We found that infecting MC3T3-E1 cells with a virus impairing both Pit1 and Pit2 severely reduced their ability to mineralize. Infection with this virus only reduced Pi uptake with about 30 % suggesting that the 2 type III transporters are not responsible for the bulk Pi uptake in the cells. However, Pit1 has previously been shown to be upregulated during osteoblastic differentiation implying that at least Pit1 has a specialized function in osteoblasts. To further analyze the role of Pit1, we investigated Pi uptake in undifferentiated MC3T3-E1 cells overexpressing epsilon-tagged human Pit1 or Pit2. These results surprisingly showed that although human Pit1 was present in the cell membrane, it did not facilitate an increased Pi uptake compared to wt cells. In contrast, Pi uptake was more than tripled when Pit2 was overexpressed. Thus, Pi transport does not seem to be Pit1's primary function in undifferentiated MC3T3-E1 cells. Moreover, while osteocalcin could still be upregulated in cells infected with a virus impairing Pit2 function, its expression was undetectable in cells infected with a virus impairing both Pit1 and Pit2 function suggesting that Pit1 has a direct effect on osteoblastic differentiation. In conclusion, the results strongly suggest that Pit1 is necessary for osteoblastic differentiation and, possibly as a consequence of this, also for mineralization. The data do not reveal the exact role of Pit1 in differentiation, however, since overexpressed Pit1 does not appear to facilitate an increase in Pi uptake in undifferentiated MC3T3-E1 cells, we speculate that 1) Pit1 Pi transport function is differently regulated in the membrane in differentiated osteoblasts compared to undifferentiated cells and/or 2) Pit1 may function in signaling.

Heparan Sulfate Proteoglycan (HSPG) Aulfation During In Vitro Osteogenesis. L. M. Haupt^{*1}, A. van Wijnen², G. S. Stein³, V. Nurcombe^{*1}, S. M. Cool¹. ¹Stem cell and tissue repair laboratory, IMCB, Singapore, Singapore, ²Department of Medicine, University of Massachusetts, Worcester, MA, USA, ³Medical School, University of Massachusetts, Worcester, MA, USA.

The heparan sulfate proteoglycans (HSPGs) are a family of extracellular matrix (ECM) and cell membrane-associated complexes that mediate a host of soluble, cell-cell, and ECM interactions. They are composed of a core protein to which highly variable glycosaminoglycan (GAG) sugar chains of the heparan sulfate class are attached, and they are capable of interacting with multiple morphogens, including the fibroblast growth factors (FGFs), Wnts, and the bone morphogenic proteins (BMPs), based upon their side chain sulfation patterns. Structural heterogeneity within the HS chain is generated during chain initiation and polymerisation, with the key modifications performed by the specific, coordinated actions of the glycosyltransferases (Ext-1 and -2), the N-deacetylase/N-sulfotransferases (NDST1-4), as well as 2-O-sulfotransferase and 6-O-sulfotransferase enzymes. Under osteogenic conditions in vitro, MC3T3 cells reach confluence between days 6 and 8, exit the cell cycle and commit toward the osteogenic lineage. We have compared the expression profile of the glycosyltransferase and sulfotransferase enzymes under non-osteogenic and maintenance media culture conditions between the proliferative (Day 6) and differentiative (Day 14) phases of cell culture to determine a role for HSPG sulfation activity during in vitro osteogenesis. Under osteogenic conditions, MC3T3 cells demonstrated increased gene expression of osteogenic markers with a coincident decreased gene expression of Ext-1 and -2 genes but increased expression of NDST-3. Significantly, the osteogenic driven cells dramatically increased their syndecan-1 and glypican-3 gene expression profiles as compared to their non-osteogenic counterparts. In addition, these cells alter their FGFR profile, increasing FGFR2, FGFR3 and FGFR4 gene expression levels. Combined this data implicates the production of shorter, highly sulfated HSPGs during in vitro osteogenesis. In particular, glypican-3 and syndecan-1 appear to be central to the in vitro differentiation of MC3T3 pre-osteoblast cells by the mediating growth factor response of the cells.

Continuous Treatment with PTH Is Anabolic in Cultured Osteoblasts from COX-2 Knockout Mice. H. Huang^{*}, S. Choudhary, L. Raisz, C. Pilbeam. Endocrinology Division, University of Connecticut Health Center, Farmington, CT, USA.

PTH is a potent anabolic agent in vivo, but its anabolic effects in vitro are difficult to demonstrate. Since PTH induces cyclooxygenase (COX)-2 and PGE₂ production in osteoblasts and PGE₂ is anabolic in vitro, we hypothesized that whatever anabolic effects PTH might have in vitro would be diminished in cells from COX-2 knockout (KO) mice compared to cells from wild type (WT) mice. Marrow stromal cells (MSCs) and primary calvarial osteoblasts (POBs) from 6-8 wk old COX-2 KO and WT mice in a CD-1 background were treated with PTH (10⁻⁸ M) or vehicle (control) for up to 21 d. Alkaline phosphatase (ALP) and osteocalcin (OCN) mRNA levels were determined at d 14 and 21, respectively, by real-time PCR and mineralization at d 21 by alizarin red staining. In both MSC and POB cultures, ALP and OCN mRNA expression were 35%-50% lower in KO control cultures than in WT control cultures. PTH had no effect on ALP and OCN mRNA expression in either MSC or POB WT cultures but did increase expression in KO cultures relative to controls. PTH increased ALP and OCN expression 6.5-fold (p < 0.01) and 4.4-fold (p < 0.01), respectively, in KO MSC cultures and 2.1-fold (p < 0.05) and 7.0-fold (p < 0.01), respectively, in KO POB cultures. PTH had no effect on mineralization in WT MSC or POB cultures but increased mineralization in both KO MSC and POB cultures. Basal cAMP levels in POB cultures, in the presence of the phosphodiesterase inhibitor IBMX, were 2-fold higher in WT compared to KO cells (p < 0.05). PTH treatment for 15 min increased cAMP 70-fold in WT and only 40-fold in KO cells. Hence, the increased anabolic effects of PTH in KO cells do not appear to be associated with increased cAMP production. To screen for other factors that might be responsible for the differences in PTH-mediated anabolic effects, POBs from WT and KO mice were cultured for 1 wk and treated with and without PTH for 1, 3 and 24 h and mRNA expression measured by real-time PCR. No change in BMP-2 mRNA expression was observed with PTH. PTH increased Runx-2 mRNA by 2-fold in both WT and KO cultures at 3 h (p < 0.01). PTH increased IGF-1 by 1.7-fold in KO cultures at 24 h (p < 0.01) but had no effect in WT cultures. In contrast to the increased anabolic effects of PTH in KO cells, the PTH stimulation of osteoclast differentiation in marrow cultures, measured by counting TRAP positive multinucleated cells at d 7 of culture, was decreased 70% (p < 0.01) in COX-2 KO cultures compared to WT cultures as reported previously. We conclude that absence of COX-2 increases the stimulatory effects of PTH on osteoblastic differentiation in vitro but decreases the stimulatory effects of PTH on osteoclastic differentiation in vitro. These data are consistent with the observation that intermittent PTH has greater anabolic effects in COX-2 KO mice than in WT mice.

Bioactive Tripeptides Enhance Osteoblast Function In Vitro. M. M. Huttunen*, M. Pekkinen*, M. E. Ahlström*, C. J. Lamberg-Allardt. Dept. of applied chemistry and microbiology/Nutrition, University of Helsinki, Helsinki, Finland.

The purpose of this in vitro study was to elucidate the short- and long-term effects of bioactive tripeptides Ile-Pro-Pro (IPP), Val-Pro-Pro (VPP) and Leu-Lys-Pro (LKP) on osteoblast proliferation, differentiation and bone formation. Preliminary screening of the peptides on osteoblast proliferation was carried out on rat osteosarcoma UMR-106 cells. Further studies were carried out on human mesenchymal stem cells (Poietics, Cambrex Bio Science) purified from bone marrow and osteoblasts differentiated from them. Cell proliferation experiment was carried out with 5, 50 and 500 µM peptide concentrations and 6-, 24- or 48-h treatment time. DNA synthesis activity was assessed by a Cell Proliferation ELISA kit (Roche Diagnostics GmbH, Germany). The expression profiles of osteoblasts were compared after a 24-h treatment with 50 µM IPP, VPP or LKP with a Hum16-K protocol, consisting of 16 000 human gene probes. Microarray results were confirmed by qRT-PCR (Mx3000P, Stratagene) according to the manufacturer's instructions using a Brilliant SYBRGreen qPCR Master mix kit. IPP's long-term effects on nine genes in hMSC-differentiated osteoblasts was analysed by qPCR on days 13, 17 and 20. Total protein content and bALP activity were assessed on days 3, 7, 12, 14, 17, 21 and 34 of culture. Cell culture mineralization was assessed by Alizarin Red S staining. The results show increased UMR-106 and hMSC proliferation. Microarray data analysis revealed IPP to upregulate 270 genes and downregulate 100 genes. The respective numbers for VPP were 25 and 10 and for LKP 16 and 14. IPP regulated genes associated with cell differentiation, cell growth and cell signal transcription. The upregulation of these genes indicates that IPP enhances osteoblast proliferation and differentiation. Long-term treatment with IPP enhanced osteoblast gene expression in favour of bone formation and increased mineralization, but did not influence bALP activity. Apoptosis related caspase-8 and PTHrP were downregulated. Our results show that bioactive peptides stimulate pathways resulting to increased osteoblast function and bone formation. Agents that increase the number and function of osteoblasts can improve bone mass and structure and decrease fracture risk. Bioactive peptides such as IPP may well conduct some of the positive effects dietary protein has on bone.

Progenitor Cells in Traumatically Injured Muscle Have Characteristic Similarities to Bone Marrow-Derived Stem Cells. W. M. Jackson*¹, S. M. Koehler*¹, J. R. Giuliani*², R. S. Tuan¹, L. J. Nesti². ¹Cartilage Biology and Orthopaedics Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, Bethesda, MD, USA, ²Department of Orthopaedics and Rehabilitation, Walter Reed Army Medical Center, Washington, DC, USA.

Heterotopic ossification (HO), or the formation of mature bone in soft tissues, is prevalent in patients with severe time-of-war extremity wounds. Although the cellular mechanisms of HO pathogenesis are unclear, it is likely that mesenchymal progenitor cells in the traumatized muscle (tmMPCs) are responsible for HO formation. The relationship between these MPCs and bone marrow-derived mesenchymal stem cells (bmMSCs) is unknown; therefore, the objective of this study was to compare the phenotype and differentiation potential of tmMPCs in traumatically injured muscle to bmMSCs. With IRB approval at Walter Reed Army Medical Center, muscle debridements were obtained from patients sustaining traumatic orthopaedic injury, and bone marrow was obtained from total hip arthroplasties. The tmMPCs were isolated from the muscle after extensive mincing, collagenase digestion and direct plating onto tissue culture plastic (TCP). bmMSCs were isolated from the marrow by direct plating onto TCP. After culture expansion, the expression of characteristic cell surface markers for MSCs was assayed by flow cytometry. Both groups of cells were cultured in defined differentiation media for osteogenesis, chondrogenesis, adipogenesis and myogenesis. The differentiation potential was assayed with histology (osteogenesis: alizarin red; adipogenesis: oil red O; chondrogenesis: alcian blue; myogenesis: hematoxylin) and by expression of lineage dependent genes (osteogenesis: ALP, Col I, and Runx2; adipogenesis: LPL and PPARγ; chondrogenesis: Col II, Col IX, AGN and Sox 9; myogenesis: MyoD and myosin heavy chain).

Although there were slight morphological differences between tmMPCs and bmMSCs, both populations expressed cell surface markers characteristic for MSCs (CD 73, CD 90 and CD105), and did not express markers absent on MSCs (CD14, CD34 and CD45). After 21 days in differentiation media, the histological staining and genetic expression of tmMPCs and bmMSCs was characteristic for differentiation into osteoblasts, chondrocytes and adipocytes but not into myoblasts.

This study demonstrates that MPCs in traumatized muscle have similar phenotype and differentiation potential as bmMSCs. The tmMPCs appear to be distinct from myogenic progenitors since they do not readily differentiate into myoblasts or form myotubes. Our findings suggest that dysregulation of the tmMPCs by inflammatory and wound response signals associated with trauma would be sufficient to induce ectopic osteogenesis.

Temporal Regulation of Histogenesis by Mesenchyme During Craniofacial Bone Development. A. H. Jheon*, B. F. Eames*, R. A. Schneider*. Orthopaedic Surgery, UCSF, San Francisco, CA, USA.

Development of bones involves a vast array of molecular and cellular interactions. Although, the roles of mesenchyme and epithelium in the patterning of facial bones have been studied extensively, little is known about their roles in the temporal control of bone histogenesis, which involves distinct and sequential modules including pre-osteoblast specification, osteogenic condensations, osteoid deposition, and mineralization. In the present study, we exploit the different developmental rates between quail and duck (quail hatch in 17 days whereas duck hatch in 28 days) to test the extent to which mesenchyme and epithelium control the initiation and progression of these modules during intramembranous bone development. By transplanting faster-developing quail mesenchyme adjacent to slower-developing duck epithelium (to generate chimeric quack), or conversely, slower-developing duck mesenchyme adjacent to faster-developing quail epithelium (to generate dual), the contribution of mesenchyme or epithelium can be determined. We show that mineralization of intramembranous bones occurs concordant with the developmental times of the donor. Thus, in quack, the first trace of facial bone mineralization occurs 36 hours earlier on the quail-donor side compared to the duck-host side, whereas in dual, mineralization occurs approximately 36 hours later on the duck-donor side. Further observations in quack show that deposition of osteoid and appearance of osteogenic condensations also occur according to the donor time line. These histological observations correlate with the molecular expression profiles of various genes necessary in osteoblast differentiation and mineralization. Preosteoblast-specification, measured by Runx2 expression, arises at a stage far before any evidence of bone and its expression is concomitant with a decrease in cell proliferation and an increase in cell differentiation. Thus, by utilizing the quail-duck chimeric system, we conclude that the temporal control of the various modules of intramembranous bone development is determined by mesenchyme, whereas epithelium appears to play a permissive role.

Flow Cytometric Immunophenotyping of Human Periodontal Ligament Cells. N. Kawanabe, K. Murakami*, S. Murata*, T. Yamashiro*. Department of Orthodontics and Dentofacial Orthopedics, Okayama University, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.

To characterize its primitive phenotypes analogous to mesenchymal stem cells, we investigated cell surface antigens' expression in cultured human periodontal ligament (PDL) cells. After obtaining approval from the Ethical Committee, intact permanent teeth were collected from healthy patients who were undergoing orthodontic treatment at Okayama University Hospital. The PDL cells isolated from these teeth were cultured. The cells were incubated with antibodies, then subjected to flow cytometric analysis. Primary human PDL cells used in this study showed fibroblastic spindle shape and capillary network formation. Flow cytometric studies demonstrated that PDL cells express mesenchymal stem cell markers, including CD9, CD13, CD29, CD44, CD73, CD90, CD105 and CD166, while they are negative for many hematopoietic markers (CD2, CD3, CD4, CD8a, CD14, CD16, CD19, CD20, CD24, CD33, CD34, CD38, CD41a, CD45, CD66b, CD117, CD133 and CD235a), endothelial cell markers (Flt-1, Flk-1 and von Willebrand factor), and an epithelial cell marker (cytokeratin 5/8). Integrins positive for PDL cells were CD29 (β1), CD41a (α1) and CD51 (αv). Positive cytokine receptors were CD71 (Transferrin R), CD105 (endoglin), CD119 (IFNγ R) and CD120a (TNF RI), and negative were CD117 (c-kit), CD121a (IL-1 R) and CD124 (IL-4 R). PDL cells expressed matrix receptors such as CD54 (ICAM-1) and CD166 (ALCAM), but lacked CD31 (PECAM-1), CD56 (NCAM) and CD106 (VCAM-1). Human leukocyte antigen (HLA) expressed in PDL cells was HLA-ABC, however, HLA-DR expression was not detected. No reactions of STRO-1 and CDPC-1 (CUB-domain-containing protein 1) were observed in PDL cells. Thus, the antigens expressed in PDL cells were basically identified with that of bone marrow stromal precursors, suggesting that PDL cells possess primitive characteristics as mesenchymal stem cells.

Effects of BHH9, an Ethanol Extract from Herbs, on Expression of Vascular Endothelial Growth Factor and Their Receptors During Human Osteoblasts Differentiation. D. Kim¹, J. Huh^{*2}, Y. Baek^{*2}, D. Choi^{*2}, D. Park^{*2}, J. Lee^{*2}. ¹Internal Medicine, Kyung Hee University Hospital, SEOUL, Republic of Korea, ²Acupuncture & Moxibustion, College of Oriental Medicine, Kyung Hee University, SEOUL, Republic of Korea.

Endochondral bone formation is regulated by systemically and locally acting growth factors. Vascular endothelial growth factor (VEGF) is an important regulator of bone formation and osteoblast differentiation. The aim of this study was to identify the BHH9 that may induce the angiogenic factor VEGF and its receptors (VEGFR) in osteoblast from human subchondral bone.

BrdU assay was used to determine the proliferation of human osteoblast cells. RT-PCR and ELISA assay were used to demonstrate the message and protein expression of VEGF, and extracellular matrix proteins including alkaline phosphatase (ALP), osteocalcin (OCN), osteopontin (OPN) and collagen I (ColI). Flow cytometry analysis (FACS) was used to confirm the expression of VEGF, VEGFR-1 and VEGFR-2.

BHH9 slightly increased cell proliferation, and dramatically increased ALP activity in human

osteoblast cells. Also, the expression of OCN, OPN, and Col I mRNA did not affected by treatment with BHH9 at 3 days and 7 days, but BHH9 was markedly enhanced at 14 days of culture. In addition to, BHH9 stimulated message and protein expression of VEGF and VEGFR-2 expression at 7 days of culture.

These results suggest that BHH9 plays an important role in bone remodeling by stimulating osteoblast differentiation via up-regulation of VEGF expression and possibly lead to the development of bone-forming drug.

Hairy Enhancer of Split 1 (HES-1) Is an Anti-adipogenic Mediator of Osteogenic Oxysterols and Hedgehog Signaling. W. Kim¹, V. Meliton^{*1}, C. M. Amantea^{*1}, T. J. Hahn², F. Parhami¹. ¹David Geffen School of Medicine, UCLA, Los Angeles, CA, USA, ²VA Greater Los Angeles Healthcare System and Geriatric Research, Education, and Clinical Center, Los Angeles, CA, USA.

Age-related bone loss is associated with a progressive decrease in bone formation and an increase in adipogenesis in the bone marrow. An increase in adipose tissue volume and a decrease in trabecular bone volume in bone marrow have been observed with aging and in patients with osteoporosis. Growing evidence indicates that PPAR γ plays an important role in the regulation of bone metabolism. It has been shown that hedgehog signaling pathway, activated by sonic hedgehog protein, inhibits adipogenic differentiation. Previously, our lab reported that osteogenic oxysterols inhibit PPAR γ expression and adipogenic differentiation of pluripotent bone marrow stromal cells (MSC) by activating hedgehog signaling. The present report identifies the molecular mechanism(s) by which oxysterols and hedgehog signaling inhibit PPAR γ expression and adipogenic differentiation. Microarray-based gene expression analysis revealed that osteogenic oxysterols caused a 2 fold induction of HES-1 mRNA expression in the pluripotent M2-10B4 (M2) MSC after 48 hours of treatment. Q-RT-PCR analysis of M2 cells showed that HES-1 expression was induced by the osteogenic oxysterol 20S-hydroxycholesterol (20S) and sonic hedgehog (Shh) in a time-dependent manner. HES-1, a target of notch signaling, is a basic helix-loop-helix DNA binding protein that is down-regulated during adipogenesis, and notch signaling profoundly inhibits adipogenesis through HES-1. After 48 hours, 20S (5 μ M) or Shh (200ng/mL) completely blocked PPAR γ mRNA expression in M2 cells treated with the PPAR γ ligand, troglitazone. 20S- and Shh-induced HES-1 expression was completely blocked by the inhibitor of hedgehog signaling pathway, cyclopamine (4 μ M), suggesting that HES-1 is a downstream target of hedgehog signaling. We also found a HES-1 binding site in the mouse Gli1 promoter using a Genomatix software, suggesting a potential feedback loop between Gli1 and HES-1. To demonstrate that HES-1 is a repressor of adipogenesis in MSC, we transfected M2 cells with 0.5, 1, 2, and 4 μ g of pCMV-HES-1 overexpression vector, and the effect of HES-1 overexpression on PPAR γ expression was assessed by Q-RT-PCR. Results showed that troglitazone-induced PPAR γ expression was inhibited by HES-1 overexpression in a dose-dependant manner. Altogether, the present study suggests that the anti-adipogenic effects of osteogenic oxysterols and Shh are mediated by a HES-1 dependent mechanism.

Proinflammatory Control of BMP-Smad-driven Transcription and Osteogenesis. O. Korchynskyi¹, P. ten Dijke^{*2}, D. D. Patel^{*3}, S. S. Makarov^{*4}. ¹Orthopedic Surgery, Virginia Commonwealth University, Richmond, VA, USA, ²Leiden University Medical Center, Leiden, The Netherlands, ³Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, ⁴Thurston Arthritis Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA.

Impaired bone homeostasis contributes to development of osteopenia, osteolysis and joint erosions during the rheumatoid arthritis (RA). Bone morphogenetic proteins (BMP) are crucially important regulators of osteogenesis. Activation of specific BMP receptors (BMPR) leads to activation of the major BMP signaling pathway, namely intracellular Smad proteins, as well as other, Smad-independent, pathways that transduce BMP signals to the nucleus. Using in vitro tissue culture approaches we show that activation of NF- κ B pathway with proinflammatory cytokines IL-1 β and TNF α inhibits osteogenic differentiation of pluripotent mesenchymal precursor cells through Smad7-independent inhibition of Smad1/5 transcriptional activity. Immunoblot and EMSA experiments show that correspondingly neither Smad1/5 phosphorylation by BMPR-Is, nor direct Smad1/5 binding to DNA into BMP target genes promoters are affected by the activation of NF- κ B pathway with TNF α , or by the overexpression of NF- κ B signaling components. Nevertheless, Smad1/5 transactivation and, consequently, transcription of BMP target genes is greatly reduced upon activation of NF- κ B signaling. Neither ectopic expression of Smad1/5, nor CBP/p300 can rescue the negative effect of NF- κ B pathway activation. We used Real time PCR to analyse BMP and TNF α target genes mRNA induction in the presence of protein synthesis cycloheximide and found that negative effect of NF- κ B activation requires new protein synthesis due to the induction of BMP signaling inhibitor expression. Furthermore, we found two distinct TNF α /NF- κ B target genes (T/NTG) that are novel potent inhibitors of BMP signaling. Interestingly, overexpression of T/NTG1 induces apoptotic death of osteoblasts. shRNA-mediated knockdown of the expression of each T/NTG results in partial rescue of BMP-Smad-driven transcription from inhibition by TNF α . Thus, our data suggest these T/NTGs as possible central candidates responsible for the

development of osteolysis and joint erosions during the RA. We are validating this current hypothesis in vivo using BMP reporter mice and ectopic bone formation in SCID mice models.

BK Channels in Human Osteoblast-like Cells - Properties and Function. B. Li^{*1}, N. C. Henney^{*1}, B. A. J. Evans², P. Reviriego^{*1}, A. K. Campbell^{*3}, K. T. Wann^{*1}. ¹Welsh School of Pharmacy, Cardiff University, Cardiff, United Kingdom, ²Child Health, School of Medicine, Cardiff University, Cardiff, United Kingdom, ³Medical Biochemistry & Immunology, Cardiff University, Cardiff, United Kingdom.

Ion channels which are normally associated with excitable cells are also emerging players in the life and death decisions of many other cells. We have focussed on large conductance Ca²⁺-activated K⁺ channels (BK channels) in osteoblast-like cells. BK channels exist as a tetramer of 4 α subunits associated with β subunits, and the type of β subunit, modifies both the voltage- and Ca²⁺-sensitivity and the pharmacological fingerprint of BK channels¹. Here we attempt a pharmacology of the channel, test its role in proliferation and try to specify the subunit composition of BK channels in MG63 cells.

Single channel activity was measured using patch-clamp methods. Determination of numbers of osteoblast-like cells was achieved by use of the MTS assay. RT-PCR was carried out to investigate the expression of α (KCNA) and β (KCNMB) subunits of the BK channel.

BK channels were observed in cell-attached patches at potentials close to rest. In excised outside-out patches external tetraethylammonium chloride (TEA, 500 μ M) reduced the open probability, producing reversible flickery block. Intriguingly, both BK-selective blockers, iberiotoxin (IbTX- 5-60nM) and tetrandrine (5-30 μ M) also blocked the channel in outside-out patches. Internal paxilline (10 μ M) blocked reversibly. The BK channel opener, isopimaric acid (10 μ M), also increased channel activity. RT-PCR showed that the α (KCNA) subunit and the β 1-4 (KCNMB1-4) subunits were present. Some blockers had a dual effect on cell numbers. Thus TEA and tetrandrine increased cell numbers at low (1mM and 3 μ M respectively), and reduced cell numbers at high concentration (>10mM and >10 μ M). In contrast, IbTX (10 - 300nM) was inactive.

These data are the first systematic description of the pharmacology of the BK channel in bone cells and it turns out to be novel. This has implications for both the subunit composition of the channel and its use in therapeutic intervention. The data also show that BK may have a role in modulating MG63 cell numbers and future investigations are focusing on characterising further the pharmacology of the channel and defining the native subunit composition, and the role of the channel in mineralization and secretion in osteoblast-like cells.

Application of Bioluminescence in Stem Cell-Based Bone Formation. K. E. de Rooij¹, G. van der Horst^{*1}, H. C. M. Sips^{*1}, I. Que^{*1}, L. J. A. van der Wee-Pals^{*1}, C. H. F. Bloys^{*1}, J. Hoogendam^{*2}, C. W. G. M. Löwik¹, M. Karperien¹. ¹Endocrinology, LUMC, Leiden, The Netherlands, ²Pediatrics, LUMC, Leiden, The Netherlands.

Current treatments for osteoporosis suppress bone resorption, thereby blocking further deterioration, but do not restore bone. Therefore, therapies stimulating bone formation would greatly enhance treatment of osteoporosis.

The bone forming osteoblasts originate from the multipotent mesenchymal stem cells (MSCs). MSCs have great potential for application in tissue engineering of bone and cartilage. However, differentiation of MSCs in vitro or in vivo as well as interactions with other cells or biomaterials in vivo is poorly understood. Therefore, we have created a stem cell model which, in combination with bioluminescent imaging, allows us to study these processes in intact mice over time.

The murine mesenchymal progenitor cell-like KS483 cell line was genetically modified enabling efficient generation of isogenic stable cell clones by Flp-mediated recombination by integrating 1 copy of a FRT-target site into the cell's genome. After we had tested the efficacy of the FRT-site by the overexpression or knock-down of the RunX2 gene, it was used to insert a luciferase2 gene containing a His tag enabling us to follow cell fate in vivo by bioluminescence after implantation in nude mice and the detection of cells ex vivo by immunohistochemistry using antibodies against the His tag. KSfrt HisLuc2 cells were used to perform a bone marrow ablation assay in which the cells were injected in the marrow cavity. Cell fate was followed by non-invasive bioluminescent imaging. At several time points, mice were sacrificed and both tibias were isolated for analysis. Using an antibody against the His tag, we could identify KSfrt HisLuc2 cells in the callus which was formed following bone marrow ablation. In addition, to study their fate outside the bone forming environment and to study possible adverse effects, cells were also transplanted subcutaneously. We have followed cell fate non-invasively for 20 weeks and afterwards isolated the luciferase expressing tissue for immunohistochemical analysis.

Finally, we used the genomic FRT site for the insertion of gene reporter constructs, which respond to Wnt- or BMP-signaling. Isogenic stable cell lines were obtained that were highly sensitive for Wnt and BMP, respectively, and retained multipotency. In conclusion, genetically modified KSfrt cells provide a simple and fast model to study MSC function. In combination with bioluminescent imaging, we will use this model to evaluate the effects of biomaterials on stem cell function in vitro and in vivo as a first step towards a bone replacement therapy for osteoporosis.

The LIM Protein, LMD1, Modulates Osteoblast Differentiation and Function. H. F. Luderer¹, S. Bai^{*2}, G. Longmore^{*3}. ¹Cell Biology, Washington University in St. Louis School of Medicine, St. Louis, MO, USA, ²Pathology, Washington University in St. Louis School of Medicine, St. Louis, MO, USA, ³Cell Biology and Medicine, Washington University in St. Louis School of Medicine, St. Louis, MO, USA.

Recent studies have shown that LMD1 contributes to osteoclast (OC) differentiation in vivo, suggesting LMD1 may be involved in maintaining normal bone homeostasis. To test this hypothesis, bone density measurements of Wild Type (Wt) and Lmd1^{-/-} mice were compared. In addition, the capability of primary calvarial cells isolated from Lmd1^{-/-} and Wt mice to differentiate, mineralize, and regulate OC differentiation was analyzed to determine if LMD1 affected osteoblast (OB) function. While Lmd1^{-/-} mice lack any gross skeletal abnormalities at steady state, defects in both differentiation and function of primary calvarial cells in culture were found. Lmd1^{-/-} calvarial cells display increased mineralization and accelerated differentiation compared to Wt controls despite equivalent rates of proliferation. More specifically, RT-PCR analysis of differentiating calvarial cells demonstrated that Runx2 regulated genes are expressed earlier in Lmd1^{-/-} calvarial cells compared to Wt. Intriguingly, LMD1 interacts with Runx2 by co-immunoprecipitation, suggesting a potential mechanism explaining the observed defects. Furthermore, RT-PCR analysis showed decreased expression of RANKL, a potent inducer of OC differentiation, and increased expression of osteopontin, the inhibitor of RANKL, in Lmd1^{-/-} calvarial cells. In agreement with this observation, when co-cultured with Wt primary bone marrow derived macrophages, Lmd1^{-/-} calvarial cells supported differentiation of fewer OCs than Wt controls. Since LMD1 was clearly important for OB differentiation in vitro, mice were treated with an anabolic stimulus to determine if LMD1 contributed to stress response. Wt and Lmd1^{-/-} mice were treated daily with parathyroid hormone (PTH) or vehicle for four weeks. Analysis by both micro-CT and histomorphometry showed no differences in bone density or bone growth between PTH treated groups. Interestingly, Lmd1^{-/-} PTH treated mice exhibited increased OB numbers compared to Wt. To determine if this was due to differing osteoprogenitor numbers, total marrow flushed from the long bones of Wt and Lmd1^{-/-} mice was cultured under normal, adipogenic or osteogenic conditions. Interestingly, loss of Lmd1 resulted in an increased number of osteoprogenitor cells while the number of adipogenic and fibroblastic colonies was unchanged. In conclusion, LMD1 affects OB differentiation, OB function and contributes to maintaining mesenchymal stem cell lineages.

