patients treated with imatinib. Bone density tended to be higher than age and gender-matched normal values. These data suggest that nilotinib may have important effects on bone metabolism. Prospective studies should be conducted to determine the long-term effects of nilotinib on bone density and calcium metabolism.

Bone-seeking Labels as Markers for Bone Formation in Sclerostin Knockout Mice. Nicole Collette^{*1}, Darren Hillegonds², Kenneth Turteltaub¹, Gabriela Loots³. ¹Lawrence Livermore National Laboratory, USA, ²Lawrence Livermore National Library, USA, ³LLNLUC Merced, USA

The gold standard approach for evaluating bone turnover rates is dynamic histomorphometry, a laborious approach with limited clinical application. Calcium (Ca) tracer kinetic studies can be used to determine bone formation and resorption rates. To validate isotopic approaches to bone metabolism we used ⁴¹Ca as a tracer to measure the net bone calcium balance in animal models of high (Sost KO) and low (Lrp5 KO) bone mass. Unlike other stable Ca isotopes, ⁴¹Ca is radiologically benign, has low natural abundance, and a small dose remains distinctly quantifiable in body fluids and excreta for many years. To determine the metabolic profile of ⁴¹Ca in mice, we measured ⁴¹Ca/Ca after an IP dose and found that the resorbing bone is the dominant source of tracer, 21 days (d) post dosing (>200 days in humans). At d28 post dosing the total tracer accumulation in tibia and femur (1.60.8% of administered dose) was >1600X higher than that in blood, heart and kidney, confirming high bone Ca retention and fast soft tissue elimination. To demonstrate the potential of ⁴¹Ca as an assay of dynamic bone turnover we collected weekly urine from 5 adult males for up to 10 weeks from three distinct genetic backgrounds: wildtype (B6; reference bone metabolism), Lrp5 KO (low anabolic bone activity/osteopenic) and Sost-/- mice (high anabolic bone activity/high bone mass). All measurements of ⁴¹Ca/Ca were obtained on the Center for Accelerator Mass Spectrometry's (AMS) 10MV FN-class tandem electrostatic AMS system at LLNL, and were corrected for instrumental drift and analytical ⁴¹Ca backgrounds with concurrently processed and analyzed isotope ratio standards and ⁴¹Ca-free blanks. Whereas we observed a significant reduction of ⁴¹Ca/Ca ratio excretion in Sost KO mice at every time point up to d35, the most dramatic reduction was at 7-days post injection. This 40% reduction in urine ⁴¹Ca/Ca (p<0.01 versus WT) in Sost KO mice suggests that high bone formation rates is reflected by a significantly higher initial uptake of ⁴¹Ca. Therefore our preliminary data suggests that AMS ⁴¹Ca/Ca can be used to distinguish mice with different bone turnover rates. The successful implementation of ⁴¹Ca assays in genetic screens and in patients with bone disease could have wide benefits, including improved risk assessment, monitoring treatment, and early detection.

Classical Osteogenesis Imperfecta is an autosomal dominant disorder caused by mutations in *COL1A1* and *COL1A2*. Affected individuals have increased susceptibility to fracture. The Brlt mouse is heterozygous for a *Col1a1* G349C mutation and reproduces the moderately severe OI phenotype. We previously demonstrated that adaptations in Brlt femoral strength and stiffness occur through changes in material properties, with potential alterations in bone mineral composition. To investigate the role of mineral and organic components in OI bone fragility, we analyzed Brlt femurs by qBEI and FTIR and quantitated expression of genes involved in matrix mineralization. Femurs from 2- and 6-month Brlt mice show BMDD changes characteristic of OI, with significantly higher matrix mineralization of both cancellous metaphyseal and mid-diaphyseal cortical bone than wt littermates. In cancellous and cortical bone, the typical mineralization density (CaPeak) was increased ~2%. Brlt cortical bone mineral heterogeneity (CaWidth) decreased at 6 months vs 2 months (~ -8%). At six months of age, Brlt CaWidth was lower (~ -11%) than wild-type femurs. Consistent with BMDD, FTIR on 2-month Brlt femurs yielded a trend toward increased mineral/matrix index in trabecular bone.

In RNA from whole femurs of Brlt vs WT 2-month mice, measurement of transcripts of late osteoblastic and osteocyte markers by real time RT-PCR revealed significant increases of *Dmp1* (1.8x) and *Phex* (1.3x) expression. On Osteogenesis PCR arrays, *Bmp2* transcripts were decreased 2.4x, while *Sost* expression was unchanged in Brlt vs WT femurs. During differentiation of newborn calvarial osteoblasts in culture, the increase in *Dmp1* and *Phex* transcripts seen in WT cells was delayed several days in Brlt. Transcripts for *Sost* and *Bmp2* were decreased over 3-fold in newborn Brlt vs WT calvarial osteoblasts throughout in vitro differentiation. Furthermore, alizarin red staining detected increased deposition of mineral by Brlt vs WT cultured osteoblasts, with and without BMP2 treatment. Preliminary cell-matrix exchange experiments

support a contribution of matrix composition to delayed Brlt cellular development, because expression of *Dmp1*, *Phex*, *Sost* and *Bmp2* is decreased in both WT and Brlt cells grown on Brlt matrix. Our data suggest that OI bone hypermineralization may be caused in part by differentiation defects of osteoblasts or osteocytes which alter expression of noncollagenous proteins involved in control of mineralization.

Generation of iPS Cells from Fibroblasts and Peripheral Blood Cells of CMD Patients. I-Ping Chen^{*1}, Xiaonan Xin¹, Mary-Louise Stover¹, Hui-Chen Chan¹, Keiichi Fukuda², Noemi Fusaki³, Akihiro Iida³, Mamoru Hasegawa³, Ernst Reichenberger¹, Alexander Lichter¹. ¹University of Connecticut Health Center, USA, ²Keio University School of Medicine, Japan, ³DNAVEC Corporation, Japan

Craniofacial dysplasia (CMD) is a monogenic human disorder characterized by hyperostosis of craniofacial bones concurrent with abnormal shape of long bones. Its lifelong progression leads to life-threatening consequences in some patients. To date, there is no treatment other than repetitive surgery. Mutations for autosomal dominant CMD have been identified in the ANK gene (ANKH). We previously revealed osteoclast (OC) defects in a knock-in (KI) mouse model (AnkKI/KI mice) carrying a CMD-causing Ank mutation. Our long-term goal is to use the patient-specific inducible pluripotent stem cells (iPSCs) to study the mutational effects of ANKH on CMD with a focus on OCs. We have reported the reprogramming of somatic cells into human iPSCs using retroviral transduction of OCT3/4, SOX2, KLF4, c-MYC and Lin28. The retroviral method did not fully reprogram CMD fibroblasts to iPSCs and some retrovirally derived-iPSCs showed incomplete vector silencing which may hinder the differentiation process. Here, we show the derivation of iPSCs from skin fibroblasts and from peripheral blood mononuclear cells (PBMCs) of CMD patients and healthy controls. We used a floxed lentiviral "stem cell cassette" (STEMCCA) combining OCT3/4, SOX2, KLF4, c-MYC in a single polycistronic vector or four separate Sendai virus vectors encoding OCT3/4, SOX2, KLF4, c-MYC. The STEMCCA allows simultaneous transfer of reprogramming factors to achieve higher reprogramming efficiency and produce transgene free iPSCs upon exposure to Cre recombinase. The Sendai virus, a cytoplasmic RNA vector, can produce iPSCs which are free of vector integration into chromosomes. The derived iPSCs have similar morphology to human embryonic stem cells (hESCs) and express pluripotency-related factors shown by gene expression analysis and immunocytochemistry. Assays for testing differentiation capability of these iPSCs by embryoid body and teratoma formation are in progress. We have derived OC-like cells from hESCs using the hESCs-OP9 cocultures. This protocol results in the formation of multinucleated cells which were TRAP positive, with actin belts at the periphery and capable of resorbing calcium-phosphate coated discs. Next, we will apply the same method to differentiate OCs from iPSCs. We expect this tool will allow us to study the molecular mechanisms, by which ANKH mutations cause impaired osteoclastogenesis in human CMD.

MO0160

The High Bone Mass Phenotype is Characterised by Increased Subcutaneous and Intra-muscular Fat, but Decreased Marrow Fat. Celia Gregson^{*1}, Adrian Sayers¹, Victor Lazar², Sue Steel², Joern Rittweger³, Jon Tobias⁴. ¹University of Bristol, United Kingdom, ²Hull Royal Infirmary, United Kingdom, ³Institute of Aerospace Medicine, German Aerospace Center, Germany, ⁴Musculoskeletal Research Unit, University of Bristol, United Kingdom

In our unique case-control study of High Bone Mass (HBM), cases have previously been found to have greater total body fat mass, reduced exercise tolerance and lower platelet levels compared to controls. To explore inter-relationships between fat, bone and bone marrow suggested by these results, we aimed to characterise adipose tissue distribution in HBM individuals using a novel application of tibial pQCT.

196 HBM index cases were identified by screening a hospital DXA database (n=105,333). HBM was defined as a) L1 Z-score of 3.2 or more and total hip Z-score of 1.2 or more, or b) total hip Z-score 3.2 or more. Cases with significant osteoarthritis and/or other causes of raised BMD were excluded. Relatives and spouses were recruited, in whom HBM affection status was defined as L1 Z plus total hip Z-scores of 3.2 or more. Controls comprised unaffected relatives and spouses. pQCT was performed at the tibial diaphysis (66% of its length), using a Stratec XCT2000L. Cases were compared with controls using linear regression, adjusting for age, gender, height and menopausal status.

98 HBM cases (71 index, 27 affected relatives) & 65 controls (43 unaffected relatives, 22 spouses) underwent pQCT; 81.6% & 50.8% were female, mean age 58 & 55 years, height 167 & 171 cm, weight 86 & 82 kg respectively; all Caucasian. As shown in the table below, compared with controls, HBM cases had 22% more intra-muscular fat and considerably greater calf muscle and subcutaneous fat areas; however, marrow cavity area was reduced at the expense of marrow fat rather than other X-ray attenuating tissue (such as haemopoietic tissue). Interestingly, after

further adjustment for body weight, HBM cases still had greater intra-muscular fat than controls (mean difference 1.79 [0.22, 3.37]cm², p=0.025) and marrow results remained unchanged.

In summary, HBM individuals have greater subcutaneous and intra-muscular fat tissue, whilst in contrast marrow fat is reduced, possibly reflecting a mechanism to maintain haemopoietic function within the reduced marrow cavity of HBM long bones. Whether increased intra-muscular fat in HBM cases has a detrimental effect on muscle function, so explaining the reduction in exercise tolerance previously observed amongst HBM cases, remains to be determined.

Table: Calf pQCT measures taken from the 66% tibia in High Bone Mass cases and family controls; all values adjusted for age, gender, height & menopausal status amongst women

66% TIBIA	HBM Cases	Controls	Adj. p
Area measures (cm ²)	(n=98) [95% CI]	(n=65) [95% CI]	value
Total bone area	7.1 (6.8, 7.4)	6.8 (6.6, 7.1)	0.05
Calf muscle	84.1 (79.7, 88.5)	79.9 (76.1, 83.8)	0.02
Subcutaneous fat	33.2 (27.6, 38.8)	28.4 (23.4, 33.3)	0.03
Intra-muscular fat	19.1 (16.7, 21.5)	15.8 (13.7, 17.9)	<0.01
Marrow cavity	2.15 (1.89, 2.41)	2.40 (2.17, 2.63)	0.02
Haemopoietic tissue	1.08 (0.92, 1.25)	1.15 (1.01, 1.29)	0.30
Marrow fat	1.07 (0.90, 1.24)	1.25 (1.09, 1.40)	<0.01

Mean areas measured in cm². Adjusted linear regression p value shown

HBM: High Bone Mass, CI: Confidence Interval

All marrow cavity tissue with density between 200 and -250 mg/cm³ was measured. Haemopoietic tissue defined as that unfiltered by Stratec F07 fat filter, whilst marrow fat defined as that filtered by F07 fat filter.

MO0161

Assessment of Bone Associated Pain in the Aged Osteomalacic Rat. Darshana Durup¹, Jesper Ryhl Plovst¹, Erik Frandsen², Solveig Petersen², Lars Thorbjørn Jensen², Niklas Jørgensen³, Anne-Marie Heegaard^{1*}.
¹Faculty of Pharmaceutical Sciences, University of Copenhagen, Denmark, ²Glostrup Hospital, Denmark, ³Copenhagen University Hospital Glostrup, Denmark

Background: Adult patients with severe vitamin D deficiency, where the mineralization of the bone is affected (osteomalacia) often suffer from musculoskeletal pain; however, the underlying mechanisms of bone pain are unknown.

The aim of this project was to develop an animal model for osteomalacia in mature rats and to quantify bone associated pressure pain threshold.

Methods: 6 months old Sprague Dawley female rats were fed either a vitamin D (vit D) deficient diet (n=25) or a control diet (n=25). After 4 months on the vit D deficient diet the phosphorus content of the diet was decreased to 0.16% (Ca:P ratio 5.85). Blood samples were taken monthly and 25-hydroxy vitamin D (25(OH)D), parathyroid hormone (PTH), total calcium, phosphorus, magnesium, albumin and alkaline phosphatase were measured. Bone associated pressure threshold was measured with the Randall Selitto test at 7 different bone-near sites. Acute pain threshold was measured by the hot plate test and von Frey filaments. Degree of calcine label and osteoid was determined by histology. The experiment was approved by the Danish Animal Experiments Inspectorate.

Results: After 4 months on a vit D deficient diet, the 10 months old rats were vitamin D deficient: 25(OH)D serum levels were 57.7 4.35 nM and 15.1 3.37 nM in rats receiving control diet and vit D deficient diet, respectively. However, no effect of the diet was observed on any of the other biochemical markers measured and no increase in osteoid was found. Also, there was no difference among the two groups of rats in any of the pain-related tests. The phosphorus (P) content in the diet was hereafter decreased to 0.16%, which, after 1 month, resulted in an increased amount of osteoid. Compared to the aged-matched rats on the control diet, the rats on the low vit D and P diet had decreased serum levels of 25(OH)D (92.1 6.26 nM vs 11.8 1.8 nM); phosphorus (1.4 0.16 mM vs. 0.53 0.12 mM), and PTH (445.4 78.7 pg/ml vs. 58.5 11.2 pg/ml). Pressure pain thresholds measured by Randall Selitto were significantly higher in the vit D and P deficient rats but no difference was found in the hot plate test and the von Frey test

Conclusion: A vitamin D deficiency diet in six-month-old female rats was not sufficient to induce osteomalacia and had no effect on pain-related behaviors. However, an additional decrease of phosphorus content lead to the development of osteomalacia. Surprisingly the osteomalacic rats had higher bone associated pressure pain threshold

MO0162

How High Dose(s) of Oral Vitamin D3 Can Correct Insufficiency in a Non Supplemented Rheumatologic Population? Olivier Lamy¹, Didier Hans^{2*}, Marc-Antoine Krieg³, Jean Dudler¹, Berengere Aubry-rozier³, Delphine Stoll¹. ¹CHUV, Switzerland, ²Lausanne University Hospital, Switzerland, ³University Hospital, Switzerland

Introduction

700 to 1000 UI Vitamin D/day prevent 20% of fall and fracture. Higher dosage could prevent other health problems, such as immune diseases. Adherence to oral daily vitamin D supplementation is low. There is no guideline on how to supplement patients with rheumatic diseases. We evaluated if 1-2 dose(s) of 300'000 UI oral vitamin D3 was enough to reach an optimal level of 25-OH vitamin D in late winter in patients with insufficiency.

Methods

During November 2009 (M0) patients attending our Rheumatology Outpatient Clinic had a blood test to measure 25-OH vitamin D. Results were classified as: deficiency <10µg/l, insufficiency 10µg/l to 30µg/l and normal >30µg/l. Patients on daily oral vitamin D3 or who received a single high dose of vitamin D3 in the last 6 months and patients with deficiency or normal results were excluded.

Patients included received a single dose of 300'000 IU of oral vitamin D3 and were asked to come back for a blood test for 25-OH vitamin D after 3 (M3) and 6 months (M6). If they were still insufficient at M3, they received a second high dose of 300'000 IU of oral vitamin D3.

Results

292 patients had their level of 25-OH vitamin D determined at M0. 141 patients (70% women) had vitamin D insufficiency (18.5µg/l (10.2-29.1)) and received a prescription for a single dose of 300'000 IU of oral vitamin D3. Men and women were not statistically different in term of age and 25-OH vitamin D level at M0.

124/141 (88%) patients had a blood test at M3. 2/124 (2%) had deficiency (8.1µg/l (7.5-8.7)), 50/124 (40%) normal results (36.7µg/l (30.5-56.5)). 58% (72/124) were insufficient (23.6µg/l (13.8-29.8)) and received a second prescription for 300'000 IU of oral vitamin D3.

Of the 50/124 patients who had normal results at M3 and did not receive a second prescription, 36 (72%) had a test at M6. 47% (17/36) had normal results (34.8µg/l (30.3-42.8)), 53% (19/36) were insufficient (25.6µg/l (15.2-29.9)).

Out of the 54/72 (75%) patients who received a second prescription, 28/54 (52%) had insufficiency (23.2µg/l (12.8-28.7)) and 26/54 (48%) had normal results (33.8µg/l (30.0-43.7)) at M6.

(figure 1)

Discussion

This real life study has shown that one or two oral bolus of 300'000 IU of vitamin D3 in autumn and winter was not enough to completely correct hypovitaminosis D but was a good way of preventing a nadir of 25-OH vitamin D usually observed in spring in a Swiss rheumatologic population.

Identification of Susceptibility Loci to Giant Cell Tumor and Paget's Disease of Bone. Daniela Merlotti¹*, Fernando Gianfrancesco², Domenico Rendina³, Teresa Esposito², Alessandra Mingione², Daniela Formicola², Riccardo Muscarello³, Pasquale Strazzullo³, Ranuccio Nuti¹, Luigi Gennari¹. ¹University of Siena, Italy, ²Institute of Genetics & Biophysics, CNR, Italy, ³Department of Clinical & Experimental Medicine, Federico II University of Naples, Italy

Paget's disease of bone (PDB) is a common skeletal disorder with a strong genetic component. Recently, mutations in SQSTM1 gene have been identified in up to 10% and 40% of sporadic and familial PDB cases, respectively. Even though patients with SQSTM1 mutations generally show an increased disease severity than SQSTM1-negative patients, we recently identified SQSTM1-negative families with a severe phenotype and the presence of peculiar phenotypic characteristics, including the occurrence of giant cell tumor (GCT). This complication may be multifocal and aggressive, leading to increased morbidity and mortality of patients. Patients with extensive, recurrent, and/or biologically more aggressive tumors may require wide excision, and generally do not respond to bisphosphonates or other antiresorptive agents commonly in use to treat classical PDB. Importantly, both familial clustering and the evidence that GCT occurs with higher prevalence in PDB patients from Campania (accounting for up to 50% of all GCT cases) even if they have lived for several years in other countries strongly suggests the hypothesis of a genetic factor in the etiology of this complication. In this study we performed a genome-wide scan in a large kindred with PDB and GCT. All the 14 affected patients had polyostotic PDB (with a mean of 5.72.6 affected skeletal sites, range 2-12) with a preferential localization of axial bones, and 4 of them had GCT. We used Affymetrix Genome-Wide Human SNP Array 6.0, containing more than 1.8 million genetic markers, including more than 906,600 single nucleotide polymorphisms (SNPs) and more than 946,000 probes for the detection of copy number variation (CNV). Parametric and non-parametric analysis identified 2 major regions on chromosomes 8 and 10 (Zmax=6.2; LODmax=2.2), while an additional region was identified on chromosome 20 by parametric analysis (LOD=2.3). Interestingly the linkage peak on chromosome 10 is just downstream from a new candidate region within the OPTN gene, recently evidenced in a large genome-wide association study on PDB, while the peak on chromosome 8 is next to the TNFRSF11B gene, encoding osteoprotegerin. Whilst further work will be required to identify the functional variants as well as the pathogenic mechanisms, the present study has provided new insights into the genetic cause of GCT in PDB.

MO0164

A Prospective Study of Dietary Calcium and the Risk for Primary Hyperparathyroidism. Gary Curhan¹, Julie Paik¹*, Eric Taylor². ¹Brigham & Women's Hospital, USA, ²Maine Medical Center, USA

Purpose: Primary hyperparathyroidism (PHPT) affects at least 2% of postmenopausal women and is associated with morbidities and costly sequelae, including decreased bone mineral density, fractures, and kidney stones. However, little is known about risk factors for PHPT. Low calcium diets in humans raise PTH level and in animals produce higher parathyroid hormone (PTH) level and cellular proliferation in the parathyroid gland. However, no study to date has prospectively examined the association between dietary calcium intake and risk for PHPT in women.

Methods: We conducted a prospective study of the relation between dietary calcium intake and the risk of primary hyperparathyroidism in a cohort of 60,502 women, 37-65 years of age in 1984 with no history of PHPT, participating in the Nurses' Health Study. Dietary calcium was measured by a semiquantitative food-frequency questionnaire in 1984, 1986, 1990, 1994, 1998, 2002, and 2006. Supplemental calcium use was also measured during those years. All cases of PHPT were confirmed by medical record review. Between 1984 and 2008, 281 cases of PHPT were documented.

Results: After adjustment for age, dietary calcium intake was inversely associated with PHPT risk; the relative risk of PHPT for women in the highest compared with the lowest quintile group for calcium intake was 0.57 (95% confidence interval, 0.41 to 0.88, p for trend < 0.01). After further adjustment for other potential risk factors, including calcium supplement use, body mass index, alcohol consumption, smoking status, caffeine intake, dietary intakes of phosphorus, vitamin D, protein, vitamin A, and magnesium, the relative risk of PHPT for women in the highest compared with the lowest quintile group for dietary calcium intake was 0.52 (95% confidence interval 0.30 to 0.91).

Conclusions: A low dietary calcium intake increases the risk of developing primary hyperparathyroidism in women.

Disclosures: Julie Paik, None.

MO0165

Aryl Hydrocarbon Receptor Interacting Protein (AIP) Gene Mutations in a Subset of Sporadic Parathyroid Adenomas. Filomena Cetani¹*, Simona Borsari², Elena Pardi², Elena Paltrinieri², Benedetta Raspini², Federica Saponaro², Antonella Picone², Piero Berti³, Paolo Miccoli³, Claudio Marcocci¹. ¹University of Pisa, Italy, ²University of Pisa Department of Endocrinology & Metabolism, Italy, ³University of Pisa Department of Surgery, Italy

Primary hyperparathyroidism (PHPT) is caused by excessive, incompletely regulated secretion of parathyroid hormone (PTH) from one or more of the four parathyroid glands. It is due to a benign parathyroid adenoma in 80% of cases and multiglandular involvement in 15-20% of cases. The molecular events involved in the formation of parathyroid lesions are poorly understood. Two genes, cyclin D1 (CCND1) and MEN1, have been established as having major roles in parathyroid tumorigenesis, but account for a rather small number of cases. Recently, Vierimaa *et al.* reported that inactivating mutations of the gene encoding aryl hydrocarbon receptor interacting protein (AIP) on chromosome 11q13.3 occurred in patients with pituitary tumors in the familial and sporadic settings. To address the potential role of AIP mutations in the pathogenesis of sporadic parathyroid adenomas, we undertook a genetic screening of AIP gene in a large cohort of apparently sporadic parathyroid tumors (n=100). Coding regions and splice junctions of AIP gene from somatic DNA were sequenced for mutations. Mutation screening revealed an AIP mutation in two apparently unrelated patients, a heterozygous missense mutation in exon 6 (c.911G>A) that brings to a substitution of an arginine to a glutamine residue at codon 304 (R304Q). This codon, situated in a CpG islet, is considered a mutational hotspot, R304X being also described. Unexpectedly this mutation was also present in the germline cells in both cases.

Pathogenic role of R304Q mutation is supported by the presence of this mutation in many familial isolated pituitary adenomas (FIPA) families, as well as in sporadic pituitary GH-secreting adenomas and is not present in a large group of healthy subjects.

In conclusion, in this study we identified a well-known mutation of AIP gene in a minority of sporadic parathyroid adenomas (2%).

Case Report: Severe Renal Osteodystrophy in a 40 Year Old Female with End Stage Renal Disease. Maria Princess Landicho¹*, Thelma Crisostomo¹, Pauline Camacho². ¹Makati Medical Center, Philippines, ²Loyola University of Chicago, USA

Background: Metabolic bone changes from chronic kidney disease can have a wide range of presentation. Clinical presentation can be mild or at the extreme end is severe renal osteodystrophy which can present with osteoporosis, osteitis fibrosa cystica, bone resorption, soft tissue and vascular calcification, and the rarely seen uremic leontiasis ossea. This patient illustrates dramatic bony deformities from severe renal osteodystrophy.

Case: We report a case of the most severe form of renal osteodystrophy in a 40 year old female with a 7 year history of undertreated ESRD due to glomerulonephritis. At age 38, she experienced occasional gum bleeding with increase in palate size. At 39, the gum bleeding became frequent, her palate expanded gradually, the gaps in-between her teeth became wider, and she started to have difficulty in eating resulting in weight loss. Her height decreased as she developed a pigeon breast due to compression deformity of the spine. Her Intact PTH then was at 4,444 pg/ml, with normal ionized calcium (1.18 meq/L), increased phosphorus (8 mg/dl) and sestamibi scan showed right parathyroid mass. BMD with T scores of -6.4 spine, -5.2 hip, and -6.9 wrist. She was offered parathyroidectomy but refused.

She was seen in the endocrine clinic at age 40. At this time, she had lost 20 cms in height, 25 kgs in weight. Her palate has expanded downward almost occupying $\frac{1}{4}$ of her oral cavity. Likewise, her maxilla and mandible had expanded forward and downward with looks similar to leontine facies. Her AV fistula was tortuous, severely calcified and enlarged. Her PTH was at 1,508 pg/ml, with normal ionized calcium (1.18 meq/L), more elevated phosphorus (8.54 mg/dl), high alkaline phosphatase (2,604 mg/dl) and creatinine (7.9mg/dl), low vitamin D (12.5 mg/dl). Skeletal survey showed skull with granular deossification, lamina dura of the teeth is gone, massive thickening of the facial bone, C5 and C6 with brown tumors, compression deformity with rugger-jersey spine of thoracolumbar, subperiosteal erosions of bilateral humerus, radius, ulna, and phalangeal bones. Extensive calcific deposits in the soft tissue of the left arm and calcified interdigital vessels. MRI showed generalized thickening of the calvarium, upper and lower jaws, with loss of the lamina propria around the roots of the teeth. Neck ultrasound showed 4 parathyroid masses. Parathyroid scintigraphy showed right parathyroid adenoma.

A multi disciplinary team of doctors discussed approach of treatment. The general consensus was she is high risk for surgery due to poor nutritional status and high anesthesia risk (Mallampati 4). The decision was to defer surgery, treat her with cinacalcet, paricalcitol, sevelamer and improve her nutritional status in preparation for surgery. However, intake of medications was erratic due to economic issues. The patient expired from hemorrhage from her palatal mass.

Conclusion: This case describes a classic severe case of renal osteodystrophy with a marked and progressive growth in the palate and severe bone deformities.

MO0167

Cushing's Disease-Induced Osteoporosis: Evaluation at Diagnosis and Two, Five and Ten Years after Hypercortisolism Resolution. Wallace Holanda-Miranda^{*1}, Sergio Luchini Batista², Aline Ramos¹, Paula Elias¹, Francisco Pereira³, Margaret Castro¹, Avrton Moreira¹, Francisco Jose De Paula⁴. ¹School of Medicine of Ribeirao Preto, USP, Brazil, ²School of Medicine of Ribeirao Preto, University of Sao Paulo, Brazil, ³University of Sergipe, School of Medicine of Sergipe, Brazil, ⁴School of Medicine of Ribeirao Preto - USP, Brazil

Introduction: Glucocorticoid-induced osteoporosis (GIO) is considered to be the most important cause of secondary osteoporosis. Clinical guidelines have clearly established effective strategies to prevent and treat GIO. However, these protocols do not include patients harboring endogenous hypercortisolism, who usually have a hormonal profile distinct from that observed in patients with exogenous hypercortisolism. The aim of the present transversal study was to evaluate bone mineral density (BMD) and bone remodeling in Cushing's disease at diagnosis and in patients after different periods of hypercortisolism resolution. **Subjects and methods:** We studied 11 control individuals (C), 17 patients with Cushing's disease at diagnosis (D) and 28 post-treatment patients with Cushing's disease, divided into 3 subgroups: 2 years (PT2, n=8), 5 years (PT5, n=10) and 10 years (PT10, n=10) after successful treatment, respectively. All groups were matched by age and body mass index. All patients were submitted to the determination of Bone Mineral Density (BMD) in lumbar spine, femoral neck and total hip. The C and D groups were submitted to bone remodeling evaluation [osteocalcin (OC) and deoxypyridinoline (DPD)]. **Results:** Patients at the diagnosis of Cushing syndrome presented significantly lower lumbar spine (C = 0.955 \pm 0.101 vs D = 0.877 \pm 0.121 g/cm², P < 0.05) and femoral neck (C = 0.887 \pm 0.097 vs D = 0.789 \pm 0.107 g/cm², P < 0.05) BMD than controls. Serum OC levels were markedly decreased in these patients (C = 41.1 \pm 26.1 vs D = 4.0 \pm 4.2 ng/ml P < 0.0001), whereas urinary DPD levels were similar to control (C = 5.4 \pm 4.3 vs D = 6.4 \pm 2.5 nmol/mmol of creatinine). At long term, cure of endogenous hypercortisolism induced an improvement in BMD Z-score in lumbar spine (Lumbar spine Z-score: 2 years = -1.13 \pm 0.67 SD, 5 years = -1.25 \pm 0.83 SD and 10 years = -0.15 \pm 1.41 SD). **Discussion:** Our data show that Cushing's disease has a great impact on BMD, which is rescued by successful treatment (after 10 years). Reduced bone formation is the main mechanism involved in bone loss associated with Cushing's disease. The study encourages further investigation to determine fracture risk and the beneficial effect of preventive therapy in Cushing's disease-induced osteoporosis. **Financial support:** National Council for Scientific and Technological Development (CNPq), Brazil.

MO0168

Effect of Long Term Stable Hypercalcemia on Kidney Function in the Elderly. Sharon Lahiri¹, Nayana Parikh¹, Sudhaker Rao¹, Manjari Devidi^{*2}. ¹Henry Ford Hospital, USA, ²St. Joseph Hospital, USA

Background: Age is a well known risk factor for declining renal function, but the additional effect of stable hypercalcemia due to primary hyperparathyroidism (PHPT) is unknown. It is argued that elderly patients are less likely to have parathyroidectomy (PTX) because of concern about surgical risk, but very little is known about the effect of untreated PHPT in this group of patients. Accordingly, we retrospectively reviewed the effect of chronic stable moderate to severe hypercalcemia on renal function as assessed by serum creatinine (Cr) in the elderly.

Materials & Methods: Twelve patients, all women, >75 years (mean age of 84 \pm 5 years) and with a disease duration of >10 years were followed for 11-21 years. Serum calcium (Ca; adjusted for albumin), ionized Ca (iCa), PTH, and Cr were measured periodically to monitor the disease. Three of the 12 patients had previous failed surgeries (1-3 PTXs) in expert hands and refused further surgery. Nine women did not want opt for PTX believing that they were "well and did not need intervention" despite repeated urging. None of the 12 had kidney stones or skeletal fractures despite moderate to severe hypercalcemia and low bone density.

Results: The mean serum Ca over the mean follow-up of 17 \pm 4 years was 11.2 \pm 0.71 mg/dl, iCa was 1.47 \pm 0.08 mmol/l, and Cr was 1.03 \pm 0.26 mg/dl with no regression of Cr on serum Ca, iCa or PTH, or age. None developed any of the known complications traditionally associated with PHPT nor hypercalcemic crisis. All were on adequate calcium and vitamin D supplements (mean serum 25-OHD was 34.3 \pm 11.9 ng/ml), and the mean PTH was 131 \pm 72 pg/ml. Mean lowest BMD T-score (spine or femoral neck) was -2.4 \pm 1.3 SD.

Conclusions: Despite traditional concerns, there does not appear to be adverse effects of stable hypercalcemia on renal function in the elderly. Our study is limited by the small sample size and lack of more sensitive measures of renal function. It is likely that adequate Ca and vitamin D supplements may have mitigated some the adverse effects. Finally, there does not appear to be compelling reason to warrant PTX in the absence of overt symptoms since the benefits of PTX may not outweigh the potential risks of surgery in these elderly subjects, especially after failed parathyroidectomy.

MO0169

Long Term Safety of Vitamin D Replacement in Mild Primary Hyperparathyroidism. Shila Begum¹, Jacqueline Berry², Peter Selby^{*2}. ¹Manchester Royal Infirmary, United Kingdom, ²Manchester University, United Kingdom

Primary hyperparathyroidism (PHP) is one of the most common endocrine disorders. It leads to increased catabolism of vitamin D and hence vitamin D deficiency and PHP frequently co-exist. There has been clinical hesitation to replace vitamin D in PHP for fear that this may lead to further increase in plasma calcium concentration. Short term studies have suggested that this may not be the case and we now report the long term safety of vitamin D replacement in patients with PHP and vitamin D deficiency.

Nineteen patients (1 male) with PHP diagnosed on standard biochemical criteria were studied. All had been found to have vitamin D deficiency (serum 25OHD <10ng/ml; n=8) or markedly insufficient (<20ng/ml) and were treated with 1.25mg (50 000iu) ergocalciferol daily for 10 days and then once a month thereafter. Six of the patient had previously been treated with bisphosphonates. Blood samples were obtained before treatment and after 12 months.

Before treatment mean 25OHD was 10.9 (SE 1.1) ng/ml; this increased to 32.6 (4.2) ng/ml after 1 year of ergocalciferol (p<0.001). Over the same period plasma calcium remained stable at 2.77 mmol/l before treatment and 2.72 afterwards. Plasma PTH fell non-significantly with the greatest fall in PTH occurring with the greatest change in 25OHD. No adverse events were recorded in relation to treatment.

We conclude that restoration of 25OHD to the normal range in patients with PHP is safe and ought to be undertaken as part of routine clinical management.

Medical Care Costs for Persons with and without Prevalent Hypoparathyroidism: A Population-based Study. Cynthia Leibson^{*1}, Bart Clarke², Jeanine Ransom¹, Hjalmar Lagast³. ¹Mayo Clinic, Department of Health Sciences Research, USA, ²Mayo Clinic College of Medicine, USA, ³NPS Pharmaceuticals, USA

Hypoparathyroidism (HypoPARA) is a rare condition which may last from a few days to an entire lifetime and with consequences ranging from asymptomatic presentation to fatal hypocalcemia. Population estimates of prevalence of HypoPARA and associated medical care costs are lacking. We addressed these issues using unique population-based, longitudinal, medical-records-linkage resources of the Rochester Epidemiology Project (REP) to 1) identify all persons residing in Olmsted County in 2009 with any diagnosis of HypoPARA ever assigned by a REP provider since 1945, 2) review detailed medical records to confirm diagnosis of HypoPARA and assign etiology, 3) assign 2 age- and sex-matched controls per confirmed case, and 4) censor follow-up for every case/control set member at shortest follow-up for each member. Since 1987, REP resources also include provider-linked line item billing data for essentially all medical services and procedures received by residents of Olmsted County, MN, with the capacity to assign nationally standardized wage- and inflation-adjusted dollar estimates. Data on outpatient prescription costs are excluded. Using these resources, we obtained all medical care costs for each year 2006 through 2008 to compare cases with controls for 2009 estimated dollar costs. There were 54 confirmed cases (71% female; mean age 5820 years; etiology=78% post-surgical, 9% secondary, 7% familial, 6% idiopathic). The prevalence of 37/100,000 translates to approximately 100,000 persons with HypoPARA in the US in 2010. Results of cost comparisons for 2006-8 are provided in the Table. In each year, mean (median) costs for HypoPARA cases [12,696 (1,062); 10,861 (1,911); 7,607 (2,716)] were approximately 3 times those for controls [4,669 (328); 3,697 (584); 2,817 (557)]. These population-based data on confirmed HypoPARA prevalence over the full range of disease and associated medical care costs reveal that, although a relatively rare condition, the burden of costs associated with HypoPARA is substantial and consistent. Additional investigation is needed to elucidate the source of excess costs.

Annual medical care costs for prevalent confirmed cases with HypoPARA and age-, sex- matched controls in 2009 \$							
Year		N	Mean	25 th Pctl	Median	75 th Pctl	Maximum

PTH (1-84) Replacement Therapy in Hypoparathyroidism: Effects on Bone Metabolism and Structure. Tanja Sikjaer¹, Lars Rejnmark¹, Annemarie Bruel², Jesper Thomsen², Leif Mosekilde¹. ¹Aarhus University Hospital, Denmark, ²University of Aarhus, Denmark

Conventional treatment of hypoparathyroidism (hypoPT) with calcium supplements and active vitamin D analogues causes reduced bone turnover and over-mineralized bone.

We studied 62 patients with known hypoPT randomized into 2 groups of treatment with either PTH (1-84) 100 µg/d s.c. or placebo, as an add-on therapy.

We investigated the changes in bone structure and density using µCT in 44 iliac crest bone biopsies (23 on PTH treatment) obtained after 24-wks of treatment. Trabecular tunnelling was evident in 11 (48%) biopsies from the PTH-group, whereas no tunnelling was detected in the placebo group. Patients showing tunnelling had significantly higher levels of biochemical markers of bone resorption (NTX and CTX) and formation (osteocalcin, bone specific alkaline phosphatase, PINP). Compared with placebo, PTH-treatment resulted in lower trabecular thickness (Tb.Th*) ($p < 0.01$), and trabecular bone tissue density ($p < 0.01$), whereas connectivity density (CD) was higher ($p < 0.05$) and structural modelling index tended to be lower indicating a change in trabecular architecture from a rod-like to a more plate like structure. The changes in Tb.Th* and CD can be explained by the intratrabecular tunnelling.

Cortical porosity tended to be higher in PTH-treated patients, especially in those with tunnelling. Occurrence of tunnelling was not associated with etiology, length of disease, concentration of PTH, ionized calcium, or 1,25-hydroxy vitamin D.

Quantitative computed tomography (QCT) at the spine and hip were performed at baseline and at week 24 in 31 patients. At the lumbar spine (L1+L2), the increase in trabecular vBMD over the study period was significantly ($p = 0.02$) higher in the PTH group (+12.2%) than in the placebo group (-0.7%). On the contrary, total vBMD decreased more in the PTH than in the placebo group at the total hip (-1.83% vs 0.43%, $p < 0.05$), at the trochanteric region vBMD (-3.28% vs 0.46%, $p < 0.03$), and at the femoral neck (-3.3% vs -0.84%, $p = 0.12$). At all three sites, there was a tendency towards an increased trabecular and a decreased cortical vBMD in the PTH treated patients.

The effect of PTH (1-84)-treatment in hypoPT is an increased bone turn-over with a decreased vBMD at cortical sites, and an increased vBMD at the trabecular sites, which is related to morphological changes in the bone microstructure with intratrabecular tunnelling and increased cortical porosity.

PTH(1-84) Lowers Circulating Sclerostin Levels in Hypoparathyroidism. Aline Costa¹, Mishaella Rubin¹, Jim Sliney Jr², Zachary Lenane¹, Rebecca Ives², Chiyuan Zhang¹, Donald McMahon³, Serge Cremers¹, John Bilezikian³. ¹Columbia University, USA, ²Columbia University Medical Center, USA, ³Columbia University College of Physicians & Surgeons, USA

The inhibitory actions of PTH on sclerostin function are seen *in vivo* but there are little human data. Hypoparathyroidism (HYPOPT), a disorder characterized by low PTH, is an ideal clinical situation to test the hypothesis that PTH regulates sclerostin in human subjects. We investigated the effect of PTH(1-84) [PTH] administration on circulating sclerostin in HYPOPT. 42 subjects with HYPOPT (11 men, 13 post- and 18 pre-menopausal women) were treated for 12 months with PTH, 100µg every other day by subcutaneous injection. Blood samples were collected prior to PTH injection, and bone markers and serum sclerostin [measured by ELISA (TECOMedical)] were assessed at baseline and throughout the treatment period: months 1, 2, 3, 6 and 12. Mean age of subjects was 48.12 yrs and HYPOPT had been diagnosed for 16.13 yrs. Baseline values: serum calcium (8.50.9mg/dL; nl: 8.5–10.4); PTH (54 pg/mL; nl: 10–65) and sclerostin: 0.8400.37 ng/mL (nl men: 0.74; postmenopausal: 0.69; premenopausal: 0.56). Baseline sclerostin was different among the gender subgroups with men showing higher sclerostin levels than the other 2 groups (1.191 vs 0.794ng/mL, $p < 0.005$

postmenopausal; vs 0.659 ng/mL, $p < 0.0001$ premenopausal women). Post- and premenopausal women did not differ from each other. As expected, bone turnover markers started to increase with PTH treatment by month 1. After month 1, the entire cohort showed a progressive decline in sclerostin reaching significantly lower values at month 6 (0.840 to 0.778ng/mL; $p < 0.05$). The PTH-associated lower sclerostin concentration was sustained thereafter, to month 12 (0.840 to 0.777ng/mL; $p < 0.05$). Among the different subgroups, postmenopausal women first showed differences in sclerostin levels from month 1 to month 2 (0.861 to 0.741, $p < 0.05$). A time-dependent, progressive decline in sclerostin levels was seen in men (1.191 to 1.041ng/dL; $p < 0.05$), and less so in pre- (0.659 to 0.618ng/dL; $p = 0.5$) and post-menopausal women (0.790 to 0.774 ng/dL; $p = 0.7$). However, the overall sclerostin response to PTH was similar among the 3 groups. The results indicate that administration of PTH in HYPOPT is associated with reduced circulating sclerostin in human subjects. The concomitant increase in bone turnover markers, a characteristic of PTH administration, may be directly related to the associated effect of PTH to reduce sclerostin levels.

Relationships Between Pharmacokinetic Profile of Human PTH(1-84) and Serum Calcium Response in Postmenopausal Women Following 4 Different Methods of Administration. John Fox^{*}, David Wells, Roger Garceau. NPS Pharmaceuticals, USA

Recombinant full-length human PTH [rhPTH(1-84)] is approved in the EU to treat postmenopausal osteoporosis (PMO) and is currently being developed as a hormone-replacement therapy in hypoparathyroidism. In PMO the optimal pharmacokinetic (PK) profile is for the sc injection to result in a transient increase in plasma PTH levels. This maximizes the anabolic response in bone and minimizes side-effects such as increased serum Ca. In contrast, in hypoparathyroidism where increased serum Ca is a required endpoint, a more-prolonged PK profile may be preferable. We have investigated the relationship between the PK profile of PTH following administration of 100 µg rhPTH(1-84) and the serum Ca response in normal postmenopausal women using 4 different dosing methods [15-min iv infusion; sc injection in abdomen or thigh, intradermal injection (1.5 mm depth) in abdomen]. Mean data are shown in the Table. The highest PTH level was achieved with iv infusion but rapid clearance resulted in the fastest restoration of preinfusion PTH levels and the smallest and shortest duration of increased serum Ca. Lower maximum PTH levels occurred later following sc injection in abdomen and PTH exposure was only 55% of that with the infusion. Predose PTH levels were not re-established until 9 h and the serum Ca response was greater with normal Ca levels not restored until 14–24 h. In contrast, sc injection in thigh resulted in a smaller but more-prolonged PTH increase and a larger and longer serum Ca response, despite a 15% lower PTH exposure vs. abdomen. Intradermal injection resulted in a shorter PTH profile and serum Ca response than with sc injection. In conclusion, the magnitude and duration of the serum Ca response to the sc administration of rhPTH(1-84) in the thigh is greater than when given sc or id in the abdomen, or iv. This has significant therapeutic implications for the various potential indications for PTH therapy, such as hypoparathyroidism.

Route (n)	Plasma PTH(1-84)			Serum Total Ca		
	Max (h)	C _{max} (pg/mL)	Time to return to predose levels (h)	Max (h)	Max increase (mg/dL)	Time to return to predose levels (h)
Intravenous (12)	0.25	8162	3	2	0.38	10
SC-Abdomen (16)	1.1	402	9	7	0.62	14,24
SC-Thigh (18)	1.0	326	12	11	0.81	>24
Intradermal (19)	0.08	440	6	6	0.82	16

MO0174

Simultaneous Quantitative Analysis of Vitamin D Receptor (VDR), Calcium Sensing Receptor (CaSR), Parathyroid Hormone (PTH) and Cyclin D1 mRNAs in Moderate to Severe Primary Hyperparathyroidism (PHPT) in Asian Indians. Shweta Varshnay¹, Sanjay Bhadada², Sudhaker Rao³, Uma Nahar¹, Anil Bhansali⁴, Arunanshu Behera¹, Ambrish Mithal⁵, Sadhna Sharma¹. ¹PGIMER, Chandigarh, India, ²PGIMER, Chandigarh, Ind, ³Henry Ford Health System, USA, ⁴PGIMER, Chandigarh, India, ⁵Medicity Hospital, Gurgaon, India

Background: PHPT has varied presentation in different parts of the world and its pathogenesis remains elusive. We previously reported reduced VDR & CaSR in sporadic parathyroid adenomas in mild to moderate PHPT, but such data is lacking in moderate to severe PHPT. In addition, the relationship between PTH secretion and cell proliferation, and adenoma size has not been fully elucidated. Accordingly, we simultaneously measured VDR and CaSR mRNAs, as well as mRNAs of PTH (marker of PTH secretion) and Cyclin D1 (marker of cell proliferation) in moderate to

severe PHPT and correlated with indices of the disease (serum Ca& PTH and adenoma weight) to better understand the varied pattern of presentation of PHPT.

Material & Methods: mRNA expressions (VDR, CaSR, PTH, and Cyclin D1) were assessed by quantitative RT-PCR in 50 surgically confirmed parathyroid adenomas and 10 normal parathyroid samples. The relative mRNA expression (mean of duplicate RT-PCR assays) was assessed by 2-^{-ΔΔCp} Method. The results are expressed as % change (up or down) after adjusting for the traditional housekeeping gene, GAPDH.

Results: Consistent with our previous immunohistochemistry findings and other reports of mRNA studies, both VDR and CaSR mRNAs were reduced by 65% and 58% respectively ($p < 0.001$ for both) in adenomatous compared to normal parathyroid tissue. In contrast, mRNAs of PTH and Cyclin D1 were increased by 17.2& 10.3 fold respectively ($p \leq 0.001$ for both). Although the PTH mRNA did not correlate with adenoma weight, there was a significant correlation between Cyclin D1 mRNA and adenoma weight ($r = 0.78$; $p < 0.001$). Also, PTH mRNA correlated with serum iPTH levels ($r = 0.86$; $p < 0.001$), but there were no correlations between VDR and CaSR mRNA levels either with indices of disease (serum Ca&PTH) or with serum 25-OHD levels. There was no relationship between decreased VDR and CaSR mRNA expression and increased PTH and Cyclin D1 mRNA expression. This implies that the reduction in VDR and CaSR gene expression may depend on parathyroid cell proliferation rather than on indices of disease (serum Ca&PTH) or vitamin D nutrition (25-OHD).

Conclusions: We reaffirmed the reduced VDR & CaSR expression in moderate to severe PHPT in Asian Indians just as in mild PHPT in the west. In addition, we demonstrated greatly increased expression of PTH and Cyclin D1 mRNAs, and the latter correlated with adenoma weight. The implications of our findings to the clinical expression of the disease and its pathogenesis deserve further study.

MO0175

Vitamin D Toxicity in a Patient with Surgical Hypoparathyroidism. Chae Kim, Heather Hofflich*. University of California, San Diego, USA

Purpose: Case Report

A 35-year-old female presented to our clinic. Patient's medical history was significant for papillary thyroid cancer diagnosed at age 19, for which she was treated with a total thyroidectomy followed by radioiodine therapy. She was diagnosed with hypoparathyroidism due to persistent hypocalcemia following thyroidectomy. Our patient was taking 50,000 alternating with 100,000 IU of Vitamin D2 (drisdol) daily. She was taking 1500 mg of calcium carbonate daily. Patient presented with symptoms of polydipsia, polyuria, muscle pain, numbness of extremities, constipation, and a 20lb weight loss over the last year. On presentation to our clinic, patient's 25-OH vitamin D level was found to be 284 ng/mL (reference range: 30-80 ng/mL) and serum calcium level was 8.9 mg/dL (reference range: 8.6-10.5 mg/dL) (ARUP labs were used). One month after stopping the vitamin D, the 25(OH) vitamin D level was 87 ng/mL and our patient was asymptomatic.

Conclusion: Different formulations of vitamin D can be used to treat hypoparathyroidism. Although calcitriol is preferred over vitamin D2 or D3 because of rapid onset and offset, daily doses of 25,000-100,000 IU of Vitamin D2 or D3 is also an accepted and less expensive way to treat hypoparathyroidism. Because of the long half-life, it is recommended to adjust the dose by checking serum levels of calcium, albumin, phosphorous, and creatinine. (1) However, it is also crucial to regularly monitor 25(OH) vitamin D levels in all patients on high dose Vitamin D supplements. This was not performed in our patient on a regular basis.

In our review of the literature, most cases of vitamin D toxicity present with elevated serum calcium levels.(2,3) Our patient had symptoms and findings of hypercalcemia, but had normal serum calcium levels throughout her clinical course. This is most likely due to her acquired hypoparathyroidism. We do know that calcium levels of 9.0-9.4 mg/dL can be high for a patient with hypoparathyroidism. We want clinicians to be aware to also look at the 24 hour urine calcium levels, especially in patient's with hypoparathyroidism.

Decreased Trabecular Tissue Mineralization Is Associated with Fracture in Patients with Kidney Disease. Thomas Nickolas^{*1}, Xiaowei Liu², Emily Stein², Mafo Kamanda-Kosse³, Ivelisse Colon¹, Serge Cremers³, Lucas Nikkel¹, Chiyuan Zhang³, Donald McMahon², Elizabeth Shane². ¹Columbia University Medical Center, USA, ²Columbia University College of Physicians & Surgeons, USA, ³Columbia University, USA

In renal osteodystrophy (ROD), abnormal Vitamin D metabolism and remodeling cause tissue mineralization defects. As degree of mineralization, or tissue mineral density (TMD), affects tissue-level mechanical properties, abnormal TMD may contribute to the high fracture (Fx) risk in chronic kidney disease (CKD) patients. Previously, invasive iliac bone biopsy was required to evaluate tissue mineralization. We have now measured TMD on non-invasively acquired high resolution peripheral QCT (HRpQCT) scans of the distal radius (DR) and tibia (DT). We hypothesized trabecular (Tb) TMD is lower in CKD patients with fracture (Fx) than both CKD patients without Fx and healthy Controls. We also hypothesized Tb TMD is inversely related to calciotropic hormones and bone turnover markers (BTM).

We performed HRpQCT (Scanco Medical, AG; voxel size 82µm) of the DR and DT in 47 patients with CKD (n=23 Fx; 24 nonFx) and 21 healthy Controls without Fx, matched for age, sex, race. By digital topological analysis (DTA), we classified Tb bone voxels as belonging to one of 3 envelopes: surface Tb bone, central Tb bone and intervening (middle) Tb bone occupying the envelope between surface and central Tb bone (Fig 1). TMD was calculated for surface (sTMD), central (cTMD), and middle (mTMD) envelopes. We also measured serum iPTH, 25-OHD and bone formation (BSAP, PINP) and resorption (CTX, Trap5b) markers.

CKD-Fx, CKD-nonFx, and Controls were well matched for age (68 yrs; F-test NS), female sex (60%, 58% and 68%, $p = \text{NS}$) and white race (28%, 29%, 32%, $p = \text{NS}$). Tb TMD was significantly lower in CKD-Fx than Controls. At the DR, sTMD and mTMD were lower by 2.6% and 3.0%, respectively (all $p < 0.05$). At the DT, sTMD, mTMD and cTMD were lower by 2.2%, 2.6% and 3.1%, respectively (all $p < 0.05$). Tb TMD in CKD-nonFx was intermediate between CKD-Fx and Controls but did not differ significantly from either. At the DT, each standard deviation decrease in s-, m- and cTMD was associated with 1.7%, 1.4% and 1.1% increased odds of Fx ($p < 0.05$ for all). Higher levels of iPTH, BSAP, PINP and CTX, were inversely and significantly correlated with s-, m- and cTMD; r values ranged from -0.40 for PINP vs DT sTMD ($p < 0.009$) to -0.53 for iPTH vs DR sTMD ($p < 0.0005$).

CKD patients with Fx have low Tb TMD, likely related to secondary hyperparathyroidism and high bone turnover. HRpQCT may provide a non-invasive approach to measurement of Tb TMD in CKD; validation against iliac crest bone biopsy is needed.

MO0178

The Influence of Growth Hormone Treatment on Bone Matrix Mineralization in Children with Chronic Kidney Disease. Kamilla Nawrot-Wawrzyniak^{*1}, Nadja Fratzl-Zelman¹, Barbara M. Misof¹, Paul Roschger¹, Sonja Lueger¹, Małgorzata Pancyk-Tomaszewska², Helena Ziółkowska², Klaus Klaushofer¹. ¹Ludwig Boltzmann Institute of Osteology at Hanusch Hospital of WGKK & AUVA Trauma Centre Meidling, 1st Medical Department; Hanusch Hospital Vienna, Austria, ²Department of Pediatrics & Nephrology Medical University of Warsaw, Poland

Patients with chronic kidney disease (CKD) develop renal osteodystrophy (ROD) that is classified by the turnover/mineralization/volume-system. Treatment with recombinant human growth hormone (rhGH) was shown to be a safe and efficacious method to improve height deficits in children with CKD. The influence of rhGH treatment on bone matrix mineralization, an important determinant of bone material quality, is unknown.

We studied bone histomorphometry and matrix mineralization in 20 children (4-16 years) with CKD before and after treatment with rhGH in paired transiliac bone biopsies (with informed consent from the parents). Bone mineralization density distribution (BMDD) was determined by quantitative backscattered electron imaging. Following parameters were used to characterize the BMDD curve: weighted mean mineral concentration (Ca_{Mean}), most frequently measured mineral concentration (Ca_{Peak}), heterogeneity of mineralization (Ca_{Width}) and portion of fully (Ca_{High}) and low (Ca_{Low}) mineralized bone areas. All BMDD data were compared to previously published reference data of healthy children.

Before rhGH-treatment the bone samples were classified to adynamic bone disease (ABD, n=5), osteomalacia (OM, n=2), normal bone (NB, n=4), mixed uraemic osteodystrophy (MUO, n=9) and osteitis fibrosa (OF, n=0). In general indices of bone formation and bone resorption were decreased or normal, while bone matrix mineralization was normal or increased.

After rhGH-treatment ROD classification was: ABD (n=1), OM (n=1), NB (n=6), MUO (n=11), OF (n=1) and bone turnover indices were normal or increased. The BMDD results showed that Ca_{Mean} (-4.1%, $p<0.03$), Ca_{Peak} (-4.4%, $p<0.01$) and Ca_{High} (-70.6%, $p<0.001$) were decreased, whereas Ca_{Width} (+16.6%, $p<0.01$) was increased compared to before treatment. There were significant correlations between bone turnover variables (BFR/BS, MS/BS) and BMDD parameters. In particular, the correlations within the former ABD subgroup were remarkably strong: Spearman coefficients ranged from -0.71 to -0.88 for Ca_{Mean} , Ca_{Peak} , Ca_{High} , and from 0.74 to 0.88 for Ca_{Width} and Ca_{Low} (p -value from <0.001 to <0.05) after treatment.

The results revealed an anabolic effect of rhGH on bone. In particular in the ABD group with abnormally high bone matrix mineralization, there was a shift towards normal BMDD. In conclusion, rhGH-treatment in pediatric CKD patients seems to improve bone material quality.

MO0179

Bone Metabolism in Diabetic Patient with or without Metabolic Syndrome. Ran Cui^{*1}, Shen Qu², Hui Sheng³. ¹Tenth People's Hospital of Tongji University, Peoples Republic of China, ²Tongji University School of Medicine, Peoples Republic of China, ³Shanghai, Fudan University, Peoples Republic of China

The features of bone metabolism in patients with diabetes and metabolic syndrome (MS) remain unclear; here we are going to explore the relationship of osteoporosis and metabolic syndrome in diabetic patients. 107 male (32-85 years) and 136 postmenopausal female patients (44-87 years) with type 2 diabetes were recruited. The patients were divided to two groups according to the diagnosis criteria of MS by IDF 2004. Each patient accepted the bone mineral density (BMD) measured by Dual Energy X-ray Absorptiometry (DEXA) and the serum bone metabolic markers including type I collagen (β -CTX), parathyroid hormone (PTH), osteocalcin (OC), calcitonin (CT). Bone specific alkaline phosphatase (BAP) and Vitamin D (VD) were measured at same time. The components of MS including fasting plasma glucose, serum insulin, blood pressure and lipid were determined. In males, the diabetic patients with MS have a higher BMD in femur neck (FN) (95%CI: (0.012, 0.110), $P=0.015$) and a lower β -CTX and OC level (95%CI (-0.223, -0.051), $P=0.002$; (-6.93, -5.7), $P=0.021$ respectively). In females, no significant differences were found in patients with or without MS. Multiple linear stepwise regression in the MS group showed the BMD of right hip (RH) and FN in males and lumbar (L) in females had positive correlations with weight ($\beta=0.382$, $P=0.023$; $\beta=0.318$, $P=0.018$; $\beta=0.446$, $P=0.000$) after adjusted for age. Waist circumference (WC) was negatively correlated with lumbar BMD ($\beta=-0.289$, $P=0.016$) and positively with FN ($\beta=0.249$, $P=0.015$). The triglyceride (TG) level was positively related to FN ($\beta=0.270$, $P=0.044$) in males, LDL was positive related to RH ($\beta=0.217$, $P=0.027$) and Total cholesterol (TC) was negative related to FN ($\beta=-0.220$, $P=0.026$) in females. Diastolic blood pressure (DBP) was positive related with RH ($\beta=0.310$, $P=0.002$) in females. In males, the BMD in diabetic patients with MS was higher in lumbar with the lower bone turnover level but there was no significant difference in females in these parameters. Weight was a positive factor on BMD in both males and females. Other components of MS, such as the blood pressure, lipid and insulin resist had dissimilar effect on different gender, more studied were expected.

Tests of Bone Density and Structure are Associated with Fractures in Stage 3-5 Chronic Kidney Disease. Sophie Jamal^{*1}, Sarah West², Angela Cheung³, Charmaine E. Lok⁴. ¹The University of Toronto, Canada, ²University of Toronto, Canada, ³University Health Network, Canada, ⁴Toronto General Hospital, Canada

Purpose: Fractures are common in patients with chronic kidney disease (CKD). Previous studies showed that bone mineral density (BMD) by dual x-ray absorptiometry (DXA) does not discriminate well (hip BMD AUROC: 0.56) among fractured and non-fractured patients with stage 5 CKD on dialysis. However, the ability of BMD by DXA and bone structure by high-resolution peripheral quantitated computed tomography (HR-pQCT) to discriminate fracture status among pre-dialysis patients with stages 3-5 CKD has not been well studied.

Methods: We utilized baseline data from an ongoing observational study in patients, age ≥ 18 yrs, with stage 3-5 CKD (using NKF criteria by MDRD eGFR) to determine if BMD by DXA (Hologic) at the lumbar spine (LS), total hip (TH), ultradistal radius (UDR); and/or cortical area, density & thickness, trabecular area, density & separation by HR-pQCT (XtremeCT) at the radius could discriminate between those with and without fracture (self-reported low trauma fractures occurring after age 40 and/or prevalent vertebral fractures identified by morphometry). Results are expressed as areas under the receiver operating characteristic curves (AUROC) with 95% confidence intervals (CI), adjusted for age and weight.

Results: Data was available for 128 men and 86 women. Compared to those without fractures (n=143), those with fractures (n=70) were older (5916 vs. 6914 yrs, $p<0.001$). There were no other differences in demographics by fracture status. The mean weight was 79.919.8 kg, most were Caucasian (70.0%), over 40% had diabetes, and most (74%) subjects had stage 4 or 5 CKD. The mean duration of CKD was 8.010.3 yrs, and 30.2% reported a fall in the last 12 months. BMD by DXA was able to discriminate among those with and without fractures (AUROC for LS: 0.70 [95% CI: 0.62-0.78]; TH: 0.69 [95% CI: 0.61-0.77]; UDR: 0.71 [95% CI: 0.63-0.78]). HR-pQCT also performed well for cortical measures (AUROC for area: 0.67 [95% CI: 0.59-0.76]; density: 0.70 [95% CI: 0.63-0.78] and thickness: 0.70 [95% CI: 0.62-0.78]) and trabecular measures (AUROC for area: 0.70 [95% CI: 0.62-0.78]; density: 0.70 [95% CI: 0.63-0.78]; and separation: 0.70 [0.63-0.78]).

Conclusions: BMD by DXA and HR-pQCT parameters are able to discriminate fracture status in stage 3-5 CKD pre-dialysis patients, which is different than what has been reported in patients with stage 5 CKD on dialysis. Prospective studies are needed to evaluate the fracture predictive ability of BMD and HR-pQCT.

Disclosures: Sophie Jamal, None.

Gene Expression Changes in Femoral Head Necrosis of Human Bone Tissue. Janos Kosa^{*1}, Bernadett Balla¹, Csaba Pinter², Janos Podani³, Laszlo Kiss⁴, Istvan Takacs⁵, Gabor Speer¹, Zsolt Nagy⁵, Balazs Horvath², Laszlo Koranyi⁶, Peter Lakatos⁵. ¹Semmelweis University, Hungary, ²Csolnoky Ferenc Veszprem County Hospital, Hungary, ³Eotvos Lorand University, Hungary, ⁴Hetenyi Geza County Hospital, Hungary, ⁵Semmelweis University Medical School, Hungary, ⁶Drug Research Center, Hungary

Osteonecrosis of the femoral head (ONFH) is the result of an interruption of the local circulation and the injury of vascular supply of bone. Multiple factors have been implicated in the development of the disease. However the mechanism of ischemia and necrosis in non-traumatic ONFH is not clear. The aim of our investigation was to identify genes that are differently expressed in ONFH vs. non-ONFH human bone and to describe the relationships between these genes using multivariate data analysis. Six bone tissue samples from ONFH male patients and 8 bone tissue samples from non-ONFH men were examined. The expression differences of selected 117 genes were analyzed by TaqMan probe-based quantitative real-time RT-PCR system. The significance test indicated marked differences in the expression of nine genes between ONFH and non-ONFH individuals. These altered genes code for collagen molecules, an extracellular matrix digesting metalloproteinase, a transcription factor, an adhesion molecule, and a growth factor. Canonical variates analysis demonstrated that ONFH and non-ONFH bone tissues can be distinguished by the multiple expression profile analysis of numerous genes controlled via canonical TGFB pathway as well as genes coding for extracellular matrix composing collagen type molecules. The markedly altered gene expression profile observed in the ONFH of human bone tissue may provide further insight into the pathogenetic process of osteonecrotic degeneration of bone.

Disclosures: Janos Kosa, None.

MO0181

Increased Visceral Adiposity during Anti TNF α Treatment for Inflammatory Rheumatic Disease is Associated with Various Changes on Serum Adipokines: A 2 years Prospective Study. Eric Toussiot^{*1}, Laurent Mourou², Nhu uyen Nguyen³, Malika Bouhaddi³, Daniel Wendling⁴, Gilles Dumoulin⁵. ¹University Hospital J Minjoz, France, ²EA3920 Physiopathologie Cardiovasculaire et Prevention, France, ³Explorations fonctionnelles Physiologie, Minjoz Hospital, France, ⁴University Hospital Minjoz, France, ⁵Explorations fonctionnelles biochimie endocrinienne et metabolique Minjoz Hospital, France

Introduction: TNF α blocking agents are very effective in rheumatoid arthritis (RA) or ankylosing spondylitis (AS) and has been associated with weight gain. Adipokines are proteins produced by the adipose tissue with many physiologic functions and can also influence the inflammatory response. Certain adipokines could represent a link between the immune response, the metabolic functions and the nutritional status.

Objectives: we evaluated the long term effects of anti TNF α treatment on body weight, body composition and distribution. The changes on the serum levels of adipokines (leptin, adiponectin and resistin) and ghrelin, a gastric peptide involved in appetite regulation were also studied.

Patients and methods: 20 patients (6F) were evaluated (12 AS [modified NY criteria], age [mean SD]: 40.7 16.1 yrs; and 8 RA [ACR criteria], age 60.5 9.7 yrs; mean disease duration: 9.6 9.8 yrs). They received infliximab (2), etanercept (6) or adalimumab (12). Body weight, body mass index (BMI), serum levels of adipokines and ghrelin were measured (IRMA) at baseline and then at months (M) 1, 3, 6, 12, 18 and 24. Body composition was evaluated at baseline and then at M6, 12 and 24. Total and regional body fat and lean masses were measured by total body DEXA (Lunar iDXA). Adiposity was calculated as the ratio between total fat tissue and total lean mass + total fat tissue. Fat distribution was evaluated as the relative proportion of fat tissue in the android (central) and the gynoid (hip and thigh) regions.

Results: there was a slight but significant increase in body weight (+ 1.35 kg) and BMI (+ 0.55 kg/cm²) (p<0.005). All the patients responded to the treatment with clinical improvement and decline of erythrocyte sedimentation rate and CRP (p<0.01). Although fluctuating during the study, leptin and resistin levels did not significantly change. By contrast, adiponectin increased at M1, and then decreased slowly and reached lower values at M24 compared to baseline (baseline: 12.1 4.8; M24: 11.4 5.4 ?g/ml; p= 0.01). We also observed a rapid decline in ghrelin which remained low until the end of the study (baseline: 1256 387; M24: 1117 429 pg/ml; p= 0.035). Lean mass and fat mass in the gynoid region did not change while there was a significant increase at M24 in adiposity (+ 1.36%; NS), in total fat mass (+ 2.4 kg; p= 0.003) and in fat tissue located in the android region (+ 366 g; p= 0.025).

Conclusion: long term administration of TNF α blocking agents was associated with gain of body weight and BMI. Leptin and resistin levels fluctuated while ghrelin decreased. However, TNF α blockade is associated with a modest but significant gain in total fat and especially fat in the android region. It is known that abdominal or visceral adipose tissue is associated with the development of atherosclerosis. These changes, together with the decrease in adiponectin serum levels, could negatively influence the cardiovascular risk of these patients.

MO0182

Toll-like Receptor 2 Heterodimer, TLR1/2 and TLR 2/6, Induces Inflammatory Bone Loss via PGE₂ Production by Osteoblasts. Chiho Matsumoto^{*}, Tsukasa Tominari, Toshio Oda, Michiko Hirata, Masaki Inada, Chisato Miyaura. Tokyo University of Agriculture & Technology, Japan

Toll-like receptors (TLRs), TLR1-TLR13, play critical roles in innate immunity, and various ligands for respective TLR are thought to regulate host defense mechanisms against pathogens. TLRs are divided into two major subgroups, one group is consist of TLR1, 2, 4, 5, 6 and 11, which are expressed on cell surfaces, and the other is composed of TLR3, 7, 8 and 9, which are mainly expressed in intracellular vesicles. TLR4 was identified as the receptor for lipopolysaccharide (LPS), which is an outer membrane component of gram-negative bacteria and known as a pathogen for periodontitis. We have reported that LPS binds to TLR4 expressed in osteoblasts, and the TLR4 signal induces prostaglandin E₂ (PGE₂) synthesis and RANKL expression in osteoblasts, leading to subsequent bone resorption in mouse alveolar bone. Recently, TLR2 is known to form heterodimers with TLR1 and TLR6, but the roles of TLR2 heterodimer signals in bone are not known. TLR1-TLR2 heterodimer (TLR1/2) is known to recognize triacylated lipopeptides from gram-negative bacteria as a specific ligand. On the other hand, TLR2-TLR6 heterodimer (TLR2/6) recognizes diacylated lipopeptides from gram-positive bacteria. Using the respective ligand for TLR1/2 and TLR2/6, we examined the effects of TLR2 heterodimer signals on bone resorption. In co-cultures of mouse bone marrow cells and osteoblasts, TLR2/6 ligand markedly induced osteoclast formation, the potency was similar to that of TLR4 ligand LPS. TLR1/2 ligand also induced osteoclast formation, but the effect was less than that of TLR2/6. Both TLR1/2 and TLR 2/6 ligands induced PGE production and the expression of RANKL mRNA in osteoblasts, and elicited bone resorption in mouse calvarial organ cultures. We detected the expression of TLR1, 2, 4, and 6 mRNAs in osteoblasts, and the level of TLR2 expression was enhanced by the treatment with TLR1/2 or TLR 2/6 ligand, but not by TLR4 ligand LPS. Then, it is possible that the TLR2 heterodimer signal potentiates the other TLR2 signal each other in osteoblasts. Both TLR1/2 and TLR2/6 ligands induced bone resorption of mandibular alveolar bone in organ cultures, and the potency was TLR2/6>TLR1/2. Here, we show that TLR2 signals mediated by TLR2/6 and TLR1/2 may play a key role in PGE-mediated inflammatory bone loss in periodontal disease.

Vertebral Deformity in Patients with End Stage Renal Disease. Eual Phillips^{*1}, Mary Leonard², Chamith Rajapakse³, Michael Wald⁴, Yusuf Bhagat¹, Felix Werner Wehrli⁴. ¹University of Pennsylvania, USA, ²Children's Hospital of Philadelphia, USA, ³University of Pennsylvania School of Medicine, USA, ⁴University of Pennsylvania Medical Center, USA

Early detection of vertebral deformity is important in organ transplant recipients due to known elevated risk for further fractures. Although DXA BMD measurements are clinically accepted as a noninvasive means for fracture risk assessment in the general population, BMD is a poor predictor of fracture risk in renal transplant patients. Here, we evaluated vertebral deformity in patients with end stage renal disease (ESRD) who were candidates for renal transplantation. The study comprised of 43 adults (24 men, 19 women) with ESRD (mean age: 40 years, $\sigma = 10.1$) and 46 healthy controls (18 men, 28 women; mean age: 37 years, $\sigma = 7.6$, p=NS). Multi-slice sagittal MR images of the midline spine were acquired at 1.5-T (Siemens Sonata) scanner using the manufacturer's surface array coil and a turbo spin-echo sequence. Acquired spine images were taken as input to a custom-built semi-automatic software tool designed for quantitative spine morphometry. Using a six-point operator-guided labeling method, anterior height (H_a), posterior height (H_p), and middle height (H_m) of each vertebral body were computed by taking the Euclidian distance between landmark points. Three types of vertebral deformities - wedge (W), biconcavity (B), and compression (C) - were calculated for each vertebra by adapting an approach developed by Eastell. A continuous measure of deformity, vertebral deformity index (VDI), was computed for the hypothoracolumbar vertebral column (T8-L5) using the sum of each deformity per vertebrae ($VDI = \sum(W_i + B_i + C_i)$). Intervertebral disc (IVD) heights were also calculated using the Dabbs height method, which is the average of the anterior and posterior IVD heights. Compared to controls, women with ESRD had greater vertebral deformity (2.5%, p < 0.0005), while the group difference in VDI of men was non-significant. H_a and H_p were higher in both men (9%, p < 0.005) and women (6%, p < 0.05) with ESRD. IVD heights were lower in both men (15%, p < 0.005) and women (22%, p < 0.0005) with ESRD. Results from vertebral and IVD heights potentially indicate disc degeneration. The increased spinal deformity reflects the markedly increased fracture incidence in the ESRD compared to the general population. We conclude that MRI-based spinal morphometry can reliably differentiate patients with ESRD from controls. Finally, we are not aware of prior observations on the effects of ESRD on the IVD, reported here.

Cellular Cholesterol Metabolism is required for Vascular Cell Calcification. Jeff Hsu^{*1}, Yifan Geng¹, Jinxiu Lu¹, Linda Demer², Yin Tintut¹.
¹University of California, Los Angeles, USA, ²David Geffen School of Medicine At University of California Los Angeles, USA

Vascular calcification impairs vessel compliance and increases the risk of cardiovascular events. We previously found that activation of the PKA pathway induces osteogenic differentiation and matrix mineralization of vascular smooth muscle cells (VSMCs), and that agonists of liver X receptor (LXR), which regulates homeostasis of intracellular cholesterol, enhance the effects of PKA. Since cholesterol is an integral component of matrix vesicles that are involved in mineralization, we examined the roles of cellular cholesterol biosynthesis and cholesterol uptake via low-density lipoprotein receptors (LDLR) in vascular cell calcification.

Results showed that aortic VSMC isolated from Ldlr^{-/-} mice had 2.5 to 4-fold less alkaline phosphatase (ALP) activity and matrix mineralization than those from WT mice. A PKA activator, forskolin, increased the ALP activity at day 4 and matrix mineralization at day 10 in Ldlr^{-/-} cells to the levels seen in forskolin-treated WT cells. This effect may be due to a compensatory increase in cholesterol synthesis, since forskolin treatment for 7 days upregulated expression of the rate-limiting enzyme for cholesterol biosynthesis, HMG-CoA reductase, only in Ldlr^{-/-} cells.

In WT cells, inhibition of HMG-CoA reductase activity with mevastatin failed to attenuate matrix mineralization. This lack of effect may be due to a compensatory increase in cholesterol uptake since mevastatin upregulated LDL receptor expression by 4-fold and increased intracellular cholesterol accumulation by 1.5-fold, as measured by a fluorometric assay. Inhibition of cholesterol uptake by culture with lipoprotein deficient serum (LPDS) completely inhibited matrix mineralization in WT cells. This inhibitory effect of LPDS on matrix mineralization was partially reversed by the addition of cell permeable cholesterol, a cyclodextrin-cholesterol complex.

In conclusion, these results suggest that upregulation of cholesterol metabolism is essential for forskolin-induced matrix mineralization by vascular cells.

The Appearance and Modulation of Osteocyte Marker Expression During Calcification of Vascular Smooth Muscle Cells. Dongxing Zhu¹, Neil Mackenzie¹, Jose Luis Millan², Colin Farquharson^{*3}, Vicky Macrae¹.
¹The Roslin Institute, University of Edinburgh, United Kingdom, ²Sanford-Burnham Medical Research Institute, USA, ³Roslin Institute, University of Edinburgh, United Kingdom

Vascular calcification is an indicator of elevated cardiovascular risk. Vascular smooth muscle cells (VSMCs), the predominant cell type involved in medial vascular calcification, can undergo phenotypic transition to both osteoblastic and chondrocytic cells within a calcifying environment. In vitro VSMC calcification studies in conjunction with ex vivo analyses of vascular tissue from Enpp1^{-/-} - a mouse model of idiopathic infantile arterial calcification, showed that vascular calcification is associated with the expression of osteocyte phenotype markers. The culture of murine aortic VSMCs in calcifying medium (medium containing α -glycerolphosphate and ascorbic acid), confirmed that calcifying VSMCs had increased alkaline phosphatase activity and Pit-1 expression, which are recognized markers of vascular calcification. Expression of DMP-1, E11 and sclerostin mRNA was also upregulated during VSMC calcification in vitro indicating the presence of cells of the osteocyte phenotype. Increased protein expression of E11, an early osteocyte marker, and sclerostin, expressed by more mature osteocytes was also observed in the calcified media of Enpp1^{-/-} mouse aortic tissue. Control wild-type tissue showed no positive staining. The reliability of these findings were confirmed by studying the terminal differentiation of murine calvarial osteoblasts into osteocytes under identical culturing conditions was also, as expected, associated with increased expression of the osteocyte markers DMP-1, E11 and sclerostin. This study has demonstrated the up-regulation of key osteocytic genes and proteins during vascular calcification. A fuller understanding of the functional role of osteocyte formation and specifically sclerostin and E11 expression in the vascular calcification process may identify novel potential therapeutic targets for clinical intervention.

Bone Geometry, Density and Microarchitecture in Patients with Type I Osteogenesis Imperfecta Compared with Age and Sex Matched Healthy Controls Utilizing High-Resolution Peripheral Quantitative Computed Tomography. Lars Folkestad^{*1}, Jannie Dahl Hald², Stinus Hansen³, Jeppe Gram⁴, Bente Langdahl⁵, Bo Abrahamsen⁶, Kim Brixen⁷.
¹Department of Endocrinology, Odense University Hospital / 3Department of Endocrinology, Hospital of Southwest Denmark / Institute of Clinical Research, University of Southern Denmark, Denmark, ²Department of Endocrinology & Internal Medicine, Aarhus University Hospital, Denmark, ³Department of Endocrinology, Odense University Hospital / Institute of Clinical Research, University of Southern Denmark /, Denmark, ⁴Department of Endocrinology, Hospital of Southwest Denmark, Denmark, ⁵Department of Endocrinology & Internal Medicine, Denmark, ⁶Department of Internal Medicine, Gentofte Hospital / Institute of Clinical Research, University of Southern Denmark, Denmark, ⁷Department of Endocrinology, Odense University Hospital / Institute of Clinical Research, University of Southern Denmark, Denmark

Background: Osteogenesis imperfecta (OI) is a hereditary, heterogeneous disease characterized by defects in the biosynthesis of collagen type I resulting in increased risk of fractures. Both bone mineral density (BMD) and bone quality is affected in OI. Only a few studies have investigated the bone architecture, geometry and volumetric BMD (vBMD) in patients with type-I OI (T1-OI). High-resolution peripheral quantitative computed tomography (HR-pQCT) allows *in vivo* assessment of cortical thickness (Ct.Th), trabecular thickness (Tb.Th), trabecular number (Tb.N) and trabecular separation (Tb.Sp) without discomfort for the patients. To investigate bone microstructure in T1-OI, we compared HR-pQCT parameters in OI patients and healthy age- and gender matched controls.

Methods and material: From our clinical database and through the *Danish OI Patient Society*, a total of 155 patients with OI were invited and 21 patients with clinical T1-OI and no known other metabolic bone disease were included in this study. Twenty-one age- and sex-matched healthy controls were invited at random from the background population through the national civil registry. All participants had both ultra distal radius and tibia investigated using a Scanco Medical Xtreme CT. We present the data as meanSD. Between-group differences are analyzed with Wilcoxon's nonparametric rank-sum test, due to a non Gaussian distribution. p-values are two-sided and the statistical significance level was set at .05.

Results: Six men and 15 women participated in each group. The mean age was 47.5 (range 21-75) years. Results are summarized in table 1. Patients with T1-OI had significantly lower number of trabeculae and increased Tb.Sp in both tibia and radius. In the tibia, patients had significantly thinner trabeculae. Moreover, vBMD was significantly lower in the cortical compartment in both regions. In the tibia, patients had significantly lower total vBMD. Finally, cortical area was significantly lower in the tibia, but not in the radius.

Conclusion: Patients with OI have altered micro-architecture in both tibia and radius and have low vBMD compared with healthy age- and gender-matched controls. This indicates that the increased fracture risk in OI patients may be the result of both low bone mass and altered bone structure.

Dental Phenotype in a Mouse Model for Craniometaphyseal Dysplasia. Eliane Dutra*, I-Ping Chen, Peter Maye, Ernst Reichenberger. University of Connecticut Health Center, USA

Craniometaphyseal dysplasia (CMD) is a genetic disorder characterized by hyperostosis of craniofacial bones and flaring metaphyses of the long bones. Mice carrying a knock-in mutation (Phe377del) in the Ank gene replicate many skeletal characteristics of human CMD as well as dental abnormalities. A known function of the transmembrane protein ANK is to transport intracellular pyrophosphate (PPi) into the extracellular environment. Although the morphologies of erupted molars and incisors appear to be normal, AnkKI/KI mice have abnormal cervical loop positioning of the lower incisors and excessive cementum deposition of molars and incisors. We hypothesize that a combination of mechanisms may contribute to the abnormal tooth development in AnkKI/KI mice: 1) reduced bone resorption and impaired function of stem cells may contribute to the abnormal development of the incisors and 2) altered Pi/PPi may cause excessive cementum formation. Cementoblasts and osteoclasts are known to express IBSP and TRAP, respectively. In order to examine the mutational effects of a CMD-causing Ank mutation on these two cell types, we crossed AnkKI/KI mice with transgenic fluorescent reporter mice expressing Ibsp-Topaz/Dmp1-mCherry and Trap-ECFP. Histology of the AnkKI/KI/Ibsp-Topaz+Dmp1-mCherry mice revealed increased Ibsp-positive cells around the roots of the molars in comparison to the Ank+/+ mice, suggesting increased numbers of cementoblasts. Characterization of the AnkKI/KI/Trap-ECFP showed increased ECFP expression, indicating more TRAP-positive mononuclear and multinucleated cells in the mandibles of the AnkKI/KI mice. Interestingly, quantification of osteoclast number and osteoclast surface of TRAP-stained paraffin sections using Osteomeasure software revealed decreased numbers of osteoclasts in the apical end of the AnkKI/KI incisor. Our data suggest that bone resorption activity may be reduced around the cervical loop of the AnkKI/KI incisor due to decreased numbers of mature osteoclasts although more TRAP-positive cells are present in this region. Our previous data showed increased apoptosis in the stellate reticulum and decreased proliferation of odontoblast precursors in the apical end of AnkKI/KI incisors. We are currently investigating gene expression in the cervical loop to determine whether the incisor phenotype is caused by a cervical loop deficiency or is secondary to reduced bone resorption.

Determination and Comparison of Serum and Plasma Sclerostin Concentrations by Commercially Available Enzyme-Linked Immunoassays. Melissa McNulty¹, Ravinder Singh¹, Eric Bergstralh¹, Xujian Li¹, Rajiv Kumar^{*2}. ¹Mayo Clinic, USA, ²Mayo Clinic College of Medicine, USA

Sclerostin alters bone formation. The precise and reproducible measurement of sclerostin concentrations in biological samples could potentially be important for assessment of metabolic bone disease. We compared sclerostin concentrations in serum and plasma using two commercially available enzyme-linked immunoassays. Serum or heparin-plasma was obtained from 25 normal human subjects. Sclerostin was measured in these samples using two commercial ELISAs available from Biomedica Medizinprodukte GmbH and TECOmedical AG following the manufacturers instructions.

With the Biomedica assay, serum sclerostin concentrations were 0.99 ± 0.12 ng/mL (mean ± SEM) and plasma concentrations were 1.47 ± 0.13 ng/mL (paired t-test, P < 0.001). With the TECO assay, serum sclerostin levels were 0.71 ± 0.05 ng/mL and plasma sclerostin concentrations were 0.80 ± 0.06 ng/mL (paired t-test, P < 0.001) (Table 1). Serum and plasma sclerostin concentrations were significantly different when determined by the two assays (serum, P = 0.015; plasma, P < 0.001). To determine whether the recovery of added exogenous sclerostin was quantitative, we obtained recombinant sclerostin produced in mammalian cells from R & D Systems, and added a known amount to serum or plasma samples. Recovery of added recombinant sclerostin to serum was less than expected with both Biomedica and TECO assays (P < 0.001, paired t-test) (Table 1).

Conclusions: The concentrations of sclerostin in serum and plasma are different when determined by the two assays. The recovery of exogenously added sclerostin is not quantitative suggesting that presence of binding proteins in serum or plasma. Serum or plasma sclerostin concentrations with current assays should be interpreted with caution. Our data suggest that the same assay should be used for comparing groups of patients or patients being followed longitudinally. Standardization of sclerostin assays is required prior to their being introduced into general clinical laboratory use.

MO0189

Epidemiogenetic Study of French Families Affected by Paget's Disease of Bone. Laetitia Michou^{*1}, Corinne Collet², Jean Morissette¹, Maurice Audran³, Thierry Thomas⁴, Edith R. Gagnon¹, Jean-Marie Launay², Jean-Louis Laplanche², Jacques Brown⁵, Philippe Orce⁶. ¹Centre De Recherche Du CHUQ - CHUL, Canada, ²Service de biochimie et biologie moleculaire, Hopital Lariboisiere, APHP, France, ³Universite et CHU Angers; INSERM U922, France, ⁴Hopital Nord - CHU de St-Etienne, France, ⁵Laval University, Canada, ⁶University Paris Diderot, France

Purpose: To search for association between environmental factors and Paget's disease of bone (PDB) and to determine the frequency of *SQSTM1* gene mutations and haplotypes in French families affected by PDB.

Methods: Unrelated PDB patients were recruited in three French Rheumatology departments. All patients had monostotic or polyostotic PDB, as defined by increased bone radionuclide uptake with typical radiographic lesions. First- and second-degree relatives of each index case completed a questionnaire and had a clinical examination, blood taken for DNA extraction and biochemical measurements, and a whole-body bone scan or X-ray. Exons 7 and 8 and exon-intron boundaries of *SQSTM1* gene were PCR amplified before sequencing. In patient carriers of a *P392L* mutation, haplotypes were determined by genotyping six intragenic markers. Prevalence of PDB was estimated in first-degree relatives and siblings. Comparisons of clinical characteristics and exposure to environmental factors between PDB patients and healthy relatives were performed.

Results: We investigated 18 families affected by PDB, totalling 83 individuals: 20 patients with known PDB, three relatives newly diagnosed with PDB and 60 healthy relatives. Four (22.2%) out of the 18 families had familial PDB. The prevalence of PDB was 8.8% among first degree relatives, and 15.4% among siblings. Index cases and/or relatives affected by Dupuytren's disease were found in eight (44.4%) out of the 18 families. Comparison of exposure to environmental factors between PDB affected patients and healthy relatives provided no statistically significant difference, but 43% of PDB patients were former or current tobacco users versus 18% of healthy relatives (p=0.02; OR=3.37 (1.04-11.09)). Five index cases (27.8%) were carriers of *SQSTM1* mutations: three carried the *P392L* mutation, one carried *P392L* and *A390X* double mutation and one carried an *A390X* mutation. Haplotype analysis revealed that the *P392L* mutation was carried by haplotype 2 in the four index cases carrier of this mutation. Dupuytren's phenotype was not associated with *SQSTM1* mutation.

Conclusions: Accurate phenotype assessment of 63 relatives of 18 French PDB patients allowed for a new diagnosis of PDB in three asymptomatic relatives. There was evidence for an aggregation of Dupuytren's disease in families of PDB, and an association between PDB and tobacco exposure. Half of PDB familial forms carried a *SQSTM1* mutation, the *P392L* mutation being the most frequent.

Implication of Gender Difference in the Association between Bone-specific Alkaline Phosphatase Activity and Serum Biochemical Parameters or Dietary Nutrients. Mayu Haraikawa¹, Rieko Tanabe², Natsuko Sogabe³, Aoi Sugimoto⁴, Toshimi Michigami⁵, Takayuki Hosoi⁶, Masae Goseki-Sone⁷.

¹Graduate School of Human Life Science, Japan Women's University, Japan, ²Division of Nutrition, Department of Food & Nutrition, Faculty of Human Sciences & Design, Japan Women's University, Japan, ³Department of Health & Nutrition Sciences, Faculty of Human Health, Komazawa Women's University, Japan, ⁴Graduate School of Human Sciences & Design, Division of Food & Nutrition, Japan Women's University, Japan, ⁵Osaka Medical Center, Research Institute for Maternal & Child Health, Japan, ⁶National Center for Geriatrics & Gerontology, Japan, ⁷Japan Women's University, Japan

Alkaline phosphatase (ALP) hydrolyzes a variety of monophosphate esters into inorganic acid and alcohol at a high optimum pH (pH 8-10). Tissue non-specific ALP (TNSALP) is associated with skeletal mineralization. Hypophosphatasia (HPP) is a rare inherited systemic bone disease caused by the presence of either one or two pathologic mutations in the TNSALP gene, and is characterized by the defective mineralization of bone and/or teeth in the presence of low serum and bone ALP activity. Clinical features range from stillbirth without mineralized bone to pathologic fractures of the lower extremities in later adulthood. Nutritional management based on the characteristic pathology of HPP seems to be important for the control and treatment of this disease. In this study, we aimed to clarify the effect of dietary nutrients on bone-specific ALP (BAP) activity in young adults in order to obtain basic information for planning a desirable nutritional management program in HPP. Serum biochemical parameters, such as serum ALP, BAP, 1 α , 25(OH)2D3, and osteocalcin were measured in healthy young males (n=97, age: 22.3 \pm 1.7 y, mean \pm standard deviation) and females (n=96, age: 21.8 \pm 1.8 y). Dietary nutrient intakes were measured based on 3-day food records before the day of blood examinations. TNSALP gene mutations were analyzed in the DNA of peripheral blood leukocytes. All subjects were unrelated volunteers and provided informed consent before the study. Through the analysis of BAP activity and other biochemical parameters, a significant positive correlation was revealed between BAP and serum 1 α , 25(OH)2D3 or osteocalcin in male subjects. However, there was no significant correlation between BAP and the other serum biochemical parameters in female subjects. As a result of 3-day food records, there was a significant positive correlation between serum 1 α , 25(OH)2D3, and Ca/P intake in female subjects ($r=0.250$, $p=0.014$). In addition, 1559delT mutation, which has been reported the most frequent in Japanese HPP, was not detected in all subjects (n=193). Our results suggest that gender difference should be considered in planning the strategies for the nutritional management of HPP.

Mutations in NOTCH2 in Patients with Hajdu-Cheney Syndrome. Michael Mannstadt¹, Wenping Zhao², Karen Miller², Rachel Gafni³, Michael Collins³, Margaret Seton², Harald Jueppner². ¹Massachusetts General Hospital Harvard Medical School, USA, ²Massachusetts General Hospital, USA, ³National Institutes of Health, USA

Purpose: Hajdu-Cheney Syndrome (HCS) is a rare disorder characterized by acroosteolysis of the distal phalanges, severe osteoporosis, dental abnormalities and a variety of other findings, including renal cysts. It occurs sporadically or can be transmitted in an autosomal-dominant fashion. Recently, heterozygous disease-causing mutations were identified in NOTCH2 (Simpson et al. and Isidor et al., Nature Genetics 2011). Here, we describe phenotypic and genetic findings in sporadic and familial HCS cases.

Methods: We studied 3 affected members of one family with an autosomal-dominant form (HCS1) and 5 patients with the sporadic form (HCS2-6). NOTCH2 exon 34 was sequenced and nucleotide sequence variations were compared to public databases.

Results: Patients had clinical findings consistent with HCS, which were of variable severity. Direct sequence analysis of NOTCH2 exon 34 revealed heterozygous mutations in all 8 HCS patients (see table). Five of the mutations are novel; the nonsense mutation c.7198C>T has been described (Simpson et al., Nature Genetics 2011).

Of the six different mutations, two are nonsense mutations; four are deletion mutations leading to a shift in reading frame and a premature stop codon. Because these mutations are located in the last exon, the resulting mRNA is predicted to escape nonsense mediated decay. All six mutations lead to the deletion of the carboxyl-terminal PEST sequence.

Conclusions: We identified heterozygous mutations in NOTCH2 exon 34 in each of our HCS patients; five of these mutations are novel. All six mutations are predicted to lead to a loss of a PEST sequence. The deletion of this protein-destabilizing motif is predicted to lead to a longer half-life of the NOTCH2 protein and the identified mutations are therefore likely to represent "gain-of-function" mutations. Our findings confirm that heterozygous NOTCH2 mutations are the cause of HCS and the findings in our patients expand the mutational spectrum of this disorder.

Serum Levels of Dkk1, Sclerostin and Secreted Frizzled Related Protein 4 are not Changed in Individuals with Gain-of-function Mutations in LRP5. Christine Simpson*, Grace Lee, Dinah Foer, Benhua Sun, Joseph Belsky, Karl Insogna. Yale University School of Medicine, USA

It is thought that gain of function mutations in LRP5 result in high bone mass syndromes because these allelic variants confer resistance to the actions of endogenous inhibitors, in particular Dkk1. Not uncommonly, resistance syndromes are associated with increased expression of the inhibitor. We therefore wondered if circulating levels of known Wnt inhibitors might be altered in patients with gain-of-function mutations in LRP5. We collected fresh serum samples from 15 individuals (60+21 yrs) with known high bone mass and mutations in LRP5 (G171V or N198S), 11 unaffected individuals (42+21 yrs) in the same kindreds and 25 normal age-matched controls (56+24 yrs). Serum levels of sclerostin (SOST), Dickkopf-related protein 1 (Dkk1), secreted frizzled protein 4 (SFRP4), c-terminal telopeptide of type 1 collagen (CTX) and serum procollagen type 1 amino-terminal propeptide (P1NP) were measured using commercially available assays. As summarized in the graph below, there were no significant differences in serum levels of SOST, Dkk1, or SFRP4 in affected vs. unaffected individuals from different kindreds. When analyzed by genetic mutation, again there were no observed differences. Further, when compared to age-matched, unrelated, normal individuals there were no differences in the levels of the three inhibitors in the individuals with LRP5 mutations. When the unaffected and normal control individuals were analyzed as a group, there was no correlation of SOST, Dkk1, SFRP4 with either CTX or P1NP, albeit the sample size was small. These data suggest that either gain-of-function in LRP5 is not reflected in circulating levels of these three inhibitors, or that the mechanism of action of the LRP5 mutations is mediated by other molecular pathways *in vivo*.

Serum Levels of Dkk1, SOST and SFR4 in the Three Study Groups

The Bone Tissue Defect in Children with Hypophosphatasia: Histomorphometric Study. Frank Rauch^{*1}, Cheryl Greenberg², Michael Whyte³, Hal Landy⁴, Rose Travers⁵, Francis Glorieux⁶. ¹Shriners Hospital for Children, St. Louis, Canada, ²University of Manitoba, Children's Hospital, Canada, ³Shriners Hospital for Children, USA, ⁴Enobia Pharma, Canada, ⁵Shriners Hospital for Children, Canada, ⁶Shriners Hospital for Children & McGill University, Canada

INTRODUCTION: Hypophosphatasia (HPP) is the inherited skeletal disorder caused by loss-of-function mutation(s) in the gene that encodes the tissue-nonspecific isoenzyme of alkaline phosphatase. The characteristics of HPP have not been assessed in detail in many affected children at the bone tissue level.

OBJECTIVE: To determine the bone tissue abnormalities of children with HPP.

METHODS: Static and dynamic histomorphometric analyses were performed in the trabecular compartment of transiliac bone biopsy samples that had been obtained from 12 children (age 6.0 to 12.5 years) with HPP as the baseline measure of an enzyme replacement trial. Results were expressed as percentages of the means of age-specific reference ranges from our laboratory.

RESULTS: Structural parameters (bone volume per tissue volume, trabecular number, trabecular thickness) were close to the age-specific average of the reference range, whereas osteoid indices (osteoid thickness, osteoid surface per bone surface, osteoid volume per bone volume) were markedly elevated (Table). Among dynamic parameters of bone formation (based on tetracycline double labeling), mineralizing surface related to bone surface was below the age-specific average of the reference range. Mineral apposition rate was slightly elevated, whereas bone formation rate per bone surface was below the expected average for age. Mineralization lag time was markedly elevated.

Qualitative evaluation suggested that the accumulation of osteoid was not distributed evenly, but rather was patchy. In many locations, trabeculae were covered by osteoid of normal thickness, whereas in some trabeculae a large proportion of the diameter seemed to consist of osteoid mixed with calcified cartilage (presumably unremodeled growth plate material).

CONCLUSION: Children with HPP have a mineralization defect that fulfills the histomorphometric criteria for osteomalacia. In addition, there are distinctive patches of unmineralized bone containing cartilage fragments.

	N	median (IQR)	P*
Bone volume/tissue volume	7	121 (116; 136)	0.03
Trabecular number	7	117 (92; 138)	0.10

Determining the Repertoire of Human Genes Bound by Osterix (SP7). Kurt Hankenson^{*1}, Jianhua Zhao², Fengchang Zhu¹, Struan Grant². ¹University of Pennsylvania, USA, ²Children's Hospital of Philadelphia, USA

Candidate gene and genome wide association studies (GWAS) have revealed a number of loci encoding transcription factors that are very strongly associated with endocrine-related traits, including *Osterix* (*Sp7*), *VDR*, and *TCF7L2* with bone mineral density (BMD), osteoporosis and type 2 diabetes, respectively. The combination of chromatin immunoprecipitation (ChIP) and massively parallel sequencing (ChIP-seq) can be used to directly identify the DNA sequences bound by transcription factors genome wide *in vivo*, including strength of binding, in order to determine the network of genes they regulate. We previously reported the mapping of the genomic regions bound by TCF7L2 using ChIP-seq and found that the list of genes bound by this transcription factor harbor a highly significant over-representation of loci uncovered in GWAS of metabolic and cardiovascular disease. Further support for our conclusions came from a subsequent VDR ChIP-seq study that gave a similar enrichment of GWAS-discovered genes, albeit for immune and cancer related traits. As such, it is our hypothesis that a substantial set of genes bound by GWAS-implicated transcription factors will also harbor genetic variants associated with a given trait of interest. With these facts in mind, we aimed to determine a set of human genes bound by Osterix. Osterix was both overexpressed and knocked-down using

adenovirus in human primary marrow-derived mesenchymal stem cells (hMSC). Cells were induced to become osteoblasts with BMP6. Knockdown inhibited terminal differentiation while *Osterix* overexpression promoted differentiation. Microarray analysis revealed a set of genes, either directly or indirectly regulated by Osterix, involved in extracellular matrix assembly and terminal osteoblast differentiation. Specifically Osterix regulates the expression of a cluster of proteoglycans on human chromosome 9, including osteomodulin (*OMD*), asporin (*ASPN*) and osteoglycin (*OGN*). Next we used ChIP to identify genomic segments bound by Osterix, revealing a promoter segment located downstream of *OMD* and upstream of *OGN*, thus demonstrating a direct interaction between Osterix and this proteoglycan locus. In summary, we have distilled loci bound by Osterix and have gained an insight in to the gene networks regulated by this key transcription factor. Our future work will utilize ChIP-seq, with this identified genomic segment acting as a positive control, to identify novel loci genome wide directly bound by Osterix.

Genome-Wide Association Analysis of Hip Structure Phenotypes in the Fels Longitudinal Study. Stefan Czerwinski^{*1}, Miryoung Lee¹, Bradford Towne¹, Joanne Curran², Thomas Dyer², Audrey Choh¹, John Blangero², Roger Siervogel¹. ¹Wright State University Boonshoft School of Medicine, USA, ²Texas Biomedical Research Institute Department of Genetics, USA

Introduction: Bone structure is important in assessing fracture risk and is moderately to highly heritable. Several recent genome-wide analyses have identified SNPs linked or associated with bone mineral density and fracture risk. However, less is known about the genetic influences on hip geometric parameters related to bone strength. In this study, we conducted an initial genome-wide association analysis of hip geometric parameters on white adults in the Fels Longitudinal Study.

Methods: The study sample includes 1,227 participants (men 569, women 658, mean age 45.4yr) aged between 18 and 91 yrs. Hip geometric parameters were obtained from existing dual energy X-ray absorptiometry scans using Hip Structure Analysis (HSA) software (Hologic, Waltham, MA). Our analyses focused on femoral neck shaft angle and three HSA phenotypes (i.e., cortical buckling ratio (BR), cross-sectional area (CSA), and section modulus (Z)) collected at three regions of the femoral neck (i.e., the shaft, intertrochanteric and narrow neck). Each participant has been genotyped with the Illumina Human 610-Quad BeadChip containing more than 550,000 SNPs. Association analyses were conducted using measured genotype analysis implemented in the software program SOLAR allowing for residual non-independence among relatives. In this sample, genome-wide significance was indicated by a chi-square > 27.85 and suggestive evidence by a chi-square > 22.70.

Results: We observed a significant association for SNP rs4314247 (chromosome (ch) 4, chi-square 30.15) and highly suggestive associations for rs1041350 (ch 9, chi-square 27.39) with shaft angle. rs4314247 lies within the intron region of a gene coding for Palladin, a cytoskeletal associated protein on ch 4q32.3. We found 19 SNPs that were suggestively associated with HSA phenotypes in the three regions. A total of 8 suggestive SNPs were associated with more than one HSA trait for the same region. In the shaft region, a highly suggestive association for rs1198121 with BR was observed (ch10, chi-square 27.03). SNP rs6549288 (ch3, chi-square 25.2) and rs7614990 (ch3, chi-square 24.6) were associated with CSA and Z. In the intertrochanteric region, five SNPs on ch 16 were suggestive with both CSA and Z.

Conclusion: In summary, we identified several significant and suggestive SNPs associated with hip geometric parameters. Further research aimed at replicating these results in other populations is planned.

MO0196

Heterogeneous Stock Rat: a Unique Genetic Resource for Rapid and Efficient Discovery of the Genetic Determinants of Bone Fragility. Imranul Alam^{*1}, Daniel Koller¹, Sun Qiwei¹, Ryan Roeder², Toni Canete³, Gloria Blazquez³, Regina Lopez-Aumatell⁴, Esther Martınez-Membrives³, Elia Vicens-Costa⁵, Carme Mont³, Sira Dıaz³, Adolf Tobena³, Alberto Fernandez-Teruel³, Adam Whitley⁴, Pernilla Strid⁶, Margarita Diez⁶, Martina Johannesson⁴, Jonathan Flint⁴, Michael Econs¹, Charles Turner⁷, Tatiana Foroud⁸. ¹Indiana University School of Medicine, USA, ²University of Notre Dame, USA, ³Autonomous University of Barcelona, Spain, ⁴Wellcome Trust Center for Human Genetics, United Kingdom, ⁵Autonomous University of Barcelona, Spain, ⁶Karolinska Institutet, Sweden, ⁷Orthopaedic Surgery, USA, ⁸Indiana University Purdue University Indianapolis, USA

Osteoporosis is a common polygenic disorder with reduced bone mineral density (BMD) and increased susceptibility to fracture at multiple skeletal sites. BMD, structure and strength are the primary skeletal determinants of osteoporotic fracture risk and are under substantial genetic control. Previously, we demonstrated that these skeletal determinants vary considerably among 11 different inbred rat strains. Subsequently, we performed quantitative trait loci (QTL) analysis in 4 inbred rat

strains (F344, LEW, COP and DA) for different bone phenotypes and identified several candidate genes influencing various bone traits. The standard approach to narrowing QTL intervals down to a few candidate genes typically employs the generation of congenic lines, which is time consuming and often not successful. A potential alternative approach is to use a highly genetically informative animal model resource capable of delivering very high-resolution gene mapping such as Heterogeneous stock (HS) rat. HS rat was derived from eight inbred progenitors: ACI/N, BN/SsN, BUF/N, F344/N, M520/N, MR/N, WKY/N and WN/N. The genetic recombination pattern generated across 50 generations in these rats has been shown to deliver ultra-high even gene-level resolution for complex genetic studies. We investigated the usefulness of the HS rat model for fine mapping and identification of genes underlying bone fragility phenotypes. We compared bone geometry, density and strength phenotypes at multiple skeletal sites in HS rats with those obtained from 5 of the 8 progenitor inbred strains. In addition, we estimated the heritability for different bone phenotypes in these rats and employed principal component analysis to explore relationships among bone phenotypes in the HS rats. Our study demonstrated that significant variability exists for different skeletal phenotypes in HS rats compared with their inbred progenitors. In addition, we estimated high heritability for several bone phenotypes and biologically interpretable factors explaining significant overall variability, suggesting that the HS rat model could be a unique genetic resource for rapid and efficient discovery of the genetic determinants of bone fragility. Currently, we are undertaking a genome-wide association study for over 1500 HS rats using 20,000 SNPs to narrow the candidate genes considerably, which will greatly enhance our ability to identify causative genes that affect bone fragility phenotypes.

MO0197

Identification of *Lpin1* as a Candidate Gene for a Quantitative Trait Locus for Bone Mineral Density. Cheryl Ackert-Bicknell¹, Dana Godfrey¹, Yaoyu Chen², Beverly Paigen¹. ¹The Jackson Laboratory, USA, ²University of Massachusetts Medical School, USA

Genome wide association studies have identified a number of loci associated with bone mineral density (BMD) in human subjects. Collectively, these loci explain a very small fraction of the variance in this phenotype, suggesting the existence of additional, yet unidentified loci for BMD. Due to the development of new resources and analysis methods, there has been increased success in finding the genes associated with BMD using mouse models. In this study, we have identified *Lpin1* as a candidate gene for a quantitative trait locus (QTL) for BMD in mice. Specifically, we mapped 7 QTLs for whole body areal BMD in an F2 cross between the C57BL/6J (B6) and NZW/LacJ (NZW) inbred strains. We identified two highly significant QTL: on Chromosome (Chr) 1 at 73.9 cM and on Chr 12 at 8.7 cM. Statistically suggestive QTL were identified on Chrs 5 (at 45.4 cM), 10 (1.9 cM), 14 (at 34.7 cM), 15 at 8.4 cM and 17 (at 12.0 cM). The confidence interval for the Chr 12 QTL extended from 2.7 to 18.7 cM and this QTL is coincident for a femoral volumetric BMD QTL mapped in MRLxSJL (at 5.5 cM) and a femoral volumetric BMD QTL mapped in B6xC3H (at 2.94 cM). Using block haplotyping, we were able to reduced this QTL to 5 genes: *Apob*, *Lpin1*, *Myt1l*, *Sntg2* and *Hdac9*. Of these genes, only *Lpin1* and *Hdac9* are expressed in bone. The fatty liver dystrophy (*fld*) strain of mice carry a spontaneous deletion of the 2nd and 3rd exons of the *Lpin1* gene which arose on a BALB/cByJ (BALB) strain background. Mice homozygous for the *fld* allele lack normal adipocytes and have greatly reduced white adipose tissue mass. Furthermore, these mice have abnormal energy expenditure in muscle. We wished to evaluate if *Lpin1* was a candidate gene for this QTL in the absence of the lipodystrophy observed in the null mutant mice. In order to do this, we bred *fld/fld* mice to wildtype BALB mice to make *Lpin1* haploinsufficient mice (*fld/+*). Female, 11 week old *fld/+* mice had normal percent body fat compared to age matched BALB controls (*fld/+* = 16.47 ± 0.24% vs. *+/+* = 16.01 ± 0.39%, *P* = 0.449). However, these mice did have reduced whole body areal BMD (*fld/+* = 0.0480 ± 0.0002, *+/+* = 0.0510 ± 0.0007, *P* = 0.007). In sum, using genetic mapping and bioinformatics methods, we have identified *Lpin1* as a candidate gene for a BMD QTL on mouse Chr 12, such that a reduction in *Lpin1* levels is associated with decreased bone mass.

Osteoprotegerin (OPG) is an osteoblast-secreted decoy receptor that is crucial for bone metabolism. There is evidence that OPG is also involved in non-skeletal disease pathology, such as cardiovascular diseases and metabolic syndrome, and that it is a predictor of mortality. In addition to age, gender, body mass index and menopause status, determinants of circulating levels of OPG remain poorly understood. However, the moderate heritability of serum OPG suggests that genetic factors play an important role. To identify common genetic variants affecting serum OPG levels, we conducted a meta-analysis of genome-wide association studies of natural log transformed serum OPG, using ~2.5 million genotyped and imputed common single nucleotide polymorphisms (SNPs) on autosomes and sex chromosomes in 8,545 participants of European and Chinese descent from the Framingham Heart Study (*n* = 3,223 and 3,685 European ancestry men and women, respectively), GOOD Study (*n* = 935 European ancestry men), and Hong Kong Osteoporosis Study (*n* = 702 Chinese women). All cohorts performed GWA analyses on genotyped and imputed data adjusting for age, age² and sex. An additive regression model was applied. Summary statistics from the individual studies were combined using fixed-effects inverse-variance weighted meta-analysis. Evidence of genome-wide significance (GWS) was set at *P* < 5 × 10⁻⁸ after a genomic control correction. Variants at 2 loci reached GWS for association with serum OPG concentrations: 8q23-q24.1 (*p* = 2.8 × 10⁻¹⁴ near *MAL2*, *COLEC10* and *OPG*), and 14q21.1 (*p* = 3.0 × 10⁻⁹ near *LRFN5*). Sex-specific meta-analysis revealed an additional locus on 15q26.2 (*p* = 3.5 × 10⁻⁸ near *MCTP2*). In summary, we identified 3 novel loci that are associated with serum OPG levels in populations of European and Chinese descent. Follow-up replication, fine-mapping, and functional studies of these genomic loci may provide additional insights into the regulation of serum OPG levels.

BMP Signaling Inhibits Myogenesis and Induces Osteoblastic Differentiation in Satellite Cells During Muscle Regeneration. Hiroki Sasanuma¹, Katsumi Yoneyama¹, Satoshi Ohte², Masashi Shin², Shoichiro Kokabu¹, Toru Fukuda¹, Takenobu Katagiri^{*3}. ¹Saitama Medical University RCGM, Japan, ²Saitama Medical University, Japan, ³Saitama Medical University Research Center for Genomic Medicine, Japan

Bone morphogenetic proteins (BMPs) induce heterotopic bone formation in skeletal muscle. Fibrodysplasia ossificans progressiva (FOP) is a rare inherited disorder characterized by progressive ectopic bone formation in skeletal muscles. Several mutations in one of BMP type I receptors, ALK2, have been identified in patients with FOP. In FOP, muscle injury induces acute heterotopic bone formation in skeletal muscle. Skeletal muscle satellite cells are quiescent progenitors located underneath the basal lamina that surrounds muscle fibers and play central roles in postnatal muscle growth and regeneration. Recently, it was reported that BMP signaling plays important role in muscle regeneration. In this study, we examined a role of BMP signaling on differentiation of primary satellite cells in vitro. We induced muscle regeneration by injecting snake venom into tibialis anterior muscle in mice. Necrotic myofibers were detected during the first 2 days, and then many mononuclear cells were gradually invaded into the muscle tissue until on day 3 after the injury. On day 5 to 7, regenerative myofibers appeared in the tissue. The numbers of satellite cells increased 2- to 3-fold than that in uninjured muscles. To examine the impact of BMP

signaling on satellite cell function, freshly sorted cells were stimulated with BMP-4. Myogenic differentiation of satellite cells was inhibited by the BMP treatment. In contrast, ALP activity of BMP was induced by BMP-4 in a dose-dependent manner. These findings suggest that satellite cells are the potential target of BMP signaling to induce heterotopic bone formation during muscle regeneration in FOP.

Increasing canonical Wnt signaling does not rescue the fracture phenotype of mice lacking Bmp2. Giuseppe Intini*, Luciane Capelo, Karen Cox, Vicki Rosen. Harvard School of Dental Medicine, USA

BMP signaling and Wnt signaling are active during fracture repair but whether these pathways work in tandem to promote healing is unknown. Mice lacking limb-specific expression of Bmp2 (Bmp2cko) display two fracture-related phenotypes: bones of the appendicular limb skeleton spontaneously fracture as the mice age; once fractured, limb bones are unable to initiate fracture repair. Among the components of the Wnt signal transduction pathway analyzed during fracture repair, Dkk1 has been identified as a negative regulator of fracture healing in mice and in humans, increased Dkk1 transcript levels are found in patients with nonunion fractures. Since BMP2 has been shown to regulate Dkk1 in the developing limb, we hypothesized that the Bmp2 fracture phenotypes might be the result of altered Dkk1 activity. Here we show that Bmp2cko mice have elevated levels of bone Dkk1 transcripts at 8 and 15 weeks of age, consistent with the lack of fracture healing we observe in these mice. Surprisingly, when we reduce Dkk1 levels (Bmp2cko;Dkk1^{-/-}), the Bmp2cko fracture phenotypes are unaffected. Spontaneous fractures occur at the same rate in Bmp2cko;Dkk1^{-/-} mice and Bmp2cko mice, and there is no initiation of healing in either mouse genotype. As we can rescue the lack of healing in Bmp2cko mice by local injection of recombinant human BMP2 at the fracture site, we believe that the periosteal progenitor cell population needed to initiate repair is resident but remains in a quiescent state in the absence of BMP2. Increasing Wnt signaling does not influence periosteal cells to initiate repair when BMP2 is absent. We believe our data suggest that BMP signaling and Wnt signaling have distinct cellular targets in adult bone, where BMPs activate periosteal progenitors required for healing while Wnts activate more mature bone cells to enhance bone formation.

The Pattern of CXCR2-related Chemokine Gene Expression by FGF2 in the Osteoblast and Endothelial Cells Supports the Mobilization of Hematopoietic Stem and Progenitor Cells. Je-Yoel Cho¹, Kyung-Ae Yoon^{*2}, Hey-Sim Cho³. ¹School of Dentistry, Kyungpook National University, South Korea, ²Kyungpook National University, South Korea, ³School of dentistry, Kyungpook National University, South Korea

The maintenance of stem cells requires a specific microenvironment. HSC (hematopoietic stem cell) niche could be mainly derived into the osteoblast (OB) niche that maintains a quiescent HSC microenvironment and the vascular niche that regulates the proliferation, differentiation, and mobilization of HSC. SDF1-CXCR4 signaling is known to be important for hematopoiesis. Recent report showed that the reduction of SDF-1 were affected the expression of OB niche-related factors in bone marrow (BM) stromal cells of the conditioned knockout mice model. Systemic administration of FGF2 failed normal hematopoiesis in the BM by the reduced SDF-1. However, FGF2 signaling was an important regulator of endothelial cell angiogenesis by increasing SDF-1. Therefore, we hypothesized FGF2 induces a change of HSCs migration in BM and investigated important factors of HSCs migration using microarray chip. We firstly confirmed FGF2 decreased the expression of HSC niche-related genes in the primary OB but not in C166 cells. We selected the regulated genes that function in extracellular region during FGF2 treatment from the gene chip analysis. We confirmed the selected genes by qRT-PCR and identified CXCR2-related chemokine candidate, CXCL5. Chemotaxis assay showed CXCL5 induced the migration of hematopoietic stem and progenitor cells (HSPCs). According to these results, FGF2 induced the change of chemokine expression, of CXCL5. Finally, the difference action of FGF2 on the OB and C166 cells affected the mobilization of HSPCs in the BM.

A Novel Role for the Estrogen Responsive Cytokine, Lipocalin-2, in Bone. Muzaffer Cicek^{*1}, John Hawse², Sarah Grygo³, Kevin Pitel⁴, Kenneth Peters³, Nalini Rajamannan⁵, Malayannan Subramaniam¹, Thomas Spelsberg¹. ¹Mayo Clinic, USA, ²Mayo Clinic College of Medicine, USA, ³Mayo Clinic College of Medicine, USA, ⁴University of Minnesota, USA, ⁵Northwestern University Medical School, USA

Neutrophil Gelatinase-associated Lipocalin-2 (LCN2) is a member of the secreted lipocalin family of cytokines which function as modulators of many different physiological processes including cell differentiation, proliferation and apoptosis. Expression of LCN2 is primarily ubiquitous with the highest levels observed in bone marrow. Despite its high expression in bone marrow, the role of LCN2 in the skeleton has yet to be studied. To begin to elucidate its role in bone, we first investigated the changes in the expression levels of LCN2 during the course of calvarial cell mineralization. These studies revealed that LCN2 expression significantly increases, upwards of 250 fold, during the course of osteoblast differentiation. Since LCN2 has been shown to be regulated by estrogen in other tissues, and since estrogen is an important anabolic hormone in bone, we next investigated the regulation of LCN2 by estrogen in bone cells. U2OS osteosarcoma cells expressing either ER α or ER β were treated with estrogen over the course of 24 hours. LCN2 was shown to be induced by approximately 5 fold after 4 hours of treatment only in cells expressing ER α . Interestingly, ovariectomy of C57BL/6 mice also resulted in increased expression of LCN2 in the cortical shell of long bones which was further magnified following estrogen replacement. These data suggest that LCN2 may in part mediate estrogen effects in bone. To further extend our investigations, we also examined LCN2 expression in hematopoietic osteoclast progenitors isolated from bone marrow following treatment with MCSF. These studies revealed that LCN2 expression was significantly elevated in the non-adherent population compared to adherent stromal cells. The addition of RANKL and MCSF to the non-adherent cells decreased the expression of LCN2 at day 0 and completely suppressed the expression of this gene in mature osteoclasts. The same patterns of LCN2 expression were also observed in RAW264.7 cells. Treatment of osteoclast precursors with a LCN2 antibody also suppressed fusion and differentiation of osteoclast. Taken together, these data suggest that expression of LCN2 is essential during early stages of osteoclast differentiation. These studies are the first to implicate an important role for LCN2 in mediating both osteoblast and osteoclast function and suggest that this estrogen responsive cytokine may also serve as a novel coupling factor contributing to bone homeostasis.

Alveolar Bone Repair under Homeostatic Conditions: Modulation of Inflammatory and Osteogenic Processes by IL-10 and TNF- α . Andreia Vieira^{*1}, Carlos Eduardo Repeke², Elcia Maria Silveira³, Carolina Favaro Francisconi³, Raissa Goncalves Carneiro Spera Andrade³, Ana Paula Favaro Trombone³, Gerson Francisco Assis³, Rumio Taga³, Gustavo Pompermaier Garlet³. ¹Bauru School of Dentistry - University of Sao Paulo, Brazil, ²Bauru School of Dentistry - University of Sao Paulo (FOB - USP), Brazil, ³Bauru School of Dentistry - University of Sao Paulo (FOB - USP), Brazil

Cytokines have been implicated in inflammatory bone loss process, however its role in bone repair process remains unknown. The objective of this study was to characterize the role of IL-10 and TNF- α (anti- and pro-inflammatory cytokines, respectively) in alveolar bone healing process after tooth extraction in IL-10KO and TNFp55KO strains compared to C57BL/6 (WT) mice. Following the extraction of the right upper incisor, the maxilla containing the remaining alveolus was collected 0, 7, 14, 21, 28 and 42 days after extraction for molecular (RealTimePCR) analysis and histomorphometric analysis descriptive and quantitative for fibers, fibroblasts, blood vessels, bone matrix, inflammatory cells, osteoblasts, osteoclasts and clot. The results demonstrated that in WT mice the initial formation of clot (0 hours) was followed by the transient appearance of foci of inflammatory infiltrate (7 days) and gradual (7-42 days) formation of connective tissue, vessels and bone. The IL10KO strain showed an increased density of inflammatory cells associated with higher levels of pro-inflammatory cytokines and chemokines (IL-1 β , TNF- α , KC/CXCL1, MCP-1/CCL-2 and MIP-1 α /CCL3) in the initial periods with lower density of the clot. It was followed by lower density of the fibroblasts, blood vessel and bone matrix, indicating a significant delay in bone repair associated with lower expression of CBFA-1, ALP, OCN and PHEX and higher density of osteoclasts. On the other hand, TNFp55KO strain presented intense increase in counts of inflammatory cells, in spite of a slight decrease of the KC/CXCL1, MCP-1/CCL-2, MIP-1 α /CCL3 and IL-10 expression. TNFp55KO also presented a delay in angiogenesis and in transition of granulation to bone tissue, associated with increased COL-I and a discreet presence of newly formed bone tissue associated with decreased CBFA-1, ALP, OCN and PHEX expression, in opposite of the higher proportion of osteoclasts in the late periods of the repair process. The results show that both cytokines interferes in alveolar bone repair through mechanisms that involve the control of inflammatory cell migration and modulation of osteogenic markers expression, since that the absence of IL-10 is associated with higher inflammatory activity and bone resorption concomitant with

lower bone formation, while the deficiency of TNF- α affect the recruitment of inflammatory infiltrates and the kinetics of alveolar bone healing.

Hedgehog Signaling Pathway Implicated in Oxysterol-Mediated Osteogenesis in Rabbit Bone Marrow Stromal Cells. Sarah Sorice^{*1}, Akishige Hokugo¹, Kenneth Fan¹, Vicente Meliton², Patricia Zuk¹, Weibiao Huang³, Timothy Miller¹, Farhad Parhami², Reza Jarrahy¹. ¹Division of Plastic & Reconstructive Surgery, David Geffen School of Medicine at UCLA, USA, ²Department of Medicine, David Geffen School of Medicine at UCLA, USA, ³Plastic Surgery Section, VA Greater LA Healthcare System, Division of Plastic Surgery, USA

Purpose: To determine the osteogenic capacity of a novel growth factor on rabbit bone marrow stromal cells

Background: Both autologous bone grafts and alloplastic materials are commonly used in the reconstruction of complex craniofacial osseous defects, but both are associated with significant morbidity profiles. Tissue engineering solutions offer an alternative to these techniques. Bone morphogenetic protein (BMP) is an effective osteoinductive growth factor, but its clinical application is limited by exorbitant cost and undesirable side effects. Oxysterols are naturally occurring cholesterol oxidation products that are capable of inducing osteogenic differentiation. The effects of oxysterol on rabbit-bone marrow stromal cells (BMSC) have not been described.

Methods: Rabbit BMSCs were incubated with various concentrations of a novel oxysterol or BMP-2. Alkaline phosphatase (ALP) activity, expression of markers of osteogenic differentiation, and *in vitro* calcification assays were performed. To determine the mechanism of action of oxysterol, rabbit BMSC conditioned with oxysterol were incubated with various concentrations of the Hedgehog (Hh) inhibitor cyclopamine and ALP activity was measured.

Results: ALP activity in rabbit BMSCs treated with oxysterol was significantly higher than in controls and was equivalent to activity in cells treated with BMP-2. Gene expression of osteogenic markers in BMSCs treated with oxysterol was significantly higher than in control groups. Addition of cyclopamine to cultures negated the positive effect of oxysterol on ALP activity.

Conclusion: Oxysterols can induce osteogenesis *in vitro* in rabbit BMSCs with an efficacy similar to BMP-2. This osteogenic activity is in part mediated through the Hh signaling pathway. Oxysterols may represent a viable alternative to BMP-2 in bone tissue engineering models.

Inhibition of Adipocytogenesis by Canonical WNT Signaling in Human Mesenchymal Stem Cells. Longxiang Shen¹, Julie Glowacki², Shuanhu Zhou^{*2}. ¹Brigham & Women's Hospital, USA, ²Brigham & Women's Hospital, USA

INTRODUCTION: Adult human mesenchymal stem cells (hMSCs), also known as marrow stromal cells, have the capacity to differentiate into adipocytes, osteoblasts, and chondrocytes. The WNT signaling pathway plays important roles in the self-renewal and differentiation of mesenchymal stem cells (MSCs). Differentiation of murine adipocytes requires Wnt4 and Wnt5a and is negatively regulated by Wnt10b. Because little is known about WNT signaling in adipocyte differentiation of human MSCs, we tested the hypotheses that canonical and non-canonical WNTs differentially regulate *in vitro* adipocytogenesis of human MSCs.

METHODS: Human MSCs were isolated by expansion of adherent, low-density progenitor cells from marrow discarded during orthopedic surgery. Growth medium was phenol red-free α -MEM, 10% fetal bovine serum-heat-inactivated (FBS-HI), and antibiotics. Adipocytogenic medium had supplements (1 μ M dexamethasone, 0.5 mM 1-methyl-3-isobutylxanthine and 10 μ g/ml insulin) with 1% FBS-HI. Transient transfection of siRNA into hMSCs was performed by electroporation with the Human MSC Nucleofector Kit (Lonza/Amara Biosystems) and either human β -catenin-siRNA (Invitrogen) or non-silencing control siRNA (NC, Santa Cruz Biotechnology, Inc.) as described (Zhou S. J Cell Biochem. 2011 Feb 22. doi:10.1002/jcb.23079).

RESULTS: The expression of adipocyte genes (*PPAR γ 2*, *lipoprotein lipase*, *adipsin*) increased during adipocytogenesis of hMSCs. Simultaneously, the expression of canonical *WNT2*, *10B*, *13*, and *14* decreased, whereas non-canonical *WNT4* and *11* increased, and *WNT5A* was unchanged (Figure). Activation of Wnt/ β -catenin signaling with highly selective inhibitor of GSK-3 β , SB-216763, increased accumulation of β -catenin protein as assessed with Western immunoblotting, inhibited induction of adipocyte genes as well as non-canonical *Wnt4* and *11* gene expression and inhibited adipocytogenesis as demonstrated with Oil-Red-O staining. In contrast, knockdown of β -catenin with siRNA resulted in spontaneous adipocytogenesis.

CONCLUSION: These findings support the view that canonical WNT signaling inhibits and non-canonical WNT signaling promotes adipocytogenesis in adult human marrow-derived mesenchymal stem cells.

Microarray Analysis of Fracture Gene Expression in Response to Cox-2 Gene Therapy Identifies Novel Angiogenic Genes. Charles Rundle^{*}, Nicoleta Popa, Subburaman Mohan, K-H. William Lau, Jerry L. Pettis Memorial VA Medical Center, USA

Cyclo-oxygenase (Cox)-2 gene therapy is one of the very few therapies that has been demonstrated to promote the bony union of the fracture callus and thereby accelerate fracture repair. To elucidate the mechanism for Cox2 regulation of fracture callus cartilage conversion, we performed a microarray analysis of gene expression in the mouse femur fracture callus in response to Cox-2 transgene expression. Gene expression was determined in femur fractures injected 1 day post-fracture at the periosteum with murine leukemia virus (MLV)-Cox2 (N=3) or MLV-B-galactosidase control (N=3) vectors. RNA was harvested from fracture calluses at 10 days post-fracture, a time coinciding with cartilage conversion to bone. Microarray hybridization utilized the Affymetrix ST-1.0 mouse exon array. Of the genes that displayed significant changes in expression ($p < 0.05$), 237 were more than 1.2-fold up-regulated, while 473 were more than 1.2-fold down-regulated. Although few of the growth factor families traditionally associated with bone formation or remodeling were represented, pathway analysis identified 2 key pathways modulated by Cox2 expression: inflammation and angiogenesis. Among the differentially expressed inflammatory genes, the chemokines Ccl7, Ccl8, Cxcl9 and Cxcl10 were between 1.6 and 3-fold up-regulated, suggesting that Cox2 promotes chemotaxis. Some inflammatory genes were up-regulated, including IL6 (1.4-fold), but many inflammatory genes were down-regulated, indicating that Cox2 regulation of cartilage conversion is complex and can be counter to its normal pro-inflammatory role. Surprisingly, the better-characterized families of angiogenic growth factors, such as VEGF, did not display significant changes in gene expression at a time when they would be expected to promote bony union of the fracture callus. Several angiogenic genes did display significant changes in expression. Angiopoietin-like (ANGPTL)-1 and ANGPTL2 were up-regulated 1.3-fold and 1.2-fold respectively, while ANGPTL7 was down-regulated 1.4-fold. These ANGPTL genes have been associated with oxidative stress, and blood vessel branching and remodeling during angiogenesis. Thrombospondins 3 and 4 were also up-regulated, suggesting that Cox2 regulates cell adhesion. We conclude that Cox2 promotes bony union of the fracture callus through 1) inflammatory pathway recruitment of osteoblasts and osteoclasts that remodel fracture cartilage to bone, and 2) angiogenesis regulated by novel angiogenic genes.

MO0208

Nerve Growth Factor (NGF) Promotes Dental Epithelial Cell Proliferation. Mariko Ono*, Tsutomu Iwamoto, YU SUGAWARA, Aya Yamada, Takashi Nakamura, Satoshi Fukumoto. Tohoku University Graduate School of Dentistry, Japan

Enamel, the outer layer of tooth, is the hardest tissue in body and is formed by dental epithelial cell, ameloblast. Nerve growth factor (NGF), a member of neurotrophins, is expressed in dental epithelial cells, but their biological functions in ameloblasts differentiation have not been cleared. Here, we report that NGF positively regulates the proliferation of undifferentiated ameloblasts. NGF activates two types of receptors: tyrosine kinase receptor A (TrkA) and p75. RT-PCR and immunohistochemistry revealed that p75 was expressed in inner dental epithelium cells during early developmental stage of ameloblasts. On the other hand, TrkA was absent in tooth germ. To analyze the function of NGF in dental epithelium, a rat dental epithelial cell line, SF2, was used in this study. Exogenous NGF increased the number of SF2 cells and the incorporation of bromodeoxyuridine (BrdU), indicating that NGF promotes proliferation of SF2 cells. Immunostaining of p75 in cultured SF2 cells showed the different expression, compared to ameloblastin expression, indicating that p75 is expressed in undifferentiated SF2 cells, but not in differentiated SF2 cells. Further, NGF induced the phosphorylation of ERK1/2, but not of both I κ B and p38. U0126, a MEK inhibitor, inhibited NGF induced SF2 cell proliferation. Taken together, these results suggest that NGF regulates dental epithelial cell proliferation via p75-ERK1/2 pathway.

Disclosures: Mariko Ono, None.

MO0209

Oncostatin M Is a Potent Regulator of Interleukin-6 and RANKL Expression in Mouse Synovial Fibroblasts and Synergises with Interleukin-1. Benoit Le Goff¹, Brett A. Tonkin¹, Sofie Singbrant¹, T. John Martin¹, Evange Romas², Natalie Sims³, Nicole Walsh^{*1}. ¹St Vincent's Institute of Medical Research, Australia, ²Department of Medicine, St Vincent's Hospital, University of Melbourne, Australia, ³St. Vincent's Institute for Medical Research, Australia

Oncostatin M (OSM) is a multipotent cytokine expressed in the synovium of rheumatoid arthritis (RA) patients. OSM alone, or in concert with pro-inflammatory cytokines like IL-1, can stimulate expression of genes that promote inflammation and joint destruction. This study determined the acute effects of OSM, IL-1, and their combination on expression of IL-6 and RANKL in synovial fibroblasts (SFs). For this study, SFs were isolated from non-arthritis mouse hind paws and stimulated with mouse OSM (2 ng/mL), mouse IL-1 (10 ng/mL), or their combination for 1, 6 and 24 hours. RNA was isolated for quantitative RT-PCR analyses. OSM and IL-1 both increased IL-6 mRNA expression, with induction by OSM being more rapid and sustained compared with induction by IL-1: 135 fold vs. 40-fold at 24 hrs. Profound synergistic upregulation of IL-6 expression was observed when suboptimal doses of OSM and IL-1 were combined (>1000-fold at 6 and 24 hrs). Both OSM and IL-1 increased RANKL mRNA expression by 6 hrs (8-fold and 3-fold, respectively) but only OSM further increased RANKL expression at 24 hrs (20-fold). Combining suboptimal doses of OSM and IL-1 significantly enhanced RANKL expression by 24 hrs (100-fold). Cells lacking OSMR expression showed no induction of IL-6 or RANKL mRNA expression in response to OSM treatment, but responded to IL-1 treatment in a similar manner to matched wild type SFs. In wild type SFs, OSM stimulated expression of its co-receptors (OSMR, 6-fold at 6 and 24 hrs, and gp130, 3-fold at 24 hrs). Furthermore, OSM increased IL-1 receptor mRNA expression at 6 and 24 hrs (5-fold) and increased IL-1 receptor protein expression at 24 hrs as determined by flow cytometry. IL-1 did not regulate its own receptor, but induced a 3-fold increase in OSMR mRNA expression at 6 and 24 hrs. Finally, immunostaining showed protein expression of OSM and its co-receptors in the synovium in normal mouse knee joints; this expression was increased in antigen-induced arthritis. Together our data shows that OSM, acting alone or in synergy with IL-1, is a potent regulator of IL-6 and RANKL expression in SFs. The ability of OSM and IL-1 to cross-regulate expression of their respective receptors likely explains their synergistic effects on SFs. The results identify a significant role for OSM, acting through OSMR, in mediating inflammation and bone destruction in arthritic joints. OSM signaling via OSMR is therefore a potential therapeutic target in the treatment of RA.

Protease-Activated Receptor-2 is Required for Normal Skeletal Growth and Repair. Smitha R Georgy¹, Charles N. Pagel¹, Natalie Sims², Eleanor Mackie^{*3}. ¹School of Veterinary Science, University of Melbourne, Australia, ²St. Vincent's Institute for Medical Research, Australia, ³University of Melbourne, Australia

The G-protein-coupled receptor, protease-activated receptor-2 (PAR₂), is expressed by many cell types including osteoblasts and monocytes, and activated by proteases including coagulation factors, mast cell tryptase and kallikreins, which are

likely to be present in bone at sites of injury, inflammation or cancer metastasis. Moreover, PAR₂ antagonists are currently being developed for the treatment of inflammatory conditions in a number of tissues, thus it is important to understand how activation of this receptor influences bone metabolism. The aim of the current study was to investigate the role of PAR₂ in skeletal growth and bone repair using wild type (WT) and PAR₂ knockout (KO) mice. Tibiae were isolated from male WT and KO mice at 50 days of age and analysed by static and dynamic histomorphometry. To identify the role of PAR₂ in bone repair, a hole was drilled through the tibiae of 14-week-old WT and KO mice then the mice were killed at various times after surgery for histological analysis of the injured bone. Bone marrow isolated from the bones of WT and KO mice was cultured and investigated for the presence of alkaline phosphatase (ALP)-positive fibroblastic colonies; osteoclasts (TRAP-positive multinucleate cells) were counted in bone marrow cultures treated with M-CSF and RANKL. Trabecular bone volume (BV/TV) was significantly greater in the tibiae of PAR₂ KO mice than in those of WT mice at 50 days of age. This high bone volume in KO mice was associated with greater trabecular number and thickness. Osteoclast surface was significantly lower in KO than in WT mice, but osteoblast surface and osteoid volume were also significantly lower in KO than in WT mice. In mice subjected to bone injury, there were significantly fewer cells in the drill site of KO mice compared to WT mice 3 days post-surgery, although macrophage numbers did not differ between genotypes. There was significantly less new bone in the drill site in PAR₂ KO mice compared to WT mice 7 days post-surgery; there were also fewer osteoclasts in KO than in WT drill sites at this stage. Bone marrow cultures from KO mice showed fewer ALP-positive colony-forming units and osteoclasts compared to cultures from WT mice. These results suggest that PAR₂ activation contributes to the determination of cells of both the osteoblast and osteoclast lineages within bone marrow, and thereby participates in the regulation of skeletal growth and bone repair.

Skeletal Phenotype of the Leptin Receptor-Deficient Db/Db Mouse. Garry Williams^{*1}, Karen Callon¹, Maureen Watson¹, Jessica Costa², Yaoyao Ding¹, Michelle Dickinson¹, Yu Wang³, Dorit Nao¹, Ian Reid¹, Jillian Cornish¹. ¹University of Auckland, New Zealand, ²University of Auckland, Nzl, ³University of Hong Kong, Hong Kong

Leptin, a major hormonal product of the adipocyte regulates appetite and reproductive function through its hypothalamic receptors. The leptin receptor is present in osteoblasts and chondrocytes and previously we have shown leptin to be an anabolic bone factor in vitro, stimulating osteoblast proliferation and inhibiting osteoclastogenesis. Leptin increases bone mass and reduces bone fragility when administered peripherally but can also indirectly reduce bone mass when administered into the central nervous system. However, data from animal models deficient in either leptin (ob/ob) or its receptor (db/db) remain contradictory. We compared the bone phenotype of leptin receptor-deficient (db/db) and wild-type (WT) mice using micro-computed tomography (μ CT) analysis of the proximal tibiae and vertebrae. In the tibia, db/db mice had reduced percent trabecular bone volume (13.0 1.62% in WT vs 6.01 0.601% in db/db, $p = 0.002$) and cortical bone volume (411 21.5 μm^3 vs 316 3.53 μm^3 , $p = 0.0014$), trabecular thickness (48.4 0.0107 μm vs 45.1 0.929 μm , $p = 0.041$) and trabecular number (2.68 0.319 mm^{-1} vs 1.34 0.148 mm^{-1} , $p = 0.0034$). In the 5th lumbar vertebral body the trabecular thickness and cortical thickness were decreased in the db/db vs WT (0.053 0.0011 mm vs 0.047 0.0013 mm, $p = 0.0002$) and (0.062 0.00054 mm vs 0.056 0.0009 mm, $p = 0.0001$) respectively whereas the trabecular and cortical percent bone volume and trabecular number did not reach significance. The total (endosteal and periosteal) cortical perimeter (12.2 0.19mm vs 13.2 0.30mm, $p = 0.01$) was increased. The serum osteocalcin levels were reduced in the db/db mouse, suggesting that bone formation rates are decreased. The material properties of db/db femora were determined by three-point bending and nanoindentation, showing decreased bone strength (13.3 0.280 N vs 7.99 0.984 N, $p = 0.0074$), and material stiffness (28.5 0.280 GPa vs 25.8 0.281 GPa, $p < 0.0001$).

Study on Structure and Function of Sclerostin by Site Directed Mutagenesis of Cysteine- Knot and Finger 2 residues. Kwang Joon Kim¹, Ajitha Jami², Kyoung Min Kim¹, Sung-Kil Lim¹, Gadi Jogeswar^{*3}, Eun Jin Kim⁴, Sena Hwang¹. ¹Division of Endocrinology & Endocrine Research Institute, Department of Internal Medicine, Yonsei University College of Medicine, South Korea, ²Brain Korea 21 Project for medical sciences, Yonsei University College of Medicine, South Korea, ³Yonsei University College of Medicine Seoul South Korea, South Korea, ⁴Severance Biomedical Science Institute, Yonsei University College of Medicine, South Korea

Sclerostin is a secreted glycoprotein, expressed and secreted by osteocytes and acts as a negative regulator of bone formation using Wnt signaling. The inhibitory action of Sclerostin in Wnt signaling is due to the binding of Wnt co-receptor LRP5. Inhibition of Sclerostin binding to Wnt receptor can enhance the Wnt signaling makes it as a highly interesting target for diseases related to bone loss such as osteoporosis.

Recent studies shows that the first missense mutation in the human Sclerostin (SOST) gene results in the exchange of a cysteine residue of the cysteine-knot motif of Sclerostin for a non-cysteine amino acid, a defect that leads to a complete loss of function of Sclerostin due to retention of the mutated protein in the ER. In order to identify the key cysteine knot motif residues contributing for the Sclerostin structure and function, we choose site directed mutagenesis method and substituted the cysteine residues with alanine. After the expression of the pcDNA3.1/Sost-mycHis (wild type) and pcDNA3.1/mut-Sost-mycHis in MC3T3-E1 cells, we found that the Sclerostin expression in the cell lysate and culture medium was significantly different in the cysteine mutants compared to wild type, we also found that the secretion into the culture medium was significantly reduced in the mutants compared with the wild type Sclerostin. The functionality of wild type and mutant Sclerostin will be determined by the Wnt signaling activity, which is measured by super-Top MC3T3-E1 stable cell lines treated with wild type and mutant Sclerostin conditioned medium. This study is crucial to elucidate the key residues essential for the structure and function of Sclerostin, which will further helpful to design molecules targeting to Sclerostin for the enhancement of bone formation.

Systemic Bone Metabolism and Inflammation in RA Patients Receiving TNF Inhibiting Therapy. Won Park^{*1}, Mie Jin Lim², Seong Ryul Kwon¹, Kowoon Ju¹, Min Jung Son¹. ¹Inha University Hospital, South Korea, ²Division of Rheumatology, Department of Internal medicine, Inha University, South Korea

Background: Etanercept is soluble Tumor Necrosis Factor (TNF)- α receptor which is effective in suppressing inflammation in Rheumatoid Arthritis (RA). However bone metabolism is not yet known after etanercept therapy.

Objective: Our aim is to assess bone metabolism along with inflammation in RA patients after etanercept treatment for 3 months and to compare bone turnover markers in RA patients with age, sex matched control group.

Methods: Twenty-two patients (20 women and 2 men; age 47.05 \pm 11.87 years) with active RA were included. Etanercept was administered at standard dose, twice a week. Age and sex matched control group were recruited. Venous blood was drawn at baseline and after 12-14 weeks of etanercept use in RA patient. Bone metabolism was assessed using bone specific alkaline phosphatase (BSAP), osteoprotegerin (OPG), sclerostin for bone formation and receptor activator for nuclear factor κ B ligand (RANKL), serum c-telopeptide (CTX) for bone resorption. Serum level of inflammatory mediators including ESR, CRP, TNF- α and IL-6 were also determined. TNF RNA expression was measured by real time RT-PCR.

Differences between two groups were examined by Wilcoxon signed ranks test. A p value of less than 0.05 was denoted statistically significant.

Results: At baseline both serum sclerostin and CTX level was significantly lower in RA patients than in control group but sclerostin increased markedly after etanercept treatment while CTX rose marginally (Table 1). BSAP and OPG were least affected by etanercept. RANKL decreased mildly after treatment.

Inflammatory mediators responded to the treatment as ESR, CRP and IL-6 all significantly decreased (Table 2). However, serum TNF- α increased to > 32 pg/mL in all RA patients after treatment and TNF RNA expression also showed concordant increase (2.04 \pm 1.38, p = 0.002).

Conclusions: Our study showed significantly lower serum CTX and sclerostin level in RA patients than in control group which increased after etanercept treatment. Thus we postulate that in addition of suppressing inflammation due to RA, etanercept normalize bone metabolism which was suppressed in RA patients and increased serum TNF level along with high TNF RNA expression after etanercept treatment seem to play some role in it.

	Age, sex matched control	RA patients Baseline	P (control vs. RA patients Baseline)	week 12-14 after etanercept	P (RA patients Baseline vs. Week 12-14)
Sclerostin (pg/mL)	2.2 \pm 1.61	1.76 \pm 2.29	0.019	3.04 \pm 4.1	0.036
Serum CTX (ng/mL)	0.4 \pm 0.19	0.28 \pm 0.13	0.016	0.34 \pm 0.17	0.108

Table 1

	Baseline	Week 12-14 after etanercept	p
ESR (mm/hr)	39 \pm 30.5	28 \pm 26.9	0.039
CRP (mg/dL)	0.94 \pm 0.86	0.51 \pm 1.15	0.044

Targeted Deletion of Chemokine Receptor (Ccr)-3 Increases Trabecular Bone Density in Mice. Bouchra Edderkaoui^{*}, Yan Hu, Anil Kapoor, Subburaman Mohan, Jerry L. Pettis Memorial VA Medical Center, USA

Chemokines are now recognized to be the major factors in inflammation-induced bone loss. The functions of chemokines are mediated by members of Ccr family. Chemokines and their receptors are known to be expressed in cells of both osteoblastic and osteoclastic lineage. Accordingly, disruption of Ccr1 in mice leads to osteopenia caused by impaired osteoclast and osteoblast functions. In contrast, Ccr2 knockout (KO) mice exhibit increased bone mass caused by deficiency in osteoclast functions. Since little is known on Ccr3 functions in bone, we evaluated the expression of Ccr3 during RANKL-induced differentiation of mouse monocyte RAW-264.7 cells into TRAP-positive multinucleated osteoclasts in vitro. We found Ccr3 expression was increased by 4-, 10- and 30-fold (all P < 0.01) compared to control cultures after 1 day, 2 and 3 days treatment with RANKL, respectively. Based on these data and the findings that Ccr3 is expressed in both osteoclast and osteoblast cells and it binds to chemokines known to influence osteoclast function, we tested the hypothesis that Ccr3 regulates peak bone mass. Heterozygous Ccr3^{+/-} mice were bred to generate homozygous KO and their corresponding littermate wild type (WT) mice. BMD measurements by PIXImus revealed significant increases in femur BMD in Ccr3-KO mice at 5 and 8 weeks of age compared to WT control mice. Micro-CT measurements revealed that trabecular (Tb) bone volume/total volume was increased by 19% (P = 0.03) in female KO mice at 10 weeks of age which was caused by both an increase in Tb thickness and a reduction in Tb separation. Accordingly, Tb BMD was increased by 15% in the KO mice compared to WT mice. To determine the mechanism for high bone mass in the KO mice, we evaluated the expression level of osteoblast and osteoclast marker genes. While the expression level of RANK in bones was not significantly different between KO mice and WT mice, Runx2 expression was increased by 2-fold (P = 0.03) in the KO mice. **Conclusions:** 1) Targeted disruption of Ccr3 increases trabecular bone density by influencing Tb thickness and Tb separation, consistent with effects on both bone formation and resorption. 2) Our data and other published data suggest complex functions for Ccrs that influence both osteoclasts and osteoblasts and thereby regulate bone mass either positively or negatively.

MO0215

Circulating Liver Derived IGF-1 is Dispensable for the Osteogenic Response to Mechanical Loading in Female Mice. Johan Svensson¹, Sara Windahl², Leanne Saxon³, Klara Sjogren¹, Joanna Price⁴, Lance Lanyon³, Claes Ohlsson⁵. ¹Center for Bone & Arthritis Research, Sweden, ²Center for Bone & Arthritis Research, Sahlgrenska Academy, Sweden, ³Royal Veterinary College, United Kingdom, ⁴University of Bristol, United Kingdom, ⁵Center for Bone Research At the Sahlgrenska Academy, Sweden

IGF-I is a key regulator of bone mass and its expression is regulated in response to mechanical loading. Conditional depletion of IGF-I in osteoblasts inhibits the bone anabolic effect of mechanical loading. 1 Serum IGF-I is mainly liver-derived and low serum IGF-I is associated with increased fracture risk. 2, 3. Mice with conditional liver-specific IGF I inactivation (LI-IGF-I mice) display reduced cortical bone mass. 4. The aim of the present study was to determine the role of liver-derived IGF-I for the osteogenic response to mechanical loading in mice.

We evaluated the osteogenic response in LI-IGF-I mice. At either 6 (adult) or 19 (aged) months of age, the right tibia was subjected to short periods of axial cyclic compressive loading, three times a week for two weeks (40 cycles, peak strains of either 2800 or 3500 μ ε for the adult and aged mice, respectively). Peripheral computed

tomography (pQCT) was used to assess the osteogenic response in the cortical and cancellous bone of the loaded (right) versus the non-loaded (left) tibia ((R-L)/L*100; n=7-11).

Mechanical loading increased the trabecular bone mineral density (BMD; adult 123%; aged 119% over non-loaded tibia, $p<0.001$) and cortical cross sectional bone area (adult 28%; aged 26% over non-loaded tibia, $p<0.001$) similarly in adult and aged wild type mice. LI-IGF-I mice had a 70% reduction of serum IGF-I ($p<0.001$), resulting in a reduced cortical cross sectional bone area ($p<0.05$). However, in contrast to the osteoblast specific IGF-I inactivated mice, which do not respond to mechanical loading, LI-IGF-I mice responded normally to mechanical loading in both the trabecular (trabecular BMD, adult 170%, aged 77% over non-loaded tibia, $p<0.001$) and cortical (cortical cross sectional bone area, adult 28%, aged 31% over non-loaded tibia, $p<0.001$) bone compartments.

These findings demonstrate that although liver-derived IGF-I regulates cortical bone mass, it does not mediate the osteogenic response to mechanical loading in female mice. We therefore propose that IGF-I produced locally in the bone, but not circulating liver-derived IGF-I, modulates the osteogenic response to mechanical loading in bone.

Adhesion to Apatite Surfaces Is Capable of Manipulating MAPK signaling and Osteogenesis in Human Adipose-derived Stem Cells. Patricia Zuk^{*1}, Benjamin Wu², Christopher Arakawa², Eric Tsang². ¹University of California, Los Angeles, USA, ²UCLA Dept of Bioengineering, USA

Background: In the past, combining pro-osteogenic growth factors with human adipose-derived stem cells (ASCs) has been proposed as a means to augment their osteogenic capacity. As an alternative to upstream growth factors, direct manipulation of downstream signaling pathways may represent another option. As such, this study explores the use of apatite surfaces in the manipulation of MAPK signaling and ASC osteogenic capacity.

Results: MAPK signaling and ASC osteogenesis were first characterized on tissue culture polystyrene (TCPS), using exogenous inhibitors to ERK, p38MAPK and JNK activation. ERK and JNK inhibitors, administered at the start of osteogenic differentiation, significantly inhibited AP activity and extracellular mineral production, suggesting that these kinases may promote osteogenic commitment. Consistent with this, altered mineralization levels were also observed upon transduction of osteo-induced ASCs with shRNA lentiviruses for ERK1/2 or JNK1/2 knockdown. Administration of these inhibitors continuously throughout the induction period also resulted in decreased osteogenesis, albeit with distinct stage- and kinase-specific effects, implying a complex role for MAPK signaling in ASC osteogenesis. Distinct changes to MAPK activity and osteogenesis were also measured upon culturing of ASCs on 2D apatite surfaces. Specifically, the apatite surface significantly increased both AP activity and mineral deposition, when compared to TCPS, suggesting that apatites can be osteoinductive to ASCs. The effect of ASC adhesion to apatites and ERK signaling was found to depend on the crystallinity of the apatite or its modification via protein adsorption. Highly crystalline surfaces were found to promote ERK activity in comparison to TCPS, while poorly crystalline surfaces decreased its activity. Adsorption of the serum protein albumin, or the matrix proteins fibronectin or collagen type I to the apatite increased ERK activity, beyond that measured on unmodified controls. ERK activation could be eliminated upon adsorption of the fibronectin peptide RDGS or recombinant osteonectin.

Conclusion: MAPK signaling appears to play a complex role in ASC osteogenesis. Its signaling can be directly manipulated through the ASC adhesion to crystalline apatite surfaces modified through protein or peptide adsorption. As such, adhesion to apatite surfaces may represent an alternative way of altering ASC osteogenesis through manipulation of the MAPK cascade.

Salubrinol Reduces Apoptosis of Mesenchymal Stem Cells and Osteoblasts Induced by Stress to the Endoplasmic Reticulum. Liming Zhao¹, Hiroki Yokota^{*2}. ¹Purdue University School of Indianapolis, USA, ²Indiana University Purdue University Indianapolis, USA

Salubrinol is a small, synthetic chemical agent, known to prevent dephosphorylation of eukaryotic initiation factor 2, alpha subunit (eIF2a). We previously demonstrated that local administration of salubrinol stimulated bone formation and accelerated healing of bone wounds. To understand the mechanism of salubrinol action, we examine its effects on apoptosis. We hypothesized that salubrinol would reduce cellular apoptosis induced by stress to the endoplasmic reticulum (ER).

To test this hypothesis, we employed primary MSCs isolated from mouse bone marrow and MC3T3 osteoblast-like cells. Cells were pre-incubated with 20 microM

salubrinol for 6 h, and then exposed to stress inducers such as thapsigargin, tunicamycin, and dexamethasone for 18 h. Thapsigargin and tunicamycin are the inducers of stress to the ER through the inhibitions of ATPase and glycosylation, respectively. Dexamethasone is a steroid, known to induce catabolic responses and apoptosis. The results demonstrated that pre-incubation with salubrinol reduced apoptosis caused by thapsigargin and tunicamycin. In response to incubation with 5 microM thapsigargin in MC3T3 cells, for instance, cell death was increased to 12.4 4.8% with elevation of an active form of caspase 3. This increase was reduced to 1.6 1.2% by pre-treatment with salubrinol. Similarly, in response to incubation with 1 mg/ml tunicamycin, pre-incubation with salubrinol reduced cell death from 10.9 3.6 % to 2.5 1.1%. For cell death induced by dexamethasone, however, salubrinol did not improve cell viability. The results suggest that salubrinol is a specific suppressor of cellular death, which was induced by stress to the ER. Studies during the last decade demonstrated that apoptosis is as important as mitosis for the growth and maintenance of the skeleton. Stress to the ER is often caused by an accumulation of unfolded or misfolded proteins and induces apoptosis. Through the elevation of eIF2a phosphorylation, salubrinol decreases translational efficiency of a majority of proteins except for a group of proteins such as ATF4 that is one of the critical transcription factors for bone formation. Further investigation of the mechanism of salubrinol-mediated bone formation and suppression of apoptosis is our future studies.

MO0218

Abnormal Mechanical Environment Affects the Morphology, Cytoskeleton and Cytoskeleton-Associated Proteins Expression in Bone Cells. Airong Qian^{*1}, Lifang Hu², Xiang Gao², Wei Zhang², Shengmeng Di², Peng Shang². ¹Northwestern Polytechnical University, Peoples Republic of China, ²Northwestern Polytechnical University, China

Osteocytes are believed to be the mechanosensors of bone and can regulate its effector cell such as osteoblasts and osteoclasts to respond to mechanical stresses. Osteoblasts, which are responsible for bone formation, may directly sense and respond to mechanical stimulation (e.g., fluid flow). The purpose of this study is to investigate the effects of abnormal mechanical environment on the proliferation, morphology, cytoskeleton architecture, cytoskeleton-associated proteins expression in cultured bone cells, and whether osteocytes have regulatory roles in osteoblasts function.

Murine osteoblast-like cell line MC3T3-E1 and osteocyte-like cell line MLO-Y4 were cultured in the bore of a superconducting magnet with large gradient high magnetic field (LG-HMF), which can simulate three apparent gravity levels [μ -g (diamagnetic levitation), 1-g, and 2-g] for 24 or 48 hrs. And then electron microscope (EM), atomic force microscope (AFM) and laser scanning confocal microscope (LSCM) were used to investigate the changes in morphology and cytoskeleton. Western blotting was used to examine the expression of cytoskeleton-associated proteins. MTT assay was employed to detect the effects of conditioned medium (CM) of osteocytes on osteoblasts proliferation.

The results showed that LG-HMF treatment of 24 or 48 hours had no acute lethal effects on both osteoblast-like and osteocyte-like cells. Compared to the natural 1-g control, simulated μ -g environment significantly altered MC3T3-E1 shape, cytoskeleton structure and decreased the expression of h2-calponin, a gene known to response to changes in mechanical environment. The elongated shape, reduced cell extension, reorganized cytoskeleton architecture (F-actin, microtubule and intermediate filament) and decreased expression of cytoskeleton-associated proteins, such as paxillin, talin, vinculin and microtubule actin crosslinker factor (MACF1) were also found in osteocyte-like cells after 48 h - exposure to simulated μ -g environment. CM of osteocytes exposed to simulated μ -g environment promoted osteoblasts proliferation. In contrast, LG-HMF-simulated 1-g and 2-g apparent gravity did not have such effects.

Our findings indicate that that bone cells are sensitive to abnormal mechanical environment, cytoskeleton-associated proteins may be involved in the interaction of bone cells with their mechanical environment and osteocytes have an a regulatory role in osteoblast function.

MO0219

Afamin, Secreted from Non-Resorbing Osteoclasts, Acts as a Chemokine for Preosteoblasts via Akt and G_i-coupled Receptor Signaling Pathway. Beom-Jun Kim^{*1}, Sun-Young Lee², Young-Sun Lee², Seung Hun Lee³, Sung Jin Bae¹, Ha Young Kim⁴, Jung-Min Koh¹, Hong-Hee Kim⁵, Shin-Yoon Kim⁶, Ghi Su Kim⁷. ¹Asan Medical Center, South Korea, ²Asan Institute for Life Sciences, South Korea, ³Asan Medical Center, University of Ulsan College of Medicine, South Korea, ⁴Wonkwang University Sanbon Hospital, South Korea, ⁵Seoul National University, South Korea, ⁶Kyungpook National University Hospital, South Korea, ⁷University of Ulsan, South Korea

In spite of the possible effects of osteoclasts on bone formation by signaling to osteoblasts, questions remain as to when coupling factors are produced during osteoclastogenesis and which stage of osteoblastogenesis is affected by these factors.

To clarify these questions, we established in vitro system for coupling phenomenon. We obtained supernatants of osteoclast culture in the stages of early and late differentiation and resorption, and then the collected conditioned media (CM) were treated on preosteoblastic MC3T3-E1 cells to evaluate influence on migration, viability and proliferation of osteoblasts. We found that secreted coupling factor from early osteoclast differentiation can stimulate recruitment of preosteoblasts. By further performing fractional analyses of the CM with liquid chromatography-tandem mass spectrometry, we identified afamin, known to have binding activity with vitamin E, as one of osteoclast-derived chemokines for preosteoblasts. Chemotactic responses were measured with Boyden chamber and wound healing assay. When we transfected Raw264.7 cell with siRNA against afamin and tested the CM of siRNA-treated osteoclasts for chemotactic activity, osteoclast-induced chemotaxis for preosteoblasts was significantly suppressed. To identify the possible mechanisms of afamin as a chemokine, we focused on several signaling pathways related to cell migration. The phosphorylation of Akt was remarkably increased after afamin treatment on MC3T3-E1 cells, whereas Akt inhibitor LY009242 significantly blocked afamin-induced preosteoblasts migration. In addition, pertussis toxin (PTX), a specific inhibitor of Gi-coupled receptor signaling, significantly diminished afamin-induced preosteoblasts recruitment. However, the level of afamin-induced phosphorylated Akt was not affected by PTX, indicating that Akt and Gi-coupled receptor pathways independently mediate afamin-induced chemotaxis. When we investigated the effect of afamin on osteoclasts themselves, it stimulated osteoclast formation in a dose-dependent manner, based on TRAP staining, and increased bone resorption by 2.8-fold compared with untreated control. In conclusion, we identified afamin as one of osteoclast-derived chemokines for preosteoblasts through activation of Akt and Gi-coupled receptor pathways. We also showed that afamin can act as an autocrine manner by increasing differentiation and resorptive activity of osteoclasts, indicating that it can cause high bone turnover state.

Bone Sialoprotein and Runx2 Are Interdependent during Osteogenic Differentiation of Adult Mesenchymal Stem Cells. Qinghua Lu, Marianna Rodova, James Bernard, Jinxi Wang*. University of Kansas Medical Center, USA

Bone sialoprotein (BSP) is one of the major non-collagenous phosphoproteins in bone and dentin. Our previous study revealed that implantation of BSP stimulates osteogenesis in surgically created rat calvarial defects, but not in rat thoracic subcutaneous tissue. The mechanisms of the tissue-specific response to BSP treatment remain unclear. This study aimed to test our hypothesis that the effect of BSP on osteogenic differentiation is principally dependent on the characteristics of responding cells. We first performed gene expression analyses by quantitative real-time PCR (qPCR) and found that the expression level of Runx2, a transcriptional activator of osteoblast differentiation, was significantly higher in normal dura and periosteum at the cranial site than in normal thoracic subcutaneous tissue of rats/mice. However, there were no significant differences in expression level of osteocalcin between these tissues. To examine if Runx2 and BSP are interdependent during osteogenic differentiation of adult mesenchymal stem cells, we performed loss- and gain-of-function analyses in cell cultures. Primary mesenchymal cells isolated from the dura (the primary source of BSP-responsive cells in vivo) or thoracic subcutaneous tissues of 3-month-old mice were cultivated in the same conditions of α -MEM media. When the cells reached ~70% confluence, they were transfected with Runx2/BSP-specific expression or RNAi lentiviral vectors with the addition of 50 μ g/ml ascorbic acid and 5 mM β -glycerolphosphate. The effects of Runx2/BSP on osteogenesis were determined by qPCR analysis of the expression level of osteoblast marker genes (e.g., osteocalcin) and histomorphometric analysis of the number of bone-like nodules in the cultures. The results revealed that: 1) knockdown of Runx2 by RNAi suppressed BSP-stimulated osteogenesis in cultured dural cells, while forced expression of Runx2 enhanced this process; and 2) forced Runx2 expression or BSP treatment alone failed to achieve osteogenesis, while forced Runx2 expression plus BSP treatment stimulated osteogenesis in cultured thoracic subcutaneous cells. These results suggest that BSP and Runx2 are interdependent during osteogenic differentiation of adult mesenchymal stem cells. BSP elicits osteogenesis in cranial defects but not in thoracic subcutaneous tissue due mainly to the lack of Runx2 expression in the latter. However, Runx2-expressing cells do not spontaneously differentiate to functional osteoblasts without BSP.

MO0221

Both TNF- α and RANKL Antagonist Peptide Stimulates Bone Formation In TNF- α Deficient Mice to the Same Extent As In Wild Type Mice. Masud Khan*, Neil Alles², Kenichi Nagano³, YURIKO FURUYA⁴, Hisataka Yasuda⁵, Keiichi Ohya³, Kazuhiro Aoki³. ¹Tokyo Medical & Dental University G-COE, Japan, ²JSPS, Tokyo Medical & Dental University, Japan, ³Tokyo Medical & Dental University, Japan, ⁴ORIENTAL YEAST CO.,LTD, Japan, ⁵Oriental Yeast Company, Limited, Japan

PURPOSE:

W9 peptide (W9) is originally designed as TNF (tumor necrosis factor) - α antagonist by using a ligand-recognition-site-structure on TNF-type1-receptor

(TNFR1). Recently we found the stimulatory effects of W9 on bone formation. Since TNF- α is proven to inhibit bone formation, we hypothesized that W9 might promote bone formation under the TNF- α dependent mechanism. In this study, we tested whether the stimulatory effects of W9 on bone formation is TNF- α dependent or regulated by the other mechanism.

METHODS:

Five weeks old male TNFR1 deficient, TNF- α deficient mice (C57BL/6 background) and the wild type (WT) mice were used. Type1-bovine-collagen discs were used as a carrier of BMP-2 and W9. Collagen discs containing either BMP-2 (1 μ g) alone or BMP-2 (1 μ g) with 0.56 mg W9 were freeze-dried, and were implanted into the mice back muscle. Mice were sacrificed on day 12 after implant, and radiological analyses were performed.

RESULTS:

Three dimensional μ -CT images showed that larger size of ectopic bone was observed in BMP-2 with W9 group compare to BMP-2 alone in WT mice. Surprisingly, W9 also increased ectopic bone formation in both TNFR1 deficient and TNF- α deficient mice. These findings were confirmed by the quantitative analysis using DXA. In WT mice, W9 increased bone mineral content (BMC) of ectopic bone by 2.6 fold more compare to the ectopic bone induced by BMP-2 alone. W9 also increased bone mineral content of ectopic bone induced by BMP-2 in both TNFR1 deficient and TNF- α deficient mice to the same extent as in WT mice (by 3.4-fold and 2.7-fold, respectively).

DISCUSSION AND CONCLUSION:

W9 is proven to bind to receptor activator of NF- κ B ligand (RANKL) as well as TNF- α . We speculated that the stimulatory effects of W9 on BMP-induced bone formation might be regulated by the other mechanism such as RANKL-related signaling not TNF- α .

MO0222

CD47 is an Integral Modulator of Osteoblastogenesis. Victoria Demambro*, Laura Maile², Casey Doucette¹, Phuong Le¹, Wesley Beamer³, David Clemmons², Clifford Rosen⁴. ¹Maine Medical Center Research Institute, USA, ²University of North Carolina Chapel Hill, USA, ³The Jackson Laboratory, USA, ⁴Maine Medical Center, USA

We reported that CD47 is a critical molecule for osteoclastogenesis through its association with SHPS-1. However $Cd47^{-/-}$ mice have decreases in body weight, aBMD, femoral length, cortical thickness, BV/TV and trabecular thickness vs $Cd47^{+/+}$ controls. To confirm the presence of a defect in osteoblast function, histomorphometry was performed on 16 wk $Cd47^{-/-}$ and $Cd47^{+/+}$ controls. $Cd47^{-/-}$ mice had reduced bone formation rates ($p < 0.05$), mineral apposition rates ($p < 0.01$), and osteoblast numbers ($p < 0.01$) vs $Cd47^{+/+}$. Serum N-terminal propeptide of type I procollagen (PINP) a marker of bone formation was reduced by ~20% ($p = 0.03$) in $Cd47^{-/-}$ mice vs $Cd47^{+/+}$ consistent with the histomorphometric findings. In vitro analysis of bone marrow stromal cell (BMSC) cultures revealed decreases in alkaline phosphatase activity at Days 7, 14 and 21 suggesting a defect in cell proliferation in the $Cd47^{-/-}$ cultures. Likewise the amount of mineral apparent by von Kossa staining was significantly reduced in the $Cd47^{-/-}$ cultures in line with the histomorphometric findings in vivo. RANKL expression was significantly greater (2 fold, $p = 0.005$) in $Cd47^{-/-}$ Day 7 BMSC pre-osteoblast cultures compared to $Cd47^{+/+}$. OPG expression was decreased by 20% ($p = .005$) resulting in a 2.5 fold increase in the RANKL/OPG ratio in the $Cd47^{-/-}$ cultures. Despite these increases, bone marrow cultures treated with either Vit D or PTH revealed significant reductions (~38%) in the number of TRAP5b staining osteoclasts (>3 nuclei), suggesting that both osteoclast and osteoblast defects in $Cd47^{-/-}$ mice are cell autonomous in nature. Two subclones of MC3T3 calvarial osteoblast cell lines, one with high osteoblast potential (Clone 4) and one with low osteoblast potential (Clone 24) were then examined. Intact CD47 levels and alkaline phosphatase staining were decreased by 40% in the low osteoblast cell line. Addition of thrombospondin-1 (TS-1) an extracellular matrix protein shown to protect CD47 from degradation increased the intact CD47 levels and alkaline phosphatase staining in the Clone 24 cells, thus confirming the importance of intact CD47 in osteoblastogenesis. In summary we have shown that CD47 is a critical factor for both bone formation and bone resorption. The low bone turnover in $Cd47^{-/-}$ is due to a defect in osteoblast proliferation/differentiation as well as osteoclastogenesis. Further studies are needed to define how CD47 affects the growth and differentiation of osteoblasts.

Delayed Fracture Repair in mice lacking the dystrophin gene. Celine Colnot¹, Shirley Lieu², Yan Yiu Yu*, Theodore Miclau². ¹INSERM, France, ²University of California, San Francisco, USA, ³UCSF, USA

Introduction: Many clinical and experimental observations have suggested that muscle plays a role in bone regeneration. To functionally assess the role of muscle in bone repair, we assessed fracture healing in Dmd^{mdx} mice, which lack of dystrophin gene. Dmd^{mdx} mice exhibit progressive muscle degeneration due to structural defects in muscle fibers. Although this phenotype is often associated with osteoporosis in

human, mice carrying this mutation are not osteoporotic, allowing us to determine the unique effects of muscle degeneration on bone repair.

Methods: Tibial fractures were created in anesthetized *Dmd^{mdx}* mice. Callus tissues were collected at different time points during fracture repair. Safranin-O and Trichrome staining were used to quantify callus, cartilage and bone volume via histomorphometry. PECAM immunohistochemistry and Tartrate-resistant acid phosphatase (TRAP) staining were used to quantify blood vessels and TRAP-positive cells via stereology.

Results: Histomorphometric analyses (Fig 1) showed that cartilage volume and the proportion of cartilage volume were comparable between wild type and *Dmd^{mdx}* mice during fracture repair. Total bone volume (BV) and the proportion of bone in the callus were significantly decreased in *Dmd^{mdx}* compared to wild type mice at day 7 post-fracture (p.f.). BV peaked at day 14 and gradually decreased until day 28 p.f. in wild type mice, but was significant increased in *Dmd^{mdx}* mice at day 21 p.f. Total callus size was comparable between the two groups from days 7 to 14 p.f. but was significantly increased in *Dmd^{mdx}* compared to wild type mice at day 21 p.f. PECAM immunohistochemistry showed that blood vessels were stained near the periosteum at the fracture site at day 5 p.f. and blood vessel surface density was significant decreased in *Dmd^{mdx}* compared to wild type mice. TRAP-positive cells were found within bone marrow and near the periosteum at the fracture site at day 5 p.f. and was significant increased in *Dmd^{mdx}* compared to wild type mice.

Conclusion: Muscle degeneration in *Dmd^{mdx}* mice affects fracture repair. During the early stage of healing, bone formation and angiogenesis are inhibited, while osteoclastogenesis is enhanced in *Dmd^{mdx}* mice compared to wild-type mice. At later stage, callus and bone remodeling are delayed in *Dmd^{mdx}* mice. Muscle may play a supporting role during fracture repair by allowing vascularization of the callus.

Figure 1

Histomorphometric measurements of total cartilage volume (CV), total cartilage volume as a proportion of total callus volume (CV/TV), total bone volume (BV), total bone volume as a proportion of total callus volume (BV/TV), and total callus volume (TV) during tibial fracture repair in wild type and *Dmd^{mdx}* mice. There is a statistically significant decrease in BV and BV/TV in the callus of *Dmd^{mdx}* mice compared to wild type mice at day 7 post-fracture, a statistically significant decrease in BV in the callus of *Dmd^{mdx}* mice at day 14 post-fracture. There is a statistically significant increase in BV and TV in *Dmd^{mdx}* mice compared to wild type mice at day 21 post-fracture.

Epigenetic Mechanisms Modulate the Expression of Genes Controlling Osteoclast Differentiation. Jesus Delgado-Calle¹, Carolina Sanudo², Agustin F. Fernandez³, Raul Garcia-Renedo⁴, Mario F. Fraga³, Jose Riancho⁵. ¹IFIMAV-H.U. Marques de Valdecilla-University of Cantabria, Spain, ²Department of Internal Medicine. Hospital U.M. Valdecilla-IFIMAV-University of Cantabria. RETICEF. Santander, Spain, Spain, ³Cancer Epigenetics Laboratory. Instituto Universitario de Oncología del Principado de Asturias (IUOPA), HUCA, University of Oviedo. Oviedo, Spain, Spain, ⁴Department of Orthopaedic surgery & Traumatology. Hospital U.M. Valdecilla. Santander, Spain, Spain, ⁵University of Cantabria, Spain

DNA methylation is increasingly recognized as a major mechanism to regulate gene expression. However, there is still scanty information about its role in bone remodeling. The aim of this study was to investigate the role of CpG methylation in the transcriptional levels of two osteoblast-derived critical factors in the regulation of osteoclastogenesis: the receptor activator of nuclear factor NF- κ B ligand (RANKL) and its soluble decoy receptor osteoprotegerin (OPG).

Bioinformatic analysis was performed to identify CpG islands within regulatory regions of both genes. RANKL (isoform I) and OPG gene expression was studied by RT-quantitative real time PCR in human primary osteoblasts (hOBs), osteoblastic (MG-63) and non-osteoblastic (HEK-293) human cell lines. DNA methylation was explored by quantitative methyl specific PCR (qMSP) and pyrosequencing.

Two CpG islands were found in the RANKL gene (region 1 and region 2) and one in the OPG gene. hOBs and MG-63 cells expressed much higher amounts of RANKL than kidney-derived HEK-293 cells. Similarly, OPG transcripts were much more abundant in osteoblastic cells than in kidney cells. qMPS and pyrosequencing analysis showed that the methylation in the region 1, but no in region 2, was inversely correlated with RANKL gene expression. On the other hand, OPG transcript abundance also correlated inversely with DNA methylation in the explored area. In addition, treatment with the DNA demethylating agent 5-azadeoxycytidine promoted a 170-fold induction of RANKL, and a 20-fold induction of OPG expression in HEK-293 cells.

Transcriptional levels of both genes were also explored in bone tissue samples from patients with hip fractures or hip osteoarthritis. RANKL transcript abundance and the RANKL:OPG transcript ratio were significantly higher in samples from patients with fractures than in those with osteoarthritis (RANKL: 0.780.23 vs 0.240.08, $p=0.014$; RANKL:OPG: 11.654.94 vs 0.900.19, $p=0.005$). However, no between-group differences in DNA methylation were found.

In conclusion, the correlation between DNA methylation and RANKL and OPG expression strongly suggests that methylation-dependent mechanisms regulate the transcriptional levels of these genes. However, other mechanisms appear to be responsible for the increased RANKL/OPG ratio of patients with osteoporotic fractures.

Fate of the Chondrocyte-Like Cells in Chondroid Bone during Distraction Osteogenesis in the Rabbits. Mitsuhiro Takahashi¹, Tetsuya Enishi², Shinjiro Takata³, Toshihiko Nishisho⁴, Takao Tsuneki¹, Natsuo Yasui⁵. ¹Orthopedics, Japan, ²The University of Tokushima Faculty of Medicine, Japan, ³Institute of Health Biosciences, University of Tokushima Graduate School, Japan, ⁴The University of Tokushima, Institute of Health Bioscience, School of Medicine, Japan, ⁵University, Japan

Distraction osteogenesis is currently a standard method of bone lengthening. Mechanical stimulation by distraction induces ossification, biological responses of skeletal regeneration which are accomplished by a cascade of biologic processes including differentiation of multipotent tissue, angiogenesis, mineralization, and remodeling. Chondroid bone, a tissue intermediate between bone and cartilage, was formed directly by chondrocyte-like cells, with transition from fibrous tissue to bone occurring gradually and consecutively. Transchondroid bone formation is difficult to research due to its restricted localization. Little is known about the chondrocyte-like cells in chondroid bone, especially about the fate of them.

The purpose of this study is to investigate the cell death of the chondrocyte-like cells in chondroid bone during transchondroid bone formation.

To study this, we used 10 Japanese white rabbits, ranging from 2.2 to 2.7 kg of body weight. Mid-diaphyseal tibial lengthening was performed. Transverse osteotomy was performed below the tibio-fibular junction between the second and third screw, using a thread wire saw. A 1-week lag phase after the osteotomy was followed by 2 weeks of distraction at a rate of 0.7 mm every 12 h (1.4 mm/day). After achieving approximately 20 mm of lengthening, rabbits were sacrificed. Histological findings demonstrated that new bone was formed by endochondral ossification at the proximal and distal ends of the distracted callus, and chondroid bone was observed at the boundary between fibrous tissue and bone. The chondroid bone was detected by expressing both type I and type II collagen using immunohistochemistry and in situ hybridization. We examined the fate of hypertrophic chondrocytes and chondrocyte-like cells by immunohistochemistry for caspase-3. Although most hypertrophic chondrocytes in endochondral bone formation were caspase-3 positive, some

chondrocytes-like cells were caspase-3 negative during transchondroid bone formation, furthermore there were no caspase-3 positive cells in chondrocyte-like cells embedded in the newly formed bone trabeculae.

In conclusion, some chondrocytes-like cells in transchondroid bone formation survive in the newly formed bone trabeculae, while most hypertrophic chondrocytes in endochondral bone formation undergo apoptosis.

Glutathione Role on Specific Markers of the Bone Remodeling. Cecilia Romagnoli*, Gemma Marcucci, Roberto Zonefrati, Carmelo Mavilia, Gianna Galli, Annalisa Tanini, Teresa Iantomasi, Maria Teresa Vincenzini, Maria Luisa Brandi. University of Florence, Italy

Reactive oxygen species and GSH have been recently linked to bone metabolism and remodeling but molecular mechanisms related to these events are little known.

Aim of this study was to evaluate the GSH role and changes in intracellular oxidative state on the mineralization and specific parameters related to osteoblast differentiation and osteoclastogenic process.

Methods: in order to modulate intracellular oxidative state SaOS-2 cells, with phenotypic properties of osteoblastic cells, were treated with buthionine sulfoximine (BSO), specific inhibitor of GSH synthesis, or with GSH itself. GSH and GSSG levels were measured by HPLC assay and calcium deposits by alizarin red S assay. Specific marker mRNA was determined by quantitative PCR.

Results: increases of GSH/GSSG ratio, index of intracellular redox state, obtained by cell treatment with GSH, enhanced the calcium production, whereas this was inhibited in GSH depleted cells. GSH was able to eliminate BSO effect, and the mineralization increase in BSO plus GSH treated cells was also observed. Indeed, we previously found a relationship between changes in alkaline phosphatase activity and intracellular oxidative state. Similarly, the GSH/GSSG ratio levels were related to marker gene expression of osteoblast differentiation and mineralization such as RUNX-2 and osteocalcin (OCN). A high oxidative state decreased RUNX-2 and OCN expression which enhanced when the oxidative state was reduced.

The expression of the receptor activator of nuclear factor κ B ligand (RANKL) and osteoprotegerin (OPG), osteoclastogenesis markers produced in osteoblasts, were also studied. OPG expression levels decreased in BSO treated cells, and GSH was able both to eliminate BSO effect and to increase OPG expression. Differently, redox alterations did not affect RANKL expression. Thereafter, RANKL/OPG ratio, a key factor in the osteoclastogenesis, was also affected by changes in oxidative state, a relationship with changes in GSH/GSSG ratio being found.

Conclusions: a high oxidative state decreases osteoblast differentiation and mineralization process, differently it induces osteoclastogenesis; GSH reverses these effects by the maintenance and increase of intracellular reduced status. These results may provide informations on GSH role in the bone remodeling and be useful to develop novel therapies in bone redox-dysregulated diseases such as osteoporosis, rheumatoid arthritis and bone inflammation diseases.

Ibuprofen Administered Pre- or Post- Simulated Resistance Exercise Training Does Not Diminish Gains in Bone Formation or Bone Mass. David Arthur Cunningham*, Kaleigh Camp, Evelyn Yuen, Brandon Macias, Stuart Solomon, Harry Hogan, Susan Bloomfield. Texas A&M University, USA

INTRODUCTION: Non-steroidal anti-inflammatory drugs (NSAIDs) have been shown to suppress bone formation when administered before, but not if administered after, an acute bout of mechanical load. The NSAID ibuprofen inhibits cyclooxygenase-2 enzyme, effectively reducing mechanically induced prostaglandin E2. Whether this affects eventual bone mass gains after multiple sessions of a more physiological mechanical loading regimen is unclear. Therefore, the aim of this study was to test the hypothesis that gains in bone mass and size will be diminished in adult rats given ibuprofen before, but not after, each exercise bout during 20 days of simulated resistance training (SRT). **METHODS:** Virgin female Sprague-Dawley rats (5-month-old, n=29) completed 9 SRT sessions using stimulated muscle contractions under anesthesia at 75% peak isometric strength on alternate days; each of 20 contractions included 1 sec isometric + 1 sec eccentric contraction. Animals were blocked assigned by body weight to one of three groups: (1) ibuprofen (30mg/kg) before exercise, placebo after (I:P)(n=9), (2) placebo before, ibuprofen after (P:I) (n=10) and (3) placebo before and after (P:P)(n=10). *In vivo* pQCT scans measured changes in total volumetric bone mineral density (vBMD) and total bone mineral content (BMC) at the proximal tibia (cancellous), and total vBMD, total BMC and total area at midshaft tibia on days -7 and 21. Dynamic histomorphometry on both midshaft tibiae (exercised and non-exercised legs) determined mineralizing surface (MS/BS), mineral apposition rate (MAR) and bone formation rate (BFR) on the periosteal surface. **RESULTS:** There were no differences in body weights among groups. There were significant gains due to the SRT but not ibuprofen treatment in total BMC (10.50 S.D. 8.15%) and total vBMD (5.29 S.D. 3.41%) at the proximal tibia. The midshaft tibia exhibited significant gains in total vBMD (6.68 S.D. 3.03%), total BMC

(19.18 S.D. 5.51%) and total area (11.68 S.D. 5.49%) due solely to SRT. Furthermore, there were significant increases in periosteal MS/BS, MAR & BFR at the midshaft tibia in the exercised vs. non-exercised legs in all groups but no effect of ibuprofen regimen was detected on these indices of bone formation. **CONCLUSION:** Ibuprofen given before or after exercise during simulated resistance training, performed at intensities similar to those used by humans, does not reduce robust increases in BFR or bone mass in cortical or cancellous bone.

MO0228

Influence Of Antiplatelet Drugs In the Pathogenesis Of Experimental Periodontitis And Periodontal Repair In Rats. Leila Coimbra*¹, Carlos Rossa Junior², Morgana Rodrigues Guimaraes², Raquel Fernanda Gerlach³, Marcelo Nicolas Muscara⁴, Denise Madalena Palomari Spolidorio², Bruno Schneider Herrera², Luis Carlos Spolidorio². ¹University of Sao Paulo State, Brazil, ²Araraquara Dental School, Brazil, ³Ribeirao Preto Dentistry School, Brazil, ⁴Institute of Biomedical Sciences, Brazil

Background: Platelets contain an array of biological mediators that can modulate inflammation and repair processes. Previous studies have shown that periodontitis and periodontal repair are associated with platelet activation. We hypothesized that drug-induced platelet inactivation might interfere in the processes of inflammation and repair in experimental periodontitis in rats by suppressing the release of biological mediators from platelets to the site of injury.

Methods: To measure the effects on periodontal disease, 40 rats were randomly distributed in four equal groups (n=10). Ligatures were placed around lower first molars in three groups and Aspirin (Asp) (30 mg/kg), Clopidogrel (Clo) (75 mg/kg) or Saline (NaCl 0.9%) were given intragastrically, by gavage, once daily for 15 days. Periodontitis was assessed by histological analysis and Interleukin-6 (IL-6), Tumor Necrosis Factor-alpha (TNF-alpha) and Thromboxane A2 (TXA-2) levels measured by ELISA. To evaluate the effects of antiplatelet drugs on periodontal repair, 50 rats were randomly distributed in five equal groups (n=10). Ligatures were placed in four groups, and the negative control group and one group with periodontitis were sacrificed 15 days after the insertion of the ligatures. The remaining three groups had the ligatures from both sides removed after 15 days of periodontitis induction and Asp, Clo or Saline were administered beginning in the following day for 15 days. Periodontal repair was assessed by micro-computed tomography (μ CT) and histological analysis.

Results: On periodontitis phase, Asp and Clo significantly reduced levels of TNF-alpha and IL-6 ($p < 0.05$), but only Asp decreased TXA-2 ($p < 0.05$). Asp and Clo decreased inflammatory infiltration, however this reduction was more pronounced with Clo treatment ($p < 0.05$). Histometric analysis showed that Asp and Clo impaired alveolar bone resorption. During the repair process and after removal of the ligatures, μ CT analysis demonstrated that treatment with Asp and Clo did not impair alveolar bone repair. In the histological analysis, there was repair of the alveolar bone and gingival tissue represented by the restoration of tissue architecture of the epithelium and connective tissue in the experimental groups.

Conclusion: Systemic administration of Asp and Clo attenuates the inflammatory process associated with periodontitis without affecting the repair process when stimulus is removed.

Osteoblast Targeted Deletion of FIP200, an Essential Component of Mammalian Autophagy Leads to Osteopenia in Mice. Dongye Yang¹, Jaclynn Kreider¹, Paul Krebsbach², Steven Goldstein³, Jun-Lin Guan¹, Fei Liu⁴. ¹University of Michigan, USA, ²Univ of Michigan, Sch of Dentistry, USA, ³University of Michigan Orthopedic Research Labs, USA, ⁴University of Michigan School of Dentistry, USA

FIP200 (200-kDa FAK-family interacting protein) plays important roles in mammalian autophagy and other cellular functions, but its role in bone cells has not been examined. To determine to what extent FIP200/autophagy regulates bone homeostasis, we conditionally deleted FIP200 in osteoblasts in vivo with *Ox-Cre* transgenic mice. MicroCT analysis revealed that FIP200 conditional knockout (CKO) male mice had severe osteopenia demonstrated by decreased bone volume/tissue volume (9.7% \pm 5.1% in CKO vs 22.8% \pm 2.5% in control, n=6-7), decreased trabecular number, decreased trabecular thickness and decreased cortical thickness in femora at 1 month. The osteopenic phenotype was also observed in 2 month and 6 month old male and female CKO mice. Four-point bending tests showed that mutant bones had compromised mechanical properties. Histomorphometry analysis corroborated MicroCT data. Interestingly, both osteoblast and osteoclast number and surface per bone surface were not altered in mutant bone. However, the bone formation rate in CKO mice was decreased to less than half of that in control mice. Alizarin red staining indicated that bone marrow cells isolated from CKO mice had significantly compromised mineralization. The mRNA levels of osteoblast differentiation markers

(ALP, BSP, OCN, Runx2, Osx) were significantly decreased in the CKO group. We also isolated bone marrow cells from FIP200F/F mice and infected them with adenovirus encoding Cre (Ad-Cre) or LacZ after 7 days osteogenic culture. In the FIP200-null group (Ad-Cre), terminal differentiation was significantly compromised, suggesting that FIP200 plays an important role at a later differentiation stage. Similarly, we found that FIP200 null primary calvarial osteoblasts had significantly compromised terminal differentiation. However, the proliferation (shown by Ki67 immunostaining and cell number counting) and early differentiation (shown by alkaline phosphatase staining and alkaline phosphatase mRNA expression) appeared to be normal. Consistent with the essential role of FIP200 in autophagy, we found that 36h nutrient-deprivation induced nearly 100% cell death in FIP200-null primary calvaria osteoblasts compared to less than 10% in control cells. Furthermore, large ubiquitin-positive aggregates were found in the osteoblasts of CKO mice, another indication of abnormal autophagy activity. In conclusion, our data suggest that FIP200 positively regulates bone mass possibly through its autophagic role.

T Cell Subsets Differently Regulate Osteogenic Differentiation of Human Mesenchymal Stromal Cells. Francesco Grassi^{*1}, Luca Cattini², Anna Piacentini², Cristina Manferdini², Elena Gabusi², Andrea Facchini², Gina Lisignoli². ¹Istituti Ortopedici Rizzoli, Italy, ²Ramses Lab. Rizzoli Orthopedic Institute, Italy

The interplay of immune cells and bone cells plays a fundamental role in inflammatory and post-traumatic lesions of bone tissue. In particular, activated T cells were shown to be a key source of osteoclastogenic cytokines and to drive the increase of osteoclast differentiation typical of post-menopausal osteoporosis as well as erosive diseases of bone following acute inflammation. Recent findings suggest that T cells can also regulate the pool of mesenchymal stromal cells (MSC) and its potential to give rise to fully differentiated osteoblasts; in particular, T cells in mouse were found to play a key permissive role for MSC to respond to PTH anabolic stimulation of bone. However, whether unstimulated T cells secrete sufficient osteogenic factors to regulate the fate of MSC is still unclear. In this study we investigated whether T cells secreted factors can support MSC osteogenic differentiation in vitro and if any differential stimulation is present between CD4 and CD8 cells. Unstimulated total T cells, CD4+ and CD8+ T cells were isolated by means of immunomagnetic negative selection by human peripheral blood obtaining a purity of $\geq 98\%$ for each of the subsets. The three subsets were cultured in RPMI medium for 72 hours; conditioned medium (CM) was then collected, filtered and added to human primary MSC cultured in osteogenic medium at a 50:50 ratio (T cells CM/?-MEM supplemented with ascorbic acid, ?-glycerophosphate and dexametazone). Osteogenic differentiation of MSC was evaluated by a) Real Time-PCR quantification of osteogenic factors expression (collagen I and XV, BSP, ALP, OC, RUNX2) at days 14 and 21 and b) functional assays of mineralization by means of Alizarin S and Von Kossa staining of cultures after 21 days. Compared to control cultures, MSC cultured in the presence of total T cells CM showed increased mineral apposition (40% increase relative to control in Alizarin S assays) as well as significantly increased expression of Collagen I, collagen XV, BSP and ALP at day 14. Interestingly, CM obtained from CD4 or CD8 differently regulated MSC differentiation: CD8-derived CM was significantly more effective in inducing mRNA upregulation of Collagens XV, ALP and BSP and induced greater mineralization in functional assays than CD4-derived CM, suggesting that CD8 T cells secrete soluble factors which can effectively support osteogenic differentiation of MSC. Our data provide preliminary evidence for a role of unstimulated T cells, and in particular CD8+ T cells, in inducing MSC osteogenic differentiation and can provide novel tools for improving the bone repair process through regulation of host to graft interaction in regenerative medicine.

The Role of the Extracellular Signal-Regulated Kinase (Erk)-Mapk Pathway In Osteoblasts During Post-Natal Bone Healing. Jason Long^{*1}, Xiang Zhao², Christopher D. Beale¹, Casey A. Boyle¹, Steven Goldstein³, Renny Franceschi¹. ¹University of Michigan, USA, ²University of Michigan, School of Dentistry, USA, ³University of Michigan Orthopedic Research Labs, USA

Using a transgenic approach, the extracellular signal-regulated kinase (ERK)/mitogen-activated protein kinase (MAPK) pathway was previously found to affect embryonic skeletal development when expressed in osteoblasts using a murine 0.6 kb mOG2 promoter.¹ Specifically, constitutively active MAPK/ERK1 (TgMEK-SP) expression accelerated bone development and dominant-negative (TgMEK-DN) was inhibitory. These effects are explained in part by ERK/MAPK-dependent activation of RUNX2. While bone healing recapitulates aspects of skeletal development, the role of the ERK-MAPK pathway on osteoblast function during post-natal repair is unknown. We investigated the influence of MEK1 transgenic expression in two experimental models: 1) tibial fracture (pre-dominantly endochondral healing) and 2) sub-critical drill hole defects (intramembraneous healing). We hypothesize that TgMek-sp expression will accelerate healing and TgMek-dn will be inhibitory compared to WT controls. **Methods:** Adult C57BL/6 mice (male and female; TgMek-

sp^{het}, TgMek-dn^{het} and WT) were enrolled into one of two experiments. For one group, left tibiae were fractured following pre-nailing of the medullary canals; for the other, 0.9mm drill holes were placed in the right, proximal tibial metaphyses and the left femoral mid-diaphyses. All animals were euthanized 14 days post-surgery. Following harvest, specimens were scanned and evaluated using micro-computed tomography. Specimens were then sectioned and stained with safranin-O/ fast green for measuring cartilage content. **Results:** Comparing fracture calluses, the TgMek-dn males had significantly higher density and bone volume fraction than the other male genotypes. For the same specimens, the TgMek-dn mice had significantly lower cartilage content than the TgMek-sp mice. Comparing the drill hole specimens, the TgMek-dn males had significantly higher neo-tissue density in the metaphysis than the other male genotypes; no significant differences were identified in the diaphysis. Similar trends, though none significant, were observed among female specimens. **Conclusions:** Contrary to our expectation, TgMek-dn males had accelerated bone formation compared to TgMek-sp and WT males based upon two mechanistically different healing experiments. The basis for these observations is yet understood, but may be due to differences in rate-limiting cell populations during development versus healing.

Ursodeoxycholic Acid Neutralizes the Detrimental Effects of Lithocholic Acid and Bilirubin on Osteoblasts. Silvia Ruiz-Gaspa^{*1}, Marta Dubreuil¹, Angels Martinez-Ferrer², Anna Enjuanes³, Pilar Peris⁴, M^aJesús Martínez de Osaba³, Luisa Alvarez¹, Ana Monegal³, Andres Combaliá³, Albert Pares¹, Nuria Guanabens⁵. ¹CIBERehd, Hospital Clinic, IDIBAPS, University of Barcelona., Spain, ²Hospital Clinic Barcelona, Spain, ³Hospital Clinic, IDIBAPS, University of Barcelona., Spain, ⁴Hospital Clinic of Barcelona, Spain, ⁵Universitat De Barcelona, Spain

Background and aims: Osteoporosis resulting from decreased bone formation is a common complication in patients with chronic cholestasis. Lithocholic acid (LCA) and bilirubin may play a role in osteoporosis given that both substances have detrimental effects on survival of human osteoblasts (hOB). Since ursodeoxycholic acid (UDCA) improves cholestasis we have assessed if this bile acid may neutralize the harmful effects of LCA and bilirubin on bone formation.

Methods: The experiments were performed in cultured human primary osteoblasts and a human osteosarcoma cell line (SAOS-2) at different times and concentrations of UDCA, LCA, cholic acid (CA) and bilirubin to assess cell viability using a colorimetric assay (Wst-1), osteoblast differentiation using alkaline phosphatase activity assay (ALP) and osteoblast mineralization by Alizarin Red assay. The differentiation experiments were performed with vitamin D (10-7M) in the culture media.

Results: Both LCA (10-4 M) and bilirubin (50 µM) decreased cell viability. UDCA significantly decreased cell survival at concentrations 10 times higher (10-3 M) to that observed with LCA, and CA did not decrease survival. Cell differentiation was not influenced by LCA and CA but was increased by UDCA. UDCA (10-4M) neutralized the detrimental effects of LCA (10-4M) and bilirubin (50 µM) on osteoblast survival at 48 and 72 h. Moreover, UDCA (10-6M and 10-5M) increased osteoblast differentiation in cells treated with toxic concentrations of LCA (30% and 35%, respectively) or bilirubin (60% and 40%, respectively), effects which were partially prevented by the presence of 10% FBS (4% and 8% for LCA and 0% and 8% for bilirubin). LCA and UDCA increased osteoblast mineralization (61% and 63% respectively) after 21 days in culture. By contrast, bilirubin (50 µM) resulted in a decreased mineralization (-60%), effect which was neutralized by UDCA (10-4M) (2%).

Conclusions: Ursodeoxycholic acid increases osteoblast differentiation and mineralization, and neutralizes the detrimental effects of LCA acid and bilirubin on osteoblastic cells. Therefore, UDCA may exert a favorable effect on bone formation in patients with chronic cholestasis.

Y1 Receptor Antagonism Increases Bone Formation in Mice. Daniela Sousa^{*1}, Ron Enriquez², Amanda Sainsbury², Paul A. Baldock², Meriem Lamghari¹, Herbert Herzog². ¹INEB - Instituto de Engenharia Biomedica, Portugal, ²Garvan Institute of Medical Research, Australia

Several lines of evidence have highlighted the critical role of the neuropeptide Y (NPY) system as a key regulator of bone metabolism. Specifically the involvement of Y1 receptor signaling in osteoblasts has been shown to be important for this process suggesting that an anti-receptor strategy may be a useful approach to prevent and/or reverse bone loss. In order to test this hypothesis, we analyzed the effects of a highly selective Y1 receptor antagonist BIBO3304 in wild-type mice.

10-week-old wild-type mice (n =6-10 per group) were treated daily with a low (500nM) or a high dose (5µM) of BIBO3304 for 8 weeks. The drug was incorporated into a jelly and administered orally to mice. Jelly without the drug was used as control. Food intake and metabolic parameters were monitored throughout the treatment. Bone remodeling alterations were analyzed by micro-CT and histomorphometry analysis on isolated femurs.

8 weeks of treatment with a dose of 500nM BIBO3304 mice showed a trend to increase bone mass but this did not reach significance. However, treatment of mice with the 5µM BIBO3304 dose resulted in significant greater femoral cancellous bone volume (8.66 0.58 vs 13.07 0.67%, $p<0.001$), trabecular number (3.28 0.15 vs 4.12 0.23/mm, $p<0.01$) and trabecular thickness (26.38 1.41 vs 32.12 2.20 µm, $p=0.05$). This was associated with an increase in mineral apposition rate (MAR) (1.61 0.06 vs 2.00 0.11 µm/day, $p<0.01$). Bone resorption rate was also elevated as shown by an increased in osteoclast number (2.20 0.22 vs 3.19 0.32/mm, $p<0.05$) and osteoclast surface (5.18 0.56 vs 7.40 0.80 %, $p=0.05$). These results are consistent with data previously described for the germ line Y1 receptor knockout mice. Furthermore, 5µM BIBO3304-treated mice showed a smaller marrow volume (1.24 0.03 vs 1.12 0.04 mm³, $p<0.05$) along with a trend towards reduced tissue volume (2.32 0.05 vs 2.20 0.05 mm³, $p=0.09$), albeit with no change in cortical volume and thickness or in endocortical MAR. Importantly, 8-week treatment with BIBO3304 did not induce significant changes on either body weight or energy metabolism, suggesting no adverse effects on other peripheral or brain functions.

Together, these findings demonstrate that the systemic BIBO3304 treatment increases bone turnover resulting in a greater bone mass *in vivo* suggesting the possible therapeutic application of BIBO3304 for treatment of bone diseases, such as osteoporosis.

Beta1 Integrin Expression In Osteoblast Progenitors Is Required for Bone Formation. Nina Kawelke, Matthaeus Vassel, Carina Wuerfel, Christine Hoffmann, Inaam Nakchbandi*. Max-Planck Institute for Biochemistry & University of Heidelberg, Germany

Integrins are cell surface receptors involved in transmitting pericellular signals into the cell. Their activation results in a variety of intracellular effects depending on the signal and receptor involved. Integrins are expressed as dimers of one α and one β subunit. Osteoblasts express mainly integrins containing $\beta 1$ subunit, while osteoclasts express mostly $\beta 1$ and $\beta 3$ containing integrins.

Deletion of $\beta 1$ integrin in differentiated osteoblasts using the collagen- $\alpha 1(I)$ 2.3 kb promoter resulted in only small defects in osteoblast function without affecting bone mineral density (BMD). This was surprising because of the critical role of integrins and the predominance of $\beta 1$ integrins in osteoblasts. To examine the role of $\beta 1$ integrin in bone further we used mice homozygote for the floxed gene of $\beta 1$ integrin and that carry the Mx promoter attached to cre. Mx is expressed in many cell types and has to be activated in mice to induce cre expression. The Mx promoter can delete floxed genes in osteoclasts and in early progenitors of osteoblasts. Deletion of $\beta 1$ integrin using the Mx promoter resulted in a decrease in $\beta 1$ integrin expression by more than 95% in peripheral blood and bone marrow *in vivo*, and by more than 90% in osteoblasts *in vitro*. BMD was significantly diminished in mice at the age of 8 weeks, 4 weeks after activation of cre with a drop in trabecular BMD by 23% in conditional knockout (cKO) mice compared to littermate controls (CT) (CT: 1511 vs. cKO: 1197 g/cm³, $p<0.0001$, $n=13$) and a drop of 14% in total BMD (CT: 52613 vs. cKO: 4529 g/cm³, $p<0.0001$). To determine the reason for this change we performed dynamic and static histomorphometry and found a decrease in bone formation (Bone formation rate; BFR/BS: CT: 0.440.08 vs. cKO: 0.140.06 mm²/mm/y, $p<0.05$, $n=4$) despite an increase in osteoblast numbers (CT: 19.70.4 vs. cKO: 28.80.1, $p<0.01$). The osteoblasts were thus dysfunctional with a delay in mineralization (Mineralization lag time, Mlt: CT: 1.90.4 vs. cKO: 8.92.0 days, $p<0.05$). In contrast, the osteoclasts did not show any defect. Thus the decrease in BMD is due to a decrease in bone formation.

In summary, loss of $\beta 1$ integrin in osteoblast progenitors is detrimental to their function resulting in a delay in mineralization despite an increase in osteoblast number. This then leads to a decrease in bone mineral density. This points to a critical role for integrins in modulating osteoblast behavior and bone mineral density.

Y-Tocotrienol inhibits RANKL Gene Expression and Reduces Osteoclast Formation by an HMG-CoA Reductase Dependent Mechanism. Wenxi Li*, Yuedi Ding, Jun Fan, Ying Peng, Runlin Yang, Lili Deng, Xiaohua Qiu, Tingting Shu, Qiang Fu. Key Laboratory of Nuclear Medicine, Ministry of Health; Jiangsu Key Laboratory of Molecular Nuclear Medicine; Jiangsu Institute of Nuclear Medicine., China

Vitamin E analogs, collectively called tocopherols, are comprised of α -, β -, γ - and δ -tocopherol and α -, β -, γ - and δ -tocotrienol. α -tocopherol is the most commonly used vitamin E supplement and the most abundant vitamin E isoform in human and animal tissues. Tocopherols exert their biological effects not only by virtue of their antioxidant properties but also by inhibiting the enzyme hydroxy-methyl-glutaryl-coenzyme A (HMG-CoA) reductase. Studies have shown that free radicals affect bone remodeling by regulating osteoclast activity, and that HMG-CoA reductase inhibitors increasing bone mass by enhancing osteoblast viability and differentiation. compared to other tocopherols, γ -tocotrienol (GT3), one of the isoforms of vitamin E which possess an isoprenoid side chain with three unsaturated bonds, has more powerful antioxidant activity and stronger inhibitor effects on HMG-CoA reductase. Based on this, we

investigated the bone protection of GT3 in ovariectomized C57BL/6 mice. We found that in mice which were one time injected subcutaneously with 100mg/kg GT3, the receptor activator of NF- κ B ligand (RANKL) expression in bone tissues induced by dibutylryl-cAMP (db-cAMP) was inhibited and the inhibition was sustained for at least 14 days after GT3 administration. The bone marrow cells harvested from GT3 treated mice had lower osteoclast formation in co-culture of osteoblast and bone marrow cells induced by PTH. Supplementation with 100mg/kg GT3 via subcutaneous injection once per month for three months significantly prevented bone loss in ovariectomized C57BL/6 mice. These beneficial effects of GT3 for bone tissues were reversible by mevalonate, the product of the reaction catalyzed by HMG-CoA reductase. Our results demonstrate the inhibition of GT3 for RANKL gene expression and osteoclast formation via an HMG-CoA reductase dependent mechanism, suggesting GT3 may have therapeutic value for treating and preventing bone loss.

MO0236

Cbf- β has a Positive Role on Postnatal Bone Formation by Regulating Runx2 Stability. Suk-Chul Bae¹, Ichiro Taniuchi², Shin-Yoon Kim³, Jung-Eun Kim⁴, MIN-SU HAN⁵, NARAE PARK⁶, Kyung-eun Lim^{7*}, Jae-Hwan Jeong⁷, Je-Yong Choi⁷. ¹5Depat. of Biochemistry, School of Medicine, Institute for Tumor Research, Chungbuk National University, South Korea, ²Institute of Physical & Chemical Research, Research Center for Allergy & Immunology, Japan, ³Kyungpook National University Hospital, South Korea, ⁴Kyungpook National University School of Medicine, South Korea, ⁵Republic of Korea, ⁶Kyungpook National University, Republic of Korea, ⁷Kyungpook National University, School of Medicine, South Korea

Bone formation requires intact Runx2 function during skeletogenesis. The core binding factor-beta (Cbf- β) is the partner protein of Runx family transcription factors. It has been known that Cbf- β binds Runx2 and enhances Runx2 function through upregulation of DNA binding. Because of embryonic lethality of Cbf- β knockout mice, function of Cbf- β has not been determined in skeletal tissue specifically. In this study, Cbf- β floxed mice were crossed with 2.3 kb Col1-Cre mice to determine the function of Cbf- β in osteoblasts specifically. The osteoblast-specific deletion of Cbf- β showed normal growth and development except bone mass at 5 and 12 weeks after birth. In μ -CT analysis, bone mass and cortical bone thickness were reduced in femur and humerus of Cbf- $\beta^{Aob/Aob}$ mice. In dynamic histomorphometric analysis, mineral apposition rate was also reduced in long bone. Although the number of osteoblasts was not changed, the population of flat-shaped one was increased in Cbf- $\beta^{Aob/Aob}$ mice. In histochemical and real-time Q-PCR analyses, Osterix, Osteocalcin and Osteopontin were decreased in Cbf- $\beta^{Aob/Aob}$ mice. Reduction of these osteogenic markers was due to the decrease of Runx2. Mechanistically, Cbf- β increased Runx2 protein stability by inhibition of its ubiquitination. It suggests that loss of bone mass in adult stage of Cbf- $\beta^{Aob/Aob}$ mice is due in part to the proteasome dependent Runx2 degradation. Collectively, these results indicate that Cbf- β has a positive role on mature osteoblasts by direct regulation of Runx2 stability *in vivo*.

Cnot3, a Crucial Factor of mRNA Stability, Controls Osteoblastic Differentiation. Chiho Watanabe¹, Masahiro Morita², Yoichi Ezura³, Tetsuya Nakamoto⁴, Tadayoshi Hayata⁴, Hiroaki Hemmi⁵, Takuya Notomi⁶, Keiji Moriyama¹, Tadashi Yamamoto², Masaki Noda¹. ¹Tokyo Medical & Dental University, Japan, ²Division of Oncology, Institute of Medical Science, University of Tokyo, Japan, ³Tokyo Medical & Dental University, Medical Research Institute, Japan, ⁴Medical Research Institute, Tokyo Medical & Dental University, Japan, ⁵Immunology Frontier Research Center, Osaka University, Japan, ⁶GCOE, Tokyo Medical & Dental University, Japan

Regulation by both transcription and epigenetic control is critical to determine bone mass. Messenger RNA stability can provide the rapid and flexible control of gene expression. Recently, new molecules which control mRNA stability have been identified, such as DCP1-DCP2 complex and PAN2-PAN3 complex (Nat Rev Immunol.2010). However, the roles of regulation of mRNA stability in the regulation of bone remodeling has not been fully understood. Among the new molecules, we focused on Cnot3. Cnot3 is a component of CCR4-NOT complex and is implicated in mRNA stability in eukaryotic cells. We observed that Cnot3+/- mice exhibited low bone mass compared to wild-type. In these Cnot3+/- mice BV/TV was decreased more in aged compared to young adult mice. To elucidate the role of Cnot3 at cellular level, we used siRNA to knockdown Cnot3 in MC3T3-E1 cells. Cnot3 mRNA was reduced by 60%. ALP activity was increased when the cells was treated with rh-BMP2 in control cells, while siCnot3-treated-MC3T3-E1 cells showed significant decrease. RT-PCR analysis revealed that gene expression level of type I collagen was down-regulated about 1/3-fold in siCnot3-treated-MC3T3-E1 cells relative to control. In

conclusion, our data indicates that Cnot3 controls osteoblastic differentiation that is critical for the maintenance of bone mass.

Essential role of Intraflagellar transport 80 in osteoblast differentiation through regulating Ihh/Gli and Wnt signaling pathways. Changdong Wang¹, Shuying Yang². ¹State University of New York at Buffalo, USA, ²State University of New York at Buffalo, USA

Intraflagellar transport (IFT) proteins are microtubule based transport machinery, which are essential for the assembly and maintenance of all eukaryotic motile cilia and flagella and nonmotile sensory cilia. Recent findings have demonstrated IFT controls gene expression, cell proliferation and differentiation, and animal development. IFT80 is newly-defined IFT protein. Mutation of IFT80 in human causes a disease, Jeune asphyxiating thoracic dystrophy (JATD) with abnormal skeletal development such as a long, narrow thorax with short ribs, shortened long bones and occasional polydactyl. However, the role and mechanism of IFT80 in osteoblast differentiation is unknown. To gain insight into the role of IFT80 in osteoblast differentiation, we first analyzed the expression pattern of IFT80 by western blot and found that IFT80 is highly expressed in mouse long bone, skull, heart and lung tissues. It was also expressed in mouse muscle, ear and eye, but to a far less extent. RT-PCR results further showed that IFT80 transcripts slightly decrease during osteoblast differentiation. To demonstrate the importance of IFT80 function in osteoblast differentiation, we used lentivirus-mediated RNA interference (RNAi) technology to knock down IFT80 expression in an embryonic mesenchymal cell line C3H10T1/2 induced with ascorbic acid (AA)/ β -glycerol-phosphate (β -g-p). In contrast to the wild-type cells, we found that the cells infected with IFT80 shRNA lentivirus contain undetectable IFT80 protein. Immunostaining and scanning electron microscope (SEM) results showed that silence of IFT80 leads to either shortening or loss of cilia and decrease of Arl13b expression. Western blotting results showed that IFT80 silencing blocks the expression of Gli2, a critical transcriptional factor in Ihh signaling pathway. By performing ALP activity assay, Alzilian Red staining and von kossa staining, we further found that IFT80 silencing in C3H10T1/2 cells not only markedly blocks the expression of osteoblast markers such as RUNX2, OCN and Col I, but also significantly inhibits ALP activity and cell mineralization. Overexpression of Gli2 can rescue the deficiency of osteoblast differentiation from IFT80-silenced cells, as well as dramatically promote the control cells to differentiate into osteoblasts. Moreover, Transcription of cAMP-dependent protein kinase A (PKA), a negative regulator of the Hh signaling pathway, is dramatically increased; on the contrary, Ihh is markedly decreased in IFT80 silenced cells. Interestingly, we also found that silence of IFT80 down-regulates GSK-beta3 and up-regulates beta-catenin transcription. Thus, these results suggested that IFT80 plays an important role in osteoblast differentiation likely through regulating Ihh/Gli and Wnt signal pathways. We have generated Col24x1 knockout model and are analyzing the role and mechanism of IFT80 in bone formation in vivo.

MO0239

Foxo1 Mediates IGF1/Insulin Regulation of Osteocalcin Expression by Antagonizing Runx2 in osteoblasts. Shengyong Yang¹, Haiyan Xu², Shibing Yu³, Huiling Cao⁴, Jie Fan⁵, Chunxi Ge⁵, Renny Franceschi⁶, Henry Dong⁷, Guozhi Xiao⁴. ¹VA Pittsburgh Healthcare System, USA, ²Rhode Island Hospital, Brown Medical School, USA, ³University of Pittsburgh Medical Center, USA, ⁴University of Pittsburgh School of Medicine, USA, ⁵University of Michigan School of Dentistry, USA, ⁶University of Michigan, USA, ⁷Children's Hospital of Pittsburgh, University of Pittsburgh, USA

In this study, we determined the molecular mechanisms whereby forkhead transcription factor Foxo1, a key downstream signaling molecule of insulin-like growth factor 1 (IGF1)/insulin actions, regulates Runx2 activity and expression of the mouse osteocalcin gene 2 (Bglap2) in osteoblasts in vitro. We showed that Foxo1 inhibited Runx2-dependent transcriptional activity and osteocalcin mRNA expression and Bglap2 promoter activity in MC-4 preosteoblasts. Co-immunoprecipitation assay showed that Foxo1 physically interacted with Runx2 via its C-terminal region in osteoblasts or when coexpressed in COS-7 cells. Electrophoretic mobility shift assay demonstrated that Foxo1 suppressed Runx2 binding to its cognate site within the Bglap2 promoter. IGF1 and insulin prevented Foxo1 from inhibiting Runx2 activity by promoting Foxo1 phosphorylation and nuclear exclusion. In contrast, a neutralizing anti-IGF1 antibody decreased Runx2 activity and osteocalcin expression in osteoblasts. Chromatin immunoprecipitation assay revealed that IGF1 increased Runx2 interaction with a chromatin fragment of the proximal Bglap2 promoter in a PI3K/AKT-dependent manner. Conversely, knockdown of Foxo1 decreased Runx2 interaction with the promoter. This study establishes that Foxo1 is a novel negative regulator of osteoblast-specific transcription factor Runx2 and modulates IGF1/insulin-dependent regulation of osteocalcin expression in osteoblasts.