Local Transplantation of G-CSF Mobilized CD34-positive Cells Contributes to Fracture Healing. Y. Mifune¹, T. Matsumoto², A. Kawamoto^{*1}, R. Kuroda^{*2}, T. Shoji^{*1}, M. Miwa^{*2}, K. Masahiro^{*2}, T. Asahara^{*1}. ¹Stem Cell Translational Research, Kobe Institute of Biomedical Research and Innovation / RIKEN Center for Developmental Biology, Kobe, Japan, ²Department of Orthopedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan.

We recently reported that human peripheral blood (PB) CD34⁺ cells, an endothelial/hematopoietic progenitor enriched cell population, contribute to fracture healing via vasculogenesis and osteogenesis in intravenous transplantation (IT) method. In addition to a confirmation of human PB CD34⁺ cell differentiation into osteoblasts (OBs) in vitro, we performed next experiments to prove a hypothesis that granulocyte colony stimulating factor mobilized peripheral blood (GM-PB) CD34⁺ cells, transplanted locally to the non-healing fracture model of immunodeficient rat, dose-dependently contribute to fracture healing. In vitro study, GM-PB CD34⁺ cells proved their capacity to differentiate into OBs by alizarin red staining and RT-PCR. In vivo study, as a proof of a therapeutic superiority of local transplantation (LT) to IT, the immunostaining for HLA-ABC at the peri-fracture site showed the significantly massive recruitment of the human cells in rats receiving LT compared to IT. RT-PCR and immunohistochemistry demonstrated significantly higher expression of human specific markers for endothelial cells and OBs in animals receiving high (10⁵) compared to middle (10⁴) and low (10³) dose of CD34⁺ cells and PBS at week 2. As enhancement of intrinsic vascularization and osteogenesis at the peri-fracture site, capillary density was significantly greater in high group compared with the other groups, as well as in middle group than low and PBS groups, and OB density was significantly greater in high group compared with the other groups. The Laser Doppler Perfusion Imager estimating a blood flow at the fracture site indicated the high and middle groups had a significantly higher perfusion value than the other groups at week 1 and 2. Radiographic assessment showed all of the high group and half the middle group obtained union at week 8, while all fractures in the other groups failed to union. The degree of fracture healing assessed by Allen's histological classification was significantly higher in high group than the other groups at week 8, as well as middle group than low and PBS groups (high, 3.8±0.13; middle, 2.1±0.16; low, 0.4±0.48; PBS, 0.0±0.00, respectively, P<0.01 for high vs other groups and middle vs low or PBS group). In this study, we suggested GM-PB CD34⁺ cells have a potential for vasculogenesis and osteogenesis with fracture healing, and more than 1x10⁴ CD34⁺ cells per rat were necessary and effective for fracture healing in LT method. These findings must be a help to close up to the feasibility for clinical application.

In Vitro and In Vivo Effects of sFRP3 Overexpressed by Phi 31 Integrase Strategy. D. Han^{*1}, S. Park^{*1}, S. Kim^{*1}, Y. Kim², Y. Rhee^{*1}, Y. Chung^{*3}, S. Lim¹. ¹Internal Medicine, Yonsei University, Seoul, Republic of Korea, ²Internal Medicine, NHIC Ilsan Hospital, Seoul, Republic of Korea, ³Internal Medicine, Ajou University, Seoul, Republic of Korea.

Wnt signaling increases bone mass through a number of mechanism. Secreted frizzled related proteins (sFRPs) do not have transmembrane and cytosolic domains, thus they bind and act as decoy receptors for Wnt proteins and antagonize the Wnt/frizzled signaling pathway. However, previous studies reported that sFRP3 decreased osteoblast proliferation and increased osteoblast differentiation. Because Tg or KO models regulating Wnt signaling may alter bone development, it is more desirable to evaluate the effects of sFRP3 in skeletally mature animals with pharmacological activators or inhibitors. In this study, we overexpressed sFRP3 by Phi 31 integrase strategy in 7-20 weeks old ICR mouse (male) to demonstrate the effects of sFRP3 in bone. sFRP3 expression in liver was documented by PCR and confocal microscopy analysis. Serum sFRP3 was detected at ~ ug range by ELISA. In sFRP3 overexpressed mice, femur BMD measured by PIXImus was increased. Both BV/TV and Trabecular number measured by μ CT were also increased, and Tb.Sp (trabecular separation) was decreased. Furthermore, three point bending test revealed increased load max and slope of femurs. To clarify the mechanism of sFRP3 induced positive effects on bone, sFRP3 was overexpressed in MC3T3E1 preosteoblast cells. Overexpression of sFRP3 reduced Wnt3a mediated proliferation, and real time PCR analysis revealed that colla1a1 expression was increased. In addition, the luciferase assay presented that Wnt-responsive gene activation were increased in sFRP3 treated group. Based on our findings, we propose that constitutive overexpression of sFRP3 increases BMD and bone strength. Furthermore, continuous over activation of Wnt signal might not be beneficial to bone, and coordinated regulated activation of Wnt signal should be necessary for optimal bone remodeling and bone strength.

Osteocyte Specific DMP1 and MEPE Expression after Mechanical Stimulation in the Mouse Ulnae Loading Model: Correlation to Strain Fields, Dynamic Bone Formation, and Potential Role in Bone Mineral Quality. S. E. Harris¹, J. Gluhak-Heinrich^{*2}, M. A. Harris¹, W. Yang¹, L. F. Bonewald³, D. Riha^{*4}, D. P. Nicoletta⁴, P. S. N. Rowe⁵, A. G. Robling^{*6}, C. H. Turner⁶. ¹Periodontics, U, Texas Health Sci Ctr San Antonio, San Antonio, TX, USA, ²Orthodontics, U, Texas Health Sci Ctr San Antonio, San Antonio, TX, USA, ³Oral Biology, U, of Missouri at Kansas City, Kansas City, MO, USA, ⁴Southwest Research Institute, San Antonio, TX, USA, ⁵Periodontics, Kansas University Medical Center, Kansas City, KS, USA, ⁶Indiana University School of Medicine, Indianapolis, IN, USA.

DMP1 and MEPE are involved in local effects on bone mineralization as well as systemic phosphate metabolism. These two genes are highly expressed in osteocytes and suggest that the osteocyte can alter its local environment as well as act as an endocrine cell. We previously have shown preliminary data that DMP1 and MEPE increased at 24hrs after a single 2.4N load for 30 sec at 2 Hz. We now show a direct highly statistically significant correlation between gene expression and strain field determinations from finite element analysis. This correlation shows osteocyte specific DMP1 and MEPE expression is highest in areas of maximal compressive and tensile strains in cortical bone. DMP1 is an early response gene and its expression is first stimulated at 1hr after loading and continues to increase up to 24hrs. Load induced MEPE expression is a late response gene and does not increase with load until 24hrs. Using a 3D model relating the 3 dimensional strain field with both DMP1 and MEPE expression, the gene expression threshold (Get) for both genes is approximately 1500 μ strain. MEPE protein is cleaved by a cathepsin like protease to a highly phosphorylated C-terminal ASARM peptide. We know that overproduction of MEPE and the ASARM peptide are associated with hypophosphatemia and osteomalacia. DMP1 affects local mineralization by proper maintenance of canaliculi and lacunar walls and, if deleted, may result in the osteocyte being overstimulated. As we previously showed, MEPE and the ASARM peptide are overexpressed in the DMP1 knock-out model, supporting that osteocytes in this model are experiencing higher local strain than control mice under normal cage conditions. The normal role of MEPE and its response to load may be related to the capacity of MEPE and the ASARM peptide to alter local mineral to matrix properties.

Figure 1. Correlation of Load Induced MEPE Expression(24hrs) with maximum surface Compressive Strain Determined by Finite Element Model. MS is the midshaft and d1 to d5 are 1mm intervals distal to MS and p1 and p2 are 1mm intervals proximal to midshaft

Cell-Cell Communication in Living Bone and Its Regulation Factor. Y. Ishihara¹, H. Kamioka^{*1}, T. Takano-Yamamoto², T. Yamashiro^{*1}. ¹Department of Orthodontics and Dentofacial Orthopedics, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan, ²Division of Orthodontics and Dentofacial Orthopedics, Tohoku University Graduate School of Dentistry, Sendai, Japan.

Intercellular network among osteocytes consists of gap junctions. Gap junctional intercellular communication (GJIC) is thought to play an important role in integration and synchronization in bone remodeling. We hypothesized that extracellular pH (pH_e) and extracellular calcium ion ([Ca²⁺]_e), which were dynamically changed by osteoclast while bone remodeling, would affect GJIC among osteocytes. GJIC among osteocytes in chick calvaria was analyzed by using Fluorescence Replacement After Photobleaching (FRAP) analysis. Simultaneously, we examined the effect of PTH on GJIC in osteocytes. Anti-Connexin43 (Cx43) immunolabelling was used to identify gap junction localization in chick calvaria. FRAP analysis was performed to osteocytes in chick calvariae which were exposed to 5.0 μM Calcein-AM. We assessed subsequent recovery of fluorescence intensity into the photobleached cell by the fluorescence replacement from surrounding cells. In each experiment, bone fragments were precultured with conditioned medium before FRAP analysis. Cx43 immunoreactivity was detected in most of osteocyte processes without any specific distribution. FRAP analysis showed dye-coupling among osteocytes in chick calvariae. Fluorescence intensity recovered to 43.7 ± 2.2% within 5 min after photobleaching. Pretreatment of 18 α-GA, a reversible inhibitor of GJIC, significantly decreased replacement of the fluorescence to 10.7 ± 2.2% in a bleached osteocyte. When pH_e was decreased from 7.4 to 6.9, replacement of the fluorescence in a bleached osteocyte was significantly decreased from 43.3 ± 2.9% to 19.7 ± 2.3%. Conversely when pH_e was increased from 7.4 to 8.0, it was significantly increased up to 61.9 ± 4.5%. When [Ca²⁺]_e was altered from 1 mM up to 25 mM, replacement of the fluorescence in a bleached osteocyte was significantly decreased from 47.0 ± 6.1% to 16.1 ± 2.1%. In addition, when bone fragments were exposed from 1 nM to 10 nM rPTH, replacement of the fluorescence in a bleached osteocyte was significantly increased up to 60.7 ± 7.2% after 3 h. These results indicated GJIC among osteocytes in bone are regulated by extracellular environment and hormonal stimulation in bone remodeling.

Greater Sensitivity of Osteocytes to Shear Stress as Compared to Osteoblasts: PGE₂ Production and Wnt/β-catenin Signaling. M. L. Johnson, M. A. Kamel, N. A. Kim-Weroha^{*}, B. Holladay^{*}, S. Kotha. Oral Biology, UMKC School of Dentistry, Kansas City, MO, USA.

The osteocyte is widely held to be the primary cell in bone responsible for sensing mechanical loads due to its location in bone and it has been shown that primary osteocytes are more sensitive to shear stress than primary osteoblasts. Ironically, the majority of in vitro studies examining mechanoresponsiveness have used primary osteoblast cultures and/or osteoblastic cell lines as surrogates for osteocytes. We compared the sensitivity of osteocyte MLO-Y4 cells to osteoblast 2T3 cells using fluid flow at 2 and 16 dynes/cm². Media was sampled at 5, 15, 30, 60 and 120 minutes for PGE₂ production and at 120 min for nuclear translocation of β-catenin. At 2 dynes/cm², PGE₂ was not detectable in the media from the 2T3 cells (<10 pg/ml). At 16 dynes/cm², PGE₂ was first detectable 15 min after initiation of fluid flow and increased to 90 pg/ml by 2 hours. In contrast, at 2 dynes/cm², MLO-Y4 cells produced 450 pg/ml PGE₂ by 5 minutes which continued to increase for the 2 hours of shear stress to a maximum of 1400 pg/ml. At 16 dynes/cm², PGE₂ production was 500 pg/ml at 5 minutes and reached >2000 pg/ml at 2 hours. At 2 dynes/cm², β-catenin nuclear translocation was detected by immunostaining in MLO-Y4 cells, but not in 2T3 cells. At 16 dynes/cm² both cell lines showed nuclear translocation. We further examined the sensitivity of osteocytes versus osteoblasts in vivo using ulna loading of the TOPGAL mouse. Nuclear translocation of β-catenin, assayed by lacZ activity, was initially observed in osteocytes within bone at 1 hour post load but not until 24 hrs in cells on the bone surface. At 4 hours post loading immunostaining for sclerostin, which binds to Lrp5 and acts as an inhibitor of β-catenin signaling; demonstrated high levels of sclerostin in most osteocytes, except those with active β-catenin signaling, implying a reciprocal relationship. We hypothesize that this initial activation of β-catenin signaling is PGE₂ dependent and thereby able to bypass the inhibitory effects of sclerostin on the Lrp5 co-receptor that regulates Wnt/β-catenin signaling. These observations support the hypothesis that osteocytes are first cells in bone to sense and respond to mechanical load.

Fluid Flow Shear Stress and Prostaglandin E2 Activates β-catenin Signaling in MLO-Y4 Osteocytic and 2T3 Osteoblastic Cells. M. A. Kamel, Y. Kitase, N. A. Kim-Weroha^{*}, B. Holladay^{*}, S. Kotha, L. F. Bonewald, M. L. Johnson. Oral Biology, UMKC School of Dentistry, Kansas City, MO, USA.

The low-density lipoprotein receptor-related protein 5 (Lrp5) and the Wnt/β-catenin signaling pathway that it regulates are known to be required for new bone formation in response to mechanical loading. Prostaglandins are also known to be rapidly released from bone cells in response to mechanical loading. We have proposed a model in which Prostaglandin E₂ (PGE₂) released by osteocytes and/or osteoblasts, in response to mechanical loading activates β-catenin signaling through a mechanism that is independent of Lrp5 co-receptor regulation of the Wnt/β-catenin pathway. This model accounts for the activation of β-catenin signaling in the presence of inhibitory proteins such as sclerostin that is produced by osteocytes. We hypothesized that this activation occurs through a PGE₂ mediated inhibition of Glycogen Synthase Kinase-3β (GSK-3β), a key regulator of intracellular levels of β-catenin. To test this hypothesis we treated MLO-Y4 osteocytic and 2T3 osteoblastic with 5 × 10⁻⁶ M PGE₂ for 2 hours. We observed a significant increase in phosphorylation of GSK-3β as determined by western blot compared to untreated cells. Interestingly we also observed parallel changes in GSK-3α phosphorylation, which can also regulate intracellular β-catenin levels. Immunostaining of PGE₂ treated cells demonstrated nuclear accumulation of β-catenin compared to non-treated cells. 2T3 osteoblastic and MLO-Y4 osteocytic cells were subjected to 16 dynes/cm² of fluid flow for 2 hours. Fluid flow significantly increased the phosphorylation of GSK-3β and α, and increased nuclear translocation of β-catenin. These data support our hypothesis that PGE₂ released in response to mechanical loading/fluid flow shear stress leads to inhibition of GSK-3β and nuclear translocation of β-catenin. Our data also suggests a possible, previously unsuspected role for GSK-3α in the regulation of β-catenin signaling in bone cells. We propose that this initial activation of β-catenin signaling leads to changes in key target genes, such as sclerostin and Wnts creating a permissive environment for further amplification of the Wnt/β-catenin signaling at the level of Lrp5. Loss of Lrp5 prevents this amplification step, which is required for new bone formation.

The Effects of Mechanical Strain on Osteocytes - Induced Bone Cell Proliferation and Recruitment. S. Ko, J. Lee^{*}, S. Kim^{*}. Dept. of Pharmacology & Dental Therapeutics, Kangnung National University, Gangneung, Republic of Korea.

There are several evidences that osteocyte plays a critical role in bone remodeling. Healthy or apoptotic osteocytes can send signals to other bone surface cells like osteoblasts, osteoclasts, osteoclast precursors and bone lining cells through their networking in canaliculi. And osteocyte which responds to mechanical strain may send signal to other cells. Therefore, to determine the role for osteocytes and mechanical strain in bone remodeling, we examined the effect of mechanical strain and apoptosis of osteocytes on osteoclast precursors and osteoblasts proliferation and recruitment. We used the MLO-Y4 cells as in vitro model for osteocytes, RAW 264.7 cells and MOC-P5 cells as osteoclast precursor, and 2T3 cells as osteoblasts. MLO-Y4 cells conditioned medium (Y4-CM) was collected after 24h culture. For fluid flow experiments, MLO-Y4 cells were exposed to 2 hrs of pulsatile fluid flow(PFF) at 2, 4, 8, 16 ± 0.6 dynes/cm² using Flexcell Streamer™ system. For induction of MLO-Y4 cell apoptosis, MLO-Y4 cells were treated with 100 μM etoposide and apoptosis was determined with increase of casapase-3 activity and ratio of trypan blue staining cells. We did proliferation assay of RAW 264.7 and 2T3 cells with control media or 10% Y4-CM at specific time. The migration of RAW 264.7 and 2T3 cells was assayed using transwells with control media or 10, 20, 50, 100% Y4-CM. MLO-Y4-CM increased osteoclast precursor proliferation and migration. Y4-CM decreased 2T3 cell proliferation and migration. After MLO-Y4 cells were exposed to PFF, Y4-CM decreased RAW 267.4 cell proliferation, migration and 2T3 migration compared to control CM (Y4-CM without strain). However Y4-CM exposed PFF had no effect on 2T3 osteoblastic cell proliferation. Apoptotic Y4-CM induced by etoposide increased the proliferation of 2T3 cells compared to control Y4-CM. These results suggest that osteocytes can regulate the bone remodeling by communication with osteoclast precursors and osteoblasts and that osteocytes can communicate mechanical signals and their apoptosis to other cells.

Ex Vivo Model of Stress Shielding and Osteocyte Viability in Human Trabecular Bone. H. Kroger¹, V. Mann², B. Noble². ¹MTEC and Dept. of Orthopaedics, University of Edinburgh and University of Kuopio, Kuopio, Finland, ²MTEC, University of Edinburgh, Edinburgh, United Kingdom.

Stress shielding associated periprosthetic bone loss is common after total hip and knee arthroplasty (THA, TKA). However the cell/molecular mechanism that drives this bone loss is unknown. Osteocyte death has been hypothesised to initiate localised bone remodelling. Here we test the hypothesis that mechanical unloading of specific regions of human trabecular bone will engender osteocyte death in a site and mechanical strain specific manner. Excised femoral head material was obtained from an individual patient undergoing THA. Trabecular bone cores 10mm diameter were prepared plan parallel to a height of 5mm (+/-2µm) within 2 hours post surgery under sterile conditions. Regional stress shielding (SS) was accomplished in bone cores (n = 3) through the removal of a portion of load-transmitting bone, such that mechanical stimulation below this area was disrupted. The bone cores were then randomly assigned into 4 groups: Time Zero (T0, immediately flash frozen n=4), loaded control (LC, n=3), unloaded control (UC, n=3) and stress shielded (SS n=3). These samples were maintained within a bioreactor system for 7 days under conditions of either no mechanical stimulation (UC) or mechanically stimulated (LC, SS). Mechanical stimulation was carried out for 5 minutes on a daily basis using a maximum of 3000 µstrain in a waveform corresponding to physiological jumping exercise. Osteocyte viability was analysed in unfixed/undecalcified bone sections using in situ histochemical analysis of Lactate Dehydrogenase (LDH) activity. Total cell number was determined using DAPI nuclear stain. The results are expressed as the ratio of LDH positive osteocytes to total number of osteocytes corrected for bone area (Viability Index). In the SS samples the viability index was determined separately in the region of bone which experienced mechanical loading (SSLR) and the unloaded region (SSUR) within the same sample. The viability index of bone maintained in the bioreactor in the absence of mechanical stimulation decreased relative to T0 samples (1.54 UC vs. 7.47 T0, p<0.001). Application of mechanical stimulation increased viability relative to unloaded samples (3.10 LC vs. 1.54 UC, p<0.001). In the stress shielded samples the viability was reduced in the stress shielded region relative to the loaded region within the same sample (0.96 SSUR vs. 2.74 SSLR, p<0.001). There was no significant difference between the loaded region in the stress shielded sample and the loaded control (2.74 SSLR vs. 3.10 LC, p = 0.857). In conclusion unloading is associated with a decrease in osteocyte viability. Decreased osteocyte viability may play a significant role in stress shielding induced bone resorption and bone loss.

Bone Biomarker Responses to Short-Term Training: Influence of Exercise Mode vs. Osteogenic Index. M. E. Lester^{*1}, R. K. Evans^{*1}, W. J. Kraemer^{*2}, J. S. Staab^{*1}, J. R. Pierce^{*1}, D. E. Catrambone^{*1}, H. M. Isome^{*1}, M. L. Urso^{*1}, B. A. Spiering^{*2}, D. L. Hatfield^{*2}, C. M. Maresh^{*2}, B. C. Nindl^{*1}. ¹Military Performance Division, US Army Research Institute of Environmental Medicine, Natick, MA, USA, ²Dept of Kinesiology, University of Connecticut, Storrs, CT, USA.

The value of monitoring bone turnover biomarkers during short-term exercise training is not established. Further, it is not clear whether these biomarkers are influenced by either exercise mode or the osteogenic index (OI = I * LN(N+1)), where I = mean weekly intensity of activity in bodymass units, and N = number of loading cycles per wk (Robbling and Turner, ESSR 2003). This study examined the influence of three, 9-wk exercise regimens (exercise performed 3 d/wk) on bone turnover responses. Fifty-seven women (21.7 yr) were randomly assigned to a control (CON), aerobic (AER), resistance (RES), or combined aerobic and resistance (COMB) training group. Serum markers of bone formation [BAP and Osteocalcin (OC)] and bone resorption (TRAP5b and CTx) were assessed after 0, 4, and 9 weeks of the exercise training via immunoassays. Changes were analyzed using a 4x3 repeated measures ANOVA with a Fisher's LSD post-hoc where appropriate, and significance was accepted at P<0.05. The average weekly OI for the groups were: RES group=14.1, AER=22.2, and COMB=40.1. Results for BAP and OC appear below:

Group	BAP (U/L)			OC (ng/mL)		
	Wk 0	Wk 4	Wk 9	Wk 0	Wk 4	Wk 9
COMB (n=17)	18.7 ± 1.4	20.7 ± 1.7*	22.2 ± 1.5*‡#	10.8 ± 0.9	10.5 ± 0.8	11.8 ± 0.8‡#
RES (n=17)	19.6 ± 1.4	21.4 ± 1.6*	23.4 ± 1.5*‡#	10.6 ± 0.9	10.9 ± 0.8	13.2 ± 0.8*‡#
AER (n=13)	18.9 ± 1.6	20.8 ± 1.9*	20.5 ± 1.7#	10.6 ± 0.9	10.3 ± 0.9	10.4 ± 0.9
CON (n=9)	16.5 ± 1.9	6.1 ± 2.2	14.6 ± 2.1	9.6 ± 1.2	9.0 ± 1.1	8.8 ± 1.1

Values are mean±SE; *P<0.05 vs. week 0; ‡P<0.05 vs. week 6; #P<0.05 vs. CON group. For BAP, interaction effects revealed increases at 4 weeks for all exercise groups, while further increases at 9 weeks were only evident for the RES and COMB groups. For OC concentrations, only RES and COMB increased over the training period. There were no significant changes in CTx during training; however there was a significant decrease in TRAP5b over time (wk 0: 3.7±0.1 > wk4: 3.4±0.1 = wk9: 3.3±0.1 U/L). The greatest increase in biomarkers of bone formation was observed for the RES group, which had the lowest OI. Our results demonstrate 1) biomarkers of bone formation are more responsive to short-term exercise training than are biomarkers of bone resorption, 2) exercise modes that incorporate resistance training increase biomarkers of bone formation independent of OI. While the OI was developed and validated upon structural increases in bone strength, our data indicate that exercise programs with higher OIs do not necessarily contribute to a biochemical milieu reflective of increased bone formation.

Nanoprobng Osteocytic Subcellular Compartments by Surface-Enhanced Raman Spectroscopy. I. Pavel^{*1}, M. Mahmood^{*1}, K. Vyas^{*2}, M. Whitlow^{*1}, L. I. Plotkin², S. C. Manolagas², A. S. Biris^{*1}, T. Bellido². ¹Nanotechnology Center / Applied Science Department, Univ Arkansas at Little Rock, Little Rock, AR, USA, ²Center for Osteoporosis and Metabolic Bone Diseases, Univ Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

The optical fields provided by single nanoparticles (NPs) or NP aggregates of noble metals can enhance by up to 15 orders of magnitude the Raman spectroscopic signals of neighboring molecules. This technique, called surface-enhanced Raman spectroscopy (SERS), was used herein to study the molecular composition of the nanometer-scaled environment of NPs delivered into living MLO-Y4 osteocytic cells. Gold or silver NPs of 10-20 nm diameter were prepared by citrate- or borohydride-mediated reduction of chloroauric acid or silver nitrate, respectively. Cells were exposed to growing medium without or containing NPs (10⁻¹² or 0.5x10⁻⁹ M) for 5 min to 12 h. Medium containing NPs was then removed; and cells cultured in fresh medium for a total of 12 h for all conditions and fixed. NP uptake was followed by light microscopy and their subcellular localization was visualized by transmission electron microscopy. NPs were detected in different subcellular compartments depending on their concentration and time of exposure. In cells exposed to 10⁻¹² M, NPs were detected only in the cytoplasm irrespective of the time of exposure. On the other hand, in cells exposed to 0.5x10⁻⁹ M, NPs were found near the plasma membrane and in the cytoplasm after 10 to 30 min; and in cellular organelles and the nucleus after 12 h. SERS spectra were recorded from 1 µm diameter areas of different subcellular compartments using a confocal Raman microscope in a back-scattering geometry. A He-Ne laser of 632.8 nm wavelength and 2 mW power at the sample level was used for excitation. Acquisition time was 20 sec. No signal was detected in cells not exposed to NPs. Moreover, in cells incubated with NPs, SERS signals were detected only in areas near NPs or NP aggregates. The SERS spectra indicate that distinct chemical compositions characterize different subcellular compartments. Thus, spectra recorded from cytoplasmic areas exhibited mostly vibrational modes characteristic of proteins, lipids and carbohydrates; whereas, spectra obtained from nuclear, chromatin-rich areas revealed vibrational modes typical of DNA as well as proteins. To our knowledge, this is the first demonstration that NPs serve as nanosensors by providing SERS signatures of different subcellular compartments, including the nucleus, in bone cells. This approach might be used for detecting with high sensitivity subcellular changes associated with biological processes such as cell replication or apoptosis.

Estimation of Osteocyte Density from Total Lacunar Population. S. Qiu, S. Palnitkar^{*}, D. Rao. Bone and Mineral, Henry Ford hospital, Detroit, MI, USA.

Many investigators estimate osteocyte density based on measurement of osteocyte lacunae. The prerequisite for this estimation is that the empty lacunae remaining after osteocyte death should disappear subsequently, leading to a decrease in total lacunae. There is evidence for such disappearance of empty lacunae. However, the relationship between osteocyte and total lacunar densities remains unclear. This study attempted to determine whether the decreased total lacunar density can be used to estimate the loss of osteocytes.

From our archived iliac biopsy sections, the cancellous bone in 136 white women (92 healthy and 44 with osteoporotic vertebral fracture) were examined. Ten unbroken areas were randomly selected in each section stained with Goldner's trichrome for determining the numbers of osteocytes (Ot.N), empty lacunae (EL.N) and total lacunae (Tt.L.N) per bone area. Table 1 shows the correlations of osteocyte density with densities of empty lacunae and total lacunae (Pearson test). The correlation between osteocyte and total lacunar densities was excellent in superficial, deep and whole bone (SB, DB and WB) in all subject groups (Table 1). The correlation between osteocyte and empty lacunar densities was significantly weaker in both fracture patients and normal women.

In conclusion, bone biopsy specimens contained well preserved osteocytes, so the iliac biopsy sections were used to estimate the relationship between osteocyte and total lacunar densities. The results indicate that, regardless of the location in bone, >80% variation in osteocyte density can be explained by total lacunar density in either normal subjects or patients with fragility fracture. Therefore, the decrease in total lacunar density can represent the loss of osteocyte, although the rate of osteocyte death will be underestimated due to the time lag needed for lacunar obliteration.

Histochemical Assessments on the Distribution of Osteocyte-Lacunar Canalicular System. U. Sobhan¹, M. Li², K. Oda³, T. Maeda⁴, R. Takagi⁵, N. Amizuka². ¹Oral Maxillofacial Surgery 2, Niigata University, Niigata, Japan, ²Center for Transdisciplinary Research, Niigata University, Niigata, Japan, ³Biochemistry, Niigata University, Niigata, Japan, ⁴Oral Anatomy, Niigata University, Niigata, Japan, ⁵Oral maxillofacial surgery 2, Niigata University, Niigata, Japan.

The purpose of this study is to histochemically evaluate the arrangement of osteocyte-lacunar canalicular system (OLCS) associated with bone remodeling, i.e., OLCS in sites of rapidly and slowly remodeled bone. Twelve-week-old female ICR mice were fixed with aldehyde solution, and the femora and tibiae were extracted. They were then decalcified with 10% EDTA solution prior to paraffin embedding. In order to envision the distribution of OLCS and the localization of osteoclasts and/or osteoblasts on regular paraffin sections, we performed double and triple stainings of silver impregnation (modified Schoen's method), alkaline phosphatase (ALP) immunohistochemistry and/or tartrate resistant acid phosphatase (TRAP) by Azo dye method. In addition, paraffin sections were also stained for detection of osteopontin or DMP-1 (dentin matrix protein-1) with silver impregnation. When analyzing the double and triple stainings, the bone matrix with ALP-positive plump osteoblasts, indicative of active form of osteoblasts, and TRAP-positive osteoclasts showed an irregularly arranged OLCS. In contrast, the region covered by ALP-positive bone lining cells, which are less active osteoblasts, demonstrated well arranged OLCS. Osteopontin-positive cement lines divided different bone matrices: one showed well-arranged lacunar canaliculi and the other figured haphazardly arranged canaliculi, thereby indicating the possibility that bone remodeling reconstructs the distribution of OLCS. Although DMP-1, specifically expressed in osteocytes, has been postulated to be involved with mechanotransduction in bone, DMP-1-immunoreactive osteocytes were unevenly distributed throughout the cortical bone that showed the regular arrangement of OLCS; the distribution of DMP-1 did not seem to be related to the distribution patterns of OLCS. Statistical analysis showed a higher number of canaliculi for each osteocyte in the areas that has been remodeled, compared to the area with ongoing remodeling. Our findings suggest that bone remodeling would reorganize the OLCS into regularly-arrangement.

Modulation of Site Specific Bone Adaptation by Signaling in Osteocytic Networks. B. J. Ausk^{*}, T. S. Gross, S. Srinivasan. Orthopaedics, University of Washington, Seattle, WA, USA.