Genome-wide Analysis of Epigenetic Transcriptional Control by Runx2 During Osteogenesis. Hai Wu*, Jonathan Gordon, Troy Whitfield, Seungchan Yang, Jason Dobson, Phillip Tai, Andre Van Wijnen, Janet Stein, Jane Lian, Gary Stein. University of Massachusetts Medical School, USA

Runx2 is a master regulator of osteogenesis that coordinates expression of many osteoblast-related genes. It organizes gene regulatory complexes with several classes of co-factors (histone modifying enzymes and receptor mediators of signaling pathways) in nuclear microenvironments. In addition to its role as a transcriptional regulator, Runx2 has other key functions that support bone formation. Runx2 is also involved in epigenetic bookmarking at the onset of lineage commitment and initiates chromatin remodeling events required for osteoblast-specific gene expression. However, the epigenetic mechanisms controlled by Runx2 to regulate the bone-specific reorganization of chromatin during osteoblastogenesis remain to be explored. Therefore, we employed Chromatin Immunoprecipitation coupled with high-throughput sequencing (ChIP-Seq) to profile the occupancy of Runx2 and specific epigenetic marks (histone modifications) across the mouse genome in pre-osteoblasts at defined stages of osteogenesis: pre-osteoblastogenesis (day 0, proliferation), early osteoblastogenesis (day 9, matrix deposition), and late osteoblastogenesis (day 28, mineralized). We detected ~10,000 Runx2 binding regions in the proximal promoters of genes in osteoblasts, but an even greater number (>30,000) in distal promoter regions, intronic regions, and intergenic regions. These data sets were further analyzed in relation to transcriptome and proteome profiles to identify Runx2-responsive genes and proteins. Our results provide a signature of Runx2 mediated genomic interactions that support epigenetic control during osteoblast differentiation. We propose that Runx2 is a global organizer of chromatin context during osteoblastogenesis and mediates interactions that are both short-range (proximal promoter-related) and long-range (related to enhancers, introns and intergenic regulatory regions) to maintain higher order chromatin structure in Runx2 related subnuclear domains to modulate temporal expression of osteoblast-related genes.

MO0241

Global Transcriptome Analysis of Osteoblasts in Transgenic Models of Manipulated G Protein Signaling. Lalita Wattanachanya¹, Susan M. Millard², Weidar Lu¹, Dylan O'Carroll¹, Peter Mailhot¹, Edward Hsiao³, Bruce R. Conklin⁴, Robert Nissenson¹. ¹VA Medical Center & University of California, San Francisco, USA, ²University of Queensland, Australia, ³University of California, San Francisco, USA, ⁴Gladstone Institute of Cardiovascular Disease, University of California, San Francisco, USA

The balance of Gs and Gi G protein coupled receptor (GPCR) signaling is an important regulator of bone formation. We have previously described a number of transgenic mouse models in which G protein coupled signaling has been manipulated in vivo in osteoblasts (OBs) that express the 2.3 kb-Col I promoter. These models include OB-specific expression of an engineered constitutively active Gs-coupled receptor, Rs1, and OB-specific expression of pertussis toxin (PTX) to block Gi signaling; both of which demonstrate an anabolic bone phenotype. To investigate the cellular basis for these effects, we developed a strategy to examine alterations in the OB transcriptome. Identification of OBs for isolation was achieved by OB-specific expression of Histone2B-GFP in vivo either alone or together with Rs1 or PTX under control of the same promoter. OBs were isolated from calvariae of 7 day old mice and flow cytometry was used to sort OBs based on GFP fluorescence. Expression analysis using the Affymetrix Mouse Gene 1.0 ST Array was performed on three OB preparations of RNA from each genotype. We identified 361 and 763 genes whose expression was altered in Rs1 and PTX model, compare to control, respectively (p<0.01). Significantly regulated genes were clustered using the Gene Ontology Tree Machine, and pathway analysis was done with GO-Elite software. Both models demonstrated up-regulation of a large number of genes associated with mitosis and cytokinesis. Contrary to this trend, the mitosis-associated gene FGF9 was down-regulated in both models. Decreased FGF9 was validated by real time PCR and functionally verified in primary mouse osteoblasts where FGF9 was markedly down-regulated after treatment with forskolin or PTH (-64% and -72% respectively, p<0.05). When added continuously to mouse BMSCs grown under osteogenic conditions, FGF9 suppressed (by>80%) the formation of mineralized nodules. These findings indicate that in these models of manipulated G protein signaling in osteoblasts, bone anabolism may be associated with an increase in the relative number of proliferating osteoblasts. They further demonstrate that increased Gs coupled signaling activity down-regulates FGF9 expression, and suggest that this could contribute to the observed increase in bone formation.

Increased Expression of Thrombospondin 1 in Runx2 Transgenic Mice. Guillaume de la Houssaye*, Valerie Geoffroy, INSERM Unit 606, France

Thrombospondin 1 (THBS1) is a transmembrane protein with a well known anti-angiogenic activity. Recently, its role in the regulation of resorption activity of osteoclasts and in the inhibition of mineralized nodules formation by osteoblasts has been demonstrated *in vitro*.

The Runx2 gene is essential to the function and differentiation of osteoblasts. Runx2 overexpression blunts terminal differentiation of osteoblasts and leads to an increase in bone resorption *in vivo* and to a defective formation of mineralized nodules *in vitro*.

The aim of our study is to demonstrate the involvement of THBS1 in the mineralization defect observed *in vivo* and *in vitro* in Runx2 mice. Our hypothesis is that overexpression of Runx2 increases directly or indirectly expression of THBS1 during osteoblast differentiation. We performed a comparative gene expression analysis (microarray) of primary osteoblasts isolated from transgenic mice overexpressing Runx2 (Runx2 mice) and control mice (WT) at different stages of culture. After 14 days of culture, the expression of thrombospondin is 3 times greater in the osteoblasts from Runx2 mice compared to WT. This result was validated by qPCR. We showed that expression of THBS1 is decreased during differentiation of WT primary osteoblasts. In contrast, THBS1 expression in osteoblasts isolated from Runx2 mice is stable throughout differentiation which results after 14 days of culture (d14) in a higher expression level of THBS1 in osteoblasts overexpressing Runx2 compared to WT. At the later stage of differentiation (d14), THBS1 protein expression assessed by immunoblotting is greater in Runx2 primary osteoblast than in WT. In WT mice, expression of THBS1 increases until 8 months of age and remains stable until 30 months of age. In aged Runx2 mice, the decrease in bone mineral density is inversely correlated with the expression of THBS1. Furthermore, in transient transfection experiments in MC3T3-E1, overexpression of Runx2 is responsible for a significant increase of the THBS1 promoter activity, indicating a possible transcriptional control of THBS1 by Runx2.

In conclusion, we demonstrated that overexpression of Runx2 leads to an increased expression of thrombospondin 1 *in vivo* and *in vitro*. Our results could partly explain the low bone mass observed in Runx2 mice. Ongoing experiments are being performed *in vivo* and *in vitro* to test this hypothesis.

MO0243

Interaction of Prx-1 with Runx2 Suppresses Osterix Transcription. Linda Gilbert¹, Xanghuai Lu², Hong Chen², Mark Nanes^{*3}. ¹VA Medical Center, USA, ²Emory University, USA, ³VA Medical Center & Emory University, USA

Osterix (Ox, Sp7) expression is required for differentiation of osteoblasts. We previously showed that TNF inhibition of OB differentiation was due, in part, to suppression of Ox transcription. Using the TNF response element of the Ox promoter as bait, a suppressor protein complex was identified using mass spectroscopy that contained the homeodomain-like protein Prx-1. Prx is required for limb bud formation early embryogenesis and then levels are reduced. However, TNF stimulates Prx-1 expression in adult tissues where it acts as a suppressor of OB differentiation (Lu et al, JBMR 26:209 2011). Here we report that Prx binding to the TNF response element of the Ox promoter occurs indirectly through protein-protein interactions that involve binding to RUNX2. Evaluation of the Ox promoter sequence revealed a homeobox consensus upstream of the TNF response element that is contiguous with a known RUNX2 binding site. Electrophoretic mobility shift studies using two Prx antibodies revealed that Prx-1b and Prx-2, but not Prx-1a, isoforms bind the TNF element, consistent with the isoform-specific suppression of Ox transcription. Binding of Prx to the TNF element required nuclear extract, suggesting that protein-protein interaction was required for incorporation of Prx into the suppressor complex on the promoter. Prx bound the upstream homeobox site without added nuclear extract, indicating that the homeobox site was a preferred binding site with subsequent interaction of Prx with the TNF suppressor protein complex. Since the homeobox site was contiguous with a RUNX2 binding site, we considered that PRX might interact with RUNX2. To test this hypothesis, co-immunoprecipitation studies were done using nuclear extract from C3H10T1/2 cells. Prx-1 and RUNX2 were co-immunoprecipitated using specific antibodies suggesting interaction of these proteins. We conclude that Prx1 binds the Ox promoter at a classic homeodomain binding site where it interferes with the RUNX2 organizer. The Prx anchored at this site then interacts with proteins on the TNF response element just downstream to render suppressor function to this transcriptional complex. This mechanism may contribute to suppression of OB differentiation and bone formation in inflammatory arthritis and aging.

MO0244

Interactions between ERK1/2 and p38 MAP Kinase Pathways Control RUNX2 Phosphorylation and Transcriptional Activity. Chunxi Ge^{*1}, Qian Yang¹, Guisheng Zhao¹, Hong Yu², Keith Kirkwood³, Renny Franceschi⁴.

¹University of Michigan School of Dentistry, USA, ²Department of Craniofacial Biology, Medical University of South Carolina, USA, ³Medical University of South Carolina, USA, ⁴Dept of Periodontics & Oral Medicine, University of Michigan School of Dentistry, USA

The RUNX2 transcription factor is a master regulator of osteoblast formation and bone development. Both ERK1/2 and p38 MAP kinases phosphorylate RUNX2 and stimulate its transcriptional activity. However, the relative contribution of each pathway to RUNX2-dependent transcription is not known. In this study, a combination of genetic and pharmacological approaches were used to compare ERK1/2 and p38 α /p38 β MAP kinase regulation of RUNX2 phosphorylation and activity. Because phosphorylation of RUNX2 at S319 is required for activation by both ERK and p38, we developed an antibody to monitor phosphorylation at this site and compared phosphorylation levels with transcriptional activity. ERK1, p38 α and p38 β all stimulated RUNX2 S319 phosphorylation and transcriptional activity. However, under optimal conditions, ERK1 was ten times more active than p38 α and four times more active than p38 β . ERK1 and p38 β were found to physically and functionally compete for a common docking site on RUNX2; mutation of this site abolished the ability of either kinase to stimulate transcription. One consequence of this competition is that RUNX2 phosphorylation and transcriptional activity is actually lower in the presence of both activated kinases than with ERK1 alone, due to displacement of ERK1 by the less active p38 β . Pharmacologic and genetic inhibition studies showed that ERK1/2 and p38 activities are regulated in a reciprocal manner. For example, inhibition of P-p38 with SB203580 or dominant-negative MKK6 increased P-ERK, RUNX2-S319-P and transcriptional activity while ERK inhibition increased P-p38 and reduced RUNX2 S319-P. Similarly, calvarial osteoblasts from transgenic mice over-expressing a constitutively active MEK1 had elevated P-ERK, suppressed P-p38 and elevated RUNX2-S319-P while cells from mice harboring a dominant-negative MEK had reduced P-ERK, elevated P-p38 and reduced RUNX2 S319-P. Lastly, evidence was obtained that ERK1/2 and p38 MAPKs have different roles in osteoblast differentiation. Ascorbic acid-induced osteoblast differentiation, which is known to be dependent on collagen matrix activation of α 2 β 1 integrins, is associated with parallel increases in P-ERK and RUNX2-S319-P in the absence of any changes in P-p38. In this system, ERK inhibition blocked RUNX2 S319-P and transcriptional activity while a p38 inhibitor was without effect. In contrast, when cells were treated with AA and BMP2/7, the strongly synergistic induction of RUNX2-dependent transcriptional activity was blocked by both ERK and p38 inhibition suggesting that the BMP-dependent component of the transcriptional response is at least partly dependent on p38.

MO0245

Mechanism of Akt and Erk Activation in Mechanically-stimulated Osteoblasts: Cross-talk Between Calcium and cGMP. Hema Rangaswami^{*1}, Raphaela Schwappacher², Nisha Marathe², Darren Casteel², Sanford Shattil², Gerry Boss², Renate Pilz². ¹University of California, San Diego, USA, ²UCSD, USA

Weight bearing and locomotion stimulate interstitial fluid flow through the bone canalicular system, and the resultant shear stress is thought to be a major mechanism whereby mechanical forces stimulate osteoblast growth and differentiation. Fluid shear stress (FSS) increases intracellular calcium, leading to increased NO and cGMP synthesis, and activation of cGMP-dependent protein kinases (PKG). We previously showed that NO/cGMP/PKG II signaling is required for ERK-mediated activation of *fos* family genes and proliferation in fluid shear-stressed osteoblasts. Membrane-bound PKG II directly phosphorylates and activates Shp-1, leading to activation of Src and Erk. PKG II-null mice demonstrated defective Src-Erk signaling and decreased Erk-dependent *fos* family gene expression in bone. Others showed that focal adhesion kinase (FAK) is required for Erk and Akt activation in fluid shear-stressed osteoblasts. How FAK is activated and how FAK and Src relate to each other in osteoblast mechano-transduction is unknown.

We have used biochemical and genetic approaches to order the signaling events leading to activation of Akt and Erk in mechanically stimulated osteoblasts. FSS-induced Akt and Erk activation required both calcium and NO/cGMP/PKG II signaling. Treatment with a calcium ionophore mimicked the effects of FSS on Akt and Erk; calcium effects were only partially prevented by the NO synthase inhibitor N-nitro-L-arginine methyl ester (L-NAME), although this agent completely blocked calcium-induced NO synthesis. NO/cGMP-dependent and -independent pathways activated by calcium worked at least additively to increase Akt and Erk activity. In the presence of L-NAME, calcium activated FAK and Src independently of each other; in contrast, NO/cGMP only activated Src. siRNA-mediated knock-down of either FAK or Src blocked FSS- and calcium-induced Akt and Erk activation, whereas cGMP-induced Akt and Erk activation required only Src, indicating that direct activation of PKG II can bypass FAK.

In conclusion, elevation of intracellular calcium by FSS activates FAK independently of NO/cGMP, and Src through both NO/cGMP-dependent and -independent pathways; FAK and Src cooperate in activating Erk and Akt, providing

crucial signals for osteoblast proliferation. Our results establish an important role of NO/cGMP/PKG II signaling in osteoblast mechano-transduction and support using PKG-activating drugs as mechano-mimetics for the treatment of osteoporosis.

MO0247

Protein Inhibitors of Activated STAT (PIAS) Proteins Regulate Runx2 Transactivation Activity. Masataka Nakamura, Noriko Funato*. Tokyo Medical & Dental University, Japan

Protein inhibitors of activated STAT (PIAS) proteins were initially identified as specific cofactors inhibiting DNA binding and transcriptional activation by the STAT family of transcription factors. PIAS family genes are expressed in osteoblasts. However, it still remains unknown whether any member of the PIAS family has any specific action on osteoblast differentiation. Here we report that PIAS proteins regulate the transcription factor Runx2, a master regulator of osteoblast differentiation. PIAS proteins inhibit Runx2 transactivation activity. PIAS proteins and Runx2 showed colocalization to the same intranuclear regions in cotransfected COS cells. Histone deacetylases (HDACs) are also known to directly interact with Runx2 and inhibit its transactivation activity; however, PIAS-mediated repression was unaffected by the HDAC inhibitor TSA, suggesting that the repression was independent of HDAC catalytic activity. These results indicate that PIAS proteins function as new negative regulators of Runx2.

MO0248

Sclerostin Expression Is Induced by BMPs in Human Saos-2 Osteosarcoma Cells but Not Through Direct Effects on Its Promoter or ECR5 Element. Longchuan Yu*, Marissa van der Valk, Jin Cao, Chun-Ya E. Han, Todd Juan, Michael B. Bass, Chetan Deshpande, Michael A. Damore, Richard Stanton, Philip Babij. Amgen, Inc., USA

Sclerostin is a negative regulator in the Wnt signaling pathway and plays a key role in the control of bone mass. The expression of sclerostin is mostly restricted to mature osteocytes but the transcriptional regulation of sclerostin is not well understood.

Both sclerostin mRNA and protein were increased in human Saos-2 osteosarcoma cells and rat primary calvaria cells following treatment with BMP2, BMP4 and BMP7. The increase in sclerostin expression was correlated with increases in mineralization markers, including ALP activity, osteocalcin and calcium content.

Deletion mutants of the -7.4kb upstream region of the human sclerostin promoter were examined in Saos-2 cells and no direct response from any of the promoter regions was observed to BMPs, Wnt3a or PTH treatment. The ECR5 downstream element did not have enhancer activity in Saos-2 cells and had no direct response to BMPs or PTH treatment.

The increased expression of several transcription factors with putative consensus DNA binding sites in the sclerostin promoter was identified through genome-wide microarray analysis of Saos-2 cells treated with BMP2. Among these transcription factors, the DLX family, MSX2, HEY1, SMAD6/7 and MEF2A/2C showed a range of inhibitory activity whereas SMAD9 showed no activity. However, MEF2B exhibited a positive effect on both the promoter and ECR5 element.

These observations indicate that the inducing effects of BMPs on sclerostin expression in Saos-2 cells and rat primary calvaria cells are indirect. Furthermore the dramatic increase of sclerostin expression in both types of cells is associated with the late stage differentiation of osteoblasts and the mineralization process.

MO0249

Statin Suppresses Excess Runx2 Expression in Human Osteoblastic Osteosarcoma Cells. Takashi Ikeo*, Aiko Kamada¹, Yoshihiro Yoshikawa¹, Eisuke Domaie¹, Seiji Goda¹, Isao Tamura¹, Yoshitomo Takaishi², Takuo Fujita³. ¹Osaka Dental University, Japan, ²Takaishi Dental Clinic, Japan, ³Katsuragi Hospital, Japan

Statins, the cholesterol-lowering drug, activate the promoter of the BMP-2 gene, and stimulate bone formation. However, the mechanism of the stimulation of bone metabolism by statins is not precisely clarified. Runx2/Cbfa1 and Dlx5, osteogenic master transcription factors, are known as a downstream target of BMP-2. Previously, we compared the gene expression of the human osteoblastic osteosarcoma cell line, SaOS-2, cells and normal human osteoblasts, and demonstrated continuous excess expression of Runx2 in SaOS-2, though the expression was hardly observed in normal differentiated osteoblasts. It was considered that the excess expression of Runx2

inhibited mineralization of the osteosarcoma cells. In this study, we investigated whether statins effect the expression of Runx2 and Dlx5, using SaOS-2 cells.

Real time RT-PCR analysis confirmed that compactin (mevastatin) induced BMP-2 mRNA expression in the osteosarcoma cells once on day 3, and time-dependent increase in the type I collagen. When the osteosarcoma cells were incubated with compactin, there was a significant decrease in mRNA level of Runx2 compared with controls ($p < 0.01$). There appeared to be no overall changes in Dlx5. The mineralized matrix produced by the cultured osteoblasts was visualized by von Kossa staining. Non-stimulated control cells did not form a mineralized matrix, but the cells stimulated by compactin were formed.

It is known that Runx2 is essential for the initial osteoblastic differentiation, but it inhibits the final differentiation. Our observations indicate that statins enhance the mineralization of human osteosarcoma cells through suppression of the excess Runx2 expression. Hence, it is indicated that statins promote not only the initial osteoblastic differentiation but also the final differentiation through regulation of transcription factors.

ATP stimulates Caveolar Endocytosis of P2X₇ Receptors in MC3T3-E1 Osteoblasts. Vimal Gangadharan*, Anja Nohe, Randall Duncan. University of Delaware, USA

Purinergic signaling plays a critical role in mechanotransduction in bone. We have shown that nucleotides are rapidly released by osteoblasts and osteocytes in response to mechanical stimulation to initiate a cascade of signaling events in osteoblasts through P2X₇ receptor (P2X₇R) activation. This activation ultimately leads to increased bone formation. However bone rapidly becomes desensitized to loading and we hypothesize that this loss of sensitivity results from internalization of the P2X₇R via endocytosis by caveolin-1. Using sucrose gradient fractionation following detergent-free isolation of lipid rafts, we demonstrated that P2X₇R was co-fractionated with caveolin-1. Further, treatment of these cells with ATP resulted in a shift of caveolin-1 and P2X₇R to the denser fractions indicative of endocytosis. To visualize the caveolar endocytosis in response to ATP treatment, MC3T3-E1 preosteoblastic cells were transfected with caveolin-1 GFP and visualized under Zeiss 5 Live confocal microscope. Using AF-555 albumin as a (fluorescent) selective marker for caveolar endocytosis, MC3T3-E1 cells were treated with 250μM ATP for 40 minutes. We found increased AF-555 albumin uptake with ATP stimulation and its co-localization with caveolin-1 GFP indicated endocytosis via caveolae. These data suggest ATP stimulation induces internalization of caveolin-1 from the membrane lipid rafts into the cytosol. Presence of P2X₇ receptors in the same fraction as caveolin-1 indicates an association with caveolae of MC3T3-E1 osteoblasts and that ATP stimulation may induce caveolar endocytosis of P2X₇ receptor. However we have found that caveolin-1 and P2X₇R do not co-immunoprecipitate. This association suggests that, upon purinergic stimulation, P2X₇R may be internalized, but when caveolin-1 is absent, this receptor stays on the cell surface. This postulate may explain why caveolin-1 null mice have a higher bone density than their wild-type counterparts. These data also suggest that caveolae are a major signaling hub in mammalian cells and that it's function in response to ATP stimulation could be a vital process in mechanotransduction in osteoblasts.

Gα₁₁ Over-expression in Osteoblasts of Growing Mice Results in Osteopenia. Ariana Dela Cruz*, Michael Mattocks¹, Kim Sugamori¹, Marc Grynpas², Jane Mitchell¹. ¹University of Toronto, Canada, ²Samuel Lunenfeld Research Institute, Canada

Gα₁₁, a member of the heterotrimeric Gq protein family, mediates phospholipase C-dependent signaling downstream of G protein-coupled receptors including the parathyroid hormone 1 receptor (PTH1R). Our group has previously demonstrated that dexamethasone, a potent glucocorticoid, increases Gα₁₁ expression in osteoblasts and can therefore enhance parathyroid hormone (PTH) signaling through the PTH1R. To determine the effects of increased Gα₁₁ in bone, we developed a transgenic mouse model that over-expresses Gα₁₁ (+G11) in osteoblasts under control of the 3.6kb Col1A1 promoter.

Characterization of young (3- to 8-week) +G11 mice mid-diaphysis femur and lumbar vertebrae by DEXA and microCT scans revealed significant reductions in bone mineral density (BMD), trabecular thickness, and cross-sectional geometry. We further investigated the effects of skeletal Gα₁₁ over-expression on response to secondary hyperparathyroidism induced with a low-calcium diet regimen. Femoral aBMD was significantly reduced in both wild-type and +G11 mice and remained significantly lower in +G11 mice.

Bone marrow stromal cells isolated from +G11 mice proliferate at a normal rate, but showed reduced survival and exhibit decreased mineralization with a distinct expression profile of osteoblastic genes when compared to cells from wild-type animals. +G11 bone marrow stromal cells were also more susceptible to apoptosis induced by oxidative stress.

Together, our results show that overexpression of Gα₁₁ in osteoblasts results in an osteopenic phenotype in growing mice.

Insulin Resistance Takes Place in Bone of Type 2 Diabetic Mice. Jianwen Wei*, Mathieu Ferron, Patricia Ducy, Gerard Karsenty. Columbia University, USA

The recent realization that bone is an insulin target tissue involved in the control of whole-body glucose homeostasis raises the following question: is bone also a site of insulin resistance in the case of type 2 diabetes induced by high fat diet? To answer this question wild type (WT) mice were fed a high fat diet (HFD) for 8 weeks so that they could develop glucose intolerance and insulin insensitivity. Remarkably HFD fed WT mice develop several features observed in mice lacking insulin signaling in osteoblasts, that include decreased bone resorption, increased expression of Opg and decreased circulating level of the active form of osteocalcin. To investigate the molecular bases of the insulin resistance occurring in bone, we performed cell culture experiments and treated primary osteoblasts in the presence or absence of palmitic acid (100 μ M), the most abundant saturated fatty acid we identified in the serum of HFD fed WT mice. Remarkably palmitate impaired insulin-induced phosphorylation of FoxO1 at ser256 and AKT at Thr308 and Ser473. It also increased expression of Opg. Taken together, this study provides strong experimental evidence that bone is a site of insulin resistance in animals fed a HFD. This occurs because a HFD diet raises the level of circulating free fatty acid, which in turn hampers insulin signaling in osteoblasts, as a result bone resorption is decreased and osteocalcin activation is inhibited. These results further underscore the importance of the skeleton in the control of glucose metabolism.

Phospholipase Cgamma1 and Inositol Hexakisphosphate Kinase 1/2 are Required for the Cx43-dependent Amplification of the Osteoblast Response to FGF2. Corinne Niger, Maria Luciotti, Joseph Stains*. University of Maryland School of Medicine, USA

Connexin43 (Cx43) plays a critical role in osteoblast function and, ultimately, the achievement of peak bone mass. However, the identity of the second messengers being transmitted by Cx43 gap junctions, the molecular targets of these second messengers and the manner by which they regulate osteoblast function remain largely unknown. We have previously shown that alterations of Cx43 expression in an osteoblast cell line can impact the responsiveness to FGF2, by modulating the transcriptional activity of Runx2.

In the present studies, we examine the contribution of the phospholipase Cgamma1/inositol polyphosphate cascade to the Cx43-dependent transcriptional response of MC3T3 osteoblasts to FGF2. Inhibition of PLCgamma1 activity with dominant negative constructs, pharmacological inhibitors or siRNA can abrogate the ability of Cx43 to potentiate FGF2-induced signaling through Runx2. Conversely, stabilization of 1,2-diacylglycerol levels with a DAG-lipase inhibitor fails to amplify the response to FGF2. Instead, we find that the activity of the inositol polyphosphate cascade, which converts inositol 1,4,5-triphosphate (InsP3) to higher order inositol poly- and pyrophosphates, such as InsP6 or (PP)₂InsP4, is required for the effect of Cx43 on osteoblast transcription from a Runx2-binding element. Knockdown of inositol polyphosphate multikinase (IPMK), which can convert InsP3 to InsP4 and InsP4 to InsP5, partially attenuates the Cx43-dependent potentiation of transcription in response to FGF2. Similarly, chemical inhibition of the inositol hexakisphosphate kinases, which generate inositol pyrophosphates from InsP4 or InsP6, with 10microM TNP abrogates the Cx43-dependent potentiation of transcription. Likewise siRNA-mediated knockdown of either IP6K1 or IP6K2 can inhibit the effect of Cx43 on Runx2-mediated transcription.

In summary, these data implicate PLC activity and the water-soluble inositol pyrophosphates as mediators of the Cx43-dependent amplification of the osteoblast response to FGF2. Accordingly, our data suggest that these low molecular weight second messengers may be biologically relevant mediators of osteoblast function that are communicated by Cx43-gap junctions. In total, our data establish the FGF2/PLCgamma1/inositol pyrophosphate/PKCdelta/Runx2 pathway as a modulator of osteoblast function that is influenced by Cx43 expression.

Serum Osteocalcin Is Not Associated with Energy Expenditure or Glucose Metabolism in a Cohort of Low and High Fatness Families. Sulin Cheng*¹, Kaisa K. Ivaska², Leiting Xu¹, Kalervo H. Vaananen², The Calex-family study group³. ¹University of Jyväskylä, Finland, ²Department of Cell Biology & Anatomy, Institute of Biomedicine, University of Turku, Finland, ³Department of Health Sciences, University of Jyväskylä, Finland

It has been suggested that bone may have a regulatory role in energy metabolism via osteocalcin which has been shown to affect insulin secretion and sensitivity in mice. To study whether the skeleton regulates energy metabolism also in humans, we evaluated the associations between glucose metabolism, energy expenditure, body composition and different forms of osteocalcin in low and high fatness families

consisting of 16 mother-daughter-father trios (18 subjects from 6 low fatness trios, mean total body fat =23.8%; and 30 subjects from 10 high fatness trios, mean fat =38.8%). Low and high fatness were here defined as all three members of the family trio falling in either the lowest or highest tertiles for body fat % as determined in a larger family dataset of which the current subjects were a subset. Serum concentrations of total and carboxylated osteocalcin (tOC, cOC) were determined. Uncarboxylated osteocalcin (ucOC) was indirectly calculated as the difference between tOC and cOC. An oral glucose tolerance test was performed. Insulin resistance was indicated by HOMA-IR. Total body bone mass (BM), lean mass (LM) and fat mass (FM) were measured by DXA. Total energy expenditure (TEE) was measured by doubly labeled water and rest energy expenditure (REE) by calorimetry. The high fatness families had significantly higher mean values of weight, FM, fasting, 1-hr and 2-hr insulin and HOMA-IR than the low fatness families (p<0.001 for all). No differences were found between low and high fatness families in age, height, fasting glucose, TEE, REE, LM and BM as well as in tOC, cOC, and uOC. Furthermore, tOC, cOC and uOC were not associated with fasting, 1-hr or 2-hr glucose and insulin, HOMA-IR, TEE, REE, BM, LM or FM. However, cOC was negatively associated with fasting glucose (r=-0.387, p=0.008) but this association disappeared after adjustment for age and gender. TEE and REE were positively correlated with LM (r=0.704 p<0.001, r=0.701 p<0.001) and BM (r=0.713 p<0.001, r=0.651 p<0.001). No associations were found between TEE and glucose metabolism and body fat. We conclude that osteocalcin is not associated with glucose metabolism, total energy expenditure and fat accumulation. These results challenge the view that bone has a direct regulatory role in energy metabolism in humans.

The Protein Kinase Inhibitor (PKI) Gene Family Decreases Osteoblast Differentiation by Terminating Protein Kinase A (PKA) Signaling. Edward Greenfield¹, Guang Zhou¹, Shunichi Murakami¹, Guangbin Luo¹, Janet Rubin², Erik Schnaser¹, Bryan Hausman¹, Xin Chen*¹. ¹Case Western Reserve University, USA, ²University of North Carolina, Chapel Hill, School of Medicine, USA

PKA signaling stimulates osteoblast differentiation. The PKI gene family (α , β , and γ) inactivates PKA in the nucleus and thereby terminates PKA-induced gene expression. We previously showed that γ is the primary PKI expressed in osteoblastic and fibroblastic cell lines. We also showed that γ knockdown by siRNA or antisense significantly increases the magnitude and extends the duration of effects of PTH or forskolin (FSK) on PKA activation, immediate-early (IE) gene expression, and inhibition of apoptosis. The goal of this study was therefore to determine whether PKI regulates stimulation of osteoblast differentiation by PKA signaling. We found that γ is also the primary PKI expressed in murine femoral metaphyses and calvarial osteoblasts (γ > α > β). We therefore generated γ -/- mice and compared their skeletal and cellular phenotypes to wild-type mice. PKA activation and IE gene expression induced by FSK are increased in magnitude (3-8 fold, p<0.03) and substantially increased in duration in γ -/- murine embryonic fibroblasts (MEFs). Alkaline phosphatase activity in MEFs in osteogenic media is increased by FSK or γ deficiency (8 or 6 fold respectively, p<0.001) and is further increased by the combination of FSK treatment and γ deficiency (19 fold, p<0.001). Alkaline phosphatase and osteocalcin mRNA levels induced by FSK are also increased in γ -/- MEFs (9-12 fold, p<0.001). In contrast to the dramatic effects in MEFs, γ -/- had little or no effect on IE gene expression induced either by PTH or FSK in isolated calvarial osteoblasts or by PTH in vivo. The bone phenotype of γ -/- mice was also not different from wildtype as assessed by uCT at 5 weeks. This lack of an in vivo phenotype may in part be due to the compensatory upregulation of PKI α mRNA that occurs in the γ -/- calvarial osteoblasts (2 fold, p<0.005, n=3) and the γ -/- femoral metaphyses (1.6 fold, p=0.054, n=5-6) but not in the γ -/- MEFs (p>0.3, n=4). To assess whether α and γ act together, we performed siRNA experiments in a murine marrow-derived mesenchymal stem cell line. Alkaline phosphatase mRNA levels induced by FSK are significantly increased by knockdown of either α or γ (10 or 5 fold respectively, p<0.005) and are further increased by double knockdown of both α and γ (20 fold, p<0.001). Our results strongly support the conclusion that the PKI gene family decreases osteoblast differentiation by terminating PKA signaling and may therefore be useful targets for enhancing repair of bone defects.

A Comparison of Murine Long Bone Segmental Defect Repair Models. Liping Wang*¹, Xi Jiang¹, Nathan Dymant², Aditva Chaubey², David Butler², David Rowe¹. ¹University of Connecticut Health Center, USA, ²University of Cincinnati, USA

Using a calvarial repair defect model that employs a variety of GFP reporter mice, we found that the type of donor-derived bone that was formed differed when the source of donor cells came from bone marrow stromal cells (BMSC->cortical with marrow) or neonatal calvarial osteoblasts (nCOB->membraneous without marrow). In the process of developing a long bone segmental defect model to test the relative contribution of each cell source to the repair process, we evaluated a variety of external fixation methods versus an approach based on internal fixation utilizing non-

radiopaque materials. Two key differences in the host repair response were observed. First, the circumferential periosteal metallic bands that are used to attach the external fixative devices to the bone flanking the defect site significantly blunt the periosteal response to the critical defect. Second, a pseudoarthrosis is initiated when the periosteal response fills the marrow space and caps the ends of the defect area instead of forming a cortical bridge across the defect zone. This unfavorable outcome can be blocked with an intramedullary pin that prevents the formation of the capping structure. Building on these two observations, a surgical model was developed in NOD/Scid/IL2rg null mice that inserts a 0.8 x 14 mm plastic triangular shaped pin within the intramedullary space at the time the segmental defect is generated. The stability is augmented by a 1.0 x 1.4 x 8 mm rectangular pin that is secured to the periosteal surface with a resorbable suture. This support allows the repair to maintain good alignment and normal animal ambulation for 8 weeks after induction of a 3-4 mm critical defect. When the defect area is less than 2 mm or when a critical size defect is loaded with BMSC derived progenitor cells, full cortical bridging is obtained without the development of the capping process. Donor derived BMSCs contribute significantly to the bridging process by integrating with the host's periosteal response, while nCOB failed to generate the bridge and instead formed a non-integrating bony mass. This model is attractive because radiographs of the repair process are easier to interpret in the absence of obstructing hardware, and the histology of the repair can be obtained without removing the hardware thus preserving alignment. Because the mice are immunocompromized, they can be engrafted irrespective of the genotype of the mouse and with human derived bone progenitor cells.

Copper Stimulated Differentiation of Mesenchymal Stem Cells. Ines Burghardt¹, Frank Luthen¹, Cornelia Prinz², Hans-Georg Neumann², Joachim Rychly^{*1}. ¹University of Rostock, Germany, ²DOT GmbH, Germany

In context with the design of medical implants which both stimulate the regeneration of bone tissue and are suitable to prevent infection due to bacteria, we have been interested in the effects of copper ions on the osteogenic differentiation of human mesenchymal stem cells (MSC). We hypothesized that the release of copper from an implant surface can induce bacterial death. However, because of the known physiological role of copper, lower concentration in a later phase after implant incorporation or at greater distances from the implant surface could have a stimulating effect on stem cells. Mineralization of cells as a marker for osteogenic differentiation was measured by calcein bound to extracellular calcium phosphate and visualized by laser scanning microscopy. We found that the critical concentration of copper ions for the survival of human bone marrow derived MSC was 0.5 mM. Therefore we studied the effect of copper on the osteogenic differentiation below this concentration. We found that when adding CuSO₄ into osteogenic differentiation medium for 28 days, copper ions stimulated the osteogenic differentiation of adherent cells with a maximum at a concentration of 0.3 mM. Copper in the culture medium induced a stronger mineralization when the cells were cultured on cell culture polystyrene than on titanium oxide or titanium surfaces. To see, whether copper implemented into implant materials induces an osteogenic differentiation of MSC, cells were cultured on calcium phosphate surfaces containing copper salts. These surfaces enhanced the osteogenic differentiation of adherent MSC compared with copper free surfaces. Because copper is a cofactor for the enzyme lysyl-oxidase (Lox) which catalyzes cross-links of extracellular collagen and elastin we studied components of cell adhesion. We found that copper decreased the expression of different integrin subunits. The strength of cell adhesion was slightly decreased at a low copper concentration but increased again at 0.3 mM.

We conclude that copper containing implants are suitable to promote bone regeneration by the stimulating effect on the osteogenic differentiation of mesenchymal stem cells.

Dietary Amino Acids Activate the MAPK Pathway In Bone Marrow Stromal Cells. Ke-Hong Ding^{*1}, Qing Zhong¹, Xing-Ming Shi², Wendy Bollag¹, Michael Cain¹, Clare Bergson¹, Erin Fynan¹, William Hill¹, Mona Elrefaey¹, Karl Insogna², Norman Chutkan¹, Monte Hunter¹, Mark Hamrick¹, Carlos Isaacs². ¹Georgia Health Sciences University, USA, ²Medical College of Georgia, USA, ³Yale University School of Medicine, USA

We have previously shown that amino-acid supplementation prevented bone loss in aging C57Bl6 mice placed on a low protein diet. These findings are consistent with epidemiologic data demonstrating an association between low protein intake and fractures in the elderly population. Conigrave et al. (2000) demonstrated L-type amino-acid binding to the extracellular calcium receptor. Work from our laboratory was consistent with individual amino acids binding and activating this extracellular calcium receptor in osteoprogenitor/bone marrow stromal cells (BMSCs). Since BMSCs differentiate into the bone forming or osteoblastic cells they would appear to be natural targets for any bone anabolic activity associated with dietary protein ingestion. In order to better elucidate the intracellular signaling pathways activated by these individual amino acids we used BMSCs isolated from C57Bl6 mice and tested

all twenty of the common amino-acids. We found that: (1) Aromatic amino-acids (Tyrosine, Tryptophan and Phenylalanine at 100 μ M) were the most potent in increasing intracellular calcium as measured by single cell calcium measurements with Fura-2; (2) in addition, Tryptophan and Tyrosine induced the largest increases in phospho c-Raf (7.5 and 29 fold respectively) as measured by Western blot and (3) Tryptophan and Tyrosine increased phospho MEK 1/2 (2.6 and 1.4 fold respectively); further (4) all three aromatic amino-acids transiently increased ERK phosphorylation (up at 10 minutes and down to baseline by 30 minutes) and combining two aromatic amino acids did not have an additive effect on ERK phosphorylation; and (5) Tyrosine and Tryptophan induced BMSC proliferation (measured by thymidine uptake). Taken together our data are consistent with aromatic amino-acids activating the MAPK pathway, potentially resulting in BMSC proliferation and differentiation down the osteoblastic pathway.

Ebf1: An Essential Regulator of Mesenchymal Lineage Allocation and Osteoblast Differentiation. Jackie Fretz^{*1}, Tracy Nelson², Mark Horowitz². ¹Yale School of Medicine, USA, ²Yale University School of Medicine, USA

While the osteoblast (Ob) is defined as the anabolic cell in bone capable of laying down and mineralizing new matrix, it exists along a continuum of differentiation flowing from immature mesenchymal precursors to the mature mineral-encased osteocyte. We have reported previously that Ob progenitors express Ebf1 and while bones of Ebf1^{-/-} mice have unusually large numbers of Obs and osteoid, they exhibit low bone mass. Our preliminary studies indicate that this does not appear to be a complete block in mineralization, but instead a delay in ossification. This is supported by mineralization delay observed at select sites in the skeletons of newborn pups, increased osteoblast numbers on bone surfaces accompanied by accumulation of non-mineralized osteoid in the skeletons of Ebf1^{-/-} animals, and μ CT of femora that revealed a significant lack of mineralized bone in the 4 week old Ebf1^{-/-} mice that was reversed by the time the animals were 3 months old. Mineralization defects were also seen *in vitro* from primary bone marrow, isolated MSCs, and calvarial osteoblasts deficient in Ebf1. Investigation into the mechanism underlying this phenomenon has identified two independent points at which the absence of Ebf1 results in an inhibition of Ob maturation and function. First, very early progenitor populations are reduced in number in the BM, form reduced numbers of ALP⁺ colonies, and exhibit reduced SMAD signaling. Second, when more mature Obs are induced to form bone nodules *in vitro*, they exhibit normal numbers of early to intermediate markers of Ob maturation, and equal numbers of ALP⁺ colonies, but fail to express markers of progression to late-stage Obs. The earliest of these markers that fails to be upregulated is Dentin matrix protein 1 (DMP1) which functions as transcription factor within the cell and a nucleator for mineralization when it is secreted. ChIP and luciferase assays confirm that DMP1 is directly regulated by Ebf1 though several enhancers conserved across species. Multiple transcription factors, including Runx2 and Osterix, are required for the progression of Ob cell fate along this continuum. Our data indicate that Ebf1 is also a member of this critical group.

Ectonucleotide Pyrophosphate/Phosphodiesterase-1 (Enpp1) Promotes Osteoblast Differentiation Through a Catalytic Independent Mechanism. Hwa Kyung Nam, Jin Liu, Nan Hatch^{*}. University of Michigan, USA

Purpose: Enpp1 (ectonucleotide pyrophosphate/phosphodiesterase-1) is an established regulator of tissue mineralization. Previous studies demonstrated that Enpp1 is expressed in differentiated osteoblasts and that Enpp1 influences matrix mineralization by increasing extracellular levels of inorganic pyrophosphate. Enpp1 is also expressed in pre-osteoblasts when stimulated with FGF2 and is expressed in mesenchymal precursor cells of developing molars several days prior to mineralization, but the role of Enpp1 in pre-osteoblastic and other precursor cells is unknown. Here we investigate the function of Enpp1 in pre-osteoblasts. Methods: Enpp1 expression was inhibited in MC3T3E1(C4) cells by lentiviral transduction with Enpp1 specific shRNA and by isolation of cells from Enpp1 knockout mice. Wild type and catalytic inactive Enpp1 expression was increased in MC3T3E1(C4) cells by retroviral transduction with Enpp1 and Enpp1/T238A cDNA. Enpp1 expression was measured by western blot and real time PCR. Enpp1 enzyme activity was measured by NTPPPH assay. The expression of genes associated with osteoblast maturation, including OCN, BSP, TNAP and Col1a1, was compared in Enpp1 deficient, control, Enpp1 over-expressing and Enpp1/T238A over-expressing cells by real time PCR. To determine if Enpp1 influences osteoblastic gene expression by altering extracellular levels of inorganic phosphate or pyrophosphate, OCN, BSP, TNAP and OPN mRNA levels were compared in control and Enpp1-overexpressing cells upon treatment with phosphate or pyrophosphate. Results: Enpp1 deficient cells exhibited defective osteoblastic differentiation, as indicated by a lack of cellular morphological change, a lack of osteoblastic gene expression and an inability to mineralize matrix. MC3T3E1(C4) cells in which Enpp1 or Enpp1/T238A expression was increased exhibited an increased tendency to differentiate, as exhibited by increased expression of osteoblastic genes. Notably, treatment of cells with inorganic phosphate or pyrophosphate inhibited, as opposed to enhanced, expression of BSP, a gene that is expressed in association with osteoblast differentiation, matrix deposition and mineralization.

Conclusions: Taken together, our results indicate that Enpp1 plays multiple and distinct roles in the development of mineralized tissues and that the influence of Enpp1 on osteoblast differentiation and gene expression includes a mechanism that is independent of its catalytic activity.

Disclosures: Nan Hatch, None.

MO0261

Effects of Rosiglitazone on Circulating Osteoblast and Osteoclast Cell Populations in Postmenopausal Women With Type 2 Diabetes Mellitus. Mishaela Rubin¹, John Sanil Manavalan¹, Donald McMahon², Antonio Nino³, Allison Northcutt⁴, Barbara Kravitz⁵, Paul Gitajali⁵, Lorraine Fitzpatrick⁵, John Bilezikian^{*2}. ¹Columbia University, USA, ²Columbia University College of Physicians & Surgeons, USA, ³GSK, USA, ⁴GlaxoSmithKline, USA, ⁵GlaxoSmithKline Pharmaceuticals, USA

The increase in fractures in women seen with Rosiglitazone (RSG), a PPAR- γ activator, is accompanied by a reduction in bone formation and an increase in bone resorption markers. One mechanism for these changes in bone turnover markers could be an effect of PPAR- γ activation to divert mesenchymal stem cell development from the osteoblast to the adipocyte lineage pathway. We hypothesized that circulating osteogenic and osteoclast precursor cells would be altered by RSG in Type 2 Diabetes Mellitus (T2D). A convenient comparator drug is Metformin (MET) which is not known to affect the skeleton. Two hundred and twenty six subjects with T2D were randomized to RSG or MET for 52 weeks (Wk) (double-blind period), followed by 24 Wk of MET in all (open-label period). Using flow cytometry, in 73 subjects we sorted peripheral blood mononuclear cells (PBMC) and characterized them with the osteoblast-specific ligand osteocalcin (OCN), as well as early osteoblastic stem cell markers CD34 and CD146. CD14+ PBMCs were also sorted, cultured for 8 days with M-CSF and RANK-L and stained for TRAP, a marker of osteoclast activity. There were no significant differences between RSG and MET in total osteogenic or osteoclast populations. However, with RSG, the most mature osteogenic cell sub-populations, lacking expression of CD34 and CD146 markers (OCN+/CD34-/CD146-) increased from 67.2% at Wk0 to 73.7% at Wk52 ($p=0.006$). After switching to MET, this more mature cell population returned to baseline (67.3%) by Wk76. Similarly, cells that had lost CD34 but retained CD146 (OCN+/CD34-/CD146+) fell from 7.9% at Wk0 to 4.8% at Wk52, ($p=NS$) and increased towards baseline after stopping RSG at Wk76 (9.8%; $p=0.07$). Similarly, cells that retained the CD34 marker but did not retain the CD146 marker fell from 20.8% at Wk0 to 17.0% at Wk52 ($p=0.03$). This population was stable through Wk76. Circulating osteoclast cells increased in both RSG and MET groups at Wk52, with RSG increasing from 2.9% to 14.0% ($p=0.001$) and MET increasing from 3.3% to 16.7% ($p=0.001$). The results show that RSG is associated with a change in peripheral osteogenic cells that favors a maturation sequence from earlier osteogenic forms. This pattern tends to reverse toward baseline values when RSG is discontinued. Osteoclast activity increased with both RSG and MET. These studies provide new insights into mechanisms by which RSG may affect the skeleton.

Epigenetic Control of Fetal Bone Development through HoxA10 in the Rat. Jin-Ran Chen^{*1}, Jian Zhang¹, Oxana P. Lazarenko¹, Rebecca A. Wynne², Michael L. Blackburn¹, Martin J. Ronis¹, Kartik Shankar¹, Thomas M. Badger¹. ¹University of Arkansas for Medical Science, Arkansas Children's Nutrition Center, USA, ²ACNC, USA

Epidemiological studies show that quality of nutrition during intrauterine and early postnatal life impact the risk of low bone mass and fracture later in life. Maternal consumption of high-fat diets has been demonstrated to affect health outcomes, such as: brain development; obesity; insulin resistance; and hypertension. Here, we show that fetal rat osteogenic calvarial cells (FOCC) from obese rat dams fed a high fat diet (HFD) have significantly less potential to develop into mature osteoblasts compared to cells from AIN-93G diet-fed controls. These FOCCs taken from E18.5 embryos from obese rat dams express lower levels of alkaline phosphatase (ALP), but higher levels of PPAR- γ compared to fetal cells from control dams fed low fat diets ($p<0.05$). Profiling of transcriptional genes for osteogenesis revealed a 15-fold decrease in the homeodomain-containing factor A10 (HoxA10) in these FOCCs from HFD offspring. Significant methylation of the HoxA10 promoter was found in these FOCCs, as well as in ST2 cells treated with a mixture of free fatty acids (palmitic, stearic, oleic, linoleic and arachidonic acid in the ratio of 5:1:2:3:1 similar to that found in rat serum from HFD rats), this was accompanied by lower expression of alkaline phosphatase (ALP), but higher levels of PPAR- γ . Silencing of the HoxA10 gene ex vivo in control FOCCs produced effects similar to those observed in FOCCs from HFD offspring. Treatment of FOCCs from control rats and ST2 cells with an artificial mixture of free fatty acid, significantly down regulated the HoxA10 protein expression and cells exhibit triglyceride accumulation as measured by Oil Red O staining. These results suggest that maternal obesity may affect fetal skeletal development through down regulation of the HoxA10 gene by altered free fatty acid composition in the maternal circulation, which may lead to an increase of the prevalence of low bone mass in their offspring later in life. Supported in part by ARS CRIS #6251-51000-005-03S.

Epigenetic Regulation of Human Mesenchymal Stem Cell Differentiation by Cyclin-Dependent Kinase-9 and the Histone H2B Ubiquitin Ligase RNF40. Oleksandra Karpiuk^{*1}, Andrei Shchebet¹, Zeynab Najafova¹, Moustapha Kassem², Steven Johnsen¹. ¹Georg-August University, Dept. of Molecular Oncology, Germany, ²Odense University Hospital, Denmark

Human bone marrow-derived mesenchymal stem cells (hMSCs) are multipotent cells which can differentiate into various mesenchymal cell lineages including osteoblasts, adipocytes and chondrocytes. Importantly, diseases such as osteoporosis are characterized by increased adipogenesis at the expense of decreased osteogenesis suggesting a shift in the differentiation of hMSCs from the osteoblastic to the adipocytic lineage. The differentiation of pluripotent and multipotent cells is largely controlled by epigenetic mechanisms. Cyclin-dependent kinase-9 (CDK9) is one factor that controls multiple differentiation pathways including adipocytic differentiation. Since we recently showed that CDK9 activity is essential for maintaining the global levels of histone H2B monoubiquitination (H2Bub1) we hypothesized that CDK9 may epigenetically program hMSC differentiation by directing H2Bub1. Therefore we investigated the levels of H2Bub1 during both adipocytic and osteoblastic differentiation using telomerase-immortalized hMSCs. While the levels of H2Bub1 were very low in undifferentiated hMSCs, differentiation into either lineage resulted in a dramatic time-dependent increase in H2Bub1. Consistently, CDK9 activity was also increased in a similar manner. In order to determine whether CDK9 and H2Bub1 play essential roles in determining lineage-specific differentiation we performed siRNA knockdown studies of either CDK9 or the H2B ubiquitin ligase RNF40 and induced hMSC differentiation. Knockdown of either CDK9 or RNF40 dramatically decreased osteoblast and adipocyte differentiation as assessed by von Kossa or Oil Red O staining and the expression of osteocalcin and PPAR- γ , respectively. Finally, in order to determine the global effects of H2Bub1 on hMSC differentiation, we performed transcriptome-wide gene expression microarray studies following RNF40 knockdown. While RNF40 knockdown had very little effect on the gene expression profile of undifferentiated hMSCs, the change in gene expression profile induced by differentiation to either the adipocytic or osteoblastic lineages was dramatically impaired. Thus we conclude that CDK9-dependent increases in H2Bub1 are essential for hMSC differentiation. These studies suggest that the development of small molecule inhibitors or activators which influence lineage-specific epigenetic regulation may provide a more specific and viable treatment for diseases such as osteoporosis.

Identification of the Differentially Methylated Promoter and Intragenic CpG-Cytosines in the Human Synovium and Bone Marrow Derived Mesenchymal Stem Cells. Yoichi Ezura^{*1}, Tadayoshi Hayata², Tetsuya Nakamoto³, Takuya Notomi⁴, Ichiro Sekiya³, Takeshi Muneta³, Masaki Noda³. ¹Tokyo Medical & Dental University, Medical Research Institute, Japan, ²Medical Research Institute, Tokyo Medical & Dental University, Japan, ³Tokyo Medical & Dental University, Japan, ⁴GCOE, Tokyo Medical & Dental University, Japan

Stromal progenitor cells existing in various adult tissues, including bone marrow, adipose and synovial tissues possesses multi-potency for differentiation into various cell types, and thus called as mesenchymal stem cells (MSCs). Basic characterization of the human and mouse MSCs including cell surface marker expression has shown that the cells from different origin share a common feature. However, detailed comparison also has shown that there are consistent differences among them. The synovial derived human MSCs (hMSCs) are most potent for chondrogenesis by pellet culture, whereas the osteogenesis is best reported by bone marrow derived MSCs. Basic origin of these differences have not been clarified yet. Previously we compared gene expression profiles of various hMSCs with different tissue origin, showing that there are slight differences. Here, to investigate the epigenetic ground of the differential gene expression, we compared CpG-cytosine methylation status of MSCs using single-base extension method on the beads-array (Infinium[®] assay) for bisulfite-converted DNA. Analysis of 27,551 CpG-sites showed that methylation status of synovium and bone marrow derived hMSCs was basically similar globally. However, about 6% of the CpG-sites were differentially methylated more than 20% (%-methylation), representing as differentially methylated regions (DMRs). Comparison of the methylation status and gene expression revealed that 20-30% of the differentially methylated CpG-Cites were associated with decreased gene expression, in comparison to the most CpG-cites with no difference in gene expression (about 60-70%) and the sites with opposite trend (less than 8%). In addition to the observation that the selected DMRs negatively correlated with gene expression sometimes included multiple CpG-sites, those genes included key transcription factors known to be important for chondrogenesis and maturation. The data indicated that the origin of the different gene expression with deviated differentiation features of hMSCs from different tissues includes epigenetic differences based on promoter-/intronic-CpG methylation, at least in part. Clarification of the basic cause of deviated differentiation potential of hMSCs would be beneficial for better protocol for the tissue-engineering therapies.

MO0265

Interleukin-3 Promotes Osteoblast Differentiation and Bone Formation of Human Mesenchymal Stem Cells. Amruta P. Barhanpurkar¹, Navita Gupta¹, Rupesh K. Srivastava¹, Geetanjali B. Tomar², Sameer P. Naik¹, Satish T. Pote¹, Gyan C. Mishra¹, Mohan Wani^{*1}. ¹National Centre for Cell Science, India, ²National Center for Cell Science, India

Interleukin-3 (IL-3) is an important cytokine that stimulates the proliferation, differentiation and survival of pluripotent hematopoietic stem cells. IL-3 potently inhibits osteoclast differentiation and bone resorption from hematopoietic precursors. However, its role in osteoblast differentiation is not yet known. In this study, we investigated the role of human IL-3 on osteoblast differentiation using purified population of human bone marrow-derived mesenchymal stem cells (MSCs). We found that IL-3 in a dose-dependent manner increased osteoblast differentiation and matrix mineralization in human MSCs, and significantly enhanced the expression of osteoblast specific genes such as alkaline phosphatase, collagen type-I, osteocalcin and osteopontin. In addition, expression of key osteogenic transcription factors, Runx-2 and osterix was significantly increased by IL-3.

Moreover, IL-3 induced the expression of bone morphogenetic protein-2 in a dose-dependent manner, and activated smad1/5/8. AG490, a specific inhibitor of JAK2 abolished stimulatory effect of IL-3 on matrix mineralization suggesting the possible involvement of JAK/STAT pathway in IL-3 action on osteoblast differentiation. Interestingly, IL-3 stimulated *in vivo* bone regeneration ability of MSCs in immunocompromised mice. Furthermore, migration and wound healing abilities of human MSCs were increased in presence of IL-3. IL-3 showed no effect on differentiation of MSCs into adipocytes. Thus, our studies reveal the novel role of IL-3 to promote osteoblast differentiation and bone formation. We suggest that IL-3 may be used as putative anabolic agent for bone formation in osteoporosis and other bone diseases.

Involvement of Changes in Subcellular Localization of Runx2 and Osterix in Osteoblast Differentiation Revealed by 3-dimensional Fluorescence Morphometry. Takashi Watanabe^{*1}, Ayako Nakane¹, Akiyoshi Hoshino², Yuji Makino³, Akira Yamaguchi⁴, Tadahiro Iimura¹. ¹Tokyo Medical & Dental University, Global Center of Excellence Program, Japan, ²National Center for Global Health & Medicine, Japan, ³Juntendo University Graduate School of Medicine, Department of Orthopedic Surgery, Japan, ⁴Tokyo Medical & Dental University, Japan

Runx2 and Osterix are essential transcriptional factors for osteoblast commitment and differentiation. Their transcriptional regulations have been well studied. However, their protein expression and subcellular localization associated with osteoblast differentiation were not well documented. To access this issue, we took advantages of 3-dimensional fluorescence morphometry after conducting immunofluorescence with antibodies against Runx2 and Osterix on cultured osteoblastic cells MC3T3-E1 and bone sections. Three-dimensional confocal microscopy and image processing enabled to quantify relative expression level and subcellular distribution pattern of Runx2 and Osterix *in situ*. During the course of MC3T3-E1 cells culture, the transcriptions of Runx2 and Osterix showed the highest expression on day 6 and day 12, respectively, by RT-PCR. Osteocalcin transcription was augmented on days 6 and 12 compared to that on day 2. Fluorescence morphometry analysis demonstrated that Runx2 protein expression per single cell showed the highest expression on day 2 and localized largely in nuclei, however, its expression on days 6 and 12 were faintly detected in cytoplasm. Osterix protein expression per single cell also exhibited the highest expression on day 2 and largely localized in nuclei with lower detection in cytoplasm. On days 6 and 12, lower level of Osterix was detected mainly in cytoplasm. We further analyzed protein levels and subcellular distributions of these transcriptional factors in developing rat femurs. Large numbers of Runx2 protein- and Osterix protein-positive cells were detected in trabecular bone area. Detailed analysis demonstrated that Runx2-positive cells in nuclei were detected in some cells in bone marrow and osteoblasts on trabecular bone surface, whereas some osteoblasts on the bone surface exhibited Runx2 protein in cytoplasm. Osterix-positive cells in nuclei were also observed in some cells in bone marrow and osteoblasts on the bone surface, whereas some osteoid osteocytes showed its protein expression in their cytoplasm. Our *in vitro* and *in vivo* analyses suggested that protein expression levels and subcellular localizations of Runx2 and Osterix were spatiotemporally regulated and their functional roles in nuclei were temporarily limited in early phase of osteoblast differentiation.

MO0267

MAN-1, a Novel Target to Stimulate Osteoblastogenesis and Bone Formation. Christopher Vidal^{*1}, Jessica Tong², Lee Wei Li³, Li Sze Yeo⁴, Diane Fatkin², Gustavo Duque⁵. ¹University of Sydney, Australia, ²Faculty of Medicine, University of New South Wales, Australia, ³University of Sydney, Nepean Clinical School, Australia, ⁴Victor Chang Cardiac Research Institute, Australia, ⁵Ageing Bone Research Program, University of Sydney, Australia

Apart from being a structural border to the nucleus, the nuclear membrane also plays an important role in the regulation of cell differentiation and function. MAN-1 is an inner nuclear membrane protein that is known to sequester R-Smads in fibroblasts. Loss-of-function mutations in the human *MAN-1* (*hMAN-1*) gene result in phenotypes characterized by hyperostosis. In this study we investigated the role of MAN-1 in mesenchymal stem cell (MSC) differentiation into osteoblasts both *in vitro* and *ex-vivo*. We hypothesized that MAN-1 plays an important role as a regulator of osteoblastogenesis. Initially, we performed siRNA of *hMAN-1* in osteogenic differentiating human MSC using 33 and 66 nM final concentrations of oligonucleotides. Transfections were repeated every three days. On day 9, proteins and RNA were extracted and cells were stained for mineralization using Alizarin red. Mineralization was significantly higher in *hMAN-1* siRNA-treated cells when compared to the negative siRNA control ($p < 0.001$). Quantitative real-time PCR showed 75% knockdown of *hMAN-1* and significantly increased levels of mRNA for Runx2 (28%) and for the osteoblastic genes osteopontin (2.3-fold) and alkaline phosphatase (56%) ($p < 0.05$), suggesting that the expression of these osteogenic genes is facilitated in absence of *hMAN-1*. We then assessed whether siRNA of *hMAN-1* would be associated with high levels of β -catenin expression in nuclear extracts, which would indicate an easy transit from the cytoplasm to the nucleus and constitutes a potent osteogenic stimulus. Western blot analysis of nuclear extracts suggested that in absence of *hMAN-1*, β -catenin is free to translocate to the nucleus in a significant manner ($p < 0.01$). For our *ex vivo* experiments, and since MAN-1 expression is increased in absence of lamin A/C, we performed confocal microscopy using *ex-vivo* cultured MSC derived from lamin A/C knockout (*lnna^{-/-}*) mice. A higher level of nuclear colocalization of Runx2 and MAN-1 was observed in the *lnna^{-/-}* MSC nuclei when compared to wild-type controls ($p < 0.01$). In conclusion, we demonstrate that MAN-1 plays an important role in the regulation of osteoblastogenesis and bone formation, most likely by sequestering molecules that are essential for the transcription of osteogenic genes. Due to its potent osteogenic effect, the inhibition of MAN-1 in MSC could become a novel therapeutic approach to osteoporosis.

Disclosures: Christopher Vidal, None.

Osteogenic Differentiation in Adipose Tissue Mesenchymal Stem Cells: Effect of Strontium Ion. Sergio Fabbri, Valeria Nardone, Simone Ciuffi, Francesca Marini, Gianna Galli, Carmelo Mavilia, Roberto Zonefrati, Anna Maria Carossino, Annalisa Tanini, Maria Luisa Brandi^{*}. University of Florence, Italy

Introduction and purpose:

Adipose tissue derived mesenchymal stem cells (AMSCs) are able to differentiate into osteoblasts with analogous characteristics to bone marrow mesenchymal stem cells producing alkaline phosphatase (ALP) and calcified nodules, mainly composed by hydroxyapatite (HA), collagen and osteocalcin. These characteristics, combined with the greater achievable quantity and the lower invasivity of the tissue drawing, compared with bone marrow, give the adipose tissue as an optimum source of stem cells to use in bone regeneration processes. As strontium, the active principle of the drug strontium ranelate, acts on bone metabolism by bone formation and bone resorption, the aim of our study was to evaluate the effects of different concentrations of Sr²⁺ on osteogenic differentiation of AMSCs.

Methods:

Long-term primary cultures of AMSCs were obtained from adipose tissue of seven normal subjects. The cells were cultured in growth medium (GM): Ham's F12 Coon's modification medium supplemented with 10% fetal calf serum. Cells were differentiated to osteogenic phenotype by use of osteogenic medium (OM): GM supplemented with 10 nM dexamethasone, 10 mM β -glycerophosphate and 50 μ g/ml 2-phospho-L-ascorbic acid trisodium salt. Different SrCl₂·6H₂O concentrations (0.5-100 μ g/ml) were added at different time points from 0 to 30 days. The differentiation was evaluated by quantitative fluorometric assay for ALP and HA and analysis of some specific genes expression. The total RNA was extracted, reverted to cDNA and the expression was analyzed in qPCR.

Results:

Significant increases of HA production were observed for the lower SrCl₂·6H₂O concentrations (0.5-1 μ g/ml) from 14, 21 or 28 days of induction depending on the cell line. ALP production was significantly increased for the higher SrCl₂ concentrations (50-100 μ g/ml) from 7, 14 or 21 days of induction depending on the cell line. Sr²⁺ induced an increase of the expression of almost all the genes analyzed (table 1).

Conclusions:

Our preliminary results confirm that SrCl₂·6H₂O promotes the production of early markers of differentiation as ALP at higher concentrations (50-100 μ g/ml) and the formation of bone matrix at lower concentrations (0.5-1 μ g/ml). These data show that Sr²⁺ ion can play a role in the increase of AMSCs osteogenic differentiation, promoting the formation of bone tissue from AMSCs with good perspectives for next applications in the field of cell therapy.

p53 is Required for TNF α to Inhibit Osteoblast Proliferation and Differentiation. Nicole Fleming¹, Decorian Williams¹, Christine Eischen¹, Charles Lumpkin², Daniel Perrien³. ¹Vanderbilt University, USA, ²University of Arkansas for Medical Sciences, USA, ³Vanderbilt University Medical Center, USA

Tumor Necrosis Factor alpha (TNF α) is a well documented inhibitor of osteoblast differentiation and proliferation. Preclinical models have demonstrated that overexpression of TNF α is a common mechanism of delayed bone repair in a number of comorbid conditions including diabetes, aging, and alcohol abuse making TNF α signaling an attractive target to prevent nonunions in challenging populations. We have recently described that p21 is required for TNF α to inhibit bone regeneration in vivo. This finding led to the hypothesis that p53, an immediate upstream regulator of p21 activity, is required for TNF α to inhibit osteoblast differentiation and proliferation. To test whether TNF α requires p53 to inhibit Ob differentiation, murine embryonic fibroblasts were harvested from wildtype or p53^{-/-} embryos at E12.5. Osteoblast differentiation was induced by ascorbic acid and cells were maintained for 14 days in the presence or absence of 4 ng/ml TNF α . Differentiation was measured by alkaline phosphatase staining and calculation of the percentage of AP⁺ colonies per well. The effects of TNF α on osteoblast proliferation in WT and p53^{-/-} calvarial osteoblasts were measured by BrdU incorporation in cells incubated in osteogenic media alone or containing 0.5 ng/ml - 8 ng/ml TNF α . In wildtype MEF's, TNF α significantly reduced the %AP⁺ colonies (Con = 30.4% +/- 17.3% vs 0% in TNF; p<0.0001) and significantly reduced BrdU incorporation at all doses tested (p<0.01 vs control media at all doses of TNF α). In contrast, neither the differentiation nor proliferation of p53^{-/-} cells was significantly affected by TNF α at any dose. These results demonstrate that p53 mediates the inhibitory effects of TNF α on osteoblastic differentiation of MEFs and proliferation of calvarial osteoblasts. This role of p53 in the TNF α signaling pathway in osteoblasts suggests that additional upstream effectors of p53 may be useful targets to enhance bone repair.

Thyroid Hormone Antagonist NH3 Inhibits Osteoblast Differentiation in Human Calvaria Periosteal Mesenchymal Stem Cell. Cristiane Costa^{*1}, Roberto Fanganiello², Thomas Scanlan³, Maria Rita Passos-Bueno², Cecilia Gouveia⁴. ¹Institute of Biomedical Science, Brazil, ²Institute of Biosciences, University of Sao Paulo, Brazil, ³Oregon Health & Science University, USA, ⁴University of Sao Paulo, Institute of Biomedical Sciences, Brazil

Thyroid Hormone (T3) exerts a variety of effects on bone development, growth and metabolism. It has been shown that T3 inhibits osteoblastic proliferation and stimulates osteoblast differentiation in animal cell cultures. These actions results from T3 interaction with its nuclear receptors (TRs). NH3 is a recently developed T3 antagonist that binds TRs and impairs T3-TR interaction. A previous study showed that NH3 has TR antagonist properties on T3-responsive parameters. The aim of this study was to evaluate the effect of T3 and NH3 in the formation of mineralized nodules (analysed by absorbance) and on the mRNA expression of RUNX2 (by real-time PCR) to evaluate osteoblast differentiation. Cells were maintained in osteoblast differentiation media in the presence of T3 (10⁻⁸M), NH3 (10⁻⁸M), T3+NH3 (10⁻⁸M for both) or left untreated (control cells) for 21 days. T3 stimulated mineralized nodules formation (2.3-fold versus control, p<0.05) and NH3 blocked this T3 effect. Accordingly, T3 induced RUNX2 mRNA expression in these cells (3-fold versus control, p<0.05), while NH3 blocked this effect and tended to decrease RUNX2 mRNA expression. These results show that T3 induces the differentiation of human calvaria periosteal mesenchymal stem cells to osteoblasts and that NH3 blocks this effect. Our findings suggest that NH3 could be used as a pharmacological tool to study the involvement of thyroid hormone on osteoblast differentiation in diseases where this process is accelerated, such as craniosynostosis.

Disclosures: Cristiane Costa, None.

Human And Mouse Osteoclastogenesis Are Inhibited By Cysteine Proteinase Inhibitors Through Interference With Rank Signaling. Fredrik Stralberg^{*1}, Petra Henning², Inger Gjertsson³, Pedro Souza⁴, Magnus Abrahamson⁵, Franciszek Kasprzykowski⁶, Anders Grubb⁷, Ulf Lerner⁸. ¹Molecular Periodontology, Umea University, Sweden, ²CENTRE FOR BONE & ARTHRITIS RESEARCH, Sweden, ³Department of Rheumatology & Inflammation Research, Goteborg University, Sweden, ⁴Department of Physiology & Pathology, Sao Paulo State University, Brazil, ⁵Laboratory Medicine, Division of Clinical Chemistry & Pharmacology, Lund University, Sweden, ⁶Department of Organic Chemistry, University of Gdansk, Poland, ⁷Clinical Chemistry & Pharmacology, Sweden, ⁸University of Umea, Sweden

We have previously reported that the cysteine proteinase inhibitor cystatin C inhibits osteoclast formation in both crude bone marrow and spleen cell cultures. In the present study, we show that osteoclast progenitor cells are the target cells for cystatin C. Cystatin C (EC₅₀ 0.3µM) inhibited the formation of TRAP⁺MuOCL in purified mouse bone marrow macrophage (BMM) cultures stimulated by M-CSF and RANKL. This effect was associated with decreased mRNA expression of osteoclast-specific genes such as *Acp5*, *Calcr*, *Ctsk*, *Mmp-9*, *Itgb3*, *Atp6i*, and total TRAP activity. Cystatin C did not affect proliferation or apoptosis. The effect of cystatin C on osteoclast formation and gene expression was concentration dependent with half maximal inhibition at 0.3µM. Cystatin C also inhibited osteoclast formation, resorption pits, and release of CTX when BMMs were cultured on bone slices. BMMs stimulated by RANKL and cystatin C retained macrophagic characteristics as assessed by phagocytosis of FITC-labelled zymosanA particles, and increased expression of the macrophage transcription factor *Irf-8*. Three other cysteine proteinase inhibitors, cystatin D, Z-RLVG-CHN₂, and E-64, also inhibited osteoclast differentiation of RANKL stimulated BMMs and formation of osteoclasts; however, the MMP inhibitor TIMP-1 was without effect. Cystatin C, Z-RLVG-CHN₂, and E-64 also inhibited osteoclast formation when RANKL stimulated human CD14⁺ monocytes were cultured on plastic or bone. The effect on BMM differentiation by cystatin C was exerted at an early stage (1-3h) after RANKL stimulation and was associated with decreased RNA and protein expression of c-Fos and NFATc1 and downregulated mRNA expression of *JunB* and *Fra-2*. Furthermore, cystatin C also decreased NFkB activation as assessed by decreasing RANKL induced expression of *p52*, *RelB*, and *Ikb α* mRNA. Cystatin C also gradually decreased *Tnfrsf1a* (*Rank*) mRNA and RANK protein without any effect on *Csflr* (*c-Fms*) mRNA expression. However, inhibition of osteoclast formation by cystatin C was also observed in lentivirus transfected BMM overexpressing RANK. Together, these data show that cystatin C inhibits osteoclast differentiation and formation by interfering intracellularly with signaling pathways downstream RANK, most likely through inhibition of intracellular cysteine proteinases of importance for osteoclast formation.

Disclosures: Fredrik Stralberg, None.

MO0272

Lyn and other Src-family Tyrosine Kinases cannot rescue the cytoskeletal phenotype of Src-/- Osteoclasts. Takuma Matsubara^{*1}, Lynn Neff², William Horne², Roland Baron³. ¹Oral Medicine, Infection & Immunity Harvard School of Dental Medicine, USA, ²Harvard School of Dental Medicine, USA, ³Harvard School of Medicine & of Dental Medicine, USA

c-Src is ubiquitously expressed, but germline deletion effects are predominantly restricted to osteoclasts (OCs), disrupting their cytoskeletal organization and reducing bone resorbing activity, leading to osteopetrosis. In contrast, while OCs express several Src family kinases (SFKs), single KO of other SFKs in mice does not alter OCs cytoskeleton and function. Thus, other SFKs do not compensate for the loss of Src, suggesting that Src performs a critical function not only unique among SFKs but also essentially restricted to OCs.

Although we have previously shown that both the kinase domain and the SH2 and SH3 domains of Src are required to rescue the OC phenotype, the specific feature(s) of one or more of these domains that makes Src unique has not been identified. The aim of this study is to identify this unique function of Src in OCs and the domain in which it resides. To approach this question, we measured the expression of SFKs in wild type (WT) and Src-/- OCs by rtPCR. In WT OCs, expression of Src and Lyn was similarly high. Fyn and Hck expression were respectively 1/3 and 1/10 of Src. Expression of other SFKs was very low. In Src-/- OCs, Fyn expression decreased by ~80%, Hck expression increased ~7-fold, approaching the level of Src in WT OCs, and Lyn expression further increased ~5-fold. Since both Hck and Lyn are highly expressed in Src-/- OCs, these results suggest that neither Hck nor Lyn can compensate for Src deletion. To confirm this and further investigate the roles of SFKs in OCs, we tested the ability of constitutively active forms (mutated C-terminal tyrosine) of each SFK to rescue the ability to form a podosome belt (actin ring) at the cell periphery of Src-/- OCs in vitro, first verifying that expression of Src in Src-/- OCs restored the belt. Like Src, Fyn, which is 75% homologous to Src, rescued belt formation, while Hck, Fgr or Blk only partially rescued and Lyn had no effect on belt formation. These results suggest that Fyn fails to compensate for Src's absence mostly due to its low expression in Src-/- OCLs, but that differences in the binding properties of the SH2 and SH3 domains of Src, on the one hand, and Hck, Blk, Fgr and particularly Lyn on the other, account for the failure of these SFKs to compensate for Src's absence. Thus, the unique function of Src in OCs is due to specific motifs in Src that are not found in Lyn. Domain swapping between these two SFKs should allow identification of this unique feature(s) of Src.

Disclosures: Takuma Matsubara, None.

MO0273

The activity of Dock5, an Osteoclast Specific Activator of the GTPase Rac, is Necessary for the Endochondral Ossification of Mouse Bones. Heiani Touaitahuata¹, Gaelle Cres², Anne Blangy^{*1}. ¹CNRS UMR 5237 CRBM, France, ²Centre De Recherche De Biochimie Macromoléculaire, France

During embryogenesis and after birth, endochondral ossification is the process by which the cartilaginous model of long bones is progressively replaced by bone. The cartilaginous bone primordial contains chondrocytes that are less mature at the end of the bone and more mature when looking toward the middle of the bone. These mature hypertrophic chondrocytes are characteristic of the hypertrophic cartilage that will be progressively mineralized and replaced by bone. Mineralization of the bone requires cartilage matrix remodeling in which osteoclasts are essential players.

We reported previously that osteoclasts lacking Dock5, an activator of the GTPase Rac, are defective for bone resorption due to abnormal podosome organization and absence of sealing zone formation. As a consequence, Dock5-/- adult mice have increased bone mass (Vives et al, JBMR, in press). Dock5-/- osteoclasts express all characteristic differentiation markers in culture and Dock5-/- mice have normal number of osteoclasts. We used Dock5-/- mice to further investigate how the lack of sealing zone in osteoclasts could impact the development of bones. For this we performed histomorphometry on long bones of embryonic and newborn mice. We found no obvious difference in the formation of the cartilage model of bones between Dock5-/- and Dock5+/+ embryos. But interestingly, whole embryo staining indicated a marked reduction of mineralization in Dock5-/- embryos visible from E17.5. Further histomorphometry indicated that the lack of Dock5 leads to a dramatically elongation of the hypertrophic cartilage zone in all long bones. Dock5-/- embryos retained more cartilage and showed reduced mineralization in the central part of the bone corresponding to the primary center of ossification.

These observations show that Dock5 is essential during embryonic development to ensure efficient endochondral ossification of long bones. They further suggest that during ossification, osteoclasts are not only a source of metalloproteases to degrade the cartilaginous bone primordial. The proper organization of osteoclast adhesion structures, which is essential for mineralized bone resorption, also appears as an important determinant of cartilage resorption to ensure efficient ossification of long bones.

MO0274

Cytokine Release and Osteoclast Formation from Peripheral Blood Mononuclear Cells from Patients With Chronic Periodontitis. Bruno Herrera^{*1}, Alliny Souza Bastos¹, Leila Santana Coimbra¹, Simone Aparecida Teixeira², Marcelo Nicolas Muscara², Luis Carlos Spolidorio¹. ¹Department of Physiology & Pathology, Araraquara Dental School, UNESP, Brazil, ²Department of Pharmacology, Institute of Biomedical Sciences, USP, Brazil

Introduction: Periodontitis (P), a chronic inflammation of periodontal tissues, leads to unwanted alveolar bone loss in response to inflammatory cytokines, which reflects an increased osteoclast (OCs) formation and activity.

Objectives: To investigate whether mononuclear leukocytes from peripheral blood (PBMCs) collected from patients with chronic periodontitis (CP) differ from those from periodontally healthy patients (control group) in terms of their capacity to express pro/anti-inflammatory cytokines and chemokines under lipopolysaccharide (LPS, E. coli) stimulation and their ability to form OCs and resorpt bone.

Methods: PBMC were isolated in both male patients with CP (n=10; according to American Academy of Periodontology) and without CP (n=9; control) by Ficoll density gradient and, stimulated or not with LPS for 20h. The supernatants were collected and the pool was analyzed for protein cytokines with an array panel (52 cytokines). For OC culture, cells were isolated from PBMC with CD14-labeled magnetic bead and cultured in the presence of RANKL alone or with MCSF and counted 14 days later following TRAP staining for differentiation, and after 21 days on osteologic plate for activity; cells with three or more nuclei were considered OCs and data are presented as the proportion of the culture dish area covered by OCs.

Results: Supernatants from non-stimulated MCs from the CP group expressed interleukin (IL)-1 α , IL-1 β , interferon (IFN) γ -induced protein (CXCL10) and macrophage inflammatory protein (MIP)-1 β , and higher levels (~5-fold) of IFN- γ , IL-1 α , monocyte chemoattractant protein (MCP)-1 when compared with controls. In the presence of LPS, MCs from both groups released more cytokines, but only the CP group showed tumor necrosis factor (TNF)- α and higher levels (~2.4-fold) of IFN- γ , IL-1 α , -1 β , -1 γ , CXCL10, macrophage migration inhibitory factor (MIF), MIP-1 α , and -1 β . There were no differences in OC formation and activity when stimulated with RANKL and MCSF (CP: 39.46.2% vs. control: 37.211.1%), but PBMC's CP patients resulted in a higher number of OCs in the presence of RANKL alone (28.49.2% vs. control: 3.22.1%, p<0.05) and increased resorption pit counts (to a degree comparable with increased OC growth).

Conclusion: PBMCs from patients with CP are more responsive to LPS and do not need M-CSF priming to become OC-like cells, thus suggesting that the presence of periodontitis can increase the reactivity of circulating human mononuclear cells.

IL-17A and IL-17F, but not IL-17B-E, Stimulate Bone Resorption in Mouse Calvarial Bones by Enhancing RANKL. Pedro P. C. Souza^{*1}, Catharina Lindholm², Howard Conaway³, Ulf Lerner⁴. ¹Sao Paulo State University, Brazil, ²Center for Bone Research, Sweden, ³University of Arkansas for Medical Sciences, USA, ⁴University of Umea, Sweden

Th17 cells have been implicated in inflammation induced bone resorption. In the present study, we have used mouse calvarial osteoblasts and bones to determine which IL-17 peptides in the IL-17 family increase RANKL and stimulate bone breakdown. IL-17A time- and concentration-dependently enhanced release of ⁴⁵Ca and the collagen degradation fragment CTX from calvarial bones, effects inhibited by the bisphosphonate zoledronic acid. IL-17A also enhanced mRNA expression of TRAP and cathepsin K, and the number of multinucleated cathepsin K⁺ osteoclasts in the calvarial bones. The stimulatory effect on ⁴⁵Ca release was seen after culturing bones with IL-17A and IL-17F, but not after culture with IL-17B, IL-17C, IL-17D, or IL-17E. IL-17A and IL-17F, but not IL-17B-E, enhanced *rankl* mRNA and RANKL protein in calvarial bones. IL-17A and F slightly increased *opg* mRNA, but decreased OPG protein in the calvarial bones. The stimulatory effect of IL-17A on ⁴⁵Ca release was inhibited by exogenous recombinant OPG. Calvarial osteoblasts expressed *il-17a*, *il-17c*, and *il-17e* receptor mRNA. IL-17A and IL-17F, but not IL-17B-E, enhanced *rankl* mRNA, but had no effect on *opg* mRNA in calvarial osteoblasts. In the calvarial bones, IL-17A and IL-17F, but not IL-17B-E, increased the mRNA expression of *cox-2* and *il-1b*, but had no effect on *il-6* or *tnf- α* mRNA. In calvarial osteoblasts, IL-17A and IL-17F, but not IL-17B-E, enhanced *il-6* mRNA and slightly increased *cox-2* and *tnf- α* mRNA expression without affecting *il-1b* mRNA. IL-1 receptor antagonistic protein and indomethacin strongly inhibited the stimulatory effect of IL-17A on *rankl* mRNA expression in calvarial bones. These data suggest that IL-17A and IL-17F stimulate bone resorption by increasing RANKL, a response mediated by IL-1b and prostaglandins.

MO0276

Osteoprotegerin Prevents Infection-induced Bone Loss. Yasunari Takada*, Koichi Matsuo. School of Medicine, Keio University, Japan

We reported previously that RANKL is reduced and osteoprotegerin (OPG) is increased in the peripheral blood of mice injected with bacterial lipopolysaccharide (LPS). These activities cannot be attributed to osteoblasts because expression of RANKL and OPG is induced and reduced, respectively, in osteoblasts stimulated with LPS. In this study, we focused on the mechanism and biological significance of OPG production in response to infection. Peripheral blood OPG levels were elevated in mice infected with microorganisms such as *Salmonella*, *Staphylococcus*, *Mycobacterium* and influenza virus. Moreover, injection of mice with LPS induced OPG production specifically in lymph nodes, especially in high endothelial venule cells, but not in other organs. OPG production was suppressed in c-Fos-deficient mice and enhanced in Fra-1 transgenic mice, indicating that OPG production is regulated by AP-1 transcription factors. Loss of OPG in mice did not affect either their survival or *Salmonella* proliferation in spleen and liver after infection with virulent strains of *Salmonella*. Interestingly, however, when wild-type mice were infected with an avirulent *Salmonella* strain, which can induce OPG, osteoclast development was suppressed and bone mineral density was increased. These data reveal for the first time that lymph nodes protect bones from infection-induced bone loss through OPG production.

TGF- β Represses S1P Production in Osteoclasts to Reduce Osteoblast Recruitment. Kuniaki Ota*¹, Patrick Quint², Moustapha Kassem³, Jennifer Westendorf¹, Sundeeep Khosla⁴, Merry Jo Oursler¹. ¹Mayo Clinic, USA, ²Mayo Clinic Rochester, USA, ³Odense University Hospital, Denmark, ⁴College of Medicine, Mayo Clinic, USA

In young adults new bone formation nearly precisely replaces bone resorbed by osteoclasts, coupling bone resorption to formation. Recent studies have begun to elucidate osteoclast and matrix-derived factors that recruit osteoblast lineage cells and promote mineralization. Transforming growth factor- β (TGF- β) released from the bone matrix by osteoclasts is involved in recruitment of osteoblast lineage cells and the coupling of bone resorption to bone formation. With aging and following menopause, the rate of bone resorption increases. Coupling of resorption to formation breaks down during aging, as bone formation no longer replaces all of the resorbed bone, leading to decreased bone with aging. Although the rate of bone formation increases along with resorption, it is unable to keep pace with bone loss. The reasons for this uncoupling remain unresolved. Because increased bone resorption leads to locally elevated release and activation of TGF- β , TGF- β may be involved in the increase in bone formation observed with aging. In this study we investigated whether TGF- β also regulates osteoclast coupling factor production. We have shown that osteoclasts secrete the chemokine Sphingosine 1 Phosphate (S1P) to promote osteoblast recruitment and differentiation, coupling bone resorption to subsequent bone formation. We utilized an *in vitro* model in which marrow-derived osteoclast conditioned media promotes migration and mineralization of hMSC-TERT mesenchymal cells. TGF- β had no influence on hMSC-TERT cell migration or mineralization whereas conditioned media from TGF- β treated osteoclasts reduced osteoblast migration and mineralization. Sphingosine 1 Kinase (SPHK1) and SPHK2 produce S1P in osteoclasts. TGF- β treatment suppressed SPHK1 and SPHK2 mRNA and protein expression. Mass spectrometry measurements confirm reduced S1P levels in the conditioned medium from TGF- β treated osteoclasts.

We conclude from these data that the elevated TGF- β resulting from increased resorption in aging bone suppresses coupling factor production by osteoclasts, mitigating direct TGF- β recruitment of osteoblast lineage cells. Thus, the elevated bone formation and the breakdown of coupling of resorption to formation may both be due to elevated TGF- β levels.

TNF- α Induces RANKL Expression in Gingival Epithelium through PKA Signaling. Michihiko Usui*, Ryoichi Fujihara, Akiko Yano, Akihiro Saito, Matsuo Yamamoto. Showa University School of Dentistry, Japan

Periodontitis is an inflammatory disorder of the supporting tissue of teeth, which is composed of the gingival soft tissue, the cementum covering the tooth root, the alveolar bone, and the periodontal ligament. Recent clinical studies indicate that levels of RANKL in gingival crevicular fluid are increased, while OPG level is decreased in periodontitis. Although gingival sulcus is composed of gingival tissue, RANKL expression in gingival epithelial cells (GECs) has not been fully understood.

To investigate the expression of RANKL in GECs, we examined Ca9-22 cells (human cell line), Ho-1-u-1 cells (mouse cell line) and human primary GECs. RT-PCR analysis showed RANKL mRNA was expressed by these GECs. To confirm protein levels of RANKL expression, we performed western blotting analysis using these GECs. Similar to mRNA expression, protein expression of RANKL was also detected in them. To examine RANKL expression *in vivo*, we did immunostaining of gingival epithelium

of mouse. RANKL protein expression can be seen in periodontal ligament cells and osteoblasts as reported previously. Intriguingly, RANKL positive cells exist in junctional epithelium, sulcular epithelium and oral gingival epithelium of gingival. Which factors regulate RANKL expression in GECs? TNF- α , pro-inflammatory cytokine has been reported to increase RANKL expression in periodontal ligament cells. Furthermore, TNF- α is known to be expressed in junctional epithelial cells. To examine the effect of TNF- α on RANKL expression in GECs, we treated GECs with TNF- α . Similar to periodontal ligament cells, TNF- α increases the levels of RANKL mRNA and protein expression. To investigate mechanism TNF- α induces RANKL expression, we examined the effect of both H89 and PKI (PKA inhibitors) of TNF- α -induced RANKL expression in GECs. H89 and PKI inhibit RANKL expression activated by TNF- α approximately 60%. These data indicated that TNF- α induced RANKL expression is mediated partially via PKA signaling. Finally, we performed *in vitro* osteoclast formation assays using bone marrow-derived murine osteoclast (OC) precursors to determine if GECs can directly promote differentiation of OC precursors to mature OCs. Although GECs without TNF- α in co-culture system also can very few OCs, TNF- α treatment strongly induces OC formation. These observations suggest that TNF- α induces RANKL expression in GECs, which may play a role of osteoclastogenesis in progression of alveolar bone destruction by periodontitis.

***In Vivo* Migration of Osteoclast Progenitors to the Bone Marrow and Peripheral Tissues in a Competitive Reconstitution Mouse Model.** Christian Jacome*, Sun-Kyeong Lee, Joseph Lorenzo, Hector Aguila. University of Connecticut Health Center, USA

It has been proposed that bone marrow contains a population of osteoclast progenitors (OCP) that circulate via the bloodstream and repopulate a peripheral pool of macrophages and dendritic cells while still retaining their potential to become osteoclasts (OC). We have characterized and isolated cells with OCP activity from bone marrow and spleen. These cells can differentiate clonally into macrophages, dendritic cells and OC. Using pOBCol3.6-GFP transgenic mice, which express GFP in OC, we studied the *in vivo* migration of OCP. In competitive reconstitution experiments, we transferred OCP (B220-CD3-CD11b^{low}CD115⁺CD117⁺) from the BM of pOBCol3.6 GFP CD45.2 donor mice into lethally irradiated C57BL/6 CD45.1 (WT) recipient mice. Mice were co-transferred with a radio protective source of HSC (Lin-c-Kit+Sca-1+, LKS) from WT mice. Controls included transfer of OCP from the BM of transgenic mice into non-irradiated WT mice and LKS from transgenic mice into irradiated WT recipient mice. Engraftment, assessed by histology and flow cytometry, showed that WT irradiated recipients receiving OCP from transgenic BM of donor mice had engraftment in the BM and spleen (1 and 0.2% of total CD45.2, respectively). In addition, frozen sections of femur showed fluorescent OCLs associated with the endosteal bone surfaces of irradiated but not of non-irradiated mice. We have also transferred splenic OCP (LYM-CD11b+Gr1+CD115+) from transgenic mice into irradiated WT mice and found engraftment of CD45.2 cells in the BM and spleen. Finally, we developed a new OCL labeling system by crossing Cathepsin K-Cre "knock-in" mice with a reporter mouse (LoxP-Rosa-TdTomato FP transgenic mice), which expresses red fluorescent protein (RFP) in cells only after expression of Cre. This system has greater OCL-specific fluorescent protein expression than pOBCol3.6-GFP mice. OCP isolated from the BM of these mice had red fluorescent cells *in vitro* only after stimulation with M-CSF and RANKL. We are currently using this model in transfer experiments. In summary, this work showed that BM-derived OCP transplanted into lethally irradiated mice have the ability to home to the BM and migrate to the spleen after lethal irradiation. These experiments suggest that OCP generated in the BM can circulate to peripheral tissues and become resident in spleen. These findings also demonstrate important new tools to study the development and migration of OCP *in vivo* in normal and pathological conditions.

MO0280

***In Vitro* Osteoclastogenesis is Impaired in Cells from +/R740S Osteopetrotic Mice.** Irina Voronov*¹, Noelle Ochotny¹, Celeste Owen², Morris Manolson³, Jane Aubin⁴. ¹University of Toronto, Canada, ²Centre for Modeling Human Disease, Samuel Lunenfeld Research Institute, Mt Sinai Hospital, Canada, ³University of Toronto, Can, ⁴University of Toronto Faculty of Medicine, Canada

Vacuolar H⁺-ATPase (V-ATPase), the multimeric enzyme at the ruffled border of osteoclasts, is necessary for acidification of the resorption lacunae. V-ATPases consist of 14 subunits, one of which, the "a3" subunit, is highly enriched in osteoclasts. Heterozygous mice with an R740S mutation in "a3" (+/R740S) have defective V-ATPase activity resulting in mild osteopetrosis. Osteoclast number is increased in +/R740S bones; however, *in vitro*, osteoclast number and size are decreased compared to wild type (+/+) cells, and this decrease was not due to increased cell death as demonstrated by TUNEL assay. These results suggest that "a3" is not only important for acidification, but also plays a role in osteoclast differentiation *in vitro*.

Gene expression analysis of +/R740S and +/+ bone marrow-derived osteoclasts showed that mRNA levels of key osteoclast markers (TRAP, cathepsin K, OSCAR,

DC-STAMP, "d2" subunit of V-ATPase, and NFATc1), while not affected at day 4 of culture, were significantly decreased in +/R740S cells at day 6. Immunoblotting confirmed the decrease of "d2", NFATc1, and "a3" protein levels, while the levels of ubiquitous V-ATPase E subunit were not changed. To rescue impaired osteoclastogenesis, bone marrow-derived osteoclasts were co-cultured with neonatal calvarial osteoblasts. A co-culture with +/R740S but not +/+ osteoblasts rescued impaired osteoclastogenesis, as well as gene expression of osteoclast markers measured above.

As gene expression of these key osteoclast markers is under NFATc1 control, its nuclear translocation was assessed by immunofluorescence. In +/R740S osteoclasts, the percent of nuclei per cell with NFATc1 nuclear translocation was decreased compared to +/+ cells suggesting that NFATc1 activation is affected in +/R740S osteoclasts.

A decrease in NFATc1 activation, as well as the ability of calvarial osteoblasts to rescue impaired osteoclastogenesis, points to other known V-ATPase functions such as vesicular traffic. Receptor-mediated endocytosis of transferrin did not visually appear affected in +/R740S cells as determined by immunofluorescence. Future experiments will determine whether the R740S mutation affects vesicular traffic and intracellular pH in osteoclasts. These studies will help to elucidate precise roles of the V-ATPase "a3" subunit in osteoclast maturation and activity.

MO0281

DR3 and TL1A – Effect on Osteoclast Differentiation and Function. Eddie Wang, Anwen Williams, Fraser Collins*, Anja Bloom. Cardiff University, United Kingdom

Death Receptor 3 (DR3) and its only known ligand TNF-like protein 1A (TL1A) are involved in a variety of inflammatory diseases including experimental arthritis where bone pathology was exacerbated (1). The aim of this study was to evaluate the role of DR3 in osteoclast (OC) formation and function *in vitro*.

Bone marrow cells were obtained from the femora of wild-type (WT) and DR3-deficient (DR3^{-/-}) mice (DBA-1). Cells were grown on ivory discs for 10 days in medium containing macrophage colony stimulating factor (M-CSF) and receptor activator for nuclear factor κ B ligand (RANKL). TL1A, OC number and size as well as resorption pit numbers were quantified. Gelatinase activity was observed by zymography.

In order to demonstrate a direct role of DR3 in OCgenesis we compared WT and DR3^{-/-} cultures. WT OC showed a significant increase in resorptive capacity over DR3^{-/-} OC ($p < 0.01$); a greater number of resorption pits/mm² were observed in the WT (9/mm²) compared to a negligible number in the DR3^{-/-} (0.2/mm²). OC numbers per mm² and size were comparable in the WT and DR3^{-/-} cultures. Overall a 30 fold increase ($p = 0.02$) in the number of resorption pits/OC/mm² was observed in WT (0.3 pits/OC/mm²) versus DR3^{-/-} (0.01 pits/OC/mm²). Levels of active MMP 9 were increased in WT cultures compared to DR3^{-/-} cultures.

In order to define the role of TL1A in OC function, add-back experiments were performed. Addition of TL1A to WT cultures lead to a threefold decrease in the number of resorption pits/mm² (3/mm²) compared to WT cultures without TL1A (9/mm²) and a significant decrease ($p = 0.02$) in OC/mm² (from 30/mm² to 24/mm²). TL1A did not affect the number of resorption pits/OC/mm² (0.3 pits/OC/mm²); therefore, did not significantly affect OC resorptive capacity. CCL2, a chemokine that is involved in the recruitment of monocytes and their fusion (2), was reduced in WT+TL1A cultures compared to WT-TL1A cultures. OC parameters were comparable in DR3^{-/-} cultures TL1A.

Conclusion:

Our results show that DR3 has an important regulatory function on OC; it increased OC-driven resorption a function that may be mediated by MMP9. TL1A inhibited OCgenesis, this function may be CCL2 dependent. These results highlight an important potential role for DR3 and TL1A in diseases that affect bone.

Epigenetic Regulation of Osteoclast Differentiation: Possible Involvement of Jmjd3 in the Histone Demethylation of Nfatc1. Jun Hirose*, Tetsuro Yasui², Takumi Matsumoto¹, Hironari Masuda¹, Kozo Nakamura¹, Sakae Tanaka¹. ¹The University of Tokyo, Japan, ²University of Tokyo, Japan

Recent studies have revealed that gene expression is controlled by epigenetic mechanisms such as chromatin histone modifications and DNA methylation, and that the expression of key developmental genes tend to be regulated by the trimethylation and demethylation of histone H3 lysine 4 (H3K4me3) and lysine 27 (H3K27me3). Osteoclast differentiation is tightly controlled by two essential cytokines, macrophage colony-stimulating factor and receptor activator of nuclear factor kappa B ligand (RANKL). However, the role of epigenetic regulation in osteoclast differentiation is poorly understood.

We applied massively parallel sequencing of the chromatin immunoprecipitation products using the Illumina cluster station and 1G Analyzer to investigate the H3K4me3 and H3K27me3 modification patterns around the transcription start site (TSS) of several transcription factors known to be important for osteoclastogenesis, i.e. Mitf, Nfkb1, Nfkb2, Mitf, Fos, and Nfatc1. H3K4me3 was present in both osteoclast precursors and osteoclasts in TSS of all of these transcription factors, except for Mitf. The H3K27me3 marks were present in a relatively broad peak centered on the TSS of Nfatc1, but not of the other transcription factors. Following the treatment with RANKL and subsequent osteoclast differentiation, a marked reduction in the level of H3K27me3 at the Nfatc1 locus was observed. Since the most likely explanation of H3K27me3 demethylation at the Nfatc1 locus is the involvement of H3K27me3 demethylases, we examined the expression of H3K27me3 demethylases during osteoclast differentiation. The expression of Jumonji domain containing-3 (Jmjd3), but not Utx, was time-dependently increased in osteoclast precursors and recruited in the vicinity of the TSS of Nfatc1 after stimulation with RANKL. In addition, gene silencing of the Jmjd3 gene by short hairpin RNA reduced demethylation of H3K27me3 around the TSS of Nfatc1 and markedly suppressed RANKL-induced osteoclastogenesis.

These results suggest that demethylation of H3K27me3 in the vicinity of the TSS of the Nfatc1, regulated by Jmjd3, plays a key role in RANKL-induced osteoclast differentiation.

Evidence that ITAM Related Factors in Synovial Tissue and Vasculature of Active Rheumatoid Arthritis may be Involved in Modulating Local Bone Erosion. Tania Crotti*, Ekram Alias², Kencana Dharmapatri², Helen Weedon³, Andrew Zannettino⁴, Malcolm Smith⁵, David Haynes⁶.

¹University of Adelaide, Australia, ²Discipline of Anatomy & Pathology, University of Adelaide, Australia, ³Rheumatology Unit, Repatriation General Hospital, Flinders University, Australia, ⁴Myeloma Research Laboratory, Centre for Cancer Biology, SA Pathology & Department of Medicine, University of Adelaide, Australia, ⁵Rheumatology Research Unit, Repatriation General Hospital, Flinders University, Australia, ⁶Discipline of Anatomy & Pathology, School of Medical Sciences, Australia

Elevated receptor activator NF kappa B ligand (RANKL) in active rheumatoid arthritis (RA) is associated with increased osteoclast differentiation and resorption activity. RANKL-RANK signaling induces the transcription factor nuclear factor of activated T cells (NFATc1) that is central to osteoclast formation and plays a role in the immune system. The immunoreceptor tyrosine-based activation motif (ITAM) pathway provides osteoclast co-stimulatory signals and regulates proliferation, survival and differentiation of effector immune cells. In the osteoclast, the receptors TREM2 and OSCAR and their respective adaptor proteins, DAP 12 and FcR γ , mediate ITAM signals and induce calcium signaling. NFATc1 induces OSCAR expression and they then interact via a positive feedback loop. We propose that increased expression of ITAM factors in active RA augments osteoclastogenesis and focal bone erosion development. Thus, we examined the expression of osteoclast markers, ITAM related factors and NFATc1 in human synovial tissues by immunohistochemistry. The proportions of positive cells were scored using a semi-quantitative 5-point grading system and the number of NFATc1 positive lymphoid aggregates was scored. The expression of ITAM factors was examined in cytokine stimulated HUVEC cells. Soluble OSCAR was measured by ELISA in RA and OA patient synovial fluids. NFATc1-positive cells were predominantly lymphocytic and found in aggregates with significantly higher positive aggregates in active RA versus normal synovia. The proportion of OSCAR, FcR γ , DAP12 and TREM2 positive cells was significantly higher in active RA tissues compared to the normal synovia. TREM2 and DAP12 staining was associated with synovial macrophages in the synovial lining and within lymphoid aggregates and multinuclear cells of the sub-lining. Of note, TREM2 staining was also associated with endothelial cells. OSCAR expression was mainly associated with macrophage-like cells in the subsynovial tissue. Interestingly, OSCAR was strongly expressed in the microvasculature of RA tissue (9/9) but weakly in OA and normal tissues. This was in contrast to our previous findings, where OPG (the RANKL decoy receptor), was high in microvasculature of normal tissue but weak in RA tissues. Synovial fluids from RA and OA contained 45-147ng/ml sOSCAR. Increased levels of ITAM factors in synovial tissues from RA patients support a role for ITAM factors and NFATc1 induction in the pathophysiology of RA.

MO0284

Functional Study of the RANKL Promoter Regions and the Effect of Hormone and Cytokine Treatments. Guy Yoskovitz*¹, Natalia Garcia-Giral¹, Roberto Guerri¹, Daniel Prieto-Alhambra¹, Patricia Sarrion², Roser Urreiziti², Leonardo Mellibovsky¹, Luis Perez-Edo³, Susana Balcells², Daniel Grinberg², Adolfo Diez-Perez¹, Xavier Nogues¹. ¹URFOA, IMIM, RETICEF, Hospital del Mar, Autonomous University of Barcelona, Spain, ²Genetics Dept, University of Barcelona, CIBERER, IBUB, Barcelona, Spain, ³Hospital Ntra Sra Del Mar, Spain

Aim: The bone remodelling, which determines the bone mineral density and microarchitecture, is in part regulated by the RANK/RANKL/OPG system. An imbalance in their equilibrium affects bone and may result in various pathological states, among them osteoporosis. Receptor Activator of Nuclear Factor kappa-B (RANK) and its interaction with its ligand (RANKL) is one of the main triggers of osteoclast differentiation and survival, hence plays a major role in bone remodelling. In this work we studied the functionality of the RANKL promoter.

Methods: The proximal 2015 bp region of the RANKL promoter was cloned into pUC19 vector and subsequently into pGL3 basic vector. Following, by deleting segments from the 2015 bp promoter a total of 4 structures were designed: P1 (-2015 bp promoter), P2 (-1347 bp), P3 (-1038 bp) and P4 (-330 bp) and transfected into U2OS (Human Osteosarcoma cell line) with renilla vector as control. Luciferase and renilla activities were measured after 24 hours incubation. To achieve an overall view of the promoter functionality, we treated the cells with cytokines, hormones and growth factors (Transforming Growth Factor beta (TGF- β) 10^{-7} M, Vitamin D 10^{-7} M, 17β -Estradiol 10^{-6} M, Dexamethasone 10^{-6} M, Tumor Necrosis Factor alpha (rHTNF α) 100ng/ml, Parathyroid Hormone (PTH) 10^{-7} M and Interleukin-1 (IL-1) 10ng/ml) 6 hours after transfection followed by a 16 hours incubation period.

Results: Analysis of the non-treated promoter structures showed a significantly higher luciferase expression levels for P4 comparing to the other promoters structures ($p < 0.05$) while P1, P2 and P3 presented similar expression levels.

Preliminary results of the treatments applied to the culture showed higher expression levels induced by 17β -Estradiol and PTH, while IL-1, rHTNF α and TGF- β down regulated the reporter gene expression in all structures tested in comparison to the non-treated transfected cells. On the other hand, vitamin D and Dexamethasone seemed to have no effect on any promoter structure.

Conclusions: P1, P2 and P3 structures have inhibitory elements that are able to regulate the basal promoter (P4). Furthermore, this basal promoter harbours cytokines and hormones response elements that regulate the RANKL expression.

Disclosures: Guy Yoskovitz, None.

MO0285

Gamma-Radiation Causes Trabecular Bone Loss Similar to Skeletal Aging and Stimulates Resorptive Activity In Vitro. Joshua Alwood*¹, Akhilesh Kumar¹, Luan Tran¹, Angela Wang¹, Charles Limoli², Ruth Globus¹. ¹NASA Ames Research Center, USA, ²UC Irvine, USA

Occupational exposure to ionizing radiation may pose a risk to long-term skeletal health. Gamma-irradiation at high doses (defined here as ≥ 100 cGy) causes trabecular osteopenia in humans and mice, although the influence of lower doses during subsequent aging is not known. We hypothesize low dose (≤ 10 cGy), total body irradiation accelerates skeletal changes that are characteristic of normal skeletal aging by increasing the number and activity of osteoclasts. To begin to address this, C57BL/6J mice (10wk old, male) were irradiated (IR) (10 or 100cGy 137 Cs, 90cGy/min) or were sham-irradiated (0cGy-controls). Tissues were harvested on the day of IR (basal), 1 or 4 mo. later ($n=8$ /gp). Microcomputed tomography was used to quantify 3D cancellous microarchitecture of proximal tibia metaphyses. To determine *in vitro* effects of IR on osteoclast formation and function, RAW 264.7 cells treated with RANKL (15-100 ng/mL), were irradiated within 48hrs (0, 10, 200cGy), then TRAP+, multinuclear cells counted (d5) and resorption pits quantified (BD Osteologic mineral substrate) (d14). Irradiation did not affect body weights at any dose or time post-IR. In sham-IR control mice, trabecular bone volume/total volume (BV/TV), trabecular number (TbN), and connectivity density (CnD) did not change between 0 and 1mo. post-IR ($p > 0.05$). Cancellous bone subsequently underwent an age-related decline between 1 and 4 mo. in BV/TV (-13%), TbN (-17%) and CnD (-41%) ($p < 0.05$). In 10cGy-IR mice, bone loss did not differ from 0cGy-controls. In 100cGy-IR mice, TbN and CnD declined faster between 0 and 1 mo. post-IR (-20% and -36%, respectively; $p < 0.05$, ANCOVA for slope differences between groups) compared to age-matched controls, and then remained constant between 1 and 4 mo. post-IR. *In vitro*, IR (200cGy) of RAW 264.7 cells caused an increase ($p < 0.05$) in the number of TRAP+ cells (d5) and IR (10 or 200cGy) caused an apparent increase in resorption pit area (d14). In sum, a low dose of gamma-radiation (10cGy) did not induce osteopenia relative to age-matched controls, although a higher dose (100cGy) accelerated trabecular bone loss at a rate comparable to later skeletal aging in 0cGy-IR controls. In conclusion, irradiation above a threshold of 10 cGy appears to accelerate skeletal aging by stimulating resorption of cancellous tissue.