The osteocytic network in vivo is characterized by non-uniform cellular distributions and heterogeneity in cell-cell connectivity. While the mechanosensory role of osteocytic cells is broadly posited, the functional significance of the cellular network and its complex architecture remains opaque due to its current inaccessibility. In part to explore this process, we previously developed an agent based model (ABM) that simulates how real-time Ca^{2+} signaling induced in osteocytic networks by mechanical stimuli influences osteoid secretion by osteoblastic cells. The ABM accurately simulated whole tissue bone formation induced by cyclic (1-Hz) and 10-s rest-inserted loading protocols at 3 different strain magnitudes and at 2 different loading cycle numbers (error < 15%). Using this ABM, we examined the hypothesis that cell-cell signaling within the osteocytic network influences site-specific bone adaptation induced by mechanical stimuli. The osteocytic network topology was determined via imaging of thin sections obtained from the tibia mid-shaft of C57BL/6J mice (5 μ m, n = 6, 16-wk) and the ABM was used to simulate focal osteoblastic activity around the mid-shaft for baseline loading protocols that were previously found to be osteogenic in vivo. We explored the general hypothesis by examining 3 conditions in which osteoblastic activity was: 1) linearly related to local tissue strains, 2) further modulated by strain related thresholds, or 3) further modulated by signaling within the underlying osteocytic network. We found that activation of osteoblastic cells solely by local tissue strains was poorly correlated with site specific adaptation observed in vivo ($r^2 = 0.17 \pm 0.04$). Unexpectedly, when strain thresholds further modulated osteoblast activation, the relation was only minimally improved ($r^2 = 0.23 \pm 0.05$, $p = 0.3$ vs strain magnitude only). Interestingly, when cell-cell signaling in the osteocytic network activated individual osteoblastic cells, the relation between ABM simulations and site specific osteoblastic activity observed in vivo was significantly improved ($r^2 = 0.41 \pm 0.06$, $p = 0.01$ and 0.05 vs conditions 1, 2). This dramatic improvement in ABM predictions when cell-cell signaling is included (2.4 and 1.8 fold, respectively) suggests that interactions between osteoblasts and the osteocytic network are more important in influencing focal osteoblast activity compared with just the distribution of mechanical strains. This study, for the first time to our knowledge, begins to quantify the functional significance of the bone cell network in vivo. Given this relation, knowledge of the cellular topology within a bone is likely to be critical if osteoblastic activity is to be targeted to structural sites most in need of bone accretion.

The Elastic Modulus of Osteoblasts and Osteocytes. Y. Sugawara¹, H. Kamioka², R. Ando³, Y. Ishihara⁴, S. A. Murshid², K. Hashimoto³, N. Kataoka⁴, K. Tsujioka³, F. Kajiyama⁴, T. Yamashiro¹, T. Takano-Yamamoto².

¹Department of Orthodontics and Dentofacial Orthopedics, Okayama University Graduate School of Medicine, Dentistry, and Pharmaceutical Sciences, Okayama, Japan, ²Department of Orthodontics and Dentofacial Orthopedics, Tohoku University Graduate School of Dentistry, Sendai, Japan, ³Department of Physiology, Kawasaki Medical School, Okayama, Japan, ⁴Department of Medical Engineering, Kawasaki Medical School, Okayama, Japan.

In general, growth, cell cycle progression, gene expression, and other cell behaviors are sensitive to changes in the mechanical force. Therefore, modulations of cellular mechanical properties exerted by mechanical force are intimately related to physiologically important processes. To understand the various functions of osteoblasts and osteocytes, a physical portrait of the mechanical properties of the osteoblasts and osteocytes is necessary. However, it has been difficult to study their mechanical properties because they are in mineralized tissue. In this study, we analyzed the elastic modulus of isolated osteoblasts and osteocytes. On the other hand, the cellular tension was created by the cytoskeletal components based on focal adhesion sites. Therefore, we also examine the relationship between focal adhesion and the elastic modulus. In order to isolate osteoblasts and osteocytes from embryonic chick calvariae, serial treatment was performed with collagenase type I and EDTA. The elastic modulus of living cells was analyzed with Atomic Force Microscopy. We analyzed the elastic modulus of living cells both on peripheral region of the cell body and nucleus region. Osteoblasts and osteocytes were identified by alkaline phosphatase substrate and by OB 7.3, which was a chick osteocyte-specific antibody, respectively. To examine the implication of focal adhesion formation on the elastic modulus, GRGDS, which is the inhibitor of focal adhesion, was pretreated in the culture and we analyzed elastic modulus of the cells. Elastic modulus of peripheral region was higher than that of nucleus region in both osteoblasts and osteocytes. Furthermore, the elastic modulus of peripheral and nucleus region in osteoblasts were higher than those in osteocytes. After treatment with GRGDS, the elastic modulus of osteoblasts was decreased. On the contrary, osteocyte didn't change their elastic modulus. In summary, the elastic modulus of osteoblasts was higher than that of osteocytes. Osteoblast elastic modulus might be influenced by the cytoskeleton based on cell adhesion.

Effects of 3 Months of Aerobic Exercise on Bone Turnover in Premenopausal Non-obese Women. N. I. Williams^{*1}, J. J. Sanders^{*2}, M. De Souza³. ¹Kinesiology, Penn State University, University Park, PA, USA, ²Physiology, Penn State University, University Park, PA, USA, ³Physical Education and Health, University of Toronto, Toronto, ON, Canada.

Exercise is generally believed to represent an osteogenic stimulus, especially when high impact forces are experienced. Few studies have addressed whether moderate impact aerobic activity representing a significant cardiorespiratory stimulus can favorably impact bone turnover in premenopausal non-obese women. To begin to elucidate whether moderate impact aerobic activity (treadmill running, cycling, and elliptical) can alter bone turnover we assessed the effects of 3 months of aerobic exercise and controlled diet on bone formation (PINP) and bone resorption (serum NTX) in 17 premenopausal eumenorrheic women (age = 21 +/- 1 yrs; weight = 57.7 +/- 5.6 kg). Subjects were randomly assigned to either non-exercise (n = 10) or exercising (n = 7) groups. Food intake kcals in both groups was prescribed and adjusted throughout the intervention such that subjects maintained body weight. For both groups, dietary composition was 55% CHO, 15% PRO, and 30% FAT, and a multivitamin with calcium (40 mg) was provided. Supervised exercise training was 5 days per week 30-90 minutes at 70-85% of maximal heart rate. Daily urine samples for estrone-1-glucuronide (E1G) and pregnanediol glucuronide were collected during a baseline menstrual cycle and each day during the intervention. VO2max (ml/kg/min), increased in both groups, but the increase in exercising subjects was greater (ANOVA time effect $P < 0.001$; time X group $P = 0.07$); Non-exercise, Pre = 32.4 +/- 3.1, Post = 36.9 +/- 5.1, Exercise, Pre = 36.5 +/- 4.2, Post = 44.3 +/- 4.7. A significant decrease in bone formation over time was observed when both groups were considered together (ANOVA time effect $P = 0.004$). Exercise produced a trend toward a greater decrease in bone formation (ANOVA time X group effect $P = 0.099$). Means +/- sd for PINP ($\mu\text{g/l}$) were non-exercise, Pre = 143 +/- 36, Post = 129 +/- 27; Exercise, Pre = 185 +/- 79, Post = 140 +/- 48. A significant overall increase in bone resorption was observed when both groups are considered (ANOVA time effect; $P = 0.013$), but no significant effect of exercise was revealed (ANOVA time X group; $P = 0.484$). Means +/- sd for NTX (nmol/l) were Non-exercise, Pre = 12.8 +/- 0.9, Post = 14.9 +/- 2.8; Exercise, Pre = 14.9 +/- 2.2, Post = 16.1 +/- 2.7. Overall decreases in bone formation, and increases in bone resorption are surprising and may be attributable to changes in diet or other factors. These data do not support favorable changes in bone turnover in response to moderate impact aerobic exercise in previously sedentary premenopausal non-obese women.

Knockout of Cathepsin K in Adult Mice Does Not Result in Bone Fragility. S. J. Hoffman¹, V. Shen², X. Liang¹, C. A. Capriotti^{*1}, G. B. Stroup³, S. Kumar¹. ¹Musculoskeletal Diseases, GlaxoSmithKline, Collegeville, PA, USA, ²MDS Pharma Services, Bothell, WA, USA, ³GlaxoSmithKline, King of Prussia, PA, USA.

Cathepsin K (Cat K) plays an essential role in osteoclast-mediated degradation of the organic matrix of bone. Knockout of the enzyme in mice as well as lack of functional enzyme in the human condition, pycnodysostosis, results in osteopetrosis. However, there is controversial data over the bone fragility of Cat K knockout mice. In the current study, histomorphometry as well as bone mass and strength of the mid-femur were evaluated in Cat K knockout (KO) and wild-type (WT) adult female mice.

WT and KO female mice were sacrificed at 4 and 6 months of age. The left femur was excised and underwent pQCT imaging as well as biomechanical testing of the mid-femur. Histomorphometric analysis was performed on the mid-femur of a different set of mice of the same age and genetic background.

KO mice had greater total and cortical area and moment of inertia (MI) of the mid-femur when compared to WT. In addition, total and cortical bone mineral content (BMC) and density (BMD) were greater for the KO mice at both ages. The increases in area measurements resulted from a combination of greater cortical thickness and periosteal surfaces in the KO mice. In the KO mice, cortical area, BMC, BMD, thickness and MI significantly increased from 4 to 6 months of age whereas these changes were not observed in the WT mice.

Histomorphometric analysis showed that the KO had greater total area and reduced marrow area which resulted in greater cortical area and width compared to WT mice. No difference in periosteal bone formation rate (BFR) was observed between mice but decreased with age for both genotypes. On the endosteal surface, BFR was increased and eroded perimeter decreased in the KO mice compared to WT at 6 months of age. Intracortical remodeling spaces were observed only in a small percentage of KO mice and very little woven bone was observed.

The bending test determined that maximum load and stiffness were increased 27% and 56%, respectively, in the 6 month old KO mice compared to the WT. Energy (work to failure) increased with age in both genotypes, however, no difference was detected between the KO and WT mice at either age. Post-yield displacement tended to decrease (39 and 24 % reductions in the 4 and 6 month mice, respectively) in the KO compared to the WT mouse. When the size and geometry of the bone is taken into account, no differences in ultimate strength and elastic modulus between WT and KO were observed.

These data suggest that KO mice have different bone content and geometry than WT mice and it changes with age. These data suggest that the material present in bones of both genotypes is of similar quality although this may be due to different contributing factors.

Conditional Inactivation of the Cathepsin K (Ctsk) Gene in Adult Mice Results in Osteopetrosis without Activation of Compensatory Mechanisms for Impaired Bone Resorption. R. Kiviranta¹, I. Koskivirta^{*1}, J. Morko^{*1}, J. Heikkinen^{*1}, E. Bergman^{*1}, S. L. Alatalo^{*2}, J. Risteli^{*3}, E. Vuorio^{*1}. ¹Dept. of Medical Biochemistry and Molecular Biology, University of Turku, Turku, Finland, ²Dept. of Anatomy, University of Turku, Turku, Finland, ³Dept. of Clinical Chemistry, University of Oulu, Oulu, Finland.

Cathepsin K is the major protease responsible for matrix degradation in osteoclasts. We recently reported that Ctsk-deficient mice are osteopetrotic but retain some degree of bone turnover due to several compensatory mechanisms for the impaired bone resorption, including enhanced osteoclastogenesis and elevated expression of other proteases (MMP-9, MMP-13, MMP-14). The purpose of this study was to investigate the effects of inactivation of the Ctsk gene in adult mice and to determine whether the same compensatory mechanisms would arise when the gene is inactivated after development.

For this purpose, we generated mice harboring a modified Ctsk allele where exon 5 was flanked by loxP sites and transgenic mice with ubiquitous expression of tamoxifen-controlled Cre recombinase, which were crossed to produce mice homozygous for the floxed Ctsk allele and heterozygous for the tamoxifen-controlled Cre (CKLP^{loxP/loxP}Cre⁺). Animals were treated with either tamoxifen or vehicle at the age of 2 months and given booster injections at 3 months. Samples were collected at the age of 4 months.

Northern and pQCT analyses verified that CKLP^{loxP/loxP} mice were normal. Treatment of CKLP^{loxP/loxP}Cre⁺ mice with tamoxifen for 7 days efficiently induced recombination in the Ctsk allele and thus production of truncated Ctsk mRNA. pQCT measurements revealed that inactivation of the Ctsk gene at the age of 2 months resulted in osteopetrosis by 4 months of age. The phenotype appeared more striking than in conventional Ctsk knockout mice. Furthermore, the tamoxifen-treated animals exhibited some features of pycnodysostosis, such as decreased bone size, that we did not observe in our conventional Ctsk knockout animals. Decreased levels of serum resorption markers CTX and ICTP verified the impaired bone resorption in the tamoxifen-treated animals. Serum TRACP activity was not changed, suggesting no significant change in osteoclast numbers. Molecular biological analyses of bone samples demonstrated decreased expression of MMP-14 and cathepsin L in tamoxifen-treated mice, but no changes in the expression of TRACP, MMP-9 or MMP-13, all of which were upregulated in our conventional knockout mice. In conclusion, inactivation of the Ctsk gene in adult mice results in osteopetrosis that appears more pronounced than in conventional Ctsk knockouts. This may be due to the lack of compensatory mechanisms observed in conventional Ctsk knockout mice.

Regulation of Osteoclast Activity by Cathepsin K-Generated Type I Collagen Fragments. S. R. Wilson^{*1}, C. Peters^{*2}, P. Saftig^{*3}, D. Bromme^{*1}. ¹Faculty of Dentistry, University of British Columbia, Vancouver, BC, Canada, ²Albert-Ludwigs-Universitaet Freiburg, Freiburg, Germany, ³Christian-Albrechts-Universitaet Kiel, Kiel, Germany.

Cathepsin K (catK) is responsible for the degradation of type I collagen in osteoclast mediated bone resorption. As collagen fragments are known to be biologically active, this study investigates their potential regulatory effect on mature murine osteoclasts.

Soluble type I collagen, type II collagen, and murine long bone powder were subject to degradation reactions by 200-400nM catK, L and 50nM MMP-1. Soluble collagen degradation products or a GRGDS peptide were added to isolated neonatal mature murine osteoclasts seeded on type I collagen substrate. Alternatively, the collagen I substrate was predigested with catK and L. Wild type, catK and catL deficient osteoclasts were also treated with cysteine proteinase inhibitor LHSV (5 μM) and MMP inhibitor GM6001 (5 μM). After 24h osteoclasts were stained with FITC-phalloidin and actin rings were counted as a percentage of total osteoclast number.

Mature murine osteoclasts seeded on type I collagen substrate treated with catK degraded type I collagen or bone demonstrated a lower percentage of actin rings. This was demonstrated in wild type, catK deficient and catL deficient osteoclasts. However, this was shown with neither undegraded collagen, nor collagen degraded by MMP-1 or catL. This inhibition could be partially abrogated by the presence of a vitronectin receptor blocking antibody. CatK deficient osteoclasts and wild type osteoclasts treated with LHSV were found to have a lower basal level of active osteoclasts compared to untreated wild type cells. The number of actin rings was increased by seeding catK deficient osteoclasts on catK pre-digested type I collagen but not catL pre-digested type I collagen. MMP inhibition had no effect on actin ring percentage on any cell type studied.

CatK is known to be the most efficient mammalian collagenase. These studies suggest it may release collagen fragments containing RGD sequences, which are not normally exposed. These soluble fragments may then interact with osteoclast integrin receptors disrupting the actin ring. This is a novel regulatory role for catK and collagen fragments in bone resorption.

PIAS3 Modulates Osteoclastogenesis by Down-Regulation of NFATc1 and OSCAR. K. Kim*, J. Lee*, J. Kim*, H. Jin*, N. Kim, Research Institute of Medical Sciences and Medical Research Center for Gene Regulation, Chonnam National University Medical School, Gwangju, Republic of Korea.

Protein inhibitor of activated STAT3 (PIAS3) has been shown to regulate the activity of various transcription factors. Here, we show that overexpression of PIAS3 in bone marrow-derived monocyte/macrophage lineage cells attenuates osteoclast formation and down-regulates the expression of NFATc1 and osteoclast-associated receptor (OSCAR), which are important modulators in osteoclastogenesis. PIAS3 has been shown to associate with histone deacetylase 1 (HDAC1) as well as with transcription factors, including microphthalmia transcription factor, NFATc1, and c-Fos. Moreover, overexpression of PIAS3 inhibits transactivation of target genes such as NFATc1 and OSCAR. This inhibitory effect of PIAS3 is possibly mediated by HDAC1 recruitment to the promoter regions of NFATc1 and OSCAR. Furthermore, silencing of PIAS3 by RNA interference in osteoclast precursors enhances osteoclast formation as well as gene expression of NFATc1 and OSCAR. Taken together, our results reveal that PIAS3 acts as a modulator in osteoclastogenesis.

Disclosures: K. Kim, None.

The POZ-Zn Transcriptional Regulator OCZF/LRF Is Induced by RANKL and Increases c-Fos Expression in Osteoclastogenesis. A. Kukita¹, T. Shobuike^{*1}, M. Asagiri^{*2}, H. Takayanagi², F. Pessler^{*3}, K. Matsuo⁴, T. Kukita⁵. ¹Pathology and Biodefense Medicine, Saga University, Saga, Japan, ²Cell Signaling and COE program, Tokyo Medical and Dental University, Tokyo, Japan, ³Rheumatology Pediatrics, The Children's Hospital of Philadelphia, Philadelphia, PA, USA, ⁴Keio University School of Medicine, Tokyo, Japan, ⁵Oral Biological Sciences, Kyushu University, Fukuoka, Japan.

Osteoclast-derived zinc finger (OCZF, also known as ZBTB7, FBI-1, LRF and Pokemon) is a member of the BTB/POZ zinc finger family of transcriptional regulators that have been implicated in cell differentiation and oncogenesis. We have reported that OCZF is highly expressed in rat osteoclasts in vivo and plays a role in osteoclastogenesis in bone marrow culture. In the present study, we investigated the role of OCZF and its mouse homologue LRF in RANKL-induced osteoclastogenesis. Expression of LRF mRNA and protein was specifically induced by RANKL and M-CSF but not M-CSF alone in mouse bone marrow macrophages and the macrophage cell line, RAW-D. LRF protein was localized in the nuclei of osteoclast precursor cells and multinucleated osteoclasts. Targeted inhibition of LRF by small interfering RNAs markedly suppressed the formation of TRAP-positive multinucleated osteoclasts but not mononuclear osteoclast precursor cells in the differentiation from RAW-D cells. We then expressed OCZF under the control of the cathepsin K promoter (Ctsk-OCZF) in RAW-D cell. Expression of OCZF from the cathepsin K promoter did not induce osteoclast differentiation in the absence of RANKL, but stimulated RANKL-induced osteoclastogenesis. In addition, Ctsk-OCZF expression markedly increased the protein levels rather than mRNA levels of c-Fos and NFATc1 in the presence of RANKL. Importantly, Ctsk-OCZF induced c-Fos protein in the absence of RANKL. Furthermore, immunofluorescence studies by using confocal microscopy demonstrated that LRF is co-localized with c-Fos in the nuclei of osteoclasts. Moreover, retroviral expression of OCZF did not rescue the osteoclastogenesis of c-Fos KO mice, while LRF protein levels were extremely low in the coculture of osteoblasts and spleen of c-Fos KO mice. Together, these data suggest that OCZF/LRF promotes osteoclastogenesis by positively cooperating with c-Fos protein in the presence of RANKL.

Annexin VIII Is a Critical Bone Matrix-dependent Osteoclast Gene Transcriptionally Regulated by RANKL and NFATc1. K. P. McHugh¹, Z. Shen¹, R. P. O'Sullivan^{*1}, T. N. Crotti¹, M. R. Flannery^{*1}, S. R. Goldring².

¹Rheumatology, Beth Israel Deaconess Medical Center, Boston, MA, USA, ²Hospital for Special Surgery, New York, NY, USA.

Analysis of tissues from sites of bone erosion in rheumatoid arthritis (RA) and periprosthetic osteolysis revealed that cells expressing the full morphological and functional properties of mature osteoclasts (Ocs) are restricted to the immediate bone surface. Therefore, in addition to cytokines, we hypothesize that adhesion to bone matrix plays a role in determining the genetic profile and functional properties of fully differentiated resorbing Ocs. Through expression profiling of mouse Oc cells differentiated on bone surfaces vs plastic, we have previously identified a cluster of bone matrix-dependent Oc genes, with annexin VIII (Anx8) as a prominent member. The annexins are a family of calcium-dependent phospholipid binding proteins, some members of which bind F-actin. Annexin family members perform diverse cellular functions with many mediating vesicular trafficking and targeting. Anx8 message was found, by QPCR, to increase temporally during Oc formation with kinetics similar to that of CTR and the beta-3 integrin. Anx8 expression was confirmed at the protein level in bone-adherent Ocs in peri-implant tissues and at sites of bone erosions in RA. siRNA-mediated gene knockdown in RAW264.7 cells was utilized to determine the function and requirement for Anx8 in Ocs. Consistent with a key role in Oc formation, siRNA knockdown blocked Oc spreading and actin ring formation, and was shown to result in a >50% inhibition of resorption of mineralized matrix.

We have further characterized transcriptional regulation of the Anx8 gene in Ocs by cloning the mouse Anx8 promoter and generating deletion reporter constructs. The mouse Anx8 promoter displays significant homology with its human homologue in a proximal region and in a separate region near -4kb. RANKL induced the Anx8 promoter up to 10 fold following transient transfection into RAW264.7 cells. We next tested for NFATc1 trans-activation since the Anx8 promoter responds to RANKL and the evolutionarily conserved regions contain consensus NFAT binding sites. Consistent with an Oc-specific and Ca⁺⁺ regulated gene, we find that the mouse Anx8 promoter is trans-activated by NFATc1. Using an in vitro model of bone-matrix-dependent Oc differentiation, we have identified a novel matrix-dependent and required Oc gene. We show here that the promoter region contains functional Oc regulatory elements. The Anx8 gene plays a key role in Oc formation and we speculate that Anx8 represents a potential new target for anti-Oc therapy in osteolytic and metabolic bone diseases.

Myosin IIA Regulates Precursor Cell Fusion and Osteoclast Motility. B. K. McMichael¹, R. B. Wysolmerski^{*2}, B. S. Lee¹. ¹Physiology and Cell Biology, The Ohio State University, Columbus, OH, USA, ²Neurobiology and Anatomy, West Virginia University, Morgantown, WV, USA.

Osteoclasts, large multinucleated cells formed by fusion of monocyte/macrophage precursors, differentiate by stimulation of precursors with macrophage colony stimulating factor (M-CSF) and receptor for activation of nuclear factor kappa B ligand (RANKL). M-CSF and RANKL stimulation leads to altered expression of many genes. In this work, expression of the nonmuscle myosin IIA (myoIIA) during osteoclastogenesis was examined, as was its role in regulating cell differentiation and osteoclast activity. Class II nonmuscle myosins are ATP-driven motors that contain a motor domain that binds actin and a tail that forms a coiled-coil structure. Myosin IIA has been implicated in many cellular functions including cytokinesis, maintenance of cortical tension, and cell spreading. However, its role in osteoclast function has not yet been well examined.

Our previous studies showed nonmuscle myoIIA to be distributed within podosomes and the actin ring of polarized osteoclasts, suggesting that myoIIA may play a role in osteoclast motility and bone resorption. During a normal seven day differentiation period of both mouse RAW 264.7 and primary marrow cells, myoIIA protein levels temporarily diminished on days 3-4, corresponding to the time at which fusion of osteoclast precursors is initiated. During this same time course, myoIIA mRNA levels did not change indicating the loss of expression to be a post-transcriptionally mediated process. Pulse-chase analyses demonstrated that this temporary loss of myoIIA expression was due to increased degradation of the protein during days 3-4. The timing of this alteration in expression suggests a potential role for myoIIA in osteoclast differentiation. Therefore, RNA interference was used to suppress expression of the myoIIA heavy chain during the latter stages of osteoclastogenesis in both RAW 264.7 and mouse marrow cells. This suppression led to the generation of very large osteoclasts that were a result of increased precursor fusion, as demonstrated by elevated numbers of nuclei per cell. These large osteoclasts showed decreased cell motility in addition to a failure to reattach to substrate following dissociation. On bone, these cells formed either very large actin rings or multiple rings per cell. While the large cells were capable of resorbing bone to a similar extent as normal-sized controls, their diminished motility was apparent from a clustered patterning of resorption pits. These results suggest that nonmuscle myosin IIA is required during osteoclastogenesis to limit the extent of precursor fusion and to promote osteoclast motility.

Diverging Pathways of Calmodulin Regulation of Osteoclastogenesis. K. J. Micoli, A. Zayzafoon*, S. Singhal*, J. M. McDonald. Pathology, UAB, Birmingham, AL, USA.

Osteoporosis results from an imbalance in bone remodeling that favors resorption, and increased osteoclastogenesis is one mechanism important in development of low bone mass.

The purpose of these studies was to determine the role of calmodulin (CaM) in regulating osteoclastogenesis via calcineurin (CaN)/NFAT and CaMKII. The studies utilized in vitro differentiation of RAW 264.7 cells, Western blotting, TRAcP staining, IF, CaN and CaMKII assays, PCR, and siRNA or shRNA transfection to determine the CaM/CaMKII-dependent events in the RANK pathway.

RANKL treatment of RAW 264.7 cells induces rapid phosphorylation of numerous signaling molecules, including ERK, JNK, p38, and Akt, and upregulation of c-fos. Inhibition of CaMKII with 5 μ M KN93 prevented RANKL-induced phosphorylation of ERK, JNK and Akt, c-fos upregulation, and blocked osteoclast formation without preventing NFAT nuclear translocation. CaMKII is a complex holoenzyme, composed of α , β , γ and δ isoforms, all of which are expressed in RAW cells during differentiation. RAW cells expressing CaMKII α shRNA did not form osteoclasts in response to RANKL treatment, and siRNA constructs against β , γ and δ also resulted in marked inhibition of osteoclastogenesis. Interestingly, RAW cells were also found to express a non-kinase form of CaMKII α , α KAP, which is upregulated during osteoclastogenesis and may play a role in redistributing CaMKII during later stages of differentiation. We show that CaMKII activity increases rapidly (peaking at 10-15 min) following RANKL treatment, and peaks again after 72 h, consistent with a role in regulating both early and late RANK signaling.

RANKL is known to induce nuclear translocation of NFAT, presumably through activation of calcineurin. Our data show that, in fact, RANKL activation leads to an approximate two-fold increase in CaN activity after 10-15 min, but activity drops to 50% of basal after 72h, which is when peak nuclear NFAT is detected. This apparent paradox is partly explained by data showing that RANKL treatment downregulates casein kinase 1 α , which phosphorylates NFAT. Thus, despite low levels of CaN activity, NFAT remains in the nucleus because the phosphorylation pathway is shut down to an equal extent.

These data are the first to describe actual enzyme activity for CaMKII and CaN in this system and are consistent with a model in which RANK signaling leads to rapid increases in intracellular calcium, activation of calmodulin, and CaMKII, which regulate osteoclastogenesis at early and late time points.

Together, these studies provide evidence that CaMKII is the primary target of CaM signaling in the RANK pathway, and represents a novel NFAT-independent target for inhibiting osteoclastogenesis.

Osteoclasts Generated in Ectopic Bone Are Derived from Postmitotic Osteoclast Precursors (pOCPs). A. Muto*¹, T. Mizoguchi*², T. Noguchi*¹, N. Udagawa*³, N. Takahashi*². ¹Department of Periodontology, Aichi-gakuin University school of Dentistry, Nagoya, Japan, ²Institute for Oral Science, Matsumoto Dental University, Shiojiri, Japan, ³Department of Biochemistry, Matsumoto Dental University, Shiojiri, Japan.

We have reported that when collagen pellets containing BMP-2 (BMP-pellets) were implanted into mice, osteoclasts as well as osteoblasts appeared simultaneously in the BMP-pellets (Endocrinology 147:3366, 2006). We also showed that cell cycle progression and subsequent cell cycle arrest in osteoclast precursors are required for their differentiation into osteoclasts. The quiescent osteoclast precursor cells were named "postmitotic osteoclast precursors" (pOCPs) (JBMR 20 Suppl 1: M244, 2005). Here, we examined whether pOCPs are present in the blood, using a system of the BMP-induced ectopic bone formation. BMP-pellets were implanted into dorsal muscular pouches of mice. To discriminate between proliferating and quiescent cells, mice were given 5'-bromo-2'-deoxyuridine (BrdU) in drinking water during an implantation period of 2 weeks. Then, BMP-pellets and tibiae were recovered from the mice, and subjected to TRAP and BrdU staining. The results obtained from this work are as follows: (1) In tibial sections, BrdU-positive nuclei were detected in bone marrow cells, osteoblasts, chondrocytes and mesenchymal cells. In contrast, none of the nuclei in TRAP-positive osteoclasts incorporated BrdU. (2) In BMP-pellet sections, many TRAP-positive osteoclasts were found to be in close contact with ALP-positive osteoblasts. A large number of mesenchymal cells including osteoblasts possessed BrdU-positive nuclei. Some of the macrophage-like cells also had BrdU-positive nuclei. In contrast, all the nuclei in TRAP-positive osteoclasts observed in the BMP-pellets were negative for BrdU. We have reported that osteoblasts prepare the osteoclast niche, which supports a long-term survival of pOCP. Osteoclasts were differentiated from pOCPs in the osteoclast niche in response to several stimuli including the intraperitoneal administration of RANKL. In the present study, osteoclasts in ectopic bone are also differentiated from pOCPs without cell proliferation. These results suggest that pOCPs are present in the blood flow and osteoblasts may play a role in specific homing of pOCPs to the precise sites of action of osteoclasts.

M-CSF Independent Mechanisms for Osteoclastogenesis. Y. Nakamichi¹, N. Udagawa², H. Yasuda³, M. Nakamura², Y. Kobayashi*¹, N. Takahashi*¹. ¹Institute for Oral Science, Matsumoto Dental Univ., Shiojiri, Japan, ²Dept. of Biochemistry, Matsumoto Dental Univ., Shiojiri, Japan, ³Nagahama Institute for Biochemical Science, Oriental Yeast Co., Ltd., Nagahama, Japan.

M-CSF and RANKL are osteoblast-derived cytokines essential for differentiation of monocytes (MOs)/macrophages (MΦs) into osteoclasts (OCs). M-CSF-deficient op/op mice exhibit severe osteopetrosis due to deficiencies of OCs. It is known that the defect is prominent especially in young op/op mice and OCs gradually appear with aging. However, the molecular mechanisms for OC formation in the absence of M-CSF have remained elusive. To elucidate M-CSF independent mechanisms for OC formation, we performed four experiments as follows: (1) We tried to induce OC formation by administering an 1 α ,25(OH)₂-vitamin D₃ analog (2MD) or GST-RANKL (kindly provided by Oriental Yeast Co., Ltd.) intraperitoneally in young (3-week-old) op/op mice in which OCs are totally absent. When op/op mice were administered 2MD (30 pmol /day) for 2 days, many TRAP-positive OCs were formed at the surface of trabecular bone. Similarly, when GST-RANKL (40 μ g/ day) or M-CSF (10⁵ IU/day) was administered into op/op mice for 4 days, many OCs appeared in bone tissues as if they had existed in WT mice. Concomitantly, serum TRAP5b activity, an indicator of osteoclastic bone resorption, was increased by the administration of these agents. (2) To assess the requirement of M-CSF for OC formation in normal animal, WT mice were pretreated with M-CSFR (c-Fms)-neutralizing antibody (AFS98) for a month and followed by simultaneous treatment with both 2MD and AFS98 for 4 days. 2MD effectively induced TRAP-positive cells and hypercalcemia under the conditions where the c-Fms signal was suppressed. (3) To find a substitute for M-CSF, we examined whether M-CSF-related growth factors (PDGF, SCF, VEGF, FLT3L) could replace M-CSF in the in vitro differentiation of MΦs into OCs. None of these factors supported in vitro OC formation. (4) To investigate whether cell adhesion molecules such as N-cadherin and ICAM can support OC differentiation, we tested in vitro OC formation on the plates pre-coated with adhesion molecules. N-cadherin but not ICAM induced mononuclear TRAP-positive cells even in the absence of M-CSF. These findings suggest that M-CSF is not absolutely required for in vivo OC formation in WT mice as well as op/op mice. In culture conditions, TRAP-positive cells were induced in N-cadherin-coated plates in the absence of M-CSF, suggesting that the adhesion-mediated signal may play a role in OC differentiation in vivo.

Expression of Angiotensin II Receptor in Osteoclasts and Its Roles on Differentiation and Survival. C. Nakamura¹, S. Kamiya*², T. Fukawa*², N. Nimura*¹, S. Wada*². ¹Bio-Analytical Chemistry, Josai International University, Chiba, Japan, ²Clinical Sciences, Josai International University, Chiba, Japan.

Angiotensin (Ang) II is well known for its action on vasoconstriction, vascular cell proliferation, and remodeling of myocardium. In this study, we examined whether Ang II could be involved in bone remodeling process, since it was found recently that bone marrow cells expressed high levels of Ang II receptor.

Bone marrow macrophages (BMMs) were prepared from bone marrow cells (BMCs) through incubating with M-CSF, and then treated with M-CSF/sRANKL. Ang II receptor (AT_{1A}, AT_{1B} and AT₂) expression was examined by RT-PCR and Western blot analysis through osteoclasts (OCs) development from precursors.

AT_{1A} mRNA was highly expressed and was stable throughout culture period in BMCs, BMMs and OCs, whereas AT_{1B} mRNA was increased parallel to OC differentiation. Expression of AT₁ which could not be discriminated as protein levels of AT_{1A} and AT_{1B} was not changed in these cells. AT₂ mRNA and protein expression was much lower than AT₁ but the levels were increased in either BMMs or OCs. To examine possible roles of Ang II on OC development, we studied the effects of AT₁ agonist (L-162,313, 10⁻⁵M) in the cells. Treatment with AT₁ agonist completely suppressed OC formation at the early culture period (day 0-3) and even late culture period (day 3-7). Treatment with AT₁ agonist on mature OCs 24-48h reduced the number of viable OCs. AT₁ antagonist (Losartan), AT₂ agonist (CGP42112A) and AT₂ antagonist (PD123319), however, did not affect OCs differentiation and their survival. The mechanism of these inhibitory effects of AT₁ agonist remains to be clarified, but we are currently focusing on down-stream signaling and changeable cytokine expression related to OC differentiation.

In this study, we found that AT_{1B} and AT₂ receptor expression are increased parallel to OC differentiation and that AT₁ agonist inhibits OC differentiation and survival, which may indicate possible roles of Ang II-AT₁ pathway on OC formation and bone remodeling process.

The TREM2 Pathway Is Involved in Osteoclastogenesis Induced By Nucleoside Reverse Transcriptase Inhibitors in AIDS. G. Pan*, J. M. McDonald, Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

An increased incidence of osteopenia and osteoporosis in HIV infected patients receiving antiretroviral therapy has now been reported in several studies. Our previous studies show that antiviral nucleoside reverse transcriptase inhibitors (NRTIs) stimulate osteoclast differentiation in vitro and produce osteopenia in mice. Moreover, NRTI-enhanced osteoclastogenesis is mediated through the RANK pathway. The underlying molecular mechanisms responsible for activating the RANK pathway by NRTIs have not been elucidated.

We analyzed osteoclastogenesis-associated gene expression in nucleoside-stimulated osteoclastogenesis and found that antiviral NRTIs up-regulated the expression of triggering receptor expressed on myeloid cells 2 (TREM2) in RAW264.7 cells and mouse bone marrow macrophages. To further determine the role of TREM2 in NRTI-stimulated osteoclastogenesis, antibodies against TREM2 were used to determine whether NRTI-stimulated osteoclastogenesis can be inhibited. The elevated osteoclastogenesis (TRACP) induced by RANKL plus AZT was reduced by TREM2 antibody approximately to the level of RANKL treatment alone, whereas antagonists of the purinergic receptor failed to inhibit NRTI-stimulated osteoclastogenesis. Then, we determined whether NRTI-enhanced RANKL-mediated osteoclastogenesis is associated with TREM2 expression. Our results indicated that RAW264.7 cells with high TREM2 expression were sensitive, whereas cells with low TREM2 expression were resistant to NRTI-stimulated differentiation of osteoclasts. Finally, we determined the function of the TREM2 pathway in NRTI-stimulated osteoclastogenesis. NRTIs stimulated the promoter activity of NFATc1, increased the translocation of NFATc1 into nuclei, and accelerated actin formation, all down-stream events of TREM2 signaling. In conclusion, osteoclast differentiation induced by NRTI not only requires RANK signaling, but also requires the costimulatory TREM2 pathway. NRTIs activate the TREM2 pathway, which interact with the RANK pathway enhancing osteoclastogenesis. The TREM2 pathway is largely responsible for increased osteoclastogenesis induced by NRTIs during treatment of AIDS which induces osteopenia/osteoporosis.

Cobalt Incorporation into Calcium Phosphate Layers Stimulates Osteoclast Differentiation and Activation via Hypoxia Inducible Factor Pathway. S. Patnirapong*, P. Habibovic*, P. V. Hauschka*. ¹Orthopaedic Surgery, Children's Hospital, Boston, MA, USA, ²Tissue Regeneration, University of Twente, Enschede, Netherlands Antilles.

One of the major etiologies of implant failure is activation of macrophages by particulate wear debris, resulting in inflammatory stimulation of osteolysis. Recent studies have shown an increase of metal ions released from wear particles and metallic prostheses due to mechanical stress. Furthermore, these metal ions seem to accumulate in body fluids, peri-implant soft tissues, and bone mineral. We hypothesized that metallic ions could directly activate osteolysis, particularly cobalt (II), which is a known "hypoxia mimic" activator of hypoxic gene expression and a component of alloys used for prostheses. To address this question, we prepared calcium phosphate (CaP) coatings with traces of cobalt ions to examine the effects on osteoclast formation and resorptive activation. Treatments were divided into 2 conditions with various cobalt concentrations either incorporated into the CaP layer, or added to culture media. Scanning electron microscopy (SEM) and inductively coupled plasma mass spectrometry (ICP-MS) were used to visualize the CaP crystallization, and to measure Co²⁺ concentrations in the CaP and in the culture medium, respectively. SEM demonstrated that incorporated Co²⁺ did not modify the nucleation and growth mechanism of the CaP crystallizing system. Measurement of Co²⁺ by ICP-MS indicated the release of Co²⁺ from the CaP layers during equilibration with culture medium. Low concentrations of cobalt delivered to developing osteoclast precursors by both routes increased osteoclast differentiation as well as resorptive function. A 1.7 to 1.75-fold increase in osteoclast numbers and a 2.3 to 2.7-fold more resorptive activity of the CaP layer were observed for 0.1 - 20 µM Co²⁺, which is within the range found in peri-implant tissues in vivo. In addition, we investigated the stabilization of hypoxia inducible factor alpha (HIF-α), an important transcription factor of the hypoxic pathway, and its target genes. Immunoblotting showed that HIF-1α and HIF-2α were stabilized in osteoclastic cells exposed to Co²⁺. Quantitative RT-PCR demonstrates upregulated mRNA levels of glucose transporter-1 (Glut-1), phosphofructokinase muscle (Pfkfb) and vascular endothelial growth factor (Vegf) by Co²⁺ treatment, indicating the osteoclastic switch to glycolytic metabolism. This direct effect of Co²⁺ on osteoclasts through the HIF pathway may contribute to osteolysis and aseptic implant loosening independently of the inflammation-mediated pathways.

Inhibition of Osteoclastogenesis by Prosthetic Wear Debris Involves Suppression of RANK Expression. E. Purdue*, K. Ly*, L. Ivashkiv*, B. Nestor*, T. Sculco*, S. Goldring. Osteolysis Research Laboratory, Hospital for Special Surgery, New York, NY, USA.

Osteoclasts, multinucleated foreign body giant cells, and mononuclear phagocytic macrophages are derived from a common myeloid precursor. Multiple factors control the commitment of these precursors to each of the cell types, including cytokines, cell-cell and cell-matrix interactions. There remains controversy, however, regarding the effect of activation of phagocytic pathways on myeloid cell fate. The present studies were undertaken to define the effect of phagocytic activation on osteoclast differentiation in order to gain insight into the mechanisms associated with prosthetic wear debris-induced osteolysis, the major cause of implant failure after total joint replacement. Human monocytes were cultured with MCSF in the presence or absence of polymethylmethacrylate (PMMA) bone cement or titanium wear particles followed by treatment with or without RANKL. Osteoclastogenesis was assessed by identification of TRAP-positive multinucleated cells. Real-time RT-PCR and Microarray analysis were used to determine the effects of PMMA and titanium particles on the pattern of gene expression. At doses of 30 particles per cell, both PMMA and titanium completely inhibited RANKL-induced osteoclast formation. At lower numbers, osteoclastogenesis was reduced but not obliterated. Interestingly, the osteoclasts formed in the presence of reduced particle number appeared largely devoid of particles. PMMA and titanium also inhibited RANKL-induced expression of the osteoclast markers cathepsin K and TRAP. Most strikingly, PMMA and titanium very strongly inhibited expression of RANK, both in the presence or absence of RANKL. Our data suggest a molecular explanation for the observation, first recorded over fifteen years ago, that osteoclasts within the osteolytic tissues associated with periprosthetic osteolysis do not contain particles (Willert et al, Clin Orthop Relat Res. 1990 258:108-21). Although it has been reported that PMMA can induce osteoclastogenesis and that particle-laden macrophages can differentiate into osteoclasts, our results indicate that phagocytic activation inhibits RANKL-induced osteoclast formation, and that this affect can be attributed to suppression of RANK, which is essential for RANKL-induced osteoclast formation. Taken together with the well-known ability of wear debris to activate pro-inflammatory cytokine signaling in myeloid cells, and the more recent observations that wear debris can promote alternative, non-inflammatory, macrophage activation, these results highlight the multiple ways in which wear debris can influence myeloid cell fate in periprosthetic osteolysis.

Functional Role for Spinal Muscular Atrophy (SMA) Gene Expression in Bone Remodeling. S. Shanmugarajan¹, K. J. Swoboda*, S. T. Iannaccone*, W. L. Ries¹, B. L. Maria*, S. V. Reddy¹. ¹Charles P. Darby Children's Research Institute, Medical University of South Carolina, Charleston, SC, USA, ²University of Utah School of Medicine, Salt Lake City, UT, USA, ³University of Texas Southwestern Medical Center, Dallas, TX, USA.

Spinal muscular atrophy (SMA) is the second most common fatal childhood disorder which occurs 1 in 8000 newborns. Although the core clinical features of SMA include muscle weakness caused by degenerating lower motor neurons, patients also have a high incidence of bone fractures. SMA determining gene encoding protein, SMN levels are significantly reduced due to deletions/mutations in the telomeric SMN1 gene in these patients. However, a centromeric SMN2 gene copy can not compensate for the deficiency due to an aberrant splicing of the exon 7 region. SMN expression is ubiquitous. We have recently reported SMN expression and differential splicing in bone resorbing osteoclasts. Also, we have shown SMN interaction with the osteoclast stimulatory factor (OSF). It is our hypothesis that SMN plays an important role in the osteoclast (OCL) formation/bone resorption activity. SMA bone disease involves OCL development/abnormalities due to SMN deficiency which leads to bone fractures. In the present study, we utilized the *Smn*^{-/-} - SMN2 mouse model of SMA to determine the functional role for SMN in bone remodeling. DEXA analysis demonstrated a significant decrease in total bone area and poorly developed caudal vertebra in *Smn*^{-/-}; SMN2 mice. Interestingly, these mice also showed pelvic bone fractures similar to patients with SMA. Histological analysis demonstrated a thin porous cortex of cortical bone and thin trabeculae at the proximal end of the growth plate in the caudal vertebrae of *Smn* deficient mice compared to wild-type mice. Further, histochemical staining of caudal vertebra in the *Smn*^{-/-}; SMN2 mice portrays the presence of activated osteoclasts on the sparse trabeculae and in the inner endosteal surface of the thin cortex. In contrast, OCL are mostly confined to the base of the growth plate region in wild-type mice. Histomorphometric analysis further confirmed an increased OCL number and a decreased number of osteoblast cells on bone surfaces in *Smn* deficient mice. Also, urine N-telopeptides of type I collagen (NTx) levels are significantly increased (13.6 fold) in these mice indicating excess bone resorption by osteoclasts. Furthermore, *Smn* deficient mouse bone marrow cultures demonstrated a significant increase (54%) in OCL formation and bone resorption capacity compared to wild-type mice. Taken together, our results implicate SMN function in bone remodeling. Therefore, understanding bone remodeling in SMA may lead to novel therapeutic approaches to prevent bone fractures and enhancing the quality of life in SMA children.

Adenosine Receptors in the Osteoclast. S. Stephens^{*1}, J. Auchampach^{*2}, A. Blangy³, R. Rose-Meyer^{*1}, J. Headricks^{*1}, N. Morrison¹. ¹Medical Sciences, Griffith University, Gold Coast, Australia, ²Pharmacology and Toxicology, Medical College of Wisconsin, Milwaukee, WI, USA, ³CRBM-CNRS, Montpellier, France.

The osteoclast is a cAMP-sensitive cell whose formation is stimulated by the decrease in cAMP via follicle-stimulating hormone but whose function is inhibited by the increase in cAMP via the calcitonin receptor. Adenosine receptors (ARs) are P1 G-protein-coupled receptors composed of four subtypes AR₁, AR_{2A}, AR_{2B} and AR₃. These receptors have diverse effectors but all regulate the levels of intracellular cAMP via modulation of adenylyl cyclase (AR₁/AR₃ decreases cAMP and AR_{2A}/AR_{2B} increases cAMP). We found all four ARs expressed in human osteoclasts with AR₁ being the most abundant and upregulated (~15 fold compared to non-RANKL-treated control). Later experiments confirmed the presence of all four ARs in murine osteoclasts with AR₁ being the only osteoclast-specific AR, albeit the least expressed. In this study, we set out to establish whether ARs when stimulated, could affect RANKL-induced osteoclast differentiation. Using adenosine (1-10µM), the endogenous agonist for all adenosine receptors, we showed a significant increase in osteoclastogenesis. This effect was not blocked by P2 receptor antagonists confirming that this effect is P1-selective and not via the ATP-specific P2 receptors whose role in augmenting osteoclastogenesis is already confirmed. Next, to evaluate which receptor(s) is/are responsible for increased osteoclast formation, the agonists CCPA, CGS1280, NECA and CI-IB MECA were used in place of adenosine for the specific activation of AR₁, AR_{2A}, AR_{2B} and AR₃ respectively. At specific concentrations (1-10nM), the agonists showed that all ARs can mediate an increase in osteoclast formation with up to 7 times more osteoclasts compared to RANKL-only treated cells. Moreover, the combination of all agonists did not further increase osteoclastogenesis (ie non additive actions) implying that the four ARs signal through the same pathway or converge through a common signalling gateway. A common pathway is possible through the IP₃ signalling cascade but not via cAMP. IP₃ signalling is directly linked to Ca²⁺ extrusion from the endoplasmic reticulum which can activate NFATc via calmodulin/calcineurin and potentially explains the pathway exploited by ARs in the osteoclast.

RANKL Is Produced by Adipocytes and Stimulates Osteoclastogenesis. S. Takeshita, K. Ikeda. Bone and Joint Disease, National Center for Geriatrics and Gerontology, Obu, Japan.

RANKL is an osteoclastogenic cytokine that is induced on osteoblastic/stromal cells in response to osteotropic hormones, such as 1α,25(OH)₂D₃ or PTH. However, it remains to be determined which cell types actually express RANKL in vivo in response to types of cues. We have found that long-term cultures of mouse whole bone marrow cells, under adipogenic induction with Dexamethasone and IBMX, exhibit strongly induced osteoclastogenesis without the addition of any osteotropic hormones or RANKL. In fact, RANKL expression was induced in marrow stromal cell lines, ST2 and MC3T3-G2/PA6, following adipogenic induction. RANKL was induced transiently during adipogenesis, with concomitant down-regulation of OPG, but not at a later stage with the accumulation of lipid droplets, suggesting that adipocytes at a certain stage of differentiation express RANKL and support osteoclastogenesis. In order to test this hypothesis, we used an aged model in which bone marrow is full of adipose cells. Bone marrow cells from 2-year-old C57BL/6 male mice cultured under osteogenic conditions (β-glycerolphosphate and ascorbic acid), without the addition of any stimulator, gave rise to "osteoclast colonies" (i.e. ALP-positive osteoblastic colonies containing TRAP-positive osteoclasts) that exceeded 30% of total CFU-F, whereas those from younger mice produced very few osteoclast colonies. Adipogenic cultures of bone marrow cells from the aged mice yielded even more osteoclasts than did osteogenic cultures, and RT-PCR analysis revealed RANKL was up-regulated in adipogenic cultures of bone marrow stromal cells. These results suggest that bone marrow cells in aged animals have a potent capacity for generating osteoclast colonies under adipogenic conditions without the need of any osteotropic hormones, and that adipogenic cells in bone marrow may contribute to accelerated osteoclastogenesis in senile or steroid-induced osteoporosis by producing RANKL as an adipokine.

The Matrix PRoline/arginine-rich End Leucine-rich Repeat Protein (PRELP) Inhibits Osteoclastogenesis Inactivating the NF-kappaB Signal. M. Alamanou^{*1}, N. Rucci¹, A. Rufo^{*1}, D. Heinegård^{*2}, A. Teti¹. ¹Experimental Medicine, University of L'Aquila, L'Aquila, Italy, ²Experimental Medical Science, Lund University, Lund, Sweden.

PRELP originally found in cartilage is also found at certain basement membranes where it may serve as an anchor by binding to heparan sulfate side chains of perlecan and concomitantly to collagens type I/II collagens. Loss of function mutations of PRELP are involved in the pathogenesis of Hutchinson-Gilford progeria, characterized, among other symptoms, by severe osteoporosis. PRELP is highly expressed in cartilage and developing bone. Herein we demonstrate that a peptide corresponding to the entire heparin-binding domain of PRELP inhibits mouse osteoclast formation. Treatment with the PRELP-peptide decreased osteoclastogenesis by 80% in non-fractionated mouse bone marrow cultures

exposed to 1,25(OH)₂VitD₃, and in purified bone marrow macrophages treated with M-CSF and RANKL (IC₅₀=7.3 microM). Pre-treatment of mature osteoclasts with the PRELP-peptide decreased adhesion to fetal calf serum protein substrate by 60%. In contrast, the peptide showed no activity with osteoclast precursors and neither their number, nor TRAcP activity and adhesion were affected by the treatment. Consistently, the PRELP-peptide inhibited osteoclastogenesis when added at the 4th day of culture, suggesting a late effect on pre-fusion osteoclast precursors. Although a terminally-tagged PRELP-peptide co-localized with heparan sulphate proteoglycans (HSPGs), they did not appear to physically interact. Consistently, treatment with heparinase to remove the heparan sulfate chains, failed to prevent PRELP from inhibiting osteoclastogenesis. In contrast, the peptide activity was shown to depend on binding to the chondroitin sulphate chains of cell surface proteoglycans, and the effect was abolished by treatment with chondroitinase. Tagged PRELP was internalised by osteoclast precursors by an annexin II-dependent mechanism. It translocated to the nucleus where it bound NF-kappaB reducing its transcriptional activity by 50%. Finally, the PRELP-peptide was found to affect osteoclastogenesis and bone resorption only by a direct mechanism as real-time RT-PCR failed to detect any change in expression of cytokines promoting osteoclastogenesis in mouse calvarial osteoblasts. Accordingly, the PRELP-peptide showed no effect on their alkaline phosphatase activity, nodule mineralization, gene expression nor intracellular signalling protein phosphorylations. We conclude that PRELP is a direct negative regulator of osteoclast formation, which blocks NF-kappa B signaling in late stage pre-fusion committed osteoclast precursors, with no apparent effect on the osteoblast lineage.

Comparative Analysis of Osteoclast Bone Resorption Activity and Apoptosis in Young and Old Mice. S. J. Wimalawansa, X. Wang, J. Ghosh^{*}, F. Azeez^{*}. Medicine, Robert Wood Johnson Medical School, New Brunswick, NJ, USA.

Osteoporosis is a systemic skeletal disease characterized by low bone mass and micro-architectural deterioration of bone tissue with consequent increase in bone fragility and susceptibility to fracture. Besides the effects of hormone, environmental factors and other secondary causes on bone, aging itself is believed to be a major cause of bone loss in the elderly.

In the present study, we compared the osteoclasts bone-resorbing activity and life span of old and young mice. Five, 4-6 week old (young) female mice and five, 20-24 months old (aged) female mice were utilized to obtain osteoclast progenitors and osteoclasts. The osteoclast progenitor cells were obtained from mice bone marrow of long bones in simultaneously, and cultured in 10% FBS α-MEM with 5ng/ml MCSF for two days. The non-adherent cells were further cultured for 11 days in vitro with OC medium contained 30 ng/ml MCSF and 60 ng/ml RANK. 200,000 cells were seeded on each calcium phosphate coated disc (BD Biosciences Discovery Labware, Canada) for pit resorption assay; and 200,000 cells were seeded on each pre-treated cover slip for TRAP stain and apoptosis assay. The pit area is measured using the Metavue Software version 6.0 on the Nikon 2000U confocal microscope. TRAP stain was used to quantify matured osteoclasts (>3 nuclei). The Image-iT LIVE Green Poly Caspases Detection Kit, Molecular Probes Invitrogen Technologies was used for apoptosis assay. The protocol of molecular Probes was adopted and the number of mature osteoclasts with three or more nuclei were counted using ACT-1 Software, Nikon 2000U confocal microscope. The fluorescence intensity indicated the apoptotic status of the cells.

The osteoclasts from aged mice showed more bone resorbing activity than those from young mice; the resorption area of age osteoclasts are 11.6 ± 1.2 %, while the resorption area from young osteoclast are 5.1 ± 2.5 % ($p=0.02$). Trap stain results indicated that the matured osteoclasts from aged mice are almost twice as much as those from young mice (122 vs. 69). Furthermore, the apoptotic mature osteoclasts in young were more than those in old mice (90% vs. 81%).

The etiology of age-related bone loss is complicated, and although some mechanisms involving osteoblast and osteoclast dysfunction have been reported, the process remains elusive. Our data indicate that matured osteoclast from old mice A). Survived longer, B). Less apoptotic, and thus, C). Absorbed more bone than osteoclast from young mice. Osteoclastic apoptotic-induction agents should help to combat osteoporosis in the elderly.

High D(+)-glucose Concentration Inhibits RANKL-induced Osteoclastogenesis. Y. Wittrant^{*1}, Y. Gorin^{*2}, K. Woodruff^{ff*1}, D. Horn^{*1}, S. Mohan^{*1}, H. E. Abboud^{*2}, S. Werner¹. ¹Pathology, University of Texas Health Science Center San Antonio and Audie Murphy VA Hospital, San Antonio, TX, USA, ²Nephrology, University of Texas Health Science Center San Antonio, San Antonio, TX, USA.

Diabetes is associated with altered bone metabolism that may lead to increased risk of osteoporosis and fracture. Hyperglycemia has been implicated in the pathogenesis of diabetic bone disease; however, the biologic effect of glucose on osteoclastogenesis is unclear. Although glucose is a source of energy for osteoclast resorption, effect of sustained high glucose levels on osteoclast (OC) differentiation and function have not been explored. We examined the effect of high D(+)-glucose and L(-)-glucose (osmotic control) on RANKL-induced osteoclastogenesis using RAW264.7 cells and Bone Marrow Macrophages as models. OC formation was analyzed using TRAP assay, expression of CTR and cathepsin K mRNAs. Since reactive oxygen species (ROS), caspase-3 and NF-

kB are crucial for RANKL-induced osteoclastogenesis, the effect of glucose on these factors was examined. Intracellular ROS generation was determined by measuring fluorescence intensity in cultures incubated with 2',7'-dichlorofluorescein diacetate (DCF-DA). Caspase-3 activity was quantified in cell lysates and NF- κ B-dependent luciferase activity was analyzed following transient transfection with a vector containing NF- κ B response elements linked to the luciferase reporter gene. The effect of glucose on cellular function was assessed using a migration assay. Results showed that high D-Glc, but not L-Glc, caused a profound decrease in RANKL-induced TRAP-positive OC and led to a predominance of mononuclear cells; this effect correlated with reduced expression of CTR and Cathepsin K. Compared to cultures incubated with RANKL alone, high D-Glc markedly reduced ROS levels by 90%, decreased caspase-3 activity and inhibited NF- κ B transcriptional activity, whereas high L-Glc had little or no effect. In separate experiments, incubation of cells with H₂O₂ in the absence of RANKL induced NF- κ B luciferase activity, indicating the ability of ROS to directly affect NF- κ B activity. In migration assays, fewer cells migrated into and covered the wounded site in high D-Glc-treated cultures compared to control cultures. These findings indicate, for the first time, that high D-Glc inhibits OC formation, ROS production, caspase-3 activity and migration in response to RANKL through a metabolic pathway. High D-Glc may alter RANKL-induced OC formation by inhibiting NF- κ B activity via a ROS-dependent mechanism. Our data suggest that high glucose may prevent excessive osteoclast-mediated bone loss in diabetes and provide new insight into the biologic effects of glucose on osteoclastogenesis.

The Role of Bcl2 in Osteoclastogenesis Ex Vivo. D. Yang, F. Liu, L. K. McCauley, J. Yamashita. University of Michigan School of Dentistry, Ann Arbor, MI, USA.

Activation of B-cell leukemia/lymphoma 2 (Bcl2) suppresses programmed cell death in many cell types. It has been reported that forced expression of Bcl2 in M-CSF deficient monocytes partially rescued osteopetrosis of op/op mice. We recently reported that Bcl2 homozygous mutant mice had increased bone mass and that such skeletal phenotype was at least partially attributed to osteoclast defects. These findings suggest an important role of Bcl2 in osteoclastogenesis. However, the function of Bcl2 in osteoclast differentiation and survival has not been well investigated. In this study the impact of Bcl2 on osteoclastogenesis was studied using bone marrow cells. Mononuclear cells were obtained from freshly isolated bone marrow of Bcl2 wild type (+/+) and knockout (-/-) mice and cultured. Osteoclastogenesis was induced using M-CSF and RANKL. Cell enumeration and morphometric analysis of TRAP-stained osteoclasts revealed substantial differences in a course of osteoclastogenesis between Bcl2 +/+ and -/- cultures. At day-5 a more vigorous osteoclastogenesis was observed in Bcl2 -/- cultures compared to those in +/+ (p<0.01). Not only were numbers increased in Bcl2 -/- cultures at day-5, but the average size of Bcl2 -/- osteoclasts was approximately twice that of +/+ (p<0.001). However, at day-7 and -9, Bcl2 -/- osteoclasts were no longer large and no difference was detected between genotypes. To determine the mechanism of vigorous Bcl2 -/- osteoclastogenesis, M-CSF dependent bone marrow macrophages were stimulated with RANKL and M-CSF and the expression of NFATc1, TRAP, and DC-STAMP at the RNA level was quantitatively analyzed with real-time PCR. It was revealed that the expression of DC-STAMP and TRAP was more rapid and considerably stronger in Bcl2 -/- than that in +/+ preosteoclasts. Higher expression of NFATc1 was also noted in Bcl2 -/- than +/+ preosteoclasts. The early expression of osteoclast markers fits the results of cell enumeration and morphometric analysis. These data suggest that Bcl2 plays a role in regulation of RANK signaling in myeloid cells. In summary, Bcl2 -/- osteoclastogenesis was rapid and robust, and vanished quickly thereafter, while +/+ osteoclastogenesis occurred more gently. Such vigorous Bcl2 -/- osteoclastogenesis was associated with early and elevated expression of DC-STAMP and TRAP.

Lysine-Specific Gingipain (Kgp) and Lipopolysaccharide (LPS) Synergistically Induces Osteoclast Differentiation. R. Yasuhara^{*1}, Y. Miyamoto^{*1}, M. Takami¹, T. Imamura^{*2}, R. Kamijo¹. ¹Department of Biochemistry, Showa University School of Dentistry, Tokyo, Japan, ²Department of Neuroscience and Immunology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan.

Porphyromonas gingivalis is known as a major pathogen of periodontitis associated with alveolar bone loss due to excessive bone resorption by osteoclasts. *P. gingivalis* produces cysteine proteases called gingipain divided into two types, Lys-gingipain (Kgp) and Arg-gingipain (Rgps), according to their cleavage-sites. In this study we examined the effects of gingipains on osteoclast differentiation. In cocultures of mouse bone marrow cells and osteoblasts, the addition of Kgp but not Rgp induced the formation of multinucleated osteoclasts (Kgp: 23 +/- 3.5 cells/well, Rgp: 0 cells/well). On the other hand, LPS, a constituent of gram-negative bacteria including *P. gingivalis*, induced mononuclear osteoclasts and small number of multinucleated osteoclasts (0-1 cells/well). Interestingly, simultaneous addition of Kgp and LPS to the cocultures induced significantly larger number of multinucleated osteoclasts (97 +/- 4.5 cells/well) than that induced by Kgp or LPS alone. Numerous resorption pits were developed on the surface of dentin slices on which cells were cocultured in the presence of Kgp and LPS together. However, LPS alone did not induce any resorption pits. Not only LPS but also the other bacterial constituents such as CpG ODN, poly(I:C) RNA and peptidoglycan, synergistically induced osteoclast differentiation in the combination with Kgp. We further examined the mechanisms of osteoclast differentiation by Kgp. Inactivated Kgp by Z-FK-cmk, a specific inhibitor for Kgp, completely inhibited osteoclast differentiation induced

by Kgp in the cocultures, indicating that the specific enzymatic activity of Kgp was essential for the induction of osteoclasts. Kgp did not induce the expression level of mRNAs for the receptor activator of NF- κ B ligand (RANKL) in osteoblasts, whereas Kgp significantly reduced the protein level of OPG in coculture media. In an in-vitro study, Kgp cleaved recombinant OPG protein suggesting that degradation of OPG by Kgp caused the enhancement of osteoclast differentiation in cocultures. These results suggest that Kgp exhibits synergistic virulence with LPS resulting in the inflammatory bone resorption characteristically seen in periodontitis. Therefore, we propose here that Kgp is a new target for the prevention and treatment of periodontitis.