MO0286

Hypoxia-Related Regulation of Osteoclast Formation by Pyruvate Kinase M2. Youngho Kim¹, Lexie Holliday², Edgardo Toro³, SEONG SIK KIM*⁴. ¹South Korea, ²University of Florida College of Dentistry, USA, ³University of Florida, USA, ⁴Pusan National University, USA

Hypoxic stress could enhance osteoclast differentiation. Previous study shows that osteoclastogenesis is associated with expression of increased levels of several glycolytic enzymes and with the expression of PKM2. A small molecule activator of PKM2 (NCGC00185916-01; ref. 1) at a concentration of 1 micromolar increased the number of osteoclasts (tartrate-resistant acid phosphatase expressing multinuclear cells) formed during differentiation of RAW 264.7 cells stimulated by RANKL and mouse marrow osteoclasts stimulated by calcitriol by from 1.5 to 5-fold. In this study, we have investigated (1) Pyruvate Kinase M2 expression during osteoclast formation from RAW264.7 cells with RANKL differentiation under hypoxia (1% O₂), and (2) bone resorption activity of Mouse Bone Marrow Cells with calcitriol differentiation under hypoxia. The expression levels of Pyruvate Kinase M2 (PKM2) increased at 24 hours hypoxia (1% O₂) condition with time-dependent manner, however, PKM2 expression decreased at 48 hours hypoxia. For 48 hours hypoxia induced RAW264.7 cells apoptosis and cell cycle arrest at G0/G1 phase. A small molecule activator of PKM2 under hypoxia enhances osteoclastogenesis of RAW264.7 in response to sRANKL, and mouse marrow in response to calcitriol. A small molecule activator of PKM2 stimulated osteoclastic resorption 2- to 3-fold in assays of lacunar bone resorption under hypoxia than normoxia, without affecting osteoclast viability. These results demonstrate that the small molecule activator may disrupt normal coupling and inhibit bone resorption, however, hypoxia may have a role in regulating coupling of glycolysis to V-ATPase proton pumping activity in bone resorbing osteoclasts. 1. Boxer, M. B., Jiang, J. K., Vander Heiden, M. G., Shen, M., Skoumbourdis, A. P., Southall, N., Veith, H., Leister, W., Austin, C. P., Park, H. W., Ingles, J., Cantley, L. C., Auld, D. S., and Thomas, C. J. (2010) J. Med. Chem. 53, 1048-1055.

MO0287

Identification and Isolation of Transplantable Osteoclast Progenitors from Human Pluripotent Stem Cells. Sierra Root*¹, Hector Aguila. University of Connecticut Health Center, USA

Osteoclasts (OC) are hematopoietic cells that differentiate from monocyte progenitors into bone resorbing cells during bone remodeling. Their development is tightly linked to osteogenesis and restricted to bone marrow microenvironments that support the generation of progenitors and the conditions for their terminal differentiation. In mice we have identified clonal OC progenitors (OCP) that, after injection into preconditioned recipients, engraft and form OC that localize on endosteal surfaces. The evidence of transplantable OCP and the restriction on their development led us to propose that OC could serve as restricted cellular vectors to deliver bioactive molecules to the bone marrow microenvironment. The implementation of this approach to humans is limited by the fact that OCP have not been faithfully characterized making difficult their isolation and testing for engraftment properties. Human pluripotent stem cells can serve as a renewable source for these progenitors, and they can be modified genetically to allow the expression of defined molecules under the control of OC specific promoters. We have developed an efficient method to generate active mature osteoclasts from human embryonic stem cells through the generation of embryoid bodies in the presence of hematopoietic cytokines. Characterization and isolation of candidate progenitors has been done by flow cytometry. Dissection of hematopoietic derivatives expressing CD45 showed cells expressing multiple markers of lymphoid and myeloid progenitors. OCP activity, measured by the *in vitro* formation of TRAP+ multinucleated cells after culturing with MCSF plus RANKL, was contained mostly within a fraction negative for CD14 and CD11b. This population could be further dissected in the context of CD115 and CX3CR1, two markers of transplantable murine monocyte progenitors. CD115 is expressed in around 10% of the cells and about 70% of them co express CX3CR1. Finer dissection is being done using these additional markers. We have also developed transgenic hESCs expressing GFPs, to evaluate derivatives for their ability to engraft in immuno compromised NOG mice expressing the col2.3ATK transgene, that permits the opening of hematopoietic niches after depletion of osteoblasts with gancyclovir treatment. Engraftment will be measured by the presence of GFP positive TRAP positive cells on the endosteal surface of recipient bones, or in pre-established human bone ossicles.

MO0288

Identification of the Promoter Region that Mediates Colony Stimulating Factor 1 Induction of the Jun Dimerization Protein 2 Gene. Gang-Qing Yao*¹, Karl Insogna. Yale University School of Medicine, USA

In addition to its critical role in osteoclastogenesis, Colony Stimulating Factor 1 (CSF1) also regulates mature osteoclast function. Thus, CSF1 stimulates motility, augments the activity of the Na/HCO₃- co-transporter, NBCn1 (and relevant to this

work) induces c-fos gene transcription in mature osteoclasts. As part of a microarray screen designed to identify targets for CSF1's actions in mature osteoclasts, we found that expression of Jun dimerization protein 2 (JDP2) was induced by the cytokine. This finding was confirmed by qPCR using RNA isolated from CSF1 treated osteoclast-like cells. JDP2 is an AP-1 repressor protein. Thus, as is often the case, a ligand (CSF1) induces a stimulatory signal (c-fos, part of the AP-1 complex) and also stimulates the inhibitor (JDP2) so that the agonist signal can be modulated. JDP2 has a critical role in osteoclastogenesis since suppressing its expression blocks osteoclast differentiation. Regulatory elements in the JDP2 gene have not been reported presumably because the 5' UTR of this gene is very GC rich, making cloning extremely difficult. We were able to clone a 3297 bp fragment of the JDP2 gene from -2612 to +682 (relative to the transcription start site). To approximate the locations of CSF1-responsive elements in this fragment, a series of 5'-deletions were generated and fused to a luciferase reporter gene in the pGL3 vector. Basal and CSF1-inducible activity of the deletion constructs were analyzed by transiently expressing them in p-zen cells, a fibroblast cell line overexpressing the CSF1 receptor, c-fms. We found that the JDP2 promoter region from -261 to -52 bp is required for both basal activity and CSF1 transcriptional activation. Several canonical transcription-binding sites are located in this region including AP2, STRE, CREB, GATA-1, MZF1, Ik-2, KLF4/GKLF and an SP1 site. Since it is known that CSF1-induced transcriptional activation of the VEGF gene is Sp1 dependent, we mutated the Sp1 site in the JDP2 promoter. This did not affect basal promoter activity or the ability of CSF1 to induce transcriptional activation. We conclude that CSF1 stimulates JDP2 expression via cis regulatory element(s) located in the sequence from -261 to -52 bp. Since none of the identified cis-elements (except Sp1) located in this region are regulated by CSF1, the control of JDP2 expression by CSF1 appears to involve a novel, as yet uncharacterized, DNA sequence.

M-CSF Induces Osteoclastogenesis Resistance In CD31⁺/Ly6C⁺ Osteoclast Precursors; An Effect Not Occurring In The Presence Of Bone. Teun De Vries¹, Ton Schoenmaker², Pieter J.M. Leenen³, Vincent Everts^{*4}. ¹ACTA, University of Amsterdam & VU University, The Netherlands, ²Dept Periodontology, ACTA, Netherlands, ³Dept. Immunology, Erasmus MC, Netherlands, ⁴ACTA, Vrije Universiteit, The Netherlands

We recently demonstrated that osteoclasts can differentiate from mouse bone marrow precursors of various stages of maturity (J. Leukocyte Biol. 85: 919-927, 2009). Since M-CSF may play a role in priming osteoclast precursors, we assessed how pre-incubation with M-CSF affects osteoclast formation. Successive myeloid developmental stages were isolated from mouse bone marrow. Unfractionated bone marrow, early blasts (CD31hi/Ly-6C-), myeloid blasts (CD31+/Ly-6C+) and monocytes (CD31-/Ly-6Chi) were primed for 1 to 4 days with M-CSF, followed by incubation with M-CSF + RANKL for another 4 days. M-CSF priming for 2 days significantly increased osteoclast formation from early blasts and monocytes and these cells retained their capacity to develop into osteoclasts also when primed for 4 days. Surprisingly, M-CSF primed myeloid blasts, the osteoclast precursor that differentiates fastest into osteoclasts with M-CSF and RANKL, lost this potential over time. Myeloid blasts cultured for 4 days with M-CSF and then 4 days with M-CSF + RANKL remained mononuclear and TRACP-negative and positive for mouse monocyte/macrophage markers Mac-1 and F4/80. Priming of myeloid blasts with M-CSF followed by M-CSF + RANKL did not affect RANK expression, but osteoclast-related mRNA for TRACP, calcitonin receptor and DC-STAMP were down-regulated. A completely different situation occurred when myeloid blasts were cultured on cortical bone slices. Here, priming with M-CSF followed by M-CSF + RANKL resulted in abundant osteoclast formation. Interestingly, osteoclasts formation was also evoked in myeloid blasts grown on plastic next to the bone slices. Thus, bone itself or cells grown on bone may elicit factors that drive osteoclast formation.

Our results imply that early and late stages (early blasts and monocytes, respectively) in myeloid differentiation represent a route of osteoclast differentiation which is not inhibited by M-CSF priming. Cells in the myeloid blast fraction appear to be primed for osteoclast generation, but lose this preference upon M-CSF stimulation, unless they are in the vicinity of bone. In vivo, transition of myeloid precursors to an osteoclastogenesis-resistant stage could be functional when travelling away from bone towards organs where no osteoclasts are needed. Possibly, in the vicinity of bone the formation of such osteoclastogenesis-resistant cells is prevented.

PAMM Expression During Osteoclastogenesis Is Mediated by Akt Activation. Li Zhang¹, Liang Ye², Leslie Morse³, Raquel Silva⁴, Yan Xu⁵, Ricardo Battaglini^{*1}. ¹The Forsyth Institute, USA, ²Harvard School of Dental Medicine, USA, ³Harvard Medical School, USA, ⁴School of Dentistry of Ribeirao Preto - University of Sao Paulo, Brazil, ⁵Kunming Medical University, China

Reactive oxygen species (ROS) play a central role in osteoclast differentiation and in skeletal homeostasis. ROS stimulate osteoclast differentiation and function whereas

free radical scavengers and antioxidants have the opposite effect. We identified and characterized PAMM (Peroxiredoxin expressed in M-CSF Activated Monocytes) a protein with peroxidase activity, expressed during osteoclast differentiation. In RAW 264.7 cells, PAMM over-expression prevented the reduction of GSH/GSSG induced by RANKL. Concurrently, PAMM expression completely abolished RANKL-induced osteoclast differentiation. In human Peripheral Blood Mononuclear Cells (PBMC), M-CSF was able to induce PAMM expression, while addition of RANKL resulted in decreased PAMM expression. The purpose of this study was to elucidate the molecular pathway/s mediating expression of PAMM in response to M-CSF and M-CSF/RANKL stimulation. We found that M-CSF induced both, PAMM expression and activation of Akt (by phosphorylation in Ser 473). PI3Kinase activity is required for Akt activation. Wortmannin, a specific PI3Kinase inhibitor, blocked PAMM expression in response to M-CSF. Activated Akt can, in turn, directly phosphorylate mTOR in a rapamycin-sensitive way. Rapamycin could also block M-CSF-induced PAMM expression. Stimulation of PBMC with M-CSF and RANKL, on the other hand, resulted in inhibition of Akt activation and PAMM expression. The addition of Rapamycin enhanced the effect of RANKL on PAMM expression as well as on the formation of TRAP positive osteoclasts. Akt provides a survival signal that protects cells from apoptosis induced by growth factor withdrawal and oxidative stress. This pathway involves the activity of PI3 kinase and is, therefore, wortmannin-sensitive. Our results clearly indicate that M-CSF-induced PAMM expression is mediated by Akt and suggest that RANKL-induced osteoclast formation requires downregulation of PAMM. These observations suggest that PAMM expression could play a dual role in osteoclastogenesis: inhibiting osteoclast differentiation while stimulating proliferation of osteoclast precursors by regulating the levels of intracellular ROS. These findings also point to PAMM as a potential candidate for Akt-mediated protection against oxidative stress.

Potent Inhibitory Effect of Foeniculum Vulgare Miller Extract on Osteoclast Differentiation and Ovariectomy-Induced Bone Loss. Tae-Ho Kim^{*1}, Eui Kyun Park², Hyun-Ju Kim¹, Sang-Han Lee³, Shin-Yoon Kim⁴. ¹Kyungpook National University School of Medicine, South Korea, ²Kyungpook National University School of Dentistry, South Korea, ³Department of Food Science & Biotechnology, Kyungpook National Univ., South Korea, ⁴Kyungpook National University Hospital, South Korea

Inhibition of osteoclast differentiation and bone resorption is considered as an effective therapeutic approach to the treatment of postmenopausal bone loss. To find natural compounds that may osteoclastogenesis, we screened medicinal herb extracts on bone marrow culture system. In this study, we found that aqueous extract of Foeniculum vulgare Miller (FvMs), which has traditionally been used as a treatment for variety of complaints, inhibited osteoclast differentiation and bone resorptive activity of mature osteoclasts at low concentration. We further investigated the effects of FvMs on ovariectomy (OVX) -induced bone loss using micro-computed tomography, biomechanical tests and serum markers assay for bone remodeling. Oral administration of FvMs (30mg or 100mg/kg/day) for 6 weeks had an intermediary effect on prevention of femoral BMD, BMC, and other parameters when compared to OVX controls. In addition, FvMs slightly decreased bone turnover markers that were accelerated by OVX. The bone protective effects of FvMs may be due to suppression of OVX-induced increase in bone turnover. In summary, our findings indicate that Foeniculum vulgare extract has the potential for prevention of bone loss in postmenopausal osteoporosis by reducing both osteoclast differentiation and function.

The Corning® Osteo Assay Surface for Osteoclast Differentiation and Bone Resorption. A Fawad Faruqi^{*}. Corning Life Sciences, USA

Bone related diseases such as osteoporosis, multiple myeloma, and bone metastasis from prostate and breast cancer tumors represent a significant challenge for both research and drug development. In vitro assays that can measure both the formation and function of osteoclasts are critical for furthering our understanding of the biology of normal bone remodeling. Current systems for assaying osteoclast activity using bone or dentine slices are time consuming and difficult to quantify. An inorganic coating has been developed on standard polystyrene multi-well plates by Corning® that can be used for the study of bone cell biology.

The Corning Osteo Assay Surface has been evaluated for osteoclast differentiation and bone resorption. We have compared the surface to dentine discs using cultures of primary human osteoclast precursors and found that osteoclast differentiation and activity can be assessed rapidly and accurately on the Corning Osteo Assay surface whereas use of dentine discs remains problematic. We have also demonstrated that the surface provides a convenient platform for bone related drug screening. Additionally, the surface provides a useful tool for migration and co-culture studies in combination with Transwell® permeable supports.

In summary, both osteoclast differentiation and activity can be readily measured with Corning Osteo Assay Surface, which provides consistent and reproducible results

in assays using osteoclast precursors and also provides a platform for bone related drug screening.

MO0293

Two RANK TRAF-binding Motifs Play a Pivotal Role in TNF- and IL-1-mediated Osteoclastogenesis via functional crosstalk with the IVVY motif in the RANK Cytoplasmic Domain. Joel Jules*, Zhengqi Shi, Jianzhong Liu, Shi Wei, Xu Feng. University of Alabama at Birmingham, USA

The receptor activator of NF- κ B (RANK) ligand (RANKL) promotes osteoclast formation, survival and function by activating its receptor RANK, which recruits TNFR associated factors (TRAF) via three intracellular motifs (PFQEP369-373: Motif 1; PVQEET559-564: Motif 2 and PVQEQG604-609: Motif 3). RANK also possesses a TRAF-binding motif (IVVY535-538) which plays a vital role in osteoclastogenesis by committing bone marrow macrophages (BMMs) to the osteoclast lineage. Intriguingly, mutation of the IVVY motif exerts no impact on the activation of the TRAF-binding site-mediated signaling pathways (NF- κ B, Akt, ERK, JNK and p38) in BMMs. Moreover, the IVVY motif plays a critical role in the lineage commitment not through activating any of the NF- κ B, Akt, ERK, JNK and p38 pathways. Thus, we hypothesized that the TRAF-binding sites and the IVVY motif are functionally independent. However, when these two distinct types of functional motifs were simultaneously activated in the same cells using two different chimeric receptors in which either TRAF-binding sites or the IVVY motif were mutated, we found, unexpectedly, that concurrent activation of the two chimeric receptors failed to promote osteoclastogenesis. This unexpected finding indicates that the TRAF-binding sites and the IVVY motif in the RANK cytoplasmic domain have to be present in the same RANK molecule to be functional, suggesting that one or more TRAF-binding sites functionally crosstalk with the IVVY motif. To address this possibility, we investigated the involvement of the RANK TRAF-binding motifs in TNF- and IL-1-mediated osteoclastogenesis since we have recently demonstrated that the IVVY motif plays a crucial role in TNF- and IL-1-mediated osteoclastogenesis. Motifs 2 and 3, but not Motif 1, are significantly involved in TNF- and IL-1-mediated osteoclastogenesis. Mutation of both Motif 2 and Motif 3 dramatically blocked osteoclastogenesis. Mechanistically, Motif 2 and Motif 3 play an important role in osteoclastogenesis by activating the expression of four osteoclast genes, which were previously shown to be critically regulated by the IVVY motif, in TNF- and IL-1-mediated osteoclastogenesis. Thus, our data indicate that Motif 2 and Motif 3 play a critical role in osteoclastogenesis via a functional crosstalk with the IVVY motif, and these two TRAF-binding motifs have the potential to serve as novel therapeutic strategies for preventing and treating osteoporosis and inflammatory bone loss.

A Computational Model to Examine Osteocytes' Potential to Regulate Osteoclastic Resorption. Lyndsey Schutte*, Jeffrey Hollinger. Carnegie Mellon University, USA

Medical treatment of osteoporosis and other bone diseases is limited by the lack of understanding of how bones function as a complex system. There is a disconnect between the basic science and the clinic. The purpose of this research is to develop a computational framework for integrating the known information about bone cells and their signaling pathways into one model so that the emergent behavior of bone can be better understood and predicted. As a first step towards this, an agent-based model was built to include trabecular structures, osteocytes and osteoclasts capable of forming resorption pits. The model then examined the potential capabilities of osteocytes to regulate the resorption of bone through a disuse threshold.

Using an agent-based model, the osteocytes were placed in a trabecular structure at a physiological population density, and were given the ability to produce a signaling molecule when the local mechanical stress in the surrounding mineralized matrix increased above a certain threshold. Below this threshold, the bone would be in 'disuse' and could be resorbed. At the locations where the volume of bone decreased, the local stress would increase, potentially rising above the osteocytes' threshold. The signal generated by the osteocytes would then prevent any osteoclast activity wherever the osteoclasts came in contact with it. When the osteoclasts did not receive the signal, they continued resorbing the bone. The simulation would stop when the system reached steady state-either through the whole trabecula being shielded by the osteocytes or by the bone being resorbed.

This model showed that osteocytes were able to control the remodeling of the bone to a minimal required size with just one signaling molecule and one local mechanical threshold. Increasing the population density of the osteocytes decreased the variance of the final volume of bone and significantly reduced the risk of the osteoclasts resorbing through the full thickness of the trabeculae. When bone-lining cells were added in a syncytial manner to the osteocytes, the remodeled edges became smoother and the variance in final trabecular width was also reduced.

Based on these results, it is reasonable to hypothesize that osteocytes are physiologically capable of controlling the spatial locations of bone resorption, potentially with the assistance of bone-lining cells.

MO0295

Effect of Rac GTPase Deletion on Osteoclast Cytoskeletal Organization. Monica Croke*, Wei Zou², Steven Teitelbaum². ¹Washington University School of Medicine, USA, ²Washington University in St. Louis School of Medicine, USA

Osteoclastic bone resorption requires reorganization of the osteoclast (OC) actin cytoskeleton, which we have shown is mediated by Rac, a member of the Rho family of GTPases. Rac is activated by stimulation of the OC surface receptors c-Fms and α v β 3 integrin, leading to cellular polarization, formation of the actin ring, and resorption of the bone matrix.

To study the effect of Rac GTPases on actin ring organization and bone matrix resorption, we utilized mice lacking Rac1 and 2, the isoforms expressed in the OC and its myeloid precursor. Mice lacking both isoforms (Rac dKO), in combination, develop severe osteopetrosis with bone matrix occupying one-third of the marrow cavity. Marrow cells isolated from the Rac dKO mice differentiate into TRAP-positive OCs when cultured in the presence of M-CSF and RANKL and express OC markers such as c-Src and Cathepsin K at levels comparable to WT. Rac dKO OCs fail to organize their cytoskeleton when generated on bone as manifest by a non-polarized phenotype and complete absence of actin rings. These morphological abnormalities translate into dysfunctional resorption, exemplified by absence of pit formation on bone and diminished release of collagen degradation products into the culture medium. Consistent with in vivo data from the Rac1 or 2 single knockout animals, the in vitro phenotype of Rac dKO OCs is rescued by exogenous expression of either Rac1 or 2.

We have observed a consistent decrease in β 3 integrin protein levels during early osteoclast differentiation in Rac dKO cells despite abundant mRNA. We are investigating the role of Rac in the regulation of β 3 integrin translation, stability, and cellular localization during osteoclastogenesis.

Our studies show that Rac1 and 2, through a complex network of effector proteins, are required for the dynamic process of actin ring formation in the resorptive osteoclast. Additionally, we have identified Rac as a possible mediator of β 3 integrin protein expression in the osteoclast.

Functional Involvement of the Microtubule-Binding Dynein-Dynactin Complex in Osteoclast Formation and Bone Resorption. Pei Ying Ng*, Haotian Feng², Ee Cheng Khor¹, Shiqiao Ye³, Haibo Zhao³, Ming Hao Zheng², Jiakie Xu¹, Nathan Pavlos². ¹The University of Western Australia, Australia, ²University of Western Australia, Australia, ³University of Arkansas for Medical Sciences, USA

Bone resorption by osteoclasts relies on the co-ordinated interplay between acidified carrier vesicles laden with osteolytic enzymes (e.g. Cathepsin K), motor proteins and the underlying cytoskeleton in order to sustain the specialized structural and functional segregation of the ruffled border membrane. Cytoplasmic dynein, a processive mechanochemical motor comprising heavy, intermediate and light chains coupled to the dynactin co-factor complex, powers retrograde motility of diverse cargoes to microtubule minus-ends. Despite its crucial involvement in a wide range of fundamental cellular processes, the contribution of the dynein-dynactin motor complex in osteoclasts remains unknown. Here, using a combination of complementary biochemical and morphological assays, we have dissected the intracellular localization and function of the dynein-dynactin complex in osteoclasts. By subcellular fractionation and immunofluorescence confocal microscopy we demonstrate that the dynein-dynactin complex is highly expressed in mature osteoclasts and is intimately coupled to microtubules, undergoing dramatic reorganization upon the onset of osteoclastic polarization. In bone-resorbing osteoclasts, p150^{Gluc} and CLIP-170, both major constituents of the dynactin and CAP-Gly domain-containing microtubule plus end-associated proteins, exhibit distinct polarization at the osteoclastic resorptive front, thus orientating the ruffled border as the microtubule plus-end domain. Interestingly, disruption of the dynein-dynactin complex via p50/dynactin-over-expression retards the formation and maturation of osteoclasts, owing to a delay in mitotic stasis of mononuclear progenitor cells. Moreover, uncoupling of the dynein-dynactin motor from microtubules coincides with a drastic redistribution of key osteoclastic intracellular organelles, including the Golgi and lysosomes. Finally, we provide evidence that the dynein-dynactin complex is required for the targeted positioning and delivery of Cathepsin K to the ruffled border membrane, and thus constitutes an integral component of the osteoclastic bone resorption machinery. Together, these data unveil an unexpected yet versatile role for the dynein-dynactin motor in osteoclast formation and function.

Oligomerization of the Osteoclastic Chloride Transporter CIC-7 Demonstrated by Bioluminescence Resonance Energy Transfer (BRET). Vicki Jensen*, Morten Karsdal, Kim Henriksen. Nordic Bioscience A/S, Denmark

The lysosomal chloride-proton antiporter CIC-7 plays an important role in acid secretion into the osteoclastic resorption lacunae, through its co-operation with the osteoclastic V-ATPase. Autosomal dominant mutations in CIC-7 lead to osteopetrosis, suggesting that functional CIC-7 is a homodimer, in accordance with other CLC family members; however, evidence proving the interaction for CIC-7 is absent. An important interaction partner of CIC-7 is Ostm1, which is believed to protect CIC-7 against degradation.

In this study, we investigated whether CIC-7 forms homooligomers and whether CIC-7 dimerization is specific using the Bioluminescence Resonance Energy Transfer (BRET) technique, and how this interaction is affected by Ostm1.

Recombinant proteins of CIC-7, CIC-6 and Ostm1 were fused to either green fluorescent protein (GFP) or luciferase (Luc) and co-transfected into HEK293 cells. When in close proximity the Luc-tagged proteins excite the GFP-tagged proteins upon addition of the substrate coelenterazine. The BRET signal is a ratio calculation between GFP and Luc signal. As negative control a BRET cold protein was engineered by tagging CIC-7 recombinant protein with haemagglutinin (HA). The known interaction of CIC-7 with Ostm1 was used as positive control. The expression levels were confirmed by western blotting. The BRET assays were performed in microsome membranes purified from HEK293 cells expressing the recombinant proteins.

Co-transfection of a constant amount of Luc-CIC7 and increasing amounts of GFP-CIC7 produced a dose dependent BRET signal at low levels of GFP-CIC7, while a saturation of the signal was seen at a 1:6 ratio of Luc:GFP and above, indicating specificity of the interaction. The specificity of the CIC-7-CIC-7 interaction was confirmed as no interactions of CIC-7 with fusion proteins of the closely related CIC-6 were observed. When adding different ratios of cold tagged Ostm1 to the CIC-7 homooligomer no effect was seen on the stability of the CIC-7 oligo interaction.

Taken together human CIC-7 was shown to form stable homooligomers independent of Ostm1 interaction. The establishment of CIC-7/CIC-7 BRET assay allows characterization of the CIC-7 oligomerization in the absence of protein crystallization data, and allows mutation studies delineating the interaction surfaces. This technique opens the possibility for studying molecules disrupting the CIC-7 oligomer interaction and thus will aid further molecular characterization of CIC-7.

Osthole Inhibits Osteoclastogenesis through Activation of β -Catenin-OPG Signaling. De-Zhi Tang*¹, Zhou Yang¹, Qi Shi¹, Di Chen², Yong-Jun Wang¹. ¹Spine Research Institute, Shanghai University of Traditional Chinese Medicine, China, ²University of Rochester Medical Center, USA

Osthole, a coumarin-like derivative extracted from Chinese herbs, which has been used as the treatment of bone diseases for thousands of years. It has been shown to stimulate osteoblast differentiation by increasing the expression of Bmp2 in MG-63 cells. Our published paper showed that osthole stimulated osteoblast differentiation and bone formation by activation of β -catenin-Bmp signaling. But there is no evidence to indicate the effect of Osthole on osteoclast formation and bone resorption recently. To figure out the effect of Osthole on osteoclastogenesis and underlying mechanism, we performed this study. Our in-vivo study showed that Osthole at a dose of 5 mg/kg/day increased bone mass in OPG-/- mice by stimulating bone formation, not by inhibiting bone resorption. Osteoclast number was not reduced in OPG-/- mice after the treatment of Osthole. These data suggested that OPG may be the target gene of Osthole to affect osteoclastogenesis. To test this hypothesis, we analyzed the role of Osthole on the OPG gene expression in bone marrow stromal cells. qPCR data showed that Osthole significantly increased the expression of OPG mRNA in a dose-dependent manner, especially at the concentration of 100 μ M. These data indicated that Osthole may inhibit osteoclast formation by stimulating OPG expression. To further identify our hypothesis, bone marrow stromal cells were isolated from OPG-/- mice and its littermates of OPG+/+ mice, induced to form osteoclast by M-CSF and RANKL, and treated with or without Osthole at the concentration of 100 μ M. TRAP staining data showed that Osthole reduced the number of osteoclast dramatically in OPG+/+ mice but its effect was blocked totally in OPG-/- mice, which demonstrated that Osthole inhibited osteoclast formation in an OPG-dependent manner. Since activation of β -catenin signaling promoted the expression of OPG, to determine if Osthole induced OPG expression through β -catenin signaling, the rescue assays were performed. We found that the deletion of the OPG gene did not affect β -catenin expression and the deletion of the β -catenin gene inhibited OPG expression in bone marrow stromal cells, which demonstrated that Osthole stimulated the expression of OPG through activation of β -catenin signaling in bone marrow stromal cells. Taken together, our findings verified that Osthole inhibited osteoclast formation by activation of β -catenin signaling and could be a potential agent to inhibit bone resorption.

Polarized Osteoclasts Put Marks of Tartrate-Resistant Acid Phosphatase on Dentin Slices-A Simple Method for Identifying Polarized Osteoclasts. Nakayama TAKAHIRO*¹, Mizoguchi Toshihide², Uehara Shunsuke², Yamashita Teruhito², Kawahara Ichiro², Kobayashi Yasuhiro², Udagawa Nobuyuki², Takahashi Naoyuki². ¹Matsumoto Dental University, Japan, ²Matsumoto Dental University, Japan

Osteoclasts form ruffled borders and sealing zones toward bone surfaces to resorb bone. Sealing zones are defined as ringed structures of F-actin dots (actin rings). Polarized osteoclasts secrete protons to bone surfaces via vacuolar proton ATPase through ruffled borders. Catabolic enzymes such as tartrate resistant-acid phosphatase (TRAP) and cathepsin K are also secreted to bone surfaces. Here we show a simple method of identifying functional vestiges of polarized osteoclasts. Osteoclasts obtained from cocultures of murine osteoblasts and bone marrow cells were cultured for 48 hr on dentin slices. Cultures were then fixed and stained for TRAP to identify osteoclasts on the slices. Cells were removed from the slices with cotton swabs, and the slices subjected to TRAP and Myer's hematoxylin staining. Small TRAP-positive spots (TRAP-marks) were detected in the resorption pits stained with Myer's hematoxylin. Pitted areas were not always located in the places of osteoclasts, but osteoclasts existed on all TRAP-marks. A time course experiment showed that the number of TRAP-marks was maintained, while the number of resorption pits increased with the culture period. The position of actin rings formed in osteoclasts corresponded to that of TRAP-marks on dentin slices. Immunostaining of dentin slices showed that cathepsin K and vacuolar proton ATPase were colocalized with the TRAP-marks. Treatment of osteoclast cultures with alendronate, a bisphosphonate, suppressed the formation of TRAP-marks and resorption pits. Calcitonin induced the disappearance of both actin rings and TRAP-marks in osteoclast cultures. These results suggest that TRAP-marks are vestiges of polarized osteoclasts.

Protein Kinase C- δ Regulates Osteoclastic Bone Resorption. Ee Cheng Khor*¹, Tamara Abel², Jennifer Tickner², Taksum Cheng², Keiichi Nakayama³, Keiko Nakayama⁴, Nathan Pavlos², Ming Hao Zheng², Jiaye Xu¹. ¹The University of Western Australia, Australia, ²University of Western Australia, Australia, ³Kyushu University, Japan, ⁴Tohoku University Graduate School of Medicine, Japan

The serine threonine kinase family, Protein Kinase C (PKC), consists of 10 isoforms classed into 3 groups: the classical (Phospholipid, DAG and Ca²⁺ dependent) PKC- α , - β I, - β II and - γ ; novel (Phospholipid and DAG dependent) PKC- δ , - ϵ , - η and - ζ ; and atypical (Phospholipid dependent) PKC- λ /I and - ζ . PKCs are involved in many signalling pathways including cell proliferation, differentiation and apoptosis. Previously, PKC- δ deficient mice displayed a defect in embryonic bone formation due to reduced osteoblast differentiation [1]. Here we have identified PKC- δ as a regulator of osteoclastic bone resorption that is independent of osteoblast activity. We showed that PKC- δ deficient mice were osteopetrotic as evident by increased trabecular bone volume and the presence of residual cartilaginous bars within the trabecular bone, characteristic of osteopetrosis. Osteoclasts from PKC- δ null mice have reduced bone resorption activity. The defective bone resorption is also observed in LPS-induced model of osteolysis in which osteoclasts are accumulated on the bone surface but failed to resorb bone in PKC- δ null mice. As a possible compensating mechanism for defective bone resorption, RANKL-induced osteoclastogenesis *in vitro* was enhanced in PKC- δ null mice. In addition, treatment of Rottlerin, an inhibitor PKC- δ was able to block LPS-induced bone resorption *in vivo*. In short, our data show that PKC- δ regulates osteoclastic bone resorption and thus may be a potential therapeutic target.

Versatile Roles of V-ATPase Accessory Subunit Ac45 in Osteoclast Formation and Function. An Qin¹, Taksum Cheng², Ke Rong Dai³, Ming Hao Zheng⁴, Qing Jiang⁵, Nathan Pavlos², Jiaye Xu². ¹Shanghai Jiao Tong University; The University of Western Australia, Australia, ²The University of Western Australia, Australia, ³Shanghai Jiao Tong University, China, ⁴University of Western Australia, Australia, ⁵Nanjing University, China

Vacuolar-type H⁺-ATPases (V-ATPases) are macromolecular proton pumps that acidify intracellular cargos and deliver protons across the plasma membrane of a variety of specialized cells, including bone-resorbing osteoclasts. Extracellular acidification is crucial for osteoclastic bone resorption, a process that initiates the dissolution of mineralized bone matrix. While the importance of V-ATPases in osteoclastic resorptive function is well-defined, whether V-ATPases facilitate

additional aspects of osteoclast function and/or formation remains largely obscure. Here we report that the V-ATPase accessory subunit Ac45 participates in both osteoclast formation and function. Using a siRNA-based approach, we show that targeted suppression of Ac45 impairs intracellular acidification and endocytosis, both are prerequisite for osteoclastic bone resorptive function *in vitro*. Interestingly, we find that knockdown of Ac45 also attenuates osteoclastogenesis owing to a reduced fusion capacity of osteoclastic precursor cells. Finally, in an effort to gain more detailed insights into the functional role of Ac45 in osteoclasts, we attempted to generate osteoclast-specific Ac45 conditional knockout mice using a Cre-LoxP system. Surprisingly, however, insertion of the neomycin cassette in the Ac45-FloxNeo mice resulted in marked disturbances in CNS development and ensuing embryonic lethality thus precluding functional assessment of Ac45 in osteoclasts and peripheral bone tissues. Based on these unexpected findings we propose that, in addition to its canonical function in V-ATPase-mediated acidification, Ac45 plays versatile roles during osteoclast formation and function.

α -tocotrienol Inhibits Osteoclastic Bone Resorption by Suppressing RANKL Expression and Signaling and Bone Resorbing Activity. Hyunil Ha¹, Jong-Ho Lee², Ha-Neui Kim¹, Jung-Wook Kim³, Zang Hee Lee⁴. ¹Seoul National University, South Korea, ²Department of Cell & Developmental Biology, School of Dentistry, Seoul National University, South Korea, ³Department of Pediatric Dentistry, School of Dentistry, Seoul National University, South Korea, ⁴Seoul National University School of Dentistry, South Korea

α -tocotrienol, osteoclasts, bone resorption, RANKL Vitamin E, an essential nutrient with powerful antioxidant activity, is the mixture of two classes of compounds, tocopherols (TPs) and tocotrienols (TTs). Although TTs exhibit better bone protective activity than α -TP, the underlying mechanism is poorly understood. In this study, we investigated whether α -TT and α -TP can modulate osteoclastic bone resorption. We found that α -TT but not α -TP inhibits osteoclastogenesis in coculture of osteoblasts and bone marrow cells induced by either IL-1 or combined treatment with 1 α ,25(OH)₂ vitamin D₃ and prostaglandin E₂. In accordance with this, only α -TT inhibited receptor activator of NF- κ B ligand (RANKL) expression in osteoblasts. In addition, α -TT but not α -TP inhibited RANKL-induced osteoclast differentiation from precursors by suppression of c-Fos expression, possibly through inhibiting ERK and NF- κ B activation. This anti-osteoclastogenic effect was reversed when c-Fos or an active form of NFATc1, a critical downstream of c-Fos during osteoclastogenesis, was overexpressed. Furthermore, only α -TT reduced bone resorbing activity of mature osteoclasts without affecting their survival. Overall, our results demonstrate that α -TT but not α -TP has anti-bone resorptive properties by inhibiting osteoclast differentiation and activation, suggesting that α -TT may have therapeutic value for treating and preventing bone diseases characterized by excessive bone destruction.

Class IA Phosphatidylinositol 3-kinase Regulates Osteoclastic Bone Resorption. Masahiro Shinohara^{*1}, Sakae Tanaka², Hiroshi Takayanagi³. ¹Tokyo Medical & Dental University, Jpn, ²The University of Tokyo, Japan, ³Tokyo Medical & Dental University, Japan

Osteoclasts are multinucleated giant cells which are able to resorb bone because they are polarized and have specialized machinery to attach to and degrade the mineralized matrix. Differentiation of monocyte/macrophage lineage precursor cells into mature osteoclasts is induced by a TNF family cytokine RANKL in the presences of M-CSF, which provides an activatory as well as survival signal to the osteoclast lineage. Osteoclasts secrete protons and matrix-degrading enzymes such as cathepsin K and MMPs through the ruffled border membrane into this space, enabling the efficient decalcification and degradation of bone matrix. Thus, these specialized structures, the sealing zone and ruffled border, are required for the bone resorbing activity of osteoclasts.

Class IA phosphoinositide 3-kinases (PI3Ks) are activated by growth factor receptors and regulate a wide range of cellular processes. In osteoclasts, they are activated downstream of α v β 3 integrin or c-Fms and thought to be involved in the regulation of osteoclastic bone resorbing activity. However, most of the reports are based on *in vitro* studies using PI3K inhibitors, which inhibit all classes of PI3K, and precise role of class IA PI3K in osteoclasts have not been elucidated. Here, we show that the osteoclast-specific deletion of the p85 genes encoding regulatory subunits of class IA PI3K results in a severe osteopetrotic phenotype caused by a defect in osteoclastic bone resorbing activity. We also showed that although class IA PI3K has an important role in M-CSF-induced activation of Rac and Akt, Akt rather than Rac is essential for class IA PI3K-mediated bone resorption. Electron microscopic analysis revealed that class IA PI3K is required for the formation of the ruffled border and vesicle transport, but not the formation of the sealing zone. This study identifies the role of class IA PI3K-Akt pathway regulates osteoclastic bone resorption by regulating the vesicle transport, and may provide attractive therapeutic strategies

against bone diseases such as rheumatoid arthritis and osteoporosis by targeting osteoclast-specific signaling pathway.

Osteopontin Signals through Calcium-NFAT in Osteoclasts: A Novel RGD-dependent Pathway Promoting Cell Survival. Natsuko Tanabe^{*1}, Benjamin D. Wheel², Ryan Shugg², Hong H. Chen², Stephen M. Sims², Harvey Goldberg³, S. Jeffrey Dixon². ¹Nihon University School of Dentistry, Japan, ²The University of Western Ontario, Canada, ³University of Western Ontario, Canada

Osteopontin (OPN), an integrin-binding, phosphorylated, extracellular matrix glycoprotein, enhances osteoclast activity; however, its mechanisms of action are elusive. The calcium-dependent transcription factor NFATc1 is essential for osteoclast differentiation. Activation of NFATc1 involves its dephosphorylation by calcineurin and subsequent translocation from the cytoplasm to the nuclei. The purpose of this study was to determine the effects of OPN on NFATc1 activation and survival of osteoclasts. Native OPN (nOPN, post-translationally modified) from rat bones and rat recombinant OPN (rOPN, prokaryotically expressed without post-translational modifications) were purified to homogeneity using FPLC. Osteoclasts were isolated from the long bones of neonatal rabbits and rats, and plated on coverslips – uncoated or coated with nOPN, rOPN or bovine albumin. NFATc1 activation was assessed by immunofluorescence as the percentage of osteoclasts demonstrating nuclear localization of NFATc1. Apoptosis and survival were quantified following 6 and 18 h incubation, respectively. After 3 h, nuclear localization of NFATc1 was significantly enhanced in osteoclasts plated on nOPN or rOPN, but not albumin. Activity of both nOPN and rOPN indicates that post-translational modifications are not essential for causing translocation of NFATc1. In contrast, rOPN had no significant effect of nuclear localization of NF- κ B, indicating specificity. An RGD-containing, integrin-blocking peptide prevented the translocation of NFATc1 induced by rOPN. Moreover, mutant rOPN lacking RGD failed to induce translocation of NFATc1. Thus, activation of NFATc1 is dependent on integrin binding through RGD. Using fluorescence imaging, rOPN was found to increase the proportion of osteoclasts exhibiting transient elevations in cytosolic calcium (oscillations). rOPN also suppressed apoptosis and enhanced the survival of osteoclasts. The intracellular calcium chelator BAPTA abolished calcium oscillations and inhibited the increases in NFATc1 translocation and survival induced by rOPN. Furthermore, a specific, cell-permeable peptide inhibitor of NFAT activation blocked the effects of rOPN on NFATc1 translocation and osteoclast survival. This is the first demonstration that OPN activates NFATc1 and enhances osteoclast survival through a calcium-NFAT-dependent pathway. Increased NFATc1 activity and enhanced osteoclast survival may account for the stimulatory effects of OPN on osteoclast function *in vivo*.

Poly-ubiquitination of NF- κ B Pathway Mediates Inflammatory Osteolysis. Kannan Karuppaiah, Yousef Abu-Amer^{*}. Washington University in St. Louis School of Medicine, USA

Inflammatory osteolysis is a devastating clinical challenge that undermines skeletal stability. One of the principal causes of inflammatory osteolysis that attends orthopedic implant failure is implant-derived wear debris, in the form of polymethylmethacrylate (PMMA) particles, which activate and recruit macrophages and osteoclasts around and at the implant-host interface. The ensuing bone resorption around the implant leads to loosening and implant failure. Recent work has identified important cellular entities and secreted factors that contribute to inflammatory osteolysis. In previous work, we have shown that PMMA particles contribute to inflammatory osteolysis through stimulation of major pathways in monocytes/macrophages, primarily NF- κ B and MAP kinases. The former pathway requires assembly of large IKK complex encompassing IKK1, IKK2, and IKK γ /NEMO. Interfering with the NF- κ B and MAPK activation pathways, through introduction of inhibitors and decoy molecules, impedes PMMA-induced inflammation and osteolysis in mouse models of experimental calvarial osteolysis and inflammatory arthritis. In this study, we report that PMMA particles activate the upstream transforming growth factor beta activated kinase-1 (TAK1) which is a key regulator of signal transduction cascades leading to activation of NF- κ B and AP-1 factors. More importantly, we found that PMMA particles induce TAK1 binding to NEMO and UBC13. In addition, we show that PMMA particles induce TRAF6 and UBC13 binding to NEMO and that lack of TRAF6 or TAK1 significantly attenuates NEMO ubiquitination. Supporting a key role for this signaling complex as mediator of osteolysis, we identified Lysine 392 residue in NEMO as crucial mediator of PMMA particle-induced inflammatory osteoclastogenesis and osteolysis. Using mice in which NEMO-K392R mutation has been introduced, we provide evidence that PMMA-induced osteoclasts and osteolytic responses are impaired. Furthermore, we show that this impairment is likely due to poor activation of NF- κ B and Erk, but not other MAP kinases. Altogether, our observations suggest that PMMA particles induce ubiquitination of NEMO, an event likely mediated by TRAF6, TAK1 and UBC13. Furthermore, NEMO Lysine392, a well-established K63-linked poly-ubiquitination site, is an important mediator of PMMA-induced osteolysis. Our findings provide

important information for better understanding of the mechanisms underlying PMMA particle-induced inflammatory responses.

RANK Regulates the Osteoclast Cytoskeleton in a c-Src/ α v β 3 Dependent Manner. Takashi Izawa^{*1}, Wei Zou², Steven Teitelbaum². ¹Washington University in St. Louis, USA, ²Washington University in St. Louis School of Medicine, USA

Organization of the osteoclast cytoskeleton depends upon RANKL-induced differentiation characterized by expression of the α v β 3 integrin. This integrin, when occupied, activates a canonical signaling pathway which includes c-Src, Syk, Dap12, SLP-76, the guanine nucleotide exchange factor Vav3 and its target the small GTPase, Rac. In addition to its effects on osteoclast differentiation, however, RANKL, by mechanisms unknown, also directly activates the mature polykaryon to resorb bone by organizing its cytoskeleton. Because c-Src is the most proximal known signaling molecule in the integrin-activated pathway we asked if the tyrosine kinase also mediates RANK-stimulated osteoclast activity. We find transfected c-Src and RANK associate in 293T cells and more importantly, endogenous c-Src and RANK co-precipitate in pre-fusion osteoclasts derived from marrow or spleen. This association, which occurs in lipid rafts, is dependent upon the presence of the α v β 3 suggesting a collaborative relationship between the integrin, kinase and cytokine receptor. We next transfected 293T cells with HA-RANK and various c-Src constructs and found the first myristoylation and SH2, but not SH3, domains of the kinase recognize RANK. The same obtains with endogenous RANK in c-Src-/- pre-osteoclasts retrovirally transduced with the same c-Src constructs and stimulated by RANKL. As expected, WT c-Src rescues the cytoskeleton and resorptive capacity of c-Src-/- osteoclasts and the same obtains regarding Δ SH3. In contrast, absence of the first myristoylation (Δ MYR) or Δ SH2 fail to normalize osteoclast spreading or bone degradation. These events are mirrored by RANKL activation of Syk, SLP76, c-Src itself, Vav3, and Rac. Thus, RANKL-mediated stimulation of osteoclast function is mediated by RANK/c-Src binding via the latter's first myristoylation and SH2 domains in an α v β 3 integrin-dependent manner.

Assessment Of The GPCR Landscape in Osteocytes Reveals Novel Candidate Regulators of Bone Homeostasis. Christine Halleux^{*1}, Frederic Bassilana², Ina Kramer¹, Hansjoerg Keller¹, Frederic Morvan¹, Olivier Leupin¹, Klaus Seuwen¹, Michaela Kneissel¹. ¹Novartis Institutes for Biomedical Research, Switzerland, ²Novartis Institutes for Biomedical Research, Switzerland

Osteocytes emerged in recent years as critical regulators of bone homeostasis. Moreover a rising number of osteocyte endocrine functions are identified such as regulation of mineral homeostasis and putatively lipid and energy metabolism. However the molecular mechanisms underlying these functions are only starting to be revealed. Since G protein coupled receptors (GPCRs) are critical to physiological processes and are targets of about 30% of all medicinal drugs including anti-osteoporotic drugs, we focused here on the elucidation of the GPCR expression profile of these cells. To this end we extracted RNA from GFP+ osteocytes and GFP-osteoblasts from newborn calvaria of *Dmp1-Cre;GFP* mice. Real time PCR was performed using a mouse GPCR array monitoring most (343) non-sensory GPCRs. A number of GPCRs were found to be highly expressed in osteoblasts and -cytes (e.g. *Pthr1*) and 14 were further enriched in osteocytes compared to -blasts. Expression of most was confirmed in RNA extracted from osteocyte enriched human hip cortical bone. Some of the upregulated receptors are associated with bone biology such as cannabinoid receptor 1 (*Cnr1*) or calcitonin receptor-like receptor (*Calcr*). The latter was co-regulated with *Ramp1*, indicating increased expression of functional CGRP receptors in osteocytes. Further examples of receptors, which have been implicated in bone homeostasis or skeletal development are the Wnt signaling mediator frizzled homolog 5 (*Fzd5*), lysophosphatidic acid receptor 1 (*Lpar1*) and endothelin 1 receptor (*Ednra*). Among the orphan GPCRs highly expressed in osteoblasts and further enriched in osteocytes, is *Gpr133*, which has been recently associated with human height. Moreover *Gpr153*, which has not been implicated in bone biology so far, was expressed at comparable levels as *Pthr1*. Immunohistochemistry confirmed protein expression in mouse bone osteocytes. Interestingly, we found this orphan GPCR to be upregulated during osteoblastic differentiation of human mesenchymal stem cells. This translated to the tissue level, as *GPR153* was expressed in human hip cortical bone and immunohistochemistry confirmed protein expression. As we detected no distinct bone mass alterations in the skeleton of *Gpr153* KO mice the role of osteocyte expressed GPR153 remains to be elucidated. In summary the described GPCR expression profile is consistent with critical roles of these cells for bone homeostasis and identifies novel candidate regulators of osteocyte function.

CSF-1 Deficiency in CSF-1KO Mice Leads to Osteocyte Defects. Sherry Abboud Werner^{*1}, Diane Horn², Kathleen Woodruff², Rekha Kar³, Xiaodu Wang⁴, Jean Jiang¹, Marie Harris¹, Stephen Harris¹. ¹University of Texas Health Science Center at San Antonio, USA, ²University of Texas Health Science Center, USA, ³The University of Texas Health Science Center, USA, ⁴University of Texas at San Antonio, USA

CSF-1, a key determinant of osteoclast-mediated bone remodeling, is expressed in osteoblasts/osteocytes and bone matrix. Osteoblasts differentiate into osteocytes that have dendritic processes that enable cell contact with adjacent osteocytes, osteoblasts and preosteoclasts. We have shown that global CSF-1 deficiency in *Meox2Cre-CSF-1KO* mice decreases osteoclasts and results in an osteopetrotic phenotype. However, little is known regarding the effect of CSF-1 on osteoblasts/osteocytes and bone formation. To address this issue, bones from 3 wk CSF-1KO and WT mice were tested for material properties by nanoindentation. Histologic preparations were stained with H&E, CD31, Tunel and examined under polarized light to assess morphology, vascularity, apoptosis and collagen fibrils, respectively. Undecalcified samples were processed for TEM to visualize osteocytes and mineral. Connexin43(Cx43), the major gap junction/hemichannel forming protein in osteocytes, was examined by Western blot and immunostaining and microarray analysis was performed for osteocyte markers. Compared to WT, CSF-1KO bones showed decreased modulus of elasticity and hardness. Osteoblasts in CSF-1KO were disorganized with loss of polarity and showed early entrapment in matrix. The transition of osteoblasts to form osteocytes was impaired in CSF-1KO and abnormal clusters of osteocytes within lacunar spaces were identified. Vascular sinusoids were compromised with narrow lumens. CSF-1KO cortical bone was thin and showed decreased collagen fibrils that lacked lamellar structure with randomly scattered osteocytes. Little apoptosis was identified in WT bone, whereas increased apoptotic osteocytes were detected in CSF-1KO. Osteocyte loss in CSF-1KO was associated with micropetrosis and by TEM osteocytes showed blunted dendrites and resided in patchy mineralized matrix likely due to decreased E11/GP38 and DMP1 expression. Morphologic defects in CSF-1KO osteocytes correlated with decreased Cx43 and altered gene profile by microarray with 10-fold reduction in *Sost*. These findings suggest that CSF-1 is crucial for osteoblast polarity, directional matrix deposition, formation of osteocytes, matrix mineralization and hydration. Loss of osteocyte dendrite contacts in CSF-1KO mice may exacerbate osteoblast and osteoclast defects. Importantly, our data provide a novel link between CSF-1 and osteocyte survival/function that is essential for maintaining bone mass and strength during skeletal development and aging.

Effects of Pioglitazone on Serum Levels of Sclerostin and Bone Turnover Markers in Male Patients with Type 2 Diabetes Mellitus. Antoon Van Lierop^{*1}, Neveen Hamdy¹, Rutger van der Meer², Jacqueline Jonker², Michaela Diamant³, Luuk Rijzewijk³, A de Roos², Johannes Romijn⁴, Jan Smit², Socrates Papapoulos¹. ¹Leiden University Medical Center, The Netherlands, ²Leiden University Medical Center, Netherlands, ³VU University Medical Center, Netherlands, ⁴Amsterdam Medical Center, Netherlands

Introduction

Thiazolidinediones are of proven benefit in the management of patients with type 2 diabetes mellitus (T2DM), but their use has been associated with an increased risk of fractures. This increased fracture risk may be due to activation of the peroxisome proliferator-activated receptor γ (PPAR γ) in mesenchymal stem cells, favouring differentiation into adipocytes rather than into osteoblasts. A recent in vitro study showed that TZDs also stimulate the expression of sclerostin, a negative regulator of bone formation, synthesised by osteocytes, the up-regulation of which could contribute to decreased bone formation and increased fracture risk.

Methods

We measured sclerostin, PINP, and CTX levels in stored samples of 71 male patients with T2DM, collected at baseline and at the end of a 24 weeks double blind randomised controlled study, in which patients received either pioglitazone (PIO) 30 mg once daily, or metformin (MET) 1000mg twice daily. Percentage changes in serum sclerostin, PINP and CTX were compared between the pioglitazone and metformin treated group.

Results

At baseline there was no significant difference in sclerostin levels between patients, randomised to use pioglitazone or metformin (PIO: 58.5 pg/ml, MET: 62.4 pg/ml, $p=0.42$). After 24 weeks of treatment sclerostin levels increased by on average 11% (95%CI:2.3%-19.8%) in PIO-treated patients, and decreased by 1.8% (95%CI:-8.8%-5.0%) in MET-treated patients ($p=0.027$). Intriguingly, serum PINP levels also increased by 3.7% (95%CI:-3.9%-11.3%) in the PIO group, and decreased by 19.1% (95%CI:-25.5%-12.8%) in the MET group ($p<0.001$). CTX increased by 16.8% (95%CI:4.4%-29.1%) in the PIO group, and decreased by 19.0% (95%CI:-27.1%-10.9%) in the MET group ($p<0.001$). Whereas there was no significant relation between changes in serum sclerostin and changes in serum PINP, changes in serum sclerostin did significantly correlated with changes in serum CTX in the whole population studied ($r=0.34$, $p=0.004$), and in the PIO group ($r=0.39$, $p=0.023$), but not in the MET group ($r=0.03$, $p=0.084$).

Conclusion

Our data show a small increase in sclerostin levels after 24 weeks of treatment with pioglitazone. There was however no evident change in PINP levels. The potential contribution of pioglitazone induced increased sclerostin to increased fractures risk remains unclear.

IL-6 Affects Signaling Molecule Production by Osteocytes Resulting in Inhibition of Osteoblast Differentiation. Astrid D Bakker^{*1}, Rishikesh N Kulkarni¹, Willem F Lems², Jenneke Klein-Nulend¹. ¹ACTA - University of Amsterdam & VU University Amsterdam, Research Institute MOVE, Netherlands, ²VU University Medical Center, Research Institute MOVE, Netherlands

During inflammation TNF α reduces bone mass by stimulating osteoclastic bone resorption and inhibiting osteoblastic bone formation, and by modulating the osteocyte response to mechanical loading. IL-6 produced during inflammation also affects bone mass, but conflicting reports exist regarding its' effect on bone resorption, and whether IL-6 affects the function of osteocytes is unknown. We tested whether IL-6 modulates the production of signaling molecules by osteocytes either or not subjected to mechanical loading, resulting in modulation of osteoblast differentiation or osteoclastogenesis.

MLO-Y4 osteocytes were incubated for 24h with IL-6 (10 pg/ml), sIL-6R (40 ng/ml), or control medium, and subjected to 1h mechanical loading by pulsating fluid flow (PFF; 0.70.3 Pa, 5 Hz). The cellular response was quantified by measuring nitric oxide (NO; Griess) and prostaglandin E2 (PGE2) production (ELISA), and expression of IL-6, TNF α , COX2, Rankl, Opg, and M-CSF (PCR). Osteocyte apoptosis was assessed by Caspase-Glo 3/7 assay. Osteocyte-conditioned medium was added to MC3T3-E1 osteoblasts for 5 days, and ALP activity and expression of Ki67, Runx2, and Osteocalcin were measured as differentiation parameters. Mouse bone marrow cells were cultured for 7 days on TNF α (0.1 ng/ml) or IL-6-treated osteocytes, and multinucleated TRACP+ osteoclasts were counted.

IL-6 increased expression of TNF α (2.2-fold) and IL-6 (3.0-fold) in osteocytes. It enhanced the stimulating effect of PFF on COX-2 expression but did not affect PFF-stimulated NO and PGE2 production. IL-6-treated osteocytes enhanced expression of proliferation marker ki67 (3.8-fold), but reduced Runx2 and Osteocalcin expression and ALP activity by osteoblasts. Interestingly, PFF reversed the negative effect of IL-6-treated osteocytes on Osteocalcin expression by osteoblasts. TNF α , but not IL-6, enhanced osteocyte-stimulated osteoclastogenesis. IL-6 did not affect RANKL or M-CSF expression, but reduced Opg expression and osteocyte apoptosis, resp. stimulating and inhibiting osteoclastogenesis.

In conclusion, IL-6 did not affect signaling molecule production by osteocytes in response to mechanical loading, nor osteocyte-stimulated osteoclastogenesis, which is in sharp contrast to the known actions of TNF α . However, IL-6 triggered osteocytes to produce soluble factors that strongly inhibit osteoblast differentiation, suggesting that IL-6 production during inflammation reduces bone mass by inhibiting bone formation.

Responses of Osteocytes to Microdamage in vitro. Chao Liu^{*1}, Lidan You². ¹University of Toronto, Canada, ²Mechanical & Industrial Engineering, University of Toronto, Canada

Purpose: Physiological loading of the bone creates microdamage, which has been shown to cause damage to osteocytes embedded within the bone [1]. The damaged osteocytes may signal bone remodeling of the damage site. This process may be inflammatory in nature and unlikely to be the same as unloading-induced remodeling, which involves osteocyte apoptosis, since in vivo evidence suggested that mechanical loading is required for the repair of microdamage in bone [2] and inflammatory cytokines such as TNF α were upregulated [3]. We hypothesize that MLO-Y4 cells damaged by physical trauma similar to microdamage would release increased levels of TNF α , and this response can be mechanically regulated.

Methods: MLO-Y4 osteocyte-like cells (gift from Dr. Lynda Bonewald, University of Missouri) were cultured in α -MEM supplemented with 5% FBS, 5% CS, and 1% P/S on type I rat tail collagen-coated glass slides at 37 $^{\circ}$ C and 5% CO₂. An array of 9 equally spaced 20G needles were used to mechanically damage the cells. Apoptosis were induced with serum-starvation. The cells were then incubated at 37 $^{\circ}$ C and 5% CO₂ for 4 time points: 5 minutes, 15 minutes, 30 minutes, and 1 hour. After incubation, total RNA was isolated and Q-PCR was performed to quantify TNF α mRNA level. Student's t-test was used to assess significance ($P < 0.05$).

Results: The TNF α mRNA level in MLO-Y4 cells did not change from baseline values 5 min, 15 min, or 30 min after mechanical damaged. However TNF α mRNA level was reduced by 36% at 1 hr after microdamage. In contrast, serum starvation has reduced TNF α mRNA level in 15 min. (Figure 1.)

Conclusions: This study has shown that mechanical damage to osteocyte decreases TNF α mRNA level, and it is time-dependent. In comparison with mechanical damage induced effects, serum-starved induced apoptotic osteocytes showed an earlier decrease from the cell culture. As opposed to our hypothesis, the decreased TNF α levels suggest that microdamage-initiated remodeling may not be inflammatory in nature. Also, since TNF α suppresses osteogenic differentiation, the decrease in TNF α level may suggest

increased osteogenic differentiation by mesenchymal stem cells. Future work includes investigating how mechanical loading affect osteocyte apoptosis and responses to damage.

Sclerostin Antibody Enhances Bone Repair in a Rat Femoral Defect Model. Farhang Alaei^{*1}, Amy Tang¹, Michael Ominsky², Hua Zhu Ke³, Marina Stolina⁴, Denise Dwyer⁵, Jay Lieberman¹. ¹University of Connecticut Health Center, USA, ²Amgen, Incorporated, USA, ³Amgen, Inc., USA, ⁴Amgen Inc, USA, ⁵Amgen Inc., USA

Systemic sclerostin-neutralizing monoclonal antibody (Scl Ab) has been shown to increase callus density and strength in murine and primate models. We tested Scl Ab in a 3 mm femoral defect in 12 w/o male Sprague Dawley rats to evaluate its potential in bone healing. There were 5 groups, each containing 15 rats. Scl Ab (25 mg/kg/dose twice weekly, sc) or PBS was injected in the following groups: I: Continuous Scl Ab (Scl Ab for 12 weeks), II: D-Scl Ab (Scl Ab for 10 weeks starting 2 weeks post-op), III: Vehicle 6w (PBS for 6 weeks), IV: Scl Ab 6w (Scl Ab for 6 weeks) and V: Vehicle (PBS for 12 weeks). The rats were sacrificed upon completion of the treatment. Serum bone biomarkers were measured and radiographic, μ -CT and histological analyses were performed. Union was observed in 3/15 in D-Scl Ab, 2/15 in Scl Ab, and 1/15 in Vehicle and Scl Ab 6w groups. Osteocalcin, a bone formation marker, was elevated in response to treatment, but levels of PINP (bone formation) and TRACP 5b (bone resorption) were not significantly different compared to vehicle alone. Radiographic scoring of defect healing from 0 to 5 (Fig1A) and μ -CT-based BV/TV of bone in the defect (Fig 1B) only showed significant increases in D-Scl Ab (Score: 3.07 \pm 0.06, BV/TV: 35.0% \pm 4.7) vs. Vehicle (Score: 2.53 \pm 0.13, BV/TV: 21.1% \pm 2.4, $P < 0.05$). Histomorphometric analysis showed no significant differences in defect BV/TV between the treatment vs. Vehicle at 6 or 12 weeks. μ -CT-based BV/TV of the extra-cortical new bone formed outside the defect (Fig1C) showed significantly increased amounts in both Scl Ab (71.0% \pm 1.4) and D-Scl Ab (73.3% \pm 0.8) compared to the Vehicle (61.9% \pm 1.4) ($P < 0.05$). In the contralateral femurs, Scl Ab and D-Scl Ab showed similar increases in distal femur BV/TV, trabecular thickness, and femoral shaft cortical thickness relative to Vehicle (Table 1). Distal femur BV/TV and trabecular thickness in the operated legs were also increased in treatment vs. Vehicle at 6 and 12 weeks (Table 2) ($P < 0.05$). In conclusion we demonstrated that Scl Ab can enhance new bone formation in a defect model. The more uniform response to Scl Ab outside the defect could reflect the lower number or delayed participation of Scl Ab responsive cells in the defect. In contrast a previous 6 mm defect study in Lewis rats demonstrated that continuous Scl Ab improved both radiographic scores and defect BV/TV. This difference in results may be secondary to the use of different rat strains.

age-related differences in mechanosensitivity, their function in diseases such as osteoporosis, and in genetic disease. This novel methodology should prove useful to advance knowledge regarding the role of mature osteocytes in health and disease.

Ultrastructural Evidence for Continued Synthetic Activity in Osteocytes. Ruairidh, I. Watson¹, Eman Azzam¹, Jenny, S. Gregory¹, Miep Helfrich². ¹Musculoskeletal Programme, School of Medicine & Dentistry, University of Aberdeen, United Kingdom, ²University of Aberdeen, United Kingdom

Osteocytes play an important role in the regulation of mineralisation, bone formation, phosphate metabolism, and overall energy metabolism. To do this, they produce and secrete proteins and signalling factors. Paradoxically, while such activities indicate osteocytes are metabolically active cells, they are generally described as "small, with little cytoplasm and few organelles" and "to contain 70% less cytoplasm than osteoblasts". We asked whether the transition from osteoblast to osteocyte is associated with upregulation of autophagy to recycle organelles no longer required. We used high pressure freezing (HPF) of calvarial bones from newborn mice to prepare tissue for ultrastructural examination and studied expression of the autophagy-related proteins LC3 and p62 by immunohistochemistry (IHC) in demineralised wax-embedded sections of newborn mouse and rabbit bone. Ultrastructural analysis of more than 50 cells showed that osteocytes appeared like osteoblasts with abundant rough endoplasmic reticulum (RER), mitochondria and cytoplasm. Cellular features were then measured in randomly selected osteocytes and osteoblasts (n=10 for each) and revealed no statistically significant differences between cell types in cytoplasmic area, area occupied by RER and numbers of mitochondria. Power calculations showed that a minimum of 150 cells would be required to have a chance of detecting a difference for cytoplasmic area or RER and more than 3000 cells to detect a difference in mitochondria. Osteocytes did contain significantly more autophagosomes than osteoblasts (4 vs 2 per cross section; p<0.006), but the variation between individual osteocytes was large (2-11 per cross section) and we are currently repeating this analysis with more cells and multiple layers per cell. IHC showed strong staining for LC3 and p62 in osteoclast and hypertrophic chondrocytes. Staining was also present in osteoblasts, not detected in transition cells and only in individual osteocytes, in keeping with the large variation seen in the autophagosome count in the ultrastructural analysis. In conclusion, osteocytes in calvarial bone in young animals maintain extensive synthetic capacity and the transition from osteoblast to osteocyte is not associated with systematic induction of autophagy. We suggest that osteocyte ultrastructure, including in cortical bone in adult animals, is re-examined in HPF bone and results interpreted alongside the newly discovered information on osteocyte function.

Histochemical Examination on the Distribution of DMP-1, MGP and Osteocalcin in *Klotho*^{-/-} Mice. Muneteru Sasaki¹, Chihiro Tabata¹, Tomoka Hasegawa¹, Minqi Li¹, Tsuneyuki Yamamoto¹, Nobuo Inoue¹, Norio Amizuka². ¹Hokkaido University, Japan, ²Hokkaido University School of Dentistry, Japan

[Introduction]

It is likely that osteocytes and their canaliculi, i.e., osteocytic lacunar canalicular system (OLCS) would play a pivotal role in regulating minerals such as calcium and phosphates in bone. However, *klotho* deficiency has been reported to cause hyperphosphatemia and hypercalcemia, due to disrupted function of kidney. Therefore, it seems of importance to examine the osteocytic functions in the abnormal state of hyperphosphatemia in *klotho*^{-/-} mice. In this study, we have examined the distribution of OLCS and synthesis of dentin matrix protein 1 (DMP1), osteocalcin and matrix gla protein (MGP).

[Materials and Methods]

Six 5 weeks-old *klotho*-deficient male mice and the age-matched wild-type littermates were fixed with paraformaldehyde, and their tibiae were extracted for histochemical and ultrastructural examination. Von Kossa's staining, immunohistochemistry for DMP-1, MGP and osteocalcin, which have an affinity of calcium, and double staining of ALP and TRAP were performed on the tibial paraffin sections of both mice. We employed immuno-gold technique to localize DMP-1 onto the wild-type and *klotho*^{-/-} bone under transmission electron microscope.

[Result and Discussion]

Wild-type mice showed the regularly-arranged OLCS, while the OLCS of *klotho*^{-/-} mice were disorganized. Wild-type metaphyseal trabeculae revealed even mineralization in bone, whereas *klotho*^{-/-} metaphysis demonstrated the unmineralized patchy area despite many ALP-positive osteoblasts covering the bone surface. MGP, which has been reported to inhibit mineralization, was localized at the boundary of cartilage core and surrounding bone matrix of metaphyseal mixed spicules, although the wild-type metaphysis hardly showed immunoreactivity for MGP. Abundant DMP-1 was associated with *klotho*^{-/-} osteocytes, compared with that in the wild-type specimens. Osteocalcin were found in some osteocytic lacunae and cement lines in bone, while the wild-type bone displayed osteocalcin mainly at the bone surface and cement lines.

Figure 1. A) Radiographic score in the gap defect. Data expressed as mean \pm SE (n=15/group). *P<0.05 vs. Vehicle and Sci Ab groups. B) μ -CT-based BV/TV in the gap defect. The Isolation and Culture of Primary Osteocytes from the Long Bones of Skeletally Mature and Aged Mice. Amber Stern¹, Matthew Stern², Mark Van Dyke³, Lynda Bonewald¹. ¹University of Missouri - Kansas City, USA, ²University of Missouri-Kansas City, USA, ³Wake Forest University, USA

Isolation and retrieval of osteocytes from mature, highly mineralized bone matrix has been difficult to achieve, unlike isolation from immature, hypomineralized bone such as chick calvaria or post-natal mice. Therefore, even though osteocytes are the most abundant cell type within adult bone, little is known about their function. While their location makes them ideally situated to sense bone strain, it also makes their observation and study in vivo difficult. The purpose of the work presented here was to adapt previously published osteocyte isolation techniques using immature bone to enable the study of primary osteocytes procured from skeletally mature young (4-month-old) and old (24-month-old) mice. Osteocytes were isolated from the long bones of the mice through a process of extended enzymatic digestions using collagenase (300 units/mL) followed by decalcification using 5 mM EDTA solution. The bone chips were subjected to a total of nine digestions. Following the final digestion, a tissue homogenizer was employed to reduce the remaining bone chips to a suspension of bone particles that were cultured resulting in an outgrowth of osteocyte-like cells. All of the isolated cells in the final digestion that displayed an osteocyte-like morphology (essentially 100%) also stained positive for E11/gp38, confirming the osteocyte phenotype which was further confirmed by negative staining for alkaline phosphatase. In line with previously reported data, the percentage of osteocyte-like cells increased, while the percentage of fibroblast and osteoblast-like cells decreased with each serial digestion. We are currently in the process of characterizing the secondary outgrowths of the bone particles. This technique resulted in an improved osteocyte yield over previously reported methodologies as well as facilitated the study of osteocytes procured from skeletally mature young (4-month-old) and old (24-month-old) mice. With the additional capability of isolating and culturing osteocytes from young and old mice, it is now possible to directly compare osteocytes obtained from not only immature, but also young adult and aged adult bone with regards to

Thus, an excessive amount of DMP-1 and abundant osteocalcin were accumulated in osteocytic lacunae of *klotho*^{-/-} mice. Taken together, the excessive amount of osteocyte-producing molecules appears to inhibit mineralization rather than to induce proper mineralization in *klotho*^{-/-} bone.

1,25(OH)₂D and PTH Up-regulate *Rankl* while Down-regulate *Phex* and *Dmp1* in Primary Osteocytes Isolated from Mouse Bones. Kazuaki Miyagawa^{*1}, Keiichi Ozono², Kanako Tachikawa¹, Masanobu Kawai¹, Yuko Mikuni-Takagaki³, Mikihiro Kogo⁴, Toshimi Michigami¹. ¹Department of Bone & Mineral Research, Osaka Medical Center & Research Institute for Maternal & Child Health, Japan, ²Osaka University Graduate School of Medicine, Japan, ³Kanagawa Dental College & Graduate School of Dentistry, Japan, ⁴Osaka University Graduate School of Dentistry, Japan

Osteocytes are the terminally differentiated cells of the osteoblastic lineage. In addition to their roles in the control of bone mass, those in phosphate metabolism are now getting attention. Among the molecules responsible for hereditary hypophosphatemic rickets, FGF23, PHEX and DMP1 are expressed in osteocytes. However, the regulatory mechanisms for the expression of these molecules remain still unclear, partly due to the lack of appropriate cell models. Therefore, in the current study, we utilized primary osteocytes isolated from mouse bones to address this issue. Mouse long bones were minced and subjected to sequential digestion with collagenase and decalcification with EGTA for fractionation of osteoblasts and osteocytes. Since strong expression of *Dmp1* and *Sost* was detected in fractions 6-9 among the isolated 9 fractions, we considered them as osteocyte-rich fractions. To verify that the isolated osteocytes retain the gene expression *in vivo*, we compared the gene expression in the cells isolated from wild-type mouse and *Hyp* mouse, a homologue of human X-linked hypophosphatemic rickets (XLH), with a 3' deletion in the *Phex* gene. The expression of *Sost* in isolated osteocytes was comparable between the genotypes, while that of *Fgf23* and *Dmp1* was elevated in *Hyp*-derived osteocytes. These results were consistent with those in immunohistochemistry, confirming that the isolated osteocytes kept the gene expression *in vivo*. Next, we investigated the effects of 1,25(OH)₂D and PTH on gene expression in isolated osteocytes. The primary osteocytes isolated from wild-type mice were embedded in type I collagen matrix, and cultured in the presence or absence of 10⁻⁸ M 1,25(OH)₂D or 10⁻⁶ M PTH for 48 hours before RNA was extracted for analyses. The expression of *Sost* was retained after 48-hr culture, confirming the osteocytic phenotype of the cells. Treatment with 1,25(OH)₂D markedly increased the expression of receptor activator of NF-κB ligand (*Rankl*). On the other hand, the expression of *Phex* and *Dmp1* was reduced by treatment with 1,25(OH)₂D. PTH also increased the expression of *Rankl*, while decreased that of *Phex* and *Dmp1*. These results provide the evidence that 1,25(OH)₂D and PTH exert their effects directly on osteocytes to regulate genes involved in bone homeostasis and phosphate metabolism.

Characteristics of Osteocyte Lacunae in Patients with Renal Hyperparathyroidism. Aiji Yajima^{*1}, Shigeru Satoh², Yoshihiro Tominaga³, Shigeru Otsubo⁴, Masaaki Inaba⁵, Kosaku Nitta⁶, Akemi Ito⁷. ¹Towa Hospital, Japan, ²Division of Renal Replacement Therapeutic Science, Akita University School of Medicine, Japan, ³Department of Transplant Surgery, Nagoya Second Red Cross Hospital, Japan, ⁴Department of Nephrology, Sangenjaya Hospital, Japan, ⁵Department of Internal Medicine, Metabolism, Endocrinology & Molecular Medicine, Osaka City University Graduate School of Medicine, Japan, ⁶Department of Medicine, Kidney Center, Tokyo Women's Medical University, Japan, ⁷Ito Bone Histomorphometry Institute, Japan

The type 1 parathyroid hormone (PTH)/PTH related peptide (PTHrP) receptor (PTHrP) in osteocyte plays an important role in mobilizing calcium (Ca) by the osteocytes in lactating mice as there is a high Ca demand and PTHrP levels are elevated in these mice (Hai Q, et al. JBMR Suppl 2010). In addition, a great deal of mineralization was observed around the lacunar wall through the osteocyte-canalicular system after parathyroidectomy (PTX) for renal hyperparathyroidism (Yajima A, et al. JBMR 2010). As a result, osteocytic osteolysis and bone mineralization by the osteocytes were demonstrated in these reports. Therefore, we observed the shape of osteocyte lacunar walls to investigate the osteocyte function in renal patients with high PTH before PTX. Transiliac bone biopsy specimens were obtained from 45 hemodialysis (HD) patients (age; 57.0 ± 8.6 yrs, duration of HD; 14.8 ± 7.3 yrs) and 19 subjects without renal insufficiency (age; 59.0 ± 11.9 yrs). We regarded the eroded surface-predominant lacunae (ES.Lc) as the resorption lacunae of the patients. In addition, the osteoid surface-predominant lacunae (OS.Lc) was thought to be the formative lacunae and the quiescent surface-predominant lacunae (QS.Lc) was thought to be the lacunae without both any active bone resorption and formation. We calculated the number of ES.Lc per bone volume (BV) (N.ES.Lc/BV), the number

of OS.Lc per BV (N.OS.Lc/BV), and the number of QS.Lc per BV (N.QS.Lc/BV) in these 2 groups. In HD patients with high PTH, N.ES.Lc/BV was greater than N.OS.Lc/BV (272.3 ± 91.4 vs 10.3 ± 18.0 N/mm² (P < 0.001)) and N.ES.Lc/BV was greater in HD patients than normal controls (272.3 ± 91.4 vs 23.5 ± 12.5 N/mm² (P < 0.001)). In addition, total lacunar volume of each type of lacunae was calculated. The volume of ES.Lc per BV (ES.Lc.V/BV), the volume of OS.Lc per BV (OS.Lc.V/BV) and the volume of QS.Lc per BV (QS.Lc.V/BV) was 1.17 ± 0.38, 0.49 ± 1.02 and 0.44 ± 0.11 %, respectively, in patients with high PTH. ES.Lc.V/BV was greater than both OS.Lc.V/BV (P < 0.001) and QS.Lc.V/BV (P < 0.001) significantly. In addition, ES.Lc.V/BV was greater in HD patients with high PTH than normal controls (1.17 ± 0.38 vs 0.13 ± 0.09 %, P < 0.001). These data suggest that an increase of serum Ca level and the reduction of bone mass are caused by an increase of osteocytic osteolysis and a decrease of bone formation by the osteocytes as well as osteoclastic resorption in patients with renal hyperparathyroidism.

MO0318

Menopause-related Changes in Osteocyte Lacunar Density, Volume, and Separation in Adult Human Trabecular Bone. Mohammed Akhter^{*1}, Robert Recker¹, Tiffany Fong², Donald Kimmel³. ¹Creighton University Osteoporosis Research Center, USA, ²Xradia, Inc., USA, ³Kimmel Consulting Services, USA

Synchrotron radiation (SR) microscopy (0.7μm pixel resolution [PR]) facilitates 3D imaging of whole Ot lacunae (Ot.La). The smallness of Ot.La creates difficulty for current laboratory-based 3D imaging devices to resolve them and study their properties in sizable samples of intact bone. Though osteocytes (Ot) alter their lacunar volume in response to pharmacologic/mechanical stimuli, less is known about lacunar density and separation. We report the effect of estrogen status on Ot.La volume (Ot.LaV), density (Ot.LaD), and separation (Ot.LaSp) in human trabecular and cortical bone, using measurements taken on 3-D images obtained with a laboratory instrument that achieves SR-like resolution.

Biopsy specimens were taken from opposite ilia of a healthy woman before (PRE) and at one year after (POST) her last menses, then embedded undecalcified in plastic. Activation frequency was 7X higher POST-menopause. A portion of each specimen that remained after thin-sectioning was trimmed to 2X2X8mm and scanned at 5μm PR with a laboratory-based 3D XRay microscope (MicroXCT-200). Twelve trabecular or cortical bone sub-volumes of interest (sub-VOIs; 1.3mm diameter X 0.7mm long; 6 PRE/6 POST) were selected and scanned at ~0.97μm PR. Ten additional trabecular bone sub-VOIs (0.9mm diameter X 0.5mm long; 4 PRE/6 POST) were scanned at ~0.6μm PR. Ot.La were defined as bone tissue voids >50 and <500μm³. The 3D image from each ~0.97μm PR VOI was analyzed by Ratoc Segmentation Software (RSS; Tokyo, JP) for Ot.LaD and Ot.LaV. BaryCenter (centroid) was determined by RSS for each Ot.La in all 0.6μm PR sub-VOIs. The distance of each lacuna to its nearest neighbor was calculated (Ot.LaSp). Each 0.6μm PR sub-VOI was also analyzed for Ot.LaV.

Regions with a total of >50,000 Ot.La were studied. Data are shown in the table. Study of these and other transmenopausal pairs continues.

Our data indicate that Ot.LaD decreases with menopause in trabecular bone, but not cortical bone. The data also suggest that Ot.LaV decreases with menopause in both types of bone. Ot.LaSp, the mean distance from one lacuna to the next nearest one, is ~27.51.3μm. Bone tissue with smaller, less numerous Ot.La could have reduced ability to intercept propagating microcracks. These properties may be bone qualities that change, increasing bone fragility in a way not detected by current measurements. These findings parallel data showing reduced Ot.LaV and Ot.LaD in trabecular bone of estrogen-deficient rats.

Variable	Region	PR (μm)	Units	PRE	POST
Ot.LaV	T	~0.97	μm ³	183±10	156±14*
Ot.LaV	C	~0.97	μm ³	186±9	165±3*

Skeletal Unloading Changes Phosphate (Pi) Homeostasis. Rong Zhang^{*1}, X Han², Baozhi Yuan³, Marc Drezner⁴, Lynda Bonewald⁵, Jian Feng⁶.
¹School of Stomatology, Fourth Military Medical University, Peoples Republic of China, ²Baylor College of Dentistry, USA, ³University of Wisconsin, Madison, USA, ⁴University of Wisconsin, USA, ⁵University of Missouri - Kansas City, USA, ⁶Texas A&M Health Science Center, USA

Osteocytes are mechanosensors that also act as endocrine cells to regulate Pi homeostasis through FGF23 production. Deletion of dentin matrix protein1 (DMP1) in mice or DMP1 mutations in humans leads to elevated FGF23 and hypophosphatemic rickets. To test the hypothesis that the bone malformations in this disease model of osteomalacia would be corrected in unloaded bones, both wild-type and Dmp-1 null mice were tail suspended for 30 days. In Dmp1 null mice, a dramatic improvement of osteomalacia in not only the unloaded hindlimb occurred as expected but also an improvement in morphology of the loaded forelimb was observed as determined by x-ray uCT, fluorochrome labeling, and histology. A partial improvement of protein expression, such as SOST, PHEX and FGF23 as determined by immunohistochemistry, was also observed along with increased osteoclast number. In the wild-type control mice, tail suspension also led to a significant increase of serum Pi (from 8.610.63 to 11.971.217mg/dl), and bone loss not only in the unloaded hindlimb, but also in the loaded forelimb. Bone marrow cells isolated from the loaded forelimbs and the unloaded hindlimbs had a significant increase in RANKL expression and RANKL/OPG ratio as determined by RT-PCR. Finally, healthy human subjects subjected to head down tilted bed rest (n=6) showed a significant increase in serum Pi (from 3.310.25 to 4.037mg/dl), but not calcium after 30 day period. Our data shows that chronic unloading results in an increase in serum Pi in addition to bone loss due to unloading. In Dmp1 null animals, this increased serum Pi (from 5.320.25 to 6.990.517mg/dl) is beneficial. This study has clinical relevance with regards to treatment of immobilized, chronically ill patients and astronauts.

A New Sandwich ELISA of Mouse Periostin for in-vitro and in-vivo Animal Studies. Jean-Charles Rousseau^{*1}, Marjorie Thomas², Blandine Merle¹, Cindy Bertholon¹, Olivier Borel¹, Evelyne Gineyts¹, Patrick Garnero³.
¹INSERM UMR 1033, Université de Lyon, France, ²INSERM UMR 1033, Université de Lyon, France, ³INSERM UMR 1033, Université de Lyon & Cisbio Bioassays, France

Purpose: Periostin (POSTN) is an adhesion Gla-containing protein mainly expressed in the periosteum that plays an important role in regulating bone formation. The measurement of POSTN may be useful as a biological marker of periosteal surface activity. The aim of this study was to develop a sensitive and specific ELISA for mouse POSTN and measure its concentration in the serum and in the supernatants of periosteal cell culture.

Methods: We developed a sandwich ELISA using a goat antibody directed against recombinant mouse POSTN and a rabbit polyclonal antibody raised against a synthetic peptide of 22 amino acids located in the C-terminal part of POSTN which is common to all POSTN isoforms. The ELISA was calibrated using mouse recombinant POSTN. POSTN was measured with this new ELISA in the serum of 37 Balb/c mice and in the culture medium of periosteal cells isolated from long bones of mice (C57BL/6) aged of 4 weeks.

Results: Western blot analyses show that the two antibodies recognized in mouse serum a POSTN immunoreactive form co-migrating with recombinant POSTN. The intra and inter-assay precisions of the ELISA for both serum and culture supernatant was below 6 and 12%, the mean dilution recovery was 105% and the mean spiking test was 99%, allowing accurate measurements of POSTN from 1 (detection limit) to 50 ng/ml. Serum POSTN was stable for up to 5 of thaw/freezing cycles and at least 2 hours at room temperature. In mice, serum POSTN levels ranged from 5.9 to 14.7 ng/ml (mean: 9.1 +/- 2.04 ng/ml). For the measurement of POSTN in cell culture supernatant, the protocol was modified to increase the sensitivity of the ELISA. As expected we found that the concentration of POSTN decreased with advancing stage of periosteal cell differentiation, in agreement with the qPCR data.

Conclusions: The new ELISA for mouse POSTN is specific, sensitive and reproducible. It should be useful for the investigation of periosteal metabolism in in-vitro and in-vivo animal models of osteoporosis and other metabolic bone diseases, including bone metastases.

Correlations of Urinary ⁴¹Ca with Biomarkers and Minerals in Post-Menopausal Women. George Jackson^{*}, WangHee Lee, Berdine Martin, Connie Weaver, Purdue University, USA

Urinary ⁴¹Ca measurement, expressed as the ratio of ⁴¹Ca to normal calcium (⁴¹Ca:Ca), has been used to follow the long-term changes in bone metabolism due to its significantly long half-life (T_{1/2} = 10⁵ years). We correlated the ⁴¹Ca:Ca ratio with traditional markers of bone metabolism and minerals in both the serum and urine. In particular, we looked for correlations with osteocalcin (ng/ml), bone alkaline phosphatase (ng/ml), parathyroid hormone (pg/ml), 25-hydroxy vitamin-D (ng/ml), serum alkaline phosphatase (U/L), fasting N-terminal telopeptide (nM BCE/mM Cr), fasting deoxy-pyridinoline (nM/mM Cr), fasting calcium (mg/dL), fasting creatinine (mg/dL), and fasting phosphate (mg/dL). Thirty subjects that received similar doses of ⁴¹Ca (50 or 100 nCi) were used for correlation analysis. We used data from two studies where estradiol, alendronate, and other interventions showed statistically significant effects on the measured ratio increasing the likelihood of detecting meaningful correlations. ⁴¹Ca was assayed at a different frequency than the biomarkers or minerals, but we only correlated data that was collected on the same day. Since ⁴¹Ca can be detected for many years after dose and the ratio is decreasing as the tracer is excreted from the body, care needs to be taken in how the correlations are performed. Because timing of both ⁴¹Ca dose and urinary measurement contribute to large variations, we compensated for these effects by fitting the ⁴¹Ca data with two different models (compartmental and a mathematical fit) and used the residues for correlations. However, these methods did not compensate for variation caused by the carry over effect of some treatments and individual differences. Thus, we statistically considered the subjects to offset variations among subjects and correlated the difference in consecutive biomarkers with the difference in consecutive ratios. The difference in consecutive osteocalcin (ng/ml) and NTx/Cr (nM BCE/mM Cr) concentrations were positively correlated with the consecutive differences in ratio (p values of 0.0091 and 0.0118 respectively) with all other biomarkers and minerals not being significantly correlated with ⁴¹Ca.

Disclosures: George Jackson, None.

Effectiveness of Urinary Gamma-Glutamyltransferase as Screening for Osteoporosis. Shinya Tanaka^{*1}, Sawako Moriwaki², Kazuhiro Uenishi³, Nobuo Koinuma⁴, Kiyoshi Tanaka⁵, Yoshitaka Ikeda⁶, Shumpei Niida⁷.
¹Saitama Medical University, Japan, ²Laboratory of Genomics & Proteomics, National, Japan, ³Laboratory of Physiological Nutrition, Kagawa Nutrition University, Japan, ⁴Department of Health Administration & Policy, Tohoku University Graduate School of Medicine, Japan, ⁵Department of Food & Nutrition, Kyoto Women's University, Japan, ⁶Department of Biomolecular Sciences, Faculty of Medicine, Saga University, Japan, ⁷National Center for Geriatrics & Gerontology, Japan

[Background and Aims] To undergo the osteoporosis test is effective to prevent osteoporotic fractures. In Japan, a public osteoporosis screening program has been executed to alert individuals having osteoporosis risk. However, cost of this program puts pressure on local government finance. We have previously developed a low-cost test for osteoporosis using urinary concentration of gamma-glutamyltransferase (u-GGT) which is a potent index of bone absorption. Thus, to assess the effectiveness of this new screening test for osteoporosis, we performed group examinations and analyzed the relative operating characteristic (ROC), specificity, sensitivity, and accuracy. [Materials and Methods] 1. Four-hundred one women, from 40 to 78 y-o, living in Higashiura town or Obu city, Aichi, Japan were included. The correlations between u-GGT and urinary concentration of deoxypyridinoline (u-DPD) were statistically analyzed about respective region and total regions. 2. ROC analysis was performed with use of the bone mineral density (BMD) at lumbar spine (L2-4) made on the subjects less than 70% of the young adult mean (YAM) (17 osteoporosis women) and 111 non-osteoporosis women. [Results] The correlations between u-GGT and u-DPD were 0.2833 in Higashiura (p=0.0000), 0.0211 in Obu (p=0.8297), and 0.1336 in total (p=0.0184). Weak correlation was seen in the Higashiura data. From ROC analysis, 46IU/gCr was given as a desirable cutoff point for diagnosis of osteoporosis were 100% in Higashiura, 80.0% in Obu, and 82.35% in total. Specificities of 46IU/gCr were 57.45%, 59.38%, and 58.56% respectively. Accuracies were 44.90%, 48.10%, and 46.88% respectively. 46IU/gCr had high sensitivity for osteoporosis diagnosis. [Conclusion] We confirmed that 46IU/gCr was affordable to screen osteoporosis in group examinations.

Magnesium and Osteoporosis: A Clinical Profile of Hypomagnesaemic Patients Attending a Bone Health Clinic. James Mahon^{*1}, Joseph McAndrew², Lorraine O' Keeffe², James Walsh³, Miriam Casey². ¹St James's Hospital, Ireland, ²St. James's Hospital, Ireland, ³Trinity College Dublin, The University of Dublin, Ireland

Introduction: Magnesium deficiency is associated with a number of clinical disorders including osteoporosis. Animal studies have shown magnesium deficiency leads to increased cytokine production and osteoclastic bone resorption (1). Magnesium disorders can also cause hypocalcaemia (2). St. James's Hospital Dublin Osteoporosis and Bone Health Clinic, a tertiary referral centre, has been in operation since 2004. It has compiled a database of 3,600 patients. As part of initial assessment, magnesium levels have been measured since 2008.

Methods: We interrogated our database from Jan 2008 to Dec 2010 to identify patients who had serum magnesium (Mg) levels measured at presentation. We created clinical profiles to include age, sex, T-scores, prior history of fracture, bisphosphonate use, as well as serum markers 25-OH vitamin D, parathyroid hormone (PTH), calcium (Ca), osteocalcin, Procollagen type 1 N-terminal propeptide (PINP) and CTX-telopeptide (CTX). We further compared hypomagnesaemic to normomagnesaemic patients.

Results: We identified 487 patients (83 male, 404 female) for whom Mg was measured. Descriptive statistical means were generated: Age 64 years (SD 14.3); T-score hip -1.5 (SD 1.2), T-score spine -1.8 (SD 1.6); Mg 0.85 mmol/L (SD 0.09); Ca 2.22 mmol/L (SD 0.12); 25-OH vitamin D 56 nmol/L (SD 27), PTH 43 pg/mL (SD 27), osteocalcin 23.6 ng/mL (SD 15.3); PINP 50.0 ng/mL (SD 35.1); CTX 0.33 ng/mL (SD 0.2). 66% had prior history of fracture, and 28% were taking bisphosphonates. 18 patients (4% of total group) were hypomagnesaemic (Mg <0.70 mmol/L). Analysis of this subgroup showed mean T-score hip -2.0 (SD 0.8), T-score spine -1.8 (SD 1.3), and a 71% prevalence of prior fractures. We did not find strong coefficients of correlation between Mg and other parameters.

Conclusions: In this elderly population, we found a low prevalence of hypomagnesaemia. While we did find increased presence of hip fractures and lower T-scores in the hypomagnesaemic subgroup, the absolute number of hypomagnesaemic patients was too small to attribute statistical significance. Continuing collection of these data will further characterise hypomagnesaemia in the context of osteoporosis, and help determine appropriate intervention in the treatment of an elderly, osteoporotic population.

MO0324

Serum Osteocalcin and Undercarboxylated Osteocalcin Levels Are Associated with Renal Function and Vascular Complications in Type 2 Diabetes. Atsushi Suzuki^{*1}, Junnichi Ishii², Sahoko Sekiguchi-Ueda¹, Megumi Shibata³, Yasumasa Yoshino¹, Shogo Asano⁴, Fumihiko Kitagawa², Toshiaki Sakuishi², Takashi Fujita², Takashi Ishikawa², Masaki Makino¹, Nobuki Hayakawa¹, Mitsuyasu Itoh¹. ¹Fujita Health University Division of Endocrinology, Japan, ²Department of Joint Research Laboratory of Clinical Medicine Fujita Health University, Japan, ³Fujita Health University, Division of Endocrinology, Japan, ⁴Toyokawa City Hospital, Japan

Diabetes and osteoporosis are both aging-related disease, and recent findings showed that glucose intolerance is closely associated with bone metabolism. Among bone turn over markers, osteocalcin (OC) and its inactive form, undercarboxylated osteocalcin (uOC) have been reported to affect insulin secretion and sensitivity. At the same time, both OC and uOC levels are affected by renal function, which is often damaged in diabetes patients. In the present study, we evaluated OC and uOC levels in type 2 diabetes patients, and their association with clinical complications with diabetes.

We enrolled 351 type 2 diabetes outpatients (M/F=211/140; Mean age, 65.311.5 years). Mean serum OC and uOC levels were 4.073.4 ng/ml and 3.223.6 ng/ml, respectively. Both OC and uOC levels were closely related to estimated GFR and urinary albumin concentration (UAE), but not with HbA1c. OC and uOC levels were significantly higher in the patients with severe proliferative retinopathy and chronic renal failure, and the levels of OC and uOC were higher in CKD stages 3, 4, and 5 compared with CKD stage 1 and 2. In CKD stages 1 and 2 (n=241), eGFR was not related to either OC or uOC levels, while HbA1c was inversely associated not with uOC but with OC (r=0.13, p=0.04) level. OC and uOC levels were higher in the patients with the past history of cardiovascular disease, even in CKD stages 1 and 2. On the contrary, either OC or uOC were not related to highly sensitive CRP, N-terminal BNP or troponin T levels in CKD stages 1 and 2. In conclusion, serum OC and uOC concentrations were affected by renal function, but seem to have some association with vascular complications of type 2 diabetes.

Bone loss in Patients with COPD – 3 years of Follow-up. Dorte Brask-Lindemann^{*1}, Suzanne Cadarette², Dr. Peter Eskildsen³, Bo Abrahamsen⁴. ¹Copenhagen University Hospital K1/2, Denmark, ²University of Toronto, Canada, ³Koege Hospital, Denmark, ⁴Copenhagen University Hospital Gentofte, Denmark

Background: Patients with chronic obstructive pulmonary disease (COPD) are at increased risk of osteoporosis and fractures. Several factors may contribute to this, including inadequate physical activity, vitamin D deficiency, low body mass index, and long-term use of glucocorticoids. However, it is unclear if patients have greater bone loss rates once they are diagnosed with COPD and treated for this, compared with subjects without COPD. **Aim:** To explore bone loss progression over a 3-year period in patients with COPD compared to age and gender matched pulmonary healthy controls referred for DXA examination. **Methods:** Patients with moderate to severe COPD referred for a pulmonary rehabilitation programme were consecutively recruited for the study and an age and gender matched non-COPD control group was identified in the osteoporosis clinic database. Pulmonary function was assessed by spirometry and categorized according to GOLD guidelines. DXA examination was performed using the same dual energy X-ray absorptiometry machine (DXA - Hologic Discovery A). Change in bone mineral density (BMD) over time was computed as the change in lowest T-score of the hip or spine between baseline and end of follow up period. Descriptive statistics, paired t-test and chi-square were used in statistical analysis.

Results: A total of 152 patients with COPD were included and 81 (53.3%) were alive and available for follow up three years later. Of 156 included controls, 113 (72.4%) were available for follow up in the same time period. Baseline BMD (mean of lowest T-score of hip or spine) in patients was -2.0 (SD 1.2) and in controls -1.9 (SD 1.2) (p=0.3). In patients with 3 years follow up (n=81) baseline BMD was higher (T-score -1.74 (SD 1.2) but not significantly (p=0.5), while lowest baseline T-score for controls (n=113) was unchanged. At follow up, no significant differences in bone loss progression rate in or between (p=0.5) the two groups were revealed (Patients t-score -1.74 (SD 1.2) to -1.8 (SD 1.1) (p=0.8) and controls t-score -1.9 (SD 1.1) to -1.8 (SD 1.0) (p=0.3)). **Conclusion:** These results confirm a high prevalence of low BMD in patients with moderate to severe COPD but do not suggest a COPD-associated increased rate of bone loss progression.

MO0326

Evaluation of FRAX Analysis in Patients with Glucocorticoid-Induced Osteoporosis of Connective Tissue Diseases (CTD). Ikuko Tanaka^{*1}, Shigenori Tamaki², Hisaji Oshima³. ¹National Center for Geriatrics & Gerontology, Japan, ²Nagoya Rheumatology Clinic, Japan, ³Tokyo Medical Center, Japan

Objective: We evaluated FRAX in patients with CTD, where severe secondary osteoporosis such as glucocorticoid-induced and arthritis related osteoporosis particularly at the spine. **Subjects & Methods:** One hundred and five outpatients (female; 90, average age; 65) in the rheumatology clinic were recruited by following criteria; i) more than 40 years old of age, ii) no therapeutic agents for osteoporosis. BMD data of the hip were not available. After 2 years of follow-up, incident fractures were identified with the spine X-ray. **Results:** Sixty five subjects were taking glucocorticoid (average daily dose: 5.1 mg of prednisolone) and 20 had RA. Other elements for FRAX analysis were 154 cm on average body height and 51 kg on average body weight. Ten had a history of bone fracture and 5 had the parental history. Smokers were 20, drinkers were 5, and 5 had the secondary osteoporosis. The FRAX predictive values for the incidence of major osteoporotic fracture (10 years) (FRAX-MO) and hip fracture (FRAX-HF) were 15.9% and 5.5%, respectively. Although hip fractures were not actually observed in the two-years observation, 30 showed the vertebral fractures (29%) diagnosed by X-ray. The mean of the FRAX-MO in subjects with the vertebral fracture (24.1%) was higher than those without the fracture (12.6%), but statistically not significant (p=0.110). Forty patients showed low FRAX-MO (<7%) values, but still had high incidence (5 subjects; 12.5%) of the vertebral fractures. **Conclusion:** In patients with CTD, FRAX was valuable to predict new fracture. However, more frequent morphological fractures were observed possibly due to no information of glucocorticoid dosage in FRAX. These results suggested that FRAX might be underestimated in CTD patients.

First Demonstration of Microdamages in Vivo in Computerized Magnified Radiographs of the Dental Alveolar Bone and Their Association with Vertebral Fracture and BMD. Yoshitomo Takaishi^{*1}, Aiko Kamada², Takashi Ikeo², Takami Miki³, Takuo Fujita⁴. ¹Takaishi Dental Clinic, Japan, ²Osaka Dental University, Japan, ³Osaka City University Medical School, Japan, ⁴Katsuragi Hospital, Japan

< Purpose >

Microdamages and microfractures, small fractures in bone subjected to mechanical stress, serve as markers of responses bone to external force and their repair, but have

so far been detected only in histological sections and never in radiograms in vivo. Attempts were therefore made to demonstrate microdamages in the computerized and highly magnified radiogram by Bone Right Method, to explore their relationship with spinal fracture and risk factors.

< Method >

In 33 subjects ranging between 50 and 69 years of age, microdamages were found in the magnified stereoscopic radiogram obtained by computed radiograms (Bone Right). Association among these was tested. Lumbar bone mineral density (LBMD) was measured by DXA, and vertebral fracture assessed by X-ray, and body mass index (BMI) calculated from weight and height. Dental examination consisted of pocket depth and alveolar thickness measurement and alveolar bone density (al-BMD).

< Results >

Number of microdamages in the uppermost part of alveolar bone of the first premolar showed a significant positive correlation with vertebral fracture with correlation coefficient (CV) of 0.722 ($p < 0.01$) and age with CV of 0.462 ($p < 0.01$), along with negative correlation with LBMD (CV-0.651, $p < 0.01$) and al-BMD (CV-0.63, $p < 0.01$).

< Conclusion >

Microdamages were detected in the dental alveolar bone for the first time in the computed, magnified and stereoscopic radiogram of the upper alveolar bone. The number of microdamages showed significant positive correlation with vertebral fracture and age, and negative correlation with LBMD and al-BMD.

Knowledge and Perception of Osteoporosis and Fracture Risk Among Post-Menopausal Canadian Women. Alexandra Papaioannou^{1*}, Suzanne Morin², Jonathan Adachi³, Alan Bell⁴, Sidney Feldman⁵, Heather Frame⁶, Stephanie Kaiser⁷. ¹Hamilton Health Sciences, Canada, ²McGill University Health Centre, Canada, ³St. Joseph's Hospital, Canada, ⁴University of Toronto, Canada, ⁵Baycrest Geriatrics Health Care System, Canada, ⁶Assiniboine Medical Clinic, Canada, ⁷Dalhousie University, Canada

Purpose: To explore the attitudes and knowledge related to post-menopausal osteoporosis (PMO) among Canadian women over 55, with and without diagnosed PMO, including understanding of prior fracture as a key factor for increased risk.

Methods: A survey was conducted online and via telephone with women across Canada in October 2010. Potential participants, from a database of individuals who consented to participate in surveys, were screened to confirm post-menopausal status. Only completed surveys were analyzed. The survey includes responses to questions about the potential or actual impact of PMO on their lives, understanding of PMO risk factors and experience with fractures. In parallel, another survey of awareness and assessment of PMO was conducted with 404 Canadian family physicians (FPs).

Results: Of 910 women completing the survey (445 had diagnosed PMO and 465 did not. Of women without a diagnosis, 9% stated they were very concerned about PMO. A majority of women had a good understanding of the major risk factors for PMO (e.g. low bone density, age, previous fracture) (Figures), but less than half felt it strongly impacted quality of life. Only 49% of undiagnosed women reported being tested for osteoporosis, and only 35% had discussed osteoporosis with their doctor. However, 18% of these women reported a fracture or broken bone after age 45, a key risk factor for PMO and future fractures. As 36% of these reported fractures were attributed to falls from standing or low height, it appears that ~7% of total undiagnosed women had experienced fragility fractures that might prompt further clinical evaluation. Few FPs (18%) say they routinely ask about fractures, and most (71%) were less than "fully confident" they would receive a report from the hospital regarding a patient's fracture. In the FP survey, 51% indicated that they were "very concerned" that their 55+ year female patients would develop PMO, and 36% felt their patients of this age were also "very concerned".

Conclusion: Although women without a diagnosis of PMO appear familiar with the disease and its risk factors, few reported they were greatly concerned about their own risk. Our findings suggest the awareness of fracture as a key risk factor predicting increased risk of future fracture is low in both women 55+ and FPs. As such, routine screening for patients' fracture history may not be incorporated effectively in risk assessment practice.

MO0329

Osteoporosis Intervention Threshold based on BMD versus FRAX. Peter Jackuliak¹, Eva Lalcikova¹, Juraj Payer², Zdenko Killingner^{1*}. ¹University Hospital, Bratislava, Slovakia, ²University Hospital, Ruzinov, Slovakia

Objectives: Currently, indication of antiprotective treatment in Slovakia is based on low bone mineral density (T-score below -2.5 SD). According to epidemiological data more than a half of fractures occur in patients with osteopenia. These patients are currently not treated. It seems crucial to identify these high-risk osteopenic patients using the FRAX (Fracture risk assessment tool).

Aim of the study: 1) To calculate the 10-year probability of fracture in patients sent to BMD (bone mineral density) testing according to the ISCD criteria. 2) To compare two different approaches in initiation of antiprotective treatment - one based on BMD T-score below -2.5 and another based on FRAX outcomes.

Methods and patients: We calculated the 10-year absolute risk of hip fracture and major osteoporotic fracture of 379 patients sent to the Osteocenter at University Hospital using FRAX (Austrian population). The mean age of our group was 63 years. We measured BMD at the femoral neck and lumbar spine.

Results: The absolute 10-year risk was 12% for a major osteoporotic fracture and 4.3% for hip fracture. Mean T score was -1.5 SD at the femoral neck and -1.85 at lumbar spine. 98 patients were classified as osteoporotic, 184 patients were osteopenic and 97 had their BMD in normal range. Based on BMD (T-score -2.5 and below) 98 osteoporotic patients are currently indicated for antiprotective treatment. Based on FRAX outcomes and thresholds proposed by the NOF (National Osteoporosis Foundation) (20% for a major osteoporotic fracture and 3% for hip fracture), the number of treated patients would rise to 157 (90 osteopenic, 62 osteoporotic patients and 5 patients with normal BMD).

Conclusions: Based on the FRAX tool outcomes and the NOF treatment thresholds we would identify 157 patients at high risk for osteoporotic fractures. The use of this intervention threshold in clinical practice would significantly increase (twice) the number of treated patients with considerable impact on the health-care system.

The 3/2 Power of Bone Mineral Apparent Density. Xiaohai Wan^{*}, John Krege. Eli Lilly & Company, USA

Objective: Dual-energy X-ray Absorptiometry (DXA) and Quantitative Computed Tomography (QCT) are techniques used clinically to measure bone mineral density (BMD) to evaluate the status of the skeleton. DXA, the gold standard to diagnose and monitor patients with osteoporosis, measures areal BMD (aBMD, g/cm²) via a projected radiography technique and hence cannot directly consider the thickness of the assessed bone. aBMD is calculated as bone mineral content (BMC) divided by bone area (BA). QCT provides the opportunity to assess 3-dimensional volumetric BMD (vBMD, g/cm³) measurements. The purpose of this analysis was to assess the relationship between aBMD and vBMD using data from Lilly clinical trials. On

theoretical grounds, a bone mineral apparent density (BMAD), calculated as $BMC/BA^{1.5}$ should approximate vBMD.