Analysis of Matrix Vesicle Poteins from Long Bone Growth Plates. J. Jeong^{*1}, H. Kim^{*1}, H. Kim^{*1}, E. Park¹, J. Cho¹, R. Garimella², N. N. Nahar², H. C. Anderson², J. Lim^{*1}, S. Kim¹, J. Choi¹. ¹Biochemistry & Cell Biology, Kyungpook Natl. Univ. School of Medicine, Skeletal Diseases Genome Research Center, Daegu, Republic of Korea, ²Pathology, Kansas University Medical Center, Kansas, KS, USA.

Initiation of bone mineralization is a key step to make a proper bone formation. Matrix vesicles (MVs) have been known as an initiation site for mineralization. Thus, identification of proteins from MV will provide fundamental clues to access the mechanism of the initiation step in bone mineralization. Although many components of MV have been identified by tedious single protein confirmation approach, comprehensive protein component analysis from MV has not been studied. In this study, we isolated MVs from growth plates of rachitic rat bones. Proteins from MVs were separated by SDS-PAGE and the gels were cut into 15 pieces from top to bottom. After in-gel digestion with trypsin, eluted peptides were extracted for LC-MS/MS analysis. Identified proteins from MVs were various including previously known proteins such as annexins and peptidases, along with other variety of enzymes, extracellular matrix, growth factors, and signal molecules. The systematic proteomic analysis of MVs gives an important opportunity to understand the molecular mechanism of initiation step of bone mineralization.

Comparison of In Vivo Model of Functional Bone Adaptation to the Calculated Mechanical Environment. C. J. MacKay^{*1}, G. C. Goulet^{*2}, D. Coombe^{*3}, R. F. Zernicke^{*1}. ¹Faculty of Medicine, University of Calgary, Calgary, AB, Canada, ²Faculty of Engineering, University of Calgary, Calgary, AB, Canada, ³Computer Modeling Group, Ltd., Calgary, AB, Canada.

Interest in functional adaptation of bone has led to the development of numerous experimental models [1,2,3,4]. Animal models provide insights into the molecular signaling pathways by which bone senses and adapts to changes in functional demand, but ambiguity persists about the mechanical components contributing to the principal determinants of skeletal morphology. Here, experimental results from an in vivo model of functional bone adaptation, using 12 adult female Sprague-Dawley rats, were compared to a finite element model (FEM). Animals were subjected to 28 day, daily lateral-medial cantilever tibial loading regime, consisting of 1 s pulses of a 1 Hz trapezoidal wave followed by 9 s of rest to a maximal strain magnitude of 1000 μ e, for a total duration of 120 s. Bone-targeted fluorochromes, calcein AM (days 6 and 18) and xylenol orange (days 13 and 27) were administered to estimate relative bone formation rates and localize osteogenic mineralization in response to exogenous loading. Histology and comparison of tibial cross-sections, obtained from experimental and contralateral limbs, indicated increases in bone mineralization rates on several ossification fronts across the tibial cross-section. These results were compared to the FEM model. The model calculated areas of maximal compression and tension across the experimental region of interest during loading, and estimates fluid flow vectors and pressure gradients, thereby quantifying the mechanical milieu during experimental loading. The comparison of the resultant osteogenic responses in this model with previously calculated results provided insight into the specific mechanical signals that may influence dynamic skeletal morphology. Temporal Expression of PHOSPHO1 During Chick Limb Bud Mesenchymal Cell Differentiation and Mineralization. V. E. MacRae^{*1}, M. G. Davey^{*1}, J. L. Milan², C. Farquharson¹. ¹Gene Function and Development, Roslin Institute, Midlothian, United Kingdom, ²Burnham Institute for Medical Research, La Jolla, CA, USA.

PHOSPHO1 is a phosphatase with up-regulated expression in growth plate chondrocytes and osteoblasts, and is implicated in the initiation of inorganic phosphate generation for matrix mineralization. This study has established the temporal expression of PHOSPHO1 during chondrogenesis and endochondral ossification within the developing chick limb bud. This model permits the monitoring of PHOSPHO1 expression during mesenchymal cell differentiation into mineral producing chondrocytes. Micromasses were prepared from stage 24 limb bud mesenchymal cells which were cultured for 0, 3, 7 and 10d. Alcian blue (proteoglycan synthesis) and alizarin red (mineral formation) staining was negligible at 0d, with a marked increase in staining intensity at 7d and 10d. This confirmed that the mesenchymal cultures had differentiated into chondrocytes with subsequent mineralization. mRNA expression of phospho1, tissue non-specific alkaline phosphatase (Akp2) and collagen II was also determined. Phospho1 expression was observed at all time points, however a notable increase in expression was seen by 7d. Interestingly, phospho1 expression decreased between 7d and 10d, which is in agreement with previous studies that have suggested that PHOSPHO1 is involved in the initial events of mineral formation. Akp2 was expressed at 0d and 3d, with a marked decrease at 7d and 10d. A comparable pattern has previously been reported for alkaline phosphatase activity in chick limb bud cultures. Collagen II was absent at 0d and was upregulated at 3d onwards. Further studies using chick limb tissue at E3.5 (stage 24), E5.5 (stage 28), E6.5 (stage 30) and E10.5 (stage 36) were undertaken. A marked increase in PHOSPHO1 protein expression was seen at E6.5 and E10.5. These data were complemented by increased phospho1 mRNA expression in E6.5 and E10.5 compared to E3.5 and E5.5. TNAP protein expression was noted at all developmental stages, with no obvious differences in expression levels. Collagen II gene expression was present from E5.5 onwards. Using whole-mount in-situ hybridisation, Phospho1 mRNA expression was observed in chick metatarsi (E6.5) around the mid-shaft of the bone. Immunohistochemical staining of tibia sections (E6.5) revealed that PHOSPHO1 staining was localized to the osteoid (bone collar) and associated periosteal osteoblasts within the mid-diaphyseal region. Some chondrocytes within the rudiment also stained positively for PHOSPHO1. These studies concur with our hypothesis that PHOSPHO1 has a pivotal role in the first phase of the mineralization process.

Mineralization of Murine Mesenchymal C3H10T1/2 Cells in Micromass Culture. R. Roy¹, I. Binderman^{*2}, S. Doty^{*1}, V. Kudryashov^{*1}, A. Boskey¹. ¹Hospital for Special Surgery, New York, NY, USA, ²Ichilov Hospital, Tel Aviv, Israel.

Chick limb bud mesenchymal cells have been shown to undergo mineralization in micromass culture with the addition of inorganic phosphate (iP) (J Cell Biochem. 84(3):509-19). The murine multipotential mesenchymal cell line C3H10T1/2 undergoes chondrogenic differentiation in micromass cultures when stimulated by bone morphogenic protein-2 (Differentiation. Jan;64(2):67-76). These murine cells were used in micromass culture to determine whether they mineralize similar to the chick system. Cells were expanded in monolayer culture with DMEM supplemented with 10% FBS and 1% antibiotics/antimycotics (AB/AM). For micromass cultures cells were trypsinized, counted, and resuspended in Ca free DMEM supplemented with 10% FBS and 1% AB/AM. Cells were plated at a density of 100,000 cells per 10µl spot at the center of 35mm poly-L-lysine coated cell culture dishes to aid in attachment. Cells were allowed to attach at 37°C for 2 hours. Dishes were then flooded with 2mL of Ca free DMEM with 10% FBS and 1% AB/AM along with 100ng/mL of BMP-2. Media was changed 3X/wk and on day 2 of micromass cultures L-glutamine, 25µg/ml ascorbic acid, and 1mM Ca were added to all cultures, while 4mM iP was added to some cultures to promote mineralization. Alizarin red (AR), and von Kossa (VK) stains were performed on whole mount cultures and sections to visualize mineralization. Type I and type II collagen immunohistochemistry was used to determine whether these cultures form calcified cartilage or mineralized bone. VK and AR stains showed mineralization on day 28 in 4mM (iP) cultures, while control cultures showed no mineralization (Fig). In all cultures both type I and type II collagen was present at day 16, 21, and 28. At early time points there was more type II collagen in mineralizing cultures than in control cultures. These results indicate that this murine cell line does mineralize in the presence of exogenous phosphate which has been supported by previous ⁴⁵Ca uptake data, although mineralization may be delayed relative to the chick cultures. This murine culture system is comparable to the chick system and may be more useful for study of gene expression and signaling.

Alterations in Collagen Structure and Mineral Composition in Calcified Cartilage and Subchondral Bone in a Monkey Model of OA. M. E. Ruppel¹, C. S. Carlson², L. M. Miller³. ¹Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, ²Dept. of Veterinary Population Medicine, College of Veterinary Medicine, University of Minnesota, St. Paul, MN, USA, ³National Synchrotron Light Source, Brookhaven National Laboratory, Upton, NY, USA.

Osteoarthritis (OA) can be a debilitating disease which is characterized by disorganization and calcification of the collagen matrix in the cartilage and increased turnover and thickening of the subchondral bone. In the present study, collagen structure and chemical composition were studied in the calcified cartilage and subchondral bone in plastic-embedded mid-coronal sections of proximal tibia from cynomolgus monkeys (n=26 animals; ages 6-30 yrs). These sites contained a range of histological OA lesions, from normal morphology to severe OA. Synchrotron-assisted Fourier transform infrared microscopy (FTIRM) was used to determine the level of mineralization (mineral/protein ratio), carbonate accumulation (carbonate/phosphate ratio), and collagen structure (protein amide band ratio) as a function of tissue compartment and OA severity. Preliminary results showed that the protein amide band ratios were significantly different between subchondral bone and calcified cartilage, suggesting differences in collagen organization between the two tissue compartments; however, the differences were not affected by OA severity. Both the level of mineralization (p=0.0431) and carbonate accumulation (p<0.0001) were significantly higher in subchondral bone when compared to calcified cartilage. Although the mineralization level of the calcified cartilage increased (p=0.0037) with increasing OA severity, the subchondral bone remained unchanged. Carbonate accumulation increased significantly in both tissue compartments as a function of OA severity. These compositional changes that are observed as a function of OA severity are consistent with the progression of a "mineralization front" where endochondral ossification occurs and calcified cartilage is replaced by subchondral bone. These findings indicate that calcified cartilage and subchondral bone have distinctly different collagen structure and mineral compositions that are affected by OA severity and could increase stress on the afflicted joints.

Distribution and Localization of Aluminum in Bone Tissues of Aluminum Osteopathy. Y. Teraki¹, H. Sasakabe^{*2}. ¹Internal Medicine, Shinjo Tokushukai Hospital, Mitaka, Japan, ²Internal Medicine, Shinjo Tokushukai Hospital, Shinjo, Japan.

The pathophysiology of the so-called aluminum (Al) osteopathy is yet to be fully clarified. To investigate the dynamic behavior of Al in bone tissues, we have examined aluminum in bone tissue sections by laser scanning confocal microscopy using the staining with lumogal, a new chelating reagent we have developed. On account of the reported finding that Al is not excreted in urine in the presence of impaired renal function, this study was performed in 20 5/6-nephrectomized rats which were dosed orally or parenterally with an Al preparation for 3-6 months, followed by sacrifice and preparation of bone tissue slides. Thanks to the high detection sensitivity of Al-lumogal complex, the technique allowed Al identification with a lower detection limit of 19.0 µg/g. Results: The study showed diffuse or dense granular Al deposits in osteoids rather than in the generally believed calcification front. No Al was detected in calcified bone tissues. Furthermore, Z-scans of the stained bone tissues enabled observation of a three-dimensional Al deposition status. The results indicate potential usefulness of the lumogal stain technique in the diagnosis of Al osteopathy.

Role of Cell Death and Osteogenic Activity in Injury-induced Calcification from TNF- α Receptor p55 $^{-/-}$ p75 $^{-/-}$ Mice. Y. Zhao¹, A. L. Urganus^{*1}, Y. Chen^{*2}, P. H. Stern³, A. L. Boskey⁴, L. M. Pachman^{*5}. ¹Childrens Memorial Research Center, Northwestern University, Chicago, IL, USA, ²Research Center for Genetic Medicine, Children's National Medical Center, Washington D.C., DC, USA, ³Department of Molecular Pharmacology and Biological Chemistry, Northwestern University Feinberg School of Medicine, Chicago, IL, USA, ⁴Hospital for Special Surgery, Cornell University-Weill Medical College, New York, NY, USA, ⁵Department of Pediatrics, Northwestern University Feinberg School of Medicine, Chicago, IL, USA.

Background: TNF- α receptor (p55 $^{-/-}$, p75 $^{-/-}$) null mice develop calcifications along with increased inflammation after an injection with cardiotoxin (CTX), a snake venom component. While TNF- α inhibits osteoblast differentiation in vitro and promotes osteoclast formation the mechanism of the pathological mineralization in this mouse model remains unknown.

Objective: To elucidate the potential roles of cell death and formation of osteoblasts and osteoclasts in CTX-induced calcifications.

Materials and Methods: Four-week-old wild type C57B6 mice and TNF- α receptor null mice were injected with CTX into the skeletal muscle (Tibialis anterior) and sacrificed after 3, 7, 14 and 28 days. The muscles were stained for calcifications by von Kossa or calcein pre-labeling. The osteoblast markers, core binding factor alpha 1 (Cbfa1), osteocalcin and the osteoclast marker, tartrate-resistant acid phosphatase (TRAP) were stained in the injured tissues after 3, 7 and 14 day treatment. Total RNA was extracted from the muscle for microarray analysis and realtime PCR analysis of Cbfa1 and Receptor Activator for Nuclear Factor κ B Ligand (RANKL) from the 3 day group.

Results: Calcifications were apparent in all of the TNF- α receptor null mice at day 3 and day 7 after CTX administration whereas they were observed in only 29% of wild type mice at day 3 and 7. By day 14, no calcifications were observed in either strain. Microarray result indicated that the anti-apoptotic genes (BCL2A1(+1.51), BCL2L1(+1.8)), pro-apoptotic genes (CASP7(+1.22), BID(+1.8)), Cbfa1(+1.7) and TRAP(+1.3) were marginally up-regulated in TNF- α receptor null mice compared to wild type mice. Realtime PCR failed to show difference of Cbfa1 and RANKL in the injured muscles between the mutant and control mice. Osteocalcin was expressed in mineralized muscle in both strains. TRAP staining was positive in TNF- α receptor null mice at day 7 but was much less at day 14. We speculate that the formation of osteoclasts contribute to the resorption of the minerals.

Conclusion: Cell death and osteoblastic differentiation may lead to muscle calcifications following CTX administration to TNF- α receptor null mice. Osteoclastic resorption may account for the transient nature of the calcifications.

Mx2 Promotes Late Stages of Chondrocyte Differentiation by Up-regulating Ihh Expression. K. Amano^{*1}, F. Ichida^{*2}, A. Sugita^{*2}, K. Hata^{*2}, M. Kogo^{*1}, R. Nishimura², T. Yoneda². ¹Oral and Maxillofac, Osaka Univ Grad Dent, Suita City, Osaka, Japan, ²Biochem, Osaka Univ Grad Dent, Suita City, Osaka, Japan.

A homeobox gene, Mx2 (muscle segment homeobox 2), plays important roles in the development, growth and differentiation of various types of cells and tissues including ectodermal organs, teeth, vascular cells and cancer. Accumulating data also suggest that Mx2 regulates the skeletal development by controlling endochondral ossification and/or membranous ossification. Mice deficient in Mx2 gene exhibit disturbed chondrogenesis with reduced bone formation. However, little is known about the molecular basis by which Mx2 modulates chondrogenesis. In the present study, we investigated the role of Mx2 using murine primary rib chondrocytes. Treatment of chondrocytes with BMP2 up-regulated the expression of Mx2 mRNA along with the differentiation. Overexpression of Mx2 stimulated calcification of primary chondrocytes in the presence of BMP2, whereas Mx2 alone had no effects. We also found that constitutively-active Mx2 (caMx2; Mx2P148H) more strongly enhanced BMP2-stimulated calcification than wild-type Mx2. Consistent with this, caMx2 overexpression up-regulated the expression of alkaline phosphatase and type X collagen that were stimulated by BMP2. However, caMx2 had no effects on type II collagen expression. Furthermore, organ culture experiments using mouse embryonic metatarsals showed that caMx2 markedly stimulated the differentiation of chondrocytes into the prehypertrophic and hypertrophic stages in the presence of BMP2. The stimulatory effects of Mx2 on chondrocyte differentiation were enhanced by co-overexpression of Smad1 and Smad4, but inhibited by Smad6, an inhibitory Smad of BMP2 signaling. Of note, caMx2 overexpression enhanced BMP2-induced indian hedgehog (Ihh) expression in mouse primary chondrocytes and Ihh overexpression promoted calcification of primary chondrocytes. Importantly, cyclopamine, a specific inhibitor of hedgehogs, blocked Mx2- or Ihh-induced calcification of primary chondrocytes. In conclusion, our results suggest that Mx2 plays important roles in the regulation of late, but not early, stages of chondrocyte differentiation by up-regulating Ihh expression in collaboration with BMP2/Smad signaling.

Effects of Pro-inflammatory Cytokines on Suppressor of Cytokine Signalling-2 (SOCS-2) Expression in the Growth Plate. V. E. MacRae^{*1}, S. Pells^{*1}, S. F. Ahmed², C. Farquharson¹. ¹Gene Function and Development, Roslin Institute, Midlothian, United Kingdom, ²Child Health, Royal Hospital for Sick Children, Glasgow, United Kingdom.

Abnormal growth patterns are commonly observed in children suffering from chronic inflammatory diseases, which are associated with the increased production of pro-inflammatory cytokines. Suppressor of Cytokine Signalling-2 (SOCS-2) negatively regulates the signal transduction of several cytokines and this study examined the role of SOCS2 in regulating bone growth, and the response of growth plate chondrocytes to pro-inflammatory cytokines. Initial studies indicated that SOCS2 was expressed by both murine primary chondrocytes and the ATDC5 chondrogenic cell line. Foetal (E14-E18) and neonatal (1 and 9-day-old) primary murine chondrocyte expressed SOCS-2 mRNA at similar levels whereas SOCS-2 protein expression was greater (78%) during chondrogenesis than terminal differentiation. IL-1 β and TNF α (both 10ng/ml) exposure for 48h increased SOCS-2 protein expression in primary 1-day-old murine chondrocytes (79% and 65% increase respectively). 7-week-old female mice lacking SOCS-2 (SOCS2 $^{-/-}$) expression were significantly heavier (26%; P<0.0001) and longer (6%; P<0.001) compared to wild-type (WT) mice. The tibiae of the null mice were longer (8%; P<0.001), wider (18%; P<0.001) and had wider growth plates (24%; P<0.001) than WT mice. Proliferative and hypertrophic zones were significantly wider in SOCS2 $^{-/-}$ mice compared to WT mice (10% and 14% respectively; P<0.001). The growth of metatarsals from 1-day-old female SOCS2 $^{-/-}$ and WT mice over 8-days was inhibited by TNF α (47% and 33% respectively; both p<0.001) and IL-1 β (71% and 86% respectively; both p<0.001) by comparable amounts. No effect of genotype was observed. In contrast, matrix gene expression by primary chondrocytes exposed to pro-inflammatory cytokines over 48h was dependent upon the genotype of the host animal. RT-PCR studies revealed that aggrecan expression was notably reduced only in chondrocytes from SOCS2 $^{-/-}$ exposed to IL-1 β and TNF α . Collagen Type X expression was markedly reduced in chondrocytes from both SOCS2 $^{-/-}$ and WT mice whereas collagen Type II expression was not altered by cytokine exposure. This is the first study to show the expression of SOCS-2 in growth plate chondrocytes and its dramatic effect on suppressing skeletal growth. IL-1 β and TNF α may mediate their effects through SOCS-2, influencing the growth of children with inflammatory diseases through a local effect at the growth plate.

Hormonal Regulation of Hypertrophic Chondrocyte Apoptosis. S. U. Miedlich^{*}, M. B. Demay. Endocrine Unit, MGH, Boston, MA, USA.

In vivo studies in genetically modified (Npt2a knockout, VDR knockout and hyp) and dietary manipulated mouse models have demonstrated that hypophosphatemia leads to impaired apoptosis of hypertrophic chondrocytes in the growth plate and plays a critical role in the development of rickets. However, studies in the Npt2a knockout mice demonstrate that the expansion of the growth plate and impaired apoptosis observed at 16 days of age, has reverted to normal by 35 days of age, despite the presence of persistent hypophosphatemia. The transient nature of these findings in the Npt2a null mice strongly suggests the presence of additional factors that modulate the response of hypertrophic chondrocytes to circulating phosphate levels. Thus, we are undertaking investigations in an in vitro model of chondrocyte maturation in order to investigate whether 1,25-dihydroxyvitamin D or parathyroid hormone modulate the effects of phosphate on hypertrophic chondrocyte apoptosis.

The clonal chondrocytic cell line (RCJ3.1C5.18) has been shown to recapitulate the program of chondrocytic differentiation in culture, including acquisition of markers of hypertrophic differentiation and formation of mineralized matrix nodules. To address whether these cells were susceptible to phosphate-mediated hypertrophic chondrocyte apoptosis, they were subjected to 7mM sodium phosphate or 7mM sodium chloride (control) for 18 to 72 hours. The Guava Nexin assay was employed to measure plasma membrane changes associated with apoptosis (Annexin V-PE) and to identify dead cells (7-AAD). An MTT based assay was also used to evaluate mitochondrial activity, a surrogate for cellular viability.

Western analyses were performed to insure that collagen X, a marker of hypertrophic chondrocyte differentiation, was observed in RCJ3.1C5.18 cells after 7-10 days of culture in the presence of ascorbic acid. Treatment of hypertrophic chondrocytes with phosphate (7 mM) resulted in a significant increase in apoptotic as well as dead cells after > 24 hours of treatment. Studies are underway to evaluate whether 1,25-dihydroxyvitamin D enhances the susceptibility of hypertrophic chondrocytes to phosphate-mediated apoptosis in this model. Investigations will also examine the effects of parathyroid hormone on phosphate-induced apoptosis in hypertrophic RCJ3.1C5.18 cells.

These investigations demonstrate that the RCJ3.1C5.18 cell model is an appropriate system in which to investigate the effect of hormones on phosphate-induced apoptosis. Studies of these potential regulatory factors will not only further our understanding of the pathophysiological mechanisms underlying rickets but may also provide insights into the universal regulation of cellular apoptosis.

A-Raf and B-Raf Are Dispensable for Endochondral Bone Development and PTHrP Suppresses ERK Activation in Hypertrophic Chondrocytes. S. Provot¹, G. Nachtrab^{*2}, J. Paruch^{*2}, A. P. Chen^{*3}, A. Silva^{*3}, H. M. Kronenberg². ¹Anatomy, UCSF, San Francisco, CA, USA, ²Endocrine Unit, MGH - Harvard Medical School, Boston, MA, USA, ³Neurobiology, UCLA, Los Angeles, CA, USA.

Parathyroid hormone-related peptide (PTHrP) and its PTHrP receptor (PPR) increase chondrocyte proliferation and delay chondrocyte maturation in endochondral bone development, at least partly through cAMP-dependent signaling pathways. Because some data suggest that the ability of cAMP to stimulate cell proliferation involves the MAPKKK B-Raf, we hypothesized that PTHrP's proliferative action in chondrocytes might be mediated by B-Raf. While B-raf gene expression is detected by *in situ* hybridization (ISH) in proliferative chondrocytes, its conditional removal in cartilage using a type II collagen promoter-driven cre (col2-cre) and a floxed B-raf allele does not affect chondrocyte proliferation and maturation, as indicated by histologic analyses, BrdU assays, and ISH with various chondrogenic markers on embryonic and postnatal samples. Lack of B-raf does not alter either PTHrP-induced increased chondrocyte proliferation and delayed maturation, both *in vivo* in mice expressing a constitutively active PPR in cartilage (col2-caPPR), and *in vitro* in metatarsal explants treated acutely with PTHrP. Similar results were obtained by conditionally removing B-Raf from osteoblasts using Osterix- and col1-cre mice. Because A-raf expression detected by ISH is identical to that of B-raf in cartilage, whereas that of C-raf is restricted to hypertrophic chondrocytes, we speculated that A-Raf might play a redundant function with B-Raf in this tissue. Surprisingly, mice deficient for both A-Raf (universal A-raf knockout) and B-Raf in chondrocytes exhibit normal endochondral bone development, suggesting that the Raf-ERK pathway is not critical for chondrocyte proliferation. Consistent with this idea, the presence of activated ERK detected by immunohistochemistry is essentially restricted to hypertrophic chondrocytes. Notably, acute treatment of bone explants with PTHrP or prolong activation of PPR in col2-caPPR mice suppress ERK activation in these cells, while ERK activation is increased in PTHrP KO mice. Thus, PTHrP signals suppress ERK activation in normal conditions. Taken together, these results demonstrate that B-raf and A-Raf are dispensable for endochondral bone development, and they suggest that ERK might regulate hypertrophic differentiation rather than proliferation in cartilage, possibly through its activation by C-Raf in hypertrophic chondrocytes.

Cell Death and Cell Proliferation of Cartilage Layer in Human Anterior Cruciate Ligament Tibial Insertion after Rupture. H. Mutsuzaki¹, M. Sakane², K. Honda^{*3}, K. Ikeda^{*4}, S. Hattori^{*5}, N. Ochiai^{*2}. ¹Department of Orthopaedic Surgery, Tsukuba Central Hospital, Utsunomiya, Japan, ²Department of Orthopaedic Surgery, Institute of Clinical Medicine, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan, ³Department of Legal Medicine, Doctoral Program in Social and Environmental Medicine, Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan, ⁴Department of Orthopaedic Surgery, Ichiyama Hospital, Tsukuba, Japan, ⁵Department of Agriculture, Ibaraki University, Ami, Japan.

The purpose of this study is to investigate cellular responses of cartilaginous layers in human anterior cruciate ligament (ACL) tibial insertions compared with normal ones. Sixteen tibial insertions of ruptured ACLs were obtained during primary ACL reconstructions. We also obtained sixteen normal ACL tibial insertions from cadavers. A terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate-biotin nick end labeling (TUNEL) staining assay to detect apoptosis, proliferating cell nuclear antigen (PCNA) staining and a histological examination was performed. The percentage of TUNEL-positive chondrocytes in ruptured ACL insertions ($43.6 \pm 14.8\%$) was higher than that of normal ones ($9.6 \pm 5.8\%$). The percentage of PCNA-positive chondrocytes was not significant difference between ruptured ACL insertions ($23.1 \pm 26.3\%$) and normal ones ($12.3 \pm 7.3\%$). The average thickness of the cartilage layer, the glycosaminoglycan-stained area and the number of chondrocytes per millimeter in ruptured ACL insertions were lower than that of normal ones. The decrease of chondrocytes because of imbalance of the cell death and the cell proliferation in the ACL insertions after rupture compared with those in normal could lead to histological changes of the cartilage layer in the insertions. The results may help elucidate the etiology of the histological changes, the function and the significance of existence of the ACL insertion.

Intra-articular Osteoclastogenesis Inhibitory Factor/Osteoprotegerin Prevents Cartilage Degeneration in a Murine Model of Osteoarthritis. S. Shimizu^{*1}, Y. Asou², S. Itoh^{*3}, U. Chung⁴, H. Kawaguchi¹, K. Shinomiya^{*2}, T. Muneta^{*1}. ¹Section of Orthopaedic Surgery, Graduate School, Tokyo Medical and Dental University, Tokyo, Japan, ²Department of Orthopaedic Surgery, Tokyo Medical and Dental University, Tokyo, Japan, ³Human Gene and Science Center, Tokyo Medical and Dental University, Tokyo, Japan, ⁴Department of Orthopaedic Surgery, University of Tokyo, Tokyo, Japan.

Osteoarthritis (OA) is a chronic degenerative joint disorder characterized by articular cartilage destruction and osteophyte formation. RANK, RANKL, and Osteoclastogenesis Inhibitory Factor (OCIF)/Osteoprotegerin (OPG) mRNAs and proteins are expressed in normal cartilage. Cartilage from patients with OA contains increased levels of OPG mRNA. However, the functions of OPG expressed during OA pathogenesis are poorly understood. The purpose of this study was to investigate the effect of endogenous and exogenous OPG on chondrocytes during OA pathogenesis *in vivo*. First, OA was surgically induced in young adult OPG^{-/-} mice and wild-type (WT) littermates to investigate the effect of chondrocyte-derived OPG deficiency. Four weeks after surgical induction of OA, histological evaluation of tibial cartilage demonstrated typical features of cartilage degeneration both in WT and OPG^{-/-} mice. The degenerative changes in the articular cartilage, however, were significantly enhanced in OPG^{-/-} mice compared to WT littermates. Cartilage thickness was significantly reduced in OA-induced OPG^{-/-} mice. The morphology of subchondral bone structures was not affected by OPG haploinsufficiency. Next, we investigated the effect of exogenously administered rhOPG by daily intra-articular injections following surgical induction of OA. Histological evaluation indicated that OA-induced mice in rhOPG treated group were protected from cartilage degeneration compared to vehicle group four weeks after the operation. Cartilage thickness was significantly preserved in rhOPG administered mice. Subchondral bone volume was not affected by rhOPG treatment, indicating that chondro-protective effect of rhOPG was independent of subchondral bone metabolism. TUNEL assay indicated that rhOPG administration prevented chondrocyte apoptosis in an experimental model of OA. Pro-apoptotic ligand TRAIL, one of the ligands for OPG, was co-expressed with OPG in articular chondrocytes irrespective of OPG administration. These data indicated that endogenous OPG had a protective effect against the mechanical stress-induced cartilage degeneration. Furthermore, direct administration of rhOPG to articular chondrocytes prevented cartilage degeneration via prevention of chondrocyte apoptosis.

Mechanisms of Osterix Control of Endochondral Ossification. D. Y. Soung, L. A. Kaback^{*}, A. Naik^{*}, N. Smith^{*}, E. M. Schwarz, R. J. O'Keefe, H. Drissi. Orthopaedics, University of Rochester, Rochester, NY, USA.

We investigated the expression and regulation of the zinc finger protein Osterix (Ox) during endochondral ossification in the developing embryo. Our *in situ* hybridization and immunohistochemical analyses of Ox expression showed a restricted expression of Ox transcript and protein to the immature chondro/osteoprogenitor cells and mature osteoblasts but excluded from hypertrophic chondrocytes. Using a fracture injury model we show consistent expression of Ox protein in mesenchymal progenitor cells in the periosteum and immature chondrocytes and osteoblasts embedded in the fracture callus while hypertrophic chondrocytes, vessels and fibrous tissue remain devoid of Ox expression. Additionally, using RNAs isolated from fracture calluses throughout the healing process and achievement of bony unions, we observe that Ox transcripts parallel that of Runx2 and differentially overlap both cartilage and bone phenotypic markers. Furthermore, using the limb bud-derived MLB13MYC Clone 17 cells, we show that PTHrP inhibited chondrocyte maturation while it enhanced mRNA levels of Ox in these chondro/osteoprogenitor cells. Our viral over-expression studies, complemented with siRNA mediated loss of Ox function experiments indicate that Ox serves as an inhibitor of chondrogenesis and chondrocyte terminal differentiation while it promotes osteoblast maturation. Together, our findings provide novel evidence for the molecular mechanisms underlying Ox inhibition of chondrocyte differentiation, and further suggest a role for this transcription factor in promoting endochondral ossification during bone repair.

Epigenetic Modulatory Agents Suppress the Chondrocytic Phenotype. M. Stewart¹, E. Caporali^{*1}, A. Stewart^{*1}, P. Jones^{*2}. ¹Veterinary Clinical Medicine, University of Illinois at Urbana-Champaign, Urbana, IL, USA, ²Cell and Developmental Biology, University of Illinois at Urbana-Champaign, Urbana, IL, USA.

Epigenetic processes impact gene transcription by directly altering DNA/chromatin structure, resulting in transcriptional repression. There is increasing recognition that genes active in chondrocyte differentiation, proliferation and arthritis are subject to epigenetic control, however epigenetic regulatory processes can have global impacts on cellular transcriptional activity. This study was carried out to assess the effects of epigenetic-modifying agents on the articular chondrocytic (AC) phenotype. Cartilage was collected from equine articular joints and murine epiphyses. Chondrocytes

were cultured as explants or isolated by collagenase digestion and cultured as non-adherent aggregates. 5-azacytidine (5AZA) and zebularine (ZEB) were administered to inhibit DNA methylation, while valproic acid (VA) and Trichostatin A (TSA) was used to block histone deacetylation. The phenotypic effects on these epigenetic modifying reagents on the chondrocytic phenotype were assessed by Northern blot analyses of Coll II and aggrecan mRNAs, DMMB measurement of sulfated GAG secretion and Col II ELISA assays.

Treatment of chondrocyte aggregate cultures with epigenetic modulating reagents resulted in profound suppression of Coll II and aggrecan mRNA levels, reduced sulfated GAG secretion and Col II deposition. Similar effects were noted in cartilage explants. Consequent experiments showed these profound effects were reversible, with return to control levels within 3 days of 5AZA or VA removal. In contrast, chondrocytes treated continuously for 10 days of the experiments showed persistent transcriptional suppression of chondrocyte-specific genes. In contrast to previous reports, no Coll X mRNA was detected in articular chondrocytes treated with 5AZA or co-treated BMP-2.

These data show that epigenetic-modifying agents have profound but reversible effects on the chondrocytic phenotype. The conventional effect of these reagents is to 'de-repress' genes normally silenced epigenetically. Inhibition of AC-specific genes could follow unmasking of repressive elements in the gene promoters or by activation of genes that repress the AC phenotype. The effects might also result from non-epigenetic pharmacological actions; however multiple epigenetic reagents induce similar effects on two distinct AC-specific genes, arguing against this possibility.

Runx2 Haploinsufficiency Ameliorates the Ectopic Calcification in a Mouse Model of Ossification of the Posterior Longitudinal Ligament (OPLL). S. Takeda¹, M. Iwasaki², S. Sato¹, A. Kimura¹, H. Inose¹, K. Shinomiya¹. ¹Department of Orthopedics and ²COE, Tokyo Medical and Dental University, Tokyo, Japan, ²Department of Orthopedics, Tokyo Medical and Dental University, Tokyo, Japan.

Ossification of the Posterior Longitudinal Ligament (OPLL) is a disease characterized by the ectopic calcification of the ligament, but its pathogenesis remains to be addressed. Histologically, calcification in OPLL is characterized by the existence of chondrocytes and bone marrow, suggesting that it is caused by endochondral bone formation-like mechanism. In an effort to elucidate the molecular pathogenesis of OPLL, we focused on Runx2. Runx2 is an essential transcription factor for osteoblastogenesis, whose deficiency causes the complete lack of endochondral bone formation. Induction of Runx2 expression was demonstrated in the ectopically-calcified ligaments of *ttw* mice, a mice model of OPLL, by monitoring the lacZ activity inserted into the Runx2 genomic locus. To address the functional role of Runx2 in the promotion of OPLL, we crossed Runx2 heterozygote-deficient mice with *ttw* mice. Analyzing the area of calcification in the posterior longitudinal ligament by micro-computed tomography revealed that *ttw* mice with Runx2 haploinsufficiency carry less calcification than *ttw* mice without Runx2 haploinsufficiency. Histologically, reduction of mineralized bony structures and bone marrow stroma was observed in *ttw* mice with Runx2 haploinsufficiency; Runx2 haploinsufficiency ameliorated the ectopic calcification in *ttw* mice. Taken together, our results demonstrated that Runx2 is intimately involved in the cause of OPLL *in vivo*.

Transcriptional Induction of SOX9 by NF- κ B Subunit p65 During Chondrogenesis. M. Ushita, T. Ikeda, T. Saito, A. Kan, K. Nakamura, U. Chung, H. Kawaguchi. Sensory and Motor System Medicine, University of Tokyo, Tokyo, Japan.

Although SOX9 is an essential molecule for chondrogenic differentiation from mesenchymal cells, little is known about the upstream signaling. The present study attempted to identify transcription factors to induce SOX9 expression and examined the mechanism. By exhaustive comparison of the genomic sequences between human and mouse SOX9 proximal promoters, we identified several highly conserved regions within which NF- κ B, NFAT, and CREB/ATF motifs were found as putative transcription factor binding sites. We then created expression vectors of transcription factors and co-factors for these sites: 11 for NF- κ B, 5 for NFAT, and 11 for CREB/ATF, and transfected them in mouse chondrogenic ATDC5 cells and non-chondrogenic HeLa cells with a luciferase-reporter construct containing a human 1,000 bp SOX9 promoter. Among them, an NF- κ B subunit p65 most strongly activated the luciferase activity. Deletion analysis using a series of 5'-deletion constructs of the SOX9 promoter confirmed that the core responsive element to p65 included the estimated NF- κ B motifs located around -250 bp relative to the transcriptional start site. The transcriptional activity of p65 was decreased by a site-directed mutagenesis in the NF- κ B motif, and the tandem-repeat constructs responded to p65 depending on its repeat number. Electrophoretic mobility shift assay revealed specific binding of the *in vitro*-translated p65 protein with the wild-type NF- κ B motif oligonucleotide probe, but not with the mutated probe. Cold competition with an excess of the unlabelled probe, but not with the unlabelled mutated probe, cancelled the complex formation. In addition, the complex underwent supershift by the antibody to p65, confirming the specific binding of p65 and the NF- κ B motif. *In vivo* expression of p65 was shown by immunohistochemistry to be co-localized with SOX9 in the resting and proliferative chondrocytes of the mouse growth plate. To further investigate the functional relevance of p65 to chondrogenic differentiation, we established HeLa cells or mouse primary costal chondrocytes overexpressing p65. Expressions of type II collagen and

SOX9 were markedly increased in both cells by the overexpression as compared with respective GFP-transfected control cells. In conclusion, we identified NF- κ B / p65 as a potent transcriptional signaling for SOX9 promoter activation and chondrogenic differentiation. Elucidation of the molecular network related to the SOX9 - NF- κ B / p65 axis will greatly benefit development of the regenerative medicine of cartilage.

Tissue Specific Expression of Murine Aggrecan Is Regulated Through Both Regulatory Enhancer and Repressor Elements. N. A. Wigner, T. A. Einhorn, L. C. Gerstenfeld. Orthopaedics, Boston University School of Medicine, Boston, MA, USA.

Aggrecan deposition is a hallmark of the mature chondrocyte. Thus the analysis of aggrecan's unique temporal and spatial expression regulation can extend current understanding of cartilage specific transcriptional control. Previous studies, using collagen type II as a model gene, have identified a complex transcription network during skeletal tissue development. As a result, transcription factors such as Sox9, Runx2, and Snail1 have been shown to regulate collagen type II expression and have been implicated in chondrogenesis. However, few studies have explored the cis-acting elements and the interacting transcriptional regulators of other cartilage extracellular matrix proteins such as aggrecan. The goal of these experiments was to characterize the cis-transcriptional regulatory motifs that mediate aggrecan expression during chondrogenic differentiation and to identify the temporal interaction of transcription factors that impart cartilage specific expression. The 5' proximal region of the aggrecan gene and various permutations of its promoter and 5'UTR were cloned into luciferase reporter vectors and assessed by transient transfection into both chondrogenic and non chondrogenic cell lines and C3H10T1/2 stems cells induced to undergo chondrogenic differentiation. The temporal and functional nature of specific cis-elements was further assessed by electromobility shift analysis. During the sequential pattern of chondrogenic differentiation, an increased expression of Sox9 was accompanied with a decrease in Runx2 and Snail1. Concomitant with this, was an increase in aggrecan mRNA. We have identified regulatory regions within the aggrecan promoter and 5'UTR that mediate its tissue specific regulation. This study has shown aggrecan's 5'UTR to be a robust tissue-specific regulator of expression. In undifferentiated chondrocytes, placing this 5'UTR immediately downstream of both its own proximal promoter and the promoter of collagen type II, enhanced reporter activity by 5.6-fold and 3.4-fold relative to their respective basal promoters alone. In addition, the presence of the 5'UTR was necessary to maintain observable reporter activity in differentiated chondrocytes. Co-transfection of the aggrecan reporters with Sox9 resulted in an enhanced reporter activity by 1.6-fold relative to controls, although the presence of the 5'UTR did not mediate this effect. Thus, the potential identification of both cis and trans acting factors involved in the regulation of aggrecan can provide insight into the regulation of cartilage as a whole and identify key molecular switches mediating cell differentiation.

Cartilage Extracellular Matrix Homeostasis Is Regulated by RAR γ Repression Function. J. A. Williams¹, N. Kondo¹, N. Takeshita², T. Okabe¹, M. Enomoto-Iwamoto¹, M. Pacifici¹, M. Iwamoto¹. ¹Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA, ²Orthopaedic Surgery, Tohoku University, Sendai, Japan.

Cartilage extracellular matrix is maintained at homeostasis in the upper regions of growth plate and is rapidly degraded in hypertrophic zone, but the mechanisms underlying such critical metabolic shift are not fully understood. We previously showed that transcription factor RAR γ is strongly expressed in the upper growth plate zones and mice lacking RAR γ and another family member exhibit dwarfism and low cartilage matrix content. RARs are known to serve as transcriptional repressors and activators depending on absence or presence of ligands, respectively. Given that the upper growth plate zones contain scanty endogenous retinoid levels if any, we asked whether RAR γ exerts ligand-independent repressor function and contributes to matrix homeostasis. Primary rib chondrocytes in monolayer culture were treated with a retinoid pan-agonist or pan-antagonist. As expected, agonist treatment markedly increased matrix catabolism and MMP gene expression compared to untreated control cultures. However, treatment with antagonist inhibited endogenous matrix catabolism and MMP expression to levels below control. The same was seen when RARE reporter activity was measured; the agonist increased it above control levels, whereas the antagonist reduced it to below control levels. To determine whether these responses were attributable to RAR function, we compared double-floxed and double-null RAR β /RAR γ chondrocytes. The former behaved just as wild type cells, whereas the double-null chondrocytes failed to respond to either agonist or antagonist. The zinc finger transcription factor Zac1 modulates nuclear hormone receptor function and is co-expressed with RAR γ in cartilage. We found that Zac1 over-expression enhanced RAR γ repressor activity in RAR α /RAR β double-null chondrocytes that express RAR γ only. Mammalian two hybrid tests showed that Zac1 physically associates with RAR γ and such association is lost when the LxxLL motif of Zac1 is mutated. The results of our study provide the first evidence that RAR γ acts as a ligand-independent repressor in cartilage matrix homeostasis and may do so in strict cooperation with Zac1.

Phosphate Regulates Chondrocyte Differentiation in a model of Embryonic Endochondral Bone Formation. A. A. Zalutskaya, M. Cox*, M. B. Demay. Endocrine Unit, MGH, Boston, MA, USA.

Phosphate is required for terminal differentiation of hypertrophic chondrocytes during postnatal growth plate maturation. To investigate whether extracellular phosphate plays a role during embryonic endochondral bone formation, we performed investigations in the mouse metatarsal culture model. This model recapitulates *in vivo* bone development in culture and circumvents the homeostatic changes that occur in the intact animal. Metatarsals were isolated from day 15.5 C57BL/6J embryos and cultured in phosphate-free high glucose DMEM, 1% Pen/Strep, 0.05mg/ml ascorbic acid and 0.25% heat-inactivated FBS. The estimated phosphate content of this basal medium is 0.3 μ M. Three culture conditions were used to address the effect of extracellular phosphate on chondrocyte differentiation: 0 mM added phosphate, 1.25 mM added phosphate (control) and 7 mM added phosphate. Metatarsals were cultured for 4, 8 and 12 days at 37°C, 5% CO₂. The length of each metatarsal was measured at the time of isolation, as well as at the end of the 12 day culture period. At the end of the culture period, frozen sections were obtained to permit *in situ* hybridization analyses with digoxigenin-UTP labeled probes. Metatarsals cultured in 1.25mM phosphatic demonstrated a 120 \pm 6.66 % increase in length over 12 days. While the absence of supplemental phosphate impaired growth, as did 7mM added phosphate, there was still a significant increase in the length of the metatarsals cultured under these conditions over a 12 day period (90 \pm 10.18 % and 70 \pm 2.59 % increase respectively). *In situ* hybridization analyses did not reveal a significant change in the expression of Sox 5 or Sox 6, early markers of chondrocyte differentiation, among the three phosphate concentrations. However, analyses of later markers of chondrocyte differentiation, including Col II, Col X and osteopontin demonstrated an attenuation of chondrocyte differentiation in metatarsal elements cultured under hyper- or hypophosphatemic conditions, relative to that observed in those cultured under normophosphatemic conditions. While, von Kossa staining demonstrated significant mineralized matrix formation in the metatarsals cultured under control phosphate conditions, there was marked impairment in mineral deposition in the elements cultured without added phosphate and with 7mM phosphate. Thus, extracellular phosphate has a significant effect on the differentiation of chondrocytes in the metatarsal culture system. The effects of phosphate are biphasic: both high and low phosphate attenuate growth and impair chondrocyte differentiation. Studies are underway to determine the molecular basis for these effects.

The Role of Nkx3.2 in Muscle/Cartilage Cell Fate Determination. D. Cairns*, L. Zeng*. Anatomy and Cell Biology, Tufts University School of Medicine, Boston, MA, USA.

Significance. Bone and muscle are distinct tissues that are situated adjacent to each other in vertebrates. Failure to establish and maintain their identities may lead to serious genetic diseases such as fibrodysplasia ossificans progressiva (FAP), where a mutation in the BMP receptor causes the muscle tissue to be transformed into cartilage and bone. The mechanism of how BMP signaling leads to this transformation is not fully understood. Results. In the embryo, BMP pathway is crucial for inhibiting muscle cell fate and promotes cartilage cell fate determination. Nkx3.2 is a BMP-induced transcription factor that is expressed exclusively in cartilage progenitors and is absent in the muscle progenitors. Prior work has demonstrated that Nkx3.2 promotes Sox9 expression and chondrocyte differentiation and survival. Here we show that *in vivo* Nkx3.2 ectopic expression in the progenitors of the back muscle (via electroporation of the somite) prevents the expression of Pax3, Pax7 and terminal muscle marker myosin. In addition, virally-expressed Nkx3.2 prevents muscle marker expression in the chicken limb micromass culture. Furthermore, C2C12 cells that are transfected with Nkx3.2 fail to differentiate into myotubes upon serum deprivation. Conclusion. Our work demonstrates that BMP-induced factor Nkx3.2 plays a critical role in muscle/cartilage cell fate decision in the embryo.

Localization of the Cis-enhancer Element for Mouse Col10a1 Expression in Hypertrophic Chondrocytes *In Vivo*. Q. Zheng¹, B. Keller^{*1}, G. Zhou^{*2}, D. Napierala^{*1}, Y. Chen^{*1}, B. Zabel^{*3}, A. Parker^{*4}, B. Lee⁵. ¹Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA, ²Orthopedics, Case Western Reserve University, Cleveland, OH, USA, ³Center of Pediatrics and Adolescence Medicine, University Hospital of Freiburg, D-79106, Germany, ⁴Respiratory and Inflammation Research Area, AstraZeneca, Cheshire, United Kingdom, ⁵Howard Hughes Medical Institute, Baylor College of Medicine, Houston, TX, USA.

We and others had previously shown that 4kb or 4.6kb Col10a1 promoter containing Runx2 or AP-1 (Activator Protein-1) elements contribute to its hypertrophic chondrocyte-specific expression *in vivo* (Zheng et al., 2003; Gebhard et al., 2004). These data suggest that the Col10a1 distal promoter (-4.4 to -3.8 kb) harbors a critical enhancer that mediates its tissue specificity. To further localize the tissue-specific enhancer element, we have generated series of transgenic reporter constructs containing 600, 300 or 150 bp of fragments derived from this region upstream of the Col10a1 basal promoter driving LacZ

gene. The results demonstrated that 150bp Col10a1 promoter element (-4.3 to -4.15 kb) is sufficient to direct its tissue-specific expression *in vivo*. *In silico* analysis of this region identified several transcription factor binding sites including two potential AP-1 sites within 5'- and 3'- end respectively. Interestingly, transgenic mice using reporter construct without the two putative AP-1 elements showed tissue-specific reporter activity. We have also performed EMSA studies and specific DNA/Protein complexes were observed when oligos derived from this region were incubated with the MCT cell nuclear extracts. *In vitro* transfection studies using reporter constructs derived from these oligos showed up-regulated reporter activity. These data together with previous observations suggest that there are transacting factors in addition to Runx2 or AP-1 that may bind the cis-elements within this Col10a1 distal promoter and mediate its tissue-specific expression *in vivo*.

The Diverge Effects of Noggin on BMP-2-induced Osteogenesis. T. Engstrand^{*1}, C. Aulin^{*2}, J. Hilborn^{*2}. ¹Department of Reconstructive Plastic Surgery, Karolinska Institute, Stockholm, Sweden, ²Department of Materials Chemistry, Uppsala University, Uppsala, Sweden.

The purpose of the study was to evaluate the *in vitro*-effects of noggin on BMP-2 in mesenchymal cells and the *in vivo*-effects of transplanted mesenchymal cells co-expressing noggin and BMP-2.

The W20-17 murine mesenchymal celline was retrovirally infected with either BMP-2 cDNA or co-infected with BMP-2 and noggin cDNAs. The expression and production of BMP-2 and noggin was determined by mRNA dot blot and western blot, respectively. The *in vitro* effect was measured by alkaline phosphatase activity. Ectopic bone formation induced by transplanted BMP-2- or bmp-2/noggin- overexpressing cells was visualised by radiography and histology.

The amounts of secreted BMP-2 in culture medium was dramatically enhanced in BMP-2/noggin co-expressing cells as compared to cells expressing BMP-2 alone (control). The co-expressing cells induced a 5-fold increase in ALP activity as compared to the control *in vitro*. The enhanced effects in co-expressing cells was verified *in vivo* where transplanted BMP-2/noggin cells induced abundant bone formation. However, the enhanced osteoinductive effect of BMP-2/noggin co-expressing cells was found to be concentration-dependent since noggin exerted an inhibitory effect on BMP-2 when expressed at higher rate. Using added recombinant BMP-2 and noggin we demonstrate that noggin had a stabilizing effect on BMP-2 as determined by ALP-activity in long-term cell cultures.

Noggin exerts an inhibitory effect by direct binding to BMP-2. Unexpectedly, we have found that noggin enhances the secreted amounts of BMP-2 in osteoprogenitor cells co-expressing noggin and BMP-2. These cells also demonstrate an increased osteoinduction *in vitro* and *in vivo* as compared to cells expressing BMP-2 alone. The positive effects of noggin on BMP-2 osteoinduction was dependent on the relative concentrations of BMP-2 and noggin since higher noggin expression completely inhibited BMP-2 action. Our results suggest that noggin stabilizes BMP-2 and functions as a BMP-carrier. The mechanisms of the dissociation of BMP-2 from noggin still remain to be solved.

Figure legend: Transplanted noggin/BMP-2-overexpressing cells induced abundant bone formation when implanted ectopically in rats (III) as compared to cells expressing BMP-2 alone (II). Cells transduced with vector alone had no activity in this assay (I).

***In vitro* Characterization of Bidirectional Tet-inducible Expression Systems for Bone Tissue Engineering.** G. Feichtinger*, B. Klösch*, M. van Griensven*, H. Redl*. Austrian Cluster of Tissue Regeneration, Ludwig Boltzmann Institute for exp. and clin. Traumatology, Vienna, Austria.

Gene medicine approaches for osteoinduction could provide potent alternatives to current growth factor or stem-cell based approaches being cheaper and safer. The additional employment of inducible promoters could maximize safety of these approaches. Furthermore inducible systems that express more than 1 therapeutic gene can be useful regarding differentiation processes in which more than 1 gene is required to generate a sufficient impulse. Therefore, the aim of this study was to characterize a Tet-inducible system for bidirectional expression of hBMP2 and 7, hBMP4 and 7 or Runx2 and Osterix. The TetON-system (TRETight-BI) was modified to express the reverse tet-transactivator (rtTA) on the response vector making it a single vector system. This new system mediates inducible expression of 2 different genes of interest and constitutive expression of the rtTA in only 1 plasmid making it more convenient for practical use. *In vitro* characterization was

carried out in C2C12 cells transfected with the described TetON systems at different doxycycline (doxy) concentrations (0; 50-1000ng/ml). Osteogenic differentiation was detected by alkaline phosphatase, RT-PCR and von Kossa staining (day 10). Time and dose dependent kinetics were studied for 14 days using EYFP and dsRED. Reportergene expression levels were detected by fluorescence microscopy and RT-PCR compared to constitutive promoters (CMV, human ubiquitin C promoter).

Osteogenic differentiation was confirmed for all therapeutic expression systems. These new single vector systems did not exhibit lower expression capacity as the original double vector system. The maximal level of expression was comparable to constitutive promoters. No expression was detectable at 0ng/ml doxy. There was initial expression activation 12 hours after doxy application in a dose dependent manner decreasing within 14 days.

Our in vitro data strongly supports the potential of expression systems to induce differentiation in targeted cells. We conclude from our in vitro results that the constructed single vector, bidirectional inducible expression systems provide a promising alternative to currently employed growth factor therapies in bone tissue engineering. Furthermore expression of two therapeutic genes generates more potent responses compared to single gene approaches. The TRE element together with the rtTA is a reliable and stringent inducible expression system. The major concerns for future in vivo application of the described systems are efficient non-viral in vivo transfection methods and nephrotoxic features at certain doxy concentrations.

Disclosures: G. Feichtinger, None.

Identification of Novel Factors Associated with Osteoblast Differentiation.

M. S. Friedman¹, W. Luo^{*2}, S. M. Oyserman^{*1}, H. Shitaye^{*3}, P. J. Woolf^{*2}, K. D. Hankenson¹. ¹Animal Biology, University of Pennsylvania, Philadelphia, PA, USA, ²Biomedical Engineering, University of Michigan, Ann Arbor, MI, USA, ³University of Michigan, Ann Arbor, MI, USA.

A variety of signaling molecules, transcription factors, and extracellular matrix (ECM) proteins are known to be involved in osteoblast differentiation. How these factors interact in human mesenchymal stem cells (hMSC) to yield functional osteoblasts is poorly understood. We hypothesized that by using high-throughput expression analysis of hMSC we could identify individual genes, gene expression patterns, and transcriptional networks associated with osteoblast differentiation and function. We examined how BMP treatment duration correlated with osterix and Dlx-5 expression. hMSC treated with BMP6 (20 nM) for one hour and cultured for 4 days without BMP6 show increased DLX5 and osterix expression (6 and 100 fold, respectively). However, only MSC treated with BMP for a minimum of 24 hours and cultured for 14 days without BMP, demonstrate terminal osteoblast differentiation and function (mineralization). Using this preliminary expression and function data, we designed a novel growth factor induction strategy coupled with microarray analysis. RNA was harvested following treatment, or cells were further cultured without BMP for 24h, 96h, or 10d and RNA harvested (13 Affymetrix U133+ microarrays). Genes were sorted into 20 clusters based on BMP treatment duration, gene expression levels, and gene expression patterns. The transcription factors DLX2, 3, 5, ID1, 3, and 4, and SMAD5, and 6 clustered together and were highly elevated with only 8 hours of BMP treatment and remained elevated for 10 days without additional BMP. However, expression of these genes did not correlate with osteoblast function (increased expression with increased BMP treatment). In contrast, expression of Osterix and the Notch associated transcription factors HEY1 and HEY2 correlated with osteoblast function. Osteopontin, BSP, aggrecan 1, syndecan 1, osteomodulin, and GPM6B, clustered with these transcription factors, showing expression patterns associated with osteoblast function. Results for select genes were validated by Q-PCR. To evaluate if genes in these clusters were involved in osteoblast function, we performed overexpression and loss of function studies. Importantly, antagonism of Notch signaling by gamma secretase inhibitors (L685,458) greatly inhibits BMP induced mineralization, suggesting a role for Notch signaling in BMP induced osteoblast differentiation. In contrast, neither osterix nor osteomodulin are sufficient for osteoblast induction. In conclusion, by using a novel functional microarray analysis, we identified novel factors that may be critical to osteoblast differentiation and function.

Bone Morphogenetic Protein-4 and -6 Are Over-Expressed in the Multiple Myeloma Bone Marrow Samples.

D. Grcevic^{*1}, R. Kusec^{*2}, A. Luki^{*1}, I. K. Lukic³, N. Kovacic³, D. Nemet^{*4}, A. Marusic^{*3}. ¹Department of Physiology and Immunology, Zagreb University School of Medicine, Zagreb, Croatia, ²Department of Hematology, Clinical Hospital "Dubrava", Zagreb University School of Medicine, Zagreb, Croatia, ³Department of Anatomy, Zagreb University School of Medicine, Zagreb, Croatia, ⁴Department of Hematology, Clinical Hospital "Zagreb", Zagreb University School of Medicine, Zagreb, Croatia.

Multiple myeloma (MM) is a B-lymphocyte neoplasia characterized by the slow proliferation of plasma-cells in bone marrow (BM) and bone destruction. Although several bone morphogenetic proteins (BMP) have been shown to elicit apoptosis of myeloma cells in vitro, we proposed that BMPs may have other non-apoptotic and pro-survival effects. BM was obtained from MM patients (n = 25) and control subjects (n = 14) after the informed consent and approval of the Ethical Board. Selected BM MM samples were magnetically separated for CD138 positive cells. Primary MM samples and myeloma lines (NCI H-929 and Thiell) were cultured for 48 hours and treated by recombinant human

(rh)BMP-2 or -6 (500 ng/mL for both) with or without BMP inhibitor rhNoggin. cDNA was extracted from mononuclear BM cells or cell lines, amplified by quantitative PCR using TaqMan assays for BMPs, corresponding receptors and downstream regulatory molecules, and normalized to GPDH. For detection of apoptotic and dead cells, we used flow cytometric annexin V/propidium iodide staining. ELISA assays for p53, Bax and Bcl-2 were performed on cultured cell lysates.

Expression of BMP-4, -6 and Alk-2 was significantly higher in MM BM samples compared with control BM (around 10-fold for BMP-4, 35-fold for BMP-6, 2-fold for Alk-2), with significant positive correlation of BMP-6 expression and plasma-cell percentage in MM samples (p<0.01). Upon in vitro BMP-2 or -6 treatment, insignificant changes in the percentage of death/apoptotic cells were observed paralleled by down-regulation of pro-apoptotic Bax and p21 (up to 2-fold and 5-fold respectively), and up-regulation of inhibitors of differentiation ID-1 and -2 (up to 200-fold and 5-fold respectively). Changes induced by BMPs were blocked by the addition of Noggin. ELISA confirmed the involvement of p53 pathway and decrease in the expression of Bax. Selected CD138 positive myeloma cells showed relatively higher endogenous expression of BMPs/receptors compared with corresponding full BM samples and CD138 negative population, providing a basis for autocrine action.

We found that BMP-4 and -6 are over-expressed in MM BM samples and selected CD138 positive myeloma cells, indicating the role of BMPs as proliferative and survival autocrine factors in MM. Our study opened the possibility to further test clinical application of BMP inhibitors in MM treatment.

Similar Effects of Proteasome Inhibition on Osteoblast Differentiation and Anagen Induction.

G. E. Gutierrez¹, I. R. Garrett², W. Gallwitz^{*2}, G. Rossini^{*2}, C. Christiansen³, G. R. Mundy¹. ¹Bone Center and Dept of Medicine/Clinical Pharmacology, Vanderbilt University and Medical Center, Nashville, TN, USA, ²OsteoScreen, LTD, San Antonio, TX, USA, ³Center for Clinical and Basic Research, Ballerup, Denmark.

We have noticed that the mammalian bone remodeling process shares many features in common with the hair cycle. In both, there are phases of growth, resorption or regression, and rest. Moreover, the regulatory controls of both involve many of the same extracellular and intracellular factors. For example, both anagen (growth phase of the hair cycle) and the bone formation phase of the bone remodeling cycle are controlled by the BMP-2 ligand-signal transduction pathway and downstream molecules such as Wnt and beta-catenin. Therefore, we hypothesized that manipulation of specific molecules in this pathway should increase both bone formation and anagen induction. Accordingly, we examined the effects of compounds that stimulated transcription of the BMP-2 gene for their effects on osteoblasts and the hair follicle. We have shown that inhibitors of the proteasome stimulate osteoblast differentiation and bone formation via this mechanism. During studies to determine the effects of proteasome inhibition on bone growth in vivo, we injected proteasome inhibitors (PI) into the subcutaneous tissue over murine calvaria. There was increase in bone formation and marked morphologic changes in hair follicles, with an increase in size, in the inner and outer root sheath diameters and extension into the dermal adipose tissue, all characteristic features of the anagen phase of the hair cycle. All PI tested had similar effects, independent of their chemical structure. Other non-proteasome anti-proteolytic agents had no effect. To confirm that the PI were stimulating hair growth, we examined the effects of the PI PSI on hair on the right dorsal trunk after depilation. There was a rapid increase in hair growth in the treated mice. We next examined PI on hair follicles in explants of murine skin, assessed by changes in hair follicle diameter and hair elongation. rhBMP-2 (100ng/ml) increased follicle area in these cultures. We found that increase in follicle area stimulated by both PSI and epoxomicin was inhibited by noggin, indicating that these effects are BMP-dependent. We then determined the effects of proteasome inhibition on anagen induction in subjects with male pattern baldness. Topical administration of the proteasome inhibitor PSI led to a 40% increase in anagen induction in 8 subjects over a two week treatment period.