Methods: The analysis includes postmenopausal women with osteoporosis who participated in two clinical trials ($N_1 = 203$, $N_2 = 198$). DXA measurements collected included bone mineral content (BMC), bone area (BA) and aBMD. QCT measurements collected included vBMD. Nonlinear regression was used to estimate three parameters (a_0 , a_1 and a_2) in the following formula: $E(vBMD|BMC,BA) = a_0 + a_1 \cdot BMC/BA^{1.5}$. Linear regressions were applied to assess the relationships between BMC, BA, vBMD, aBMD and BMAD.

Results: The exponent parameter a_2 in the nonlinear regression model was estimated to be very close to the value of $3/2$ ($p < 0.01$) as in the theoretical definition of BMAD at femoral neck, hip and lumbar spine.

Conclusion: We showed through nonlinear regression technique that the BMAD formula allows 2-dimensional aBMD data to be converted to an approximation of volumetric BMD in osteoporosis patients.

MO0331

Variability in Screening for Post-menopausal Osteoporosis by Canadian Family Physicians. Suzanne Morin^{*1}, Alexandra Papaioannou², Andre Belanger³, Jacques Brown³, Angela Cheung⁴, David Hanley⁵, David Kendler⁶, Daniel Ngui⁷. ¹McGill University Health Centre, Canada, ²Hamilton Health Sciences, Canada, ³Laval University, Canada, ⁴University Health Network, Canada, ⁵University of Calgary, Canada, ⁶Osteoporosis Research Centre, Canada, ⁷University of British Columbia, Canada

Purpose: To explore the attitudes and screening practices of Canadian family physicians (FPs) regarding post-menopausal osteoporosis (PMO) and its management.

Methods: In October 2010, 2594 eligible FPs, identified from a database of physicians from across Canada who had consented to participate in surveys, were invited to complete this survey. FPs were included if they routinely saw >100 patients/month, of whom $\geq 15\%$ were age 55+, and wrote ≥ 15 prescriptions per month for PMO medications. Only completed surveys were analyzed. The survey included FP responses to questions about the impact of PMO, their concern with chronic diseases and their approach to assessing patients' risk of PMO.

Results: Of 404 FPs completing the survey, 35% indicated they were "very concerned" about the quality of life (QoL) impact of PMO in their patients. However, chronic conditions judged to be of greater concern included dementia, cerebral vascular disease, breast cancer, heart disease and diabetes. Only 65% and 18% of FPs regularly screened for osteoporosis and fractures, respectively, as compared to 99% for hypertension and 95% for diabetes during routine examination of women in this age group (Figure). Despite the fact that 71% of FPs were "somewhat to not at all confident" that the hospital would inform them of a patient's fracture, FPs surveyed do not routinely ask their patients if they experienced a fracture since they were last seen. Many (42%) believe up to one-fourth of their patients have undiagnosed and untreated fragility fractures. Most FPs (68%) were aware that absolute fracture risk models, including that endorsed by the Canadian Association of Radiologists and Osteoporosis Canada (CAROC), were available, but 58% said they still relied on the DXA T-score alone for the diagnosis of PMO.

Conclusion: This survey suggests that FPs may not adequately consider fragility fractures in their PMO patients and underestimate the potential long-term impact of these fractures on women's functional status. Hip fractures, for instance, are estimated to occur at an annual rate of 86.4/100,000 women in Canada and cause lasting deficits in women's global QoL, mobility, and self-care. The new Osteoporosis Canada Guidelines emphasize fracture risk assessment over DXA-based diagnosis. However, based on the high usage of DXA alone, FPs may benefit from education in the use of predictive models of PMO, which incorporate prior fracture history and other established risk factors.

Abnormal Cortical and Trabecular Parameters in Persons with Epilepsy. Alison Pack^{*1}, Rebecca B. Bausell¹, Stephanie Boutroy², Donald McMahon³, Elizabeth Shane³. ¹Columbia University, USA, ²Columbia University Medical Center, USA, ³Columbia University College of Physicians & Surgeons, USA

Persons with epilepsy have a 2-6 fold increased risk of fracture. Both low BMD and abnormal microarchitecture are associated with fracture. Therefore, we evaluated areal BMD (aBMD) by DXA, and volumetric BMD (vBMD) and bone microarchitecture by high resolution peripheral QCT (HRpQCT) in 111 persons with epilepsy on various antiepileptic drugs: 39 older men (587), 50 premenopausal (PreM) women (377) and 22 postmenopausal (PM) women (615). Excluded were subjects with bone disease or with illnesses or on medications that affect the skeleton. aBMD was measured by DXA (Hologic QDR 4500) at the spine (LS), total hip (TH), femoral neck (FN), and 1/3 radius (1/3R). vBMD and trabecular (Tb) and cortical (Ct) microarchitecture were measured at the nondominant distal radius (RAD) and tibia (TIB) by XtremeCT (SCANCO Medical AG; voxel size ~82µm). DXA sex-specific Z-scores were compared to reference population normative values provided by Hologic Corp. HR-pQCT sex-specific Z-scores were compared to normative values provided by Boutroy for PreM and PM women and by Chaitou et al. (JBMR, 2010) for older men. DXA Z-scores did not differ from normative values at any site for men (Table). For PM women DXA Z-scores did not differ at LS, TH or FN, but were significantly higher at the 1/3R. For PreM women, FN Z score was below and 1/3R Z score was above normative values, while LS and TH were normal. At the RAD, cross-sectional area (CSA) was low in men and PM women. Total vBMD was normal in all groups, Ct vBMD were high in men and normal in PreM and PM women, and Ct thickness (CtTh) was normal in all. Tb vBMD was low in PreM women, but not PM women or men. There were consistent increases in Tb number (TbN) and decreases in Tb thickness (TbTh) in all groups. At the TIB, CSA was normal in men and PM women and high in PreM women. All groups had low Ct vBMD and CtTh and normal Tb vBMD. As at the RAD, TbN was higher and TbTh lower in all groups. In summary, compared to age-matched and gender norms, aBMD by DXA was low only at the FN and only in premenopausal women. HR-pQCT differences were most marked and consistent at the Tibia where persons with epilepsy had smaller bones with thinner, less dense cortices. Tb vBMD was normal, likely because higher TbN compensated for lower TbTh higher TbTh. These differences in bone quality, smaller bones with thinner, less dense cortices and thinner trabeculae, could contribute to increased fracture risk.

Estimation of Cortical Density with Clinical CT. Graham Treece^{*}, Kenneth Poole, Andrew Gee. University of Cambridge, United Kingdom

There is growing evidence that focal thinning of cortical bone in the proximal femur is critical in determining resistance to fracture. Accurately assessing cortices thinner than 2.5 mm in clinical MDCT is challenging, since they are corrupted by imaging blur. We recently proposed a model-fitting technique for accurate estimation down to 0.3 mm (Treece et al. Medical Image Analysis, 2010). The technique assumes a patient-specific, fixed value for true cortical density, estimated from CT data of thick cortices below the lesser trochanter. Using this technique, we have shown, for 65 osteoporotic women, precisely where in the proximal femur new bone is laid down following treatment with hPTH(1-34) (Poole et al. Plos One, 2011). We now aim to provide an improved density estimate which is more representative of the entire proximal femur, is available from incomplete CT data or patients with thin cortices, and has associated confidence intervals.

If the true cortical density is substantially constant, and the imaging blur is Gaussian, we can derive the expected distribution of peak cortical density with thickness (solid line in figure 1), which depends only on the imaging blur, true cortical

density, and background density. We sample the peak cortical density, measured in clinical CT data, at many points over the proximal femur, and compare this with the expected distribution. Modelled blur, cortical and background density are adjusted to minimise the difference between measured and expected distributions, leading to mean and 95% confidence limits for the true cortical density. Figure 1 shows typical outcomes from three different subjects in the hPTH study. The measured and expected distribution are in close agreement in figure 1(a). Figure 1(b) is a more difficult case where the model accurately predicts a true cortical density which is not apparent in the measured data. In figure 1(c), the cortex is very thin and the density estimate is hence less reliable: this is reflected in the increased confidence limits of 25 HU. Nevertheless, using the new technique on the hPTH data, the worst case confidence limits were only 38 HU, and all cases were deemed to give acceptable estimates of cortical density. The resulting baseline population cortical bone mineral density was 1185.1 67.9 mg/cm³ decreasing to 1133.6 78.1 mg/cm³ ($p < 0.001$) after 24 months' treatment.

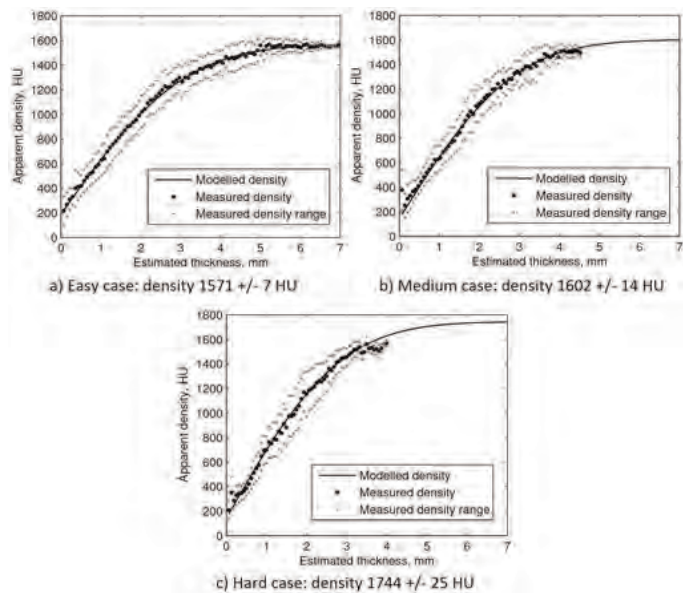

Figure 1: The distribution of cortical density against thickness for typical clinical MDCT data.

Low BMD Is not Necessarily a Measure of Bone Fragility; The Structural Basis of Areal Bone Mineral Density. Ali Ghasem-Zadeh*, Thuy Vu, Qingju Wang, Roger Zebaze, Ego Seeman. Austin Health, University of Melbourne, Australia

Background Bone mineral density (BMD) is commonly used in clinical and research to identify individuals at risk for fracture. However, it lacks sensitivity and specificity, in part, because the BMD measurement is 'blind' to the spatial organization of bone. In an attempt to quantify the material and structural basis of a BMD measurement, whether 'low' or 'high' we examined bone microarchitecture and hypothesized that, as 80% of bone is cortical at peripheral sites, the variance in BMD will mostly be explained by variance in cortical structure.

Material & Methods We studied 66 male mean age 41 yr and 99 women mean age 58 yr (range 18 to 85). High resolution peripheral computed tomography (HRpQCT) images were obtained at the distal radius and total volumetric bone mineral density (TbBMD), cortical vBMD (Ct vBMD) and area (Ct Area), trabecular vBMD (TrvBMD) and area (TrArea) and total cross sectional area (T-CSA) were measured using the manufacturer's software. BMD was measured at the same location using Lunar Prodigy.

Results In males, only Ct Area, T-CSA and TrvBMD were independent predictors of BMD explaining 93.6% of its variance. Ct Area was the best determinant of BMD explaining 80.8% of its variance whereas T-CSA and TrvBMD explained respectively 11.6% and 1.2% of the variance. In females, only Ct Area, and TrvBMD were independent predictors of BMD explaining 85.4% of its variance. Ct Area was the best determinant of BMD explaining 72% followed by TrvBMD which explained 13.4% of the variance in BMD. In both sexes, Ct vBMD correlated with BMD in univariate model but not after accounting for Ct Area.

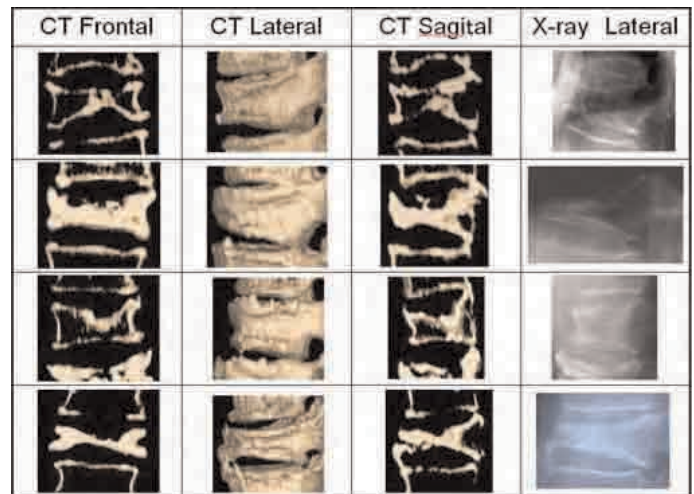

Conclusion At peripheral sites such as the distal radius, BMD largely reflects cortical area but fails to identify persons with normal BMD at risk for fracture risk due to architectural deterioration or persons with osteoporosis by BMD with normal microarchitecture. Understanding bone fragility requires the study of bone morphology.

MO0335

The Involvement of Two Forces in Osteoporotic Vertebral Fracture - Pressures of the vertebral rim or disk and their involvement in fish shaped and wedge type fractures. Hitoshi Noguchi¹, Sumiaki Okamoto², Sumitada Okamoto³, Hirovuki Suzuki⁴, Akira Itabashi⁵. ¹Noguchi hospital, Japan, ²Okamoto Clinic SORF, Japan, ³KS Okamoto Naika, Japan, ⁴Suzuki Orthodontic Clinic, Japan, ⁵SCBR, Japan

The forces that cause the vertebral fractures have seldom been discussed. The vertebral endplates neither shrink by themselves to concave shape nor are compressed by divine powers. The question is, why the fracture lines of fish-shaped vertebra are uneven, while those of wedge-type vertebra are straight. The mechanism remains uncertain due to lack of proper reading of the concave fracture lines. TV-X ray fluoroscopy was performed in 136 normal volunteers and 2,740 female osteoporosis patients. Also we created computerized 3-D renderings of 1,540 cases by Helical CT (Asteion Super 4 edition Toshiba). To make the X-ray pass through straight on the vertebral bodies, we asked the patients in an upright position to adjust their postures so that the distal and proximal edges of each vertebra would coincide. In 37 young female volunteers, the mean Central to Posterior height ratios coincide with previously reported autopsy data. When observed in 3-D CT renderings, the C/P ratio is smaller than the Anterior to Posterior height ratio in 99% of the "wedge shaped" fractures observed. Conventional diagnostic criteria for a fish shaped fracture is a C/P ratio of 80%, and the criteria for a wedge shaped fracture is a A/P ratio of 75%. But in reality, the centers of the vertebral endplates are far more compressed than the anterior vertebral rim in almost every case. Consequently, the C/P ratio has a higher recognizing power for wedge fractures than the A/P ratio. The nucleus pulposus of intervertebral disc bears the burden of vertebra, and that pressure concaves the center of the vertebral body terminal endplate. When the vertebral body become deformed into fish-shaped vertebra, fracture lines are rarely smooth but consist of the mixture of many perforated indentations, or Schmorl nodes, while the vertebral rim lines remain intact which eventually come closer together. At that time the fulcrum, posterior intervertebral joints, which have remained strong, cause enough stress to crush the anterior part of the vertebra. Eventually, the pressure of rim against rim forces the vertebra into a straightly lined "wedge type" change. None of the textbooks or guidelines has so far made any mention of this simple observation due to the fact that most of the diagnoses are based on outdated or inadequate X-ray images in which the compression of the fractured endplates cannot be observed, or due to the incompetence of the radiologist who failed to acknowledge it.

Wedge shaped vertebra almost always present terminal plate indentations

Ultrashort TE Imaging and Bi-Component Analysis of Bound and Free Water Components in Bovine Cortical Bone - Validation with Sequential Drying. Reni Biswas*, Won Bae, Eric Diaz, Christine Chung, Graeme Bydder, Jiang Du. University of California, San Diego, USA

Purpose: To evaluate the bound and free water components in bovine cortical bone as well as changes to these two components after sequential air-drying at room temperature using Ultrashort TE (UTE) imaging.

Methods: Ten bovine fragments with approximate dimensions of 20 mm long x 8 mm wide x 4 mm thick were cut from fresh mature bovine femur obtained from a local slaughterhouse, and imaged using a UTE sequence with a minimum nominal TE of 8 μ s on a clinical 3T MR scanner. UTE T2* images were repeatedly acquired after every one percent (in weight) bone water loss after air-drying at room temperature using the following imaging protocol: TR = 200 ms, FOV = 4 cm, matrix = 256 x 256, flip angle = 10, short hard pulse (32 μ s in duration), bandwidth = 62.5 kHz, 20 TEs ranging from 8 μ s to 10 ms. The drying process was terminated after three days. In-house bi-

component fitting software was used to calculate $T2^*$ and fractions of the shorter $T2^*$ (bound water) and longer $T2^*$ (free water) components. The changes in $T2^*$ as well as the fractions of bound and free water components were displayed as a function of drying time. For one sample, UTE imaging with two TRs of 100 ms and 1000 ms were also performed to investigate the effect of T1 on bi-component analysis. Free water is lost faster than bound water at room temperature.

Results: Excellent bi-component fitting was achieved for all 10 bovine cortical bone samples. Figure 1 shows typical UTE imaging and bi-component analysis of a wet bovine bone sample and the same sample after air-drying for three days. At room temperature wet bone had a 75-80% bound water, and a 20-25% free water. The free water component gradually decreased to near zero after three days of air-drying. Both $T2^*$ and the fractions of bound and free water components remained unchanged with two different TRs of 100 ms and 1000 ms.

Conclusion: The results show that UTE imaging with bi-component analysis can be used to estimate bound and free water in cortical bone, and chemical exchange between bound and free water is much slower than T1 but much faster than $T2^*$. Modeling T1 with a single component and $T2^*$ with bi-component appears appropriate.

Clinical Relevance UTE imaging and bi-component analysis can quantify the free and bound water components in cortical bone. The free water component may be used to estimate bone porosity, and bound water component may be used to evaluate collagen matrix.

Body Composition and Sex Hormones Differently Influence Quantitative Ultrasound Parameters at Calcaneus and at Phalanges in Elderly Women. Stefano Gonnelli*, Carla Caffarelli, Loredana Tanzilli, Daniela Merlotti, Luigi Gennari, Barbara Lucani, Stella Campagna, Beatrice Franci, Ranuccio Nuti. University of Siena, Italy

Quantitative ultrasound (QUS) has been applied to the assessment of bone status for almost two decades. A crucial point for a larger use of QUS in the evaluation of bone status and the assessment of fragility fracture risk is represented by the necessary definition of whether the main determinants of BMD in postmenopausal women could have a similar or a different impact on QUS parameters.

This study aimed to evaluate the influence of body composition parameters, Vitamin D and sex hormones on QUS parameters.

In 897 postmenopausal women (64.1 ± 6.6 yrs) we measured QUS at calcaneus (Stiffness) by Achilles-GE and at phalanges (amplitude dependent speed of sound [AD-SoS], bone transmission time [BTT] and ultrasound bone profile index [UBPI]) by Bone Profiler-IGEA. In all we measured fat mass (FM), lean mass (LM), android and gynoid fat by DXA. In all subjects we also assessed serum testosterone (T), estradiol (E), sex-hormone binding globulin (SHBG), free estrogen index (FEI), free androgen index (FAI), 25-hydroxyvitamin D (25OHD), and bone alkaline phosphatase (B-ALP).

No significant relationships were found between T and QUS. Estradiol was significantly correlated with Stiffness ($r=0.11$; $p<0.05$), AD-SoS ($r=0.09$; $p<0.05$) and BTT ($r=0.12$; $p<0.05$), whereas FEI showed a significant correlation with all QUS parameters. By grouping the patients according to FEI quartiles, we found that women in the lowest FEI quartile had the lowest mean QUS values and those in the highest quartile had the highest mean QUS values. This trend was statistically significant for BTT ($p=0.014$), AD-SoS ($p=0.043$) and Stiffness ($p=0.048$). BMI and LM were positively correlated with Stiffness ($r=0.14$; $p<0.01$ and $r=0.17$; $p<0.01$ respectively), whereas BMI and FM showed negative correlations with AD-SoS, BTT and UBPI. 25OHD showed positive relationships ($p<0.05$) with Stiffness and AD-SoS. In multivariate models after adjusting for all confounders LM remained independently associated with Stiffness whereas only age and E were significant

predictors of BTT. AD-SoS was negatively associated with FM and B-ALP, but positively with E and 25OHD.

In postmenopausal women QUS parameters at calcaneus and at phalanges are significantly, but diversely, influenced by body composition, sex hormones, 25OHD and bone turnover markers. This finding may increase the potential of QUS in the evaluation of bone status.

MO0338

Correlation between QUS of Phalanx and DXA in Assessment of Bone Structure in Hemodialysed Patients. Zohreh Hamidi*, Dr. Sima Maziar*, Dr. Mitra Mahdavi-Mazdeh*, Dr. Abbas Ali Keshtkar*, Dr. Ghassan Maalouf*, Dr. Bagher Larijani*. ¹Endocrinology & Metabolism Research Center of Tehran University of Medical Sci, Iran, ²Tehran University of Medical Sciences, Iran, ³St George University Hospital, Lebanon

Many hemodialysing patients, have reduced BMD. Dual X-ray absorptiometry (DXA), standard method for assessing BMD, is not always available. So this study compares the quantitative ultrasound (QUS) of phalanx (an inexpensive, mobile, and radiation-free method) with DXA in detecting bone changes in such patients.

In 64 patients, axial BMD measured by a GE-Lunar DXA device (DPX-MD) and a DBM-Sonic 1200 device used for QUS of phalanx.

Osteoporosis found in 31.3% of patients, Using DXA and in 28.1% of them, using QUS. Using ROC curve, sensitivities of T-score ≤ -2.5 of phalanx for diagnosing of osteoporosis in neck and total of hip and L2-L4 were respectively 37.5% and 50% and 80% and specificities were respectively 75% and 77% and 76%. Area under curve for neck, total and spine regions were 0.692 (Pvalue=0.022), 0.701 (Pvalue=0.031), 0.809 (Pvalue=0.023), respectively.

It seems QUS of phalanx can be recommended for screening osteoporosis among hemodialysed patients.

MO0339

Novel Density Index Method for Osteoporosis Diagnostics at Primary Healthcare. Juha Toivras*, Janne Karjalainen*, Ossi Riekkinen*, Heikki Kroger*, Jukka Jurvelin*. ¹Kuopio University Hospital, Finland, ²University of Eastern Finland, Finland

Osteoporosis is diagnosed using the axial DXA technique. However, the DXA is a X-ray method that is non-portable, uses ionizing radiation and has significant costs. Therefore, it is not suitable for primary healthcare level. Today, there are 200 million osteoporotic patients worldwide and most of them are not diagnosed until several fractures have occurred (annual cost 36 billion/EU). It is estimated that over 75% of osteoporotic patients are not diagnosed nor receive treatment for their pathological condition. At the moment, the peripheral techniques, e.g., heel ultrasound or heel DXA, which are designed for small practices, predict only moderately the results of current diagnostic standard, axial DXA ($r = 0.2 - 0.6$). Therefore, these techniques alone are not suitable for diagnosis of osteoporosis. It is approximated that 40-60% of patients screened with the peripheral techniques need an additional axial DXA measurement.

In this study, a prototype of multi-site pulse-echo (PE) ultrasound method combined with subject characteristics (i.e. density index, DI, patent pending) is proposed for osteoporosis diagnostics. Forty elderly (74 ± 3 years) women were examined *in vivo* using PE ultrasound (at 2.25 MHz) to measure cortical bone thickness in proximal and distal tibia. Further, bone mineral density in the femoral neck (BMD_{neck}) was determined by axial DXA. In addition, the DI and BMD_{neck} were inserted into FRAX® (World Health Organization fracture risk assessment tool) along with the subject questionnaire to obtain treatment proposals (available for UK population in FRAX).

Cortical bone thickness at distal and proximal tibia combined with age and weight of the subject (DI), provided a significant estimate of BMD_{neck} ($r = 0.84$, $p = 0.001$, $n = 40$). The FRAX® with DI indicated the same treatment proposal as the FRAX® with BMD_{neck} at the sensitivity and specificity of 82% and 90%, respectively. In addition, provided that FRAX® treatment proposals were calculated first using body mass index only and then, if needed, with BMD_{neck} (60% of patients) or DI, the sensitivity and specificity for treatment proposals were 100% and 89%, respectively.

Due to high correlation between the DI and BMD_{neck} and high agreement for treatment proposals using FRAX®, only few subjects would require additional axial DXA measurements. This result is encouraging and suggests that DI may improve significantly the accessibility of osteoporosis diagnostics.

Bone Mineral Density Does Not Differ Between Ethnic Groups in Preschool Aged Children Attending Daycares. Thu Trang Pham*, Sarah Finch, Sandra Dell'Elce, Sonia Jean-Philippe, Tom Hazell, Sherry Agellon, Celia Rodd, Catherine Vanstone, Hope Weiler. McGill University, Canada

The Canadian national surveillance data from 2007-2009 raises concerns that non-white individuals, due to their darker skin-pigmentation, have lower vitamin D status which is associated with lower bone mineral density (BMD). Differences have been reported for vitamin D status and BMD between ethnicities and immigration status in adolescents and adults.

The objective of this study is to determine whether BMD in young children is related to darker skin pigmentation, ethnicity and immigration status.

A cross-sectional study was conducted with 287 children (boys=161, girls=126). Sampling was done in randomly selected daycares in Montreal regions between June and December 2010. Skin colour was measured using a spectrophotometer (CM-700d/600d, Konica Minolta, Ramsey, NJ, USA). Individual typological angle (ITA) was calculated with the L* and b* values given by spectrophotometer. Forearm BMD was measured using a peripheral bone densitometer (PIXI, GE Lunar, USA). Ethnicity and immigration status were reported by parents. Capillary blood was sampled to measure plasma total 25(OH)D using a chemiluminescent immunoassay (Liaison, Diasorin, ON, Canada). Data was statistically analyzed using Pearson's correlations with log transformations where applicable. Differences in ethnicity, immigration status, plasma 25(OH)D and BMD were analysed by ANOVA. Significance was set at $p < 0.05$.

Mean age was 3.61.0 y; height for age Z-score, 0.01.03; weight for age Z-score, 0.360.92 and BMI for age Z-score, 0.780.88. Plasma 25(OH)D <75 nmol/L were seen in 47% of children. After accounting for age and sex, ITA was weakly correlated with plasma 25(OH)D ($R=0.18$, $P=0.002$), but not with BMD ($R=-0.06$, $P=0.296$). Compared to white children, 25(OH)D was lower in Black ($P=0.05$) and higher in Arab ($P=0.04$) children whereas BMD was not different (Table 1). BMD ($P=0.187$) and 25(OH)D ($P=0.822$) did not differ by immigration status. Although not significant, there was an observed trend of lower BMD in immigrant ($\mu=0.382 \text{ g/cm}^2$) compared to non-immigrant children ($\mu=0.411 \text{ g/cm}^2$).

This study is on-going and a final sample size of 500 is anticipated. The lower vitamin D status in children with darker pigmentation does not appear to compromise BMD in this age group. Future analyses including dietary assessment will clarify if endogenous synthesis or exogenous intakes underpin the lower vitamin D status. (Supported by the Dairy Farmers of Canada).

MO0341

Circulating Sclerostin Levels in a Cohort of Adolescent and Young Adult Women: Cross-Sectional Associations with Age and Bone Mass. Delia Scholes*¹, Laura Ichikawa², Andrea LaCroix³, Thy Do⁴, Puneet Arora⁵, Susan Ott⁶. ¹Group Health Cooperative/Group Health Research Institute, USA, ²Group Health Research Institute, USA, ³Women's Health Initiative, USA, ⁴Amgen, Inc., USA, ⁵Amgen Inc., USA, ⁶University of Washington Medical Center, USA

Background: Sclerostin has been identified as an important Wnt signaling pathway inhibitor that acts to inhibit bone formation. However, relatively little is known about the role of circulating sclerostin in human biology. Sclerostin serum concentrations in younger populations who are in the process of gaining bone are largely unevaluated. Thus, we assessed circulating sclerostin in a cohort of adolescent and young adult women aged 14-30 years to 1) identify factors associated with circulating sclerostin levels and 2) examine the association between sclerostin and bone measures (BMD, BMC).

Methods: Serum samples were obtained from 300 women who were part of a large cohort recruited in a defined HMO population. Serum sclerostin levels (in pg/mL) were measured using an electrochemiluminescence sandwich assay (%CV ≤ 15%; LLOQ 50 pg/mL). BMD and BMC were measured at the hip, spine, and whole body using DXA (Hologic Delphi).

Results: Mean sclerostin (+SEM) levels were 254± 8 pg/mL for adolescents ages 14-19 years, 208±13 for ages 20-23, and 261±11 for ages 24-30 ($p=0.004$ for between-group differences). An examination of sclerostin by age revealed a U-shaped pattern, with sclerostin trending downward at ages 14-20, and upward trends at ages 24-30. A quadratic term was significant ($\Delta^2=1.06$, $p=0.0012$) (Figure). Fracture risk factors including race/ethnicity, current smoking, BMI, physical activity score, calcium intake, gravidity and oral contraceptive use were not associated with sclerostin level, either by age group or overall after age adjustment. An examination of the association between sclerostin and BMD and BMC found significant positive correlations at the spine for BMD and BMC and whole body BMD in 24-30 year-old women, but not in younger women (Table).

Conclusion: In this cohort of young women, age was the factor most strongly associated with circulating sclerostin levels, with lower levels at ages 19-23 years and higher values on either side (ages 14-18 and 24-30 years). Circulating sclerostin was positively correlated with bone measures (BMD, BMC) at the spine and whole body in women ages 24-30 years, showing higher values at ages when bone growth is slowing.

Table. Correlation of baseline circulating sclerostin and bone measures, by age group

	Age 14-19		Age 20-23		Age 24-30	
	BMD	BMC	BMD	BMC	BMD	BMC
Total hip	0.001	-0.02	0.10	0.03	0.18	0.16
Spine	0.07	0.09	0.08	0.11	0.31*	0.32*
Whole body	0.02	0.02	0.16	-0.01	0.22*	0.19

BMD = Bone mineral density, BMC = Bone mineral content
* $p < 0.05$

MO0342

Effects of Age, Gender and Body Composition on Bone Mineral Density and Vitamin D metabolism. Shuanhu Zhou, Nithya Setty, Julie Glowacki, Meryl Leboff*. Brigham & Women's Hospital, USA

Low vitamin D levels have been reported in older adults and in obese individuals. We previously found that expression of vitamin D hydroxylases in human marrow stromal cells (hMSCs) are influenced by the vitamin D status of the individual from whom the hMSCs were obtained (Endocrinology 151:14, 2010). Because little is known about metabolism of vitamin D in obese subjects, we tested the hypotheses that age, gender, and body composition (body mass index, BMI, and fat mass index, FMI) influence bone mineral density (BMD) and vitamin D metabolism in hMSCs. Body composition including BMD and FMI ($\text{FM}/\text{height}^2$) were measured by DXA (Hologic, Discovery). Discarded femoral heads were obtained from 54 consented subjects whose 25OHD was obtained prior to hip surgery. Human MSCs were obtained by expansion of adherent low-density marrow mononuclear cells; RNA was extracted for measurement of constitutive gene expression.

First, among all consented subjects (32 women and 22 men), FN T-scores, BMI and FMI were inversely correlated with age; and FN T-scores were correlated with BMI and FMI. For the women, FN T-scores were correlated with BMI ($r=0.73$, $p<0.0001$) and FMI ($r=0.58$, $p=0.0028$), and inversely correlated with age ($r=-0.60$, $p=0.0009$). For the men, FN T-scores were not significantly correlated with BMI or

age, except for a trend correlation with FMI ($r=0.53$, $p=0.055$). Second, we assessed the relationship between vitamin D enzymes in hMSCs and clinical characteristics of the individual from whom the hMSCs were obtained. Constitutive expression of CYP27A1/25OHDase in hMSCs was inversely correlated with serum 25OHD ($n=26$, $r=-0.42$, $p=0.031$). Obese women ($BMI>30 \text{ kg/m}^2$) had lower serum 25OHD levels (16.04 ng/ml) than their non-obese counterparts (30.44 ng/ml) ($p=0.037$, unpaired t-test); ages of obese (656) and non-obese (683) women were similar. Cells from obese women ($n=5$), but not men, expressed higher CYP27A1 levels than non-obese women ($n=7$) ($p=0.02$). These preliminary data suggest that obese females may have a better response to vitamin D₃ than non-obese females; this may be due to the higher CYP27A1 in their bone marrow cells possibly as a result of lower serum 25OHD. In sum, our data in female subjects indicate that low BMD is associated with advanced age, low BMI or FMI. We speculate that increased expression of CYP27A1/25OHDase in marrow stromal cells in obese women may potentially contribute to autocrine actions of vitamin D on bone.

Disclosures: Meryl Leboff, None.

MO0343

Femoral Volumetric Bone Density and Dimensions in Relation to Serum 25-Hydroxy Vitamin D Levels Among Elderly Men. Elizabeth Martin^{*1}, Elizabeth Haney¹, Jackie Shannon¹, Jane Cauley², Kristine Ensrud¹, Joseph Zmuda², Eric Orwoll¹, Lynn Marshall¹. ¹Oregon Health & Science University, USA, ²University of Pittsburgh Graduate School of Public Health, USA, ³Minneapolis VA Medical Center / University of Minnesota, USA

Greater femoral neck BMD estimated with DXA is associated with higher serum 25-hydroxyvitamin D (25(OH)D) levels. However, the associations of femoral neck bone density distribution in cortical and trabecular compartments or of bone size with serum 25(OH)D are not well understood. We evaluated variation in femoral neck volumetric BMD (vBMD) and femoral neck size with serum 25(OH)D in men ages ≥ 65 years from the Osteoporotic Fractures in Men Study (MrOS). Baseline fasting serum 25(OH)D levels were measured by liquid chromatography/mass spectrometry (LC/MS) assays in a large randomly selected sample. Latitude of clinic site was defined as high latitude (40 degrees and higher) or low latitude (less than 40 degrees). Season of visit was divided into winter (January-March), spring (April-June), summer (July-September) and fall (October-December). Femoral neck measures obtained from quantitative computed tomography (QCT) were integral, cortical and trabecular vBMD; cross-sectional area; and integral, cortical, and percent cortical volume. QCT image processing was completed centrally without knowledge of 25(OH)D status. The analytic cohort was comprised of 888 men with both serum 25(OH)D and femoral neck measures. Multivariable linear regression models with adjustments for age, race, BMI, height, latitude of clinic site and season of visit were used to estimate adjusted means of femoral neck measures and their 95% confidence limits (CI) within quartiles of vitamin D, with quartile 4 (highest) as the referent. Tests of linear trend were performed for each femoral neck measure across increasing serum 25(OH)D concentrations. On average, femoral neck vBMD measures all increased with increasing 25(OH)D concentration (Table). Overall femoral neck size, as represented by cross-sectional area and integral volume did not vary according to serum 25(OH)D concentration. However, both cortical volume and cortical volume as a percent of integral volume increased significantly with increasing 25(OH)D concentration. We observed positive associations of femoral neck cortical and trabecular vBMD and percent cortical bone volume to serum 25(OH)D among elderly men. These data suggest that higher serum vitamin D levels may inhibit endosteal resorption.

Table: Distribution of QCT measurements of the femoral neck within Vitamin D quartiles (N=888)

	25(OH)D Quartile				p-trend
	Q1 [11.1-19.7 ng/ml]	Q2 [19.7-24.4 ng/ml]	Q3 [24.4-29.6 ng/ml]	Q4 [29.7-55.8 ng/ml]

Occurrences of Falls in Elderly People within the Domicile. Bianca Segantin¹, Fabiana Fonseca^{*2}, Manuela Santos¹, Thais Sabbag¹, Ana Elisa Rosa¹, Ursula Karsch¹, Roberto Queiroz¹. ¹PUC - SP, Brazil, ²PUC Sp, Brazil

The falls are the leading cause of accidents in the elderly and in most cases occur in the home, being responsible for 70% of accidental deaths in this group of citizens and the 6th leading cause of death in the elderly (Edelberg, 2001). This study is based on

field research, the data were collected with semi structured interview on 40 patients aged from 60s, interned in orthopedics Hospital public server Sao Paulo State, Brazil. In the year 2010 with the goal of revealing the location of fall of elderly hospitalized with fracture of femur, and therefore in need of surgical support. 23% of patients surveyed suffered the fall outside his domicile (bus, walk, work, etc). And 77% suffered the fall in his home. The local prevalence of falls in the home for the elderly was fourth with 32%, followed by 12%, 10%, 10% in ladder lounge, 5% in the bathroom, 2% on laundry, 2% in the service area in the yard, 2% and 2% by nearest domestic pet. Which begs the need for environmental adaptation and permanent education for care not to suffer falls.

Disclosures: Fabiana Fonseca, None.

MO0345

Reduction in Hip Bone Mass in Elderly Women Is More Related to Loss of Cortical Bone Than Trabecular Bone. ZhiFeng Yu¹, Keenan Brown², Ben Khoo³, Kun Zhu⁴, Marie Pollock⁵, Colin Binns⁶, Deborah Kerr⁶, Vicky Solah⁶, Amanda Devine⁷, Richard Prince^{*5}. ¹School of Medicine, University of Western Australia, Australia, ²Mindways Software, USA, ³Western Australian Health Department, Australia, ⁴University of Western Australia, Sir Charles Gairdner Hospital, Australia, ⁵Sir Charles Gairdner Hospital, Australia, ⁶Curtin University, Australia, ⁷Edith Cowan University, Australia

Quantitative computed tomography (QCT) is able to discriminate cortical and trabecular bone compartments. This study compares the difference in cortical and trabecular bone compartments over 2 years in elderly women.

135 females mean age 74.1 (SD 2.6) were recruited from the general population to participate in a 2 year study of protein supplementation. At baseline height was 160.2 (SD 5.9) cm and weight 68.4 (SD 10.7) kg. Subjects were scanned on a Phillips Brilliance 64 MDCT with 1mm in plane resolution. The image was analysed with Mindways CTX Hip software. Segmentation of cortical and trabecular compartments used a 300 mg/cm³ threshold.

Cortical mass and volume decreased but density remained constant. Trabecular mass decreased but without significant reduction in volume or density.

Reduction in total hip density obscures a substantial loss of cortical bone volume but not density in aging with relative preservation of remaining trabecular bone.

Disclosures: Richard Prince, None.

Risk Factors for Osteoporosis in Greek Male Population. George Trovas^{*}. Greece

Introduction: Although not as common as in women, osteoporosis remains a significant health care problem in men. Data concerning risk factors for low Bone Mineral Density (BMD) and fractures are lacking for Greek male population. The objective of the current cross-sectional study was to determine the factors associated with BMD in Greek men.

Methods: A total of 1084 men (age range 50-93 years) from 92 sites all over Greece, participated in the present study. Demographic, medical, family history and life style information were obtained by interview and physical examination and anthropometric data by examination. Spine and hip BMD was measured using dual-energy x-ray absorptiometry. Univariate, multivariate and logistic regression analyses were performed.

Results: The prevalence of osteoporosis and osteopenia were 48,1% and 27,9% respectively. A number of nutritional, life style characteristics and medical conditions were associated with BMD. The multiple regression analysis found that age, Rheumatoid arthritis (RA), Chronic Obstructive Pulmonary Disease (COPD) and family history of osteoporosis were independently associated to the osteoporosis status and on the other hand BMI and exercise until 30years of age, were associated with higher BMD.

Conclusions: Aging, Rheumatoid Arthritis, Chronic Obstructive Pulmonary Disease and family history of osteoporosis are the main risks factors associated with osteoporosis in a population of Greek adult men.

Disclosures: George Trovas, None.

MO0347

The Association of Bone Marrow Fat with Areal and Volumetric Bone Mineral Density Differs by Diabetic Status. Yahtyng Sheu^{*1}, Francesca Amati², Ann Schwartz³, Xiaojuan Li³, Christine Lee⁴, Christopher Gordon⁵, Bret Goodpaster⁶, Robert Boudreau⁶, Joseph Zmuda¹, Jane Cauley¹. ¹University of Pittsburgh Graduate School of Public Health, USA, ²University of Lausanne, Switzerland, ³University of California, San Francisco, USA, ⁴OHSU, USA, ⁵McMaster University, Canada, ⁶University of Pittsburgh, USA

Osteoblasts and adipocytes share a common precursor cell. During normal aging process, differentiation of these precursor cells in the bone marrow compartment is thought to favor adipogenesis. Recent small studies have shown a negative association between bone marrow fat (BMF) and areal BMD (aBMD) in both men and women. However, little is known about this relationship among older adults and whether results are similar for volumetric BMD (vBMD). We recruited 156 men aged 74-96 years old from the Osteoporotic Fracture in Men study to test whether BMF is inversely correlated with both aBMD and vBMD. All men underwent measures of spine BMF using magnetic resonance spectroscopy, spine and hip aBMD by dual-energy x-ray absorptiometry, and cortical (CRT) and trabecular (TRAB) vBMD at the radius and tibia by peripheral quantitative computed tomography (pQCT). BMF was expressed as lipid to "lipid + water" ratio (%). Pearson correlation and multivariable linear regression were used to examine our hypothesis. All analyses were adjusted for age, weight and height. The mean BMF was 55.6 % (ranged 23.5%-76.4%). We observed no significant correlation between BMF and aBMD at both hip and spine. For vBMD, the correlation was only significant for CRT vBMD at the tibia 66% site. However, the prevalence of diabetes (DM) was significantly higher in higher quartile of BMF (lowest: 18% vs. highest: 41%). Thus, we stratified our results by DM status: the correlations were significant for total hip aBMD (DM group) and CRT vBMD at the tibia 66% site (non-DM group). Moreover, one standard deviation (SD) increase in BMF was associated with 5.8% lower hip aBMD in DM group and 1.2 % lower CRT vBMD at the tibia 66% site for the non-DM group. We found no association between BMF and aBMD until analyses were stratified by DM status. Using pQCT, our study demonstrates for the first time a negative correlation between BMF and cortical, but not trabecular, vBMD. In addition, our study is also the first to identify differences in the relation of BMF and BMD by DM status. Further investigation on the role of DM in the BMF and bone connection may provide a better understanding of the high fracture rates among DM individuals despite their high BMD.

Table: Correlation coefficients between BMF and BMD in older men

	All	DM (n=38)	Non-DM (n=118)

MO0348

Are Plasma Concentrations of B Vitamins or Homocysteine Associated with Bone Volumetric Density and Size? The Framingham Study. Robert McLean^{*1}, Shivani Sahni², Paul Jacques³, Jacob Selhub⁴, Kerry Broe⁵, Mary Bouxsein⁶, Douglas Kiel⁷. ¹Hebrew SeniorLife, Harvard Medical School, USA, ²Hebrew SeniorLife, Institute for Aging Research, USA, ³Jean Mayer U.S. Dept of Agriculture Human Nutrition Research Center on Aging at Tufts University, USA, ⁴Jean Mayer U.S. Dept of Agriculture Human Nutrition Research Center on Aging at Tufts University, USA, ⁵Hebrew Senior Life, USA, ⁶Beth Israel Deaconess Medical Center, USA

Decreased bone mineral density (BMD) has been hypothesized as one potential mechanism linking low B vitamin status and related elevated homocysteine (Hcy) with increased fracture risk, yet blood concentrations of B vitamins and Hcy have been inconsistently associated with DXA-based BMD across population-based studies. Areal BMD, however, does not provide information on volumetric and compartment specific bone density or bone geometry, which are important determinants of bone strength. We thus determined the cross-sectional associations of plasma concentrations of folate, vitamin B12, vitamin B6 and Hcy with QCT measures of spinal bone density among community-dwelling middle-aged and older adults. We hypothesized that plasma B vitamin concentrations would be positively associated, and Hcy concentrations negatively associated, with volumetric BMD. Participants included 615 men and 665 women from the Framingham Offspring cohort who had plasma B vitamins and Hcy measured in 1998-2001 and QCT scans of the lumbar spine in 2002-06. Plasma folate (nmol/L), vitamin B12 (pmol/L), vitamin B6 (nmol/L) and Hcy (μmol/L) were measured from fasting blood samples. Trabecular volumetric BMD (Tb.vBMD, g/cm³), integral volumetric BMD (Int.vBMD, g/cm³) and cross-sectional

area (CSA, cm²) at L3 were measured from QCT scans using custom software. Separately for men and women, multivariable linear regression determined the associations (β coefficient) of log-transformed B vitamins and Hcy with each bone measure, adjusting for age (yrs), height (in), BMI (kg/m²), smoking (y/n), alcohol (oz/wk), osteoporosis medication use (y/n), and estrogen use (y/n) and menopause status (y/n) in women. Mean age was 64 yrs (range 41-86). B vitamins and Hcy were not associated with QCT measures in men (Table). In women, folate and vitamin B6 were not associated with QCT measures. Though vitamin B12 was not associated with volumetric BMD, there was a borderline statistically significant positive association with CSA (β=0.271, P=0.04). Hcy in women tended to be positively associated with Int.vBMD (β=0.010, P=0.05), but not with Tb.vBMD or CSA. Our results suggest that plasma B vitamins and Hcy are not associated with volumetric bone density and geometry of the lumbar spine. Longitudinal studies that include additional bone sites are needed to confirm our results, and alternate mechanisms linking B vitamins and Hcy to fracture risk should be explored.

QCT measure	Folate (nmol/L)		Vitamin B12 (pmol/L)		Vitamin B6 (nmol/L)		Hcy (μmol/L)

Distribution and Determinants of Serum 25-hydroxyvitamin D (25[OH]D) Levels and Change in Serum 25[OH]D Levels in Older Women: Data from the Study of Osteoporotic Fractures. Marc Hochberg^{*1}, Li-Yung Lui², Jane Cauley³, Kristine Ensrud⁴, Lisa Fredman⁵, Teresa Hillier⁶, Erin LeBlanc⁷, Steven Cummings⁸. ¹University of Maryland School of Medicine, USA, ²California Pacific Medical Center Research Institute, USA, ³University of Pittsburgh Graduate School of Public Health, USA, ⁴Minneapolis VA Medical Center / University of Minnesota, USA, ⁵Boston University School of Public Health, USA, ⁶Kaiser Center for Health Research, USA, ⁷Oregon Health Sciences University School of Medicine, USA, ⁸San Francisco Coordinating Center, USA

Purpose: To examine the distribution and determinants of serum 25-hydroxyvitamin D (25[OH]D) levels and change in serum 25[OH]D levels in older women. **Methods:** Serum 25[OH]D levels were measured using liquid chromatography tandem mass spectroscopy (LC-MS/MS) (ThermoFisher Scientific, Franklin, MA and Applied Biosystems-MDS Sciex, Foster City, CA) at the Mayo Clinic in 1297 randomly selected women who participated in the 6th biannual visit (V6) in the Study of Osteoporotic Fractures (January 1997 to January 1999). The distribution of serum 25[OH] levels was examined and cutpoints were identified at the quartiles. Characteristics of subjects by category of 25[OH]D were compared using analysis of variance for continuous and chi-square tests for categorical data. Multiple linear regression analysis was performed including age, clinic and all variables with P < 0.10 in bivariate analysis. Change in serum 25[OH]D levels since the 4th biannual visit (V4) (March 1992 to December 1994) was calculated for the 1044 white women with longitudinal data. Characteristics of subjects according to tertiles were compared as above and multiple logistic regression analysis was performed. Results: The 1297 women had a mean (SD) age of 79.5 (4.6) years and 130 (10%) were African-American; mean (SD) serum 25[OH]D level was 24.4 (10.1) ng/ml (interquartile range: 17, 31). Factors associated with categories of serum 25[OH]D in bivariate analysis are shown in Table 1. Multiple regression analysis showed that Caucasian race, lower body mass index, use of calcium and vitamin D supplements as well as estrogen and thiazide diuretics were all significantly associated with higher 25[OH]D levels. Among 1044 white women with serial data (mean [SD] 4.5 [0.6] years apart), the mean (SD) change in serum 25[OH]D level was 2.0 (9.8) ng/ml (interquartile range: -3.6, 7.0). Factors associated with categories of change in serum 25[OH]D levels in bivariate analysis are shown in Table 2. Multiple regression analysis showed that women who used vitamin D supplements were significantly more likely to have an increase in 25[OH]D levels while those with a history of stroke were significantly more likely to have a decline in 25[OH]D levels. Conclusion: These data demonstrate that older white women have higher adjusted serum 25[OH]D levels than older African-American women, and that use of vitamin D supplements is associated with an increase in serum 25[OH]D levels over time in older white women.

Characteristics of 1297 Women by Category of Serum 25(OH)D Level

Variable	≤ 16 ng/ml N = 327	17-23 ng/ml N = 328	24-30 ng/ml N = 296	≥ 31 ng/ml N = 346	P value
African-American	63 (19.3%)	42 (12.8%)	13 (4.4%)	12 (3.5%)	<0.0001
Calcium use	118 (36.1%)	146 (44.5%)	168 (55.5%)	243 (70.2%)	<0.0001

BAP (p= 0.002). Among non-users, higher dietary alpha-tocopherol intake was associated with lower uNTx/Cr (p=0.001).

Conclusions: Higher serum levels of gamma-tocopherol are associated with increased bone formation among supplement users, while higher intake of alpha-tocopherol was associated with increased bone resorption. This may be because high intake of alpha-tocopherol, due to supplement intake, suppresses serum gamma-tocopherol level. More studies are needed to confirm these findings.

Physical Activity Patterns and Preferences in Women with Low Bone Mass. Carly Skidmore^{*1}, Michel Saccone¹, Nicole Mittmann², Lora Giangregorio¹. ¹University of Waterloo, Canada, ²Sunnybrook Health Sciences Centre, Canada

Objectives: Balance and resistance training can reduce fall risk and positively impact bone density and geometry among persons with low bone mass, whereas there is less evidence that walking can reduce fall risk or influence bone strength. It is not known whether physical activity participation in this population is consistent with current evidence or physical activity guidelines. Further, future research or community programs should consider patient preferences and willingness to pay. The current study characterized physical activity patterns and preferences of women with low bone mass. **Methods:** Women ≥50 years old were recruited from 3 osteoporosis support groups. The Community Healthy Activities Model Program questionnaire was used to characterize physical activity. A Physical Activity Preferences questionnaire developed and pilot tested by our team was used to assess activity preferences and willingness to pay for exercise instruction. **Participant characteristics and outcomes** are summarized using descriptive statistics. **Results:** 54 women (mean [SD] age 73.8 [7.47] years) participated; 39 (72%) and 14 (26%) reported having osteoporosis or osteopenia, respectively. Mean (SD) total frequency and hours per week of moderate intensity weight-bearing or resistance exercise were 5.2 (3.6) times a week and 3.7 (3.2) hours, respectively. Walking was reported most frequently (62% [n=31] engaged in uphill or brisk walking), followed by light (using <5lbs) resistance training, reported by 44% of participants. Only 24% reported resistance training with weight ≥5lbs. Half of the participants reported doing balance exercises. 71% of participants reported moderate intensity weight bearing exercise ≥ 3 times per week, but it dropped to 53% when walking/jogging was removed. 35.2% reported that they prefer a combination of individual and group exercise, with the rest being divided between the two. Many (42.6%) were not interested or not willing to pay for individualized exercise prescription. 68.5% received exercise recommendations from a physician, with walking being the most common recommendation (31.5%). **Conclusions:** Many, but not all of our sample reported regular moderate intensity weight-bearing exercise. Further, participation in interventions for which there is strongest evidence, namely resistance and balance training, are practiced much less frequently. Finally, cost may be a barrier in delivering evidence-based exercise prescription.

Positive Association of Total Dairy and Milk Intake with Bone Mineral Density (BMD): Results from the Framingham Offspring Study. Shivani Sahni^{*1}, Katherine Tucker², Douglas Kiel³, Lien Quach⁴, Virginia Casey⁴, Marian Hannan⁵. ¹Hebrew SeniorLife, Institute for Aging Research, USA, ²Northeastern University, USA, ³Hebrew SeniorLife, USA, ⁴Institute for Aging Research, Hebrew SeniorLife, USA, ⁵HSL Institute for Aging Research & Harvard Medical School, USA

Objective: Health effects of dairy foods may be due to more than a single nutrient. We evaluated the association of intake of milk, yogurt, cheese, cream and total dairy intake (with/without inclusion of cream since cream has high fat content) with bone mineral density (BMD) at the hip [femoral neck (FN), trochanter (TR)] and spine (lumbar spine, LS) in the Framingham Offspring Study.

Methods: 2,733 men and women completed a food frequency questionnaire (FFQ) in 1992-95 or 1995-98 (baseline exam) and a BMD assessment of hip and spine completed in 1996-2001 using dual-energy X-ray absorptiometry. We used linear regression to estimate mean BMD for men and women separately and combined, by quartile/categories of dairy intake (servings/week) with adjustment for age, sex, total energy intake, weight, height, menopause and estrogen use in women alone, calcium supplement use and vitamin D supplement use. Final models simultaneously included dairy items adjusting for each other.

Results: Mean age was 55y (SD: 9.6, range: 26-86) at the baseline exam. In the combined sample of men and women, total dairy (excluding cream and ice cream) was positively associated with hip and spine BMD (Table 1) while total dairy (including cream and ice cream) was associated only with FN and TR but not LS-BMD. Milk intake was associated with hip and spine BMD. However, cream intake tended to be negatively associated with FN but not with other BMD sites. Subjects with high yogurt intake (>4 servings/week) had higher BMD compared to those with no intake. Although not significant, a similar trend was seen for cheese intake. When milk, yogurt, cheese and cream were included simultaneously in the model, milk and high

Effects of Dietary and Serum Alpha-tocopherol versus Serum Gamma-tocopherol Levels on Bone Turnover Markers among US Postmenopausal Women. Maryam Hamidi^{*1}, Paul N Corey², Valerie Tarasuk², Angela Cheung³. ¹University of Toronto/University Health Network-TGH, Can, ²University of Toronto, Canada, ³University Health Network, Canada

Background: Alpha- and gamma-tocopherol are different forms of vitamin E. In vitro and animal studies suggest that gamma-tocopherol may have an anabolic effect on bone, while alpha-tocopherol may have anti-bone resorptive properties. Human studies are limited. We examined the associations between alpha-tocopherol intake (dietary or supplements), serum alpha- and gamma-tocopherol levels and bone turnover markers (BTMs) among postmenopausal women in the United States.

Methods: We used cross-sectional data from the National Health and Nutrition Examination Survey 1999-2002 cycles. We included 518 postmenopausal women aged ≥ 45 years who were not taking steroids, estrogen, osteoporosis treatment medications; were free from kidney and liver disease, cancer, rheumatoid arthritis; and were fasting > 9 hours prior to examination. Data for dietary gamma-tocopherol intake was not available. Natural logarithmic transformation of all biomarkers and dietary data was performed to reduce the within sample variability and to avoid inappropriate exclusion of outliers. Multiple regression models with adjustments for relevant confounders were used to examine the relationship between the vitamin E variables and serum bone-specific alkaline phosphatase (BAP, a biomarker of bone formation) and urinary N-Telopeptides/Creatinine (uNTx/Cr, a biomarker of bone resorption).

Results: The geometric means (95% CI) for dietary alpha-tocopherol, serum alpha- and gamma-tocopherol levels were 4.45 (4.06, 4.89) mg/day, 1482.97 (1428.91, 1539.06) mcg/dL and 194.06 (177.77, 211.84) mcg/dL respectively. 44% of women took vitamin E (alpha-tocopherol) supplements. We found that the association between dietary alpha-tocopherol intake and serum gamma-tocopherol and BTMs varied among vitamin E supplement users and non-users. Among vitamin E supplement users, higher dietary alpha-tocopherol intake was associated with higher uNTx/Cr (p= 0.001); and higher serum gamma-tocopherol was associated with higher

yogurt intake remained positively associated with BMD while cream remained negatively associated with hip and spine BMD (Table 2). The positive associations for cheese did not reach significance.

Conclusion: Total dairy intake, specifically milk and yogurt intake, were significantly associated with BMD at hip and spine in men and women, while cream adversely influenced BMD suggesting that not all dairy products are equally beneficial on the skeleton.

Table 2: Association of dairy intake (servings/week) with BMD (g/cm³) adjusting for other dairy products in men and women from the Framingham Offspring Cohort.

Atypical Humeral Fractures and Bisphosphonate Use. Maria Yavropoulou¹, Andrea Giusti², Sharita Ramautar¹, Sanders Dijkstra³, Neveen Hamdy⁴, Socrates Papapoulos⁴. ¹Leiden University Medical Center, Department of Endocrinology & Metabolism, Netherlands, ²Galliera Hospital, Italy, ³Leiden University Medical Center, Department of Orthopedic Surgery, Netherlands, ⁴Leiden University Medical Center, The Netherlands

Background: Atypical fractures of the femur have been reported to occur in patients on long-term treatment with bisphosphonates (BPs) but causality has not been proven and it is not known whether similar fractures may occur in other long bones. We have addressed this issue by examining the relationship between humeral shaft fractures and BP use. Patients and Methods: We identified all patients aged ≥ 50 years consecutively admitted to a single center with a new humeral fracture over a 9-year period. All individual radiographs were examined and fracture site was classified according to the Muller AO classification of Fractures of Long Bones. A case-control study was undertaken in patients with humeral shaft fractures using as controls sex and age matched patients with proximal humeral fractures in a 1:4 ratio. Patients with shaft fractures and radiographic characteristics similar to those of atypical femoral

fractures, including cortical thickening and unicortical beaking, were compared with those with ordinary shaft fractures. The relationship of "atypical" fractures and BP or GCs use was examined. Results: One hundred and ninety eight patients had a low-energy fracture of the humerus and in 20 of those this was a shaft fracture (10%). These 20 patients (cases) were matched with 80 patients with proximal fractures (controls). BPs were used by 5% of cases and by 6.3% of controls (OR, 0.80; 95%CI, 0.09-6.85) and GCs were used by 10% of cases and 8.8% of controls (OR, 1.15; 95% CI 0.23-5.83). There was no difference in cortical thickness between cases and controls and BP or GCs users and non-users. Four of the 20 patients with shaft fractures had "atypical" radiographic features (20%). None of these patients had ever been treated with BPs or GCs and two of them had diabetes type 2. Conclusions: Data of our study suggest that low-energy "atypical" fractures of the humeral shaft are infrequent (2% of low energy humeral fractures) and are not associated with the use of BPs or GCs.

Fracture Risk Is Increased in Young Women with Rheumatoid Arthritis. Shreyasee Amin*, Sherine Gabriel, Sara Achenbach, Elizabeth Atkinson, L. Joseph Melton. Mayo Clinic, USA

Rheumatoid arthritis [RA] is the only cause of secondary osteoporosis singled out in the WHO's fracture [fx] prediction algorithm, FRAX[®]. Nevertheless, the risk for fx among younger women and men with RA is not well established. We examined the risk for fx by sex and by age at diagnosis in a population-based RA cohort.

We studied Olmsted County, MN residents (age ≥ 18 yrs) first diagnosed with RA between 1955-2007, all of whom met 1987 American College of Rheumatology criteria for RA, and an equal number of age- and sex-matched controls. All incident fxs were identified through a complete review (inpatient and outpatient) of medical records. Excluding fxs resulting from severe trauma, the risk for first osteoporotic fx [OP fx] (hip, spine, wrist and proximal humerus), and for any first fx following their RA diagnosis was compared with their matched control, stratified by sex, using a Cox proportional hazards model, where follow-up time (until death or last known follow-up) ended at the first date reached by either within a pair. We then stratified by age at RA diagnosis (<50 yrs, ≥ 50 yrs). For those <50 yrs, we examined the risk for fx over all available follow-up as well as until age 50 yrs.

In 1155 RA cases (810 women and 345 men, mean age at RA diagnosis SD: 56 16 yrs and 58 14 yrs, respectively) followed for 12,585 person-yrs [p-y], 205 women (25%, 23 per 1000 p-y) and 67 men (19%, 19 per 1000 p-y) had an OP fx, while 276 women (34%, 31 per 1000 p-y) and 87 men (25%, 24 per 1000 p-y) had any fx. Women and men with RA were at increased risk for fx relative to controls, regardless of age at diagnosis [see table]. When follow-up was limited to age 50 yrs in the 304 women <50 yrs with RA (mean age at RA diagnosis: 39 yrs), the hazard ratio [HR] for OP fx was 6.7 (95% CI: 1.5, 29.5), with 13 women having at least one OP fx (7 per 1000 p-y) vs. 2 (1 per 1000 p-y) in matched controls; the HR for any fx was 1.9 (95% CI: 1.04, 3.4), with 31 women with RA having at least one fx (16 per 1000 p-y) vs. 17 (9 per 1000 p-y) in matched controls. In men <50 yrs with RA (N=109, mean age: 41 yrs), too few had a fx before age 50 yrs (N=2 with OP fx; N=5 for any fx) for any robust conclusion on fx risk relative to controls.

Women and men with RA, including those younger than age 50 yrs when diagnosed, have an increased fx risk. Furthermore, we have identified that young women with RA are at an increased risk for fx occurring even before age 50 yrs.

Hazard Ratio (95% CI) by Age at RA Diagnosis			
Women	Any Age	<50 yrs**	≥ 50 yrs
OP Fx*	1.7 (1.4, 2.2)	4.3 (2.4, 7.8)	1.4 (1.1, 1.8)
Any Fx*	1.6 (1.3, 1.9)	2.4 (1.6, 3.5)	1.4 (1.1, 1.7)
Men			
OP Fx*	1.6 (1.1, 2.4)	1.4 (0.7, 3.0)	1.8 (1.1, 2.8)
Any Fx*	1.4 (1.02, 1.9)	1.7 (0.9, 3.2)	1.4 (0.9, 2.0)

*excludes any severe trauma fx

**based on all available follow-up

MO0355

Incidence of Subsequent Fractures According to Age and Site of Initial Non-Vertebral Fractures: The First 3 Years of the OPTIMUS Initiative. Fran ois Cabana¹, Michele Beaulieu², Dominique Lambert³, Pierre-Yves C  te⁴, Marc Vaillancourt⁵, Marie-Claude Beaulieu⁶, Sophie Roux⁷, Gilles Boire⁸. ¹Centre hospitalier universitaire de Sherbrooke, Division of Orthopaedics, Canada, ²Merck Canada - Medical Liaison, Canada, ³Warner-Chilcott Canada Co., Canada, ⁴Amgen Canada, Canada, ⁵Novartis Canada, Canada, ⁶Universit  de Sherbrooke- Department of Family Medicine, Canada, ⁷University of Sherbrooke, Canada, ⁸Centre Hospitalier Universitaire De Sherbrooke, Canada

Introduction: Although a previous fragility fracture (FF) is a well-documented risk for subsequent fracture, the impacts of sex, age, and site of non-vertebral FF on subsequent fracture risk are less well known.

Objectives: To describe the rates of subsequent fractures over the first 3 years following a non-vertebral FF according to age group and site of initial FF.

Methods: An ongoing prospective cohort of men and women over 50 years of age was followed up in the OPTIMUS study, a placebo-controlled intervention aimed at increasing the rate of initiation and persistence on osteoporosis treatment after an incident non-vertebral FF leading to an orthopaedic consultation. After inclusion, the consenting participants were counselled about osteoporosis and its relationship to FF. A letter also informed their Family Physician (FP) to stress the importance of treating osteoporosis unmasked by a FF according to the 10-year fracture risk, with reminders sent to the FP of patients still untreated at the time of regular phone follow-up. At year 1, the delivery of anti-osteoporosis medication was confirmed with the patients' pharmacists (56% were then compliant with an appropriate treatment). The occurrence of novel FF was obtained from patients during phone follow-ups.

Results: From January 2007 to December 2010, 1043 patients (861 women, 182 men) with non-vertebral FF were included in the OPTIMUS intervention, including 200 control patients. Consent was obtained from 80% of the targeted population. Up to 43% (451) of the patients were younger than 65 (mean age 57); the mean age of patients 65 and over was 77 years. Follow up was obtained from 788/841 (93.7%), 587/634 (92.6%) and 289/346 (83.5%) surviving patients at year 1, 2, and 3, respectively. The rates of FF following inclusion according to age and site of FF are shown (Table). Ankle FF, the only FF site more frequent in younger patients, was associated with a lower but significant 3-year risk for recurrent FF. Rates of recurrent FF were not statistically different between younger and older age groups.

Conclusions. Our data suggest that any non-vertebral FF indicates a high risk for new FF over the following 3 years, even when fractures occurred before the age of 65 and at sites considered as Minor (i.e. other than hip, wrist or proximal humerus). This risk is underestimated as it applies to FF patients who were apt to consent, who survived at least one year and of which more than 50% were treated at year 1.

Site of the initial fracture (Number of patients with fracture)	Incidence of New fractures per 100 person-years (Number of new fractures/Total person-years)		
	All patients	< 65 years	≥ 65 years
Any fragility fracture (n= 1043)	5.1 (79/1545)	4.4 (29/661)	5.7 (50/884)
Hip (n= 214)	6.5 (20/309)	11.6 (5/43)	5.6 (15/266)
Wrist (n= 327)	4.9 (23/471)	5.0 (11/218)	4.7 (12/253)
Ankle (n= 206)	3.6 (11/307)	3.1 (6/196)	4.5 (5/111)
Proximal humerus (n= 187)	4.7 (13/278)	2.5 (3/121)	6.4 (10/157)
Other nonvertebral sites* (n= 109)	6.7 (12/180)	4.8 (4/83)	8.2 (8/97)

*Upper limb (50), Lower limb (35), Clavicle (10), Pelvis (11), Scapula (2) and Ribs (1).

Mortality after Vertebral Fracture in Korea : Analysis of the National Claim Registry. Young-Kyun Lee¹, Yong-Chan Ha², Jae-Suk Chang³, Hyun-Koo Yoon⁴, Deog-Yoon Kim⁵. ¹Seoul National University Bundang Hospital, South Korea, ²Chung-Ang University Hospital, South Korea, ³Ulsan University, Asan Medical Center, South Korea, ⁴Cheil General Hospital & Women's Healthcare Center, South Korea, ⁵Kyung Hee University Hospital, South Korea

Purpose: A vertebral compression fracture is a serious complication associated with osteoporosis of the spine. We evaluated the incidence of vertebral fracture and subsequent mortality in Korea, using nationwide data from the Health Insurance Review Agency (HIRA).

Methods: The used HIRA database was the National Korean Health Insurance claims database, which covered about 97% of the Korean populations. All clinics and

hospitals submit data on inpatients and outpatients, including data on diagnosis and medical costs, for claims. Therefore, virtually all information about patients and diseases is available from the Korean HIRA database, which has been used on several occasions for epidemiological studies. All new visits or admissions to clinics or hospitals for fractures were recorded in nationwide cohort by the Korean HIRA using ICD-10 code. The incidence of vertebral fracture and excess mortality associated with vertebral fracture were evaluated, in men and women aged 50 years or more between 2005 and 2008. Standardized mortality ratio (SMR) was calculated to determine excess mortality associated with vertebral fracture.

Results: The crude overall incidence of vertebral fractures was 984 per 100,000 person years from 2005 to 2008. The overall mortality rate at 3, 6 months, 1 year, and 2 years after vertebral fracture in men (55.6 %, 94.1 %, 146.1 %, and 206.1 %, respectively) were higher than women (24.1 %, 43.6 %, 71.6 %, and 104.8 %, respectively). In both genders, the age-specific mortality rates were more than those of the general population. The SMR was highest during the first 3 months and gradually declined to 2.53 in men and 1.86 in women at the 2-year period.(Figure 1)

Conclusions: The incidence of vertebral fracture in Korea was comparable with other countries such as Switzerland, and the mortality after vertebral fracture is higher than that of normal populations. The incidence of osteoporotic vertebral fracture and following high mortality are likely to become serious socioeconomic problems.

MO0357

Myocardial Infarction and Stroke Predict Fractures - A 13-Year Follow-Up Study in Men and Women. Kerstin Landin-Wilhelmsen^{*1}, Penelope Trimppou², Anders Lindahl³, Goran Lindstedt³, Goran Olerod³, Per-Olof Hansson⁴, Anders Oden⁵, Lars Wilhelmsen⁴. ¹Sahlgrenska University Hospital, Sweden, ²Section for Endocrinology, Department of Internal Medicine, Sahlgrenska University Hospital, Sweden, Swe, ³Department of Clinical Chemistry, Sahlgrenska University Hospital, Sweden, ⁴Department of Medicine, Sahlgrenska University Hospital, Sweden, ⁵Department of Mathematical Sciences, Chalmers University of Technology, Sweden

Purpose Fractures and cardiovascular disease (CVD) are a burden to society. The purpose was to study prospectively a possible link between fractures and CVD, especially myocardial infarction and stroke during 13 years of follow-up.

Methods A random population sample of Gothenburg, Sweden; 410 men and women, aged 25-64 years in 1995, from the WHO MONICA Project, was re-studied in 2008. Calcaneal Quantitative Ultrasound (QUS) and physical examination were performed. CVD, lifestyle factors and medical treatment were retrieved via medical records and questionnaires. Fractures were verified by X-ray. Blood samples were taken in fertile women on cycle day 7-9.

Results Since 1995, 26% of the subjects had fractured (women 29%, men 17%). Myocardial infarction, stroke, total CVD ($p=0.001$), low QUS, physical inactivity, low sex hormone levels in women, and use of antidiabetics and tranquilizers in 1995, predicted future fractures. In subjects with fractures, CVD, mainly stroke ($p=0.0005$), and higher cholesterol levels but less treatment with lipid-lowering agents were more common than in subjects without fractures in 2008.

After adjustment for age and BMI, changes in QUS were positively correlated with changes in serum estradiol and negatively correlated with changes in cholesterol levels in women. HRT decreased from 31% in 1995 to 8% in 2008, along with serum estradiol. Use of calcium/vitamin D (0-10%), anti-osteoporotics (0-3%), tranquilizers (15-29%), and lipid-lowering agents (0-15%) was increased in all subjects. Total cholesterol decreased, irrespective of treatment.

Conclusions Myocardial infarction, stroke, diabetes, tranquilizers and a sedentary lifestyle predicted future fractures. Fractured subjects had higher cholesterol levels but fewer lipid-lowering agents than subjects without fractures. Use of anti-osteoporotics was low at 13 years of follow-up, indicating undertreatment. The results point towards a link between metabolic bone disease and cardiovascular disease.

MO0358

Nitrate Use For Angina Is Not Associated with a Reduction in Osteoporotic Fractures in Elderly Women. Yasuyo Abe^{*1}, Helena Johansson², Kiyoshi Aoyagi¹, Anders Oden³, Diane Charlesworth³, Monique Beneton³, Jenny Cliffe³, Linda Kersh³, Carol McGurk³, John Kanis⁴, Eugene McCloskey⁵. ¹Nagasaki University, Japan, ²Swedish University of Agricultural Sciences, The Biomedical Center, Sweden, ³WHO Collaborating Centre for Metabolic Bone Diseases, United Kingdom, ⁴University of Sheffield, Belgium, ⁵University of Sheffield, United Kingdom

Nitric oxide stimulates bone formation, inhibits bone resorption and prevents bone loss in postmenopausal women. The impact of nitric oxide donors on fracture risk is controversial.

We studied 5212 women, aged 75 years and older, randomly selected from the local population regardless of the presence or absence of osteoporosis. Hip BMD and other risk factors were captured at entry to a randomized, double-blind, placebo controlled trial of daily oral clodronate. At baseline, concomitant medications and conditions were documented including nitrate use and angina. The incidence of hip or any osteoporotic fractures was captured during a median of 4 years follow-up.

Overall, 951 women took intermittent ($n=351$, largely glyceryl trinitrate) or continuous ($n=600$, daily oral or patch) nitrate donors. Compared to 4261 women without nitrate use, those exposed to nitrates were slightly but significantly older, reported recent multiple falls more frequently (6% vs. 3%), more frequently took or had taken glucocorticoids (12% vs. 9%) and more frequently had difficulty in the sit-to-stand test (40% vs. 29%) at baseline. However, they had higher body mass index and higher femoral neck bone mineral density (BMD) at baseline. In total, 749 incident fractures including 186 hip fractures occurred during follow-up. When adjusted for age, time since baseline and study treatment, nitrate use was associated with a non-significant reduction in the risk of any fracture or hip fracture (HR 0.87, 95%CI 0.61-1.25 and 0.85, 0.39-1.83 respectively, both $p>0.3$). No difference was observed between continuous and intermittent users. Further adjustment for falls (or sit-to-stand), glucocorticoid use and femoral neck BMD showed no significant effect of nitrates on any fracture or hip fracture.

Our study demonstrates that population cohort studies of nitrate use and fracture rates are likely to be confounded by other risk factors. Our results suggest little or no impact of nitrates on fracture in women with angina. Further, large intervention trials are required of nitrates in men and women without angina.

MO0359

Prevalence of Back Pain in Postmenopausal Osteoporosis and Associations with Multiple Spinal Factors. Naohisa Miyakoshi^{*1}, Michio Hongo¹, Hiroyuki Kodama², Akira Horikawa³, Yoichi Shimada¹. ¹Akita University Graduate School of Medicine, Japan, ²Minamiakita Orthopedic Clinic, Japan, ³Igarashi Memorial Hospital, Japan

Introduction: Back pain is a major source of morbidity among patients with osteoporosis. Although back pain in osteoporosis is often attributed to vertebral fractures (VFs), the cause of back pain in osteoporosis has been suggested as likely to show relationships with multiple factors. However, concomitant prevalences of back pain and multiple spinal factors in patients with osteoporosis have not yet been reported. The present study evaluated: 1) prevalence of back pain in patients with postmenopausal osteoporosis; and 2) associations of back pain to multiple spinal factors such as VFs, spinal alignment, mobility, and back extensor strength (BES) in these patients.

Methods: A total of 174 postmenopausal women with osteoporosis (mean age, 68 years) who visited their practitioner were asked whether they had clinically relevant back pain, and bone mineral density (BMD), number of VFs, kyphosis angle and range of motion (ROM) of the thoracic and lumbar spine, and isometric BES were evaluated. As patients with documented VFs within the last 6 months were not included, back pain for patients enrolled in this study indicated chronic back pain not attributable to fresh VFs. Measured variables were compared between subjects with back pain (BP group) and without back pain (non-BP group). In the BP group, associations between back pain intensity and other measured variables were further evaluated.

Results: Prevalence of back pain was 91.4% ($n=159$). No significant differences were seen between BP and non-BP groups with regard to age, BMD, number of VFs, thoracic and lumbar kyphosis angles, and thoracic and lumbar ROMs. However, BES was significantly less in the BP group than in the non-BP group ($p=0.013$). In the BP group, pain intensity showed a significant positive correlation with number of VFs ($r=0.171$, $p=0.031$), and negative correlations with lumbar spinal ROM ($r=-0.264$, $p<0.001$) and BES ($r=-0.268$, $p<0.001$). However, no significant correlations were observed between pain intensity and age, BMD, thoracic or lumbar kyphosis angles, or thoracic spinal ROM. Multiple regression analysis for pain intensity revealed lumbar spinal ROM ($p=0.017$) and BES ($p=0.014$) as significant contributors to pain intensity.

Conclusion: Prevalence of back pain in women with postmenopausal osteoporosis is high and the pain is significantly related to limited lumbar spinal mobility and decreased BES.

MO0360

Prevalence of vertebral fractures in Venezuela. Preliminary report from the Latin American Vertebral Osteoporosis Study (LAVOS). Gregorio Riera-Espinoza^{*1}, Jennv Ramos², Ada Colmenares³, Patricia Clark⁴, Fidencio Cons Molina⁵, J.O Talavera⁶. ¹Unidad Metabolica. CEAM, Venezuela, ²Unidad Metabolica, CEAM, Venezuela, ³INE Venezuela, Venezuela, ⁴Laboratorios Clinicos De Puebla, Mexico, ⁵Centro De Investigacion En Artritis Y Osteoporosis, Mexico, ⁶CMN Siglo XXI-IMSS, Mexico

The prevalence of vertebral fractures in women from Latin-America (Brazil, Argentina, Mexico, Puerto Rico and Colombia) has been shown to be similar to the rest of the world according to the population-based study LAVOS. The present study reports and expand the information of vertebral fractures in Latin America adding the prevalence of vertebral fractures in Venezuela using the same protocol as reported in the first LAVOS study.

A Population based sampling frame was obtained from the city of Valencia in Venezuela in women 50 years and older. Using the LAVOS design an age-stratified random sample of (50-59, 60-69, 70-79 and 80+) of 368 women in Valencia, Venezuela participated in the study. A questionnaire to get information on demographics, osteoporosis conventional risk factors, and some life styles characteristics was applied in all participants. BMD in two regions and lateral dorsal/lumbar X rays were obtain in all cases accordingly with LAVOS protocol to be able to have cross-national comparisons. Digital Morphometry was used to determine vertebral deformities by modified Eastell criterion. Morphometry and BMD readings were concentrated in one center

Results: A total of 383 women from Venezuela were included, however x rays of 15 cases were excluded due to position errors. Therefore the present report is based in 368 women. The overall prevalence of vertebral fractures was 14.4%. Over 50% of the women 80 and over contacted were unable to participate due to several reasons. The overall prevalence of Women from Venezuela is similar than the one reported as pooled prevalence in the LAVOS study.

Conclusion: The prevalence of vertebral fractures in Venezuela is similar as in the other Latin American Countries using the same methodology.

Age	LAVOS Venezuela n=368	Fx vs no fx	Prevalence 95% CI	LAVOS pooled data, n=1902*

Risk Factors Associated with Secondary Fractures & Mortality in Fracture Patients Managed by a Fracture Liaison Service. Alastair McLellan^{*1}, Mayrine Fraser¹, Frances Lovell². ¹Western Infirmary, United Kingdom, ²Royal Infirmary, United Kingdom

The Fracture Liaison Service (FLS) delivers systematic identification & assessment for treatment for prevention of secondary fractures to women & men age 50+yr who present with 'low trauma' fractures or are reported to have a vertebral fracture. 11727 patients (incl. 2944 men) in whom dates of incident fractures & dates of death (if occurred) were recorded were subject to survival analysis to ascertain outcomes incl. rates of secondary fractures & mortality; logistic regression was performed to identify associated risk factors (RF). In the first 5yr of the FLS, 19% of women & 16% of men sustained a secondary fracture; 13% of women & 19% of men died. The 5yr secondary fracture rate (5yrSFR mean(95%CI)) & mortality rate (MR) in the context of site of index fracture, prevalence of osteoporosis (OP) & treatment (treated (bisphosphonate + calcium/vit D(CaD) (total incl. CaD only)) are shown in table. Using logistic regression, in men, after adjustment, site of fracture, fracture history, alcohol excess, recurrent falls, being seldom on feet, low weight, low FNBMd were all associated with significantly increased secondary fracture risk (OR 1.59 to 4.17) (the greatest being history of 4+ fractures (compared to 1 fracture). Treatment was associated with OR of secondary fracture of 0.5(0.35to0.70). In women, in addition to the above, early menopause & height loss were also associated with significantly increased fracture risk with OR 1.16 to 2.09 (greatest risk being associated with fracture history of 4+ fractures (versus 1 fracture). Treatment (typically with BP/CaD) was associated with OR of secondary fracture of 0.65(0.55-0.77). RFs significantly associated with mortality are male gender, increasing age, alcohol excess, smoking, low weight, low FNBMd & fractures at specific sites (hip, humerus and 'other sites'), the most influential being male gender OR 1.94(1.67-2.26). Treatment with BP has no influence on mortality after correction for the above RFs. Conclusion: An FLS effects high rates of treatment for fracture secondary prevention, that are associated with 35-50% reduction in secondary fracture incidence. Treatment does not alter mortality rate. Despite these interventions, widely differing secondary fracture rates & mortality accompany fractures at different sites in women & men.

Secondary Prevention of Osteoporotic Fracture: A Systematic Approach to Case-finding in Brazil. Adriana Machado^{*1}, Wellington Monteiro Machado¹, Regina Celia Popim², Maria Virg nia M Alves², Angela M A Zeller³, Paul James Mitchell⁴. ¹Internal Medicine Department - Univ. Estadual Paulista, Brazil, ²Nurse Department - Univ. Estadual Paulista, Brazil, ³Nutrition Service - Univ. Estadual Paulista, Brazil, ⁴Auckland, New Zealand & University of Derby, UK, New Zealand

It is widely known that a significant care gap exists in relation to the secondary prevention of osteoporotic fractures. To fill this gap in our city, we started a clinic to assess people who have sustained a probable osteoporotic fracture and assess their

bone health and their risk of falls with further education and treatment. The clinic is based in the rehabilitation unit of a University Hospital (430 beds) in a median size city (130,000 habitants) in the inner of Sao Paulo State, Brazil. It is an initiative of the Geriatrics Discipline and has one geriatrician, two nurses, one nutritionist and one physiotherapist. The clinic is held once a week and accepts referral from any part of the hospital, in particular from the orthopaedic ward and outpatient's clinic and the emergency department. The referral criteria are patients aged 50 or above, both genders, with history of an atraumatic or a low impact fracture (with focus on hip, wrist, vertebra and humerus). When a new patient comes, they have an appointment with the geriatrician, who will check the clinical risk factors, the circumstances of the fall, and will request the bone densitometry measurement and the laboratory tests (full blood count, glycaemia, creatinine, albumin, sodium, potassium, magnesium, serum calcium, serum phosphate, urinary calcium, vitamin D, PTH and TSH levels). Subsequently, a nurse will assess independence in the activities of daily living, the eye test (Snellen chart) and the walking ability (timed up and go - TUG test). The nutritionist will assess the whole nutritional status, with a special focus on calcium and vitamin D. Based on these assessments, further referrals to physiotherapist will happen when needed. Everyone in the team is engaged in education aspects - life style changes, falls prevention and diet. A second visit will be arranged with the geriatrician to check the laboratory exams and the bone densitometry results, and a proposal of treatment. During the first year, the patient will have repeated appointments with the nurse every 4 months to check compliance with therapy, falls and new fractures. Our pilot program provides one of the first examples of a systematic approach to case-finding of fragility fracture patients in Brazil. Post-fracture coordinator models have been advocated by professional associations, patient societies and policymakers throughout the world. Our programme will be audited in an ongoing fashion which will inform future publications.

MO0363

Vertebral Fracture Assessment: A Valid Tool to Detect Vertebral Fractures in Elderly Community. Diogo Domiciano^{*1}, JAQUELINE LOPES², Camille Figueiredo¹, Valeria Caparbo¹, Liliam Takayama¹, Rosa Pereira¹. ¹Faculdade de Medicina da Universidade de Sao Paulo, Brazil, ²Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil, Brazil

Introduction: Vertebral fractures (VFX) are associated with higher morbidity and mortality, increasing the risk of incident fractures. Although only 30% of the VFX cause symptoms, this finding is a relevant issue for managing patients with high fracture risk, as well prevention of new fractures, independently of bone mineral density. Studies have shown effectiveness of Vertebral Fracture Assessment (VFA) to detect prevalent VFX comparable to the spine X-ray, considered as gold standard method. The aim of this study was to compare the performance between VFA and X-ray to identify VFX in healthy elderly men and women from community. Patients and Methods: 429 non-institutionalized subjects (60% women), aged over 65 years, from community (Butanta area, Sao Paulo, Brazil) were enrolled in this cohort. VFA by DXA measurements and spine X-ray (T4 to L4) were analyzed according to semiquantitative method (Genant HK, 1993). The first one was evaluated by two expert rheumatologists by consensus between them. The second one was evaluated by one expert radiologist. The interobserver correlation between VFA and spine X-ray to identify VFX was analyzed by kappa (k) scores. P<0.05 was set as significant. Results: The prevalence of VFX in both methods was 29.4%, without significant difference between men and women. Unavailable vertebrae were significantly lower in spine X-ray than VFA (1% and 5.5% respectively, p<0.001), especially among T4-T6. According to VFA, 5013 (96%) vertebrae were considered as normal, 144 (2.7%) had grade 1 fractures, 58 (1.1%) with grade 2 fractures and 12 (0.2) grade 3 fractures. To identify VFX, the sensitivity of VFA was 73% and the specificity was 99.1%. After excluding deformities grade 1, the sensitivity increased to 93% and specificity to 99.6%. The correlation between VFA and X-ray was good (k=0.74). Again, without grade 1, the agreement was also better (k=0.84). The correlation vertebrae by vertebrae between VFA and spine X-ray was lower in T5-T7. There was not significant difference between methods, according by gender (k=0.72 in men, k=0.75 in women).

Conclusion. In elderly community, VFA had similar performance to conventional spine X-ray to identify VFX in visible vertebrae. The sensitivity increased after excluding of mild deformities. Thus, this methodology is easy and feasible to be performed during routine DXA measurements, in order to improve the management of patients with higher risk of osteoporotic fractures.

MO0364

Which Types of Fractures Should in General be Regarded as Related to Osteoporosis? Bjorn Rosengren¹, Ingemar Peterson², Magnus Karlsson¹, Martin Englund². ¹Skane University Hospital Malmö, Lund University, Sweden, ²Musculoskeletal Sciences, Department of Orthopedics, Clinical Sciences Lund, Lund University, Lund, Sweden, Sweden

Purpose: In epidemiological studies, fractures of the hip, os pubis, proximal humerus, wrist, proximal tibia, and the ankle are often considered as typical osteoporotic fractures when occurring in individuals aged 50 years or older. However, it is currently unclear if all these fractures actually follow an age trend influenced by osteoporosis, i.e., showing a stable incidence during adulthood until age 50-60 years, followed by an exponential increase into older age.

Methods: Through the Skane Health Care Register, a diagnosis-based register covering all in- and outpatient health care data of residents in the County of Skane in Sweden (1.2 million inhabitants), we included adult men and women (aged 20-95 years) and registered all fractures of the hip (n=31 872), os pubis (n=4 388), proximal humerus (n=13 674), wrist (n=28 842), proximal tibia (n=4 769) and ankle (n=15 179) from year 1998 until 2009 (9.8 million person-years). We calculated age and sex-specific annual incidence estimates using the mid-year adult population as the population at risk for each calendar year, respectively. These estimates were then averaged over the 12-year study period to obtain age- and sex-specific incidence figures over a one-year time frame.

Results: A pattern typical for osteoporosis-related fractures (as detailed above) was seen for fractures of the hip, os pubis, proximal humerus, and the wrist (Figure). The increment with advancing age was more prominent in women than in men. In contrast, the incidences of fractures of the ankle and proximal tibia were fairly stable throughout life with only a slight increase in incidence of proximal tibial fractures in persons at about 90 years of age (Figure).

Conclusion: The incidence of hip, os pubis, proximal humerus, and wrist fractures follows an age pattern suggesting a clear influence by osteoporosis, while fractures of the ankle and proximal tibia show a relatively stable age-related incidence pattern. This knowledge is essential when deciding which fracture sites should be regarded as related to osteoporosis in epidemiological studies, and also when predicting the future demand for health care resources.

A Genome-wide Screen of Gene-Gene Interactions for Osteoporosis Susceptibility. Tie-Lin Yang¹, Yan Guo¹, Hui Shen², Qing Tian², Hong-Wen Deng². ¹Xi'an Jiaotong University, China, ²Tulane University, USA

Osteoporosis is a typical complex disease determined by both actions and interactions of multiple genes. Bone mineral density (BMD) is the most important risk phenotype for osteoporosis. Recent genome-wide association studies (GWAS) identified several genes for their independent effects on osteoporosis. However, no studies have been performed to identify gene-gene interactions in GWAS analyses. Here, we performed a genome-wide gene-gene interaction analysis for osteoporosis susceptibility in two independent US Caucasian populations. Sample 1 consisted of 916 unrelated subjects with extreme hip BMD Z-scores (458 high and 458 low) selected from a 2286 subjects. Sample 2 consisted of 400 unrelated subjects with extreme hip BMD Z-scores (200 high and 200 low) selected from 1000 subjects. Combining results from these two samples, we detected one SNP-interaction pair

(rs8047431 and rs1975460) significantly associated with hip BMD after FDR adjustment for multiple testing, with the original P value of 1.88×10^{-10} . SNP rs8047431 was located at WW domain-containing oxidoreductase (WWOX) gene, which encodes a tumor suppressor. WWOX functionally suppressed RUNX2 transactivation ability in osteoblasts. Wwox^{-/-} mice exhibited a delay in bone formation and developed metabolic bone disease. The evidence suggested that WWOX might be a potential candidate gene for BMD. SNP rs1975460 located at 16q23.1, the nearest gene was ribosomal protein L36a pseudogene (RPL36AP46). In addition, we detected some other interaction pairs of SNPs showing suggestive association with osteoporosis susceptibility ($P = 3.77 \times 10^{-8}$ to 4.85×10^{-9}), such as SNPs in LNX1 and TMEM132D, and SNPs in SOX6 and HAUS6. In summary, our findings suggest that gene-gene interactions may play a role in osteoporosis susceptibility.

Allelic Determinants of Vitamin D Insufficiency, Bone Mineral Density and Past and Prospective Bone Fractures. Olivia Trummer¹, Elisabeth Wehr¹, Verena Schwetz¹, Daniela Walter¹, Markus Gugatschka¹, Wilfried Renner¹, Astrid Fahrleitner-Pammer², Harald Dobnig³, Thomas Pieber¹, Barbara Obermayer-Pietsch^{*2}. ¹Medical University, Austria, ²Medical University Graz, Austria, ³Diagnostikinstitut Univ.Prof.Dr.H.Dobnig GmbH, Aut

Purpose: Low 25-hydroxyvitamin D (vitamin D) status is known to play an important role in many diseases with focus on bone health. Based on recently reported genetic determinants of vitamin D insufficiency we investigated GC, DHCR7 and CYP2R1 variants for their potential role in predicting vitamin D and bone mineral density (BMD) status as well as bone fractures.

Methods: Replication was performed in two cohorts, a cross sectional BMD and fracture study in 541 elderly unrelated subjects (mean age 56.13 years) and in a prospective cohort study on bone fractures in 1119 very old nursing home patients (mean age 84.6 years), both with clinical and biochemical patient characterisation.

Results: Mean vitamin D level was 33.13 ng/ml in the elderly and 9.6 ng/ml in the nursing home population. The GC genotype was significantly associated with lower mean vitamin D levels in both cohorts ($p=0.001$ and $p=0.048$, respectively). CYP2R1 and DHCR7 variants showed only a trend, but a linear gene-dose-effect in both cohorts.

There was no association with BMD in any of the genotypes at all sites measured and no relationship to the various types of past fractures. However, prospective fractures were significantly different between DHCR7 ($p=0.01$) and GC ($p=0.02$) genotypes, but did not differ between CYP2R1 groups. Moreover, DHCR7 genotypes differed significantly in prospective hip fracture cases (overall $n=48$) compared to persons without fractures ($n=923$; $p<0.001$) and GC genotypes in prospective radius fracture cases (overall $n=23$) compared to participants without fractures ($n=950$, $p<0.001$). DHCR7 variants were significantly associated with months to hip fracture ($p=0.04$, risk ratio of recurrence (RR) 0.73 [95% CI 0.53-0.99]) and were significantly associated with time to fracture by Kaplan-Meier analysis.

Conclusions

In our cohorts, GC, and probably DHCR7 and CYP2R1 variants were associated with vitamin D status even in view of markedly low mean vitamin D levels in the nursing home cohort, but not with BMD. However, prospective fracture risk might be related to these gene variants. Further studies in large cohorts are warranted to confirm our findings.

Association of Common Variants in Obesity Related Genes with Osteoporosis and Fracture among Swedish Women. Jitender Kumar¹, Fiona McGuigan^{*2}, Mattias Callreus¹, Paul Gerdhem³, Kristina Akesson⁴. ¹Lund University, Sweden, ²University of Lund, Malmö, Skane University Hospital, Malmö, Sweden, ³Karolinska Institutet, Sweden, ⁴Skane University Hospital, Malmö, Sweden

Purpose: The opposing phenotypes of osteoporosis and obesity are complex disorders of body composition, whose consequences are a worldwide public health concern. Bone mineral density (BMD) and body mass index (BMI) are used as surrogate markers for osteoporosis and obesity respectively. Body composition, particularly fat mass and lean mass, are established determinants of BMD, although recent studies highlight the complexity of interactions between bone-fat. In this study we analyzed associations between single nucleotide polymorphisms (SNPs) from three obesity related genes with osteoporosis and fracture. **Methods:** Two population-based cohorts of women from Sweden: PEAK-25 (all aged 25 years, $n=1005$) and OPRA (all aged 75 years, $n=1010$) were utilized. Five SNPs (rs9939609, rs1121980, rs17782313, rsrs1770633, rs7566605) from three obesity associated genes involved in energy metabolism and identified through genome-wide association studies (Fat mass and obesity associated, FTO; Melanocortin 4 receptor, MC4R; and Insulin induced gene 2, INSIG2) were genotyped in both cohorts to determine age related effects on bone

phenotypes and fracture. Results: Total body (TB) fat mass and TB lean mass were the strongest determinants of BMD in OPRA and PEAK-25 respectively. SNP rs9939609 from the FTO gene showed significant association with BMI and TB fat mass ($p=0.004$) in PEAK-25. Individuals carrying the minor allele had increased BMI and TB fat mass. There was no association with BMD however regression analysis showed association with fracture ($p=0.04$) independent of BMD and fat mass in the OPRA cohort. Carriers of the minor allele had fewer fractures. SNP rs17782313 from the MC4R gene showed significant association with bone ultrasound (QUS) measurements in the OPRA cohort ($p<0.007$) – carriers of the minor allele had higher values of all QUS parameters. No association with BMD or fracture was found. INSIG2 SNPs failed to reach significance for any of the parameters studied. Conclusion: We have identified associations between SNPs from obesity related genes, bone quality and fracture. Association of FTO SNPs with fat mass was age dependent, suggesting interaction with environmental factors. The association between MC4R and bone quality is supported by rat studies whereby the absence of Mc4r leads to decreased bone resorption and increased BMD. Further studies are warranted to reveal the exact mechanism of the role of these genes on osteoporosis and fractures.

Linkage Analysis in an Australian Cohort Identifies a Region Associated with Femoral Neck BMD. Sing Nguyen*, Jacqueline Center, John Eisman, Tuan Nguyen. Garvan Institute of Medical Research, Australia

Genome-wide association studies, with their large cohorts and dense sequencing coverage, have been extremely successful at identifying the gene regions which influence many different traits, including bone mineral density (BMD). Whilst they continue to be useful, the numbers needed to detect and replicate signals is at times prohibitively large. Given the high heritability of BMD traits, linkage studies using related individuals represent a cost-effective alternative for detecting regions associated with variation in BMD. A moderately-sized linkage study using related individuals can have the same power to detect gene regions as a much larger association study using unrelated individuals.

Here we perform a linkage analysis for BMD at the femoral neck, lumbar spine and total body in 500 people across 90 extended pedigrees from the Dubbo Osteoporosis Genetics Study (DOGS). This study is a sister study of the Dubbo Osteoporosis Epidemiology Study (DOES), and is a multi-generational family study with ongoing recruitment and follow-up.

Using a multipoint linkage scan, we find evidence for linkage at chromosome 3q25 with respect to variation in femoral neck BMD (but not lumbar spine or total body BMD). Furthermore we find evidence for suggestive linkage at regions previously identified in other linkage and association studies looking at BMD. Overall there is reason to once again pursue linkage as a study design for identifying gene regions associated with BMD traits.

Factors Associated with Use of Anti-Osteoporosis Medication. The Global Longitudinal Study of Osteoporosis in Women (GLOW). Stephen Gehlbach*, Pamela Guggina², Frederick Hooen³, Julie Flahive⁴, Steven Boonen⁵, Juliet Compston⁶, Cyrus Cooper⁷, Adolfo Diez-Perez⁸, Susan Greenspan⁹, Robert Lindsay¹⁰, Coen Netelenbos¹¹, Philip Sambrook¹², Stuart Silverman¹³, Nelson Watts¹⁴. ¹University of Massachusetts, USA, ²University of Massachusetts School of Public Health, USA, ³University of Massachusetts Medical School, USA, ⁴UMass Medical School, USA, ⁵Center for Metabolic Bone Disease & Division of Geriatric Medicine, Belgium, ⁶University of Cambridge School of Clinical Medicine, United Kingdom, ⁷University of Southampton, United Kingdom, ⁸Autonomous University of Barcelona, Spain, ⁹University of Pittsburgh, USA, ¹⁰Helen Hayes Hospital, USA, ¹¹VU Medical Center, The Netherlands, ¹²Royal North Shore Hospital, Australia, ¹³Cedars-Sinai/UCLA, USA, ¹⁴University of Cincinnati Bone Health & Osteoporosis Center, USA

Osteoporosis is a common condition for which there are effective medications. Many women at high risk for fracture are not treated, while some low-risk women are on anti-osteoporosis medications (AOMs).

Aim: To identify characteristics associated with AOM treatment and determine whether these characteristics differ between high- and low-risk women.

Methods: The Global Longitudinal Study of Osteoporosis in Women (GLOW) is a multinational prospective cohort study involving 60,393 women aged ≥ 55 yr. Data were collected via self-administered questionnaires at baseline and annually for 3 years. Women were eligible if they had visited the practice within the previous 2 years, were non-institutionalized and had no barriers to completing a questionnaire. The high-risk category contained women ≥ 65 yr with a prior fracture or ≥ 2 FRAX risk factors (history of fracture, low bone mineral density, low body mass index, oral glucocorticoid, rheumatoid arthritis, risk factors for secondary osteoporosis, parental history of hip fracture, tobacco use and ≥ 3 alcoholic drinks/day). The low-risk

category contained women <65 yr with no FRAX risk factors. Variables included were diagnosis of osteoporosis/osteopenia, education, age, comorbidities, prescription drugs, concern about osteoporosis, self-perception of fracture risk and vitality score. The outcome of interest was AOM use.

Results: 3645 women were in the low-risk group; 941 reported osteopenia, 335 osteoporosis and 2369 neither. 3759 women were in the high-risk group; 872 had osteopenia, 1322 osteoporosis and 1565 neither. 14.2% of low-risk women and 35.7% of high-risk women were treated ($p<0.0001$). Characteristics associated with AOM are listed in the Table. Diagnosis of osteoporosis was the most significant. The odds ratio (OR) was 69.4 in the low-risk group and 17.9 among high-risk women. An osteopenia diagnosis was also significant, with an OR of 18.7 among the low-risk women and 6.2 for those at high risk. Age was associated with treatment among high-risk women while prescription drug coverage was associated with treatment among the low-risk group. Education level was not related to treatment.

Conclusion: While a diagnosis of osteoporosis or osteopenia is most strongly associated with treatment with AOM in both high and low risk women, several other factors are also associated with treatment, including presence of comorbid conditions, concern about osteoporosis, perceived fracture risk and vitality.

Variable	Low risk OR (95% CI)	High risk OR (95% CI)
Age by 5-year increment	1.3 (1.0, 1.7)	1.2 (1.1, 1.3)
Diagnosis of osteoporosis vs. neither	69.4 (45.2, 106.4)	17.9 (13.9, 22.9)
Diagnosis of osteopenia vs. neither	18.7 (13.0, 27.1)	6.2 (4.8, 8.0)
More than high-school education vs. high-school education or less	1.3 (0.9, 1.8)	1.2 (1.0, 1.5)
No comorbidities vs. at least 1 comorbidity	1.4 (1.1, 1.8)	1.5 (1.1, 1.9)
Prescription drug coverage vs. no drug coverage	5.6 (2.3, 13.5)	1.0 (0.7, 1.5)
Osteoporosis concern: very/somewhat vs. not at all	2.1 (1.1, 4.3)	1.9 (1.3, 2.7)
Perceived fracture risk: higher vs. same/lower than others	2.0 (1.5, 2.6)	1.6 (1.3, 1.9)
Vitality, above vs. below median	1.7 (1.3, 2.2)	1.7 (1.4, 2.0)

Table. Characteristics associated with AOM use in low- and high-risk women (adjusted for study site)

Secular Trends in Fractures and Sex Hormones in Men and Women. Penelope Trimpou^{*1}, Anders Lindahl², Goran Lindstedt², Goran Olerod², Lars Wilhelmsen², Kerstin Landin-Wilhelmsen². ¹Section for Endocrinology, Department of Internal Medicine, Sahlgrenska University Hospital, Sweden, Swe, ²Sahlgrenska University Hospital, Sweden

Purpose Age, hormones and life style are determinants for many conditions and diseases. The purpose was to study secular trends in fractures, sex hormones and life-style factors in a random population sample of men and women, during 13 years.

Methods This is a prospective, longitudinal study in a random sample of the general population of Gothenburg, Sweden. Totally 1257 men and women, aged 35-64 years, from the WHO, MONICA Project, Goteborg 1995 was restudied in 2008. Subjects with a mean age of 40, 50 and 60 years were compared at similar ages 13 years apart. Body composition was measured with bioimpedance and bone mass with calcaneal ultrasound. Life-style factors were estimated via questionnaires. Fasting serum hormones were measured in every 4th subject from the 1995 year cohort. In fertile women collections were made in cycle day interval 7-9. Fractures were X-ray verified.

Results When comparing men from 1995 with men of similar age in 2008, body composition, physical activity and fracture incidence were similar. Postmenopausal women 45-64 years, had increased physical activity during leisure time and bone mass but decreased physical activity at work in 2008 the fracture incidence in the same age groups increased from 17 to 28% between 1995-2008 ($p<0.001$). The majority was fall fractures i.e. radius, upper arm and ankle. Vertebral crush increased in postmenopausal women in 2008, from 9% to 28% of all fractures ($p=0.0085$). Estrogen replacement therapy (HRT) declined from 28% to 7% ($p<0.0001$) as did serum estradiol.

Conclusions Secular trends were seen both in fracture incidence and fracture type in postmenopausal women but not in men during 13 years. A decrease in HRT use concomitant with an increase in leisure time physical activity might explain the results.

Association of Red Blood Cell n-3 and n-6 Fatty Acids and Hip Fracture.
Tonya Orchard¹, Steven Ing¹, Bo Lu¹, Martha Belury¹, Andrea Lacroix², Charles Kooperberg², Aaron Aragaki², Rebecca Jackson¹. ¹The Ohio State University, USA, ²Fred Hutchinson Cancer Research Center, USA

Title: Association of Red Blood Cell n-3 and n-6 Fatty Acids and Hip Fracture

Purpose: The objective of this research was to examine red blood cell (RBC) n-3 and n-6 fatty acids (FAs) as a biological marker of hip fracture in postmenopausal women and to investigate the relation of these FAs to regulators of bone turnover.

Methods: A nested case-control study (n=400 pairs) was completed within the Women's Health Initiative (WHI) prospective cohort. RBCs and serum were collected from blood drawn at the baseline screening visit. RBC FAs were analyzed using gas chromatography. Bone biomarkers (osteoprotegerin (OPG) / receptor activator of NF κ B ligand (RANKL) ratio) in serum were analyzed in an on-going WHI study. Serial measures of bone mineral density (BMD) were obtained at baseline, year 3 and year 6. Hip fractures were confirmed by medical record review. Cox proportional hazard models were constructed to estimate risk of fracture. The association of FAs to OPG/RANKL and BMD was estimated using generalized linear models.

Results: After exclusion of 116 samples due to potential RBC degradation and their corresponding case-control match (n=98), 293 matched pairs were included in statistical analysis. Higher alpha linolenic acid (ALA) was associated with lower hip fracture risk in multivariate analysis [Hazard Ratio (HR) for tertile 3: 0.39; 95% CI: 0.19-0.78; p for linear trend 0.04] and a 7-fold higher OPG/RANKL ratio (Tertile 3 mean: 489.79; SEM: 149; p for linear trend 0.07). HR for hip fracture based on the highest tertile of the n-3 index [%eicosapentaenoic acid (EPA) +docosahexaenoic acid (DHA) in RBCs] was 0.53; 95% CI: 0.28-1.01; p for linear trend 0.09, and based on highest tertile of total n-3 FAs HR was 0.53; 95% CI: 0.28-0.99; p for linear trend 0.07. There was no association between n-3 and n-6 FAs and BMD. Although total n-6 FAs tended to decrease the OPG/RANKL ratio (Tertile 3 mean: 95.71; SEM: 150; p for linear trend 0.0508), there were no associations between n-6 FAs in RBCs and risk of hip fracture. However, HR for hip fracture increased with an n-6/n-3 ratio > 6.01 in RBCs (HR tertile 3: 2.31; 95% CI: 1.03-5.16; p for linear trend 0.05).

Conclusions: The n-3 FA, ALA, in RBCs was inversely associated with hip fracture risk, potentially related to a more favorable OPG/RANKL ratio. Higher total n-6 FAs tended to be associated with lower OPG/RANKL and an n-6/n-3 ratio >6.01 in RBCs more than doubled relative risk of hip fracture in these postmenopausal women.