These results point to the similarities between the bone remodeling process and the cycling of the hair follicle and suggest both processes are responsive to proteasome inhibition and are dependent on the BMP-2 ligand-signal transduction pathway.

Increased Expression of BMP Antagonists During Distraction Osteogenesis in a Mouse Model. T. Haque^{*1}, F. Hamadeh^{*1}, N. Alam^{*1}, M. Kotsioprifitis^{*2}, D. Lauzier^{*1}, R. St-Arnaud^{*1}, V. Rosen^{*3}, R. C. Hamdy¹.

¹Orthopaedics, Shriners Hospital for Children, Montreal, PQ, Canada, ²Orthopaedics, Montreal Childrens Hospital, Montreal, PQ, Canada, ³Oral and Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA.

Distraction osteogenesis (DO) is a widely used technique for limb lengthening and replacement of bone loss due to trauma, infection or malignancies. The procedure involves gradually applying controlled distraction of two bony segments post osteotomy resulting in the generation of new bone within the distracted gap. Although the technique is widely used, one of its limitations is the long period of time required for the newly formed bone to consolidate. It has previously been shown that the application of bone morphogenetic proteins (BMPs) can increase bone formation during DO, however, exogenous BMPs have many drawbacks. An alternative method for accelerating the rate of bone formation may be to modulate the intrinsic BMP signaling pathway. The aim of this study was to identify BMP antagonists involved in distraction osteogenesis in order to determine if targeting BMP antagonists can be used for increasing BMP signaling and hence the rate of bone consolidation during DO.

DO was applied to the right tibia of 60 adult wild type mice. The surgery involved applying a mini ilizarov fixator and performing an osteotomy in the centre of the tibia. Distraction began after a latency period of 5 days at a rate of 0.2mm/12hrs for 2 weeks. Mice were sacrificed in groups of 12 during the following times post surgery: day 5 (latency), days 11 and 17 (distraction) and days 34 and 51 (consolidation). Specimens were examined using x-rays, µCT, histology, real-time PCR and immunohistochemistry. The expression of the extracellular BMP inhibitors: BMP3, Noggin, Gremlin and Chordin; intracellular BMP inhibitors: Smad 6, 7, Smurf 1, 2; as well as the receptor level inhibitor: BAMBI was analyzed. In addition, the expression of the BMP ligands 2, 4, 6 and 7 and their receptors were also monitored.

Results revealed an increase in BMP 2, 4 and 6 during the distraction phase. Most interestingly, a significant increase in the expression of BMP3, noggin, chordin, BAMBI, Smad 7 and Smurf 1 were observed. Activin receptor expression was also upregulated in the distraction and consolidation phases. Altogether, our results suggests that regulation of BMP signaling through noggin as well as BMP3 and Activin receptors may be important in the distraction system.

The current study provides a clearer understanding of the genes involved in DO. According to the results, future studies should be targeted at blocking specific intrinsic BMP inhibitors as a means for accelerating the rate of bone formation during DO.

Regulation of Mouse BAMBI Gene Expression. T. Kondo, R. Kitazawa, K. Mori, S. Kitazawa. Division of Pathology, Kobe University Graduate School of Medicine, Kobe, Japan.

BMP and activin membrane-bound inhibitor (BAMBI) is a transmembrane glycoprotein structurally similar to the transforming growth factor (TGF)- β family type I receptor, except that it lacks an intracellular kinase domain. As a pseudoreceptor, BAMBI interacts with many of the type I and II TGF- β receptors and functions as a negative regulator of TGF- β signaling. To elucidate the role of BAMBI during skeletogenesis and osteoblastic differentiation, we first immunohistochemically analyzed the localization of mouse BAMBI expression in mouse bone tissue. BAMBI expression was seen in some of periosteal osteoblasts, in chondrocytes in articular cartilage and in hypertrophic chondrocytes in the growth plate. Most of the osteocytes embedded in trabecular bone were, however, negative for BAMBI. In vitro studies revealed that BAMBI mRNA expression increased 95-fold in recombinant human bone morphogenetic protein 2 (rhBMP-2)-treated C2C12 myoblastic cells induced into the osteoblastic lineage. Furthermore, BAMBI knockdown by siRNA increased alkaline phosphatase and Runx2 expression in ST2, suggesting that BAMBI expression plays an important role as part of the negative feedback loop system in TGF- β /BMP signaling during osteoblastic differentiation. Additionally, transient transfection studies with the use of the mouse BAMBI promoter reporter construct showed that BAMBI promoter activity in ST2 increased 1.8-fold by TGF- β treatment, 1.2-fold by rhBMP-2 treatment, and 1.9-fold by treatment with lithium chloride, an agonist of the β -catenin signaling pathway. Since both BMP responsive elements and TCF-1 binding sites are conserved in mouse and human BAMBI promoters, BAMBI gene expression is regulated by both TGF- β /BMP and Wnt/ β -catenin signaling pathways. We then assessed the methylation status of the BAMBI promoter region by Southern blot analysis and found tissue-specific distribution of promoter hypermethylation. Sodium bisulfite mapping, however, revealed no CpG locus methylation around the transcription start site in primary cultured osteoblasts or osteocytes. We therefore speculate that the epigenetic regulation of BAMBI gene expression by CpG hypermethylation is physiologically involved in tissue- and development-specific BAMBI expression, and that decreased BAMBI expression in terminally-differentiated osteocytes is due not to epigenetic gene silencing but passively to decreased β -catenin and/or BMP signaling in osteocytes. Thus, BAMBI is a target gene of both BMP and Wnt/ β -catenin signaling and may be involved in preventing some of the osteoblast precursors and chondrocytes from terminal differentiation.

Type III TGF β Receptor Regulates BMP Signaling in Differentiating Osteoblasts In Vitro and In Vivo. M. Ni^{*1}, G. R. Mundy², R. L. Caldwell³.

¹Department of Pharmacology, Vanderbilt University School of Medicine, Nashville, TN, USA, ²Department of Medicine/Clinical Pharmacology, Vanderbilt University School of Medicine, Nashville, TN, USA, ³Department of Orthopaedics and Rehabilitation, Vanderbilt University School of Medicine, Nashville, TN, USA.

Several cell surface receptors for TGF- β are now well established. Type I and II receptors (TRI and TRII) express intracellular kinase domains responsible for receptor activation and signaling. The type III TGF- β receptor (TRIII) is an 849-amino acid transmembrane proteoglycan that exists as a co-receptor for TGF- β , yet maintains biological functions distinct from TRI and TRII. TRII has a short, highly conserved 43-amino acid cytoplasmic domain (CD). TRII regulates TGF- β signaling by recruiting TGF- β ligand to TRII, driving endocytosis of the signaling complex, and guiding regiospecificity of cellular differentiation. BMPs are necessary for osteogenesis from early embryonic tissue patterning to postnatal skeletal development. BMPs promote bone development by stimulating proliferation and differentiation of osteoblasts, and recent work has suggested that non-union of bone may be the result of decreased levels of BMP activity. Due to signaling homology shared between TGF- β and BMP, we hypothesized that BMP-induced bone formation is regulated by TRII from early embryogenesis through development of mature skeleton, and that the TRII CD is central to these functions. Our hypothesis was tested by phenotypic analysis of TRII knockout mice, immunohistochemical (IHC) localization of TRII in developing and mature bone, and transfection assays using 2T3 osteoblasts. We observed TRII null mice exhibit a shorter skeletal phenotype (<10%) than WT mice. IHC analysis of femoral bone from WT 2-month old mice revealed enhanced TRII expression in bone marrow as well as the growth plate, while IHC analyses for TRII in adult mice reveal little TRII expression in mature bone. In committed bone cells, TRII attenuates BMP signaling. We found that forced TRII expression down-regulates SMAD 1, 5 and 8 phosphorylation after BMP2 stimulation, and deletion of the TRII CD further decreases SMAD phosphorylation. Bone cells demonstrate decreased alk phos activity upon TRII forced expression. TRII up-regulates SMAD6 after BMP2 stimulation, and represses BMPRII promoter activity via the TRII CD. We conclude that TRII plays a dual role in regulating BMP signaling throughout bone development. Furthering our understanding of TRII in bone biology will give insights into the control of normal bone formation and provide better understanding of disorders of bone formation.

Protein Related to DAN and Cerberus (PRDC) Is Expressed in Skeletogenesis and Prevents Osteoblastic Differentiation. A. Nifuji¹, H. Ideno^{*2}, R. Takanabe^{*2}, A. Shimada^{*1}, R. Araki^{*2}, M. Abe^{*2}.

¹Department of Pharmacology, Tsurumi University of Dental Medicine, Yokohama, Japan, ²National Institute of Radiological Sciences, Chiba, Japan.

Protein related to DAN and cerberus (PRDC) is a secreted protein with a cysteine knot structure that binds bone morphogenetic proteins (BMPs) and inhibits BMP actions. In this study we investigated PRDC expression and regulation in skeletogenesis and examined if PRDC functions during skeletal cell differentiation. First we examined mRNA expression of PRDC by real-time PCR using RNA extracted from primary calvaria derived osteoblastic (pOB) cells and MC3T3-E1 (MC) cells. We observed constitutive expression of PRDC mRNA in those osteoblastic cells. By in situ hybridization analysis for embryonic day 18 calvaria in mice, we found that PRDC mRNA was localized in calvarial osteoblast-like cells adjacent to osteopontin and osteocalcin expressing cells. In both of pOB cells and MC cells, PRDC mRNA expression level is significantly elevated in treatment with recombinant BMP2. Next to investigate PRDC functions, we constructed an adenovirus expressing PRDC. We infected PRDC expressing adenoviruses into pOB, MC and C1 mesodermal stem (C1) cells and analyzed their effects on those cells. PRDC infection did not alter cell numbers when compared with cells infected with LacZ expressing control adenoviruses in pOB cells. Expression of mRNAs for osteoblastic markers, alkaline phosphatase and osteocalcin, as well as a BMP target gene, Id1, were suppressed in pOB, MC and C1 cells infected with PRDC expressing adenoviruses. Furthermore, forced expression of PRDC inhibited alkaline phosphatase activity and mineralized nodule formation during pOB cell differentiation. Finally, we blocked PRDC expression by using siRNA against PRDC mRNA. We found that transfection of siRNA against PRDC mRNA resulted in elevation of alkaline phosphatase activity when compared with control siRNA. These results suggest that PRDC is expressed in skeletogenesis and prevents osteoblastic differentiation possibly through inhibition of BMP action.

Membrane Domain Dynamics During Osteoblast Differentiation. K. Young^{*1}, B. Bragdon^{*1}, L. G. Horton^{*2}, W. G. Beamer², A. Nohe¹. ¹Chemical and Biological Engineering, University of Maine, Orono, ME, USA, ²The Jackson Laboratory, Bar Harbor, ME, USA.

Bone Morphogenetic Proteins (BMPs) belong to a subgroup of the TGF-beta superfamily of receptor ligands. BMP levels influence multipotent mesenchymal cells to differentiate into chondrocytes, osteoblasts, myocytes, and adipocytes. They are crucial during skeletal development and homeostasis, affecting osteoblast and osteoclast differentiation. Defects in BMP signaling are linked to several bone diseases. The bone marrow of osteoporotic patients show high levels of adipocytes suggesting the differentiation of bone marrow stromal cells (BMSCs) markedly favors adipocytes. The initiation of the BMP signaling involves binding of the cognate ligand to a combination of BMP receptors (BMPR) on the plasma membrane. Using the Family of Image Correlation Spectroscopy (FICS) methodology combined with molecular biological approaches current research indicates that not only do BMP type-I (BRIa) and type-II (BRII) receptors aggregate and cluster in specific domains on the cell surface, but that these receptors must shuttle between distinct membrane rafts in order to transduce their signals. Interdomain shuttling influences BMP signaling and regulates the early steps of osteoblast differentiation. Using a cell culture model our data further suggest that the aggregation status of BMP receptors with membrane domains was crucial in prevention of heterotopic ossification. Additionally, using these techniques we showed that membrane domain organization was disturbed in mice displaying an osteoporotic phenotype. These results point to the importance of membrane domains in regulating osteogenesis. Moreover, we identified casein kinase-2 (CK2) as a key protein that mediates osteoblast differentiation. Utilizing FICS and Fluorescence Energy Transfer methods, our data showed that CK2 was not only involved in the regulation of receptor re-shuttling and signal silencing on the cell surface but also in osteoblast differentiation. In detail peptides derived against the CK2 binding domains of BRIa led to enhanced mineralization of bone marrow stromal cells (BMSCs). These data indicated that membrane and receptor dynamics are crucial during osteoblast differentiation and that CK2 was a key player in regulating these dynamics.

Smad1 and Smad4 Differentially Regulate Osteoblast Differentiation and Myogenesis in Myoblasts. J. Nojima¹, T. Fukuda¹, K. Kanomata^{*1}, T. Yoda^{*2}, T. Katagiri¹. ¹Division of Pathophysiology, Saitama Medical University, Research Center for Genomic Medicine, Hidaka-shi, Saitama, Japan, ²Oral and Maxillofacial Surgery, Saitama Medical University, Moroyama, Saitama, Japan.

BMPs inhibit terminal differentiation of myoblasts and convert them into osteoblast lineage cells. Fibrodysplasia ossificans progressiva (FOP) is a genetic disorder of skeletal malformation and undergoing ectopic bone formation in muscle. Recently, a mutation of BMP type I receptor was identified in FOP patients, suggesting that BMP signaling is involved in both pathological and physiological bone formation. In the present study, we examined a role of Smad pathway, how to inhibit myogenesis prior to induce bone formation. We previously reported a constitutively activated form of Smad1 (caSmad1), which induced osteoblast differentiation in C2C12 myoblasts even in the absence of BMPs. Co-expression of Smad4, a partner of Smad1, synergistically enhanced the osteoblast differentiation induced by caSmad1, although Smad4 alone failed to induce any markers of osteoblast differentiation. Over-expression of Smad1 and Smad4 suppressed myogenic differentiation induced by MyoD. To examine roles of translocation of Smad proteins from cytoplasm to nucleus on osteoblast differentiation and myogenesis, we further generated NLS-Smad1 and NLS-Smad4, in which a nuclear localization signal derived from SV40 was fused to each Smad. NLS-Smad1 neither induced osteoblast differentiation nor inhibited myogenesis. In contrast, targeted expression of NLS-Smad4 markedly suppressed myogenesis, but it did not induce osteoblast differentiation. Deletion of MH1 or MH2 from NLS-Smad4 destroyed the inhibitory activity on myogenesis. Taken together, these results clearly indicate that both the induction of osteoblast differentiation and the inhibition of myogenesis are dependent on Smad proteins. A complex formation between Smad1 and Smad4 seems to be essential for the transactivation of downstream targets required for the osteoblast differentiation. In contrast, translocation of Smad4 to nuclei, even in the absence of Smad1, was the critical event for suppression of myogenesis. It was suggested that Smad4 moved into nuclei as a part of the Smad complex inhibits myogenesis, then it induces osteoblast differentiation cooperate with Smad1.

Endogenous Cyclic Adenosine 3', 5'-Monophosphate Response Element-Binding Protein (CREB) Signaling Enhances Smad-Mediated Bone Morphogenetic Protein (BMP) Signaling. Y. Ohta^{*1}, K. Nakagawa¹, Y. Imai¹, T. Katagiri², T. Koike¹, K. Takaoka¹. ¹Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka City, Japan, ²Division of Pathophysiology, Research Center for Genomic Medicine, Saitama Medical School, Saitama, Japan.

It has been reported that increase in intracellular cyclic adenosine 3',5'-monophosphate (cAMP) accumulation by pentoxifylline, a nonspecific inhibitor of phosphodiesterase and rolipram, a phosphodiesterase-4 specific inhibitor and prostaglandin E2 EP4 receptor selective agonist can enhance BMP-induced osteoblastic differentiation of mesenchymal cells both in vivo and in vitro. However, the mechanism by which cAMP enhances BMP-induced osteoblastic differentiation remains unclear in detail. To further clarify the mechanism of enhancement of BMP signaling by cAMP, we examined the BMP signaling pathway at the transcriptional level in C2C12, muscle-derived mesenchymal cells expressing BMPR1 and BMPR2.

In the present study, we examined the relationship between cAMP and BMP signaling at the transcriptional level, using the promoter of the Id1 gene, an early response gene to BMPs which includes both BMP responsive element (BRE) and cAMP response element (CRE), and performed luciferase activity assay. In the cells transfected with wild-type Id1 promoter, treatment with BMP-4 increased relative luciferase activity (RLA), which was further enhanced by the addition of dibutyryl cAMP (dbcAMP), a cell membrane-permeable analogue of cAMP. Interestingly, RLA levels which were increased by treatment with both BMP-4 and dbcAMP or BMP-4 alone were decreased when the CRE site was inactivated (with wild-type BRE present). We also examined the effects of down-regulation of endogenous CREB on the transcriptional activity mediated by Smads using an Id1 promoter construct. Cells were transfected with CREB RNAi and wild-type Id1 promoter construct and treated with or without BMP-4 or dbcAMP. Inhibition of BMP signaling was observed when endogenous CREB was knocked down using RNAi technology. Similar findings were obtained when cells were co-transfected with reporter plasmid containing the wild-type Id1 promoter and A-CREB, a dominant-negative inhibitor of CREB plasmid.

In this study, we showed that cAMP/CREB signaling enhances the BMP-induced transcriptional activity of the BRE in the Id1 gene promoter by activating the CRE close to the BRE in this promoter. We also confirmed that endogenous CREB/CRE signaling plays an important role in Smad-mediated BMP signaling.

Bone Metabolism After Posterolateral Lumbar Fusion Using Osteogenic Protein-1. K. Shigenobu^{*}, T. Hashimoto^{*}, M. Kanayama^{*}, F. Oha^{*}. Orthop. Surgery, Hakodate Central General Hosp., Hakodate, Hokkaido, Japan.

INTRODUCTION: Bone morphogenetic proteins are being used clinically for spinal fusion. Numerous pre-clinical investigations have demonstrated efficacy of osteoinductive proteins in spinal fusion, but the metabolism of the BMP induced fusion process has not been well studied in human clinical setting. This study compares the expression of bone metabolic makers following posterolateral lumbar fusion using Osteogenic Protein-1 (rhBMP-7) to fusion with HA / TCP granules and local autograft. **METHODS:** Nineteen patients with symptomatic degenerative spondylolisthesis underwent a single-level (L3-4 or L4-5) posterolateral fusion using pedicular screw fixation. The patients were randomly divided into two groups: 10 cases with HA/TCP granules and local autograft (HA/TCP group), and 9 cases with OP-1 putty [3.5mg OP-1/g collagen matrix] (OP-1 group&). The mean age was 59 years in the HA/TCP group, and 70 years in the OP-1 group. Two bone formation markers were measured; serum bone-specific alkaline phosphatase (BAP) and type I pro-collagen C-terminal propeptide (PICP). Three bone resorption markers were measured; serum type I collagen C-terminal telopeptide, urinary deoxypyridinoline and cross-linked N-telopeptides of type I collagen. Samples were obtained preoperatively and 1 day, 1, 2, 4, 12, and 24 weeks postoperatively. **RESULTS:** The bone resorption marker levels peaked at 4 weeks and decreased to preoperative levels by 24 weeks. There were no significant differences between the study groups. The bone formation marker levels exhibited a different pattern in each study group. BAP rapidly increased over 2 weeks in both groups; however, the level peaked earlier in the OP-1 group. PICP gradually increased after surgery in both groups, however it elevated earlier in OP-1 group. **DISCUSSION:** PICP increases in the early stages of osteogenesis influencing the synthesis of collagen fibrils. BAP is a specific marker for the function of osteoblasts. Both of these markers were elevated earlier in OP-1 group despite the older patient population. These results suggest that OP-1 has the potential to enhance earlier bone formation in posterolateral fusions.

Assessing BMP-2 Activated Osteoblast Differentiation with Nanopatterned Surfaces. K. H. Szymczyk*, J. P. Spatz*, E. A. Cavalcanti-Adam. Biophysical Chemistry, University of Heidelberg, Heidelberg, Germany.

Bone morphogenetic proteins (BMPs), found in bone extracellular space in soluble and bound form, are necessary for osteogenesis during embryonic development, and in post-natal mammals for bone growth, remodeling, and repair. Elucidating the structural and molecular mechanisms behind BMP signaling will augment current knowledge of bone formation and contribute to advancements in skeletal defect repair. One new approach to assessing ligand clustering and signaling is by the use of nanopatterned-surfaces presenting a regular, repeating pattern of proteins. Consequently, the local density of these molecules can be varied and the ligand/receptor activation can be evaluated. Thus, the purpose of this study was 1) to create a surface with nanopatterned BMP-2 and 2) to characterize the effects of nanoscale variations in spacing and density of BMP-2 ligands on osteoblast cell adhesion and differentiation.

We used a well-established method of nanopatterning to create a BMP-2 coated glass surface. Surfaces were decorated with various nanospaced gold-dots (100nm), and a homogeneously gold-coated surface was used as a control. Scanning electron microscopy confirmed that the surfaces were composed of a regular repeating pattern. BMP-2 protein was deposited onto the surface in anticipation that the terminal cysteine residue covalently linked to the gold-dots. Characterization of the homogenous surface was performed by immunohistochemical and X-ray photoelectron spectroscopy (XPS) analysis. These methods indicated that BMP-2 was deposited on to the surface.

To study cell behavior and differentiation, C2C12 cells were plated on the homogenous surfaces and allowed to adhere overnight. Proliferation and viability was then determined using the MTS assay. Viability was not compromised on the BMP-2 functionalized surface however, proliferation was decreased. Cell adhesion behavior was assessed using phase contrast time-lapse microscopy. These results indicated that cell motility was reduced on the BMP-2 coated nanosurface in comparison to tissue culture plastic. Differentiation was evaluated by measuring alkaline phosphatase enzyme activity after 21 days. C2C12 cells grown on the BMP-2 surface had increased AP expression.

Well-defined nanopatterns of peptides are a unique tool to investigate the relevant ligand densities necessary in cell differentiation, with a resolution as small as single proteins. On going investigations will determine whether osteoblasts can distinguish between different surface densities of BMP-2 proteins and respond with altered attachment, spreading, migration, and differentiation.

Noggin Short Interfering RNA Gene Transfer Enhances the In Vivo Ectopic Bone Formation Induced by Bone Morphogenetic Protein-2. K. Takayama*, A. Suzuki*, T. Manaka*, S. Taguchi*, Y. Hashimoto, K. Takaoka. Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan.

Noggin is one of major extracellular antagonists of bone morphogenetic proteins (BMPs). It is reported that noggin is upregulated in undifferentiated mesenchymal cells and myoblasts in response to BMPs, and this may cause diminish the performance of BMPs in bone formation. In this study, we investigated the effect of noggin silencing by short interfering RNA in osteogenic differentiation in vitro, and the ectopic bone formation in vivo.

Noggin expression induced by BMP-4 in C2C12 cells, a myoblastic cell line, was confirmed by real-time RT-PCR. Noggin mRNA expression was elevated by BMP-4 stimulation in dose- and time- dependent manner. We designed six double-stranded short interfering RNAs (siRNAs) for targeting noggin. Plasmid vectors expressing noggin and siRNAs were co-transfected into C2C12 cells, and successful specific suppression of noggin protein expression was confirmed in one of six siRNAs by Western blot. Transfection of the noggin siRNA into C2C12 cell also suppressed the endogenous noggin mRNA expression induced by BMP-4, and enhanced BMP-4 induced alkaline phosphatase activity up to two fold.

In vivo effect of noggin siRNA gene transfer on rhBMP-2 induced bone formation was examined by ectopic bone formation assay in mice. Noggin siRNA plasmid (10 µg) was injected into the dorsal muscle and electroporation procedures was applied to the left paravertebral muscle, and then collagen sponge disk (6mm diameter) containing 5 µg of rhBMP-2 was implanted into the muscle. On days 4 after surgery, total RNA was extracted from muscle tissue around the collagen disk for real time RT-PCR analysis. Electroporation-mediated transfer of noggin siRNA markedly decreased expression of noggin mRNA, which increased after implantation of the collagen disk containing rhBMP-2. At 3 weeks after surgery, the implants were harvested and radiographed with a soft X-ray apparatus, and bone mineral content (BMC) of each ossicle was measured by dual-energy X-ray absorptiometry. The size of new bone induced by rhBMP-2 and the mean BMC were significantly increased by noggin siRNA gene transfer.

Conclusively, these findings suggest that noggin siRNA gene transfer enhances the osteoblast differentiation induced by BMP-4 in vitro and the bone formation induced by BMP-2 in vivo. While further study is needed, this approach may be useful tool in clinical application.

Gremlin Induces Mitogen Activated Protein (MAP) Kinase Signaling in Osteoblasts. S. Zanotti, A. Smerdel-Ramoya, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

Gremlin, the product of gremlin, is a 20 kDa secreted glycoprotein that binds bone morphogenetic proteins (BMPs) -2, -4 and -7, and antagonizes BMP actions. Gremlin plays a central role in limb bud patterning and development, and in skeletal homeostasis. Targeted over expression of gremlin in the bone environment in mice leads to osteopenia and the in-vivo conditional deletion of gremlin in bone tissue causes an increase in bone formation and trabecular bone volume. Furthermore, down regulation of gremlin expression by RNA interference (RNAi) sensitizes osteoblasts to BMP signaling and activity. These observations suggest that the skeletal effects of gremlin can be explained by its ability to bind and oppose BMP activity. However, activities independent of BMP binding have been postulated. To determine whether gremlin has direct effects in osteoblasts, we examined its ability to induce signaling through Smad2/3 (Smad) or MAP kinase activity in ST-2 stromal cells and calvarial mouse osteoblasts. Gremlin did not stimulate Smad signaling, and suppressed the BMP-2 induced Smad 1/5/8 phosphorylation. In contrast, gremlin as well as BMP-2 induced extracellular regulated kinase (ERK) -1/-2 phosphorylation. To determine whether the effects of gremlin and BMP on ERK 1/2 phosphorylation were interdependent, we tested the effects of gremlin in the presence of the BMP antagonist noggin in excess and the effects of BMP-2 under conditions of gremlin down regulation by RNAi. Noggin prevented the effect of gremlin on ERK signaling indicating that endogenous BMPs were required for the gremlin effect. Down regulation of gremlin decreased the effect of BMP-2 on ERK phosphorylation, confirming that gremlin is necessary for this BMP activity. These results indicate that BMP and gremlin effects on ERK phosphorylation are interdependent. To determine whether ERK activation is used as a mechanism to modulate BMP effects on Smad signaling, the effect of the ERK inhibitor U0126 was tested. Inhibition of ERK caused an increase in BMP-2/Smad signaling in the absence and presence of gremlin. In conclusion, gremlin and BMP-2 have interdependent activities to enhance ERK signaling, possibly by conformational changes that favor specific BMP receptor interactions. ERK activation may be a mechanism to temper BMP/Smad signaling and activity.

Treatment of XLH with Calcitriol and Phosphate Increases FGF23 Concentration. E. A. Imel¹, L. A. DiMeglio¹, S. L. Hui^{1*}, T. O. Carpenter^{2*}, M. J. Econs¹. ¹Indiana University School of Medicine, Indianapolis, IN, USA, ²Yale University, New Haven, CT, USA.

X-Linked hypophosphatemic rickets (XLH), due to mutations in PHEX, causes rickets and osteomalacia due to renal phosphate wasting, with inappropriately low or normal 1,25-dihydroxyvitamin D concentrations. The PHEX mutation results in increased expression of fibroblast growth factor 23 (FGF23) in bone cells, and elevated circulating FGF23 concentrations are reported. XLH is treated with high dose phosphate and calcitriol, both of which could further increase FGF23 concentrations.

We measured FGF23 concentrations in 8 subjects, age 2 to 30 years, using an ELISA that detects only full-length FGF23. FGF23 concentrations were determined before treatment and following initiation of treatment with phosphate and calcitriol. Pretreatment, 1-3 samples were obtained. Post-treatment, 1-5 samples were obtained over 0.5 to 3.5 years.

Because doses of phosphate and calcitriol were generally changed together, there was high correlation between treatment doses with these two agents. All pretreatment FGF23 concentrations were elevated (compared to a normal control range of <71pg/ml). Average pretreatment FGF23 ranged from 127 to 1353 pg/ml (mean 349 ± 408 pg/ml). During the course of therapy, post-treatment FGF23 concentrations ranged from 136 to 3270 pg/ml (mean 807 ± 839 pg/ml). Most subjects had an increase in FGF23 concentrations after treatment, but the degree of elevation varied in extent and timing. FGF23 increased > 20% in 5/8 and >100% in 3/8 subjects during treatment. FGF23 did not decrease in any subject with treatment. FGF23 concentrations correlated with both phosphate (p = 0.03) and calcitriol doses (p = 0.004). When controlling for combined treatment, calcitriol dose remained a significant predictor of FGF23 concentrations (p = 0.01), while phosphate dose was no longer significant.

Although our sample size was small, treatment of XLH with phosphate and calcitriol was associated with concurrent increase in FGF23 concentrations. This effect is more strongly associated with the calcitriol dose. Previous studies indicated that current therapy improves the bone disease. However, increasing FGF23 concentrations may make the disease more difficult to manage, or contribute to complications of therapy and is an undesirable consequence. Although more study is needed, it may be preferable to adjust therapy to minimize the effect on FGF23 concentrations.

	FGF23 concentrations			
	Average pretreatment FGF23 (pg/ml)	FGF23 concentration at highest calcitriol dose for each subject	Calcitriol dose (ng/kg/day)	Phosphate dose (mg/kg/day)
Case A	145	229	14	7
Case B	219	235	16	24
Case C	224	226	17	25
Case D	225	1136	22	14
Case E	223	271	29	28
Case F	277	1826	30	22
Case G	127	136	31	27
Case H	1353	3270	31	31

Regulatory Mechanism of Production and Circulatory Level of FGF23 in Human. N. Ito*, S. Fukumoto, H. Suzuki*, T. Fujita*. Division of Nephrology & Endocrinology, Department of Medicine, University of Tokyo Hospital, Tokyo, Japan.