Body Mass Index and Bone Mineral Density in Adults over 50: Results from NHANES 2005-2008. Jennifer Lloyd¹, Dawn Alley¹, William Hawkes¹, Shari Waldstein², Marc Hochberg³, Denise Orwig¹. ¹University of Maryland, Baltimore, USA, ²University of Maryland, Baltimore County, USA, ³University of Maryland School of Medicine, USA

The objective of this study is to examine variation in bone mineral density (BMD) across body mass index (BMI) groups among older adults using recent, nationally representative data. Although previous studies have reported a positive relationship between BMI and BMD, this relationship hasn't been examined in more recent cohorts. Using data from the National Health and Nutrition Examination Survey (2005-2008), we examined the association between BMI and low BMD and osteoporosis (defined as >1 SD and >2.5 SD below young, sex-specific mean, respectively). There were 3,801 adults >50 years (mean 63 years), predominately female (52%), white (83%), and overweight or obese (72%), with a mean femoral neck

prevalence of both cardiovascular risk factors and cardiovascular morbidity. Moreover, osteoprotegerin (OPG) and soluble RANK ligand (sRANKL) have been consistently associated with the incidence and prevalence of coronary artery disease. However, little is known about serum OPG and sRANKL levels in postmenopausal women with breast arterial calcification. The purpose of this study is to clarify the relationship between plasma OPG and sRANKL levels and breast arterial calcification in Japanese osteoporotic postmenopausal women. This study was carried out in fifty-one postmenopausal women aged 46-82 years who underwent screening mammography. Each mammogram was reviewed for the presence of arterial calcifications. Participants were divided into four groups of the number of calcified vessels including, 0BAC: no calcification, 1BAC: one calcified vessel, 2BAC: two calcified vessels and >3BAC: more than 3 calcified vessels. Serum OPG, sRANKL, alkaline phosphatase (Alp), low density lipoprotein-cholesterol (LDL-C), high density lipoprotein-cholesterol (HDL-C) and urinary type-I collagen cross-linked-N-telopeptide (uNTX) were measured. The mean age of these 51 women was 64.5 ± 1.1 years-old, 0BAC; n=25, 1BAC; n=11, 2BAC; n=8 and >3BAC; n=7. The prevalence of low bone density (osteopenia) and osteoporosis was 33.3% and 56.9%, respectively. The prevalence of BAC was 58.6% in osteoporosis and 47.1% in osteopenia higher than 20.0% in women without osteopenia and osteoporosis. In the subgroups of BAC, BMD in >3BAC group was clearly decreased, and serum OPG and sRANKL levels were significantly increased in >3BAC group compared with those in 0BAC group. In addition, sRANKL/OPG ratio was pivotally higher in 2BAC and >3BAC groups compared with that in 0BAC group. In contrast, serum Alp, the ratio of LDL-C/HDL-C and uNTX were not significantly changed, increasing the number of BAC in postmenopausal women. In conclusion, the prevalence of BAC in Japanese postmenopausal women was remarkably high in osteopenia and osteoporosis. Especially, the result in the subgroups of BAC showed that sRANKL/OPG ratio was increased in severe calcification of breast artery, suggesting that BAC may be associated with surrogate markers of reduced BMD and subclinical cardiovascular disease including coronary artery calcification.

Aging Males' Symptoms (AMS) Scale and Bone Mineral Density in HIV Positive Males Treated with Highly Active Anti-Retroviral Therapy (HAART). Jessica Pepe¹, Andrea Isidori¹, Mario Falciano¹, Giancarlo Iaiani¹, Emilia Sbardella¹, Romano Del Fiacco², Addolorata Scarpello¹, STEFANIA RUSSO³, Cristiana Cipriani⁴, Elisabetta Romagnoli⁴, Salvatore Minisola⁴. ¹Sapienza, University of Rome, Italy, ²University "Sapienza" - Rome, Italy, ³UNIVERSITY SAPIENZA OF ROME (ITALY), Italy, ⁴University of Rome, Italy

Background: HIV infection is frequently associated with osteoporosis which is considered mostly attributable to hypogonadism; this last has been considered secondary to HAART.

Aim: We administered the Aging Males' Symptoms (AMS) questionnaire (currently used to clinically evaluate partial androgen deficiency of aging men) to HIV patients and concomitantly investigated their skeletal health.

Methods: We studied 50 men with HIV type-1 (mean age: 48.79 ± 4 yrs; diagnosis: 10.1 ± 5.9 yrs; CD4, cells/microL: 626.266; HIV RNA, copies/mL: 55.425.9) and 27 age-matched HIV negative men (49.18 ± 3 yrs). We measured main parameters of mineral metabolism and hormonal status; each subject underwent lumbar and femoral DXA densitometry (iDXA, GE Medical Systems Lunar, Madison WI, USA) and quantitative ultrasound of the proximal phalanges using DMB Sonic 1200 device (IGEA, Carpi, Italy). Ultrasonometric parameters considered were speed of propagation of ultrasound dependent on the amplitude of the ultrasound wave crossing bone tissue (Amplitude-Dependent Speed of Sound, ADSoS) and a parameter calculated by computer analysis of dynamic parameters of ultrasound signal (Ultrasound Bone Profile Index, UBPI).

Results: 31.5% of HIV patients were osteoporotic at the lumbar and/or femoral sites compared with 3.7% of control subjects (p = 0.02). Mean ADSoS values of HIV patients were significantly reduced (206775 vs 212189 m/s, p < 0.01). HIV patients were characterized by a higher prevalence of biochemical hypogonadism compared with controls (26% vs 4%, p = 0.04), as determined by free testosterone levels. 62% of HIV patients (40.7% of controls, p = 0.04) had values of AMS above the pathological threshold (≥ 27). Among HIV-infected population, AMS score was negatively correlated with neck BMD (r = -0.36, p = 0.016) and with both ADSoS values and UBPI (r = -0.47, p = 0.009, r = -0.39, p = 0.002, respectively), even after adjusting for covariates (age and BMI).

Conclusion: There is a significant prevalence of hypogonadism in HIV men, which is also accurately reflected by AMS scores. The correlation between AMS score and neck BMD, might support the use of this questionnaire as a screening tool for low bone mass in this condition. The significantly reduced ultrasonometric parameters in HIV positive patients suggests, for the first time, a qualitative other than quantitative involvement of skeletal tissue, strongly related to the hypogonadism.

Disclosures: Salvatore Minisola, None.

BMD of 0.772 gm/cm² (SD=0.14). Both overweight and obese persons had significantly lower odds of low BMD (OR=0.56 CI: 0.37-0.84; and OR=0.19, 95% CI: 0.08, 0.44, respectively) and osteoporosis (OR=0.22, 95% CI: 0.15, 0.33; and OR=0.21, 95% CI: 0.08, 0.59, respectively). Gender and race were not significant effect modifiers. Stratified analysis examined gender and race/ethnic groups to determine if the BMI and BMD association was linear. Including a BMI squared term in stratified analysis indicated a possible significant curvilinear relationship among some racial/ethnic groups and among men. Results demonstrate the strong positive association between BMI and BMD, consistent with prior research. Although, there may be a threshold for the protective effects of high BMI after which additional weight does not continue increase BMD.

Disclosures: Jennifer Lloyd, None.

MO0375

Does Optimal Risk Factor Profile Guarantee Better Bone Health During The Postmenopause? - A 15-Year Population Based Study. Joonas Sirola^{*1}, Toni Rikkinen², Marjo Tuppurainen³, Risto Honkanen⁴, Heikki Kroger³.

¹University of Eastern Finland / Kuopio, Finland, ²Researcher, University of Eastern Finland, Finland, ³Professor, Kuopio university hospital, Finland, ⁴Adjunct Professor, University of Eastern Finland, Finland

Aim: To investigate long-term effects of selected modifiable and non-modifiable risk-factors on the development of osteoporosis. **Methods:** The study population consisted of 1895 postmenopausal women from Osteoporosis Risk Factor and Prevention (OSTPRE) -study cohort (n=14 220), Kuopio, Finland. Risk-factor inquiry and femoral neck (FN) bone mineral density (BMD) measurements were performed between and 2004 at 5-year intervals. Low-trauma energy fractures during the follow-up were validated from medical records. The study population was categorized into: 1) quartiles of score calculated based on presence of modifiable osteoporosis risk-factors (BMI, smoking, alcohol intake, physical activity, use of HT and calcium intake) and 2) number of non-modifiable osteoporosis risk-factors (age, glucocorticoid use, rheumatoid arthritis, insulin dependent diabetes, coeliac disease, chronic liver disease, early menopause or biovariectomy and fracture history) 3) three groups of total risk based on number of both modifiable and non-modifiable risk factors. All risk-factors were selected 'a priori' to analyses based on current clinical conception of osteoporosis risk and preventive factors. **Results:** Women with highest modifiable risk (group A) had T-score -0.59 SD at baseline and T-score -1.13SD at 15-year while women with lowest modifiable risk (group B) had FN T-score -0.21 SD at baseline and -0.57 SD at 15-year (p<0.001 vs. group A in ANOVA). Women with three or more non-modifiable risk-factors for osteoporosis (group C) had baseline T-score -0.65 SD and 15-year T-score -1.20 SD whereas women with no non-modifiable risk factors (group D) had baseline T-score -0.26 SD and 15-year T-score -0.73 SD (p<0.01 vs. group C in ANOVA). Women with the highest total risk (group E) had baseline T-score -0.83 SD and 15-year T-score -1.41 SD whereas women with the lowest total risk (group F) had baseline T-score -0.08 SD and 15-year T-score -0.41 SD (p<0.001 vs. group E in ANOVA, see Figure). In logistic regression model groups A/C/E had 1.8/3.0/4.7 higher odds of suffering follow-up fracture in comparison to groups B/D/F, respectively (p<0.001, see table). **Conclusions:** Both modifiable and non-modifiable factors have clinically significant impact on development of low BMD and low trauma energy fractures. All risk-factors selected for the present study accounted for a 1 SD difference in FN T-score and 5 fold odds' difference in fracture risk during the 15-year follow-up.

MO0376

Does Work Disability Predict Fractures? Paivi Rauma^{*1}, Risto Honkanen², Marjo Tuppurainen³, Heli Koivumaa-Honkanen⁴, Heikki Kroger⁵.

¹University of Eastern Finland, Finland, ²BCRU & Public Health, University of Eastern Finland, Finland, ³Kuopio University Central Hospital, Finland, ⁴University of Oulu, Finland, ⁵BCRU, University of Eastern Finland, Finland

The purpose was to examine if disability before old age is related to osteoporotic fractures and if this relationship varies according to fracture site and cause of disability. The study population consisted of the 9759 women (born in 1932-41) of the Kuopio Osteoporosis Risk Factor and Prevention (OSTPRE) Study cohort who responded to enquiries in 1989, 1994, 1999 and 2004. Information on work disability pensions was obtained from the national register which covered all pensions in Finland. Pensions allowed before March 1996 (n=3240) were included. The ICDIX diagnosis displayed the cause of disability. Self-reported fractures in 1999-2004 were validated by perusal of radiological reports. Fracture risks were estimated with logistic

regression. The risks were adjusted for age, height, weight, year of menopause, fracture history, estrogen use and medication.

A total of 905 women had sustained a fracture and 461 women an osteoporotic fracture (wrist 351, humerus 67, clinical spine 56 and hip 30). A pension increased the overall fracture risk by 18% ($p=0.019$), the risk of osteoporotic fracture by 9% ($p=0.224$) and the risk of non-osteoporotic fracture by 27% ($p=0.016$). It decreased the risk of wrist fracture by 13% ($p=0.224$). It increased the risks of hip fracture by 202% ($p=0.002$) and humerus fracture by 201% ($p<0.001$), while the spine fracture risk change was slight (+30%) ($p=0.332$). Pensions due to mental (626), neurological (134), cardiovascular (395), musculoskeletal (1621) disorders or injury (102) did not increase the overall fracture risk, while respiratory disease (150) increased it by 98% ($p=0.002$). Neurological disease increased hip fracture risk by 419% ($p=0.013$) and respiratory disease the humerus fracture risk by 431% ($p<0.001$). Mental disorders increased the risk of hip fracture by 193% ($p=0.022$) and depression the risk of humerus fracture by 257% ($p=0.004$). Adjustments (Cf. above) weakened predictions to about half. When the medication variable was dropped from the model, the predictions resumed most of their original strength.

In women before old age, disability increases the risks of hip and humerus fracture but not that of wrist fracture. Wrist fracture dominance may mask fracture risk increasing effects of disability.

Introduction: Fracture prediction algorithms such as FRAX[®] are available worldwide, and are in constant evolution. It has been suggested that greater awareness of the relationship between specific co-morbidities and fracture risk might improve fracture prediction. We utilised data from a large, multinational cohort study to investigate the effect of single or multiple co-morbidities on fracture risk.

Methods: 52,960 women were recruited from the Global Longitudinal Study of Osteoporosis in Women (GLOW). GLOW is an observational prospective study of women aged 55 years and older recruited through 723 primary physician practices in 17 sites in 10 countries. All non-institutionalized women visiting a practice within the prior 2 years were eligible. At baseline, women completed a questionnaire detailing medical history, including co-morbidity history and fracture. They were re-contacted annually thereafter and incident clinical fracture history was elicited and validated. A co-morbidity index, defined as number of co-morbidities reported at baseline from the following medical conditions, was derived: high blood pressure, high cholesterol, heart disease, stroke, asthma, chronic obstructive pulmonary disease (COPD), arthritis (reported osteoarthritis and rheumatoid arthritis), inflammatory bowel disease, coeliac disease, cancer, diabetes, multiple sclerosis and Parkinson's disease.

Results: 3224 (6.1%) women sustained an incident fracture over the 2 years of follow-up. Co-morbidities were common, with 26,215 women (49.5%) reporting hypertension, and 26,084 women (49.3%) reporting high cholesterol levels. All recorded co-morbidities were significantly associated with fracture except high cholesterol, and coeliac disease; the strongest association was seen with Parkinson's disease [hazard ratio 2.13 (95% CI 1.51-3.01), $p<0.0001$]. The hazard ratio of fracture increased with increasing co-morbidity index (Table). A stepwise model of incident fractures found that the co-morbidities that contributed most to fracture prediction, in order of importance, were: arthritis, Parkinson's disease, COPD, diabetes and multiple sclerosis.

Conclusion: Co-morbidities, particularly arthritis and Parkinson's disease, contribute significantly to fracture risk. Increasing co-morbidity index was associated with increasing fracture risk. The mechanism of this effect is unclear but might be related in part to increased risk of falling.

Table 1. Hazard ratios for the adjusted model according to co-morbidity index (adjusting for age, BMI, prior fracture, alcohol ≥ 3 drinks/day and current smoking)

Co-morbidity index	HR (95% CI)
1 vs 0	1.08 (0.94, 1.26)
2 vs 0	1.24 (1.08, 1.43)
3 vs 0	1.21 (1.04, 1.41)
4+ vs 0	1.35 (1.12, 1.61)

MO0378

Fragility Fracture and Osteoarthritis: Interaction between Bone Mineral and Bone Mass Index. Mei Chan^{*1}, Tuan Nguyen², Jacqueline Center², John Eisman², Nguyen Nguyen². ¹Osteoporosis & Bone Biology, Australia, ²Garvan Institute of Medical Research, Australia

Increased bone mineral density (BMD) and bone mass index (BMI) are associated with increased risk of osteoarthritis (OA) and reduced risk of fragility fracture. However, little is known about the relationship between fragility fracture and osteoarthritis. In this study, we sought to examine the interactions between BMD and BMI in the determination of the OA-fracture relationship. The study was part of the on-going Dubbo Osteoporosis Epidemiology Study, which involved 2,412 women and 1,452 men aged between 46 to 99 years. The individuals had been followed up for a median of 7 years (range: 0.1 to 21 years). Baseline BMD was measured at femoral neck (FNBMD) and lumbar spine (LSBMD) by dual energy X-ray absorptiometry (GE-Lunar, Madison, WI). Osteoarthritis was ascertained by self-report. The incidence of fragility fracture was ascertained by X-ray report during the follow-up period. In addition, data concerning demographic characteristics, clinical history, and lifestyle factors were obtained by a structured questionnaire. A total of 1,077 participants (691 women and 386 men) had reported a diagnosis of OA. Overall, the risk of OA was associated significantly with increased LSBMD in men (odds ratio [OR] 1.34, 95%CI, 1.19-1.52) and women (1.20; 1.09-1.32). Elevation in FNBMD was significantly associated with increased risk of OA in men (OR 1.16; 1.02-1.32), but not in women. When stratified by BMI, significant association remained between OA risk and high LSBMD amongst women with BMI < 25kg/m² (OR 1.26; 1.07-1.47) and BMI >30kg/m² (1.26; 1.05-1.51); and in men with BMI < 25kg/m² (OR 1.75; 1.37-2.27) or BMI 25-30kg/m² (1.21; 1.02-1.43). OA was associated with an increased risk of fracture. After adjusting for LSBMD women with OA had significant increased fracture risk (1.41; 1.16-1.72); however, the association was not significant in men (OR 0.96; 0.69-1.32). Moreover, the association between OA and fracture risk was particularly pronounced in women with BMI 25-30kg/m² (OR 1.45; 1.05-1.99, adjusted for LSBMD). These data suggest that high BMD is associated with a greater risk of OA in both men and women, particularly those with low BMI. The results also suggest that BMD could be a useful measure for identifying individuals at high risk of OA, particularly among those at lower BMI spectrum. Despite having higher bone density, women with self-reported OA, especially those overweight, have an increased risk of fragility fracture, suggesting that the OA-fracture association is mediated via non-BMD factors.

MO0379

Insulin Resistance Independently Had the Negative Association with the Bone Mineral Density in Normal Fasting Glucose Tolerance and Impaired Fasting Glucose Not in Diabetes. Sangmo Hong^{*1}, Chang Beom Lee¹, Yong Soo Park¹, Dong Sun Kim¹, You Hern Ahn¹, Tae Wha Kim¹, Woong Choi². ¹Endocrinology & metabolism, Hanyang University College of medicine, South Korea, ²Hanyang University Hospital, South Korea

The relationships between insulin resistance and BMD are not clear. Therefore, we conducted a cross-sectional study to examine the relationship between insulin resistance and BMD among Korean population which was divided with glucose level. This study is based on the Korea National Health and Nutrition Examination Survey (KNHANES) IV (2008). BMD and body composition were measured by DXA method. Insulin resistances were obtained by HOMA-IR equation. We divided the population according to fasting glucose level (NGT, IFG, DM). The relationship between BMD and HOMA-IR were analyzed with multiple regression models which were adjusted with age, body weight, body fat mass, body lean mass, alcohol drink, exercise level and 25(OH) vitamin D level. Among 3290 persons, 1368(41.6%) persons were men and 1922(58.4%) persons were women. In whole population, HOMA-IR showed positive correlations with total body BMD and lumbar BMD in men but not femur BMD in men and all BMD in women. However, NGT group showed negative correlation with all site BMD in both gender (table 1) and IFG group also have negative relations with BMD in total body BMD of men ($B=-0.007$, $p<0.001$) and

serum specimens from all 435 men who experienced any non-vertebral fracture from baseline until February 2007 (average follow-up 4.7 years), all 168 men with first hip fracture from baseline until August 2010 (average follow-up 7.6 years), and a sample of 1602 men randomly selected from the cohort. Cystatin C was measured using a particle-enhanced immunonephelometric assay (inter- and intra-assay CV 3.1% and 2.8%, respectively). Fractures were confirmed with x-ray reports. Modified proportional hazards models were used to estimate the relative hazards (RH) of fracture in men across quartiles of cystatin C (cutpoints 0.80, 0.90, 1.03 mg/L). In a model adjusted for age, race, site and body mass index, higher cystatin C was not related to risk of nonvertebral fracture (p-trend 0.88), but was associated with an increased risk of hip fracture (RH (95% CI): 1.0 [Q1, referent group]; 0.9 (0.5-1.7) [Q2]; 1.1 (0.6-1.9) [Q3]; and 1.6 (0.9-2.8) [Q4]; p-trend 0.04). The majority of the effect of cystatin C on hip fracture was observed among men in Q4 who had a 1.6-fold (95% CI 1.1-2.3) increase in risk compared with men in Q1-3 (Table). Adding potential confounders (including fall history, prior fracture, prevalent cardiovascular disease, frailty status and total hip BMD) one at a time to the base model modestly attenuated the association, with frailty status having the greatest impact. After simultaneous adjustment for multiple confounders, the association no longer reached significance (RH (95% CI) Q4 versus Q1-3: 1.3 (0.9-1.9)). In conclusion, older men with higher serum cystatin C are at increased risk of hip (but not any nonvertebral) fracture. The association between cystatin C and hip fracture is due at least in part to the greater prevalence of frailty among men with higher cystatin C levels.

Table. Association between Cystatin C and Risk of Hip Fracture

	Relative Hazard of Hip Fracture (95% CI)			
	Model 1 (Base)	Model 2 [†]	Model 3 [‡]	Model 4 [§]
Quartile 4	1.6 (1.1-2.3)	1.5 (1.0-2.2)	1.4 (1.0-2.0)	1.3 (0.9-1.9)
Quartiles 1-3	1.0 (referent)	1.0 (referent)	1.0 (referent)	1.0 (referent)

[†]Base model adjusted for age, race, site and body mass index

[‡]Base model + total hip BMD

[§]Base model + frailty status

[§]Final model adjusted for age, race, site, body mass index, fall history, prior fracture, prevalent cardiovascular disease, frailty status and total hip BMD

MO0383

The Presence of Arteriosclerosis is a Risk Factor for Vertebral Fracture in Patients with Type 2 Diabetes. Masahiro Yamamoto^{*1}, Toru Yamaguchi¹, Mika Yamauchi¹, Shozo Yano¹, Toshitsugu Sugimoto². ¹Shimane University Faculty of Medicine, Japan, ²Shimane University School of Medicine, Japan

Purpose: We previously reported that patients with type 2 diabetes (T2DM) have an increased risk for vertebral fractures (VFs) compared to non-T2DM controls independent of bone mineral density (BMD) (JBMR 2009). However, it is still unclear what kind of variables could become risk factors for VFs in T2DM. It is well known that low BMD is associated with prevalent cardiovascular disease in the general population, suggesting that bone fragility may be linked to atherosclerosis. The aim of this study is to investigate whether or not atherosclerosis is a risk factor for VFs in T2DM patients.

Methods: We compared parameters for atherosclerosis including maximal intima-media thickness (Max IMT), carotid plaque score (PS) and brachial-ankle pulse wave velocity (baPWV) as well as bone metabolic markers and BMD values at the lumbar spine, femoral neck and one-third of radius between Japanese T2DM patients with and without VFs (203 men over 50 years old and 171 postmenopausal women), whose creatinine levels are within normal range.

Results: Comparison between patients with and without prevalent VFs revealed no significant differences in baPWV, HbA1c, BMD values at any site, or bone metabolic markers in either sex. In contrast, Max IMT and PS in those with VFs were significantly higher than the parameters in those without VFs in each sex (Men: 2.29 1.30 mm vs. 2.68 1.30 mm, P = 0.03, 5.9 4.5 vs. 8.1 5.0, P < 0.01; Women: 2.03 0.90 mm vs. 2.61 1.37 mm, P < 0.01, 5.7 4.2 vs. 9.0 6.3, P < 0.01, respectively). Multivariate logistic regression analysis adjusted for age, BMI, HbA1c, serum creatinine, duration of diabetes, LDL-cholesterol, systolic blood pressure levels, smoking habits, and lumbar spine BMD showed that the presence of prevalent VFs was significantly associated with PS in each sex [Men: Odds ratio (OR)=1.63, 95% CI=1.09-2.43, P = 0.02; Women OR=1.85, 95%CI=1.17-2.93, P = 0.01], and with Max IMT in women (OR=1.61, 95%CI=1.04-2.49, P = 0.03).

Conclusion: These findings showed that atherosclerotic parameters were associated with prevalent VFs independent of BMD in T2DM patients, suggesting that atherosclerosis may be linked to deteriorating bone quality and become a risk factor for VFs in the population.

MO0384

Thyroid Function, Bone Loss, and Fracture in Older Men: The MrOS Study. Douglas Bauer^{*1}, Stephanie Harrison², Howard Fink³, Mary H. Samuels⁴, Peggy Cawthon⁵, Avantika Waring¹, Joseph Zmuda⁶, Eric Orwoll⁴.

¹University of California, San Francisco, USA, ²San Francisco Coordinating Center, USA, ³GRECC, Minneapolis VA Medical Center, USA, ⁴Oregon Health & Science University, USA, ⁵California Pacific Medical Center Research Institute, USA, ⁶University of Pittsburgh Graduate School of Public Health, USA

Excess thyroid hormone is associated with increased bone loss and fracture risk in older women, but there are few data in men. We performed a prospective study to determine if thyroid function, as assessed by thyroid stimulating hormone (TSH) and free thyroxine (FT4), were independently associated with bone loss and fracture risk in the Osteoporotic Fractures in Men Study (MrOS).

At the baseline MrOS visit hip DXA (Hologic QDR4500) was measured and fasting serum was archived at -80C in 5994 men over 65. Repeat hip DXA was obtained in 4418 men after a mean follow-up of 4.6 yr., and incident non-spine fractures were centrally adjudicated. We used baseline serum to measure TSH and FT4 (ADVIA Centaur, Siemens Diagnostics, Deerfield, IL) in 436 men with confirmed non-spine fracture (including 168 hip fractures) and 1604 randomly selected men. TSH and FT4 were analyzed as both continuous and categorical variable using the manufacture's normal range (TSH 0.55-4.78 mIU/L, FT4 0.70-1.85 ng/dL). Bone loss was examined using age-adjusted multivariate regression models in 1604 randomly selected men, and fractures were examined using clinic and age-adjusted hazard models that account for the case-cohort sampling and further adjusted for BMI, race, self-reported health and thyroid hormone use.

In the randomly selected subgroup, 123 (7.7%) men reported thyroid hormone use at baseline and mean (+/-SD) values of TSH and FT4 were 2.54 (2.23) and 0.99 (0.16), respectively. Compared to those without fracture, men with non-spine fracture during follow-up were significantly older (75.5 yr vs. 73.8), had lower total hip BMD (0.89 gm/cm² vs. 0.95) and were more likely to be Caucasian (95% vs. 91%), but TSH and FT4 levels were similar (TSH: 2.542.63 vs. 2.54 2.23, p=0.70, FT4: 0.980.17 vs. 0.980.16, p=0.99). In fully adjusted analyses of TSH as a continuous variable, lower TSH (indicating thyroid excess) was associated with an increased risk of the hip fracture (relative hazard=1.35 per SD decrease, 95% CI: 1.03, 1.77) but fracture risk did not differ significantly by TSH category (Table). FT4 was not associated with fracture risk and neither TSH nor FT4 were associated with bone loss (data not shown).

We conclude that in this cohort of older men lower TSH is weakly associated with an increase in hip fracture risk, but neither abnormal TSH nor FT4 are associated with bone loss or a significant increase in hip or non-spine fractures.

Fracture Outcome	Adjusted Relative Hazard (95% CI)		
	TSH<0.55 (n=52)	0.55<TSH<4.78 (n=1757)	TSH >4.78 (n=164)
Any Non-spine	1.02 (0.53, 1.94)	1.0 (referent)	0.80 (0.54, 1.19)
Hip	0.69 (0.21, 2.27)	1.0 (referent)	0.67 (0.36, 1.25)

MO0385

Vitamin D Insufficiency and Occurrence of Osteoporosis and Disability: The ROAD Study. Noriko Yoshimura^{*1}, Shigeyuki Muraki¹, Hiroyuki Oka¹, Hiroshi Kawaguchi², Kozo Nakamura³, Toru Akune¹. ¹22nd Century Medical & Research Center, University of Tokyo, Japan, ²University of Tokyo, Faculty of Medicine, Japan, ³The University of Tokyo, Japan

The aim of this study is to clarify predictive capacity of the levels of serum 25(OH)D with occurrence of osteoporosis (OP) and disability in the general population. We initiated ROAD (Research on Osteoarthritis/osteoporosis Against Disability), a large-scale population-based cohort study in urban, mountainous and seaside areas of Japan in 2005-7, and a total of 3,040 participants were registered at baseline. The present study enrolled 1,690 subjects (596 men; 1,094 women, mean age 65.2 yrs) in the mountainous and coastal areas. Of them, 1,439 (85.1%) individuals participated in the second surveillance visit in 2008-10 and 1,384 subjects (446 men, 918 women; mean age, 63.9 yrs) underwent BMD examination by DXA (Hologic Discovery) of lumbar spine (L2-4) and femoral neck (FN) at both visits. The cumulative incidence over 3 years of OP was estimated in 1,384 completers. The information of occurrence of disability, certified by a committee consisted of clinical experts, of the 967 subjects (368 men, 599 women) with 65 years and older at baseline was collected. Serum 25 (OH)D levels of all subjects were measured and VD insufficiency was characterised as a serum level of 25(OH)D <30 ng/mL. The mean levels (SD) of serum 25(OH)D of baseline participants were 25.7 (6.5) ng/mL in men and 22.0 (6.2) ng/mL in women. The prevalence of VD insufficiency was 44.4% in men and 69.0% in women (men vs. women, p<0.001). The cumulative incidence over 3 years of OP at L2-4 and FN was 2.2%/3yrs (men, 0.9%/3yrs; women, 3.0%/3yrs) and 5.8%/3yrs (men, 2.2%/3yrs; women, 7.9%/3yrs). A logistic regression analysis using occurrence of OP as an objective factor and serum levels of 25(OH)D as an explanatory factor, after

adjustment for age, weight (kg) and menstrual status (0: pre- and perimenopause, 1: menopause) in women, showed serum 25(OH)D concentration was significantly associated with occurrence of FN OP in women (+1SD, odds ratio, 0.70; 95% confidence interval (CI), 0.51-0.95, $p<0.05$). We confirmed occurrence of disability in 87 individuals (28 men, 59 women) and the incidence was estimated as 2.35/100 person-year (men, 1.96/100 person-year; women, 2.58/100 person-year). Cox's proportional hazards analysis using the incidence as an objective factor and serum levels of 25(OH)D as an explanatory factor, after adjustment for age, gender and weight showed that serum 25(OH)D level was associated with occurrence of FN OP in women (+1SD; hazard ratio, 0.75; 95%CI, 0.61-0.93, $p<0.01$). In conclusion, this longitudinal study showed that high serum 25(OH)D levels could be preventive factors for OP occurrence in women and for disability in both genders in the near future.

What Are the Risk Factors for Bone Loss in Lupus Patients?. Ioana Moldovan*, Emmanuel Katsaros, Loma Linda University, USA

The purpose of this study was to study risk factors associated with low bone density in a lupus cohort from our university clinic. The charts of 120 patients that fulfilled the American College of Rheumatology criteria for SLE (systemic lupus erythematosus) were reviewed. Forty patients had bone mineral density (BMD) assessed by dual absorptiometry scan (DXA) and their charts were reviewed in detail. Age, race, body mass index (BMI) and disease duration were recorded. Disease activity was assessed by the SLEDAI (SLE disease activity index) score. Laboratory test results were reviewed, including erythrocyte sedimentation rate (ESR), presence of double stranded DNA (dsDNA), complement levels, complete blood counts and presence of proteinuria. Vitamin D levels were included when available. Medications were recorded, including glucocorticoids, immunosuppressants, osteoporosis medications, calcium and vitamin D. The patients were aged from 21 to 76 years, with a median of 44 years old. 23 patients (57.5%) were premenopausal and 17 (42.5%) were postmenopausal. In the premenopausal group, the patients had moderate disease activity, as opposed to the postmenopausal group, where disease activity was low. 8 patients (20%) had osteoporosis, 22 (55%) had osteopenia and 10 (25%) had normal bone density. No racial predominance was observed in any of the three groups. The majority of patients were on chronic low dose glucocorticoids, however only approximately half were taking osteoporosis-preventing medications. The patients with BMD within normal and osteopenic ranges were younger and had moderate disease activity. A higher prevalence of dsDNA antibodies was also observed, supporting the higher disease activity in those groups. The patients with osteoporosis were older, in majority postmenopausal, had longer disease duration and low disease activity. ESR and vitamin D levels were not significantly different in the three groups. BMI was higher, in the overweight range, for the patients with normal BMD, and normal in the osteopenic and osteoporotic groups. In conclusion, in our study, the main determinants for low bone density were lupus disease duration and postmenopausal status. Disease activity and inflammation at the time of obtaining the DXA did not seem to play a major role in bone density. Higher BMI seemed to have a protective effect. Larger, prospective studies would be necessary to better define the risk factors associated with low bone density in lupus patients.

MO0387

Comparison of Comparison of Histomorphometric Parameters of Bone Structure in the Femoral Neck in Osteoporosis and Osteoarthritis. Yasemin Cinar¹, Funda Atamaz Calis², Yesim Kirazli³, Basak Doganavsargil³, Murat Sezak⁴, Nadir Ozkayin⁴, Semih Aydogdu⁴, Kemal Aktuglu⁴. ¹Ege University Medical Faculty, Physical Therapy & Rehabilitation, Turkey, ²Ege University Medical Faculty, Turkey, ³Ege University Medical Faculty, Pathology, Turkey, ⁴Ege University Medical Faculty, Orthopaedic Surgery, Turkey

Background: Osteoarthritis (OA) and osteoporosis (OP) are common disorders resulting in significant morbidity and an extensive use of health-care resources with the aging of population. Although they have been studied in detailed, the association of OA and OP has always been debated. In this study, we compared the histomorphometric parameters of bone structure in the femoral neck taken from patients who sustained an osteoporotic hip fracture compared with patients with OA. In addition, we aimed to assess the association between the histomorphometric parameters and bone mineral density (BMD) values. **Method:** Femoral head specimens were obtained from 18 patients (11W/ 7M) with OA and 17 patients (12W/ 5M) with femoral neck fracture due to OP during total hip arthroplasty. Histomorphometric analysis was performed by using Zeiss AxioVision LE, Rel. 4.6 (Carl Zeiss micro-imaging Inc., North America) software program to measure trabecular area (Tb.a, mm²), trabecular thickness (Tb.th, μ m) and trabecular separation (Tb.s, μ m). BMDs of lumbar spine (L1-L4) and proximal femur were measured by dual-energy X-ray absorptiometry (DXA) using a Hologic QDR 4500A apparatus (Hologic, Waltham, MA). Also, urine deoxypyridinoline (DPD), serum osteocalcin, 25(OH)D, PTH, calcium and phosphate were measured in all patients. **Results:** The mean age was 68.6 7.8 and 79.1 5.7 for OA and OP patients, respectively. While the Tb.a and Tb.th parameters were significantly higher in the OA

group (Tb.a was 23.2 9.8 vs 13.6 5.5 and Tb.th was 282.2 92.3 vs 123.6 27.5, $p<0.05$), Tb.s was 1084.8 366.1 in the OP group with a significant difference when compared with OA group (496.2 136.1, $p<0.05$). Among the biochemical and hormonal parameters, urine DPD was significantly higher in OP patients (17.5 9.8 vs 9.8 4.3, $p<0.05$). All histomorphometric parameters were highly correlated with the BMDs of lumbar spine and proximal femur ($p<0.01$). **Conclusion:** We observed significant differences in histomorphometric parameters between the patients with OA and OP suggesting that the loss of the trabecular bone plays an important role in the osteoporotic hip fracture. In addition, the high correlations between histomorphometric parameters and BMDs support the value of DEXA measurement in the detection of OP.

Determinants of Circulating Vitamin D and Bone Density in a Young Adult Physician Population. Terri Washington, Buvana Manickam*, Aaron Benjamin, Elena Barengolts, Elizabeth Villagrana, Subhash Kukreja, University of Illinois, USA

Introduction: In this prospective cohort study, we examined determinants of serum 25-hydroxyvitamin D (25OHD) level and bone mineral density (BMD) in young physicians.

Materials and Methods: We evaluated lifestyle, serum 25OHD, parathyroid hormone (PTH) and calcium levels as well as BMD by dual-energy X-ray absorptiometry in apparently healthy resident physicians and medical students including Caucasian subjects (CS), Asian (South and East Asians) subjects (AS), and other ethnic (Hispanic and Black) subjects (OS) working at an urban hospital.

Results: Among 104 participants 75% were females and 42% were whites. Prevalence of 25OHD deficiency (25OHD<20 ng/ml), insufficiency (25OHD 20-29 ng/ml), and sufficiency (25OHD \geq 30 ng/ml) was 48%, 29%, and 23% respectively. Prevalence of normal BMD, osteopenia, and osteoporosis was 63%, 31%, and 6% respectively. Table summarizes the distribution of risk factors and clinical characteristics according to the ethnic groups. Caucasians were taller and had higher serum 25OHD level than AS and OS groups ($p=0.023$ and $p<0.0001$, respectively). Serum 25OHD level was higher in CS than in AS and OS but PTH level and proportion of physicians with relative secondary hyperparathyroidism (PTH >43 pg/ml) were similar among the groups. There was a significant negative linear association between serum 25OHD and PTH in Caucasians ($r=-0.48$, $p=0.008$) and Asians ($r=-0.38$, $p=0.02$) but not in OS ($r=-0.46$, $p=0.26$).

Subjects with vitamin D deficiency were more likely to be of Asian ethnicity (67.4%, $p=0.003$), had higher prevalence of family history of osteoporosis (65.8%, $p=0.01$), were less likely to take vitamin D supplements (61.2%, $p=0.03$) but more likely to be exercising (62.3%, $p=0.01$).

In multiple regression analysis of the entire group, independent determinants ($p<0.05$ for all) of serum 25OHD level included age, race, family history of osteoporosis, use of vitamin D supplements, and sun exposure. These parameters explained 49% of serum 25OHD level variation ($r^2=0.49$). Sun exposure was associated with 25OHD level in CS and AS but not in OS group. Significant determinants of low BMD (osteopenia plus osteoporosis) included gender ($p=0.005$) and BMI ($p<0.0001$).

Conclusion: Young resident physicians and medical students have relatively high prevalence of low serum vitamin D and low BMD despite of healthy lifestyle. Serum 25OHD level in this population is determined in part by modifiable risk factors such as vitamin D supplements and sun exposure.

Effect of Voluntary Exercise and Energy Restriction on Bone Mineral Density in Female Rat Model. Kaoru Yanaka^{*1}, Mitsuru Higuchi², Yoshiko Ishimi¹. ¹Waseda University & National Institute of Health & Nutrition, Japan, ²Waseda University, Japan

Female Athlete Triad is a syndrome of that involves disordered eating, amenorrhea, and low bone mass/osteoporosis in female athletes. The main pathophysiologic mechanism that leads low bone mass is low energy availability and functional hypothalamic amenorrhea. The aim of the present study was to establish animal model of osteoporosis for female athlete. We have designed to investigate the effect of long-term energy restriction on bone mineral density (BMD), and 17 β -estradiol (E2), and luteinizing hormone (LH) levels in voluntary wheel running female rats. Fourteen female Sprague-Dawley rats (8 wk old) were randomly assigned to two groups, running group (n=8) or sedentary group (n=6). Water and diet were available to all rats initial 10-wk baseline period. Running group were free access to wheels throughout the study. At 18 wk of age, the rats in running group were randomized into two groups: Run-Control-fed (ad lib-fed) group (RC group, n=4) or Run-Restricted-fed (30 % energy restriction for 14-wk) group (RR group, n=4). Daily food intake, body weight, and running distance were collected throughout the 24-wk experimental periods. Serum E2 and LH concentration were measured by ELISA. Femoral BMD were determined by dual-energy X-ray absorptiometry (DXA). Histomorphometric analysis of the femur was performed with an image analyzing system linked to a light microscope. The food intake and body weight, in RR group were significantly decreased during food restricted phase. The running distance was not different in both running groups. The BMD in the RR group was significantly lower than RC and sedentary groups. Histomorphometric analysis showed that the bone volume (BV/TV) in distal femoral cancellous bone was lower in the RR group than that in the sedentary group. Serum E2 levels were significantly low in the RR and RC groups than sedentary group. Furthermore, LH level was markedly reduced in RR group compared with RC and sedentary groups. These distinct endocrine profiles in this model suggest that energy restriction with voluntary exercise disturbs the hypothalamic-pituitary-ovary axis. The present study indicated that the long term energy restriction in voluntary wheel running induced bone loss in female rats with intact ovary. This may establish a foundation for osteoporosis for female athlete rat model caused by the dysfunction of reproductive system.

Bone Turnover Markers in Subclinical Hyperthyroidism. Ana Paula Barbosa^{*1}, Mario Rui Mascarenhas², Antonio Gouveia de Oliveira³, Vera Simoes⁴, Ana Gonçaves⁵, David Santos Pinto⁶, Manuel Bicho⁷, Isabel do Carmo⁵. ¹Endocrinology University Clinic & Metabolism & Endocrinology Center, Genetics Laboratory (FMUL), CEDML - Endocrinology, Diabetes & Metabolism Clinic, Lda., Endocrinology, Diabetes & Metabolism Department, Santa Maria Hospital, CHLN-EPE, Portugal, ²Faculdade de Medicina Lisboa, Portugal, ³Biostatistics Department, FCMUNL, Portugal, ⁴Metabolism & Endocrinology Center, Genetics Laboratory (FMUL), CEDML - Endocrinology, Diabetes & Metabolism Clinic, Lda., Portugal, ⁵Endocrinology, Diabetes & Metabolism Department, Santa Maria Hospital, CHLN-EPE, Portugal, ⁶CEDML - Endocrinology, Diabetes & Metabolism Clinic, Lda., Portugal, ⁷Metabolism & Endocrinology Center, Genetics Laboratory (FMUL), Portugal

Subclinical hyperthyroidism, a clinical condition defined by a low TSH level with normal T4 and T3, can predispose to reduced bone mineral density (BMD), osteoporosis and fragility fractures. Recently, the data of some studies suggest that TSH is a direct negative regulator of bone remodeling, inhibiting both formation and survival of osteoclasts and inhibiting the differentiation of osteoblasts.

PURPOSE

To evaluate the relationships between the bone turnover markers plasma levels, the hormones affecting bone metabolism and BMD, in patients with subclinical hyperthyroidism.

MATERIAL AND METHODS

In a group of 32 subclinical hyperthyroid postmenopausal patients the plasma bone turnover markers osteocalcin, CTX, and bone alkaline phosphatase, as well as the blood concentrations of the thyroid hormones, TSH, PTH, IGF-1, calcium, SHBG and 25(OH)vitamin D were measured.

The BMD (g/cm²) at the lumbar spine (L1-L4), at the proximal femur, at the distal radius and at the whole body and the total body soft tissues composition (lean and fat masses, Kg) were evaluated by dual X-ray absorptiometry, using the Hologic QDR Discovery W densitometer.

No patient was previously treated for hyperthyroidism and/or OP.

Descriptive and regression tests were used and statistical significance was considered for P < 0.05.

RESULTS

These women with subclinical hyperthyroidism presented a mean age (SD) of 59.1 (12.5) years and the mean height was 1.56 (0.06) m, the mean weight was 70.1 (11.4) kg and the mean BMI was 28.8 (4.1) kg/m².

The CTX plasma levels were significantly correlated to PTH and IGF-1 plasma levels. The TSH plasma levels were significantly related with the PTH and the 25(OH) vitamin D plasma levels. Finally, the osteocalcin plasma levels were significantly related with the bone alkaline phosphatase blood concentrations.

CONCLUSIONS

These results may suggest that in subclinical hyperthyroidism the bone turnover markers and some of the hormones involved in bone metabolism are already modified even before the increase of the thyroid hormone levels, indicating a possible important isolated role for the TSH in bone tissue. Thus, the measures for changing life style, namely the increase in calcium intake and the sun exposure, should be precociously instituted, in order to minimize the bone mass loss and the possible increase of osteoporotic fractures risk.

MO0391

Idiopathic Osteoporosis in Premenopausal Women: Bone Turnover Provides Clues to Pathogenesis. Adi Cohen^{*1}, Emily Stein², David Dempster³, Hua Zhou⁴, Serge Cremers³, Clifford Rosen⁵, Thomas Nickolas¹, Thomas Kohler⁶, Andreas Wirth⁷, Harry Van Lenthe⁸, Ralph Muller⁶, Polly Chen¹, Robert Recker⁹, Joan Lappe¹⁰, Elizabeth Shane². ¹Columbia University Medical Center, USA, ²Columbia University College of Physicians & Surgeons, USA, ³Columbia University, USA, ⁴Helen Hayes Hospital, USA, ⁵Maine Medical Center, USA, ⁶ETH Zurich, Switzerland, ⁷Institute for Biomechanics, ETH Zurich, Switzerland, ⁸Katholieke Universiteit Leuven, Belgium, ⁹Creighton University Osteoporosis Research Center, USA, ¹⁰Creighton University, USA

Idiopathic osteoporosis (IOP) in premenopausal women is an uncommon disorder in which fragility fractures occur in otherwise healthy women with intact gonadal function. Whether women with idiopathic low bone mineral density (BMD) and no fractures truly have IOP is uncertain. To investigate the pathogenesis of IOP, we conducted a case-control study of premenopausal women with IOP: 45 with fractures, 19 with low BMD (Z score < -2.0), and 40 controls. All had tetracycline-labeled transiliac biopsies analyzed by 2D histomorphometry and micro-CT, and stiffness estimated by finite element analysis. Women with IOP had lower BMI than Controls, but serum/urine calcium, estradiol, vitamin D metabolites, IGF-1 and most bone turnover markers (BTMs) were similar. Only serum PTH (2912 vs 229 pg/ml) and the resorption marker, TRAP5b (2.312 vs 1.610 U/l), were significantly higher in Subjects than Controls (both p < 0.01). Compared to Controls, women with IOP had thinner cortices, fewer, thinner, more widely spaced and unevenly distributed trabeculae and lower stiffness. Static remodeling parameters reflecting osteoblast synthesis of osteoid were lower in Subjects than Controls; osteoid width (OWi) was 12% lower (p = 0.02) and mean wall width (WWi) 4% and 6% lower at endocortical and intracortical surfaces, respectively (p < 0.02). Dynamic parameters, bone formation rate (BFR/BS), mineral apposition rate and activation frequency were variable, but comparable on average to Controls. All biochemical and histomorphometric parameters were indistinguishable between IOP subjects with and without fractures. Hypothesizing that the pathogenesis of IOP may differ between women with low and high bone turnover, we analyzed subjects by tertiles of BFR/BS (Table). Women in the low BFR/BS group had significantly lower BTMs, OWi, WWi, Bone Volume Fraction (BV/TV) and stiffness than those in the high tertile. The low BFR/BS group also had higher age adjusted IGF-1 than the upper two tertiles (195+43 vs 170+43; p = 0.04), suggesting osteoblast dysfunction and resistance to IGF-1. Women in the high tertile had higher serum 1,25(OH)₂D and a trend toward higher PTH (p = 0.06) and urine calcium (p = 0.07), suggestive of mild idiopathic hypercalciuria. In conclusion, diagnosis of IOP in premenopausal women should not require a history of fracture. Bone turnover is heterogeneous in women with IOP and the pathogenesis of IOP may differ according to whether bone turnover is high, normal or low.

Preliminary Clinical Study Regarding Improvement Of Dental Implants Stability In Osteoporosis. Horia Barbu^{*1}, Andreea Brehar¹, Monica Comaneanu¹, Adi Lorean², Doina Ghergic¹, Constantin Dumitrache¹.
¹Romania, ²Israel

Purpose: There is a general concern for finding practical solutions that allow for the best possible primary stability of dental implants, an essential condition for a favorable long-term prognosis of implant-prosthetic treatments and improving patient's quality of life. The aim of our study is to investigate and increase stability of the inserted implants in patients with osteoporosis, according to their size and shape, but also to the biomechanical properties of bone.

Methods: We studied two groups of patients, group A consisting of patients without osteoporosis and group B consisting of patients with osteoporosis. Bone quality and risk of implant failure assessment were evaluated by several investigations, including bone turnover using telopeptides Beta Crosslaps (B-ctx) measurement. For group A, surgical protocols specific for clinically healthy patients were applied. In group B, the classic bisphosphonate treatment was replaced with strontium ranelate for 3-12 months, in order to avoid complications such as osteonecrosis of the jaw. Surgical procedures for insertion of dental implants were performed after the B-ctx value passed the 150 pg/mL threshold. We used Resonance Frequency Analysis (RFA) every 3 weeks to monitor variations in the curve drawn by ISQ (implant stability quotient) values from the beginning (primary stability), to the moment of obtaining osseointegration. After prosthetic loading, records of ISQ values were done every three months for one year.

Results: Although the original ISQ index had a greater value (69-87 in group A, 51-64 in group B, respectively), it was observed that in the first 2 months after implant insertion, ISQ value shows a significant decline and over the next 4-6 months implant stability quotient increases, but fails to reach baseline. Those initial values are equaled, or even surpassed 8-10 months after prosthetic loading.

Conclusions: Interdisciplinary collaboration is essential to improve long-term predictability of implant-prosthetic treatment applied to patients with osteoporosis. Strontium ranelate intake for 9-12 months has clearly improved primary stability in subjects belonging to group B and no case of osteonecrosis was found. Inserted implant macro-geometry has a decisive role in obtaining a rigid mechanical fixation in osteoporotic bone and good results are achieved with implants with rough and bioactive surfaces. RFA is a noninvasive, atraumatic and very reliable method of investigation.

Reduction in Circulating Estrogen and Increase in Postprandial Serotonin Levels in Subjects with Helicobacter Pylori CagA+ Infection: Effects on Circadian Rhythm of Bone Turnover and Skeletal Health. Luigi Gennari^{*1}, Daniela Merlotti¹, Natale Figura², Maria Stella Campagna², Maria Beatrice Franci², Anna Calabro², Annalisa Avanzati², Barbara Lucani², Stefania Lardiello², Leonardo Vaglio², Konstantinos Stolkakis², Ranuccio Nuti¹.
¹University of Siena, Italy, ²Department of Internal Medicine, Endocrine-Metabolic Sciences & Biochemistry, University of Siena, Italy

Helicobacter pylori (HP) is a gram-negative bacterium that affects more than 30% of the world population and elicits a chronic inflammatory response in the gastric mucosa. Several lines of evidence indicate that HP is a major cofactor for the development of upper gastrointestinal disorders but more recent studies also indicated that HP may influence the clinical course of other chronic, age-related conditions such as atherosclerosis and glucose tolerance. In a preliminary analysis in elderly men we demonstrated that infection by HP strains bearing the cytotoxin associated gene A (CagA, that is associated with enhanced inflammatory response) increases bone resorption and is more prevalent in osteoporotic than non-osteoporotic subjects. Here we confirm these results in an extended population-based analysis showing a consistent association between seropositivity for CagA bearing HP strains and osteoporosis or fractures in a large cohort of 1109 elderly male and female subjects. In order to provide further insight on the potential mechanisms underlying this association, we explored the relationship between HP infection and bone turnover markers (bone alkaline phosphatase and serum CTX), 25OH vitamin D, PTH, sex hormone and SHBG levels, as well as other gastrointestinal peptides such as adiponectin, ghrelin and serotonin. Half of the patients underwent all measurements at 8.00 am in a fasting state while the remaining half underwent blood sampling post-feeding, at 3.00 pm, in order to uncover potential effects on circadian rhythms. Consistent with our previous preliminary observation we observed reduced total and free estradiol levels in both male and female subjects affected by HP CagA positive strains, with an higher and statistically significant difference in the fasting state. Moreover, in CagA positive patients circulating ghrelin was significantly lower than in CagA negative or non-affected subjects. Interestingly, while serum CTX significantly decreased after feeding in all subjects, we observed a statistically significant decrease in postprandial levels of bone alkaline phosphatase only in CagA positive subjects that was associated with an increase in serum and plasma serotonin levels. In conclusion, the presence of chronic HP infection by strains expressing CagA may be considered a risk factor for osteoporosis and fractures in males as well as in females. The underlying pathogenetic mechanisms may include variation in estrogen and other gastrointestinal peptides and need to be clarified in further studies.

Aging of Iliac Cortical Bone in Normal Women and Men. ANNE-SOPHIE BRAVO MARTIN^{*1}, Jean-Charles Giunta¹, Roland Chapurlat², Georges Boivin³.
¹INSERM, UMR 1033 ; Université de Lyon, France, ²E. Herriot Hospital, France, ³INSERM, UMR 1033 ; Université de Lyon, France

In Human, bone structural changes with age have been mainly described rather in cancellous bone than in cortical bone. Yet, about 80% of all fractures with aging occur at sites mainly cortical (1). Cortical bone organization depends on bone remodeling (2) which is unbalanced with aging in favor of bone resorption leading to bone loss and fragility (3,4). The aim of this study is to evaluate, in a normal human population, the structural changes with aging in cortical bone. Iliac bone samples were taken at necropsy from 99 men and 68 women aged from 17 to 91 years, who died suddenly without apparent bone disease. This population is well distributed with similar numbers of women before and after 50 years, and with 2/3 of men between 17 and 49 years. Undecalcified 100 µm-thick bone sections perpendicular to Haversian canals were microradiographed (5). Cortical thickness, cortical porosity, number of intact osteons, number of fragments of osteons, Haversian canal diameter, cortical mean wall thickness (MWT) and degree of mineralization (DMB) were measured on calcified cortical bone tissue. Cortical thickness decreases ($p < 0.01$) and its porosity increases ($p < 0.02$) with age in both sexes. These are explained by an increase of bone resorption with time leading to enlarged cavities incompletely refilled. The increase of cortical porosity with age can also be partly due to an augmentation of the number of Haversian canals in men (number of intact osteons, $p < 0.05$), and by the enlargement of Haversian canals in women ($p < 0.01$), especially after 50 years. In women, the increase of the number of fragments of osteons ($p < 0.0001$), more marked from 50 years, results from increased bone remodeling, leading to extension of interstitial bone. To the contrary of trabecular MWT (8) but in agreement with data on rib cortical osteons (2), iliac cortical MWT doesn't change significantly with age in men and women. Cortical DMB increases with age in both sexes, but significantly only in men ($p < 0.0001$). To conclude, in women and men, aging and unbalanced bone remodeling lead to cortical thinning, extended cortical porosity and increased amount of interstitial bone.

The Interaction Between Calcium and Vitamin D Intake on PTH and Bone Biomarkers. Mageda Mikhail*. Winthrop University Hospital, USA

Background: Adequate calcium and vitamin D are needed to maintain calcium homeostasis and to support skeletal health. **Objective:** To examine the influence of calcium supplementation and vitamin D supplementation separately as well as their interaction and their combined effect on serum PTH and bone biomarkers in healthy postmenopausal women. **Design:** Healthy women, age 45 and older who were menopausal for over 1 year were recruited to participate in a 6-month study. Participants were randomly assigned one of four groups: 1) placebo, 2) vitamin D 100 mcg daily alone, 3) calcium 1200 mg daily alone, 4) vitamin D 100 mcg + calcium 1200 mg daily. Fasting serum calcium, PTH, 25-OHD, 1,25-OH2D, CTX, P1NP, and urine calcium/creatinine ratio were measured at baseline, and at 15 and 28 weeks after baseline. Results: One hundred and fifty nine participants were randomized, with an average age of 60 years and average BMI of 27 kg/m², and 120 participants completed the study. After adjusting for baseline differences and time, the three active treatments all significantly reduced the fasting PTH levels from baseline. The reduction in PTH was highest in the combined calcium + vitamin D treatment group. Using the stringent analysis for multiple comparisons, calcium + vitamin D treatment significantly lowered PTH compared to placebo. For CTX and P1NP, the largest and most significant drop occurred with the use of calcium. Using the stringent analysis for multiple comparisons, either calcium treatment or calcium + vitamin D treatment significantly lowered CTX, compared to placebo. For P1NP, however, only calcium treatment significantly lowered it. A table of mean declines from baseline of PTH, CTX, and P1NP by treatment group is provided. **Conclusion:** Calcium plus vitamin D treatment caused the most significant lowering of PTH compared to placebo, while calcium treatment alone caused the most significant lowering of CTX and P1NP compared to placebo.

Mean Declines (from Baseline) of PTH, P1NP and CTX, by Treatment Group

Group	PTH (pg/ml)	p-value	P1NP (ug/L)	p-value	CTX (ng/ml)	p-value
Vitamin D	-3.59	0.0193	-0.284	0.8698	0.059	0.0093
Placebo	-0.74	0.6837	0.523	0.8068	0.049	0.0732
Calcium + D	-8.67	< 0.0001	-5.115	0.0008	-0.046	0.0456
Calcium	-4.40	0.0139	-7.896	0.0002	-0.077	0.0042

Note: A negative sign indicates a decline.

By a stringent analysis for multiple pair-wise comparisons, we find the following group differences ($p < 0.05$): For PTH, there was a significant difference in decline for Calcium + D vs. Placebo. For P1NP, there were significant differences in declines for Calcium vs. Vitamin D and Calcium vs. Placebo. For CTX, there were significant differences in declines for Calcium vs. Vitamin D and Calcium vs. Placebo. For CTX, there were significant differences in declines for Calcium + D vs. Vitamin D and Calcium + D vs. Placebo.

Bone Mineral Density (BMD) Loss Due to Weight Reduction Differs in Obese and Overweight: The Contribution of Fat and Lean Tissue. Sue Shapses¹, Claudia Pop¹, Deeptha Sukumar¹, Robert Zurfluh¹, Steven Heymsfield², Yvette Schluskel¹. ¹Rutgers University, USA, ²Pennington biomedical Research Center, USA

Changes in soft tissue composition accompany voluntary weight reduction but whether the loss in these tissue compartments can predict the change in BMD by obesity status is not clear. We examined pooled data from 231 overweight and obese women and men 24-74 years of age who were assigned to six months of a weight loss (WL, > 2.5% loss) or weight maintenance (WM) intervention from 1995-2010. Participants were asked to maintain their usual physical activity level. Body composition, BMD and hormones were measured. Multiple regression analysis was performed to examine whether soft tissue changes could explain the variance in BMD loss using body mass index (BMI) definitions of overweight (25-29.9 kg/m²) or obese (> 30 kg/m²) classification in the model. Results: Total fat loss explained the variance for BMD loss at the trochanter, and ultra distal (UD) and 33% radius ($r^2 = 2-6\%$; $p < 0.05$), whereas lean tissue loss explained the variance for total body BMD (TBBMD, $r^2 = 10\%$, $p < 0.001$) and there was no difference due to BMI classification. 157 individuals lost 7.2 4.8% of their weight and 74 maintained their weight (0.1 2.3%). Compared to the WM group, the WL group lost more BMD ($p < 0.05$) at the 33% radius (-1.2 3.0%) and trochanter (-0.8 3.8%). Due to baseline differences in the population, we also analyzed a subset of postmenopausal women ($n=121$) and found that total fat loss remained a predictor of the UD radius and lean tissue remained a predictor of TBBMD ($r^2=14\%$). BMI classification explained ($r^2 = 5-6\%$) the BMD loss at the 33% radius and trochanter. Two-way ANOVA (WL/WM by BMI classification) shows a greater reduction in fat:lean tissue in the overweight (3:1) than obese (1:1) women despite similar weight loss of 6.0 2.9 kg. Surprisingly, at the 33% radius, BMD loss was greater in the obese compared to overweight, irrespective of weight loss. In contrast, only the overweight showed weight-loss induced BMD loss (-2.1 4.3% at trochanter; $p < 0.005$). These findings show that fat loss explains most of the loss in BMD at sites vulnerable to fracture in the entire population, and that bone and soft tissue loss occurs differently in obese and overweight women. Loss of BMD at the 33% radius (non-weight bearing) is vulnerable to bone loss irrespective of weight reduction in the obese, whereas overweight women attempting to lose moderate weight are at greater risk of bone loss despite attenuated loss of lean tissue.

Determination of Serum Sclerostin Levels in Women with Anorexia Nervosa. Christina Bittighefer¹, Julia Wild², Angela Trubrich¹, Judith Haschka³, Roland Kocian⁴, Wolfgang Woloszczuk⁵, Stylianios Kapiotis⁶, Sebastian Dinu⁶, Christian Muschitz³, Heinrich Resch⁷. ¹The VINFORCE Study Group - St. Vincent Hospital – Medical Department II, Academic Teaching Hospital of the Medical University of Vienna, Austria, ²Medical University of Vienna, Department of Obstetrics & Gynecology, Austria, ³St. Vincent's Hospital, Austria, ⁴St. Vincent Hospital Vienna, Austria, ⁵Biomarker Design ForschungsGmbH, Vienna, Austria, ⁶Central Laboratory St. Vincent Group, Austria, ⁷Medical University Vienna, Austria

Purpose: Bone metabolism is severely altered in patients with anorexia nervosa (AN) causing bone loss and consequently an increased fracture risk. However, the pathophysiology is still under debate. AN is classified into two subgroups, the restricting type (increased physical activity, rejection of eating) and the binge/purging type (self-induced vomiting, misuse of laxatives, diuretics, or enemas). It has been recently recognized that sclerostin (scl), a glycoprotein expressed by osteocytes, regulates bone mass by inhibiting Wnt signaling and bone formation. However, the importance of sclerostin in patients with AN and low bone mass is unknown. Methods: We compared serum scl levels in 18 patients (pts) with AN (mean age 23.3 4.3 ys; mean BMI 14.8 1.2 kg/m²). Subsequently we allocated the AN pts into the restricting type ($n=8$; mean age 20.8 2.5 ys; mean BMI 14.2 1.2 kg/m²) and the binge/purging type ($n=10$; mean age 24.4 4.4 ys, mean BMI 15.2 1.1 kg/m²). Pts were

compared with 21 healthy premenopausal women (mean age 27.1 2.7 ys; mean BMI 21.8 2.9 kg/m²). Sclerostin was determined by a quantitative sandwich ELISA assay (Biomedica, Vienna, Austria). Scl levels were correlated with demographic data, female sex hormones and BMD measurements at hip and lumbar spine. Results: Scl levels were significantly lower in women with AN compared to controls (12.7 4.8 pmol/L vs 17.0 7.4 pmol/L, $p=0.03$). Particularly pts in the restricting subgroup showed lower scl levels than women in the binge/purging subgroup (9.8 2.0 pmol/L vs 14.4 5.2 pmol/L, $p=0.03$). The restricting type had significantly lower scl levels ($p=0.01$) compared to healthy women, whereas the scl levels in the binge/purging type were similar to scl levels in the control group. Serum scl levels were positively correlated with BMI in women with AN ($r=0.49$, 95% CI 0.5595; 0.7763; $p=0.03$), but not with female sex hormones and BMD values. Conclusion: Our data clearly show significantly decreased scl levels in pts with AN compared to healthy, age-matched female controls. Within the two AN subgroups the restricting type showed significantly lower scl levels, most likely caused by the hyperactivity in this AN type as a possible explanation for these differences. Furthermore, there seems to be no relationship between estrogen levels and scl secretion, giving evidence of an uncoupling in bone remodeling.

MO0398

Factors Associated with Fractional Calcium Absorption (FCA) in Postmenopausal Women. Karen Hansen¹, Andrea Jones², Lisa Davis¹, Elizabeth Crone¹, Christina Lemon¹, Diane Burroughs¹, Martin Shafer³. ¹University of Wisconsin, USA, ²University of Wisconsin School of Medicine & Public Health, USA, ³Wisconsin State Lab of Hygiene, USA

Introduction: Increasing calcium absorption efficiency was associated with higher femoral neck bone mineral density and lower risk of hip fracture in the Study of Osteoporotic Fractures. In a post-hoc analysis of three separate calcium absorption studies, we evaluated associations between demographic, dietary and laboratory characteristics and FCA in postmenopausal women.

Methods: 50 postmenopausal women were recruited for studies evaluating changes in calcium absorption related to correction of vitamin D insufficiency ($n=19$), use of proton pump inhibitors ($n=21$) and use of aromatase inhibitors to treat breast cancer ($n=10$). The baseline calcium absorption visit was used for the current analysis. Levels of dual stable isotopes in a 24-hour urine collection were used to calculate FCA. Food during each 25-hour inpatient study replicated subjects' outpatient diet based on analysis of 7-day diet diaries. Demographic variables included race, age, height, weight and body mass index. Dietary variables included the average daily intake of kilocalories, carbohydrates, protein, fat, fiber, calcium, vitamin D, magnesium, iron, sodium, caffeine and oxalate. Laboratory variables included serum calcium, creatinine, parathyroid hormone, 25(OH)D and 1,25(OH)₂D levels. We used Pearson's correlation coefficients, independent sample t-tests and multivariate linear models to assess characteristics associated with FCA.

Results: 50 women with a mean (SD) age of 60 (8) years and FCA of 20% (8%) of were studied. FCA was significantly lower in Caucasian compared to non-Caucasian women (19% versus 29%, $p=0.001$). Table 1 presents a comparison of variables in women with FCA above and below the median. FCA correlated negatively with age ($r = -0.48$, $p < 0.001$), calcium intake through diet and supplements ($r = -0.53$, $p < 0.001$), dietary protein ($r = -0.35$, $p = 0.02$), dietary magnesium ($r = -0.38$, $p = 0.008$), and serum 25 (OH)D levels ($r = -0.50$, $p < 0.001$). In multivariate models, age and calcium intake accounted for 42% of the variance in calcium absorption, with no improvement in the model with the addition of other variables.

Conclusions: In this cross-sectional assessment of variables associated with FCA postmenopausal women, increasing age and increasing calcium intake were inversely associated with FCA and accounted for 42% of the variance in FCA. Interventions to increase FCA in postmenopausal women might be of limited benefit in the elderly or in women with high calcium intake.

Table: Characteristics of women with fractional calcium absorption above and below the median

Variable	Mean (SD) or % for Subjects with FCA Below the Median (n=23)	Mean (SD) or % for Subjects with FCA Above the Median (n=25)	p-value
Demographic Variables			
Age, years	64 (7)	56 (7)	<0.001

Physiological Supplementation of Sex Steroids Suppresses Bone Turnover in Male But Not Female Gonadectomized Mice. Alexandra Heyny*, Carmen Streicher, Reinhold Erben. University of Veterinary Medicine, Austria

Although mice are very often used as models of estrogen and androgen deficiency-induced bone loss, the existing data about the bony effects of a physiological supplementation of estradiol (E2) and testosterone in gonadectomized (GX) mice are scarce. It was the aim of this study to assess the skeletal effects of physiological doses of sex hormones in GX C57BL/6 mice. Physiological doses were defined by estrogenic and androgenic effects on typical target organs such as the uterus in females and seminal vesicles in males. Twelve-week-old male and female C57BL/6 mice were ovariectomized (OVX) or orchietomized (ORX). OVX mice received vehicle (benzylbenzoate/ricinus oil 1:5, v/v, B/R) or daily doses of 1.25, 2.5, 5, and 10 µg/kg E2 five times per week. ORX mice were treated with vehicle (B/R) or 20, 30, and 40 mg/kg testosterone undecanoate (TUD) twice weekly. All mice were killed 4 weeks post-GX after in vivo calcein labeling. Ten µg/kg estradiol in OVX mice, and 30 mg/kg TUD in ORX mice completely prevented uterine and seminal gland atrophy, respectively. Peripheral quantitative computed tomography (pQCT) and µ-CT analysis revealed femoral and lumbar vertebral cortical and cancellous bone loss in vehicle-treated OVX and ORX mice at 1 month post-GX. Osteopenia in male mice was associated with increased cancellous bone formation rate, higher osteoclast numbers, and augmented urinary excretion of collagen crosslinks, whereas vehicle-treated OVX mice did not show an increase in bone turnover, relative to sham-operated mice. In both ORX and OVX mice, the doses of E2 and TUD which prevented uterine and seminal gland atrophy also completely prevented post-GX bone loss. However, 30 mg/kg TUD in ORX mice suppressed bone formation rate, osteoclast numbers, and urinary collagen crosslink excretion relative to vehicle-treated ORX mice, whereas 10 µg/kg E2 lacked a suppressive effect on bone turnover in OVX mice. We conclude that male C57BL/6 mice show a typical high turnover osteopenia after androgen withdrawal at 1 month post-ORX which is suppressed by physiological doses of testosterone. In contrast, post-OVX bone loss in female C57BL/6 mice is not associated with increased bone turnover at 1 month post-OVX, and supplementation of OVX mice with physiological doses of E2 does not suppress bone turnover.

Sclerostin Production Decreases after Ovariectomy in Mouse Bones in Association with an Increase in Bone Formation. Sandra Jastrzebski¹, Judith Kalinowski¹, Yurong Fei¹, Shilpa Choudhary¹, Carol Pilbeam¹, Farayal Mirza¹, Maria Marie Hurley², Joseph Lorenzo^{*1}. ¹University of Connecticut Health Center, USA, ²University of Connecticut Health Center School of Medicine, USA

Sclerostin (SOST) is a negative regulator of Wnt signaling and bone formation. In postmenopausal women SOST and serum estrogen (E) levels negatively correlate. We examined if ovariectomy (OVX) altered bone SOST production and bone turnover in mice. 8-wk-old C57BL/6 females were either sham-operated (SHAM) or OVX. In this model bone loss begins 3 wks after OVX and is maximal after 5 wks. Femurs and calvaria were examined for SOST mRNA and protein by qRT-PCR and western blotting. Bone turnover was determined by serum CTX and osteocalcin (OC) ELISA. In vitro osteoclastogenesis in bone marrow cells was induced with M-CSF and RANKL for 6 d. We also cultured murine bone marrow cells for 16 days in osteogenic conditions +/- E (estradiol 10 nM) and measured medium SOST by ELISA and SOST and alkaline phosphatase (AP) mRNA by qRT-PCR. Our ELISA can measure murine SOST in medium but not in serum because of interfering substances.

The effects of OVX on SOST mRNA and protein differed between skeletal sites. In calvaria there was a trend for a 33% decrease in SOST mRNA with OVX (p=0.09) at 3 wks. At 6 wks the decrease in calvaria SOST mRNA was 52 % (p<0.01). In femurs SOST mRNA decreased by 53% (p<0.01) with OVX at 3 wks but was not different from SHAM at 6 wks. SOST protein in calvaria decreased with OVX by 62 % at 3 wks and 42 % at 6 wks (p<0.01 for both). There was no difference in SOST protein in femurs between SHAM and OVX at either time point. Bone turnover also differed with time. Formation (OC) increased by 36% at 3 wks and 34 % at 6 wks (p<0.01 for both). However, resorption (CTX) was increased at 3 wks (by 33%, p<0.01) but not at 6 wks. Similar to CTX, in vitro osteoclastogenesis increased by 38% in cells from 3 wk OVX mice (p<0.01) but not from 6 wk OVX mice. SOST protein was detected in the medium of osteogenic cultures at d 12 and was maximal at d 14-16. SOST and AP mRNA levels at d 16 were similar and E treatment did not alter SOST protein or mRNA.

These results demonstrate that after 3 and 6 wks OVX had inhibitory effects on SOST production in mouse bones, which varied with the time and site examined. The effect of E on SOST appeared to be indirect since it was not reproduced by E treatment of primary cultures. However, it was associated with an increase in bone formation at both times but not resorption, which increased at 3 but not 6 wks. We speculate that a decrease in SOST is a mechanism by which bone formation increases after OVX.

Myostatin Serum Concentrations in Men – Age-Related Changes and Correlates– the STRAMBO Study. Pawel Szulc^{*1}, Claudia Goetsch², Michael Schoppert³, Roland Chapurlat⁴, Lorenz Hofbauer⁵. ¹Hopital E. Herriot, Pavillon F, France, ²University of Dresden, Germany, ³University of Marburg, Germany, ⁴E. Herriot Hospital, France, ⁵Dresden University Medical Center, Germany

Serum myostatin levels in men and its determinants have not been defined. We measured serum myostatin in 1,153 men aged 20 to 87 using an ELISA detecting the dimeric full-length peptide and its C-terminal active protein (Immundiagnostik AG, Bensheim, Germany). We assessed lumbar aortic calcification (AC) on the Vertebral Fracture Assessment scans and relative appendicular muscle mass (RASM, kg/m²) by DXA. Between 20 and 60 years of age, circulating myostatin increased by 28% (n=353, r=0.16, p<0.005), whereas RASM was stable. After 60 years, serum myostatin and RASM decreased (n=800, r= -0.12 and r= -0.21, p<0.001). We analyzed data in 780 men aged ≥60, who did not take vitamin D or calcium supplements, using the multivariate analysis of covariance. Men having aortic calcifications had lower myostatin levels (3.3%, 0.23 SD, p<0.005). Men in the highest myostatin quartile (>39.5 mg/L) had lower average AC score compared with the three lower quartiles combined (p<0.005 adjusted for confounders). In multivariate models, prevalence of AC decreased with increasing myostatin levels (OR=0.76 per 1SD decrease, 95%CI: 0.64-0.91, p<0.001). AC prevalence was lower (OR=0.48, 95%CI: 0.33-0.68, p<0.001) in the highest quartile vs three lower quartiles combined. Serum levels of myostatin and 25-hydroxyvitamin D (25OHD) were positively correlated (partial r=0.20, p<0.001). Serum myostatin levels were 12% higher (0.76 SD, p<0.001) in 45 men with 25OHD>40 ng/mL compared with 369 men with 25OHD<20 ng/mL. In multivariate models, low calcium intake (<590 mg/day, lowest quartile) was associated with 11% lower (0.37 SD, p<0.01) serum myostatin vs three higher quartiles combined. Elevated concentration of C-reactive protein (CRP, >3.27 mg/L, highest quartile) was associated with 4.3% lower (0.30 SD, p<0.001) serum myostatin levels compared with the three lower quartiles combined. Serum myostatin levels were 5% lower (0.43 SD, p<0.05) in 45 current mild smokers (median: 8 cigarettes/day) compared with non-smokers. Men who drank >110 g alcohol/week (median) had 12% lower (0.41 SD, p<0.001) myostatin level compared with men who drank less.

Thus, in men serum myostatin concentrations increased until the age of 60, then decreased. In older men, aortic calcification, lower 25OHD level, low calcium intake,

higher CRP level, current smoking, and higher alcohol intake were all independently associated with lower myostatin levels.

Relationship Between Serum Testosterone and Fracture Risk in Men: A Comparison of Radioimmunoassay Versus Liquid Chromatography Tandem Mass Spectrometry. Thach Son Tran^{*1}, Nguyen Nguyen¹, Jacqueline Center¹, Markus Seibel², John Eisman¹, Tuan Nguyen¹. ¹Garvan Institute of Medical Research, Australia, ²Bone Research Program, ANZAC Research Institute, The University of Sydney, Australia

Low serum levels of testosterone are associated with fracture risk in elderly men. Serum levels of testosterone can be measured by several laboratory methods, including the liquid chromatography tandem mass spectrometry (LC-MS) and radioimmunoassay (RIA) method. This study was designed to determine whether the testosterone-fracture relationship is affected by methods of measurement at the population and individual level.

The study was part of the on-going Dubbo Osteoporosis Epidemiology Study, which was initiated in 1989. Total testosterone (TT) was measured by LC-MS and RIA methods from serum samples collected from 609 men, whose incidence of fractures had been continuously ascertained (by X-ray reports) from 1989 to 2010. Baseline clinical risk factors were obtained by a structured questionnaire. The concordance in serum levels of TT between LC-MS (MS-TT) and RIA (RIA-TT) methods was evaluated by the Deming regression model. The association between TT and fracture risk was assessed by the Cox's proportional hazards model.

On average, MS-TT was higher than RIA-TT by 26 ng/dL (95% confidence interval [CI]: 11 to 41). The coefficient of concordance between MS-TT and RIA-TT was 0.70 (95% CI: 0.66 to 0.74). Using the threshold of TT ≤ 300 ng/dL, 25% and 28% of the men were classified as hypogonadal by MS-TT and RIA-TT, respectively. The Deming's equation linking the two measurements was: MS-TT = 0.91 + 0.86*RIA-TT, R² = 0.50.

Among 560 men with complete data, 103 had sustained at least one fragility fracture during the median duration of follow-up of 5.8 years. After adjusting for age, weight, bone mineral density, fracture history, smoking status, calcium intake, and sex hormone-binding globulin, TT was significantly associated with fracture risk. The hazard ratio of fracture per standard deviation decrease in TT was 1.29 (95%CI: 1.09 to 1.52) for MS-TT, and 1.26 (95% CI: 1.06 to 1.48) for RIA-TT. The correlation between predicted probabilities of fracture by MS-TT and RIA-TT was R² = 0.99 (Figure), with average difference in the predicted probability of fracture being 0.01% (95%CI: -6.1% to 6.2%) for any fracture.

These results indicate that lower serum levels of total testosterone was associated with increased risk of fracture in elderly men. Despite the modest concordance between methods of measurement, TT measured by RIA could predict fracture risk as good as LC-MS method.

Ten-year predicted probability of fracture based on serum testosterone measured by LC-MS and RIA

Contribution of Enzymatic and Non-Enzymatic Collagen Crosslinks to Femoral Neck Fragility. Comparison Between Osteoporosis and Osteoarthritis. Evelyn Gineyts^{*1}, Nathalie R Portero-Muzy¹, Hubert Blain², Roland D Chapurlat¹, Pascale M Chavassieux¹. ¹INSERM, UMR 1033, Université de Lyon, France, ²Department of Geriatrics, CHU of Montpellier, France

We have previously shown that the relative protection of patient with hip osteoarthritis (OA) against fracture may be due to cortical thickening and preservation of the trabecular microarchitecture at the femoral neck (Blain et al, 2008). Changes in collagen crosslinks concentrations may also contribute to skeletal fragility. We have investigated the collagen crosslinks composition in the ultradistal part of femoral necks collected during hip replacement in 16 hip OA patients (668 yrs) and 16 osteoporotic (OP; 799 yrs) postmenopausal women. Mature enzymatic crosslinks pyridinoline (PYD), deoxypyridinoline (DPD) and the non-enzymatic crosslink pentosidine (PEN) were analyzed by reverse phase-HPLC in the cortical and trabecular bone. When compared to OA, trabecular bone in OP was characterized by significant higher amounts of PYD (+38%), DPD (+32%) and PEN (+43%) (p<0.001)

but without change of the PYD/DPD ratio. In cortical bone, only PEN was significantly greater in OP than in OA (+43%; p<0.001). The magnitude of collagen crosslinks contents increase in OP was greater than previously reported with ageing (Saito et al, 1987). In OA, PYD and the PYD/DPD ratio were significantly lower in the superior quadrant than in the 3 others. In contrast, in OP, the distributions between the four quadrants were similar. Trabecular PYD, PEN and PYR/DPD ratio were significantly correlated with 2D-histomorphometric parameters of bone mass BV/TV (r²=0.59, 0.58, 0.46 respectively; p<0.01) and trabecular connectivity TBPf (r²=0.52, 0.58, 0.39; p<0.03). In conclusion, modifications of the enzymatic and non-enzymatic collagen crosslinks may contribute to femoral neck fragility in OP and to the relative resistance in OA.

Increased Expression of the Purinergic P2Y2 Receptor Results in Increased Resorption and Decreased Bone in vivo. Ning Wang¹, Peter Schwarz², Susanne Syberg^{*2}, Solveig Petersen³, Cansu Agca⁴, Niklas Jorgensen⁵, Yuksel Agca⁶, Alison Gartland⁷. ¹The University of Sheffield, United Kingdom, ²Glostrup Hospital, Denmark, ³Laboratory Technician, Denmark, ⁴Research Scientist, postdoc, USA, ⁵Copenhagen University Hospital Glostrup, Denmark, ⁶Prof, Assoc, USA, ⁷The Mellanby Centre for Bone Research, The University of Sheffield, United Kingdom

Nucleotides such as adenosine triphosphate (ATP) are released from bone cells in response to a number of stimuli including fluid shear stress. They act on P2 purinergic receptors. The P2Y2 subtype is a G-protein coupled receptor and is expressed in osteoblasts and osteoclasts. In vitro activation of the receptor nucleotides results in inhibition of alkaline phosphatase production and of matrix mineralization. The aim of this study was therefore to investigate whether increased expression of the receptor affects bone mass and structure in vivo. Ten wildtype (WT) and 10 P2Y2 overexpressing (P2Y2R) female nullipara rats were sacrificed at age 3 months. At -10 and -2 days before sacrifice, bones were labelled by injection with Alizarin Red 30 mg/kg body weight i.p. Bones were collected for bone mass measurements on a Piximus densitometer, for micro-CT of bone microstructure, and for histomorphometry. Serum was collected for bone marker analysis. Bone mineral density (BMD) was reduced in P2Y2R compared to WT, meanSEM: 0.181 (0.003) g/cm² vs. 0.190 (0.002) g/cm², respectively (p<0.05). This was partially due to an increase in area: 2.26 (0.03) cm² vs. 2.12 (0.04) cm², (p<0.05). In addition, femurs of P2Y2R were slightly longer than WT (3.52 (0.02) cm vs. 3.46 (0.01) cm, (p<0.01). Micro-CT showed reduced trabecular thickness in the P2Y2R (0.057 (0.0005) U vs. 0.059 (0.0005) U), and increased structure model index (1.45 (0.05) vs. 1.23 (0.08)). The reduced bone mass was supported by an increase in bone resorption measured as TRAP-5b in P2Y2R vs. WT (2.1 (0.2) U vs. 1.5 (0.1) U, p<0.01), while no differences could be detected for bone formation. Finally, the increased resorptive activity was confirmed by histomorphometry, where P2Y2R showed increased erosive surfaces with ES/BS% of 18.6 (0.5) % vs. 16.9 (0.5) % (p<0.05). In contrast, the number of actively forming surfaces (MS/BS %) was decreased in the P2Y2R (56.9 (0.5) % vs. 60.6 (1.0) %, p<0.01). In conclusion, P2Y2 receptor overexpression in rats results in decreased BMD, but not BMC. This is partially due to increased bone resorption, and decreased formation. Furthermore, P2Y2R have slightly increased length growth compared to WT. This is consistent with previously published in vitro effects of P2Y2 receptor activation in osteoblasts. Further studies will show whether P2Y2 receptor inhibition could increase bone mass and thus be a potential pharmacological target for treatment of bone loss.

Normal Histomorphometric Reference Ranges for Cortical Bone Width and Cortical Porosity in Adult Females. Donna Jewison^{*1}, Robert Wermers², Stephen Hodgson², Thomas J. Sebo³, Michael Yaszemski⁴, Theresa Hefferan². ¹Mayo Clinic Rochester, MN, USA, ²Mayo Clinic, USA, ³Mayo Clinic Rochester, USA, ⁴Mayo Clinic College of Medicine, USA

Cortical bone porosity and cortical bone thickness are known determinants of bone strength and fracture susceptibility. Whenever bone histology is evaluated quantitatively, it is necessary to compare the results with data from a properly controlled group. Histomorphometric quantitation of cortical bone in metabolic bone disorders is important to provide insight into the underlying pathophysiology of the disease process. The purpose of this study was to generate a unique histomorphometric-based reference range for cortical width and cortical porosity from a population of normal healthy females. Archived transiliac crest biopsies from the Institutional Review Board (IRB) approved studies were used to generate the normal reference ranges. The biopsies were obtained from 13 premenopausal women, 30-45 years old, and 33 postmenopausal women, 50-70 years old. The results were reported from the combined premenopausal and postmenopausal data (n=46). The biopsies were embedded in glycol methacrylate and 5 micron thick sections were stained with a modified Goldner's trichrome. These sections were used for quantitative static

histomorphometry using an OsteoMeasure analysis system with the following cortical parameters measured: cortical width, cortical area and cortical porosity. The mean cortical width was 879.1 ± 291.9 microns with a range of 369.0 – 1699.2 microns, mean cortical area was 11.89 ± 3.74 mm² with a range of 6.09 – 24.53 mm² and mean cortical porosity was $10.22 \pm 6.37\%$ with a range of 2.59 – 31.87%. Although data analysis by Pearson correlation coefficient revealed no correlation with age and cortical width ($r=0.2115$, $p=0.1583$), cortical area ($r=0.2571$, $p=0.0845$) or cortical porosity ($r=0.1982$, $p=0.1868$), there was a trend towards a decrease in cortical width and an increase in cortical porosity in advancing age ($r=0.2571$, $p=0.0845$). Cortical bone may be directly impacted by metabolic bone diseases; therefore it is necessary to compare the results to a normal reference range, which we have defined here.

Osteoblastic Differentiation is Inhibited by Warfarin and 18- α -glycyrrhetic Acid. Dong Jin Chung^{*1}, Yun-Hey Jin², Dong Hyeok Cho¹, Hyung Min Jeong², Jin Ook Chung¹, Min Young Chung¹, Kwang Youl Lee².

¹Chonnam National University Medical School, South Korea, ²College of Pharmacy & Research Institute of Drug Development, Chonnam National University, South Korea

Anticoagulation therapy with vitamin K antagonists such as warfarin is widely used to prevent and treat stroke in patients with chronic atrial fibrillation or mechanical heart valves. Because vitamin K is an essential factor for γ -carboxylation of osteocalcin, vitamin K antagonists might cause bone loss. Although the association between warfarin use and bone metabolism is still controversial, several studies show that bone mineral density is decreased and fracture risk is increased with warfarin therapy. Meanwhile, attenuation of gap junctional communication (GJC) by warfarin is reported in rat liver epithelial cells. However, the effect of warfarin on osteoblasts, in which GJC is important for osteoblastic differentiation, remains unknown. Here we investigated whether warfarin has an inhibitory effect on osteoblastic differentiation using an osteoblastic cell line (C2C12). Warfarin and 18- α -glycyrrhetic acid (AGA), which is known as a nontoxic reversible GJC inhibitor, had the same effect on osteoblastic differentiation. Warfarin and AGA inhibited the bone morphogenetic protein (BMP)2-induced mRNA levels of alkaline phosphatase (ALP), collagen I α 1 (col1 α 1), osteocalcin (OC) and osteonin, which are specific markers for osteoblastic differentiation, in a dose-dependent manner. Moreover, the activities of OC- and ALP-luciferase reporters, which are induced by BMP2, and the transcriptional activity of Runx2 on OC and ALP promoters were inhibited by warfarin and AGA. The amount and activity of alkaline phosphatase (ALP) induced by BMP2 were also decreased by warfarin and AGA. These results suggest that warfarin and AGA, a GJC inhibitor, have an inhibitory effect on osteoblastic differentiation.

Total and Carboxylated Osteocalcin Associate with Serum Insulin and Bone Mineral Density in Young Adults. Paivi Maria Paldanius^{*1}, Kaisa Ivaska², Petteri Hovi¹, Sture Andersson¹, Johan Eriksson³, Kalervo Vaananen⁴, Eero Kajantie¹, Outi Maki¹. ¹Children's Hospital, Helsinki University Hospital, Finland, ²University of Turku, Department of Cell Biology & Anatomy, Finland, ³Department of General Practice & Primary Health Care, University of Helsinki, Finland, ⁴University of Eastern Finland, Finland

Serum osteocalcin (OC) is an osteoblast-derived protein with a role in the regulation of glucose and energy metabolism. The regulatory role of OC is most likely exerted via uncarboxylated OC, which in mice induces expression of adiponectin, insulin, and markers of pancreatic islet cell proliferation. Young adults born with very low birth weight (VLBW) have altered glucose regulation and lower bone mineral density (BMD) when compared with those born at term. The aim of this study was to explore the association between bone and glucose metabolism by evaluating OC, carboxylated osteocalcin (cOC) and markers of glucose metabolism at fasting and during a 75-g oral glucose tolerance test, in apparently healthy young adults. The cohort comprised 332 normoglycemic young adults (age range, 18 to 27 years) born either with VLBW ($n=163$; 92 females, 71 males) or at term ($n=169$; 101 females, 68 males). The mean adult weight, height and BMD were significantly lower in VLBW subjects. They also had higher fasting levels of OC (ANOVA, $p=0.027$) and cOC ($p=0.005$) than the term-borns and their mean lumbar spine Z score was significantly lower (-0.94) than in those born at term (-0.42 , $p<0.001$). OC and BMD were inversely correlated in all subjects ($r=-0.239$, $p<0.001$). Subjects with VLBW had higher 2-hour insulin ($p=0.001$) and 2-hour glucose concentrations ($p=0.037$) and marginally elevated fasting insulin ($p=0.068$). The glucose load induced a significant reduction in total OC and cOC levels in all subjects, mean (95% CI) decreases being -17.4% (-19.0 , -15.8) and -18.5% (-20.0 , -16.9) for OC and cOC, respectively. This reduction in OC was not associated with OGTT-induced increases in insulin ($p=0.54$) but weakly with increase in glucose levels ($r=0.13$, $p=0.022$). Total OC and cOC were, however, negatively correlated with fasting insulin after adjustment for age, gender, BMD and VLBW status ($r=-0.182$, $p=0.009$ and $r=-0.283$, $p<0.001$, respectively). The study shows that fasting insulin and VLBW status predicted cOC values, whereas OC

and cOC correlated only weakly with glucose values at 120 min. Changes in OC during OGTT were not associated with changes in insulin suggesting that serum OC is associated with long-term glucose regulation whereas acute changes during OGTT are mediated via other mechanisms. Increased OC and cOC may partly explain reduced BMD and decreased insulin sensitivity in subjects with VLBW.

MO0408

Vertebral Marrow Fat and Body Composition in Older Men and Women: Preliminary results from the AGES-BMA study. Trisha Hue^{*1}, Xiaojuan Li¹, Clifford Rosen², Vilundur Gudnason³, Thomas Lang¹, Sigurdur Sigurdsson³, KRISTIN SIGGEIRSDOTTIR³, Gunnar Sigurdsson⁴, Keerthi Shet¹, Tamara Harris⁵, Lisa Palermo¹, Ann Schwartz¹. ¹University of California, San Francisco, USA, ²Maine Medical Center, USA, ³Icelandic Heart Association Research Institute, Iceland, ⁴Landsþítali, Iceland, ⁵Intramural Research Program, National Institute on Aging, USA

Bone marrow fat (MF) increases with age, and in older adults, the total volume of MF is approximately the same as that of visceral fat. Although MF is a relatively large fat depot, little is known about the mechanisms regulating accumulation. In young women with anorexia nervosa, MF increases even as other fat depots are depleted. However, previous studies in healthy men and women have generally found no association between MF and body mass index (BMI), subcutaneous adipose tissue (SAT), or total adipose tissue (TAT). Only one study in premenopausal women demonstrated a positive correlation between MF and visceral adipose tissue (VAT).

We assessed the association of MF and body composition in men (means: 79.9 years, BMI 27.1) and women (means: 78.5 years, BMI 29.0) in the Bone Marrow Adiposity, Bone and Body Composition (BMA) study. BMA is a cross-sectional ancillary study to Age Gene/Environment Susceptibility-Reykjavik (AGES-Reykjavik), an ongoing population-based cohort study in Iceland. BMA enrollment is currently ongoing and this preliminary analysis includes the first set of participants, excluding those with diabetes, users of bisphosphonates, glucocorticoids, or hormone therapy. Measures include vertebral (L1-L4) marrow fat content estimated from single voxel proton magnetic resonance spectroscopy; total body fat percent (BF%), fat and lean mass by dual-energy X-ray absorptiometry; VAT, SAT, and TAT by quantitative computed tomography; and BMI. General linear models were adjusted for age and evaluated for significance. To assess for effect modification by sex and BMI, interaction terms were included in the models. With $\alpha < 0.10$, the models including the sex interaction term with SAT ($p=0.06$) and TAT ($p=0.07$) resulted in possible interaction. Therefore, results are stratified by gender (see table).

These preliminary results suggest that in older men, vertebral MF is associated with SAT, TAT, and BF%. In contrast, no significant associations were found in the older women. Consistent with other studies, we did not find any association between MF and BMI. Our data suggest that the association of MF with body composition in older adults may be modified by gender and may be fat-depot specific. Future analyses are planned when enrollment is completed.

Clinical Development of An Orally Delivered Recombinant PTH Analog. Nozer Mehta^{*1}, Roxanne Tavakkol², Kristine Erickson², Bill Stern², Tamara James², Seymour Fein², Sheela Mitta², Amy Sturmer², Paul Shields², Andy Rasums², Lorraine Fitzpatrick³. ¹Unigene Laboratories, Incorporated, USA, ²Unigene Laboratories, USA, ³GlaxoSmithKline, USA

An oral tablet formulation of a PTH analog has been developed and initially optimized in a dog model. The PTH analog was produced by recombinant expression in *E. coli*. An initial rising dose pharmacokinetic (PK) study in postmenopausal women examined PTH levels following administration of tablets containing 2, 4, 6 and 8 mg of the PTH analog. A linear dose-dependent response was seen at the three higher doses. A second two-period replicate dose PK study was then carried out to evaluate the safety as well as the inter- and intra-subject variability of two dosing

regimens in an open label study in postmenopausal women. Blood samples were collected over a 6 hour period following dosing and PTH levels were quantified using a specific sandwich ELISA. The C_{max} values with both the 6 mg and 2x4 mg tablets were in the 200 to 300 pg/mL range, and hence achieved or exceeded blood levels that have been shown to be anabolic with an existing injectable formulation. The PK profiles were consistent with the requirement for bone anabolic activity, with an elimination $t_{1/2}$ of 13-21 minutes. Both the inter- and intra-subject variability was deemed to be more desirable with the 6 mg dose. There were no clinically significant changes in serum calcium, phosphate, magnesium or endogenous PTH activity and no serious adverse events were reported. A phase 2 study has been initiated at the appropriate dose in postmenopausal osteoporotic women to further evaluate the safety and efficacy of the oral PTH formulation. This 24 week double blind, randomized, repeat dose parallel group study will evaluate the oral PTH formulation or a placebo tablet. The study also includes an open label active comparator Forsteo® arm. The study will measure the change in bone mineral density at the lumbar spine, compared to baseline, in the three arms of the study. Serum markers of bone formation and resorption will also be measured as a secondary endpoint.

Cumulative Doses of PTH (1-84) Stimulates Vasodilation in the Bone Vasculature of Rats: the Role of VEGF and NO Signaling Pathways.
Rhonda Prishby*, Jeremiah Campbell, Thomas Menezes. University of Texas at Arlington, USA

Parathyroid hormone (PTH) is a vasodilator in several vascular beds. In cultured human umbilical cord vein endothelial cells, PTH stimulates eNOS through PKA and PKC pathways. Since intermittent PTH administration augments bone mass and is a treatment for osteoporosis, it is paramount to determine the effects of PTH on the bone vasculature. Previous data demonstrate that 15 days of intermittent PTH augments ACh-induced vasodilation in the femoral principal nutrient artery (PNA), the primary conduit for blood flow to long bones. Further, this modification is related to vascular endothelial growth factor (VEGF). To date, it is unknown whether PTH directly stimulates vasodilation of the bone vasculature. Therefore, the purposes of the study were to 1) determine whether PTH augments vasodilation of the femoral PNA and 2) determine the signaling mechanism(s) responsible for mediating the presumed vasodilation. **METHODS:** Right femoral PNAs were dissected from male Wistar rats and cannulated to assess vasodilation to PTH 1-84 (10-13 – 10-8 M). Inhibition of nitric oxide (NO) via L-NAME and vascular endothelial growth factor (VEGF) via an anti-VEGF antibody (i.e., Avastin) were used to determine the signaling pathways involved. **RESULTS:** Vasodilation peaked at 63% of maximum dilation to cumulative doses of PTH 1-84. Inhibition of VEGF reduced vasodilation by 38% (PTH, n=5: 63 7%; PTH + anti-VEGF, n=5: 39% relaxation). Inhibition of NO nearly abolished vasodilation in the femoral PNA (PTH: 63 7%; PTH + L-NAME, n=3: 94% relaxation). **DISCUSSION:** To our knowledge, these are the first data to demonstrate vasodilation to PTH in the bone vasculature. Moreover, these data demonstrate two pathways related to PTH that result in NO-mediated signaling; whereby blockade of VEGF receptor binding and NO production reduced vasodilation by 38% and 90%, respectively. This indicates that PTH-stimulated release of VEGF serves to augment endothelial NO independent of a second signaling mechanism which also enhanced NO production. The role of PTH in bone accrual may involve the influence of the bone vascular system and its ability to increase bone perfusion in response to bone metabolism. Further work will elucidate the mechanisms of PTH-mediated bone vasodilation (i.e., signaling related to PKA and PKC in the vascular endothelium) including the role, if any, of the vascular smooth muscle cells.

MO0411

Effects of One Year Daily Teriparatide Treatment on Trabecular Bone Material Properties in Postmenopausal Osteoporotic Women Previously Treated with Alendronate or Risedronate. Sonja Gamsjaeger¹, Birgit Buchinger¹, Roger Phipps², Klaus Klaushofer¹, Eleftherios Paschalis^{*1}. ¹Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK & AUVA Trauma Centre Meidling, 1st Medical Department, Hanusch Hospital, Austria, ²Husson University School of Pharmacy, USA

Many osteoporotic patients treated with teriparatide (TPTD) are likely to have been treated previously with a bisphosphonate (BP). Questions remain about whether BP treatment affects the efficacy of subsequent TPTD therapy.

The purpose of the present study was to investigate TPTD effects on bone material properties after BP treatment. The properties measured were: 1. mineral to matrix ratio, corresponding to ash weight measurements; 2. mineral crystallite maturity / crystallinity, having a direct bearing on crystallite shape and size; 3. relative proteoglycan content, regulating mineralization commencement; 4. pyridinoline to divalent collagen cross-links ratio, two of the major enzymatic collagen cross-links, independent of bone turnover. To do this we used Fourier Transform Infrared Imaging (FTIRI) and Raman spectroscopy to examine thirty two paired iliac crest biopsies (before and after one year TPTD) from sixteen osteoporotic women during

the OPTAMISE clinical trial. Prior to TPTD treatment, these women had previously been treated with either alendronate (ALN, 10mg/day or 70mg/week) or risedronate (RIS, 5mg/day or 30-35mg/week) for at least 24 months (mean duration of therapy 37.2 months for ALN and 38.0 months RIS). The patients stopped their BP therapy and were then treated with TPTD (20µg/day subcutaneously) for 12 months. In addition, we compared the two BPs groups at baseline. Analysis was focused on actively bone forming sites, specifically between fluorescent double labels, thus the results are independent of bone turnover.

TPTD produced significant changes in mineral / matrix ratio, mineral maturity / crystallinity and collagen cross-link ratio, while changes in relative proteoglycan content were observed only in the prior-RIS group. Collagen cross-link ratio was also significantly different between the two BPs groups at baseline, the ALN group of patients having a significantly higher one.

The results show a response to TPTD treatment in newly forming bone material properties. There was a significant difference at baseline in the collagen cross-link ratio between ALN- and RIS-treated patients, suggesting potentially differential effects of BPs on bone material properties. On the other hand, there were no significant differences between the prior-ALN and prior-RIS groups in any of the outcomes after 12 mo TPTD treatment, suggesting that the TPTD effect on the monitored bone material properties is independent of prior BP used.

MO0412

Postmenopausal Women Treated with Combination Parathyroid Hormone and Ibandronate Experience Different Cortical Bone Microstructural Changes at the Radius and Tibia: The PICS Study. Anne Schafer^{*1}, Andrew Burghardt², Lisa Palermo², Deborah Sellmeyer³, Sharmila Majumdar², Dennis Black². ¹University of California, San Francisco & the San Francisco VA Medical Center, USA, ²University of California, San Francisco, USA, ³The Johns Hopkins Bayview Medical Center, USA

Parathyroid hormone (PTH) therapy and bisphosphonates are proven to decrease fracture risk in postmenopausal osteoporosis, but their effects on bone microstructure and strength remain insufficiently characterized. While increasing spinal trabecular bone mineral density (BMD) substantially, PTH therapy may decrease cortical BMD, possibly by stimulating intracortical remodeling. We evaluated bone microarchitecture and biomechanics at the radius and tibia in women receiving PTH(1-84) and ibandronate over 1 year. Postmenopausal women with low bone mass (n=43) were treated with either 3 or 6 months of PTH(1-84) (100 µg/day) and either 9 or 12 months of ibandronate (150mg/month) over 1 year. Participants underwent high-resolution peripheral quantitative computed tomography (HR-pQCT) imaging at baseline and after 6 and 12 months of therapy. HR-pQCT evaluation included BMD and microarchitectural assessment, cortical porosity quantification, and micro-finite element analysis including estimation of stiffness and failure load. Cortical thickness and cortical BMD decreased at the radius over 12 months (p<0.01 for each), consistent with changes in dual-energy X-ray absorptiometry at the radius, while these parameters did not change at the tibia (p<0.01 for difference between radius and tibia). In contrast, cortical porosity and cortical pore volume increased at the tibia (p=0.02 and 0.01, respectively) but not at the radius. The percentage of stiffness and failure load deficits at the tibia that were due to cortical porosity increased over time. Meanwhile, there was a differential change in trabecular BMD at the 2 sites, with an increase in trabecular BMD over 12 months at the tibia but a decrease over 6 months at the radius (p=0.04 and <0.01 for difference between radius and tibia over 6 and 12 months, respectively). Overall, stiffness and failure load decreased at the radius, while there were no changes in these measures at the tibia. In summary, our study suggests that changes in response to PTH/ibandronate therapy are different at the radius versus the tibia. At the radius, the decreased cortical thickness and cortical BMD, with no change in trabecular BMD, contributed to decreased estimated bone strength. In contrast, at the tibia, while cortical porosity increased, cortical thickness did not change and trabecular BMD increased, maintaining bone strength. Our results suggest the possibility that weight bearing may optimize the effect of anabolic therapy.

TABLE. Mean 1-year percentage changes in microstructural and biomechanical measures

Parameter	Radius (% change)	Tibia (% change)	p-value for difference (radius vs. tibia)
Cortical thickness	-1.86 ± 2.40*	-0.24 ± 2.10	<0.01
Cortical BMD	-0.55 ± 1.63	0.04 ± 2.03	<0.01
Cortical porosity (CtPo)	1.27 ± 17.83	5.12 ± 12.38	0.28
Cortical pore volume	-0.38 ± 18.03	4.70 ± 12.83	0.16
Trabecular BMD	-0.10 ± 2.56	1.36 ± 2.55*	<0.01
Stiffness	-1.42 ± 2.34*	0.29 ± 2.33	<0.01
Stiffness deficit due to CtPo	2.36 ± 27.62	7.41 ± 19.83	0.28
Failure load	-1.43 ± 2.28*	0.20 ± 2.10	<0.01
Failure load deficit due to CtPo	7.03 ± 32.25	7.41 ± 19.55	0.82

MO0413

Teriparatide Treatment for 24 months in Postmenopausal Women with Osteoporosis Differentially Impacts Cortical and Trabecular Bone at the Tibia Assessed by HRpQCT. Jeri Nieves¹, Felicia Cosman¹, Stephanie Boutroy², Nancy Barbuto¹, Marsha Zion¹, Elizabeth Shane³, David Dempster², Robert Lindsay¹. ¹Helen Hayes Hospital, USA, ²Columbia University, USA, ³Columbia University College of Physicians & Surgeons, USA

Teriparatide (TPTD) clearly increases bone mass by BMD and there is histomorphometric evidence of increased bone formation rate at the iliac crest. There are relatively few reports of the longitudinal effects of TPTD on bone structure utilizing High Resolution Peripheral Quantitative Computed Tomography (HRpQCT, Scanco Medical AG). We analyzed scans from 40 women with osteoporosis who were either treatment naive (n=17) or who had been previously treated with alendronate (n=23) and were then randomized to receive daily teriparatide (20 mcg continuously) or cyclic TPTD (20 mcg daily for cycles of 3 months on and 3 months off) for a total treatment period of 24 months. Alendronate treatment was continued (70 mg/week) in the alendronate group. The cyclic and daily TPTD results were not different and were therefore combined. HRpQCT of the tibia was performed at baseline and 2 years. Analysis was limited to those scans with image quality above 3 on the manufacturer's suggested 5 grade scale, those with overlap of 70 % or greater and scans without any artifact. At the tibia, in those on prior alendronate therapy, there were no significant changes in trabecular density or trabecular number, but trabecular thickness increased (3.3%, p<0.05). Furthermore, there were significant reductions in cortical bone density (-2.4%, p<0.005), but no change in cortical thickness. In the treatment naive women, results were similar. There was no change in trabecular density or trabecular number and a significant increase in trabecular thickness (4.7%, p<0.05). In cortical bone, there was no significant change in cortical thickness, but a significant reduction in cortical bone density was seen (-2.3%, p<0.001). In summary, preliminary data indicate that TPTD given for 24 months may improve some aspects of trabecular bone, but a larger sample size may be needed to detect changes in trabecular number and density. There was also a modest decrease in cortical bone density without a decrease in cortical thickness. This contrasts with our prior observations of increased cortical thickness in the iliac crest by histomorphometry. This inconsistency may be due to newly formed bone not yet fully mineralized and/or an increase in cortical porosity. Follow-up HRpQCT measurements of the tibia after antiresorptive treatment alone might provide useful data. Although more patients are needed, HRpQCT may elucidate the effects of TPTD at peripheral skeletal sites

MO0414

Two-Year Effects Of PTH(1-84) On Cortical Bone In Hypoparathyroidism. Stephanie Boutroy¹, Mishaela Rubin², Jim Sliney Jr¹, Rebecca Ives¹, John Bilezikian³. ¹Columbia University Medical Center, USA, ²Columbia University, USA, ³Columbia University College of Physicians & Surgeons, USA

Hypoparathyroidism (HYPOPT), a disorder characterized by hypocalcemia and low PTH levels, is a low turnover disease associated with bone mineral density (BMD) that typically is not reduced. With PTH treatment, cancellous BMD at the lumbar spine increases and cortical BMD at the distal 1/3 radius decreases, yet it is not known to what extent bone microstructure and other aspects of bone quality might be affected. To this end, we studied 30 patients (25 women/5 men, baseline serum calcium 8.61.0 mg/dl and PTH 3.12.3 pg/ml) with HYPOPT who were treated for 2 years with PTH(1-84) [PTH], 100 mcg SC qod. We analyzed volumetric BMD (vBMD) and microstructure by high resolution peripheral quantitative tomography (HRpQCT, Scanco Medical AG) at the distal radius (DR) and tibia (DT) over a 2 year treatment period with PTH. Additional parameters of cortical bone were performed with an advanced algorithm (Burghardt, JBMR 2009 and Nishiyama, JBMR 2009).

At the DR, neither vBMD nor trabecular microarchitecture changed but there was an increase in cortical thickness (+1.2%, p=0.03) as analyzed by advanced segmentation. At the DT, cortical BMD fell (-2.4%, p=0.001) and there was a more heterogeneous distribution of the trabecular network (4.1, p=0.02). Further segmentation of cortical bone confirmed the decrease in cortical vBMD, with an increase cortical pore volume and no change in cortical thickness; thus leading to an increase cortical porosity. The loss in cortical vBMD can not only be explained by this increased cortical porosity but also by the decreased cortical tissue mineral density (TMD, -1.9%, p=0.001).

The results provide new insight into how PTH affects skeletal microstructure when the skeleton is exposed to it de novo. These changes are reminiscent of the skeletal effects of PTH in both primary hyperparathyroidism and PTH treatment of osteoporosis.

Baseline values and percentage changes in cortical parameters at the distal tibia

	Baseline values (mean±SD)	% difference from baseline
Cortical vBMD (mg HA/cm ³)	944 ± 52	-2.5% *
Cortical TMD (mg HA/cm ³)	1006 ± 39	-1.9% *
Cortical thickness (µm)	1325 ± 249	-1.0%
Cortical pore volume (mm ³)	54.1 ± 28.1	11.8% *
Cortical porosity (%)	4.8 ± 1.9	12.2% *

MO0415

Antiresorptive Treatment for Spaceflight Induced Bone Atrophy: Preliminary Results. Adrian Leblanc¹, Toshio Matsumoto², Jeff Jones³, Jay Shapiro⁴, Thomas Lang⁵, Linda Shackelford⁶, Scott Smith⁶, Harlan Evans⁷, Elisabeth Spector⁷, Robert Ploutz-Snyder⁸, Jean Sibonga⁶, Toshitaka Nakamura⁹, Kenjiro Kohri¹⁰, Hiroshi Ohshima¹¹. ¹USRABaylor College of Medicine, USA, ²University of Tokushima Graduate School of Medical Sciences, Japan, ³Baylor College of Medicine, USA, ⁴Johns Hopkins, USA, ⁵University of California, San Francisco, USA, ⁶NASA, USA, ⁷Wyle, USA, ⁸USRA, USA, ⁹University of Occupational & Environmental Health, Japan, ¹⁰Nagoya City University, Japan, ¹¹JAXA, Japan

Detailed measurements from the Mir and ISS long duration missions have documented losses in bone mineral density (BMD) from critical skeletal sub-regions. The most important BMD losses are from the femoral hip averaging about -1.6%/mo integral to -2.3%/mo trabecular. Importantly these studies have documented the wide range in individual BMD loss from -0.5 to -5%/mo. Associated elevated urinary Ca increases the risk of renal stone formation during flight, a potential serious impact to mission success. To date, countermeasures to this bone loss have not been satisfactory.

The purpose of this study is to determine if the combined effect of antiresorptive drugs plus the standard in-flight exercise regimen will have a measurable effect on preventing space flight induced bone loss (mass and strength) and reducing renal stone risk. To date, 4 crewmembers have completed the flight portion of the protocol in which crewmembers take a 70-mg alendronate tablet once a week before and during flight, starting 17 days before launch. Compared to previous ISS crewmembers (n=14) not taking alendronate, DXA measurements of the spine, femur neck and total hip were significantly improved from -0.8 0.5%/mo to +1.0 1.1%/mo, -1.1 0.5%/mo to -0.2 0.3%/mo, -1.1 0.5%/mo to +0.04 0.3%/mo respectively. QCT-determined trabecular BMD of the femur neck, trochanter and total hip were significantly improved from -2.7 1.9%/mo to -0.2 0.8%/mo, -2.2 0.9%/mo to -0.3 1.9%/mo and -2.3 1.0%/mo to -0.2 1.8%/mo respectively. Significance was calculated from a one-tailed t test on pre-post difference scores, with corrections for multiple comparisons. Resorption markers were unchanged compared to preflight, in contrast to measurements from previous ISS and MIR crewmembers that showed typical increases of 50-100% above preflight excretion levels. Urinary Ca showed no increase compared to baseline levels, also distinct from the elevated levels of 50% or greater in previous crewmembers.

While these results are encouraging, the current n (4) is small and the SDs are large indicating that while the means are improved there is high variability in individual response. Another confounder is that the exercise protocol has varied over time. Three additional crewmembers have been recruited to participate in this experiment, with expected completion in late 2011.

MO0416

Atypical Femoral Fractures in Association with Long-term Bisphosphonate Use: Clinical, Radiographic and Bone Biopsy Data from 7 Cases. Aliya Khan¹, Angela Cheung², Sama Thomas¹, Nazir Khan¹, Kenneth Pritzker², Brian Lentle³. ¹McMaster University, Canada, ²University of Toronto, Canada, ³University of British Columbia, Canada

Purpose:

This study describes the patient characteristics and histomorphometric and radiographic features of atypical femoral fractures (AFF) as seen in 7 cases referred for evaluation. Methods: All patients referred for evaluation of AFF were reviewed. Patients meeting the ASBMR criteria for AFF were further evaluated and tetracycline labelled bone biopsies were completed. Radiographs were reviewed by a musculoskeletal radiologist.

Results: All fracture lines were transverse or short oblique with thickened cortices. We report 7 cases of AFF in patients on long term bisphosphonate (BP) therapy. 6 of 7 fractures occurred without a fall or direct trauma to the femur with 1 case occurring after a fall from standing height. All patients were female; average age was 67 yrs (range 54-80 yrs). 2 of the 7 cases were of Chinese descent, 2 were East Indian with 3 being Caucasian. Average BP duration of use was 8.5 years (range 7-14 years). 5 of 7 patients were on alendronate alone, 2 patients were on risendronate. 1 patient had

received 18 months of teriparatide, 3 years prior to the AFF and had received a total of 10 years of BP use prior to teriparatide. Prodromal thigh or groin pain was seen in 5 of the 7 patients for 3 to 12 months prior to fracture. Proton pump inhibitor use was present in 1 patient for the previous 2 years. 1 patient was on prednisone for rheumatoid arthritis.

Rheumatoid arthritis was present in 2 cases. Diabetes was not present in any of the 7 cases. Bilaterality occurred in 1 patient with the second AFF occurring 1 month after the first AFF.

Renal function was well preserved with estimated glomerular filtration (eGFR) rates > 60 ml/min in all cases. 25 hydroxy Vitamin D levels were >75 nmol/L in 5 cases. 2 cases had mild Vitamin D insufficiency (>50nmol/L).

Detailed histomorphometry data will be finalized and presented.

Summary: A large number of the AFF occurred in women of Asian descent, (4 of 7). 6 of the 7 AFF occurred in the absence of a fall. Prodromal pain was commonly seen. Proton pump inhibitors were used in only 1 patient. Histomorphometric features included absence of mineralization abnormalities and decreased bone formation.

Conclusion: AFF in association with long term BP use are being seen in a disproportionately large number of Asian women. Further evaluation of all AFF with identification of predisposing key clinical risk factors is needed. Improved understanding of the pathophysiology may be gained with further histomorphometric data in larger numbers of patients.

MO0417

Augmentation of Bisphosphonate Effects Increasing Lumbar Bone Mineral Density and Decreasing Vertebral Deformity by Addition of Active Absorbable Algal Calcium (AAACa). Yoshitomo Itakura¹, Yoshio Fujii², Yasuyuki Takagi³, Takuo Fujita⁴, Mutsumi Ohue⁴, Akimitsu Miyauchi³, Mikio Nakajima⁶. ¹Komatsu Hospital, Japan, ²Calcium Research Institute Kobe Branch, Japan, ³National Hyogo Chuo Hospital, Japan, ⁴Katsuragi Hospital, Japan, ⁵Miyauchi Medical Center, Japan, ⁶Dept of Orthopedic Surgery, Osaka Medical College, Japan

Purpose Bisphosphonates decrease Ca release from bone by suppressing osteoclastic resorption prompting temporary Ca deficiency in other part of the body, fall of serum Ca, increased PTH secretion, rise of cytosolic Ca and disturbance of signal transduction and cell function (Ca Paradox) which may limit the effect of bisphosphonates themselves in return, without adequate Ca supplementation. Effect of addition of active absorbable calcium (AAACa) to bisphosphonates on lumbar bone mineral density (LBMD) and vertebral deformity was therefore studied.

Methods Among 30 subjects with osteoporosis and/or spinal osteoarthritis consented to participate this study, 5 mg / day alendronate was administered in 20 and 2.5 mg/day risendronate in 10 (Treatment 1). AAACa containing 900 mg elementary Ca was then added to the on-going treatment (Treatment 2). At the beginning and throughout the course of both Treatment 1 and 2, LBMD was measured by DXA (DPX, General Electric) in anterior-posterior projection, to calculate mean and SD of L1-L4 and coefficient of variation (CV) as SD/mean (%). Student t-test was applied to test the significance of difference between the 2 groups.

Results Mean LBMD was 0.7930,095 in Treatment 1 and 0.8440,091 in Treatment 2, (P<0.0001) indicating a definite improvement in the latter. Intraindividual CV of L1-L4 was 11.85.9% in the former and 10.46.4% in the latter with a significant fall indicating an alleviation of deformity (p=0.0017). Vertebral deformity due to osteoarthritic changes and other causes was reported to raise CV values from 7.22.9% in subjects younger than 50 years without osteoarthritic changes. No significant differences were noted between alendronate and risendronate in the effect of addition of AAACa on the fall of CV (L1-L4).

Conclusion Increase of LBMD and improvement of vertebral deformity mainly due to osteoarthritic changes in response to bisphosphonate treatment was significantly augmented by addition of AAACa.

Biochemical markers and its relation with Bisphosphonate-related Osteonecrosis of the Jaw in Female Osteoporosis patients. Tae-Geon Kwon¹, Je-Yong Choi², So-Young Choi³. ¹Kyungpook National University, School of Dentistry, South Korea, ²Kyungpook National University, School of Medicine, South Korea, ³Kyungpook National University, Republic of Korea

BACKGROUND AND PURPOSE: There had been no agreements that the any biological marker can predict the development and reflect the severity of Bispho-

sphosphate-related osteonecrosis of the jaw (BRONJ). This study intended to determine whether there is any difference in serum biochemical markers of BRONJ patients compared to control patients who were treated with oral bisphosphonates (BP) for osteoporosis but without BRONJ. **PATIENTS AND METHODS:** This retrospective, case-control study analyzed female BRONJ patients (n=55, Age 72.97.3) who was previously treated with oral BP for osteoporosis. Demographic and clinical information were collected with laboratory dates of bone turn-over marker [(C-terminal telopeptide (CTX), Osteocalcin (OCN), bone-specific Alkaline phosphatase (bALP)) and inflammatory activity markers [erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) level] at the time of the BRONJ diagnosis, 1 and 3 months after the treatment of BRONJ. These were compared to the dates of baseline, 6, 18, 30, and 42 months after the oral BP therapy for female osteoporosis patients without osteonecrosis of the jaw (n=85, Age 71.67.6). **RESULTS:** At the time of diagnosis, BRONJ patients showed significantly higher ESR and CRP than control patients. Compared to serial CTX level after the BP treatment in control patients, measurements of BRONJ patient was not different from any time points. In control patients, bALP level was decreased after the BP treatment and this was level was similar to BRONJ patients. Severity of BRONJ was highly correlated with ESR (r=0.346, p<0.05) and CRP (r=0.312, p<0.05) but not with CTX (r=0.163, p>0.05), OCN (r=-0.043, p>0.05), and bALP (r=0.132, p>0.05). Reduced CTX values were not associated with BRONJ stage, invasiveness of ONJ or sequestrate formation in BRONJ. **CONCLUSION:** Bone turnover marker such as serum CTX level cannot be used for predictor of BRONJ progression or risk assessment of BRONJ.

Generic Alendronate Use in Medicare Part D Data. Huifeng Yun^{*1}, Jeffrey Curtis¹, Wilson Smith¹, Robert Matthews¹, Kenneth Saag¹, Nicole Wright¹, Meredith Kilgore², Elizabeth Delzell¹. ¹University of Alabama at Birmingham, USA, ²University of Alabama At Birmingham School of Public Health, USA

Background: Generic alendronate (ALN) was approved in the United States in 2008. Medicare beneficiaries might pay for generic ALN out-of-pocket without submitting claims, resulting in incomplete generic ALN claims in Medicare part D data.

Objectives: To estimate the completeness of identification of generic ALN use in Medicare part D data in 2008; to evaluate characteristics of beneficiaries who switched to generic ALN after being adherent to brand ALN.

Methods: Using 2006-2008 Medicare 5% sample data, we created two cohorts of brand ALN users ('07 and '08) who: used brand ALN during the respective time periods; were not enrolled in a Medicare Advantage plan; had fee-for-services and part D Medicare coverage during 1/1/06-2/6/07 for the '07 cohort or 1/1/07-2/6/08 for the '08 cohort; had a medication possession ratio (MPR) $\geq 80\%$ during that period; and had 11 months of followup (from Feb 6 - Dec 31 in '07 or '08). Medication status at study end was classified as: continued brand product, switched to generic, switched to another bisphosphonate (BP) or presumed discontinued. A higher proportion of discontinuation in the '08 than the '07 cohort would provide evidence of incomplete claims for generic ALN. Cox regression analysis estimated the hazard ratio for discontinuing use in the '08 cohort compared to the '07. Multinomial logistic regression identified factors associated with medication status at the end of follow-up.

Results: Of 9708 ALN users in the '07 cohort; 87.8% continued brand product, 3.3% switched to another BP, and 8.9% discontinued. Of 16720 users in the '08 cohort, 9.6% continued brand ALN, 78.5% switched to generic, 1.4% switched to another BP, and 10.5% discontinued. The adjusted hazard ratio (95% CI) for presumed discontinuation in the '08 cohort compared to '07 cohort was 1.05 (0.97, 1.14). Factors associated with switching to generic were younger age, Asian race, living in rural areas, lower income, higher baseline MPR, and having more comorbidities.

Conclusion: Using a study design that maximized internal validity by evaluating adherent users of ALN, there does not appear to be a substantial amount of missing claims for generic ALN in 2008.

MO0420

Prevention of Postmenopausal Osteoporosis With Two Intermittent Alendronate Regimens: Bone Mineral Density and Bone Markers Changes After 12 months. Yves Boutsen^{*1}, Jacques Jamart², Catherine Vynckier², Thierry Vander Borgh², Jean-Pierre Devogelaer³. ¹Cliniques Universitaires UCL de Mont-Godinne, Belgium, ²Cliniques Universitaires de Mont-Godinne, Belgium, ³St. Luc University Hospital, Belgium

The aim of this prospective study was to compare the efficacy of two regimens of low-dose oral alendronate (ALN) as a prevention of postmenopausal osteoporosis for women who don't want or may not take hormone replacement therapy. Primary end-point was lumbar spine (LS) bone mineral density (BMD) changes after two years.

Secondary end-points included changes in bone markers levels. We present here changes in BMD and C-telopeptide crosslinks of type I collagen (S-CTX) levels after a one-year pre-planned interim analysis.

Patients and methods: A total of 82 postmenopausal women (age range 45-60 years, at least 1 year since menopause) were randomly allocated to receive: ALN 70 mg (Fosamax[®]) every two weeks (group A); a placebo, similar to the ALN tablet, every two weeks (group B) or Fosamax[®] 70 mg once-monthly (group C). All patients were recommended to take supplemental calcium 500mg and vitamin D 400 IU daily. Randomisation was performed by a minimization procedure taking into account baseline BMD and S-CTX values. S-CTX levels were assessed using a one-step ELISA (β -CrossLaps[®]; Roche Diagnostics). Lumbar spine and hip BMD measurement were performed at baseline and after 12 months. Treatment effects were compared between groups by analysis of variance (ANOVA), followed by 2 by 2 comparisons with the method of Least Significant Difference, and studied over time by ANOVA for repeated measurements.

Results: Data were available at 12 months for 76 patients. S-CTX levels (table 1) significantly decreased at 3, 6 and 12 months in both ALN groups (p<0.001 for all comparisons, except p=0.029 for group C at 3 months). Significant difference in S-CTX levels was observed between groups A and B after 3 months (p=0.008), 6 months (p=0.012) and 12 months (p=0.004) and between groups C and B after 6 (p=0.046) and 12 months (p=0.028). Significant LS BMD increase was observed after 12 months in both ALN groups (group A 1.2 %, p < 0.001 ; group C 1.8 %, p=0.005) with a significant difference between groups A and B (p=0.001) and between groups C and B (p=0.01). At the total hip, BMD increase occurred in group A only (0.8%, p=0.039).

Conclusion: One year of intermittent ALN regimen, given 70 mg every two weeks or once-monthly, increased LS BMD with a significant difference as compared to placebo. Both ALN regimens were effective at decreasing rapidly osteoclastic activity in postmenopausal women, the response being slightly delayed with the monthly treatment.

Table 1. S-CTX values expressed as mean \pm SD (pg/ml).

	Baseline	3 months	6 months	12 months
Placebo	526.6 \pm 183.0 n = 27	440.2 \pm 156.5 n = 25	464.9 \pm 261.2 n = 24	444.4 \pm 194.6 n = 22
ALN once-monthly	539.1 \pm 228.0 n = 28	394.5 \pm 221.4 n = 28	343.4 \pm 195.0 n = 28	327.6 \pm 181.6 n = 28
ALN every 2 weeks	522.3 \pm 210.2 n = 28	300.7 \pm 161.9 n = 27	306.1 \pm 187.5 n = 25	285.9 \pm 174.5 n = 26

Real-Life Effectiveness of Zoledronic Acid in Patients with Osteoporosis. Emmanouil Rampakakis¹, Georges Tsoukas², John S. Sampalis^{*3}. ¹JSS Medical Research, Canada, ²McGill University, Can, ³McGill University & Jewish General Hospital, Canada

Background

The efficacy of zoledronic acid in bone metabolism RA has been demonstrated in several controlled clinical trials. Longitudinal observational studies assessing the real-life effectiveness of therapeutic interventions are essential in order to demonstrate true population based benefits.

Methods

This was a retrospective chart review database analysis with data obtained from 4 clinics on patients initiating treatment with zoledronic acid.

Results

A total of 291 patients were included in this analysis with a mean (SD) age of 64.7 (11.4) years. Among these, 262 (90.0%) patients were female. The mean (SD) T-score at baseline was -2.9 (1.0) and -2.3 (0.8) for the spine and femur, respectively, and the mean (SD) zoledronic acid dose was 4.3 (0.78) mg.

After a single infusion of zoledronic acid, significant improvements were observed in spine bone mass density (BMD) (Mean (SD) = 0.02 (0.05) gm/cm²; P < 0.001), femur BMD (Mean (SD) = 0.01 (0.05) gm/cm²; P < 0.001), alkaline phosphatase (Mean (SD) = -5.5 (18.6) U/l; P < 0.001), and osteocalcin (Mean (SD) = -4.7 (12.7) μ g/ml; P < 0.001).

The changes in these parameters further improved after an additional 2 infusions; mean (SD) changes in spine BMD, femur BMD, alkaline phosphatase, osteocalcin and C-terminal telopeptide of type I collagen were 0.03 (0.06) gm/cm² (P < 0.001), 0.02 (0.06) gm/cm² (P=0.012), -6.9 (23.2) U/l (P=0.046), -4.2 (6.9) μ g/ml (P=0.001), and -0.07 (0.14) (P=0.007), respectively, after 3 infusions.

Conclusions

The results of this real-life study demonstrate that long-term treatment with zoledronic acid is effective in reducing symptom severity and improving bone turnover markers in patients with Osteoporosis.

Disclosures: John S. Sampalis, None.

MO0422

Regional Bone Metabolism at the Lumbar Spine and Hip Following Discontinuation of Alendronate and Risedronate Treatment in Postmenopausal Women. Michelle Frost¹*, Musib Siddique¹, Glen M. Blake¹, Amelia EB. Moore¹, Paul K. Marsden¹, Paul J. Schlever¹, Richard Eastell², Ignac Fogelman³. ¹King's College London, United Kingdom, ²University of Sheffield, United Kingdom, ³Guy's Hospital, United Kingdom

Bisphosphonates such as alendronate (ALN) or risedronate (RIS) have persistent effects on bone following discontinuation of treatment. The aim of this 12-month prospective study was to investigate changes in regional bone metabolism at the lumbar spine and hip following discontinuation of ALN and RIS in postmenopausal women. Positron emission tomography (PET) was used to examine bone metabolism at the spine and hip in 20 postmenopausal women treated with ALN (n=11) or RIS (N=9) for a mean duration of 5 years. Subjects underwent a 1-hour dynamic scan of the lumbar spine and a 10-minute static scan of both hips at baseline and 6 and 12-months following treatment discontinuation. ¹⁸F-fluoride plasma clearance (K_i) at the lumbar spine was calculated using a 3-compartment model. Standardised uptake values (SUV) were calculated for the spine, total hip, femoral neck and femoral shaft. Measurements of K_i and SUV reflect the level of osteoblastic activity in bone and are therefore considered to be a valid measure of bone metabolism. Measurements of BMD at the spine and hip and biochemical markers of bone turnover were also performed. With the exception of a significant decrease in spine BMD in the ALN group BMD remained stable during the 12-month follow-up period. Bone turnover markers increased significantly from baseline by 12 months for both study groups. Measurements of K_i and SUV at the lumbar spine and femoral neck, did not change significantly in either group. In the ALN group SUV at the femoral shaft and total hip increased at 12 months by 33.8% (p = 0.028) and 24.0% (p = 0.013) respectively. No significant changes were observed at any region of the hip following RIS treatment discontinuation. In conclusion, an unexpected decrease in lumbar spine BMD was observed for the ALN group. Bone metabolism at the lumbar spine remained suppressed following treatment discontinuation. A significant increase in SUV at the femoral shaft and total hip after 12 months was observed in the ALN group. The reasons for this differential response at the hip between the ALN and RIS groups are speculative. This study highlights the potential difficulty in identifying meaningful differences between BPs in clinical practice and that it is likely that more than 1 year is required to fully expose these differences.

MO0423

Relationship Between Baseline Serum 25-Hydroxyvitamin D and Response to Risedronate in Postmenopausal Osteoporosis Patients - A Pooled Analysis of Clinical Trials in Japan. Ryo Okazaki¹*, Ryoichi Muraoka². ¹Teikyo University Chiba Medical Center, Japan, ²Ajinomoto Pharmaceuticals Co, Ltd., Japan

Vitamin D deficiency/insufficiency could affect treatment response to bisphosphonates (BPs). However, conflicting results have been reported in this regard. Different cut-off serum 25(OH)D values to define vitamin D status and/or the use or non-use of supplemented vitamin D with BPs may account for this conflict. We performed post-hoc analyses of risedronate (RIS) Phase III trials conducted in Japan to evaluate the influence of basal serum 25(OH)D level on the responses to RIS using various cut-off serum 25(OH)D values. Data from 766 subjects whose serum 25(OH)D were measured prior to RIS administration were analyzed. RIS was administered for 48 weeks without vitamin D supplementation in those trials. With the cutoff level of basal serum 25(OH)D at 20 ng/mL, the lumbar spine BMD increase rates were 5.224.36% in the <20 ng/mL group and 5.884.34% in the ≥20 ng/mL group, which were not significantly different [difference (?) -0.66 (95% CI, -1.51 to 0.18)]. Among bone turnover markers (BTMs) at the baseline, serum bone-type alkaline phosphatase (BAP, U/L) [31.910.2 vs 29.710.1; ? 2.22 (95% CI, 0.42 to 4.03)] and serum CTX (μg/nmol-Cr) [272.3147.7 vs 247.4110.1; ? 25.0 (2.18 to 47.8)] were higher in patients with < 20 ng/mL 25(OH)D, whereas urinary NTX (nmolBCE/ mmol-Cr) [51.023.9 vs 48.921.0; ? 2.08 (-1.10 to 5.28)] were comparable. The differences in BTMs between the groups were gradually disappeared and after 48 weeks of RIS administration all three BTMs were comparable; (BAP: 19.75.9 vs 19.06.2; CTX: 106.667.0 vs 100.269.1; NTX: 29.113.6 vs 28.913.1). In contrast, with the cutoff value of serum 25(OH)D at 15 ng/mL, the BMD increase rates were significantly low in the < 15 ng/mL group compared with > 15 ng/mL at 12, 24, and 48 week. At 48 week BMD increase rates were 3.994.51% in the <15 ng/mL group and 5.844.28% in the ≥15 ng/mL group, respectively (? -1.85, 95% CI, -3.13 to -0.56). Further, when the subjects were stratified into four groups by serum 25(OH)D (<16, 16-20, 20-24 ≥24 ng/mL), BMD increase rates tended to be low, whilst the BTMs tended to be high in the groups with lower serum 25(OH)D. These results suggest that, when using BPs without vitamin D supplementation, serum 25(OH)D level should be adequately increased prior to treatment initiation. Further studies are needed to evaluate whether or not vitamin D status affect BPs response in terms of anti-fracture efficacy.

MO0424

Relationship of Changes in Total Hip Bone Mineral Density to Vertebral and Non-Vertebral Fracture Risk in Women with Postmenopausal Osteoporosis Treated with Once-Yearly Zoledronic Acid 5 mg (ZOL): the HORIZON-PFT study. Richard Jacques¹, Steven Boonen², Felicia Cosman³, Ian Reid⁴, Douglas Bauer⁵, Dennis Black⁵, Richard Eastell¹. ¹University of Sheffield, United Kingdom, ²Center for Metabolic Bone Disease & Division of Geriatric Medicine, Belgium, ³Helen Hayes Hospital, USA, ⁴University of Auckland, New Zealand, ⁵University of California, San Francisco, USA

Bone mineral density is considered a useful surrogate for fracture risk prediction. However, in some clinical trials the percent change in bone mineral density has not related closely to fracture risk reduction. To examine the reasons for this in more detail, we carried out a year-by-year analysis of the percent of treatment effect (PTE) explained by change in total hip BMD in the HORIZON Pivotal Fracture Trial in which patients received three annual infusions of ZOL 5 mg. We examined the associations between changes in total hip BMD and vertebral and non-vertebral fracture incidence in 7736 women. Altogether 406 women sustained a vertebral fracture (odds ratios were calculated from a logistic model), and 487 women sustained a non-vertebral fracture (hazard ratio was calculated from a Cox model). The table shows the relationship between change in total hip BMD (THBMD) from baseline to 1, 2 and 3 years with vertebral fracture occurring during the same time periods i.e. baseline to 1, 2 and 3 years. We also examined the change from baseline to 3 years and fracture occurring at anytime during the 3 years of the study. PTE was estimated using the Li method (2001).

For non-vertebral fracture, the hazard ratio was not significant on a year-by-year basis, but over the 3 years, the hazard ratio was 0.80 (0.67, 0.95) and the PTE was 59% (23, 152). Thus, change in total hip BMD appears to be a surrogate for fracture risk reduction with zoledronic acid.

	Vertebral fracture risk, odds ratio (95% CI)	PTE by change in THBMD (95% CI)
Year 1	0.40 (0.28, 0.57)	42 (29, 61)
Year 2	0.19 (0.12, 0.31)	39 (28, 54)
Year 3	0.35 (0.25, 0.49)	42 (28, 63)

The Intra-Venous Zoledronic acid once Yearly (IVORY) observational study: Baseline and one year data. David Kendler^{*}. Osteoporosis Research Centre, Canada

Background: Zoledronic acid (ZOL) is an annual iv bisphosphonate effective for the prevention of vertebral, non vertebral and hip fractures in postmenopausal women, for the treatment in men with osteoporosis (OP) and glucocorticoid-induced OP. IVORY is a 4 year, observational study in a real-life Canadian setting comparing patient adherence and osteoporosis outcomes in patients treated with ZOL and oral bisphosphonate (OBP). Methods: 1504 women with OP over 45 years were recruited in 182 Canadian sites. Patients treated prior to study entry were enrolled in a 2:1 ratio ZOL (n=1029) to OBP (n=475). Through this 1-year data interim analysis we report adherence to therapy, bone mineral density (BMD) changes and SAEs. Results: Baseline demographics were comparable in both groups (Table 1), except in pre-treated patients, where 64.1% (ZOL) and 86.7% (OBP) of patients received an OBP before study entry. The most common fractures prior to study entry were spine (13.5% and 12.6%) and wrist (9.1% and 9.3%) in ZOL and OBP respectively. Mean BMD total hip were 0.76 and 0.78 g/cm² (T-score -1.80 and -1.66) and at lumbar spine were 0.88 and 0.91 g/cm² (T-score -2.33 and -2.12) in Zol and OBP respectively. At one year, lumbar spine BMD remained stable (0.90 g/cm² and 0.91 g/cm²; T-score -2.16 and -2.03 in ZOL and OBP respectively). Both total hip and femoral neck BMD and T-score remained similar in both groups. When stratified, naive patients, mean change BMD at lumbar spine were 0.026 g/cm² and 0.013 g/cm² (3.4% and 1.6%) for Zol and OBP respectively. No difference was observed between ZOL and OBP pre-treated patients from baseline to month 12. No change was observed for the femoral neck and total hip BMD when both ZOL and OBP stratified by naive and pretreated patients were compared. Adherence (patients returning for the one year visit), was 66.8% and 53.1% in the naive patients and 75.1% and 81.9% in the pre-treated group for ZOL and OBP respectively. At one year, SAEs occurred in 4.7% (ZOL) and 3.2% (OBP).

Conclusion: Treatment-naïve ZOL patients were more likely to have a greater increase in BMD compared to OBP. In the pre-treated patients, mean changes in BMD were similar. Annual therapy with ZOL may have a favourable impact on persistence. Longer term follow-up in this real-life setting may show greater BMD and eventually lower fracture incidence with ZOL compared to OBP.

MO0426

The Use of Screening Radiographs to Detect Incomplete Atypical Femoral Fractures in Asymptomatic Patients on Bisphosphonate Therapy. Renata La Rocca Vieira¹, Zehava Sadka Rosenberg¹, Mary Allison², Shelly Im¹, Valerie Peck¹. ¹NYU Medical Center, USA, ²NYU Langone Medical Center, USA, ³NYU School of Medicine, USA

Objectives: Progression of an incomplete atypical femoral fracture (IF) to a complete fracture in patients on long term bisphosphonate (BISPH) therapy can be catastrophic. Our aims were to determine the frequency and imaging features of IF in asymptomatic patients on long-term BISPH therapy and to identify distinguishing clinical and laboratory markers in the subset of patients who develop these fractures. **Material and methods:** 200 femoral radiographs in 100 asymptomatic patients (93 females, 7 male, age range 57-70, mean 62.8) were prospectively reviewed by 2 radiologists. All patients were on BISPH therapy for at least 3 years and had no history of hip/thigh pain or recent trauma. MRI studies were performed when a fracture was suspected on radiographs. Bone mineral density (BMD), serum calcium, albumin, 25-hydroxy vitamin D, intact parathyroid hormone, serum c telopeptide and urine n telopeptide were obtained in all patients. **Results:** 2 of 100 patients (2%) had 3 IF (bilateral fractures in 1 patient). Both patients, age 50 and 57 respectively, were Caucasian, active and on BISPH therapy for 8 years. The patient with bilateral fractures demonstrated typical features of bisphosphonate-related IF: Bilateral focal, lateral cortical thickening with left incomplete transverse fracture line and no right fracture line. Lumbar spine and femoral neck BMD T-scores were -2.5 and -1.7 respectively. Laboratory data were normal. In the 2nd patient the radiographs were less typical demonstrating linear, intramedullary, subtrochanteric sclerosis. Lumbar spine and right femoral neck BMD T-scores were -1.4 and -2.7 respectively. Laboratory data demonstrated decreased bone turnover. MRI confirmed the radiographic findings in both patients. The 2 patients with IF were significantly younger ($p=0.0286$) than those without IF. There were no significant differences in other clinical or laboratory data ($p>0.15$) between the 2 groups. **Conclusion:** The 2% frequency of IF fractures in asymptomatic patients on long term BISPH therapy is higher than suggested in the literature. Aside from age, there were no significant differences in clinical or laboratory data between the 2 groups. **Clinical relevance:** Early detection of BISPH related IF may require screening radiographs. Larger studies are necessary to validate our findings and identify other discerning clinical and laboratory markers.

Thirteen Cases of Atypical Subtrochanteric and Diaphyseal Femoral Fractures among the 2,238 cases of Femoral Fractures Occurred during 2006 to 2010 in Japan. Yoshitomo Saita¹, Muneaki Ishijima¹, Atsuhiko Mogami², Tomonori Baba³, Masashi Nagao⁴, Kensuke Sakai⁴, Yasuhiro Homma², Rui Kato⁵, Kei Miyagawa⁶, Nana Nagura², Tomoki Wada², Osamu Obavashi², Hogaku Gen⁶, Hajime Kajihara⁵, Masahiko Nozawa⁴, Katsuo Shitoto⁷, Kazuo Kaneko¹. ¹Department of Orthopaedics, Juntendo University School of Medicine, Japan, ²Department of Orthopaedic Surgery, Juntendo Shizuoka Hospital, Japan, ³Department of Orthopaedic Surgery, Juntendo Urayasu Hospital, Japan, ⁴Department of Orthopaedic Surgery, Juntendo Nerima Hospital, Japan, ⁵Department of Orthopaedic Surgery, Koto Hospital, Japan, ⁶Department of Orthopaedic Surgery, Chiba Central Medical Center, Japan, ⁷Department of Orthopaedic Surgery, Juntendo Urayasu Hospital, Japan

The ASBMR task force defined major and minor features of atypical femoral fractures in response to the reports linking long-term use of bisphosphonates (BPs) with these fractures (JBMR, 11, 2267-94, 2010). It recommends that all major features be present to designate as atypical and also developed a case definition so that subsequent studies report on the same condition.

Following this definition, we retrospectively investigated all 2,238 proximal and diaphyseal femoral fractures treated in 6 hospitals related to our university in Japan during 2006-2010.

During this period, 13 cases (9 patients) (0.53%) of atypical fractures were found. All these cases showed major features. While 7 of 13 cases showed subtrochanteric fracture (0.36% of proximal femoral fractures), residual 6 cases were diaphyseal fracture (1.1% of diaphyseal fractures). All the 9 patients were female. While the mean age of 13 cases was 64.5y, that of subtrochanteric fractures (54.0y) were much younger than that of diaphyseal fractures (76.7y) ($p<0.05$). Bilateral fractures were occurred in

4 patients (44%) and in almost same place of their femurs. The majority (88.9%) occurred after oral BPs monotherapy (Alendronate: 6 patients, Risedronate: 2 patients). The duration of BP therapy was; within one year: 1 patient, 1-5 years: 4, over 5 years: 3. The history of glucocorticoids therapy was found in 6 patients (67%). Among them, 4 patients (44%) were long-term glucocorticoid users due to collagen diseases, such as systemic lupus erythematosus and dermatomyositis from their early-life. It should be emphasized that all these glucocorticoid users showed subtrochanteric fractures. The proton pump inhibitors were used in 2 of 9 patients (22%). Twelve of thirteen cases were operated with nail fixation and residual one case with locking plate (due to narrow medullary space). Prophylactic nail fixation was performed in 2 patients, as they complained prodromal pain and radiographic changes were detected in contralateral side. Delayed healing was observed in 4 cases (31%).

If this study is applied to the ASBMR task force evidence hierarchy, this study would be corresponded to have the "acceptable evidence". The atypical femoral fractures were shown to be occurred not only BPs users but also patients who have not been treated with BPs. However, our data suggest that the long-term combination therapy of glucocorticoids and BPs might be one of risk factors for the atypical subtrochanteric fracture.

Disclosures: Yoshitomo Saita, None.

MO0428

Three-monthly i.v. Ibandronate Following Long-term Treatment With Oral Alendronate; Results From a Two-year Prospective Open-labeled Study. Astrid Fahrleitner-Pammer¹, Karlheinz Fenzl², Doris Wagner³, Christian Muschitz⁴, Karin Amrein³, Thomas Pieber⁵, Barbara Obermayer-Pietsch¹, Hans Dimai¹. ¹Medical University Graz, Austria, ²Roche Austria, Austria, ³Medical University of Graz, Austria, ⁴St. Vincent's Hospital, Austria, ⁵Medical University of Graz, Dept of Internal Medicine, Div. of Endocrinology & Metabolism, Austria

Ibandronate (IBN) is a potent third generation bisphosphonate (BP) that is administered intravenously (i.v.) every three months. Therefore, it is widely used as an alternative to oral BPs in patients who are unable to ingest these drugs adequately, or who are prone to, or suffer from gastro-intestinal problems such as chronic gastritis or peptic-ulcer. The aim of the present study was to investigate the effect of IBN i.v. administered three-monthly in postmenopausal women who had previously been on long-term treatment with the oral BP alendronate (ALN).

The present study was carried out at an osteoporosis outpatient facility. 197 consecutive postmenopausal women (mean age 66 + 12 yrs) who had stopped long-term treatment with ALN for GI reasons, were switched to treatment with 3mg IBN three-monthly. The median time of treatment with oral ALN had been 37 + 14 months, and duration of consecutive treatment with IBN was 24 months.

After 2 years of treatment with IBN (following long-term treatment with ALN), serum crosslaps (sCTX) decreased significantly from 2.4 + 1.7 to 0.9 + 0.8 [$p<0.0001$; normal range 1.0 - 3.4nmol/L], and serum osteocalcin levels decreased from 23+14 to 18.2 + 10 [$p<0.0001$; normal range: 1-35 ng/ml]. Bone mineral density (BMD) measurement at the lumbar spine (dual energy X-ray absorptiometry, Hologic QDR 4500) revealed a significant increase of +8% (0.754 + 0.121 versus 0.844 + 0.170g/cm²; $p<0.0001$), and +8% at the femoral neck (0.622 + 0.103 vs 0.685 + 0.124g/cm²; $p<0.0001$). Serum creatinine levels and electrolytes showed no significant change throughout the entire period of observation. Three patients experienced flue-like symptoms after the first IBN injection, but no such side effects were seen after the second injection.

To our knowledge, the present study is the first to assess the effect of 2 years of i.v. IBN treatment following long-term treatment with an oral BP. Our data indicate that patients who have been pre-treated with the potent antiresorptive BP ALN may further benefit from a subsequent treatment with i.v. IBN in terms of increasing BMD, and decreasing bone turnover as assessed by biochemical markers. IBN i.v. 3-monthly appears to be well tolerated with no detrimental effects on renal function.

Associations Between Osteoporosis (OP) Treatment Change, Adherence, and Incident Fractures Among Members in a Medicare Advantage Prescription Drug (MAPD) Plan. Yihua Xu¹, Melea Ward¹, Hema Viswanathan², John Adams³, Bradley Stolshek², Reginald Clay², John Kallich², Kenneth Saag⁴. ¹Competitive Health Analytics, Inc, USA, ²Amgen Inc., USA, ³RAND Corporation, USA, ⁴University of Alabama at Birmingham, USA

Purpose: High medication adherence (medication possession ratio [MPR] of ≥ 0.8) is known to be associated with better treatment outcomes. Treatment change (i.e. medication switch) patterns in OP and associated impact on MPR and fracture outcomes have not been well characterized. We examined the relationship between OP treatment change, medication adherence, and incident fractures among MAPD members newly initiated on an OP treatment.

Methods: This was a retrospective cohort study of MAPD members, aged ≥ 50 newly initiated on an OP medication between Jan2006 and Dec2008. Treatment change, defined as a change in therapy or dose was examined during the 12 month

MO0431

First Interim Results of the German Non-Interventional Study (NIS) VIVA to Assess the Compliance, Safety, and Effectiveness of Quarterly i.v. Ibandronate (IBN) vs. Weekly Oral Alendronate (ALN) in Patients with Postmenopausal Osteoporosis. Peyman Hadji*. Philipps-University of Marburg, Germany

Purpose: The objectives of this NIS are to evaluate compliance, persistence, safety, and effectiveness of quarterly 3mg i.v. IBN vs. weekly 70mg p.o. ALN in patients with PMO in a real world setting. Here, we present preliminary results from a first interim analysis.

Methods: This NIS was started in MAR-2010 and a total of 6,000 pts have been enrolled until November 2010. Baseline documentation (VB) is available for 5,838 pts; 3,982 pts returned for their 1. interim visit (V1). This interim analysis focused on baseline characteristics and pain reduction from VB at V1; all analyses were purely descriptive. A pre-planned "matched-pairs" analysis was applied in order to enhance the comparability between treatment groups with regard to missing randomization. Criteria for matching included age, BMI, prevalent fractures, prevalent vertebral fractures, pre-treatment with bisphosphonates (BP), concomitant diseases, and start of current treatment in relation to VB date.

Results: As expected, the IBN (N=4,363) and ALN (N=1,475) groups comprised significant differences with regard to baseline characteristics. While median age was 73yrs and median PMO duration was 22yrs in either group, noticeable differences were found for start of current therapy in relation to date of VB (-89,0251 days in the IBN group vs. -205490 days in the ALN group; $p=0.001$), no. of pts with previous fractures (45.7% vs. 40.0%; $p<0.01$) and vertebral fractures (34.3% vs. 27.9%; $p<0.01$), and no. of BP-naïve pts (48.1% vs. 64.9%; $p<0.01$). In addition, differences in the pattern of concomitant diseases were apparent. We performed a matched-pair analysis for 1,778 pts, resulting in 889 pairs of IBN and ALN groups. 3,982 pts had V1 data reported (performed approx. 90 days on median after VB). A reduction in analgesics use from VB to V1 was performed in 39.2% and 34.2% of pts, and the rate of patients with no or mild OSM-related pain had increased from VB to V1 by 16.8 and 12.0%-points (IBN vs. ALN).

Conclusions: The presented data of the first interim analysis suggests that there might be differences with regard to pain reduction between the groups. This needs to be confirmed with the final data in the matched-pair population which are expected to be available in 2012.

MO0432

Optimizing Communication of DXA Results and Fracture Risk to Patients: A Mixed Methods Study. Stephanie Edmonds*¹, Samantha Solimeo¹, Douglas Roblin², Kenneth Saag³, Peter Cram¹. ¹University of Iowa, USA, ²Kaiser Permanente, USA, ³University of Alabama at Birmingham, USA

BACKGROUND: There is growing interest in sharing clinical information with patients to facilitate medical decision making and improve healthcare quality. However, it remains uncertain how to best present this information in a way that patients understand. As part of a multi-center randomized trial, we conducted a mixed-methods study to examine how best to communicate written DXA results and fracture risk information to patients.

METHODS: Our team of clinicians and health communication experts developed three different letters (A, B, and C) and four visual graphic representations of fracture risk (Bar, Stoplight, Arrow, and Faces), designed to be mailed to patients after a DXA appointment. Each letter/graphic combination provided DXA result (T-score), diagnosis (normal, low BMD, osteoporosis) and FRAX fracture risk. We presented the letters and arrays in random order to a convenience sample of adults aged 50 years or older drawn from a large academic medical center. We collected patient demographic information and educational attainment. Participants were asked to identify which letter and graphical representation they preferred as well as ease of understanding and perceived risk of each.

RESULTS: We interviewed 35 subjects (34% female, mean age 65.3 years \pm 8.8, 25.7% completed high school or less). Of the three letters, 36% preferred version A, 33% preferred Letter B, and 31% preferred Letter C. However, Letter B was rated easiest to understand by 33% of respondents while only 25% rated Letter A easiest to understand. Factors that participants felt important in the letters were: a) to give numerical data (e.g., T-score, FRAX) as well as the overall impression; and b) to give patients specific "next steps" to take. Subjects reported that the specific definition of a T-score was confusing, but appreciated a general overview. Of the four graphical arrays, 40% of subjects preferred the "Bar" graph and 17% preferred a "Stoplight" array. Subjects stated the "Bar" image showed their risk category best and was "clean," "clear," and "easy to read."

CONCLUSION: Using a mixed methods approach, we were able to identify a letter and graphical array for effectively conveying DXA results and fracture risk to patients. These templates should be used by others looking to convey DXA results to patients.

(mos) post-index period (date of the first OP medication). Adherence, measured by MPR, was categorized as low (<0.5), partial (0.5 to <0.8), and high (≥ 0.8) at 12 and 24 mos post index. Fractures in the first 12 months post-index were identified based on a validated algorithm. Members who discontinued the index medication and did not restart an OP medication were excluded from the fracture analysis. The relationship between treatment change and incident fracture was evaluated using a pooled logistic regression model which allowed for specification of treatment change to have occurred prior to the fracture using a time varying covariate.

Results: Of 33,823 members identified as having newly initiated OP therapy, 3,573 (10.6%) changed therapy within 12 mos. The proportion of patients with low, partial, and high adherence, respectively, 12 mos post index was 41.4%, 26.7%, and 31.9% in the change cohort, and 51.3%, 17.6%, and 31.1% in the no-change cohort. The proportions at 24 mos post index were 50.1%, 24.3%, and 25.5%, respectively, in the change cohort, and 58.0%, 16.8%, and 25.1%, respectively, in the no-change cohort. The fracture risk analysis included 19,574 members. At 12 and 24 mos, the change cohort had a higher fracture incidence (11.2% and 15.3%, respectively) compared to the no-change cohort (8.2% and 12.7%, respectively). However, fracture incidence was not significantly different between the two cohorts after adjusting for covariates (Odds Ratio=0.98, 95% CI=0.85-1.1, $P=0.77$).

Conclusions: Overall adherence was low in both cohorts. Changing OP therapy was not found to be associated with a decrease in fracture risk. An opportunity to improve fracture outcomes exists given that less than a third of members in each cohort achieved high adherence with currently available therapies.

MO0430

Does Medication Adherence Itself Confer Fracture Protection? An Investigation of the Healthy Adherer Effect in Observational Data. Jeffrey Curtis*¹, Jeff Lange², Huifeng Yun¹, Elizabeth Delzell¹. ¹University of Alabama at Birmingham, USA, ²Procter & Gamble, USA

Background

Prior studies have shown a relationship between bisphosphonate (BP) adherence and reduced fractures. One potential concern about the interpretation of this association is the healthy adherer effect, a phenomenon whereby patients who adhere to medications are systematically different than those who do not. The extent to which fracture-adherence analyses might be confounded by the healthy adherer effect in real-world settings is unclear.

Objective

To quantify the association between high adherence with different medications and fracture risk.

Methods

Using Medstat MarketScan from 2000 to 2008, we identified 125,000 women with a new clinical fracture at the hip, spine, humerus, or wrist. We defined three mutually-exclusive cohorts of patients who initiated within 6 months post-fracture: 1) oral BPs; 2) selective serotonin reuptake inhibitors (SSRI); or, 3) ace inhibitor, angiotensin receptor blocker, or calcium channel blocker (ACE/ARB/CCB). These medications were chosen for their expected favorable, unfavorable, and neutral effect on fracture risk. Adherence (medication possession ratio [MPR]) was assessed after 1 year of new use, updated every 90 days. Follow-up time for new fractures began after the MPR measurement and extended up to 4 years. Patients were categorized as highly adherent (MPR $\geq 80\%$) vs. less adherent (MPR $< 50\%$). Cox proportional hazards models evaluated the association between high (vs. low) adherence within each medication group and fracture.

Results

We identified a BP cohort (11,712 patients, mean age=75), SSRI cohort (5,570 patients, mean age=76), and ACE/ARB/CCB cohort (5,731 patients, mean age=77) who initiated these therapies ≤ 6 months after fracture. For these 3 cohorts, 46%, 43%, and 53%, respectively, had MPR $\geq 80\%$ at 12 months.

Crude hazard ratios for hip and non-vertebral fractures (Table) showed that high adherence (vs. lower adherence) with BPs decreased fracture risk; high adherence with SSRIs increased hip fracture risk, and high adherence with ACE/ARB/CCBs was neutral toward fracture risk.

Conclusion

In this observational analysis of women enrolled in a commercial health plan, we did not find evidence of a healthy adherer effect that suggested that medication adherence itself conferred fracture benefit. Based upon this result, observational analyses evaluating the association between osteoporosis medication adherence and fracture risk appear to not be meaningfully confounded by the healthy adherer effect.

Table. Relationship between High (vs. Lower) Adherence to Bisphosphonates, SSRIs, and ACEI/ARB/CCBs

Fracture Type	Bisphosphonates		SSRIs		ACEI/ARB/CCB	
	N, rate per 100py	HR (95% CI)	N, rate per 100py	HR (95% CI)	N, rate per 100py	HR (95% CI)
Hip, adherent	48, 0.5	0.56	47, 1.4	1.42	288, 1.2	1.15
Hip, non-adherent	84, 1.0	0.39-0.80	40, 1.0	0.93-2.17	187, 1.0	0.74-1.77
Nonvertebral, adherent	495, 5.6	0.76	226, 6.7	1.01	54, 6.3	1.05
Nonvertebral, non-adherent	635, 7.3	0.68-0.86	271, 6.6	0.85-1.20	32, 6.0	0.87-1.26

Persistence of Therapy With Zoledronic Acid Infusion For Osteoporosis.Christine Simonelli^{*1}, Julie Morancey¹, Jean Lian², Yoona Kim².
¹HealthEast Osteoporosis Services, USA, ²Novartis, USA

We report the re-infusion rate for zoledronic acid treatment for osteoporosis in our osteoporosis center. To maximize persistence with treatment we developed a simple process to track osteoporosis patients who were treated with annual 5mg zoledronic acid infusion. When patients receive their first infusion a 'tickler' file is created and placed at the month before their next infusion due date. Patients are given a patient education video about osteoporosis and an information brochure on zoledronic acid. Patients are contacted to schedule their clinical appointment the month before their due date if it is not already scheduled. If they miss their appointment an attempt is made to contact them and determine the reason for their failure to comply with prescribed treatment and discuss options. We report one-year follow-up on 74 patients and two-year follow-up on 37 patients who received their first zoledronic acid infusion between August 2008 and January 2010. There were 66 women (89.2%), mean age 71.9 (9.2SD) and 8 men, mean age 71.3 (9.4SD). One prior fracture was noted in 28 patients (37.8%), two prior fractures in 11 (14.9%) and three prior fractures in 7 (9.5%). Twenty-nine patients had prior vertebral fracture (39.2%), 10 prior rib fracture (13.5%), 6 prior hip fracture (8.1%) and 9 prior wrist fracture (12.2%). Sixty-seven patients had prior bisphosphonate use (90.5%); 54 alendronate (73%), 20 oral ibandronate (27%), 11 IV injections of ibandronate (14.9%) and 13 risedronate (17.6%). Thirty-three patients (44.6%) had prior teriparatide use. The most common reasons for choice of zoledronic acid treatment were BMD decline 30 patients (40.5%), GI adverse event on oral bisphosphonate 23 patients (31.1%), known upper GI disease 22 patients (29.7%), completion of teriparatide treatment 22 patients (29.7%). All 74 patients received their first infusion; 57 received their second infusion (76%). Eight patients (13.5%) were greater than one month late for their second infusion; 5 patients (6.8%) changed medication as physician preference, 6 (8.1%) patients lost to follow-up, 2 (2.7%) had BMD improvement and changed to every two year regimen; 2 (2.7%) had serious co-morbidity, 1 (1.4%) had dental work pending and 1 (1.4%) declined second infusion. 20 of 37 patients (54%) had a third infusion. Providing patient education materials and tracking patient appointments allowed for a high 2-year persistence of osteoporosis treatment with zoledronic acid.

MO0435

Persistence, Gaps in Therapy, and Re-initiation of Osteoporosis (OP)

Therapy Among Women in a Commercially Insured US Population. Akhila Balasubramanian^{*1}, Alan Brookhart², Vamshidar Goli³, Cathy Critchlow⁴. ¹Amgen Inc, USA, ²University of North Carolina at Chapel Hill, USA, ³Amgen Inc., USA, ⁴Amgen, USA

Purpose

Long-term persistence is a significant challenge for OP treatment. As such, it is important to understand patterns of utilization, including persistence, discontinuation and re-initiation of OP therapy. This study describes utilization patterns of OP therapy and factors associated with re-initiating therapy following an interruption.

Methods

This study was conducted using 2005-2009 data from a large commercially-insured population. Women aged ≥ 55 yrs who had a new prescription claim for oral OP therapy following a 12 month (baseline) period with no OP therapy claims and ≥ 24 months of follow-up after therapy initiation, were eligible. Discontinuation was defined as the presence of a gap in prescription claims >60 days (30-90 days in sensitivity analyses). Re-initiation was defined as a prescription claim for the same or a different OP therapy following the therapy gap. Kaplan-Meier analysis was used to describe discontinuation and re-initiation patterns within 24 months following therapy initiation. Multivariate Cox regression was used to assess the impact of baseline clinical and demographic factors on re-initiation following the first gap in therapy.

Results

Of the 92,839 subjects, 55%, 42%, and 30% were persistent with therapy at 6, 12, and 24 months following initiation, respectively. Of those who discontinued therapy within 24 months of initiation, 46% re-initiated therapy; the majority (64%) did so within 6 months of discontinuation. Patients were less likely to re-initiate therapy if they were older ($p < 0.0001$), had a history of hospitalization during baseline ($p = 0.0007$), or were on therapy for a shorter (<6 months) period ($p < 0.0001$) prior to therapy interruption. The median time on therapy following re-initiation was 90-197 days across strata of patients categorized by time on and off therapy and with at least 12 months of observation time following discontinuation. Longer allowable gap periods in the definition of discontinuation resulted in slightly lower discontinuation rates, but did not appreciably change the overall findings.

Conclusions

Persistence with OP therapy is low. While approximately half of patients who discontinue treatment return to therapy, their uninterrupted time on therapy upon re-

Osteoporosis Treatment Initiation and Withdrawal: Evidence of Therapeutic Hysteresis in Clinical Practice. William Leslie^{*1}, Suzanne Morin², Lisa Lix³.

¹University of Manitoba, Canada, ²McGill University Health Centre, Canada, ³University of Saskatchewan, Canada

BACKGROUND: BMD testing strongly impacts on physician behavior in terms of osteoporosis therapy (OTX) initiation. Factors leading to OTX withdrawal have not been well studied. **METHODS:** Clinical BMD testing in the Province of Manitoba, Canada, uses an integrated program structure with a BMD database linkable to administrative health databases to identify all OTX dispensations. Prior to Jan 1, 2006, fracture risk reporting was based upon T-scores only; after this date 10-year fracture risk was reported using a FRAX-like model with risk categorized as low ($<10\%$), moderate (10-19%) or high ($>20\%$). Non-HRT OTX use was studied in women age 50+ who underwent BMD testing before (PRE = March 2005-Dec 2005) and after (POST = Jan 2006-Mar 2007) introduction of 10-year fracture risk reporting. We excluded women with any prior non-trauma fracture or with >90 days of steroid use at any time in the preceding 10 years. Two subgroups were defined: women with no OTX use in the year prior to BMD testing ($N=6,581$) and women with moderate to high OTX adherence in the year prior to BMD testing based upon medication possession ratio $>50\%$ ($N=1,352$). We examined the rate of OTX initiation in the untreated women (any OTX dispensation in the year post BMD) and treatment withdrawal in the previously treated women (any OTX dispensation >90 days post BMD). **RESULTS:** The overall rate of OTX initiation in untreated women was 19%, with a significant difference between the periods (PRE 22% vs POST 17%, $P < 0.001$). In contrast, among treated women there was a high rate of OTX persistence with no significant period effect (PRE 88% vs POST 85%, $P=0.074$). Similar results were seen for OTX use >180 days and >365 days post BMD. Although BMD category and risk category strongly affected OTX initiation, there was only a weak effect on OTX withdrawal (POST treatment rates 70% for normal BMD and 76% for low fracture risk). The OTX treatment curves by BMD category or risk category (Figure) for previously untreated and treated women were non superimposable suggesting significant hysteresis (path dependence). **CONCLUSIONS:** OTX withdrawal is infrequent in previously adherent women. BMD results are not a major trigger for treatment withdrawal even when BMD is normal and the estimated fracture risk is low. Factors contributing to treatment withdrawal need to be better defined given concerns regarding adverse effects from long term OTX, particularly among individuals who are not at high fracture risk.

Figure: OTX treatment rates Jan 2006-Mar 2007 according to BMD and 10-year risk category.

MO0436

The Persistence in the Health District of Cosenza (Calabria, Italy). *Claudia Carbone*¹, Alfonso Reda², Maria Gabriella Bartoletti³, Brunella Piro¹, Luisa Gallo¹.* ¹Servizio Farmaceutico ASP Cosenza, Italy, ²Italy, ³Centro di Riabilitazione Biolife, Italy

The persistence is an important problem in patients treated for the osteoporosis disease. We wanted to see what is the persistence in our referring population. We have considered the patients in the health district of Cosenza in Italy. The treated patients are 11094, all women, above 50 years old, affected by post-menopausal osteoporosis. We have considered two years 2009-2010 and all the patients treated with: teriparatide, parathyroid hormone, raloxifene, alendronate, ibandronate, risedronate. The patients treated by Teriparatide (84) had 6.68 as average prescription for each patient; the patients took the drug less 33% (six months) were 46 (60.7%); between 33 and 66% (between 6-12 months) were 9 (10.7%), till 100% (18 months) were 24 (28.6%). The patients treated by parathyroid hormone (only 2) had 7 as average prescription for each patient. The patients treated by raloxifene (317) had 7.91 as average prescription for each patient; the patients took the drug less 25% (six months) were 178 (56.2%); between 25 and 50% (between 6-12 months) were 38 (11.9%); between 50 and 75% (between 12-18 months) were 60 (18.9%), more 75% were 41 (13%). The patients treated by alendronate (4610) had 7.92 as average prescription for each patient; the patients took the drug less 25% (six months) were 2458 (53.3%); between 25 and 50% (between 6-12 months) were 614 (13.3%); between 50 and 75% (between 12-18 months) were 956 (20.7%), more 75% were 582 (12.7%). The patients treated by ibandronate (1082) had 8.78 as average prescription for each patient; the patients took the drug less 25% (six months) were 539 (49.8%); between 25 and 50% (between 6-12 months) were 143 (13.4%); between 50 and 75% (between 12-18 months) were 228 (21.2%), more 75% were 170 (15.6%). The patients treated by risedronate (2649) had 8.36 as average prescription for each patient; the patients took the drug less 25% (six months) were 1384 (52.2%); between 25 and 50% (between 6-12 months) were 332 (12.6%); between 50 and 75% (between 12-18 months) were 580 (21.9%), more 75% were 353 (13.3%). The patients treated by strontium ranelate (2350) had 4.77 as average prescription for each patient; the patients took the drug less 25% (six months) were 1782 (75.8%); between 25 and 50% (between 6-12 months) were 225 (9.6%); between 50 and 75% (between 12-18 months) were 274 (11.7%), more 75% were 69 (2.9%). Conclusions: Our observation confirms the low persistence at the therapy for osteoporosis.

Treatment of Osteoporosis with zoledronic acid: what is the Persistence at one year in Clinical Practice?. *Estelle Rose¹, Thierry Lequerre², Chantal Bougneres¹, Pascal Bennet¹, Xavier Le Loet¹, Olivier Vittecoq¹, Alain Daragon*¹.* ¹Rheumatology Department, France, ²Rheumatology Department, France

Purpose: Zoledronic acid 5mg infusion is the only bisphosphonate administered once a year to treat osteoporosis. We could expect to an improved persistence compared to oral forms. Some studies showed a patient preference for a yearly infusion of zoledronic acid compared with oral therapy but no data on adherence or persistence is available. The objective of this study was to assess the proportion of patients who benefit a second infusion of zoledronic acid out of clinic after a first prescription given in the rheumatology department.

Methods: The retrospective study was conducted over 2 years. After searching for patients who received an initial infusion either during hospitalization or following a consultation, between August 2008 and November 2009, we phoned the general practitioners initially to know whether the second infusion was made ?? in the following year. When the general practitioner had no information, we contacted the rheumatologist or sometimes the patients themselves.

Results: Of 52 patients, 7 died within the year after the first infusion and 3 were lost of follow up. Of the 42 evaluable patients, 10 (24%) have not received the second infusion. This overall figure hides a wide disparity between patients who get out of hospitalization (n = 20) and those emerging from the consultation (n = 22). Indeed, after hospitalization 60% of patients received their second infusion against 91% after a consultation. This retrospective study provides disappointing results on the therapeutic persistence of infusions of zoledronic acid. To explain these results, it is possible that patients simply forget the second infusion because of the spacing of one year, or because another disease interfered. Also, the reports of hospitalization for physicians may not highlight enough the need to renew the infusion. Finally, the difference in persistence after hospitalization and after consultation may be explained by the fact that an infusion performed during an hospitalization is less well remembered than an infusion made at home on a given date.

Conclusion: Although the frequency of administration of zoledronic acid is not constraining, persistence seems disappointing with only 76% of second infusion

performed. Improving persistence need a better information for the physician and a systematic specialized consultation at one year could be proposed.

MO0438

Antioxidant Enzyme Genes' Polymorphisms Influence Raloxifene Therapy Outcome in Postmenopausal Osteoporosis. *Simona Jurkovic Mlakar¹, Andrej Zavratnik², Tomaz Kocjan³, Janez Prezelj⁴, Janja Marc*¹.* ¹Department for Clinical Biochemistry, Faculty of Pharmacy, Slovenia, ²Department of Endocrinology & Diabetes, University Medical Centre Maribor, Slovenia, ³University of Ljubljana Medical Faculty, Slovenia, ⁴Medical faculty, University of Ljubljana, Slovenia

Levels of antioxidative enzymes are decreased in postmenopausal osteoporosis, probably as a consequence of estrogen deficiency. Studies showed that estrogens participate in gene expression of some antioxidant enzymes, for example GPX1. Raloxifene, the selective estrogen receptor modulator, might have even more pronounced antioxidant function than estrogen. For instance, in osteoporotic women on raloxifene the antioxidant enzymes such as catalases and superoxide dismutases, as well as serum concentration of glutathione were found to be increased.

We studied effects of one-year raloxifene treatment on bone mineral density (BMD) and biochemical markers of bone turnover in 52 Slovenian postmenopausal women, aged 60-65 years, in relation to genetic polymorphisms of major antioxidant enzymes involved in the metabolism of glutathione (GPX1, GSR, GSTM3, GSTM1, GSTT1 and GSTP1), thioredoxin system (TXNRD2, TXN) and interceptors of oxygen intermediates (CAT, SOD2 and SOD1).

Bone mineral density (BMD) at lumbar spine (BMD_{ls}), femoral neck (BMD_{fn}) and total hip (BMD_{th}) was measured by DXA and biochemical markers of bone turnover bone alkaline phosphatase (sBALP) and plasma osteocalcin (pOC) were obtained at baseline and after one-year of treatment with raloxifene 60 mg once daily. For genotyping the real-time PCR, triplex-PCR, DHPLC and restriction fragment methods were used.

After treatment there was on average an increase of BMD at lumbar spine and femoral neck of 2.14.5% and 1.65.2%, respectively and a decrease of 0.615.1% at total hip. The increase in BMD_{fn} was significantly greater among individuals with T/T genotype of SOD1 promoter SNP (rs4998557) (p=0.043) and Ile/Ile genotype of GSTM3 gene Val224Ile polymorphism (p=0.022). On the other hand, the same treatment resulted in greater increase of BMD_{ls} in individuals with Ala/Val genotype of GSTP1 gene Ala114Val polymorphism and Ala/Ala genotype of TXNRD2 gene Ala66Ser polymorphism. Interestingly, the significantly greater decrease of plasma osteocalcin concentration was observed among individuals with A/T genotype of 1154-393T>A polymorphism of GSR gene compared to A/A genotype subgroups (p=0.007).

This study shows for the first time a significant influence of SOD1, GSTM3, GSTP1, TXNRD2 and GSR genetic polymorphisms on raloxifene therapy outcome in postmenopausal osteoporosis.

Decomposing Health Care Expenditures Relative to Fractures. *Meredith Kilgore*¹, David Becker², Jeffrey Curtis², Kenneth Saag², Elizabeth Delzell², Tarun Arora³, Michael Morrissey².* ¹University of Alabama At Birmingham School of Public Health, USA, ²University of Alabama at Birmingham, USA, ³UAB School of Public Health, USA

Objective: The purpose of this study is to evaluate reasons for health care expenditures both prior to and after the occurrence of fractures among Medicare beneficiaries.

Background: In a previous study we examined health services expenditures immediately prior to and following fractures and used the difference, incremental expenditures, as an estimate of avoidable costs associated with fractures. We also classified expenditures as attributable if they were directly linked to a fracture diagnosis code. Attributable expenditures accounted for only 24-60% of incremental expenditures, depending on the fracture site.

Methods: We examined health care expenditures between 1999 and 2007 among Medicare beneficiaries who experienced fractures (cases) and among beneficiaries who did not experience fractures (controls), matched to cases on age, race and sex. We also examined health care expenditures for cases and controls for 24 months prior to the fracture index date.

Results: When expenditures associated with diagnoses for aftercare, joint pain, and osteoporosis, other musculoskeletal diagnoses, pneumonia and pressure ulcers were included, the fracture of incremental costs directly related to fracture care rises substantially, to between 59% and 71%. We found that expenditures prior to fracture were higher for cases than controls, and that the rate of increase in health care expenditures was much higher among those about to experience hip fractures up to 18 months prior to the event (see figure).

Conclusions: Our findings confirm that the original incremental cost analysis constituted a very reasonable method for estimating avoidable costs associated with fractures and also suggest that patterns of health services utilization may provide a means to improve fracture prediction rules.

Fracture Liaison Service in a Non-regional Orthopaedic Clinic - A Cost-effective Service. Joe O Beirne¹, John Quinlan¹, Isweri Pillay², Mohamed Ahmed^{*2}. ¹Waterford Regional Hospital, Ireland, ²South Tipperary General Hospital, Ireland

Introduction: Secondary prevention of osteoporotic fracture is widely neglected with only a minority of patients offered investigations and treatment. It is proposed that in Ireland, a dedicated FLS be available in every hospital to which a patient presents, with a fracture. The FLS at South Tipperary General Hospital (STGH) is the first non-regional orthopaedics unit to provide this service in Ireland. The aim of this study was to evaluate the role of a FLS in providing cost-effective secondary fracture prevention.

Methods: All patients attending the orthopaedics service at STGH were screened by the fracture liaison nurse; an existing retrained orthopaedics nurse. Data were entered prospectively on to a standardised proforma. Patients were identified based on age, type of fracture sustained and their risk factors for osteoporosis. Screening consisted of fracture risk estimation, phlebotomy and DXA scanning. Treatment recommendations were based on international guidelines for secondary prevention of osteoporosis and included: Diet and lifestyle modification, calcium and vitamin D supplementation and pharmacotherapy.

Results: A total of 3164 patients attended the fracture clinic between July 2009 and February 2011. 4% (n=124) were identified as having a fragility fracture and fulfilled the criteria for fracture prevention assessment. Of those 80.6% (n=100) were females and 19.4% (n=24) were males. The average age of all patients was 67 years (range 46-94). Nearly 50% of all patients (n=58) had one or more previous fracture. Upper limb fractures accounted for the majority of fragility fractures screened (55.6%), with distal radius fracture being the commonest fracture sustained 23.3% (n=29). 92.7% (n=115) were offered BMD testing and of those 94% (n=108) completed their DXA scan. Two thirds of the patients (n=69) were either osteoporotic or osteopenic. All patients (100%) had blood tests for secondary osteoporosis screening. 90.2% of all patients (n=111) received verbal and written information regarding diet and lifestyle modification, and of those 106 patients (95%) received additional calcium and vitamin D. 48.7% of all patients (N=60) required anti-resorptive therapy.

Conclusion: the FLS at STGH successfully identified those at increased risk of further fragility fractures and effectively delivered an evidence-based standard of care for the secondary prevention of osteoporotic fractures on a Whole Time Equivalent cost-neutral basis.

Healthcare Costs for Males After Closed Fracture in Commercially Insured and Medicare Advantage Populations From a National Health Plan. Susan Brennenman¹, Laura Christensen¹, Nicole Yurgin^{*2}, Ying Fan¹. ¹Innovus, USA, ²Amgen Inc, USA

Purpose: To determine annual total health care costs following hip, vertebral and non-hip/non-vertebral (NHNV) fractures among commercial (COM) and Medicare Advantage Plan (MAP) male enrollees.

Method: Administrative claims from a large, national health plan were analyzed. Men 45 or older were included if they had: at least one medical claim for a new closed fracture (identified through primary ICD-9-CM diagnosis indicating closed hip, vertebral, or NHNV fracture) at a single site between January 1, 2005 and December 31, 2008, were continuously enrolled with the plan for 12 months before and after the fracture, and had at least two fracture-related outpatient visits during the follow-up period. Those with hip, femur, tibia and humerus fractures were required to have

inpatient care associated with the first fracture claim. COM and MAP members were analyzed separately. Costs were calculated and stratified for hip, vertebral, and NHNV fracture patients as paid amounts and were adjusted to 2009 dollars. The difference between the individual patient's 12 month pre-fracture costs and 12 month post fracture costs are reported to estimate the change in costs associated with fracture.

Results: The study identified 18,917 (COM 16,191; MAP 2,726) closed fragility fractures during the study period. The sample mean age was 58 yrs and 74 yrs for COM and MAP, respectively. In the COM group, the proportions of fractures were: 22% vertebral fractures, 4% hip fractures, and 74% NHNV fractures. For the COM members, the difference in healthcare cost 12 months before and after fracture was: \$15,906 for vertebral fractures, \$30,176 for hip fractures and \$8,313 for NHNV fractures. In the MAP group, the proportions of fractures were: 38% vertebral fractures, 9% hip fractures, and 52% NHNV fractures. For the MAP members, the difference in healthcare costs 12 months before and after fracture was: \$7,439 for vertebral fractures, \$25,232 for hip fractures, and \$6,561 for NHNV fractures. In both populations, mean healthcare cost per fracture was highest for hip fracture but hip fracture was the least common type of fracture.

Conclusion: Healthcare costs associated with fragility fractures in men are high. Hip fracture had the highest cost per fracture (~\$30,000 in COM and ~\$25,000 in MAP) but a lower incidence of fracture compared to NHNV and vertebral fractures.

A Phase 3 Study of the Efficacy and Safety of Denosumab in Men With Low Bone Mineral Density: Design of the ADAMO Trial. Eric Orwoll¹, Christence Stubbe Teglbjærg², Bente Langdahl³, Roland Chapurlat⁴, Edward Czerwinski⁵, David L Kendler⁶, Jean-Yves Reginster⁷, Alan Kivitz⁸, E. Michael Lewiecki⁹, Paul Miller¹⁰, Michael A Bolognese¹¹, Henry G Bone¹², Osten Ljunggren¹³, Bo Abrahamsen¹⁴, Yu-Ching Yang¹⁵, Andreas Grauer¹⁵, Cesar Libanati¹⁵, Jesse W Hall¹⁵, Steven Boonen¹⁶.

¹Oregon Health & Science University, USA, ²Centre for Clinical & Basic Research, Denmark, ³Aarhus University Hospital, Denmark, ⁴Hopital Edouard Herriot, France, ⁵Krakow Medical Center, Poland, ⁶University of British Columbia, Canada, ⁷University of Liege, Belgium, ⁸Altoona Center for Clinical Research, USA, ⁹New Mexico Clinical Research & Osteoporosis Center, USA, ¹⁰Colorado Center for Bone Research, USA, ¹¹Bethesda Health Research Center, USA, ¹²Michigan Bone & Mineral Clinic, USA, ¹³Uppsala University, Sweden, ¹⁴University of Southern Denmark & Gentofte Hospital, Denmark, ¹⁵Amgen Inc., USA, ¹⁶Leuven University, Belgium

Purpose: Denosumab increased bone mineral density (BMD) and reduced fractures in both postmenopausal women with osteoporosis (N=7808; Cummings, NEJM, 2009) and in men with prostate cancer on hormone ablation therapy (N=1468; Smith, NEJM, 2009). To evaluate the effects of denosumab in men with osteoporosis, a phase 3, 1-year, double-blind, placebo-controlled study in men with low BMD is currently in progress. Here, we describe the design and participant baseline characteristics of this fully-enrolled, ongoing study.

Methods: ADAMO is a multicenter, randomized, double-blind, placebo-controlled study to compare the efficacy and safety of Denosumab 60 mg every 6 months versus placebo in Males with Osteoporosis. All participants receive daily calcium and vitamin D supplementation throughout the study. Men between 30 to 85 years of age were eligible for enrollment if they had low BMD (T-score ≤ -2.0 and ≥ -3.5 at the lumbar spine or femoral neck) or had experienced a prior major osteoporotic fracture and had a T-score ≤ -1.0 and ≥ -3.5 . The primary efficacy endpoint is the percent change from baseline in lumbar spine BMD. Secondary efficacy endpoints include percent change from baseline in BMD of the total hip, femoral neck, trochanter, and 1/3 radius, and the percent change from baseline in serum C-telopeptide (CTX). Safety endpoints include incidence of adverse events. Following the 1-year, double-blind, placebo-controlled study period, all subjects will receive open-label denosumab for an additional year.

Results: The baseline characteristics of the men who were randomized in the ADAMO study (N=242) were similar to those of men enrolled in other completed male osteoporosis trials. Men in the ADAMO study had a mean age of 65.0 years, 94.2% were white, and 37.2% had a history of fracture (Table 1). Mean T-scores at the lumbar spine and femoral neck were -2.0 and -1.9, respectively. The study results are not available since the trial is ongoing and remains blinded.

Conclusions: In light of the BMD gains and associated fracture reductions reported in the pivotal denosumab fracture trials of postmenopausal women with osteoporosis and of men with prostate cancer on hormone ablation therapy, ADAMO is being performed to confirm the effects of denosumab on BMD and bone turnover markers in men with osteoporosis.

Association Between Polymorphisms In Wnt Antagonist Genes and Bone Response to Hormone Therapy In Postmenopausal Korean Women. Jung-Gu Kim¹, Hoon Kim², Dong Ock Lee³, Seung-Yup Ku³, Seok Hyun Kim³, Young Min Choi³. ¹Seoul National University Hospital, South Korea, ²Department of Obstetrics & Gynecology, Incheon Medical Center, South Korea, ³Department of Obstetrics & Gynecology, College of Medicine, Seoul National University, South Korea

Purpose: The purpose of this study was to investigate the association between polymorphisms in Wnt antagonist genes and bone response to hormone therapy (HT) in postmenopausal Korean women.

Methods: The dickkopf (Dkk) 1 c.318A>G, Dkk2 c.437G>A, Dkk3 c.1003A>G, secreted frizzled related proteins (sFRP) 3 c.970C>G, sFRP4 c.958C>A, and c.1019G>A and sFRP5 c.20G>C polymorphisms were analyzed by polymerase chain reaction-restriction fragment length polymorphism (PCR-REFLP), Taqman assay or direct DNA sequencing in 303 postmenopausal Korean women receiving sequential HT for 1 year. BMD at the lumbar spine and femoral neck was determined by dual energy X-ray absorptiometry.

Results: When a non-responder was defined as a woman who had lost more than 3% of BMD per year after HT, Dkk1 c.318A>G polymorphism and the haplotype genotype of sFRP4 c.958C>A and c.1019G>A polymorphisms among gene polymorphisms studied was associated with the risk of non-response of HT. The GG genotype of Dkk1 c.318A>G polymorphism showed a 2.38-times higher risk of non-response at the lumbar spine and/or femoral neck, as compared with the AA genotype. Among major haplotype genotypes composed of sFRP4 c.958C>A and c.1019G>A polymorphisms, the AA/AG haplotype genotype showed a negative percent changes in BMD at the femoral neck after 1 year of HT. The AG/CG haplotype genotype showed a 2.4 times higher risk of non-response at the lumbar spine and/or femoral neck, compared with the AA/AG haplotype genotype.

Conclusions: The Dkk1 c.318 A>G genotype and haplotype genotype of sFRP4 c.958C>A, and c.1019G>A polymorphisms may be associated with risk of non-response to HT in postmenopausal Korean women.

Combined Effect of Calcitonin with Risedronate for Osteoporotic Patients with Chronic Back Pain. Michio Hongo^{*1}, Naohisa Miyakoshi², Yuji Kasukawa², Yoshinori Ishikawa³, Yoichi Shimada³. ¹Akita University School of Medicine, Japan, ²Akita University Graduate School of Medicine, Japan, ³Akita University, Japan

Introduction: Calcitonin has been described to reduce acute back pain following vertebral fractures. However, the effect of calcitonin for the osteoporotic patients with chronic back pain is still unclear. The purpose of this study was to evaluate the combined effect of calcitonin with risedronate for osteoporotic patients with chronic back pain. **Methods:** Thirty-seven women with chronic back pain diagnosed as postmenopausal osteoporosis by dual energy absorptiometry of lumbar spine and femoral neck were included in this study, after excluding women with fresh vertebral fractures or severe acute back pain within the last 6 months. The average age was 69 years. Patients were randomly allocated to risedronate group (risedronate alone, n=19) and combined group (risedronate and calcitonin, n=18). Risedronate (17.5 mg) was administered once per week for both groups, and calcitonin (20 unit) was injected for the combined group. Visual analogue scale (VAS) and back extensor strength was assessed at baseline, 1, 3, and 6 months follow up. Bone mineral density, number of fracture by plain lateral radiography, Roland-Morris questionnaire, Short-form-36 (SF-36), and Japanese osteoporosis quality of life score (JOQOL) were evaluated at baseline and 6-months. **Results:** VAS at final follow-up significantly decreased in the combined group compared with baseline (p=0.0008), 1 month (p=0.008), and 3 months (p=0.004). No change was found for VAS in the risedronate group. There was no change for RDQ score in both groups. There were significant improvement in the SF-36 scores for mental health status (p=0.013) and the JOQOL domains for back pain (p=0.04) and general health (p=0.01) in the combined group. Back extensor strength significantly increased in both groups. **Conclusion:** Calcitonin was reported to reduce acute back pain within one month. In contrast, chronic back pain evaluated with visual analogue scale significantly reduced after administration of calcitonin for three months. Risedronate itself has been shown to relief pain, although current results failed to detect the analgesic effect of risedronate alone. The current study suggests that the use of calcitonin combined with risedronate more than three months seems effective for reducing chronic back pain.

First Experiences with Denosumab in Patients with Painful Disabling Transient Regional Osteoporosis (TRO) of the Hip. Johann D. Ringe^{*}, Parvis Farahmand. Medizinische Klinik 4 (Rheumatology, Osteology) & West German Osteoporosis Center (WOC), Klinikum Leverkusen, University of Cologne, Germany

Introduction: Transient Regional Osteoporosis (TRO; Bone Marrow Edema Syndrome) is an increasingly diagnosed condition characterized by an acute onset of disabling bone pain, which typically occurs at the hips or other localisations of the lower extremities. The subcutaneous injection of Denosumab, a fully human monoclonal antibody to RANKL, is followed by an immediate steep decrease of bone turnover markers, i.e. a rapid and strong decrease of osteoclastic bone resorption. We therefore became interested in studying the efficacy of this new antiresorptive drug in cases with TRO at the hip.

Methods: We enrolled 3 patients with TRO of the hip for this 3-month, open label, case study to investigate the therapeutic efficacy of one subcutaneous injection of 60 mg Denosumab. Additionally all patients received a daily supplementation of 1200 mg calcium and 800 IU vitamin D. Diagnosis of the two men and one woman (mean age 38 years) was based on the typical history of acute pain in one hip, negative findings in x-ray and CT-imaging and finally MRI-finding of bone marrow edema in the affected area. Local pain at the affected hip was measured at onset, after 2 weeks, 1 month, and 3 months, respectively, by a visual analogue scale (VAS 1-10). Walking disability and impairment in quality of life were documented during follow-up. BMD at the lumbar spine and both femoral neck areas was measured at baseline and month 3.

Results: There was a rapid pain reduction from an initial average VAS-score of 9.0 to 3.0, 1.7, and 1.0 at 2 weeks, 1, and 3 months, respectively. The average mobility score (0-3) improved from 2.7 at onset to 0.3 at month 3. DXA measurement had revealed a systemic osteopenia before intervention (average lumbar spine T-Score -2.0) and lower values at the affected hip vs. the unaffected side (average T-Score values -1.7 vs. -0.9). After three months mean increases of +2.3% at the lumbar spine, +7.9% at the affected hip and +0.8 at the unaffected hip were documented. MRI controls at month 3 showed in all cases a significant amelioration. There were no AEs, quality of life increased significantly.

Conclusion: We found that a first injection of Denosumab in patients with TRO of the hip leads to rapid pain relief, improvement of mobility and regression of bone marrow edema. After only 3 months there were highly significant increases in BMD at the involved hip together with a moderate improvement of systemic osteopenia.

MO0446

Good Vibrations: A Short Term Pilot Study of Low Magnitude Vibration Therapy in Patients with Thalassemia. Catherine Garipey^{*1}, Dru Haines, PNP¹, Ashutosh Lal, MD¹, Ellen Fung². ¹Children's Hospital & Research Center Oakland, USA, ²Children's Hospital & Research Center, Oakland, USA

Approximately 70% of adults with thalassemia (Thal) have low bone mass which can lead to fracture and decreased quality of life. The most effective way to treat low bone mass is through prevention, by building strong, dense bones in childhood. Weight bearing physical activity strengthens bone by increasing mineralization as well as bone size. However, adherence to regular exercise can be difficult for patients with Thal due to low hemoglobin and energy levels or pre-existing cardiomyopathies. Recent advances in the field have shown that low magnitude mechanical stimulation or "vibration therapy", can also strengthen bone. This simple therapy can be conducted in the home without increasing cardiac stress.

A pilot and feasibility trial was conducted to evaluate "vibration therapy" as an anabolic stimulus to bone in 20 patients with Thal (11 Male, 22.1 10.7, range 9-45 yrs). Subjects were asked to stand on the vibrating platform (30 Hz, 0.3g) for 20 min/day, 6 days per week for 6 months. We measured bone parameters by DXA, pQCT and serum markers of bone turnover at baseline, 6 and 12 months post intervention. 13 subjects have completed the protocol to date. Baseline spine and hip Z-scores are -2.41 and -1.708 respectively. Baseline 25OH vitamin D was 2911 ng/mL. As hypothesized, adherence to the intervention is better in the first 3 months (7231%) compared to the second 3 months (5034%, p=0.019). Average length of time on the platform also decreased from 13 to 9 min/day (p=0.003). Two subjects dropped, one adult due to back pain after 1 month and one adolescent due to dizziness after 3 weeks. Thus far, the adult participants are more likely to be adherent to the protocol. Using intention to treat analysis, no differences in aBMD were observed at any site. However, for the most adherent adult participants (>75%), a significant increase in whole body BMC was observed (p=0.02) and a trend towards an increase in hip aBMD (p=0.08). Results for bone markers are pending.

These preliminary findings suggest that vibration therapy may be an effective intervention in subjects with Thal. Similar to previous studies, the intervention was most effective at increasing BMD in those who were adherent to the protocol. Future research should expand upon this study with a larger sample size and include ways to improve adherence in patients burdened by chronic medical conditions.

Lycopene Does Not Alter Bone Turnover In a Healthy Population of Men and Women - An Intervention Study. Claire Macdonald^{*1}, David Reid¹, Frank Thies¹, Helen Macdonald². ¹University of Aberdeen, United Kingdom, ²University of Aberdeen Bone & Musculoskeletal Research Programme, United Kingdom

Lycopene, mainly originating from tomatoes, has been associated with lower incidence of osteoporosis and high dietary lycopene intake has been reported to be protective against fracture risk in cross sectional and longitudinal studies. A pilot intervention study showed that high serum lycopene was associated with decreased bone resorption in a population of postmenopausal women. The aim of this investigation was to determine the effects of lycopene intake on percentage change of bone turnover markers amino-terminal procollagen propeptides of type 1 collagen (PINP) and C-terminal telopeptide of type 1 collagen (CTX).

A randomized controlled trial (RCT) was conducted in a healthy population of men and women (N=239) aged 29-69y (mean age [SD] 51.1 [6.8] years). Participants were randomly assigned to 3 groups: 1. high lycopene/tomato diet (minimum 10mg/day), 2. 10mg lycopene supplement and 3. low lycopene/tomato diet. The serum bone formation marker PINP and plasma bone resorption marker bone CTx were measured at baseline (week 4) and at 12 weeks for each of the participants.

Two hundred and twenty seven participants completed the final visit (95%). Serum and plasma was available for 221 participants. One extreme outlier was removed leaving 76 in group 1, 66 in group 2, and 78 in group 3, for analysis.

One-way ANOVA showed no significant difference in percent change in bone turnover between groups (mean [SD]): plasma CTx: +7.7% [27.2%], +6.8% [23.9%] and +5.4% [26.4%] and serum PINP: -1.0% [24.3%], +4.26% [22.0%] and +2.8% [15.4%] in groups 1, 2 and 3 respectively.

These data suggest that an eight-week lycopene supplementation or a diet high in lycopene does not alter bone turnover in a healthy population of men and women. Future research is required to determine whether lycopene effects bone turnover longer term or attenuates bone resorption in groups at high risk of osteoporosis.

Oxidative Stress and the Risk of Osteoporosis: the Role of Dietary Polyphenols and Nutritional Supplements in Postmenopausal Women.

Nancy Kang^{*1}, Venketeshwer Rao², Katrine De Asis², Loren Chan³, Leticia Rao¹. ¹University of Toronto, St. Michael's Hospital, Canada, ²University of Toronto, Canada, ³St. Michael's Hospital, Canada

Purpose: Oxidative stress has been shown to be associated with the development of osteoporosis, and antioxidants can be beneficial in counteracting this damaging effect. There is a renewed interest in the use of nutritional supplements which are rich in antioxidants as alternative or complimentary strategies for the prevention and management of osteoporosis because of the reported undesirable side effects of Hormone Replacement Therapy (HRT) and other approved drugs. Nutritional supplements such as greens+TM, a blend of several botanical products, has recently been shown to contain a number of water-soluble antioxidant polyphenols. Another nutritional supplement, greens+bone-builderTM, contains the same formulation as greens+TM, but includes additional antioxidants, vitamins, minerals, trace minerals, and amino acids, all of which have been individually shown to be beneficial to bone. Our laboratory showed that in vitro, greens + and greens+bone-builderTM stimulated bone formation by human osteoblasts. Based on these results, the purpose of our study was to initiate clinical studies to test our hypothesis that greens+bone builder may be effective in reducing oxidative stress, thus potentially reducing the risk of osteoporosis in postmenopausal women.

Methods: Sixty postmenopausal women, 50-60 years old, were recruited for a ten-week clinical trial with the following study design: Week 1, participants recorded their baseline food intake; Week two ('washout' period), they refrained from consuming polyphenol-rich foods and supplements and Weeks 3 to 10, they were randomized to either greens+ bone builderTM (N = 30) or placebo (N = 30), during which they took to take 1 scoop (equivalent of ¼ cup) of their assigned treatment daily. Blood samples collected at week 1, 2, 6, and 10 of supplementation were processed and serum samples assayed for total antioxidant capacity (TAC), lipid, and protein oxidation.

Results: Statistical analysis using two-way ANOVA and t-test showed that greens +bone-builderTM significantly increased total antioxidant capacity (p<0.05) compared to placebo after 10 weeks of treatment. There were no significant differences in lipid and protein oxidation between the placebo and supplemented groups.

Conclusion: Our findings suggest that the daily supplementation of greens+bone-builderTM may be important in reducing the risk of osteoporosis through its antioxidant potential.

The Impact of Vitamin K Therapy on Bone Metabolic Markers in Severe Motor and Intellectual Disabilities.

Akiko Kuwabara^{*1}, Akiko Nagae², Naoko Tsugawa³, Mari Kitagawa², Kunihiro Tozawa⁴, Hiroaki Kohno⁵, Masakazu Miura⁶, Toshio Okano³, Masao Kumode², Kiyoshi Tanaka⁷. ¹Osaka Shoin Women's University, Japan, ²Biwako Gakuen Kusatsu Medical & Welfare Center, Japan, ³Kobe Pharmaceutical University, Japan, ⁴EIDIA Co. Ltd., Japan, ⁵Orthopaedics, Japan, ⁶Hokuriku University, Japan, ⁷Kyoto Women's University, Japan

Purpose: Based on our recent finding that vitamin K was deficient both in the liver and bone in subjects with severe motor and intellectual disabilities (SMID) (ASBMR 32nd Annual Meeting), vitamin K therapy to these subjects was studied. Previous studies on vitamin K therapy in subjects with SMID have been scarce, and had limited scope. For example, vitamin K₂ was the only analog employed, and biomarkers reflecting vitamin K status were seldom studied. Then we have aimed to study the effects of vitamin K therapy on biomarkers for vitamin K insufficiency; protein induced by vitamin K absence (PIVKA-II), undercarboxylated osteocalcin (ucOC), and ucOC/OC ratio. PIVKA-II and ucOC are indices for hepatic and skeletal vitamin K insufficiency, respectively. The alteration of bone turnover markers was also studied.

Methods: Forty-one subjects with SMID were assigned to two study groups by their nutritional feeding routes. K₁ group consisted of 24 subjects under enteral feeding. Vitamin K₁ was added in enteral nutrition as a form of RacoTM, ranging from 55 to 219 µg/day (Median; 175 µg/day), with its dose being determined to meet each subject's energy requirement. K₂ group consisted of 17 subjects with oral feeding. They were treated by 15 mg/day of menaquinone-7 (GlakayTM). Study duration was for 3 months. Biomarkers of vitamin K insufficiency and bone turnover markers were measured at baseline and 1-, 3-month after the start of therapy.

Results: Median vitamin K intake in K₂ group was 115.0 µg/day. In K₁ group, it was 66.5 µg/day at baseline and 193.6 µg/day after intervention. At baseline, serum PIVKA-II, ucOC and ucOC/OC ratio were significantly higher in K₁ group than in K₂ group. After 3 months treatment, while K₂ therapy significantly decreased all biomarkers of vitamin K insufficiency, only serum concentrations of PIVKA-II and ucOC/OC ratio significantly decreased in K₁. Serum BAP significantly increased in both therapies. Serum TRACP-5b responded differently to each therapy; significant increase in K₁ therapy, and significant decrease in K₂. Logistic regression analyses revealed that K₂ therapy was a significant factor for changing bone turnover markers beyond minimal significant changes.

Conclusions: The ucOC/OC ratio sensitively responded to K₁ therapy. All biomarkers were sensitive to K₂ therapy. K₂ therapy was more potent than K₁ in changing bone turnover markers such as BAP and TRACP-5b even when adjusted for baseline level of each marker.

The Potential Effect of Calcitonin in Osteoporotic Patients with Diabetic Peripheral Neuropathy.

Shen Qu^{*1}, Ran Cui², Xiaoyun Cheng³, Peng Yang⁴, Hui Sheng⁵. ¹Tongji University School of Medicine, Peoples Republic of China, ²Tenth People's Hospital of Tongji University, Peoples Republic of China, ³Department of Endocrinology, China, , ⁵Shanghai, Fudan University, Peoples Republic of China

To investigate the effect of calcitonin on osteoporotic patients with painful diabetic neuropathy. Numerous studies report that diabetes is a risk factor for osteoporosis. Osteoporotic patients complicated with diabetes need concurrent treatment of osteoporosis and diabetes. The bone promotion effect and analgesic effect of calcitonin for osteoporotic patients are well known, but this study examines not only the effectiveness of calcitonin for osteoporosis treatment, but also for diabetic neuropathy treatment.

Thirty-nine patients with type 2 diabetes and diabetic neuropathy were recruited for this study. Basic treatment for these patients was comprised of hypoglycemic agents, antihypertensive drugs, and antilepileptic agents. The patients were randomly divided into two groups. Group 1 (G1) patients were given calcitonin injection (20 units, twice weekly) while Group 2 (G2) patients acted as the control. Pain was assessed before start of treatment and then at 2, 4, 8, and 12 weeks of treatment using a visual analogue scale (VAS) and the Wong-Baker Face Scale (FS) method. The patients' subjective assessment of treatment was recorded as "not effective," "effective," or "very effective." Repeated-measures data analysis and a nonparametric test were used to analyze the VAS, FS, and the subjective treatment assessment scores.

Both VAS and FS scores showed that pain was significantly alleviated in G1 (P=0.014 and P=0.014, respectively). With time, the discrepancy between G1 and G2 was more remarkable (P=0.000 and P=0.000, respectively). Patients' subjective assessment of treatment in G1 was not significant at 2 weeks (P=0.760), but it was significant at 4 weeks (P=0.004), 8 weeks (P=0.000), and 12 weeks (P=0.007), which is consistent with the VAS and FS scores.

Calcitonin significantly alleviated pain in osteoporotic patients with painful diabetic neuropathy.

MO0451

A Novel Technique for Cement Augmentation of Pedicle Screws Reduces Cement Leakage Rates. A Prospective, Controlled, Clinical Trial in Osteoporotic Bone.

Thomas Blatter^{*}. Orthopaedische Fachklinik Schwarzbach, Deu

Introduction

Cement augmentation techniques have been developed to increase purchase of pedicle screws in osteoporotic bone. Different augmentation techniques are being used based on screw types and surgical methods. For solid screws, vertebral bodies can be pre-filled with cement in a vertebroplasty technique before screws are inserted. In a modification, pre-tapped voids can be filled with cement before screw insertion. As an alternative, fenestrated screws have been developed for in situ injection of cement through the screw itself. Extravertebral, epidural, and endovascular leakage of cement, however, remains a problem in either technique. To reduce leakage rates, a novel augmentation technique was developed.

Methods

Inclusion criteria: fracture type A3 or higher; t-score ? 2.5. **Exclusion criteria:** non-traumatic fractures. Fenestrated screws measuring 6.5mm in diameter were used (CD Horizon Legacy FNS, Medtronic). In the trial group (TG), screw beds were pre-tapped. The tap used has a regular diameter of 5.5mm and can be expanded to 8.0mm after pedicle passage. For the vertebral body, this results in an overtapping of 1.5mm for the screw bed in comparison to the screw itself. After screw insertion, cement augmentation with 1.5cc of PMMA (KyphXHV-RTM, Medtronic) was performed. Leakage rates were evaluated with post op CT scans. In the control group (CG), the screw bed was probed, but not tapped. FU time was 24 months.

Results

In TG, 20 patients with 96 augmented pedicle screws were included. Leakage rate was 8/96 (8.3%). CG consisted of 52 patients with 208 screws. Leakage rate was 41/208 (19.7%). This difference is statistically significant (p<0.005). At 2 years FU, 17/18 patients in TG showed no signs of implant loosening. 1/18 patient suffered from secondary loss of correction with screw cut out. For CG, there were 2/47 cases with implant loosening (p>0.05).

Conclusion

Use of the novel technique described here results in a significant reduction of cement leakage rates if compared to the control group. We found no difference,

however, for the rate of secondary implant loosening. Obviously, the cement leaving the screw is being distributed reliably within the void created around the screw shaft, rather than being directed into unwanted regions of less resistance. On the other hand, implant purchase is not being compromised by this technique.

MO0452

Methods to Simplify Recruiting for Pragmatic Clinical Trials (PCTs) in Osteoporosis in the Community: iPad vs. Interactive Voice Response (IVRS) Systems. Amy Mudano^{*1}, Lisa Gary¹, Mary Melton¹, Amy Warriner², T. Michael Harrington¹, Meredith Kilgore³, Penelope Jester¹, Nicole Wright¹, Jeffrey Curtis¹, Cora Lewis¹, Elizabeth Delzell¹, Kenneth Saag¹. ¹University of Alabama At Birmingham, USA, ²UAB, USA, ³University of Alabama At Birmingham School of Public Health, USA

Purpose: Osteoporosis PCTs require large numbers of patients and efficient enrollment strategies are needed to conduct such trials in busy physician practices. To facilitate simplified subject recruitment, we developed two screening and enrollment tools using 1) an iPad tablet computer with internet access and 2) an IVRS telephone system accessed via cell phone, and we evaluated patient and physician preference for these tools.

Methods: We recruited community physician offices through the local Practice-Based Research Network. A series of 8 screening questions were developed to determine initial eligibility for a mock PCT of osteoporosis therapeutics. Offices were given 5 days to use the iPad and IVRS technologies for identifying potential study participants. Office staff offered all women age 65 years and older study participation and randomly assigned them to either the iPad or IVRS. Each patient completed the screening questions and a brief survey on preferences for the technologies using a 5-point Likert scale from "strongly agree" to "strongly disagree". Follow-up debriefings were conducted with the office staff to determine the effects of iPad vs. IVRS recruitment on office workflow.

Results:

The iPad and IVRS technology was tested in 7 physician offices. A total of 113 patients (82% of the 138 eligible) participated. All 60 women randomized to the iPad completed the screening questions. Of 53 women randomized to IVRS, only 40 completed all screening questions. The women who tested the iPad were slightly older (average age 75.5 + 7.4) compared to the women who tested the IVRS (average age 73.0 + 6.6) ($p=0.07$). Compared to IVRS, patients who tested the iPad technology found it easier to use and understand and less time-consuming. They were more likely to agree to participate in an osteoporosis clinical trial and would spend extra time in their physician's office to enroll. Office staff reported that recruitment of patients using these technologies was not burdensome and did not interrupt clinic flow. Approximately 30% of patients screened would be potentially eligible to participate in an osteoporosis PCT based on the inclusion criteria.

Conclusion:

Compared to the IVRS phone system, patients preferred use of the iPad technology to complete a short screening survey to determine initial eligibility for an osteoporosis PCT. This process did not put an undue burden on the physician practice and generated a sizable yield of potential study participants.

Disclosures: Amy Mudano, None.

MO0453

How Can We Improve Bone Health in the Long-term Care Setting? Lessons from the ViDOS study. Courtney Kennedy^{*1}, Alexandra Papaioannou², George Ioannidis¹, Lora Giangregorio³, Sharon Marr¹, Suzanne Morin⁴, Lehana Thabane¹, Robert Josse⁵, Richard Crilly⁶, Laura Pickard¹, Susanne King¹, Mary-Lou van der Horst¹, Ruth McCallum¹, Glenda Campbell⁷, Jackie Stroud⁷, Lisa Dolovich¹, Anna Sawka⁸, Lynne Lohfeld¹, Jonathan Adachi⁹. ¹McMaster University, Canada, ²Hamilton Health Sciences, Canada, ³University of Waterloo, Canada, ⁴McGill University Health Centre, Canada, ⁵St. Michael's Hospital, University of Toronto, Canada, ⁶University of Western Ontario, Canada, ⁷Medical Pharmacies Group Limited, Canada, ⁸Toronto General Hospital, Canada, ⁹St. Joseph's Hospital, Canada

The ViDOS study is a Knowledge Translation (KT) Randomized Controlled Trial currently underway in 40 Long-term Care (LTC) homes ($n=20$ intervention, $n=20$ control) across Ontario, Canada. The aim is to implement and evaluate a multi-faceted KT intervention, targeted at interprofessional teams, to increase the uptake of osteoporosis (OP) best practices in the LTC setting using a quality improvement process. Outcomes include prescribing of vitamin D (primary), calcium and pharmacologic therapies; falls and fractures; and organizational-level process/policy changes. The intervention homes take part in three problem based sessions led by an Expert Opinion Leader conducted approximately 6-months apart. The target audience is the Professional Advisory Committee (PAC), an existent committee who meets

quarterly and includes the medical director, director of care, administrator, pharmacist, dietician, and other rehabilitation, nursing, and physician representatives. "Action Planning" for quality improvement is a key component of our multi-faceted study. PAC teams discuss and complete a work-sheet at each session to address barriers and facilitators and identify strategies for improving bone health including specific action items for team members. Ideas generated from initial sessions were used to help guide discussion in subsequent sessions. Currently, 8 intervention homes have completed the action planning process. Common barriers identified include: limited medical history on OP/fractures; lack of assessment of height annually; OP diagnoses often not recorded in electronic system; OP/fractures (and related prescribing) not a specific focus in care plans, falls programs, quarterly reviews; standard admission process does not assess need for vitamin D and pharmacologic therapies; incorrect dispensing of bisphosphonates; cost of vitamin D; lack of information/resources prior to the ViDOS study. PAC teams proposed and/or implemented several strategies for bone health including: incorporating OP/fracture history on admission processes and quarterly reviews; standard admission orders for vitamin D and OP therapies; dietitian review of calcium intakes; quarterly pharmacist review including point of care tools; education of resident/family councils (e.g. DVD on bone health protection). The ViDOS intervention has provided a forum for interprofessional teams to better coordinate efforts and to develop action-oriented policies and procedures that support bone health.

Disclosures: Courtney Kennedy, None.

MO0454

Serum 25-hydroxyvitamin D in Rural and Urban Postmenopausal Women. Irina Haller^{*1}, Diane Krueger², Jean A Engelke², Neil Binkley³. ¹Essentia Institute of Rural Health, USA, ²University of Wisconsin, Madison, USA, ³University of Wisconsin, USA

Vitamin D status in rural, urban and American Indian (AI) postmenopausal women was compared using data from two phases of a randomized control trial of vitamin D fortified food: an ongoing study focusing on the effect of ethnicity and an earlier phase focused on the effect of age. To date, 41 white and 34 AI women from rural communities in the upper Midwest have been screened for study participation. Eligible women were randomly assigned in 1:1 ratio within each ethnicity cohort to receive a low calorie chocolate disk fortified with 2,500 IU of vitamin D₃ or placebo daily for 4 months. Study activities in the AI cohort are ongoing. Thirty-two rural white women finished the study in January 2011. Additional data included screening results from 34 comparably aged white urban women who completed study by August 2009. AI women were slightly younger than rural and urban women with mean (SE) age of 57.4 (1.1), 62.3 (1.1) and 60.6 (0.6) years, respectively. There were no differences in albumin, creatinine, ALT, or PO₄ between the three groups. Serum calcium was higher ($p<0.01$) in the urban [9.6(0.1) mg/dL] than rural [9.3 (0.1) mg/dL] or AI group [9.3 (0.1) mg/dL]. Mean screening serum 25(OH)D in the AI group [25.3 (1.8) ng/mL] was lower ($p<0.01$) than in rural [34.5 (1.9) ng/mL] or urban group [34.2 (2.2) ng/mL]. Moreover, 37% of rural, 44% of urban and 65% of AI women had low vitamin D status (defined as a 25 (OH)D concentration < 30 ng/mL). Applying a 20 ng/mL cut point, 7% of rural, 12% of urban, and 38% of AI women would be classified as low. On average, among rural white women 25(OH)D increased from 31.2 (1.7) to 48.4 (2.9) ng/mL in the vitamin D group over the 4 months of study, while 25(OH)D was unchanged in the placebo group. There were no changes in serum calcium and urine calcium/creatinine ratio with 4 months of vitamin D supplementation. These preliminary data support previously reported outcomes on safety and efficacy of food fortified with higher dose of vitamin D. Results regarding the effects of ethnicity and rural/urban location on response to vitamin D supplementation by food will be available upon completion of the study in the AI cohort in August 2011. Consistent with our pilot data, AI women had lower vitamin D status compared to white women from rural and urban settings. Further examination of the underlying causes for these differences is warranted.

Disclosures: Irina Haller, None.

MO0455

Solitary Calcium Supplementation in Alendronate Treated Postmenopausal Women with Low Bone Mass Does Not Prevent Secondary Hyperparathyroidism Sufficiently. Oliver Bock^{*1}, Hendrikje Borst¹, Heinz-Jürgen Roth², Martin Runge³, Ze'ev Mazor⁴, Erich Schacht⁵, Peter Martus⁶, Dieter Felsenberg¹. ¹Charité - Campus Benjamin Franklin, Centre for Muscle & Bone Research, Germany, ²Labor Dr. Limbach und Kollegen, Medizinisches Versorgungszentrum, Germany, ³Aerph Kliniken Esslingen-Kennenburg, Germany, ⁴Teva Pharmaceuticals Industries Global Products Division, Israel, ⁵Pharma Consulting, Switzerland, ⁶Charité - Campus Benjamin Franklin, Institute for Biometrics & Clinical Epidemiology, Germany

Objectives: To examine the effect of solitary calcium supplementation on the risk of developing secondary hyperparathyroidism (sHPT) in postmenopausal, alendronate treated women with reduced bone mass and increased risk to fall.

Patients and Methods: This is a post-hoc analysis from the ALFA study, including a total of 279 postmenopausal women (mean age 73.74.7 years), randomized 1:1 into a

placebo-controlled, double-blind study of 3 years (ALFA study) with two treatment arms: daily oral alfacalcidol 1µg or placebo. All patients received alendronate 70mg once weekly and calcium 500mg daily. Biochemical markers of bone turnover, iPTH, 25OH-vitamin D, 1,25(OH)₂-vitamin D and calcium were measured semi-annually (during the first year) and annually (during years 2 and 3).

Results: None of the patients had elevated PTH serum levels before randomization (in accordance with the exclusion criteria of the study). 199 patients completed the study, 193 had all laboratory measurements available at the end of the study. Out of these patients, 36.8% (35/95) of the completers in the control group, but only 6.1% (6/98) in the verum group showed PTH serum levels above 65 ng/l ($p < 0.05$). Serum levels of calcium, 25OH-vitamin D and 1,25(OH)₂-vitamin D did not differ significantly between patients with or without hyperparathyroidism in the control group. Serum calcium levels were, in general, relatively low in both treatment arms with a mean of 2.30(0.09) and 2.32(0.10) mmol/l, respectively. 91.4% (32/35) of cases with elevated PTH in the alendronate/calcium group showed a typical biochemical pattern for sHPT. Contrariwise, three other patients with elevated PTH in this group showed slightly increased serum calcium (2.53, 2.59 and 2.66 mmol/l). This might be considered as an evidence for mild primary hyperparathyroidism as a possible result of autonomous PTH secretion by hyperplastic parathyroid glands in original sHPT.

Conclusions: The results from this post-hoc analysis showed sHPT in a considerable proportion of more than one third in alendronate treated patients who got additional calcium supplementation only. The additional use of alfacalcidol 1 µg daily in the verum arm of this study, however, minimized significantly the risk for sHPT in alendronate/calcium treated patients.

MO0456

The Relationship Between Serum Vitamin D Levels and Bone Histomorphometry In Elderly Patients with Hip Fracture. Abbas Ismail^{*1}, Anthony Freemont², Nicky Makepeace¹, Stockport Bone Group¹. ¹Stockport NHS Trust, United Kingdom, ²University of Manchester, United Kingdom

Background

Vitamin D deficiency is common in elderly people, studies suggesting up to 65% of patients with hip fracture have severe vitamin D deficiency (1). However, routine bone biochemistry is frequently normal despite low or even undetectable serum Vitamin D levels (2). The clinical significance of low serum Vitamin D levels therefore remains uncertain.

Aims

To assess the relationship between serum vitamin D concentration and bone biochemistry with static bone histomorphometry parameters in elderly patients with hip fracture.

Methods

Hip fracture patients were identified prospectively from the Orthopaedic wards in Stockport, UK between July 2009 and July 2010. After obtaining consent, blood samples were taken for serum vitamin D and bone biochemistry prior to surgery. Parathyroid hormone levels were not measured. Serum 25-hydroxy vitamin D levels were measured by mass spectrometry. At the time of surgery for the hip fracture the operating orthopaedic surgeon retained either the femoral head in the case of subcapital fracture or took a small bone biopsy in the case of trochanteric hip fracture. The bone samples underwent histomorphometric analysis at the University of Manchester. Dynamic histomorphometry was not possible because of the clinical setting in which the bone samples were obtained.

Results

18 hip fracture patients were included in the analysis, 12 female and 6 male, mean age 84.2 years (range 70-92 years). There were 15 subcapital fractures and 3 trochanteric hip fractures. 15 patients had low serum Vit D levels of less than 20ng/mL and 5 patients had very low levels of less than 12ng/mL (normal level > 30ng/mL). In all 18 patients, bone histomorphometry showed evidence of osteoporosis with the mean age and sex adjusted Z score for trabecular bone volume being -2.8 and mean Z score compared to peak bone mass being -5.6. However, there was no evidence of mineralization defect or osteomalacia in any of the bone samples. Serum calcium and alkaline phosphatase levels were within normal limits.

Conclusion

In this preliminary study of elderly hip fracture patients, low or very low serum vitamin D levels were not associated with either biochemical nor histological evidence of osteomalacia although osteoporosis was universal. However, treatment with vitamin D may still be of benefit to help reduce falls by improving muscle strength.

MO0457

Effects of Adenosine Triphosphate (ATP) on Bone and Fat Metabolism. Solveig Petersen^{*}, Susanne Syberg, Peter Schwarz, Niklas Jorgensen. Copenhagen University Hospital Glostrup, Denmark

Adenosine triphosphate (ATP) is a molecule of life. Inside the cell it provides energy and participates in other essential processes while outside of the cell it acts as a short-range signal between cells. Extracellular ATP signalling, also known as purinergic signalling, includes a range of P2 receptors, that are important in the regulation of bone turnover, but ATP might also be implicated in fat/energy metabolism. The aim of this study was therefore to investigate the in vivo effects of ATP treatment on bone and fat metabolism in mice.

Female mice were ovariectomized (OVX) or sham operated (SHAM) at the age of 16 weeks. Twelve mice were randomly allocated to each treatment group after 4 weeks. Vehicle (VEH), 40 mg/kg PTH (PTH), 33 mg/kg ATP (ATP) or a combination of ATP and PTH (ATP/PTH) were administered twice daily for 28 days. After sacrifice, bone mineral density (BMD) and body composition (fat % and % lean mass) were assessed on a PIXImus DXA scanner. Serum and bones were collected for analysis of bone markers and fat/energy metabolism including blood glucose (BG).

BMD levels decreased upon OVX from (meanSEM) 0.0505 (0.0008) g/cm² to 0.0485 (0.0010) g/cm². By treating OVX mice with ATP alone BMD was only slightly changed to 0.0480(0.0008) g/cm². PTH alone significantly increased the BMD to 0.0519(0.0012) g/cm². As expected, body weight of the animals increased upon OVX in all treatment groups, but no differences were detected between VEH and the different treatments. More interestingly, fat percent was significantly different between groups ($p < 0.01$). OVX increased fat % (VEH: 17.80.4% vs. SHAM: 15.70.4%), while ATP treatment prevented the OVX-induced increase either or in combination with PTH (ATP: 16.60.5%; ATP/PTH: 15.80.5%). PTH alone did not alter fat %. However, when looking at BG, major differences between groups were detected ($p < 0.001$). Firstly, OVX did not change BG compared to SHAM (VEH: 3.50.1 mM vs. SHAM: 3.60.2 mM), and neither did PTH treatment (PTH: 3.90.2 mM). In contrast, ATP administered alone (ATP: 7.60.5 mM) or in combination with PTH (ATP/PTH: 7.20.5 mM) significantly increased BG levels in the animals.

In conclusion, OVX induced increased body weight and fat % and reduced BMD in the animals. Furthermore, treatment with the nucleotide ATP, induced profound changes in BG and counteracted the OVX-induced increase in fat %. Thus, ATP might therefore act diabetogenic. The exact mechanism is still undetermined.

Enhanced Peri-Implant Bone Formation and Fixation by Sclerostin Antibody in a Rat Ovariectomy Model. Amarjit Viridi^{*1}, Kotaro Sena¹, Min Liu², Hua Zhu Ke³, D. Rick Sumner¹. ¹Rush University Medical Center, USA, ²Amgen, USA, ³Amgen, Inc., USA

Effective fixation of orthopedic implants is dependent on the quantity and quality of de novo peri-implant bone formation. This becomes an issue when the host bone stock at the site is depleted as seen in osteoporosis. Sclerostin is a negative regulator of bone formation and treatment of intact and ovariectomized rats with a sclerostin-neutralizing monoclonal antibody has shown marked increase in bone formation. This study sought to determine if sclerostin antibody (Scl-AbIII) treatment enhances peri-implant bone formation and fixation in an ovariectomy rat model (ovx).

Ovx or sham-ovx surgery was performed on 4.5-mo old rats. After 6.5 months, titanium implants were placed bilaterally in the distal femurs. Animals receiving no implants were used as baseline control to reveal bone loss due to ovx. The rats with implants were randomly assigned to receive sclerostin antibody treatment (Scl AbIII [Amgen Inc. and UCB Inc.]; 25mg/kg; twice weekly; subQ) or saline as control. After 4, 8, or 12 weeks (n=12 each), bone surrounding the implant was assessed by micro computed tomography (µCT) while mechanical pull-out testing revealed strength of fixation, stiffness and energy to failure.

µCT confirmed severe osteopenia in ovx with lower BV/TV (-77%), Tb.N (-69%) and Tb.Th (-16%), and higher Tb.Sp (258%, all $p < 0.001$). Scl-AbIII treatment in the sham-ovx group led to increased BV/TV (50 to 106%) and Tb.Th (44 to 131%) at all time points ($p < 0.001$), decreased Tb.Sp (-16 to -26%) at 4 and 8 weeks ($p < 0.05$), but no change in Tb.N. Strength of fixation and energy to failure were increased at 8 (33%) and 12 weeks (97%, $p < 0.01$) and stiffness was increased at 4 weeks (87%, $p < 0.05$). Scl AbIII treatment in the ovx group elevated BV/TV (97 to 177%) and Tb.Th (46% to 74%) at 4 and 12 weeks ($p < 0.05$) as well as strength of fixation (100%) at 12 weeks ($p < 0.05$), stiffness (126%) at 4 weeks ($p < 0.05$) and energy to failure at 8 and 12 weeks (143 to 215%, $p < 0.05$). In general, positive benefits of Scl AbIII treatment in the ovx were delayed compared to the sham-ovx presumably because of the severity of ovx-induced osteopenia. More specifically, the trabecular architecture and mechanical fixation values following Scl AbIII treatment for 12 weeks in the ovx rats were similar in magnitude to those of the 4 week sham-ovx rats. The findings of this study support the utility of inhibiting sclerostin to achieve improved implant fixation in individuals with osteopenia.

Growth Hormone Partly Counteracts Immobilisation-induced Bone and Muscle Loss. Marie-Claire Grubbe¹, Jesper Thomsen², Annemarie Bruel^{1,2}.¹Aarhus University, Denmark, ²University of Aarhus, Denmark

Growth hormone (GH) increase bone mass by stimulating periosteal bone formation through activation of osteoblasts. Furthermore, GH has an anabolic effect on skeletal muscles. The aim of the study was to investigate whether treatment with GH could attenuate the loss of bone and muscle mass during immobilisation in a rat model.

Immobilisation was obtained by injecting 4 IU Botox (BTX) into the muscles of the right hind limb, thereby inducing a loss of bone and muscle. Sixty female Wistar rats, 3-months-old, were divided into the following groups: Baseline, control, BTX, BTX+GH, and control+GH (n=12 in each group). GH was given as s.c. injections at a dosage of 5 mg/kg/d divided into two daily doses. The experiment lasted for 4 weeks. The rectus femoris muscles were weighed and the mean muscle cell diameter was estimated using stereology. The BMC of the entire femora were determined with DEXA. The microstructure of the distal femoral metaphysis was analysed using μ CT. Fracture strength of the femoral mid-diaphysis, femoral neck, and distal femoral metaphysis was determined using a materials testing machine. Dynamic histomorphometry was performed on the femoral mid-diaphysis.

Compared to the controls, BTX reduced rectus femoris muscle mass by 67% ($P < 0.001$), mean muscle cell diameter by 73% ($P < 0.001$), total femoral BMC by 15% ($P < 0.001$), distal femoral metaphysis BV/TV by 24% ($P < 0.05$) and trabecular thickness by 15% ($P < 0.001$), periosteal bone formation rate by 71% ($P < 0.001$), and fracture strength of the femoral mid-diaphysis by 12% ($P < 0.01$), femoral neck by 17% ($P < 0.05$), and distal femoral metaphysis by 25% ($P < 0.01$). Compared to BTX, BTX+GH resulted in significantly higher rectus femoris muscle mass ($P < 0.001$), total femoral BMC ($P < 0.01$), and periosteal bone formation rate ($P < 0.01$). Furthermore, BTX+GH tended to have increased mean muscle cell diameter ($P < 0.065$). In contrast, no significant differences were found between BTX and BTX+GH in any of the microstructural measures at the distal femoral metaphysis. Likewise, the fracture strength at any of the tested sites did not differ between BTX and BTX+GH.

The BTX-induced loss in muscle mass, BMC, and bone formation rate was partly inhibited by treatment with GH. In contrast, treatment with GH did not influence the loss of mechanical strength, which may be due to the relative short treatment period.

Osteogenic Effects of Black Bear PTH (1-84) in a Mouse Model of Duchenne Muscular Dystrophy. Sarah Gray¹, Meghan McGee-Lawrence², Samantha Wojda¹, Seth Donahue³. ¹Michigan Technological University, USA, ²Mayo Clinic, USA, ³Michigan Technological University, USA

Duchenne muscular dystrophy (DMD) is a progressive X-linked disease affecting cardiac and skeletal muscle. By the age of 5, boys with DMD show diminished mobility, and are usually confined to a wheelchair by 12-15 years of age. Decreased mobility, which decreases mechanical stresses on bone, has a deleterious effect on the long bones of the lower limb. In boys with DMD, approximately 20% will experience a long bone fracture by the age of 16 compared to 2-4% in healthy boys. These fractures often result from falls from standing height or falls from a wheelchair.

An anabolic therapy for bone could be beneficial in preventing fractures in DMD patients. During disuse (hibernation), black bears maintain a balance in bone formation and resorption. Human parathyroid hormone (hPTH) has been shown to be anabolic for bone, and black bear PTH (bbPTH) may be even more anabolic to account for the bone maintenance observed during hibernation. The aim of this study was to evaluate black bear PTH's potential to prevent and restore bone losses characteristic of DMD.

Dystrophin-deficient male *mdx* mice (a model of DMD recently shown to have low bone mass) and C57BL/6 wild-type controls were injected daily with 24 nmol/kg bbPTH (1-84) or acidic saline vehicle for six weeks. At the conclusion of the study, animals were euthanized by carbon dioxide asphyxiation and their leg bones were extracted for evaluation.

Micro-computed tomography of distal femoral trabecular bone demonstrated *mdx* mice have lower ($p = 0.0024$) bone volume fraction (BV/TV) than wild-type mice. However, treatment with bbPTH increased BV/TV in *mdx* mice to beyond wild-type levels ($p = 0.0002$). We also found *mdx* mice are more responsive to bbPTH treatment than wild-type mice, with a 7-fold increase in BV/TV in *mdx* mice compared to a 2-fold BV/TV increase in wild type mice. Treatment with bbPTH increased trabecular number ($p < 0.0001$) and trabecular thickness ($p < 0.0001$) in *mdx* mice, but not wild-type mice.

Three-point bend testing of femurs to measure cortical bone strength showed no differences in either ultimate force or energy to failure between *mdx* and wild-type mice ($p > 0.1314$) or between bbPTH and vehicle treatments ($p > 0.1445$).

Increases in trabecular microarchitecture with bbPTH administration indicate an increased level of bone formation. Over time, this increased formation could lead to increased resistance to fracture, improving the quality of life for patients with Duchenne muscular dystrophy.

Sclerostin Antibody Increases Peri-implant Bone Formation in Sham-ovariectomized and Ovariectomized Rats. John Irish^{*1}, Amarjit Viri², Kotaro Sena², Min Liu³, Hua Zhu Ke⁴, D. Rick Sumner². ¹Rush University, USA, ²Rush University Medical Center, USA, ³Amgen, USA, ⁴Amgen, Inc., USA

Improving implant fixation in orthopedics and dentistry is of interest because of growing concerns with implant loosening. Neutralizing sclerostin is a promising approach to enhancing bone volume and use of sclerostin antibody (Scl-Ab) has been shown to enhance implant fixation in rat models. Here, we test the hypothesis that Scl-Ab increases bone formation rate (BFR) at the endocortical and trabecular surfaces and at the marrow-facing and implant-facing surfaces of the rim of bone adjacent to the implant in rats with normal and depressed bone volume. 4.5-month old Sprague-Dawley rats received sham-ovx or ovx followed by bilateral femoral intramedullary titanium rod insertion in the distal femur 6.5 months later. The rats were injected twice-weekly with either saline or Scl-Ab (25mg/kg) throughout the study or with Scl-Ab for the first 2, 4 or 8 weeks, for rats terminated at 4, 8 or 12 weeks, respectively (n = 7-9 per group/time). BFR/BS and BV/TV were determined for a metaphyseal region of interest adjacent to the implant. BFR/BS was elevated in sham-ovx and ovx rats treated with Scl-Ab throughout the duration of the study compared to the saline controls at most of the bone surfaces at all 3 time points (Table 1). BFR/BS remained elevated compared to saline controls in the group receiving 2 weeks of Scl-Ab followed by 2 weeks of no treatment, but in groups in which there was a 4 week period between cessation of Scl-Ab treatment and termination, BFR/BS had returned to control levels with rare exception (Table 1). BV/TV in the treatment cessation groups was not different from the groups with Scl-Ab throughout for all timepoints. Generally, increases in mineralizing surface rather than increases in mineral apposition rate accounted for the elevated BFR/BS. BFR/BS tended to decrease over time in rats in which Scl-Ab was administered throughout the study, but remained elevated compared to the saline-injected controls at 3 of the 4 bone surfaces at 12 weeks (Table 1). Thus, the increase in peri-implant BFR induced by Scl-Ab treatment had similar bone surface- and time-dependence in sham-ovx and ovx rats. These increases were no longer apparent 4 weeks after discontinuation of treatment, but reversion of BFR to control levels was not associated with a decrease in BV/TV. It remains to be determined if elevated BFR during Scl-Ab administration at all 4 of these surfaces contributes equally to the increased mechanical fixation observed in rat models.

Smurf Inhibition Does Not Increase Bone Mass. Ina Kramer¹, Janet Dawson-King¹, Rohan Beckwith², Rene Lattmann¹, Nils Ostermann¹, Marcel JJ Blommers¹, Ji-Hu Zhang², Michael Kiffe¹, Alex Shih-Min Huang², Michaela Kneissel¹, Sabine Guth-Gundel^{*1}. ¹Novartis Institutes for BioMedical Research, Switzerland, ²Novartis Institutes for Biomedical Research, USA

It has been previously demonstrated that deletion of the E3 ubiquitin ligase Smurf1 results in increased bone formation and mass in naive animals and in an arthritis model of bone loss. The described increase in bone mineral density was progressive, but relatively modest. A concomitant increase in Smurf2 levels was observed indicating putative functional compensation. We hence aimed at generating a dual Smurf1/2 inhibitor as a potential novel bone anabolic principle for treatment of osteoporosis and arthritis induced bone loss. Through a combination of biochemical, biophysical, and cellular assays we identified a specific low molecular weight Smurf1/2 inhibitor. The compound inhibits Smurf1 and 2 with low nM IC50 in a biochemical auto-ubiquitination assay and stabilizes Smurf1 protein substrates in cellular assays.

Sclerostin Antibody Enhances Spine Fusion in a Rat Posterolateral Transverse Process Fusion Model: Preliminary Results. Andre Shaffer^{*1}, Owolabi A Shonuga¹, Brandon Hirsch², Matthew E Cunningham³, Jeffrey E Mait⁴, Chaoyang Li⁵, Hua Zhu Ke⁶, Joseph Lane³. ¹Hospital For Special Surgery / Weill Cornell Medical College, USA, ²Hospital for Special Surgery / Yale University School of Medicine, USA, ³Hospital for Special Surgery, USA, ⁴Hospital for Special Surgery / SUNY Downstate Medical Center, USA, ⁵Amgen, Incorporated, USA, ⁶Amgen, Inc., USA

Introduction

Sclerostin is a Wnt-signaling pathway inhibitor specific to bone. Monoclonal antibodies to sclerostin (Scl-Ab) have been shown to enhance bone mass and healing in diaphyseal fracture models in animals[1,2]. Spinal fusion is a commonly performed procedure indicated in a number of conditions including degenerative and traumatic conditions[3]. We hypothesize that lumbar spinal fusion is enhanced by subcutaneous Scl-Ab injections.

Methods

Sixty male 10 wk old Lewis rats underwent posterolateral intertransverse process spine fusion between L4 and L5 with 0.2g of morselized bone graft from a donor rat and randomized prior to surgery into two groups. Rats were started on a twice weekly regimen of saline (n=30) or 0.25 mg/kg Scl-Ab (Amgen, Inc, Thousand Oaks, CA) on post-op day 2 that continued until sacrifice at six wks postoperatively. At sacrifice spines were harvested en-bloc from sacrum to L1 and cleaned of soft tissue. Harvested spines were frozen and underwent microCT (uCT) imaging. Thawed spines (n=30) were evaluated for gross motion by manual palpation by three blinded authors, with fusion defined as no motion and scored by consensus. uCT was evaluated for total bone mass in the spines (n=30) and fusion mass in selected spines from each group (n=6).

Results

Manual palpation revealed no statistically significant differences between the two groups. Scl-Ab and saline, with fusion rates by manual palpation of 61% and 60% respectively (p = 0.92). uCT imaging revealed significantly increased bone volume in the spines of animals treated with Scl-Ab with mean bone volume of 554.7458.71 mg HA/ccm and 362.11134.60 mg HA/ccm in spines treated with Scl-Ab and saline respectively (p < 0.001). Bone volume in the fusion mass was also significantly increased in spines treated with Scl-Ab over saline (BV=255.53040.63 mg HA/ccm [Scl-Ab], BV=137.2618.71 mg HA/ccm in [saline], p < 0.001).

Conclusions

Scl-Ab is an effective adjunct for spinal fusion in a rat model, showing increased bone mineral volume and density in the fusion mass and entire spine. Scl-Ab increased fusion mass and overall bone stock. While greater fusion rate was not seen, bone in Scl-Ab treated animals was denser and fusion mass contained more bone than saline treated animals. Greater bone volume and density may lead to greater clinical benefits, since greater bone density and growth is associated with lower rates of pseudoarthrosis and instrumentation failure in spinal fusion.[4,5,6,7]

Direct binding of the compound to the targets was demonstrated by NMR and other biophysical methods. Since its pharmacokinetic (PK) properties allow for oral in vivo application we tested the impact of 8-week twice daily application of three doses, predicted to be sufficient for Smurf1/2 inhibition in vivo, on bone mass in skeletally mature female rats. Moreover we analyzed the bone phenotype of Smurf1 and Smurf2 KO mice during growth and ageing. Bone mass and density changes were monitored by microCT and pQCT. Serum osteocalcin and TRAP levels were determined at 4 and 8 month of age. In addition we subjected rats treated with the Smurf 1/2 inhibitor and Smurf1 and Smurf2 KO mice to antigen-induced arthritis. Knee swelling and bone changes were monitored. Despite its favorable PK profile the compound had no impact on bone mass, density and biomarkers. Consistent with these results and in partial opposition to published data neither Smurf1 KO nor Smurf2 KO mice displayed increased bone mineral density over the 8 month monitoring period. While the compound did not induce any bone changes in the antigen-induced arthritis model it reduced knee swelling thus demonstrating in vivo efficacy. In line with the latter observation a reduction in knee swelling was also observed in Smurf1 KO and Smurf2 KO mice. Taken together, our data demonstrate the feasibility to develop specific Smurf1/2 inhibitors identifying E3 ubiquitin ligases as novel drug targets. However, they also suggest that inhibition of Smurf1 and Smurf2 does not provide a bone anabolic strategy for restoration of bone mineral density.

Comparison of Zoledronic Acid and Teriparatide Effects on Iliac Bone Microarchitecture, Remodeling and Collagen Crosslinks in Ewes. Nathalie R Portero-Muzy¹, Pascale M Chavassieux², Mary L Boussein³, Evelyne Gineyts¹, Roland D Chapurlat¹. ¹INSERM, UMR1033, Universite de Lyon, France, ²INSERM UMR1033, Universite de Lyon, France, ³Orthopedic Biomechanics Laboratory, Beth Israel Deaconess Medical Center & Harvard Medical School, USA

Zoledronic acid and teriparatide have different mechanism of action. Their respective effects on 3D-microarchitecture, collagen crosslink composition and bone remodeling have not been compared. Thus, we conducted an experimental study to distinguish their effect in the iliac bone, in ewes. Three groups of 24 aged ewes received either vehicle (CTRL; 8.4±0.4 yrs, n = 8); single injection of 10 mg of zoledronic acid (ZOL; 8.1±0.4 yrs, n = 8) or daily injection of 20µg/d of teriparatide (TPTD; 8.1±0.4 yrs, n = 8). After double tetracycline labeling, a transiliac bone biopsy was collected after 3 months. 3D-microarchitecture was assessed with Scanco microCT 40 with a 20µm³ isotropic voxel size. The content of both mature enzymatic crosslinks pyridinoline (PYD), deoxypyridinoline (DPD) and the non-enzymatic crosslink pentosidine (PEN) were analyzed by reverse phase-HPLC. Static and dynamic parameters of bone remodeling were measured by 2D-histomorphometry. Three months after a single dose of ZOL, MS/BS, BFR/BS and Acf were significantly decreased by 97.8% (p<0.001), 95.3% and 94.7% (p<0.01) respectively when compared to CTRL. Tb.BV/TV by histomorphometry was 31.3% and 33.6% higher in ZOL than in CTRL and TPTD (p<0.04 and p<0.01 respectively). This was confirmed by 3D-µCT measurements which showed an increase in Tb.BV/TV (19.8%, p<0.04), ConnD (30%, p<0.03) and TbN* (8.3%, p<0.03) vs CTRL. ZOL had, in the cortical bone, lower DPD and a higher PYD/DPD ratio (p=0.05) compared to CTRL. In contrast, after 3 months of TPTD, the bone turnover (ie, MS/BS, BFR/BS and Acf) was significantly higher than in ZOL, but was not significantly different than CTRL. Tb.BV/TV evaluated with 3D-µCT did not differ from CTRL. DPD was decreased and PYR/DPD ratio increased in TPTD when compared to CTRL (p<0.01). In conclusion, in adult ewes ZOL improves bone microarchitecture parameters within 3 months, whereas the effect of TPTD seems to take longer. These observations might depend on skeletal site, and other sites with different proportion of trabecular and cortical bone should be examined.

Effect of Timing of Post-Exercise Carbohydrate and Protein Ingestion on Markers of Bone Turnover. Julie Greeves^{*1}, Ricardo Costa², Neil Walsh³, Craig Sale⁴, Ruth Hobson⁴, John Dutton⁵, William Fraser⁵. ¹HQ Army Recruiting & Training Division, United Kingdom, ²Coventry University, United Kingdom, ³Bangor University, United Kingdom, ⁴Nottingham Trent University, United Kingdom, ⁵University of Liverpool, United Kingdom

Oral administration of carbohydrate (CHO) and protein (PRO), shown to suppress bone resorption at rest, might also attenuate the marked increase in bone resorption associated with running (Scott et al. 2010, JCEM, 95, 3918-25). CHO-PRO consumption is an established post-exercise feeding strategy, rapidly replenishing energy stores if ingested within 60 min of exercise. CHO-PRO might also modulate bone resorption in a time-dependent manner. This study aimed to examine the influence of immediate or delayed ingestion of CHO-PRO on bone metabolism following prolonged exercise. Eight male runners (age: 29 10 y; height: 1.79 0.08 m; body mass [BM]: 72.7 7.4 kg; VO2max: 61.5 6.1 ml·kg⁻¹·min⁻¹) completed 3 randomised feeding interventions after 2 h of running at 75% VO2max. During control (CON), participants received water (12 ml·kg BM⁻¹) immediately and 1 h post-exercise. During immediate feeding (IF), participants received a CHO-PRO solution equal to 1.2 g CHO·kg BM⁻¹ and 0.4 g PRO·kg BM⁻¹ immediately post-exercise and water 1 h post-exercise. During delayed feeding (DF), participants received water immediately post-exercise and CHO-PRO solution 1 h post-exercise. Venous blood samples were obtained before exercise (BASE), immediately post-exercise (POST), and every 20 min until 140 min post-exercise. Serum/plasma was analysed for Ò-CTX, PINP, OC and PTH. Data were analysed using Linear Mixed Model ANOVA, and post-hoc with Newman-Keuls and Dunnett's test. There was a significant condition x time interaction for Ò-CTX (P<0.001), but not for PINP, OC or PTH. Ò-CTX increased between BASE and 20 (P<0.05), 40 and 60 min post-exercise in all conditions (p<0.005), but decreased below BASE between 100 and 140 min in IF (P<0.05), and 120 and 140 min in DF (P<0.05). Differences between groups are shown in Table 1. Main effects of time were significant for PINP, OC and PTH (P<0.0001). The increase in bone resorption following exhaustive exercise is attenuated with post-exercise feeding of CHO-PRO. These effects are observed earlier with immediate feeding, but are comparable 140 post-exercise. In addition to the widely acknowledged benefit of early post-exercise CHO-PRO ingestion for restoring energy supply, these findings suggest that post-exercise ingestion of CHO-PRO has favourable effects on bone turnover. This work was sponsored by the UK Ministry of Defence (Army)

Effects of Dietary Coral Calcium and Zeolite on Ovariectomy Induced Bone Loss. Jameela Banu^{*1}, Erika Varela¹, Ganesh Halade¹, Ali Bahadur¹, Kokichi Hanaoka², Gabriel Fernandes³. ¹University of Texas Health Science Center at San Antonio, USA, ²Bio-REDOX Laboratory Inc, Japan, ³University of Texas Health Science Centre, USA

Patients that have osteoporosis mainly lose calcium from bones making them weaker and easily susceptible to fractures. Supplementation of calcium is one treatment option for such condition. The source of calcium however plays an important role in the amount of calcium that is assimilated into bone. Naturally occurring coral calcium and zeolite are popular nutritional supplements, and probably they can be used to prevent bone loss. We have measured bone loss in ovariectomized (OVX) mice supplemented with coral calcium and Zeolite.

Female C57BL/6 mice, 3 months of age were purchased from Jackson laboratories and divided into the following groups: 1. AIN93 -SHAM (10% CO); 2. AIN93 - OVX (10% CO); 3. AIN93+0.5% calcium - SHAM; 4. AIN93+0.5% calcium - OVX; 5. AIN93+1% Coral powder - SHAM; 6. AIN93+1% Coral powder - OVX; 7. AIN93 +1% Zeolite powder - SHAM; 8. AIN93+1% Zeolite powder - OVX. The mice were either sham-operated (n=10/group) or ovariectomized (OVX; n=10/group). One week after surgery, they were put on the respective diets for the next 6 months and sacrificed. Serum was analyzed for bone biochemical markers. Long bones were analyzed using µCT densitometry and lumbar vertebrae were analyzed using DXA.

There was significant decrease in the trabecular number and increase in trabecular separation in distal femoral metaphysis of control OVX mice, while the calcium, coral

calcium and zeolite fed mice did not show significant differences between sham and OVX mice. Bone mineral density (BMD) of the lumbar vertebrae (L2-L4) was significantly decreased in control OVX mice, when compared to those of control sham mice. BMD of calcium, coral calcium and zeolite fed mice did not change significantly between the treated sham and OVX mice. Bone turnover markers like alkaline phosphatase and osteocalcin increased in OVX mice fed coral calcium significantly.

In conclusion, coral calcium and zeolite protect ovariectomy induced bone loss in mice.

Soy Isoflavones, Alone or in Combination with Risedronate, Do Not Reduce Bone Resorption in Ovariectomized Rats. Emily Hohman*, George McCabe, Connie Weaver. Purdue University, USA

Bisphosphonates are highly effective in reducing risk for osteoporotic fractures, but have recently been associated with adverse effects following long term use. Combination therapy with other antiresorptive therapies may increase effectiveness of bisphosphonates and allow for reduced doses, possibly reducing risk for adverse effects. Soy isoflavones have been shown to reduce bone resorption in post-menopausal women, making them a potential co-therapy agent. We investigated the effects of dietary soy isoflavones alone and in combination with two doses of risedronate on bone resorption as measured by deep bone label excretion in ovariectomized (OVX) rats. Four-month-old rats were given an intravenous injection of 50 μ Ci 45 Ca following one month of recovery from OVX. After an additional month to allow the 45 Ca clear from soft tissues and label only bone, urine was collected to determine baseline 45 Ca excretion. Twenty rats were then assigned to receive soy isoflavone and risedronate treatments in a semi-randomized, crossover design. The treatments were 1) a soy isoflavone diet (875 mg/kg diet Novasoy added to AIN-93M diet, total isoflavone content = 350 mg/kg diet), 2) low risedronate (0.8 μ g/kg body weight sodium risedronate injected subcutaneously every other day), 3) low risedronate + soy isoflavone diet, 4) high risedronate (1.2 μ g/kg body weight sodium risedronate injected subcutaneously every other day), and 5) high risedronate + soy isoflavone diet. Treatments were given for ten days with ten day recovery periods between treatments. Twenty-four-hour urine pools collected throughout the treatments were analyzed for 45 Ca by liquid scintillation counting. Relative resorption (RR) was calculated as the ratio of 45 Ca excretion during treatment to 45 Ca excretion during the baseline period, adjusted for time and subject. On the soy isoflavone diet (trt 1), RR was 1.18 ($p=0.01$), indicating that bone resorption was not reduced. Risedronate alone significantly reduced bone resorption at both the low (trt 2, RR=0.70, $p<0.0001$) and high (trt 4, RR=0.78, $p<0.0001$) doses. Addition of soy isoflavones to risedronate did not further reduce bone resorption (low risedronate + soy [trt 3], RR=0.76, $p<0.0001$; high risedronate + soy [trt 5], RR=0.76, $p<0.0001$). These results indicate that soy isoflavones may not be effective as a monotherapy or as a co-therapy with risedronate for preventing bone resorption in the OVX rat model of post-menopausal osteoporosis.

Estradiol Release Kinetics Determine Tissue Response in Ovariectomized Rats and Mice. Ingrid Kantner*¹, Christiane Otto², Reinhard Nubbemeyer², Jenny Schkoldow², Iris Fuchs², Elisabeth Krah², Richardus Vonk², Christiane Schuler¹, Karl-Heinrich Fritzsche², Reinhold Erben¹. ¹University of Veterinary Medicine, Austria, ²Bayer Schering Pharma AG, Germany

Estrogen replacement is an effective therapy of postmenopausal symptoms such as hot flushes, bone loss, and vaginal dryness. Major side effects are the stimulation of uterine and mammary gland epithelial cell proliferation as well as hepatic estrogenicity. In this study in ovariectomized (OVX) rats and mice, we tested the hypothesis that the tissue response to estradiol might be modulated by different release kinetics. Pulsed release kinetics were achieved by intraperitoneal (i.p.) or subcutaneous (s.c.) administration of estradiol dissolved in physiological saline containing 10% ethanol (EtOH/NaCl), whereas continuous release kinetics were achieved by s.c. injection of estradiol dissolved in benzyl benzoate/ricinus oil (B/R, 1:5). Initial 3-day and 3-week experiments in OVX rats and mice showed that pulsed i.p. estradiol had a profoundly reduced stimulatory effect on uterus and mammary gland compared with continuous release kinetics, whereas both release kinetics prevented vaginal atrophy. Based on these results, we compared the effects of pulsed (s.c. in EtOH/NaCl) versus continuous (s.c. in B/R) estradiol release kinetics on bone, uterus, mammary gland, and liver in a 4-month study in 6-month-old OVX rats. We found that both application regimens had comparable ability to protect against ovariectomy-induced bone loss. However, pulsed estradiol resulted in lower uterine weight, reduced induction of hepatic gene expression, and a lower proliferative effect on the mammary gland, relative to continuous estradiol. We conclude that estradiol release kinetics can determine organ responsiveness, a fact which might be exploited to reduce unwanted side effects of estradiol therapy.

Callus Resolution and Fracture Healing is Not Hindered in Cathepsin-K Null Mice. Michael Gentile^{*1}, Do Soung², Gregg Wesolowski¹, Pavithra Ramakrishnan¹, Carlyle Horrell¹, Hicham Drissi², Le Thi Duong³. ¹Merck & Co., Inc., USA, ²University of Connecticut Health Center, USA, ³Merck Research Laboratories, USA

Cathepsin K (CatK) is a cysteine protease expressed predominantly in osteoclasts which degrades demineralized bone matrix. Adult CatK deficient mice have high bone mass in both cortical and cancellous regions as the result of significant reduction in osteoclastic bone resorption as well as enhanced bone formation. Here, a mouse femur fracture model was employed to assess fracture healing in CatK knock-out (KO) versus wild type (WT) mice. Pre-pin stabilized, mid-diaphyseal femoral fractures (Fx) were made with an Einhorn device in 8-11 week old mice. Callus formation and resolution were assessed *in vivo* via a dental x-ray at the time of Fx and at 4, 7, 14, 21, and 28 days. Based on blind scoring of Fx radiographs at 14 days, KO and WT mice were randomized into 3 groups ($n=6-8$ /group) which were sacrificed at for 14, 18 and 28 days post-Fx, respectively. Similar procedures were applied in a separate experiment to assess callus strength at 28 and 42 days. The fractured and intact contra-lateral femora were harvested and the calluses were assessed *ex vivo* by caliper, DEXA, μ CT and histomorphometry. Original cortical bone within the forming callus was manually excluded from μ CT slices allowing assessment of bone formed post fracture. The callus size as assessed by caliper, DEXA-derived area, histomorphometry and μ CT-derived volume was similar in KO vs. WT at 14 days with a strong trend towards smaller callus size in KO at 18 and 28 days post-Fx. The calluses from KO mice had statistically significantly ($p<0.05$, one way ANOVA, Fisher's PLSD) greater overall BMD at each timepoint relative to WT controls as assessed by both DEXA and μ CT. Callus BMC as measured by μ CT demonstrated a higher trend in KO mice at 14 days and gradually declined from 14 to 28 days during callus resolution in both KO vs. WT bones. Histomorphometric analysis of calluses revealed higher bone area/total callus area, % in KO vs. WT at all time points. Cartilage area/total callus area, % was similar in KO vs. WT at all time points. Furthermore, CatK KO calluses had overall higher bone mass at all time points. Biomechanical testing and histomorphometric analyses are ongoing to determine callus turnover and strength during the healing process. We conclude that callus resolution and healing of fracture is not hindered in Cat K deficient mice.

Disclosures: Michael Gentile, None.

Cellular and Molecular Mechanisms Of Accelerated Fracture Healing By Cox-2 Gene Therapy. Studies In A Multiple Fracture Mouse Model. Vishal Kothari¹, Xiaobing Zhang², K.H. William Lau³, David Baylink², Amitava Das^{*2}. ¹Loma Linda University School of Medicine, USA, ²Loma Linda University, USA, ³Loma Linda University School of Medicine, USA

Cox-2 gene therapy is highly effective in accelerating bridging of fracture gaps, but the mechanism by which the Cox-2 gene therapy promotes fracture repair is not known. This study sought to determine the cellular and molecular mechanisms of Cox-2 to promote fracture repair using a multiple fractures model, in which 3 fractures were created on the tibia of C57BL/6 mice by 3-point bending. The lenti-Cox-2-GFP or lenti-GFP control vector was injected into fracture site on day 1. Our study indicated that Cox-2 therapy affected the fracture repair at two distinct phases: 1) at an early phase, therapy reduced the callus size, and 2) at a later phase, it promoted remodeling of the cartilaginous callus and bony bridging of the fracture gap. Accordingly, the Cox-2-treated mice formed smaller cartilaginous calluses at day 7-14 ($p<0.001$) and had less cartilage content at day 14-21 ($p<0.001$) than control mice. Two findings of our mechanistic exploration of the reduction in callus size are novel. First, expression of Sox-9 mRNA was 7-fold less in Cox-2-treated calluses than in control calluses (9.2 vs. 67.6-fold, $p<0.04$, $n=3$) at day 14. This decrease corresponds to the reduction in callus size (6.10.9 vs. 9.81.0, $p<0.01$, $n=6$), implying that Cox-2 reduces chondroblastic differentiation of MSCs in the callus. Second, the therapy increased cellular staining of vWF and α -SMA (>2.5 -fold over controls) in the cartilaginous callus at day 14-21, suggesting an increase in angiogenesis. This was associated with 2-fold increase ($p<0.05$) in TRAP+ osteoclasts along the surface of the woven bone. The removal of cartilage was also associated with an earlier and more robust onset of osteogenesis (2-fold increase in osteocalcin+ cells, $p<0.001$), indicating that Cox-2 promotes bony remodeling of callus cartilage. Injection of endostatin (2.5 mg/kg/day for 10 days) into the fracture site at the time of the viral injection to block angiogenesis resulted in a marked increase in staining for hypertrophic chondrocytes with concomitant reduction in TRAP activity ($p<0.01$). Thus, angiogenesis is essential for the Cox-2-mediated remodeling of cartilaginous callus. In conclusion, the mechanism whereby Cox-2 promotes fracture healing involved 2 independent actions: 1) decreased formation of cartilaginous callus at an early phase, and 2) promoted angiogenesis-dependent cartilage remodeling at a later phase which involved a more robust osteogenesis to support bridging and accelerated fracture healing.

Combined Effect of Methylprednisolone and Fish Oil ^{RX} Against Bone Mineral Density Loss in Spontaneous Autoimmune Disease Prone MRL-lpr/lpr Mice. Md Rahman*, Paul Williams, Kazi Nishu, Gabriel Fernandes. University of Texas Health Science Centre, USA

MRL-lpr/lpr mice spontaneously develop various manifestations of autoimmunity including an inflammatory arthropathy and immune complex glomerulonephritis. Autoimmune diseases induce bone mineral density (BMD) loss in this mouse. This study examines the combined effect of immunosuppressive drug, methylprednisolone (MP) and anti-inflammatory fish oil RX against bone mineral density loss in MRL-lpr/lpr female mice. At 4 months of age mice were either treated weekly with PBS or 5 mg/kg MP or 20 mg/kg MP and fed AIN93M diet supplemented either with 4% corn oil or 4% fish oil RX daily for 8 weeks. Before starting the drug injection and dietary intervention, mice were scanned with dual energy x-ray absorptiometry (DXA) to determine the baseline BMD values. Mice were again scanned with DXA 8 weeks later just before sacrifice to determine final BMD values. Slight protection of BMD loss in femur, tibia and lumbar regions was observed in MP and FO alone treated groups as compared to PBS and CO treated groups. However BMD loss protection in femur, tibia and lumbar regions was dramatic in combined MP and FO RX treated groups as compared to other groups. Higher protection of BMD loss was correlated with lower number of tartrate resistant acid phosphatase positive area and higher number of alkaline phosphatase positive area in tibial sections. Treatment of mice with MP and FO RX prevented the development of glomerulonephritis and reduced the intensity of inflammatory arthritis in MRL-lpr/lpr mice. These data emphasize the importance of suppressing inflammation by immunosuppressive drug and fish oil RX in mice with active autoimmune diseases to maintain bone health. Comparison of the Efficacy of Odanacatib or Alendronate on Bone Remodeling and Biomechanical Properties of the Lumbar Spine in Estrogen-deficient Rhesus Monkeys. Brenda Pennypacker*, Charles Chen², Ya Zhuo², Maureen Pickarski², Le Thi Duong¹. ¹Merck Research Laboratories, USA, ²Merck & Co., Inc., USA

Cathepsin K (CatK) is a lysosomal cysteine protease highly expressed in osteoclasts that degrades Type I collagen during bone resorption. Odanacatib (ODN) is a selective, potent and reversible CatK inhibitor in development for the treatment of osteoporosis. We previously reported that ODN treatment reduced trabecular bone remodeling, while increasing cortical bone formation in ovariectomized (OVX) rhesus monkeys. Here, direct comparison of the efficacy and bone quality in the lumbar spine of ODN and alendronate (ALN) were compared on BMD, bone turnover, strength and collagen organization in the lumbar vertebrae (LV). OVX rhesus monkeys (age 12-22 yrs; N=16/group) were treated either with vehicle, ODN (2mg/kg/d, po), or ALN (30µg/kg/wk, sc). The ODN dose provided steady state exposure of 11µM•24h as compared to the equivalent clinical 50 mg dose exposure of ~7 µM•24h. A group of age- and BMD-matched intact monkeys (Int, N=12) was included as control. Calcein (8 mg/kg, IM) at 12 mo. and tetracycline (40 mg/kg IV) prior to necropsy were given at 14-d intervals. A significant treatment-related increase in LV4-5 BMD vs. Veh was observed in ODN (6.7%) and ALN groups (6.4%). Compared to Veh, ODN and ALN significantly reduced (p<0.001) trabecular LV2 mineralizing surface (MS/BS, %) and bone formation rate (BFR/BS). Static measurements including osteoblast surface (Ob/BS, %), osteoid surface (OS/BS, %) and thickness (Os.Th, µm), and osteoclast surface (OcS/BS, %) and number (OcN/BS, #/mm) were measured. ODN and ALN both decrease Ob/BS and OS/BS vs Veh. Unlike ALN, ODN increases OcS/BS and OcN/BS. Increases in LV4-5 peak load, apparent strength, yield load, and yield stress were noted for ODN- vs. ALN-treated monkeys, compared to Veh or Intact. From compression testing, peak load from all groups was positively correlated with DXA-derived BMD (R=0.699, p<0.0001) and BMC (R=0.4656, p<0.005), and QCT-derived BMD (R=0.577, p<0.001) and BMC (R=0.670, p<0.0001). LV2 trabecular collagen orientation (ROI 0.8X0.55 mm²) was scored by polarized light microscopy. There was no significant difference in the percentage of non-lamellar vs. lamellar bone over total bone area between groups. Taken together, the present data demonstrates that comparable to ALN, ODN treatment for 20 mo. at an equivalent daily clinical exposure effectively increases BMD, reduces bone remodeling, and maintains normal bone strength and collagen organization in OVX non human primates.

Effects of Herb Extracts on Osteoclasts, Osteoblasts and Chondrocytes as Novel Drug Candidates for Osteoporosis. Seika Banka¹, Satoru Shintani¹, Kazunaga Yazawa², Kondo Seiji¹, Yoshiki Mukudai³. ¹Department of Oral & Maxillofacial Surgery, School of Dentistry, Showa University, Japan, ²Laboratory of Nutraceuticals & Functional Foods Science, Graduate School Marine Science & Technology, Tokyo University of Marine Science & Technology, Japan, ³Showa University, Japan

[Purpose] In these latter years, the therapy for osteoporosis (OP) is the most required for the quality of life. Bisphosphonate is the most applied for the therapy for osteoporosis, regardless of the serious side effects, such as ?Bisphosphonate Related Osteonecrosis of the Jaw. Therefore, it is suggested that study for finding a novel drug instead of bisphosphonates is a matter of great urgency. In the present study, we sought the herb extracts, which is effective on the therapy for OP *in vitro*, among more than 400 samples.

[Methods] At the first screening, RAW264.7 cells were utilized. The cells were grown at the presence of receptor activator NF-kappa B ligand (RANKL), were derived to osteoclasts, and were cultured for other 3 days in the presence of various herb extracts. Thereafter, the cells were subjected to TRAP staining, and the herb extracts, which effected on suppression and/or apoptosis to the osteoclasts, were subjected to the subsequent experiments. In the next, MC3T3 cells were grown in the differentiation medium, and supplemented with the herb extracts, which were selected from the experiments in RAW264.7 cells, for 3 day. As well, ATDC5 cells were grown in the presence of ITS (Insulin-Transferrin-Sodium selenite), and were driven into the proliferating chondrocytes. These 2 strains were, then, subjected to alkaline phosphatase (ALPase) assay, DNA measurement assay, sulfated glucosaminoglycan measurement assay, calcium measurement assay and osteocalcin ELISA assay, which are the differentiation markers of osteoblasts and chondrocytes. Thereby, further screening was carried out, for effects of proliferation and differentiation on osteoblast and chondrocytes.

[Results] After third screening, 3 herb extracts were found, and all of those increased apoptosis on osteoclasts, whereas, had proliferating and differential effects on both osteoblasts and chondrocytes. In addition, the effective dosage of the herb extracts was from 1 to 1000 mg/ml.

[Conclusions] In the present study, we found the several herb extracts, which might be novel drugs for OP. At present, purifying of the molecules, which are comprised in the herb and are effective for the therapy of OP, and *in vivo* experiments are ongoing. In addition, patents for the herb extracts are under application in Japan.

Calcium-Sensing Receptor Mediated Suppression of cAMP by Agonists and Allosteric Modulators. Vimesh Avlani*, Arthur Conigrave². ¹University of Sydney, Aus, ²University of Sydney, Australia

The extracellular calcium-sensing receptor (CaR) is a multimodal chemosensor that belongs to G Protein-Coupled Receptor (GPCR) class C. The CaR couples to the heterotrimeric G-proteins G_{q/11}, G_{i/o} & G_{12/13} resulting in the activation of various signalling pathways. The CaR is also subjected to allosteric modulation by compounds like L-amino acids, glutathione and its analogues including S-methylglutathione (SMG) that bind in the Venus Fly Trap domain and phenylalkylamines including NPS R-467 and Cinacalcet that bind in the heptahelical domains. The majority of CaR signalling studies use the activation of G_{q/11} as measure of CaR activity. However, systematic characterization of CaR mediated activation of other G-proteins such G_{i/o} and G_{12/13} and second messengers such as cAMP and ERK_{1/2} are required for a detailed understanding of CaR signalling and biological activity. In the present study we show that CaR mediated reduction in cellular cAMP levels arises from reduction in its synthesis as well as an increase in its degradation. Real-time measurement of changes in intracellular cAMP levels was achieved using the cAMP biosensor CFPnd-Epac1-cpVenus in a Fluorescence Resonance Energy Transfer (FRET)-based microfluorescence assay. EPac is a guanine nucleotide exchange protein directly activated by cAMP. All allosteric modulators tested, including L-Phenylalanine, SMG, NPS R-467 and cinacalcet enhanced extracellular calcium (Ca²⁺) induced decreases in cAMP levels. Overnight treatment of cells with pertussis toxin, an inhibitor of G_{i/o} G-protein, abolished not only Ca²⁺_o mediated cAMP inhibition but also the effects of the allosteric modulators suggesting a key requirement for G_{i/o} G-proteins. Isobutyl Methyl Xanthine (IBMX), a phosphodiesterase (PDE) inhibitor, also significantly reduced the potency of Ca²⁺_o. The results suggest that CaR mediated reduction in cAMP requires both inactivation of adenylyl cyclase via G_{i/o} and activation of PDE.

Alpha-2-Macroglobulin as a Biomarker for Glucocorticoid-induced Osteonecrosis of the Femoral Head. Alberto Carli¹, Edward J Harvey², Mireille Savegh¹, Bouziane Azeddine^{*1}, Ailian Li³, Ayoub Nahal², Rene Michel², Janet E Henderson³, Chantal Seguin². ¹McGill University, Canada, ²McGill University Health Centre, Canada, ³McGill University Health Centre-Research Institute, Canada

Relevance: Osteonecrosis (ON) of the femoral head is a serious complication of high dose glucocorticoid (GC) therapy in young people with haematologic malignancy. These patients present with end stage osteoarthritis, associated with endothelial dysfunction and loss of vascular integrity, which requires total hip arthroplasty for symptomatic relief. The current study was designed to test the hypothesis that genetic susceptibility predisposes individuals to GC-induced ON and that alpha-2-macroglobulin (A2M) may be a biomarker for the onset of disease.

Methods: Young adult Wistar Kyoto and Fischer rats were randomized to receive the equivalent of a daily dose of 1.5mg/kg/day of prednisone or placebo by slow release pellets implanted subcutaneously and bled each month for serum glucose and A2M before being euthanized at six months. Femoral heads were harvested and scanned at high resolution by micro computed tomography (m CT) before embedding and sectioning for histological analyses.

Results: Serum A2M remained below 10µg/ml in all placebo treated rats and variable increases were seen between two and four months of treatment in GC treated rats. Median levels dropped back to baseline in Fischer rats but remained elevated in Wistar Kyoto rats at six months. Subchondral bone was reduced in both Fischer and Wistar Kyoto rats treated with GC compared with placebo treated control and preliminary histological analyses that are still ongoing revealed some evidence of ON in either strain. However, unlike all Fischer rats most of GC treated Wistar Kyoto rats showed evidence of articular cartilage degradation.

Conclusion: We have shown Wistar Kyoto rats to be susceptible to GC-induced degeneration of the femoral head in association with elevated circulating levels of A2M.

Disclosures: Bouziane Azeddine, None.

MO0476

ROS, FoxOs, and Akt are Critical Mediators of the Actions of both Glucocorticoids and TNFα on Osteoblastic Cells. Maria Almeida^{*}, Li Han, Elena Ambrogini, Shoshana Bartell, Srividhya Iyer, Aaron Warren, Charles O'Brien, Robert Jilka, Robert Weinstein, Stavros Manolagas. Center for Osteoporosis & Metabolic Bone Diseases, Central Arkansas Veterans Healthcare System, University of Arkansas for Medical Sciences, USA

An increase in endogenous glucocorticoids (GC) or inflammatory cytokines are thought to contribute to the age-associated loss of bone mass and strength but the molecular mechanisms responsible for their deleterious effects on bone are unclear. Based on this and evidence that oxidative stress (OS) is a causal mechanism of the insulin resistance produced by these two agents, we tested the hypothesis that their adverse skeletal effects also result from increased OS. We report that dexamethasone (Dex) or TNFα increased reactive oxygen species (ROS), the phosphorylation of p66^{shc}, an amplifier of H₂O₂ generation in mitochondria, and the activity of FoxOs, transcription factors that defend against OS, in several established osteoblast cell models as well as murine calvaria-derived osteoblasts. These effects were abrogated in osteoblasts from p66^{shc} knockout mice or by the addition of Apocinin or LY393351, agents that inhibit activation of PKCβ which is required for ROS-induced phosphorylation of p66^{shc}. The effects of Dex and TNFα were also abrogated by the anti-oxidants NAC and Ebselen. In addition, both, Dex and TNFα induced the apoptosis of osteoblasts and this effect was abrogated in osteoblasts from mice lacking p66shc or wild type osteoblasts treated simultaneously with the anti-oxidants. The pro-apoptotic effect of Dex or TNFα was also abrogated in osteoblasts derived from mice in which FoxO3 has been selectively overexpressed in osteocalcin expressing cells. Further, TNFα or Dex suppressed the Wnt3-induced activation of a TCF-reporter construct, and this effect was attenuated in calvaria cells from FoxO1,3,4 knockout animals, but not by PKCβ inhibitors. The suppressive effects of Dex and TNFα on TCF transcription were prevented by transient transfection of a plasmid expressing Akt, a kinase that is inhibited by Dex and TNFα. In agreement with the in vitro findings, administration of prednisolone for 28 days to 5-month-old C57BL/6 mice increased ROS levels in the bone marrow, as well as p66shc phosphorylation in bone, and these effects were prevented by administration of NAC. We conclude that ROS-induced activation of a PKCβ/p66 signaling cascade is responsible for the pro-apoptotic effects of Dex and TNFα on osteoblastic cells. Moreover, activation of FoxOs and inhibition of Akt by GCs and TNFα are cell-autonomous mechanisms of Wnt/β-catenin antagonism contributing to the adverse effects of GC excess and inflammatory cytokines on bone alike.

A Moderate Oral Dose of Mixed Isoflavones Was Most Effective at Reducing Bone Resorption in Postmenopausal Women. Jessica Wiersma^{*1}, Berdine Martin¹, George McCabe¹, Linda McCabe¹, George Jackson¹, Munro Peacock², Stephen Barnes³, Connie Weaver¹. ¹Purdue University, USA, ²Indiana University Medical Center, USA, ³University of Alabama, USA

The ability of soy isoflavones to reduce bone loss associated with estrogen deficiency is hypothesized to be dependent on isoflavone composition and dose. The aim of the study was to determine the response of genistein alone and as part of a mixed isoflavone supplement on bone resorption in postmenopausal women. The study was a blinded, randomized, crossover trial in which subjects received 5 soy isoflavone extract interventions; a bisphosphonate (risedronate) as an active control was administered at the end of the study period. The 5 interventions were as follows: purified genistein (>80% pure) as 1) 44 mg genistein and 53 mg total isoflavones and 2) 94 mg genistein and 114 mg total isoflavones, or mixed isoflavones containing various ratios as 3) 46 mg genistein, 44 mg daidzein, and 105 mg total isoflavones, 4) 91 mg genistein, 55 mg daidzein, and 161 mg total isoflavones per day, and 5) 96 mg genistein, 93 mg daidzein, and 220 mg total isoflavones. Subjects were 14 healthy postmenopausal women who received intravenous ⁴⁵Ca to label their skeletons. Treatments were given as 50 day interventions with 50 day washouts. Bone resorption was assessed by multiple measurements of urinary ⁴⁵Ca. Relative resorption (RR) was calculated as the difference between the measured ⁴⁵Ca excretion in the intervention period and the expected value determined from all washout periods. Serum measurements of isoflavones to verify compliance and bioavailability and biochemical markers of bone turnover were taken at the end of each intervention and washout period. All interventions except for 2) were able to reduce bone resorption (RR=0.889 to 0.966, p<0.05). The risedronate RR was 0.737 (p=0.0009). Genistein did not demonstrate an antiresorptive dose response and other isoflavones were neither agonistic nor antagonistic. A moderate level of mixed Isoflavones (intervention 3), Novasoy[®] was most effective at reducing bone resorption.

Effect of Soy Treatments on Bone Resorption

DNA Binding Mutations in ERα Lead to Suppression of Wnt Signaling in Bone. Ulrike Moedder¹, Sundeep Khosla¹, David Monroe^{*2}. ¹College of Medicine, Mayo Clinic, USA, ²Mayo Foundation, USA

Estrogens play vital roles in the function, homeostasis and remodeling of bone. The cellular mechanisms of estrogen receptor (ER) action can broadly be categorized into those involving direct binding to estrogen response elements (classical), or indirect DNA binding (non-classical). The generation of non-classical ER knock-in (NERKI) mice provides a unique opportunity to define these pathways in bone. Previous data from our laboratory have demonstrated that mice expressing only the NERKI receptor exhibit an osteoporotic phenotype; however, the mechanism(s) for this remain unresolved. Gene expression analyses of cortical bone from NERKI mice revealed suppression of lymphoid enhancer factor-1 (Lef1) expression, a classic Wnt-responsive transcription factor that associates with β-catenin. Since Wnt signaling is generally considered bone anabolic, this observation leads to the interesting hypothesis that NERKI-induced suppression of Wnt signaling may contribute to the low bone mass phenotype. To this end, we generated NERKI mice crossed with TOPGAL transgenic mice, a reporter strain that expresses β-galactosidase (β-gal) in response to Lef1-mediated Wnt signaling. Histochemical analysis of β-gal stained bone sections revealed significantly less β-gal in NERKI mice, confirming suppression of Wnt activity in vivo. Adenoviral expression of the NERKI receptor using an in vitro cell system revealed suppression of the Wnt target genes Tcf7, connexin 43 and versican when compared to wildtype ERα, confirming the in vivo findings. Interestingly, expression of NERKI caused induction of axin2, dickkopf homolog (DKK)-3, DKK4, secreted frizzled-related protein-4 and sclerostin, all known

repressors of Wnt signaling. Furthermore, expression of wildtype ER α , but not NERK1, stimulated Wnt activity in a lentiviral-mediated reporter assay. Collectively, these data suggest the osteoporotic phenotype of NERK1 mice may involve the suppression of Lef1-mediated Wnt signaling through both the repression of activators and stimulation of repressors of Wnt signaling. The inability of NERK1 to properly regulate Wnt activity may be due to the elimination of classical ER signaling as well as interference in the known roles of ER α in intracellular trafficking of β -catenin. Experiments are underway to discriminate among these possibilities.

Estrogen Protects Against Arthritis and Inflammation-Mediated Bone Loss Via Estrogen Receptor Alpha. Cecilia Engdahl¹, Anna Borjesson², Ulrika Islander², Sara Windahl², Alexandra Stubelius², Annica Andersson², Andree Krust³, Pierre Chambon³, Claes Ohlsson⁴, Hans Carlsten², Marie Lagerquist⁵. ¹Centre for Bone & Arthritis Research, GU, Sahlgrenska Academy, Medicine, Sweden, ²Center for Bone & Arthritis Research, Sahlgrenska Academy, Sweden, ³Institut de Genetique et de Biologie Moleculaire et Cellulaire (CNRS UMR7104; INSERM U596; ULP, College de France), France, ⁴Center for Bone Research At the Sahlgrenska Academy, Sweden, ⁵Sahlgrenska University Hospital, Sweden

Background: Many inflammatory diseases including rheumatoid arthritis leads to bone loss. The female sex hormone estrogen can prevent bone loss, but due to negative side-effects, long-term estrogen treatment is no longer an option.

Objective: The aim of this study is to investigate the mechanism behind the protective effects of estrogen against inflammation-mediated bone loss in order to facilitate the development of new estrogen-like treatment strategies lacking negative side-effects.

Methods: We have used transgenic female mice lacking estrogen receptor alpha (ER α)¹. The mice were ovariectomized and a placebo or estradiol (1.5 μ g/day) pellet was implanted subcutaneously. 10 days after the operation, arthritis (AIA, antigen-induced arthritis) was induced in one knee by injection of methylated BSA (mBSA), while the other knee was used as internal control and injected with saline. At termination, 14 days after the induction of arthritis, knees were harvested for histological examination of bone destruction. T lymphocytes in the spleen were analyzed using flow cytometry and proliferation assay.

Results: We observed that estrogen protects against both synovitis (-22%, $p < 0.05$) and bone erosion (-62%, $p < 0.001$) in wild type (WT) females, while no protective effect of estrogen was detected in females lacking ER α . Both the frequency of T lymphocytes (-29%, $p < 0.01$) and T cell proliferation (-52%, $p < 0.001$) in spleen was decreased after estrogen treatment in WT mice, while no effect of estrogen was seen in mice lacking ER α .

Conclusions: These findings lead us to conclude that ER α is required for the protective effects of estrogen against inflammation-mediated bone loss and that T cells might be involved in the estrogenic anti-arthritis and bone-protective effects.

Estrogen Response Element Binding Protein is a Multi-Site Regulator in Bone Cells at the Level of Chromatin Remodeling, Transcription and mRNA Handling. Hong Chen^{*1}, Linda Gilbert², Thomas Lisse³, Martin Hewison⁴, Mark Nanes⁵, John Adams⁶. ¹VA / Emory University School of Medicine, USA, ²VA medical Center at Atlanta, USA, ³UCLA/Orthopaedic Hospital Research Center, USA, ⁴UCLA, USA, ⁵VA Medical Center & Emory University, USA, ⁶University of California, Los Angeles, USA

The estrogen response element binding protein (ERE-BP) is a heterogeneous nuclear ribonucleoprotein that competes in a dominant-negative mode with the estradiol (E2)-liganded estrogen receptor-alpha (ER) for occupation of EREs possessing a half-site motif of AGGTCA. ERE-BP stimulates pre-osteoblast (preOB)-like cell RANKL expression by 2-4-fold, antagonizing E2 up-regulation of OPG and enhancing osteoclastogenesis. Although the RANKL promoter (8000bp) in human preOB does not harbor a full ERE, it does possess a consensus half-site to which both the ER and ERE-BP are bound in chromatin immunoprecipitation (ChIP) assays with an affinity for ERE-BP >> E2-liganded ER > unliganded ER. ERE-BP directly stimulates RANKL transcription 2-3 fold. Increased transcription is also observed with the histone deacetylase inhibitor trichostatin A (TSA). Recruitment of HDAC3 to the RANKL promoter was inhibited by ERE-BP over-expression in preOB cells and completely blocked in the presence of TSA. These events were accompanied by a 4-fold increase in acetylated histone 3, suggesting that ERE-BP acts to preserve euchromatin at the RANKL gene locus. Binding in *cis* to DNA in the RANKL promoter is not the only means by which ERE-BP can interact in *trans* with nucleic acid recognition motifs. Compared to vector-alone transfected cells, preOB over-expressing the ERE-BP demonstrated a specific binding of the ERE-BP, but not the ER, to an AGGUCA *cis* element in the 3'UTR instability domain of the RANKL mRNA by RNA immunoprecipitation (RIP) assay. As was previously observed in its ds DNA binding activity, the ERE-BP cycled on and off the AGGUCA ssRNA

element at 45-minute intervals. Finally, ERE-BP over-expression was shown to be capable of regulating mRNA splicing events, presumably through its ss nucleic acid binding actions, in an E2-ER-ERE-driven CD44 minigene expressed in preOB; ERE-BP over-expression increased the ratio of spliced:unspliced minigene present in preOB cells. In sum these data suggest that when abundantly expressed in preOB, ERE-BP can promote the generation of mature RANKL RNA via its ability to interact in *trans* with RNA and DNA, modulating chromatin remodeling, transcription, splicing and 3'UTR-controlled mRNA handling events.

1, 25-dihydroxyvitamin D Inhibits Growth and Induces Apoptosis of Breast Cancer Stem Cells. Jiarong Li^{*1}, Jing Lian¹, Richard Kremer². ¹McGill University, Canada, ²McGill University, Royal Victoria Hospital, Canada

Growth of many types of cancer is sustained by cancer stem cells (CSC's). It is widely believed that tumour recurrence is linked to CSC's survival following standard therapeutic regimen. 1,25-dihydroxyvitamin D (1,25(OH)2D) is a potent growth inhibitor of many cancers including breast cancer. However, its effect against CSC's has never been investigated. In this study we isolated breast cancer cells from polyomavirus middle T transgenic mice. Single-cell suspensions isolated from mouse mammary tumours were suspended at a density of 40,000 cells per millilitre in mamoculture basal medium containing proliferation supplements (Stemcell Technologies, Vancouver, Canada) in 6 well ultra low attachment tissue culture plates. Primary mammospheres were allowed to form in serum free medium containing increasing concentrations of 1, 25(OH)2D or vehicle. At 7 days primary mammospheres were centrifuged, dissociated with trypsin for 5 minutes at 37C and passed through a 23 gauge needle to obtain single cells. Cells were plated at a density of 10,000 cells per millilitre in ultra low attachment tissue culture plates to obtain secondary spheres. At 7 days the process was repeated to obtain tertiary mammospheres. Before each passage spheres were counted manually using Zeiss Axiovision software (Carl Zeiss, Jena, Germany) and isolated cells were also analyzed by immunofluorescence. Breast CSC's were identified by CD44, CD24 and ALDH1 staining. Apoptosis was examined by TUNEL assay and bcl2 expression. Addition of 1, 25(OH)2D resulted in a dose dependent growth inhibition of primary mammosphere cultures with 50% inhibition seen at 10⁻⁷M concentration. This inhibition was sustained in secondary and tertiary mammospheres. There was also a significant reduction in ALDH1 positive cells and a significant increase in apoptotic cell death in 1, 25(OH)2D treated mammospheres.

These data therefore suggest that 1, 25(OH)2D exerts its anti-cancer effect at least in part through inhibition of cell viability and engenderment of apoptosis in the CSC's population.

25-Hydroxyvitamin D, Parathyroid Hormone and Muscle Relationships in Early Pubertal Adolescents. Jamie Williams¹, Ashley Ferira¹, Emma Laing^{*1}, Dorothy Hausman¹, Connie Weaver², Munro Peacock³, Kathleen Hill⁴, Berdine Martin², Stuart Warden⁵, Norman Pollock⁶, Richard Lewis¹. ¹The University of Georgia, USA, ²Purdue University, USA, ³Indiana University Medical Center, USA, ⁴Indiana University School of Medicine, USA, ⁵Indiana University, USA, ⁶Georgia Health Sciences University, USA

The link between vitamin D status and muscle is an emerging area of interest based on studies in older adults that demonstrate a positive influence of vitamin D on muscle strength and function. Much less is known regarding this relationship in pediatric populations, of which a large number of US children have low circulating 25-hydroxyvitamin D [25(OH)D] concentrations. The objective of this study was to determine associations between serum 25(OH)D and intact parathyroid hormone (PTH) and muscle-related parameters [i.e., radial and tibial muscle cross-sectional area (MCSA) and density by peripheral quantitative computed tomography, forearm muscle strength by handgrip dynamometry, and total body fat-free soft tissue (FFST) by DXA] in early pubertal children (N=126), and if race and sex modify these relationships. Serum 25(OH)D and PTH concentrations were measured using RIA. Black (n=21) and white (n=40) males (aged 10 to 13 years) and black (n=25) and white (n=40) females (aged 9 to 12 years) living at 34N latitude participated in this study. Statistical analyses were performed using bivariate and partial correlations, controlling for race and sex. No significant relationships were found between serum 25(OH)D and MCSA, muscle density, forearm strength or FFST. Serum 25(OH)D was negatively correlated with PTH ($r = -0.36$; $p < 0.01$). PTH was positively related to radial and tibial MCSA ($r > 0.19$; $p < 0.04$) and negatively related to tibial muscle density ($r = -0.22$; $p = 0.02$). Though not statistically significant, PTH was positively related to FFST ($r = 0.16$; $p = 0.08$). After adjusting for differences in race and sex, positive correlations for PTH remained for radial and tibial MCSA, and showed a significant relationship to FFST ($r > 0.21$; $p < 0.03$). This cross-sectional study did not support a relationship between serum 25(OH)D and muscle strength indices in a sample of early pubertal children. However, the results suggest that PTH may be a more relevant marker of muscle function than 25(OH)D in early pubertal children. A vitamin D intervention trial is underway to help elucidate these relationships and

determine if there is an optimal vitamin D status for musculoskeletal strength and development during growth.

MO0483

Associations between Serum Vitamin D, Cardiometabolic Risk Factors and Visceral Adiposity in Obese Children. Ashley Ferira¹, Norman Pollock², Emma Laing¹, Dorothy Hausman³, Yanbin Dong², Richard Lewis¹, Catherine L. Davis². ¹The University of Georgia, USA, ²Georgia Health Sciences University, USA, ³University of Georgia, USA

Limited data exist on the relationship between circulating vitamin D levels and cardiometabolic risk factors (CMR), particularly in children at risk for cardiovascular disease and diabetes. This study examined whether lower vitamin D levels are associated with CMR in obese (OB) children living in the southeastern United States (latitude: 33N). Associations between vitamin D levels and adiposity distribution were also determined. OB sedentary children (N=222, aged 7-11 years, 58% female, 58% black) were classified into four groups: OB+Healthy (n=43), OB+1CMR (n=94), OB+2CMR (n=59), and metabolic syndrome (OB+≥3CMR, n=26). Serum 25-hydroxyvitamin D (25-OHD) concentrations were assayed by RIA. CMR were measured using standard methods and defined according to pediatric definitions of metabolic syndrome: fasting glucose ≥100 mg/dL, HDL cholesterol ≤40 mg/dL, triglycerides ≥110 mg/dL, systolic or diastolic blood pressure ≥90th percentile for age, sex and height, and waist circumference ≥90th percentile for age and sex. Visceral adipose tissue and subcutaneous adipose tissue were assessed using magnetic resonance imaging. The CMR distributions in the participants were: 19% with fasting glucose ≥100 mg/dL, 18% with triglycerides ≥110 mg/dL, 25% with HDL-cholesterol ≤40 mg/dL, 3% with blood pressure ≥90th percentile for age, sex and height, and 67% with waist circumference ≥90th percentile for age and sex. Using ANCOVA, controlling for age, sex, race and season, 25-OHD levels were examined across participants grouped by number of features of the metabolic syndrome. Serum 25-OHD levels were significantly higher in OB+Healthy and OB+1CMR groups compared to those with metabolic syndrome (both $P < 0.05$, Figure). Multiple linear regression, adjusting for the same covariates, revealed that fasting glucose ($\beta = -0.18$), HDL-cholesterol ($\beta = 0.19$), waist circumference ($\beta = -0.19$), and visceral adipose tissue ($\beta = -0.24$) were associated with 25-OHD concentrations (all $P < 0.04$). No relations were found between 25-OHD and triglyceride level, blood pressure or subcutaneous adipose tissue. In obese children, lower circulating vitamin D levels are associated with multiple measures known to increase cardiometabolic disease risk. In addition, it appears that greater levels of visceral, rather than subcutaneous, adiposity may be an important mediating factor in the correlation between lower vitamin D levels and increasing number of risk factors for cardiovascular disease and diabetes.

FIGURE. Mean (±SE) serum 25-OHD concentrations by number of features of the metabolic syndrome in 7-11 year old obese children (N=222). * P for trend on the basis of analysis of covariance, adjusted for age, sex, race, and season. $^{\dagger}P < 0.05$, significantly different from metabolic syndrome group (Tukey's honestly significant difference adjustment for multiple comparisons).

MO0484

Co-expression of Human hnRNPC1 and C2 Suppresses Vitamin D Receptor-mediated Transcriptional Responses in Mouse Osteoblastic Cells. Thomas Lisse¹, Rene Chun², John Adams³, Martin Hewison⁴. ¹UCLA/Orthopaedic Hospital Research Center, USA, ²Orthopedic Hospital Research Center UCLA, USA, ³University of California, Los Angeles, USA, ⁴UCLA, USA

Heterogeneous nuclear ribonucleoprotein (hnRNP) C plays a key role in RNA processing but also exerts a dominant negative effect on responses to 1,25-dihydroxyvitamin D (1,25D) by functioning as a vitamin D response element-binding protein (VDRE-BP). While constitutive over-expression of hnRNPC results in a form of hereditary vitamin D-resistant rickets (HVDRR) in both humans and New World Primates (NWP), the actions of hnRNPC have never been directly assessed in mouse bone or bone cells. The physiologically active form of human hnRNP C is a tetramer of hnRNPC1 (huC1) and hnRNPC2 (huC2). As such, oligomerization and organization of subunits is critical to in vivo nucleic acid-binding activity. Studies were therefore carried out to determine whether huC1/C2 proteins expressed in mouse osteoblastic cells promote resistance to 1,25D as observed in higher species. Transient (CMV) over-expression of either huC1 or huC2 alone, or stable lentiviral transfection using a bone-specific mouse type I collagen (2.3kb) promoter-driven huC1 plasmid resulted in no change in 1,25D-induced (10 nM, 6 hrs) Cyp24a1 mRNA expression compared to empty vector control. By contrast, co-over-expression of both huC1 and huC2 or use of a bone-specific polycistronic vector using a "self-cleaving" 2A peptide to co-express huC1/C2 suppressed Cyp24a1 mRNA and another osteoblast target for 1,25D, the mTOR-inhibitor DDIT4, in a 1,25D-dose-dependent manner. In all cases, endogenous levels of mouse hnRNPC mRNA remained constant following transfection with huC1/C2. Structural diversity of hnRNP C between human/NWPs and mouse/rat/rabbit/dog was highlighted by sequence variations at the last helix in the CLZ domain. The predicted loss of distal helical function in hnRNP Cs from lower species provides an explanation for the lack of interaction between huC1/C2 and their mouse counterparts. These data provide new evidence of a role for hnRNP C1/C2 as a dominant-negative-acting inhibitor of 1,25D-driven gene expression in bone, and further suggest that species-specific tetramerization is a crucial determinant of its actions as a regulator of VDR-directed transactivation.

Comparison of Two Fully Automated Total 25 Vitamin D Immunoassays. Heather Pham¹, Benny Larsson². ¹Immunodiagnostic Systems, United Kingdom, ²Universitetssjukhuset i Malmö, Sweden

Background: Two fully automated immunoassays for Total 25-OH vitamin D were compared with a validated liquid chromatography-tandem mass spectrometry (LC-MS/MS) method. We assessed the analytical performance of the IDS-iSYS 25-OH vitamin D assay on the IDS-iSYS platform and compared it to a recently commercialized Architect 25-OH vitamin D.

Methods: The IDS-iSYS 25-OH Vitamin D assay is based on chemiluminescence technology for use on the IDS-iSYS platform. This method is traceable to UV quantification. The Architect 25-OH Vitamin D assay is a delayed one-step immunoassay and is referenced against the Liaison Total Vitamin D method. The LC-MS/MS method used protein precipitation of serum with a hexa-deuterated 25-OH vitamin D3 internal standard to correct for recovery. The ionisation source was APCI, and the method was calibrated with Chromsystems calibrator. This calibrator has direct traceability to NIST reference standards for 25-OH vitamin D3 and 25-OH vitamin D2. The Total 25-OH vitamin D level was measured in 88 serum samples using the above described methods. The correlation between the methods was analysed using Passing-Bablok comparison fit; the 25-OH vitamin D levels were classified by vitamin D status.

Results: A comparison of IDS-iSYS 25-OH vitamin D with LC-MS/MS yielded the regression equation: IDS-iSYS = 1.03 x (LC-MS/MS) + 1.50 (average bias: +2.6ng/mL). The corresponding equation with Architect was: IDS-iSYS = 0.69 x (Architect) - 1.24 (average bias: -15.5ng/mL). The comparison between Architect and LC-MS/MS produced an equation: Architect = 1.55 x (LC-MS/MS) + 3.10 (average bias: +17.9ng/mL). Table below summarised number of samples classified vitamin D status by each method.

Conclusions: The IDS-iSYS 25-OH vitamin D concentrations were in good agreement with those determined by the LC-MS/MS. It has proven itself as a sensitive and precise fully automated, co-specific 25-OH vitamin D assay for clinical laboratories. On the contrary, the Architect was not only under-classified insufficient samples; it also classified 5 samples as possible intoxication.

25-OH vitamin D Level (ng/mL)	Number of samples (%)		
	LC-MS/MS	IDS-iSYS	Architect
Insufficient <30	51 (58%)	47 (53%)	29 (33%)
Sufficient 30-100	37 (42%)	41 (47%)	54 (61%)
Possible Intoxication >100	0	0	5 (6%)

Number of samples classified vitamin D status

Effect of Growth Factors on Vitamin D Receptor and its Role in Vitamin D-Mediated Growth Suppression in Porcine Coronary Artery Smooth Muscle Cells. Gaurav Gupta¹, Tanupriya Agrawal¹, Devendra Agrawal². ¹Creighton University, USA, ²Creighton University School of Medicine, USA

Purpose: Recent studies have demonstrated that Vitamin D, a steroid hormone precursor, has biological activity in different tissues including cardiomyocytes, cancer cells, cells of immune system, and vascular smooth muscle cells (VSMC). Calcitriol is the bioactive form of vitamin D that binds to vitamin D receptor (VDR) in target cells and triggers downstream signaling to produce phenotypic changes in these cells. These effects suggest potential use of VDR ligands in the management of different diseases including restenosis. VSMC proliferation by platelet derived growth factor (PDGF)-BB and insulin like growth factor (IGF-1) play an important role in development and progression of restenosis. The purpose of this study was to examine the effect of PDGF-BB and IGF-1 stimulation on VDR expression in porcine coronary artery smooth muscle cells (PCASMCs). We also examined the effect of calcitriol on PDGF-BB and IGF-1 induced proliferation in VDR knockdown PCASMCs.

Methods: PCASMCs were isolated and cultured from domestic swine. PCASMCs were stimulated with PDGF-BB and IGF-1 with and without calcitriol and mRNA and protein expression of VDR were analyzed by real-time PCR and Western blot, respectively. PCASMCs were transfected with control siRNA or VDR siRNA and cells proliferation was examined after stimulation with platelet derived growth factor (PDGF)-BB and insulin like growth factor (IGF)-1 with and without calcitriol by analyzing proliferating cell nuclear antigen (PCNA) expression and MTT assay.

Results: Stimulation of PCASMCs with IGF-1 and PDGF-BB significantly downregulated mRNA transcripts and protein expression of VDR in PCASMCs. VDR expression was significantly downregulated by VDR siRNA in PCASMCs. Anti-proliferative effect of calcitriol was abolished in PCASMCs treated with VDR siRNA.

Conclusion: These data suggest that high concentration of PDGF-BB and IGF-1 downregulate VDR expression in PCASMCs. Calcitriol acts through VDR to inhibit PDGF-BB and IGF-1 induced cell proliferation in PCASMCs. Thus, downregulation of VDR in SMCs of post interventional arteries due to high concentration of growth factors could be a potentially contributing factor in neointimal hyperplasia.

Prevalence of Vitamin D Deficiency and Its Relationship with Sun Exposure and Skin Phototype in Elderly Men Living in the Tropics. marcelo cabral¹, carla borges¹, Daniele Fontan², Leonardo Bandeira¹, NARRIANE CHAVES¹, Francisco Bandeira³. ¹doctor(MD), Brazil, ²Brazil, ³UPE, Brazil

Objectives: To determine the prevalence of vitamin D deficiency among men and, its association with sun exposure and skin phototypes in the city of Recife, Brazil (8°S), in 284 men (mean age 69.446.49 years, body mass index(BMI) 25.674.31 Kg/ m2, sun index= hours of sun exposure per week x fraction of body surface area exposed=5.495.05). **Methods:** We evaluated the serum levels of 25 hydroxyvitamin D (25OHD), the sun index and skin phototype according to Fitzpatrick classification. **Results:** The mean serum 25OHD was 27.8713.52 ng/ml. The prevalence of vitamin D deficiency was 31.5% (95% CI 26.236.8) and 66.7% (95% CI 61.372.1) when cutoff of less than 20ng/ml and 30ng/ml were used, respectively. There were no statistically significant differences (p=0.113) between the mean serum 25OHD (23.9814.66 vs 29.8813.78) of the individuals in the lower quartile of the sun index(Q1:1.96), compared with those in the upper quartile(Q4:7.86), nor the prevalence of vitamin D deficiency between lower quartile and upper quartile (33.3% x 27.1%) when a cut point of 30ng/ml for serum 25OHD levels was used. Mean sun index was significantly different between those who had serum 25OHD levels below or above 20ng/ml(4.463.69 vs 6.015.54, p=0.006); however, no differences were seen when the cutoff of 25ng/ml(5.074.31 vs 5.955.69;p=0.149) and 30ng/ml(5.224.43 vs 6.126.14;p=0.160) were used. After adjustment, by linear regression analysis, for potential confounders, the sun index and body mass index were positively and negatively associated with serum 25OHD, respectively. Most subjects (67%) had skin types IV,V or VI. Low calcium intake was observed in 72% of the individuals, and only seven (2.5%) were using vitamin supplements. **Conclusion:** We found a high prevalence of vitamin D deficiency in elderly men, despite a high sun exposure. Sun exposure, had an independent effect on serum 25OHD levels, but this effect had a minimal impact on prevalence rates, suggesting that even large amounts of sun exposure may not be sufficient to achieve serum 25OHD targets of 25-30ng/ml.

Similar Vitamin D₂ and D₃ Pharmacokinetics with a Single and Daily Doses. Silvina Mastaglia¹, Mariana Seijo², Graciela Brito³, Guillermo Keller⁴, Julia Somoza⁵, Roberto Diez⁴, Guillermo Di Girolamo⁴, Beatriz Oliveri⁵. ¹Seccion Osteopatías Medicas, Hospital de Clínicas, Universidad de Buenos Aires. Consejo Nacional de Investigaciones Científicas y Tecnológicas (CONICET), Argentina, ²Seccion Osteopatías Medicas, Hospital de Clínicas, Universidad de Buenos Aires, Argentina, ³Seccion Osteopatías Medicas, Hospital de Clínicas, Universidad de Buenos Aires. Agencia Nacional de Promocion Científica y Tecnológica (ANPCyT), Argentina, ⁴2 Catedra de Farmacología, Facultad de Medicina, Universidad de Buenos Aires, Argentina, ⁵Seccion Osteopatías Medicas, Hospital de Clínicas, Universidad de Buenos Aires. Consejo Nacional de Investigaciones Científicas y Tecnológicas (CONICET), Argentina

Some studies found cholecalciferol (D3) to be superior to ergocalciferol (D2) based on the effect of increasing or maintaining serum 25-hydroxyvitamin-D (25OHD) levels. However, others reported both calciferols to be equivalent. The aim of this study was to clarify and compare the pharmacokinetics of D2 and D3. We carried out a single-blind, placebo-controlled randomized trial during 11 weeks (September to December 2010) in Buenos Aires city (34°S). Thirty-three young healthy volunteers (7M/ 26F) with an age of (meanSD) 33.46 years and BMI 22.62 Kg/m2 were included. The subjects were divided in groups: D2 (n=11); D3 (n=11) and placebo (n=11). In the D groups the subjects received at the start a single dose of 100,000IU and 4,800 IU/day (d) of the vitamin D allocated from 7 to 21 d. No vitamin D was administered from 22 to 77 d. The serum samples were obtained at basal and d: 3, 7, 14, 21, 35, 49, 63 and 77 to measure sCa, sP, iPTH, BAP, 25OHD (RIA-DIASORIN) and 2 hours urinary uCa/uCr ratio. Baseline 25OHD (ng/ml) levels were: D2: 16.37; D3: 24.26 (p<0.01) and placebo: 22.67. No differences were observed in the other biochemical parameters whereas placebo values of 25OHD did not increase over treatment, vitamin D administration augmented serum 25OHD levels in each sampling point, as shown in figure 1. To take into account variability in basal 25OHD serum levels, subtraction of basal values was performed before pharmacokinetic analysis. For D3-treated subjects, AUC was 1107481 ng.d.ml-1 (range 331-1920, 95%CI 823-1391), ke -0.2460.104 day-1 (range: -0.479 to -0.125, 95%CI -0.307 to -0.185) and t_{1/2} 3.2671.274 days (range 1.448-5.545, 95%CI 2.514-4.020). For D2-treated subjects AUC was 1005352 ng.d.ml-1 (range 638-1784, 95%CI 797-1213), ke -0.3210.245 day-1 (range: -0.911 to -0.107, 95%CI -0.466 to -0.176) and t_{1/2} 3.1051.658 days (range 0.761-6.469, 95%CI 2.124-4.085). Under this administration scheme, no pharmacokinetic differences were found between the two treatments. **Conclusion:** under the experimental conditions selected, vitamin D2 was equally effective as vitamin D3 in raising and maintaining 25OHD and levels.

Figure 1: Incremental serum 25(OH)D levels mean ± SE in the time course corresponding to the two calciferol and placebo treatment groups.

MO0489

State of the Art of Vitamin D Assays: Latest Generation Assays. Christopher-John Farrell¹, Steven Martain², Isabella Straub³, Paul Williams⁴, Markus Herrmann⁴. ¹PaLMS & Laverty Pathology, Australia, ²Laverty Pathology, Australia, ³University of Sydney, Australia, ⁴Royal Prince Alfred Hospital & University of Sydney, Australia

Background: A number of pre-existing automated vitamin D assays have recently been modified and several new assays have been launched. This study aimed to

compare latest generation automated vitamin D immunoassays with liquid chromatography tandem mass spectrometry (LCMS) measurement.

Methods: 170 randomly selected serum samples were divided into 6 aliquots, stored at -20°C and analysed in batches, with freshly thawed aliquots used for all analyses. Vitamin D was measured by LCMS (2 different methods at independent laboratories), a radioimmunoassay (RIA) from DiaSorin as well as 5 automated chemiluminescent immunoassays from Abbott, DiaSorin, IDS, Roche and Siemens. The Roche assay used was the recent monoclonal vitamin D assay which specifically detected 25-hydroxy vitamin D₃. All other immunoassays detected both 25-hydroxy vitamin D₂ and D₃ and reported a total vitamin D result. The DiaSorin immunoassay was a pre-market assay. To assess intra- and inter-assay variability we measured 5 replicates of a high and of a low serum pool over 5 consecutive days.

Results: The two LCMS methods correlated well with $r = 0.984$ and an average bias of 2.0%. In the cohort tested, all immunoassays correlated well with LCMS with the exception of Roche (table 1). At vitamin D levels between 25-120 nmol/L DiaSorin, Siemens and RIA showed excellent accuracy, while Abbott, IDS and Roche exhibited variable bias (table 1). Vitamin D levels < 20 nmol/L were only measured accurately by DiaSorin, IDS and RIA, while Siemens and Abbott showed substantial bias at these concentrations. Intra- and inter-assay precision differed between assays but was within the acceptable range for all tests.

Conclusion: Latest generation automated vitamin D immunoassays demonstrated significantly improved performance and compared well with LCMS. While most automated assays produced acceptable results across the clinically relevant range Siemens and DiaSorin demonstrated superior accuracy. The assays tested showed variable performance at low vitamin D concentrations and laboratories should adapt their reportable range accordingly.

	Versus avg. of 2 LC Tandem MS methods		
	Correlation coefficient	Avg. bias if vit D > 25 nmol/L	Avg. bias if vit D < 25 nmol/L
Abbott	0.932	25.21%	102.62%

The antimicrobial peptide cathelicidin (hCAP18) is stored in several cell types of the system immune, mainly in the granules of neutrophils (PMN). 1,25 (OH)₂D is a direct inducer of expression of the gene encoding hCAP18. The aim of the present study was to evaluate the expression of leukocytes' cathelicidin in young healthy volunteers supplemented with vitamin D₂ and D₃. Thirty-three young healthy volunteers (7M/ 26F) with an age of (mean SD) 33.4 6 years and BMI of 22.6 2 Kg/m² were included in this randomized placebo controlled trial for 11 weeks (Sep-Dec 2010). Subjects were allocated to the following groups: Vitamin D₂ (n=11); Vitamin D₃ (n=11) and placebo (n=11). At the start of the study a single dose (100,000 IU/day) of vitamin D₂ or D₃ according to the group was administered. Thereafter, from d 7th to 21st of the study, volunteers received 4,800 IU/d of the corresponding vitamin D. No vitamin D was administered from 22 to 77 d. No infection or allergic symptoms were reported during the study. At baseline and d: 7, 21, and 63 blood samples were obtained to measure serum Ca, P, BAP and 25OHD (RIA-DIASORIN). At each sampling point, the expression of hCAP18 in peripheral blood PMN was assessed by flow cytometry with a FACSort® (Becton-Dickinson, San Jose,

CA, USA) and the CellQuest® software (Becton-Dickinson), using the mouse monoclonal antibody OSX12 (Abcam, UK), specific for hCAP18, and a secondary incubation with FITC anti-murine IgG (Abcam). A protocol of permeation used for neutrophil myeloperoxidase was used, and myeloperoxidase labeling was included as control. Region corresponding to PMN was defined by side and forward scattering; PMN expressing a higher level of hCAP18 were identified in the fluorescence histogram of the neutrophils region and defined as M1. Most (>95%) PMN expressed intra-granular cathelicidin, either at the basal sample or after vitamin D or placebo treatment. Only 1% to 2% depicted higher expression (Figure1). No significant differences were observed among groups in the expression hCAP18 in PMN, either as level of expression (mean fluorescence) or as percentage of cells over-expressing hCAP18, in spite of the significant increment of 25OHD levels in both supplemented groups (d7:100%;d21:90% and d63:60% compared to basal levels). Under these experimental conditions, PMNs cathelicidin is not modified by vitamin D supplementation, independently of calciferol used.

Figure 1: Comparison of hCAP18 expression in PMN-M1 baseline and D21 of the study

TSH and Bone: An Update. Li Sun^{*1}, Ramkumarie Baliram¹, L.L. Zhu¹, R. Latif¹, G. Colaianni¹, T. Yuen¹, G. Zhu¹, J. Berkowitz¹, Y. Peng¹, S. Fritz¹, J. Li¹, J. Iqbal¹, T. F. Davies¹, Mone Zaidi². ¹Mount Sinai School of Medicine, USA, ²Mount Sinai Medical Center, USA

We have shown that TSH receptor (TSHR) deficient mice exhibit bone loss; that TSH inhibits bone resorption by suppressing TNF α ; and that TSH stimulates bone formation to restore post-ovariectomy bone loss. We now extend these observations. We show that murine ES cells can be induced to form mature, mineralizing osteoblasts. TSH stimulates osteoblast differentiation by activating protein kinase C δ and up-regulating the Wnt components Frz (frizzled) and Wnt5a. We suggest that a TSH-induced, fast-forward, short loop permits Wnt5a production in bone marrow, which not only enhances osteoblast differentiation, but also stimulates osteoprotegerin synthesis to inhibit resorption. In separate studies, we provide direct evidence that effects of TSHR deficiency on bone are mediated through TNF α . We generated compound mutants by crossing TSHR^{-/-} with TNF α ^{+/-} mice. Micro-CT confirmed reduced BV/TV as a function of decreasing TSHR levels, accompanied by increased trabecular spacing and reduced trabecular number. The genetic deletion of TNF α completely reversed the bone loss in both TSHR genotypes. Thus, for example BV/TV of TSHR^{+/-}/TNF α ^{+/-} mice was significantly greater than that of TSHR^{+/-}/TNF α ^{+/+} mice. Likewise, the enhanced TRAP-positive osteoclast and CFU-f/CFU-ob seen in TSHR^{-/-} mice was abrogated in compound mutants lacking TNF α . That the genetic removal of TNF α fully rescued osteopenia in TSHR^{-/-} mice proved that TNF α mediates, at least in part, the bone loss of TSHR deficiency. Finally, to determine that TSHR deficiency causes the bone loss in hyperthyroidism, wild type and TSHR^{-/-} mice were first treated with carbimazole, and then, implanted with 0, 1, or 5 mg T4 pellets to render the mice hypothyroid, euthyroid or hyperthyroid, respectively. The hypothesis was that, if TSHR-deficiency caused bone loss independently of high T4 levels, then bone mass (BMD) and bone resorption (serum CTx) would be markedly greater in hyperthyroid-TSHR^{-/-} than in hyperthyroid-TSHR^{+/+} mice. This indeed was the case, establishing that, at least in the setting of experimental hyperthyroidism, TSHR deficiency was permissive to further bone loss. Together, the studies substantiate the osteo-protective action of TSH, establish its mediation through TNF α suppression, and prove that TSH deficiency is an independent trigger for bone loss in hyperthyroidism.

Teriparatide, Vitamin D, and Calcium Healed Bilateral Subtrochanteric Stress Fractures in a Postmenopausal Woman with a 13-Year History of Continuous Alendronate Therapy. Stephen J. Gomberg, Rosanna L. Wustrack, Nicola Napoli, Claude D. Arnaud, and Dennis M. Black; West Oaks Orthopaedic Associates (S.J.G.), Thousand Oaks, California 91361; University of California; San Francisco (R.L.W., C.D.A., D.M.B.), San Francisco, California 94143; and Università Campus Bio-Medico di Roma (N.N.), 00128 Rome, Italy.

Background: Oral bisphosphonates comprise the most widely prescribed class of antiosteoporotic drugs. Recent reports, however, propose a link between prolonged bisphosphonate use and atypical, low-energy, subtrochanteric fractures. **Objectives:** The aim was to describe the clinical course of a patient treated long-term with alendronate who developed subtrochanteric stress fractures and to propose a hypothesis to explain teriparatide's potential contribution in healing the patient's stress fractures. **Results:** Magnetic resonance imaging (MRI) showed classical bilateral stress fractures of the mid-femora. Baseline serum 25-hydroxyvitamin D3 was low; bone-specific alkaline phosphatase was slightly increased; serum carboxyterminal cross-linking telopeptide of bone collagen and urine aminoterminal cross-linking telopeptide of bone collagen were low to normal, as was serum osteocalcin. Dual-energy x-ray absorptiometry showed osteopenic vertebral bone mineral density and osteoporotic hip values. Treatment with large doses of oral vitamin D increased serum 25-hydroxyvitamin D3 to normal within 2 months, after which it remained in the normal range with maintenance doses. High pain, present as an initial symptom, intensified, and the MRI appearance of the fractures worsened. Teriparatide treatment commenced, and 6 months later, repeat MRI showed decreased edema at the fracture sites with faint cortical bridging. High pain and lower limb weakness disappeared over the next year, and complete fracture healing was established (MRI). **Conclusions:** Based upon the chronology of fracture healing in our patient and published evidence that teriparatide heals stress fractures in a rat model, we think that teriparatide was probably primary in this patient's positive response to therapy, with calcium, vitamin D therapy, and alendronate discontinuation playing secondary roles. Familial Fibrogenesis Imperfecta Ossium (FFIO) Bhadada SK*, Bhansali A*, Rao DS** Department of Endocrinology Postgraduate Institute of Medical Education & Research Chandigarh, India*. Bone and Mineral Laboratory, Henry Ford Health System, Detroit, Michigan, USA**.

Introduction: Fibrogenesis imperfecta ossium (FIO) is an uncommon, crippling, relentlessly progressive and ultimately fatal metabolic bone disease. The disease is of adult onset with unknown etiology. Clinically, it is characterized by generalized bone pains, multiple spontaneous fractures in both the axial and appendicular skeleton. The plasma biochemistry is normal except for elevated alkaline phosphatase activity. A distinctive "fishnet appearance" is observed on radiographs in advanced disease. Histopathology consists of abundant osteoblasts and osteoclasts with thick osteoid seams. Tetracycline labeling of decalcified bone tissue confirms the presence of osteomalacia. However, on polarized light microscopy, bone collagen fibrils are not birefringent. We describe a family of FIO, in whom four adult members were affected, suggesting an autosomal dominant inheritance pattern. To the best of our knowledge this is the largest family of FIO in the world literature. **Case Report (Index Case):** A 40-year-old man presented with a 10 year history of generalized bone pains requiring round the clock analgesics. One year before presentation he developed spontaneous pain in the right hip, since then he had required a stick to walk. A worsening of symptoms 3 months before presentation meant that then required the help of somebody to perform the activities of daily life. He had strong family history of similar illness in the mother, maternal uncle and younger brother, with both his mother and maternal uncle having died after prolonged similar illness. He had difficulty in getting up from squatting position and needed a stick to help with walking. The hip joint movements were painful and restricted. The rest of the systemic examination was non-contributory. His laboratory evaluations including TmP/GFR were normal except mild elevation in total alkaline phosphatase (AP). The serum intact PTH level by immunochemiluminometry was 30 pg/ml (reference range: 10-69 pg/ml). Serum 25-hydroxyvitamin D level was 59.9 (reference range 9 – 37 ng/ml). Serum 1,25-hydroxyvitamin D level was 76.6 ng/ml. Arterial blood gases and urine pH were within normal range. Thyroid function tests were normal. Serum tissue transglutaminase antibody (tTG) titre was negative. Urine for Bence Jones protein was negative and serum electrophoresis was normal. Radiographs of the skull and hands were normal. The lumbar spine showed "rugger-jersey" spine with osteopenia. Views of the pelvis showed bilateral coxavara and bilateral femur neck fracture with "fishnet appearance". The chest radiograph showed multiple Looser zones with fractures of several ribs. The lower end of tibia showed "fishnet appearance", tendon calcification and new bone formation. Bone mineral density (BMD) of the hip with a T-score of -2.2 SD. Magnetic resonance imaging of pelvis showed fracture of bilateral neck and hypointense marrow on T1W and T2W sequences. A 99mTc MDP bone scan showed increased radiotracer uptake bilaterally in the shoulders, elbows, wrists, small joints of

hands, multiple sites at bilateral ribs, the entire vertebral column, and lower end of tibia but not the skull. Transiliac bone biopsy showed thickened bony trabeculae with obliteration of marrow spaces and at places, focal areas of exaggerated osteoclastic activity. There was prominent osteoblastic proliferation as well as osteoid like areas were also seen. At places it showed sclerosis, eaten up edges of bone and foci of new calcification (bone formation). With the above mentioned clinical and investigation profile a diagnosis of FIO was considered most likely.

Conclusion: To the best of our knowledge, this is the largest family of FIO and index patient successfully treated with a bone formation and antiresorptive agent with positive outcome.

WG3

Characteristic clinical and radiologic features of Prodromal Bone Deterioration (PBD) in patients on long term bisphosphonate therapy: A case series of seven patients. Manjari Devidi, Shijing Qiu, Saroj Palnitkar, D. Sudhaker Rao. Saint Joseph Hospital, Chicago, IL & Bone & Mineral Research Laboratory, Henry Ford Hospital, Detroit MI.

There has been a great concern about long term use of bisphosphonate (BP) resulting in severe suppression of bone turnover, impaired ability to repair microdamage, and atypical femoral fractures (AFF). We report a case series of 7 patients (all women) with post menopausal osteoporosis on long term BP therapy (duration 3-13 years), who were referred for evaluation and advise for possible BP induced insufficiency fracture of the outer cortex of the femoral mid-shaft with little or no trauma. The mean age was 65.57 years (range 52 to 87 years). Retrospectively six out of these patients had mid thigh pain and characteristic radiographic findings of focal cortical beaking with lucency along the lateral aspect of proximal third of the femur, confirmed by bone scan and/or MRI as insufficiency fracture. A few had bilateral findings even though the pain was unilateral. Bone turnover markers were low to low normal at presentation. Although the incidence of AFF due to BP use is thought to be very rare accounting for about 1% of all femur fractures, the incidence of incomplete femoral outer lateral femoral fractures, which we designated as prodromal bone deterioration (PBD), is likely to be lot higher considering the fact that they can occur without prodromal pain and likely underreported by the physicians. Our retrospective study suggests that prodromal thigh pain is not a prerequisite to PBD and may explain the sudden onset of complete AFFs without trauma; "break & fall" instead of the usual "fall & break" paradigm. Our experience with potential role of bone scan in selected patients to detect impending AFF, prophylactic intra-medullary rod to prevent complete AFF, and anabolic therapy to promote PBD healing will be discussed.

WG4

Vitamin D and Calcium Nutritional Status in Patients with Hip Fractures & Elective Joint Replacement Surgery: Preliminary Results of a Prospective Case Controlled Study. S. Makhoul-Ahwach, S. Ahmadi, J. Miragaya, L. Garcia MD, J. Shah, D. Cadena, N. Shareef, M. Al-Abed, J. Khalil, S. T. Guthrie, M. Laker MD, A. Al-shoha, D. Sudhaker Rao. Bone Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, USA.

Background: Much has been written about the role of vitamin D in the pathogenesis of hip fractures (HFx), but very little is known about the calcium and vitamin D nutritional (VDN) status in acute HFx patients. **Materials & Methods:** We measured serum 25-OHD levels, the best available index of VDN, and PTH, a reasonable surrogate marker for both calcium and VDN status, in acute HFx and elective joint replacement surgery (JRS) patients. Both groups of patients were recruited during the same time period (2009 – 2010) with a final target of at least 100 patients in each group. This is a preliminary report of the first 66 patients (21 HFx & 45 JRS). The main outcome measures were serum 25-OHD and PTH levels. **Results:** As expected, the HFx patients were older (by 10y) and lighter than the JRS patients, but the proportion of genders was similar in the 2 groups (Table). Interestingly, mean 25-OHD was lower in the HFx, but not significantly, than in JRS patients (Table). However, serum PTH levels were significantly higher in the HFx patients.

Variable	HPF Patients	JRS Patients	p≤
Age (years)	76 9	67 9	<0.001
Men/Women (n)	6/15	12/33	n.s.
BMI (kg/m ²)	25.7 6.1	30.6 7.0	0.008
25-OHD (ng/ml)	19.0 11.2	23.7 11.3	n.s.
PTH (pg/ml)	140 160	118 48	<0.05
Ca (mg/dl)	8.2 0.57	8.4 0.66	n.s.
P (mg/dl)	3.0 0.97	2.64 0.79	n.s.
Mg (mEq/L)	2.00 0.28	2.08 0.35	n.s.

Serum Ca, P, & Mg (Table) were similar in the 2 groups. The proportion of patients with 25-OHD <15 or <20, or <30 ng/ml was significantly higher in the HFx compared to JRS patients. Most disturbing was that only 3 of the 21 HFx patients ever had a bone density. **Conclusions:** Many HFx patients still have lower VDN but much better than reported a decade ago implying some improvement in VDN. However, continued high PTH levels imply that calcium intake is also very poor. Chronic hyperparathyroidism, however initiated, may be more important in the pathogenesis of HFx than VDN as has been long assumed, but further studies are needed either to refute or support this hypothesis.

WG6

Oncogenic Osteomalacia: What we have been missing, what we need to do and what we need to change. Ekram T, Dalal I, Bolton C, van Holsbeeck M, Rao D.

Tumor-induced osteomalacia is a rare paraneoplastic syndrome which results in significant morbidity due to generalized skeletal pain, myalgia, fatigue and fractures. The causative tumor, usually a benign osseous or soft tissue tumor, secretes a substance which causes renal phosphate wasting, impaired vitamin D metabolism and osteomalacia. AIM: The purpose of this exhibit is to: 1) Define the role of the physician including the radiologist in clenching the diagnosis of oncogenic osteomalacia -clinical cases of our four patients including pitfalls 2) Identifying a step wise approach in the diagnosis of oncogenic osteomalacia using musculoskeletal radiology and nuclear medicine modalities along with appropriate laboratory work up. 3) Discuss the emergence and pathophysiology of oncogenic hypophosphatemic-osteomalacia. Case series: We describe four patients in whom hypophosphatemic-osteomalacia for years before proper imaging was obtained. We'll discuss what they perceived on their clinical scenario and how the diagnostic workup was achieved. We'll describe what imaging modality used for localization and timing and frequency of testing if previous study was negative. Patients demonstrated characteristic hypophosphatemia, low calculated renal absorption of phosphate and elevated FGF-23. Diagnosis of this rare paraneoplastic syndrome is often delayed and difficulty isolating the causative tumor causes further delay in definitive treatment. We also suggest an imaging algorithm based on these cases and a literature review. The role of radiology in workup is crucial and has not been comprehensively defined. A vast array of imaging modalities may be used in search for the causative tumor including Tc-99m MDP bone scintigraphy, In-111 pentetreotide scintigraphy (Octreoscan), Tc-99m sestamibi scintigraphy, screening MRI, CT, PET CT and FGF-23 venous sampling. Conclusion:

Our cases represent the unfortunately typical pattern of diagnosis and workup for tumor-induced osteomalacia in that patients suffer long before a diagnosis is made and undergo different imaging before identification of the tumor which allows for definitive treatment. It is hoped that the presented imaging algorithm will expedite identification of the causative tumor and definitive treatment.