FGF23 has been identified as a phosphaturic factor which plays important roles in the development of hypophosphatemic rickets/osteomalacia. Because FGF23-null mice show hyperphosphatemia and high 1,25-dihydroxyvitamin D [$1,25(\text{OH})_2\text{D}$] levels, and deficient action of FGF23 results in familial hyperphosphatemic tumoral calcinosis, FGF23 seems to be a physiological regulator of serum phosphate and $1,25(\text{OH})_2\text{D}$. Previous studies indicated that high phosphate diet increases and phosphate restriction decreases FGF23 levels both in human and rodents. It has been also shown that $1,25(\text{OH})_2\text{D}_3$ increases FGF23 level and enhances promoter activity of FGF23 gene in rodents. However, it remains largely unknown how circulatory FGF23 level and production of FGF23 are controlled in human. Especially, it has not been shown whether phosphate directly regulate production and serum level of FGF23. Therefore, we first examined whether acute changes of serum phosphate modify FGF23 levels in vivo. Serum phosphate levels were modulated by infusion of dibasic potassium phosphate or ingestion of partially hydrolyzed starch in 4 volunteers. While serum phosphate significantly increased by phosphate infusion and conversely decreased by ingestion of carbohydrate, these maneuvers did not change serum FGF23 levels within 6 hours. These results indicate that acute changes of serum phosphate do not modify FGF23 secretion in human. We then investigated whether phosphate regulates FGF23 production in vitro by reporter assay with human FGF23 gene in osteoblast-like HOS-TE85 cells. We have cloned promoter region of human FGF23 gene with various length. Relative luciferase activity of -3990 bp promoter was 5.7 times, and -1826 bp promoter was 13.8 times higher than that of pGL3 basic. Shorter promoters (-1384 bp to -446 bp) showed lower activities. Changes of phosphate concentrations in culture media did not affect either promoter activity of FGF23 gene. These results suggest that phosphate does not directly modify expression of human FGF23 gene although it is also possible that HOS-TE85 cells do not have a mechanism to sense extracellular phosphate level. Together with the in vivo study, our results suggest that the regulation of FGF23 by phosphate in vivo is indirect and some other factor(s) is necessary for changing production and serum level of FGF23 in human.

FGF23 Is an Independent Predictor of BMD in a Population-based Cohort of Elderly Men: MrOS Sweden. R. Marsell*, E. Grundberg*, T. Krajsnik*, H. Mallmin*, M. Karlsson*, D. Mellstrom*, E. Orwall*, C. Ohlsson*, K. B. Jonsson*, O. Ljunggren*, T. E. Larsson*. ¹Department of Surgical Sciences, Uppsala University Hospital, Uppsala, Sweden, ²Department of Medical Sciences, Uppsala University Hospital, Uppsala, Sweden, ³Uppsala University Hospital, Uppsala, Sweden, ⁴Department of Surgical Sciences, Malmö University Hospital, Malmö, Sweden, ⁵Sahlgrenska University Hospital, Gothenburg, Sweden, ⁶Oregon Health and Science University, Portland, OR, USA, ⁷Department of Medical Sciences, Uppsala University Hospital, Uppsala, Sweden.

Fibroblast Growth Factor-23 (FGF23) is a circulating factor that regulates serum levels of phosphate (Pi) and $1,25(\text{OH})_2\text{D}_3$. Increased FGF23 levels are central in the pathogenesis of several hypophosphatemic disorders with rickets/osteomalacia, such as ADHR, XLH and TIO. Since both Fgf23 null mice and FGF23 transgenic mice harbor skeletal phenotypes, the objective of the current study was to investigate the association between intact serum FGF23 and BMD. We used a population-based epidemiological prospective study; the Swedish MrOS Study in Uppsala. In total, 1000 men aged 70-80 years were randomly selected from population registries. BMD was measured with dual x-ray absorptiometry (DXA) at the femoral neck, total hip, lumbar spine and total body. In addition, serum levels of intact FGF23, Pi, calcium, albumin, PTH, $25(\text{OH})_2\text{D}_3$ and glomerular filtration rate (GFR, calculated from cystatin C), were analyzed. Mean FGF23 levels were 44.1 ± 54.1 pg/mL; femoral neck BMD 0.919 ± 0.138 g/cm²; total hip BMD 0.998 ± 0.152 g/cm²; lumbar spine BMD 1.231 ± 0.219 g/cm²; total body BMD 1.194 ± 0.109 g/cm². Univariate linear regression analysis revealed that FGF23 positively correlated to BMD in femoral neck ($r=0.080$, $p=0.018$), total hip ($r=0.082$, $p=0.015$), lumbar spine ($r=0.080$, $p=0.016$) and total body ($r=0.096$, $p=0.004$). In parallel, multi-regression analysis including FGF23, PTH, GFR, calcium, Pi, $25(\text{OH})_2\text{D}_3$, age and weight as independent variables, revealed that FGF23 and PTH were the only significant explanatory variables for femoral neck (FGF23: $\beta=0.104$, $p=0.004$; PTH: $\beta=-0.073$, $p=0.042$) and total hip BMD (FGF23: $\beta=0.117$, $p=0.001$; PTH: $\beta=-0.081$, $p=0.023$). In addition, FGF23 and calcium were independently associated with lumbar spine BMD (FGF23: $\beta=0.089$, $p=0.013$; Calcium: $\beta=-0.074$, $p=0.045$) as well as total body BMD, where age also showed an independent association (FGF23: $\beta=0.121$, $p<0.001$; Calcium: $\beta=-0.071$, $p=0.049$; age: $\beta=-0.074$, $p=0.035$).

In conclusion, our study indicates that FGF23 is an independent and positive predictor of BMD in elderly men, further supporting an important role of FGF23 in bone and mineral metabolism.

Possible Direct Regulatory Role of Active Vitamin D Increased by Ultraviolet B on Fibroblast-growth factor 23 in Healthy Adults. Y. Rhee¹, J. Lee², H. Choi¹, S. Kim¹, K. Lee², Y. Park², S. Lim¹. ¹Internal Medicine, College of Medicine, Yonsei Univ., Seoul, Republic of Korea, ²Dermatology, College of Medicine, Yonsei Univ., Seoul, Republic of Korea.

Fibroblast growth factor (FGF) 23 is known as a phosphaturic factor regulating phosphate homeostasis. FGF23 acts negatively on the NaPi2a cotransporter and 1α -hydroxylase with a resultant decrease in renal phosphate reabsorption. Its expression is up-regulated by $1,25$ -dihydroxyvitamin D₃ ($1,25(\text{OH})_2\text{D}_3$). It is thought that there exists a novel vitamin D-FGF23 feedback system affecting phosphate homeostasis and biomineralization. Several studies suggest that dietary phosphate, serum phosphate and $1,25(\text{OH})_2\text{D}_3$ are candidates as the regulators. While the human studies which modulated the dietary phosphate showed in rather controversial results, manipulation of the active vitamin D in animals definitely affected FGF23. Therefore, we tried to elucidate the relationship between active vitamin D directly stimulated by UVB exposure on FGF23 level in human. Ten healthy young adult (28-38 y.o., female 3) were recruited to get the UVB exposure thrice a week at sub-minimal erythral dose (MED)[20-50 sec/session] with gradual increment by 10% for 4 weeks. Blood tests for calcium, inorganic phosphorus (P), mineral-related hormones [$25(\text{OH})_2\text{D}$ (VD), $1,25(\text{OH})_2\text{D}_3$ (AVD), parathyroid hormone (PTH), FGF23], and bone markers were checked before, during and after the exposure. Surprisingly, vitamin D insufficient group comprised about 90%. VD increased by 215% (19.8 ng/mL to 40.5 ng/mL, $p<0.001$) after 4 weeks of UVB exposure. While AVD increased by 175% (49.9 pg/mL to 64.4 pg/mL, $p<0.001$) then both level decreased to 141%, 130% respectively after 4 weeks of withdrawal. No significant changes in iP or PTH were noticed. C-telopeptide rised early as 2nd week then decreased, while osteocalcin gradually increased. FGF23 gradually went up then, significant increase was detected at 4th weeks after withdrawal of UVB by 194% (27.8 pg/mL to 41.4 pg/mL, $p=0.025$). In conclusion, AVD and VD were effectively increased by sub-MED UVB exposure for 4 weeks with interesting stimulatory effect on FGF23. We could presume that FGF23 in human body might be directly affected by the AVD even with P in normal range.

Treatment of Mice with Antiresorptive Agents Increases Circulating FGF23, Decreases Renal mRNA Expression of 25-hydroxyvitamin D 1α -hydroxylase, and Reduces Circulating 1,25 Dihydroxyvitamin D. R. Samadfam*, C. Richard*, Q. Xia*, D. Goltzman. Department of Medicine, McGill University, Montreal, PQ, Canada.

We examined the effect of two anti-resorptive agents, alendronate (ALN) and osteoprotegerin (OPG), on the hormones regulating calcium (Ca) and phosphorus (P) homeostasis. Four month old ovariectomized (OVX) mice were treated with either vehicle, ALN (100 µg/Kg/week), or OPG (2.5 mg/kg twice a week), for 2 months. After sacrificing the animals, blood was collected for determination of serum Ca, P, $1,25$ dihydroxyvitamin D [$1,25(\text{OH})_2\text{D}$], PTH, the phosphaturic factor FGF23 and the bone turnover markers TRAP-5b and osteocalcin. The tibia, and lumbar spine were collected for histology and histomorphometry, and the kidney was collected for RT-PCR analysis. Our results indicate that, at the doses used, OPG, and to a lesser extent ALN produced decreases in circulating $1,25(\text{OH})_2\text{D}$ but increases in circulating FGF23. The decreased $1,25(\text{OH})_2\text{D}$ was associated with down-regulation of gene expression of 25-hydroxyvitamin D 1α hydroxylase (1OHase) in kidney. Bone turnover was markedly decreased with OPG and to a lesser extent with ALN at the doses used. The levels of TRAP-5 b and osteoclast numbers correlated positively with levels of $1,25(\text{OH})_2\text{D}$ and negatively with FGF23. No statistically significant changes were observed in circulating Ca, P or PTH. The experiment was repeated in 3 month old male mice with a shorter treatment period (20 days). The effects of OPG treatment on reducing gene expression of renal 1OHase, decreasing circulating $1,25(\text{OH})_2\text{D}$, and increasing serum FGF23, and the marked reduction of serum TRAP5b and osteoclast number were similar to the results obtained in older OVX females. However in male mice, ALN, a less potent antiresorptive agent compared to OPG, had no significant effects on serum $1,25(\text{OH})_2\text{D}$ or FGF23. With the shorter treatment period employed, serum P was decreased in OPG treated animals compared to controls. The reduction in serum P was associated with decreased protein expression of the sodium phosphate co-transporter NaPi2 in renal tubules as assessed by immunohistochemistry. Serum Ca and PTH were not significantly changed after treatment with either OPG or ALN. In conclusion, our results demonstrate that antiresorptive agents decrease the expression of renal 1OHase and consequently the levels of serum $1,25(\text{OH})_2\text{D}$ by increasing the levels of FGF23. The magnitude of these effects correlates with their antiresorptive potency. Furthermore, the effect of antiresorptives on serum P is normalized after long term treatment with these agents suggesting the existence of other regulatory mechanisms, in P homeostasis.

Effects of Pit-1 Type III Sodium-dependent Phosphate Transporter Overexpression on Calcium Phosphate and Bone Metabolism. A. Suzuki¹, P. Amman², S. Sekiguchi¹, S. Asano^{*1}, K. Nishiwaki-Yasuda^{*1}, S. Nagao^{*3}, H. Takahashi^{*3}, M. Hirabayashi^{*4}, M. Itoh^{*1}. ¹Department of Internal Medicine, Fujita Health University, Aichi, Japan, ²Service of Bone Diseases, Department of Rehabilitation and Geriatrics, University of Geneva, Geneva, Switzerland, ³Education and Research Center of Animal Models for Human Diseases, Fujita Health University, Aichi, Japan, ⁴National Institute of Physiological Sciences, Aichi, Japan.

The Pit-1 type III Pi transporter, initially thought to be a house keeping gene, was previously found to be preferentially expressed in developing long bones. Several studies also described a regulation of its expression in cultured bone cells by osteotropic factors suggesting a role of this transporter in bone metabolism. In the present study, we investigated the effects of Pit-1 overexpression in Wistar rats on calcium phosphate and bone metabolism. Skeletal development was not affected by the transgene. In four months old adult transgenic rats, serum Pi was significantly increased in both females and males compared with WT littermates. Enhanced serum Pi was associated with a significantly increased renal Pi transport. In males, elevated serum Pi was associated with a slight decrease in calcium and increased in PTH serum levels. Variations in serum Pi in WT and Pit-1 Tg rats were negatively correlated with serum FGF-23 whereas 1,25-dihydroxyvitamin D₃ was not affected by Pit-1 overexpression. Analysis of bone by DXA indicated that the bones of transgenic rats were significantly smaller, had less mineral and a significantly decreased BMD due to alteration in both trabecular and cortical bone compared with WT littermates. Volume densitometric analysis by μ CT indicated that the bones of females was more affected than those of males by Pit-1 overexpression.

In conclusion, Pit-1 overexpression in rats was associated with enhanced serum Pi and renal Pi transport without influencing skeletal development. Changes in serum Pi correlated negatively with circulating FGF-23, suggesting that Pi is not a direct in vivo regulator of FGF-23 synthesis. Excess serum Pi concentration was rather deleterious for the integrity of bone and was associated with decreased bone mass at several sites.

Analysis and Importance of Glycosylation Status in FGF23 Protein. H. Suzuki^{*}, S. Fukumoto, N. Ito^{*}, T. Fujita^{*}. Division of Nephrology & Endocrinology, Department of Medicine, University of Tokyo Hospital, Tokyo, Japan.

Previous studies have indicated that a part of FGF23 protein is cleaved between Arg¹⁷⁹ and Ser¹⁸⁰ into inactive fragments. Familial hyperphosphatemic tumoral calcinosis is characterized by hyperphosphatemia from enhanced tubular phosphate reabsorption. Two genes, FGF23 and GALNT3, were shown to be responsible for this disease and patients with mutations in these genes have extremely high C-terminal fragment of FGF23 with rather low full-length FGF23. These results suggest that the processing and production of FGF23 protein is enhanced in these patients. GALNT3 gene product is involved in the synthesis of O-linked glycans indicating that O-linked glycosylation affects the cleavage of FGF23. However, it has been unclear which amino acids are actually glycosylated and how mutations of FGF23 gene affect the processing. In order to clarify these issues, we have analyzed various mutant FGF23 proteins by Western blotting. The processing-resistant FGF23 mutant protein (FGF23RQ) was created by substitution of Arg¹⁷⁶ and Arg¹⁷⁹ by Gln. When FGF23RQ was expressed, three proteins around 32 kDa were observed. We have previously shown that these three proteins were FGF23 with one, two and three O-linked glycans between amino acids Asn¹⁶² and Arg²²⁸, respectively. There are 10 Ser or Thr residues as potential sites for glycosylation in this region. Therefore, we first changed each of these 10 Ser or Thr residues into Ala in processing-resistant FGF23RQ. When Thr¹⁷¹, Thr¹⁷⁸ or Thr²⁰⁰ was substituted by Ala, the protein with the highest molecular weight disappeared. Substitutions of other Ser or Thr residues did not affect the three protein bands indicating that O-linked glycans attach to Thr¹⁷¹, Thr¹⁷⁸ and Thr²⁰⁰. Substitution of Thr¹⁷¹, Thr¹⁷⁸ or Thr²⁰⁰ by Ala in wild-type FGF23 virtually vanished the full-length FGF23 protein indicating that only FGF23 with three O-linked glycans is resistant to the processing. Substitution of Ser⁷¹ by Gly or Ser¹²⁹ by Phe in FGF23RQ that was reported in patients with familial hyperphosphatemic tumoral calcinosis did not modify three protein bands around 32 kDa indicating that these mutant proteins have three O-linked glycans. These results indicate that FGF23 has three O-linked glycans at Thr¹⁷¹, Thr¹⁷⁸ and Thr²⁰⁰, and these three glycans are essential for the maintenance of full-length FGF23. Finally, mutations in FGF23 gene enhance the processing by other mechanisms than inhibiting O-linked glycosylation.

The Calcium Phosphate Regulating Hormone Stanniocalcin 2 Is Positively and Negatively Regulated by 1,25(OH)₂D₃ and PTH in Renal Proximal Tubular Cells. H. Yamamoto, Y. Takei^{*}, M. Masuda^{*}, T. Sato, Y. Taketani, E. Takeda. Clinical Nutrition, University of Tokushima School of Medicine, Tokushima, Japan.

Stanniocalcin (STC) is a hormone that was originally identified in fish, where it inhibits calcium (Ca) uptake by the gills and gut and stimulates phosphate (Pi) adsorption by the kidney. We previously have been identified human (h) STC-2 by its primary amino acid sequence identity to the hormone STC-1, and observed the inhibition of phosphate uptake and Npt2 gene promoter activity by hSTC-2 in opossum kidney (OK) cells. It has been also reported that mice deficient in klothe expression (klothe mice) have hypervitaminosis D, hypercalcemia and hyperphosphatemia, and increased renal gene expression of STC-2 compared with wild-type mice. However, the regulation mechanism of renal STC-2 gene expression is not well known. In this study, we addressed the mechanisms by which 1,25-dihydroxyvitamin D₃ [1,25(OH)₂D₃] and parathyroid hormone (PTH) modulates STC-2 gene expression in renal proximal tubular cells. We first examined the effects of 1,25(OH)₂D₃ on the secretion of STC-2 from opossum kidney (OK) cells. Western blot analysis of media conditioned by untreated OK cells revealed no detectable levels of STC-2, but the levels of STC-2 in the media increased markedly after exposure of cells to 1,25(OH)₂D₃ and its analogues. Surprisingly, PTH inhibited the 1,25(OH)₂D₃ induced STC-2 secretion. We also observed that the injection of PTH to rat decreased the levels of STC-2 protein and mRNA expression in kidney compared with control animals. Real-time PCR analysis revealed the mRNA levels of STC-2 in OK cells was increased by 1,25(OH)₂D₃ and rapidly decreased by PTH. In contrast, PTH increased the STC-1 mRNA levels. Moreover, the experiments using activator or inhibitor of PKC indicated that PKC signaling pathway is involved in the down-regulation of STC-2 gene expression by PTH. In summary, STC-2 gene expression is positively and negatively regulated by 1,25(OH)₂D₃ and PTH in proximal tubular cells. Such regulation suggests a link between Ca, Pi and vitamin D homeostasis in the kidney.

Disclosures: H. Yamamoto, None.

Extracellular Inorganic Phosphate Induces ERK1/2 Phosphorylation and Up-regulates a Target Gene of FGF23 in Renal Proximal Tubule Cells via Type IIa Sodium-Phosphate Co-transporter. M. Yamazaki^{*}, M. Kimata^{*}, K. Tachikawa^{*}, K. Ozono, T. Michigami. Department of Bone and Mineral Research, Osaka Medical Center and Research Institute for Maternal and Child Health, Osaka, Japan.

It has been recently established that extracellular inorganic phosphate (Pi) functions as a signaling molecule and regulates gene expression in mineralizing bone cells such as osteoblasts and mature chondrocytes. Pi exerts various biological functions besides mineralization of bone, and renal proximal tubule plays a central role in Pi homeostasis. Therefore, we hypothesized that alteration in extracellular Pi concentration might trigger the signal transduction in proximal tubular cells as well as bone cells. In the current study, using HEK293 human embryonic kidney cells and LLC-PK1 porcine proximal tubular cells, we examined the effects of altered extracellular Pi (0-10 mM) on signal transduction and gene expression. Treatment with increased extracellular Pi induced ERK1/2 phosphorylation within 15 min in a dose-dependent manner. Phosphorylation of c-Raf at Ser338 was also induced by increased extracellular Pi, indicating that the extracellular Pi signals through c-Raf/MEK/ERK pathway. Since it is reported that phosphaturic hormone FGF23 induces the expression of early growth response-1 (Egr-1) through ERK1/2 phosphorylation, we examined the effect of altered extracellular Pi on the expression of Egr-1. Interestingly, the expression of Egr-1 was up-regulated by increase in extracellular Pi, suggesting the commonality between extracellular Pi and FGF23 in terms of the downstream signaling networks. Next, we examined whether type IIa sodium-phosphate co-transporter (NaPi-IIa) is involved in Pi-induced ERK1/2 phosphorylation and increased expression of Egr-1. Treatment with phosphonoformic acid, an inhibitor of sodium-phosphate co-transporter, inhibited the Pi-induced phosphorylation of ERK1/2 and cancelled the up-regulation of Egr-1. In addition, transfection of the expression vector encoding NaPi-IIa enhanced both the Pi-induced phosphorylation of ERK1/2 and up-regulation of Egr-1 expression. These results suggest the involvement of NaPi-IIa in the signaling triggered by alteration in extracellular Pi. In conclusion, in proximal tubular cells, extracellular Pi induces the phosphorylation of ERK1/2 and regulates gene expression in a NaPi-IIa-mediated pathway. Since the expression of Egr-1, a target of FGF23, was regulated by extracellular Pi, extracellular Pi might share the downstream signaling network with FGF23.

CREB Phosphorylation and DNA Binding Along with Demethylation and Deacetylation Are Required for Ultimate Activation of CYP27B1 Promoter by PTH. M. N. Forster^{*1}, A. Maiti¹, M. J. Beckman². ¹Orthopaedic Surgery, Virginia Commonwealth University, Richmond, VA, USA, ²Biochemistry and Molecular Biology, Virginia Commonwealth University, Richmond, VA, USA.

1,25-Dihydroxyvitamin D₃ is synthesized by the mitochondrial P450 enzyme 1- α -hydroxylase (CYP27B1) expressed in the renal proximal tubule. Low serum Ca²⁺ increases parathyroid hormone (PTH), the main regulator of CYP27B1. The signaling pathway of PTH to increase CYP27B1 involves PKA activation and recruitment of p300 to the CYP27B1 promoter, but the molecular mechanisms that alternately stimulate and repress CYP27B1 are not fully solved. Our hypothesis is that PTH transmits signaling through the PKA/CREB pathway in order to up-regulate CYP27B1. A mouse proximal tubule epithelial cell (MPCT) model stably transfected with human PTH receptor type 1 was used to study the temporal regulation of phospho-CREB at 0, 2, 6, 8, 12, 16, and 24 hrs. In order to study the regulation of CYP27B1 promoter (-1500/+74 bp), mRNA, and protein levels RT-PCR, western blots, and luciferase assays were used. A 50nM PTH treatment to MPCT cells showed that all of these components were optimally and significantly activated at the 12 hour time point. The next several studies involved both low and normal Ca²⁺ medium with and without PTH treatment. A forskolin (10 μ M) treatment similarly increased CYP27B1 promoter activity at 12 hrs demonstrating involvement of cAMP, and the PKA inhibitor H89 (100 μ M) blocked CYP27B1 promoter activity indicating the involvement of PKA. To test the role of CREB phosphorylation and binding on CYP27B1 promoter activation two approaches were used; the dominant negatives CREB133 and KCREB were transfected into MPCT cells, significantly blocking CYP27B1 promoter activation by PTH. However, transfection of wild-type CREB further enhanced CYP27B1 promoter activity in the presence of PTH. In addition, treatment with the histone deacetylase inhibitors trichostatin A (10 μ M) and apicidin (1 μ M) suppressed CYP27B1 promoter at the 12 hr time point, suggesting that deacetylase activity is a required determinant of phospho-CREB-mediated activation of CYP27B1. Finally, a treatment with a methylation inhibitor, 5' Aza-cytidine, increased the expression of CYP27B1 thus illustrating that methylation is a second important component of phospho-CREB mediated activation of CYP27B1. This study provides evidence for the key involvement of PTH-mediated CREB phosphorylation and DNA binding for ultimate activation of CYP27B1 promoter in MPCT cells, and demonstrates a requirement of reversing basal repression of CYP27B1 in MPCT cells by DNA demethylation and histone deacetylation at the promoter level.

Endogenous PTH Measurements in Cynomolgus Monkey Serum: Wide Immunoassay Kit-to-Kit Variation. T. Greutzner^{*}, J. Reeves^{*}, P. Oldfield. Charles River Laboratories, Preclinical Services Montreal, Senneville, PQ, Canada.

This study was conducted to identify an immunoradiometric assay (IRMA) for parathyroid hormone (PTH) equivalent to the discontinued Diagnostic Products Corporation's (DPC) Coat-a-Count IRMA.

The DPC assay was compared with two alternative IRMAs: the Diagnostic Systems Laboratories (DSL) Active Intact PTH assay, and Scantibodies Total Intact PTH coated bead method. Duplicate assays were performed according to the manufacturer's instructions and applied to the serum of 20 naive Cynomolgus monkeys. Inter-method comparisons used the Bland Altman method.

Table 1: Descriptive statistics

Method (assay range)	Mean PTH concentration	PTH concentration range
DPC (15-3000 pg/mL)	69.2 pg/mL	15.2-211.9 pg/mL
DSL (10-2000 pg/mL)	98.8 pg/mL	22.4-268.4 pg/mL
Scantibodies (10-2500 pg/mL)	55.3 pg/mL	9.9-188.2 pg/mL

Table 2: Inter-method comparisons

Comparison	Mean ratio (95% CI)*	+/- 1.96 SD of ratios**
DPC/DSL	0.78 (0.72-0.85)	0.50-1.07 (63-137% of mean ratio)
DPC/Scantibodies	1.30 (1.21-1.38)	0.94-1.65 (72-127% of mean ratio)
Scantibodies/DSL	0.61 (0.56-0.67)	0.38-0.84 (62-138% of mean ratio)

* Mean ratio represents bias from one method to the other. ** The standard deviation of the ratios x 1.96 represents the range where 95% of samples are predicted to fall when one method is used in place of another.

The three methods produced different results, with significant bias ($p < 0.001$) between each justifying the use of correction factors to bring one method into the range of another. The Scantibodies results x 1.30 produce PTH values that are predicted to be within 27% of the DPC values in 95% of samples in the concentration range tested. The DSL values x 0.78, give PTH results that are likely to be within 37% of the DPC values in 95% of samples. The results from the Scantibodies assay more closely resemble the DPC data than do the results from the DSL assay. Of concern is the wide range in absolute values given by the three IRMAs which have been designed to measure the same analyte. This may be the result of different kit calibrators or due to the use of antibodies with differing specificities for the various PTH truncation fragments.

In a parallel study, a non-radioactive alternative method requiring low sample volume (Immutopics, Human PTH ELISA) was validated according to current regulatory guidelines with acceptable selectivity, sample stability, dilution linearity and precision and accuracy in the range of 13-426 pg/mL.

Biomarker Effect of Daily Dosing of Human PTH1-34 on Intact Cynomolgus Monkeys for Twelve Days. L. C. Dare^{*1}, J. A. Vasko^{*1}, G. B. Stroup², S. Kumar¹, V. R. Vaden^{*2}, S. J. Hoffman¹. ¹Musculoskeletal Diseases, GlaxoSmithKline, Collegeville, PA, USA, ²GlaxoSmithKline, King of Prussia, PA, USA.

Parathyroid hormone (PTH) is known to stimulate bone formation when administered intermittently to animals and humans. In cynomolgus monkeys, increases in bone mass and strength have been observed with 6 months of PTH treatment. In addition, biochemical markers of bone resorption and formation have been used to assess the effects of PTH on bone in the longer term. The purpose of this study was to determine if daily injection of PTH for twelve days is sufficient to see biomarker changes and to determine how long the biomarker effect remains once dosing is discontinued.

Fourteen female cynomolgus macaques were divided into two treatment groups (n=7/group) and treated daily by SC injection for 12 days with either vehicle (saline, 0.1% BSA) or human PTH1-34 at 1 μ g/kg. Serum was collected on fasted animals prior to dosing on days 1, 5, 8, 12, and at the same time on days 15, 19, and 22. The bone formation biomarkers, osteocalcin (OC), bone specific alkaline phosphatase (BALP), and amino-terminal propeptide of type I procollagen (PINP) as well as the bone resorption biomarker, serum N-terminal telopeptide of type I collagen (NTx), were determined. All procedures were approved by the Institutional Animal Care and Use Committee.

Daily transient elevations of plasma PTH1-34 (C_{max} 215 pg/mL) were seen following SC injection. This resulted in significant increases compared to vehicle treatment in the bone formation markers OC and PINP but not BALP. These elevations were first noted after 7 consecutive days of PTH administration and remained elevated compared to vehicle treatment throughout the duration of the dosing period. Osteocalcin levels continued to be elevated compared to vehicle 7 days after the last injection (day 19; $p < 0.075$). PINP levels were significantly elevated compared to vehicle on days 8 and 12 and returned to vehicle levels by day 19. BALP levels, although not significantly different than vehicle treatment group at anytime, did appear to increase slowly in response to the daily injection of PTH (in comparison to the daily fluctuations of the vehicle treatment group). The BALP levels continued to increase until 3 days after the last injection (day 15). Interestingly, significant reductions in NTx were detected 4 days after the first PTH injection and remained reduced throughout the duration of the study. The reduction in NTx levels were significant compared to vehicle treatment on days 5, 8, 12, and 22.

This study demonstrates that daily injection of PTH1-34 results in significant changes in bone biomarkers as early as 5 days after the first daily administration in the monkey and the biomarker effect is maintained for up to 10 days post-dosing.

Serum Parathyroid Hormone Is Associated with Cortical Bone Dimensions in Young Men - The GOOD Study. M. Lorentzon, D. Mellström, C. Ohlsson. Center for Bone Research at the Sahlgrenska Academy (CBS), Dept. of Internal Medicine, Gothenburg University, 413 45 Gothenburg, Sweden, Gothenburg, Sweden.

An excess of parathyroid hormone (PTH) as seen in primary hyperparathyroidism has been associated with low bone mass, but PTH administered intermittently has bone anabolic effects. The role of physiological levels of parathyroid hormone (PTH) on trabecular and cortical volumetric bone mineral density (vBMD) or cortical bone dimensions has not previously been investigated in young men.

The aim of the present study was to determine if PTH was associated with volumetric BMD (vBMD) and/or bone geometry of the trabecular and cortical bone compartments in a large cohort of young men.

The Gothenburg Osteoporosis and Obesity Determinants (GOOD) study is a population-based study that consists of 1068 young men, age 18.9 \pm 0.6 yrs (mean \pm SD). Serum levels of intact PTH were measured using an immunoluminometric assay while 25(OH)D level were measured using a competitive RIA. vBMD and bone size of the trabecular and cortical bone of the radius and tibia were measured using peripheral quantitative computerized tomography (pQCT).

PTH levels were correlated to adult stature ($r=0.06$, $p<0.05$) and to length of the long bones (radius: $r=0.09$, $p<0.01$; tibia: $r=0.07$, $p=0.03$), but not to the sitting height ($r=0.00$, $p=0.89$).

Regression models including age, height, weight, smoking status, amount of physical activity, calcium intake, serum levels of 25(OH)D, cystatin C, month of measurement, as well as PTH, demonstrated that PTH was an independent positive predictor of cortical periosteal circumference (radius: $\beta=0.07$, $p=0.02$; tibia $\beta=0.07$, $p<0.01$), and endosteal circumference (radius: $\beta=0.08$, $p<0.01$; tibia $\beta=0.07$, $p=0.01$) of the long bones. Using the same regression model, PTH negatively predicted cortical vBMD of the tibia ($\beta=-0.09$, $p<0.01$), but not of the radius ($\beta=-0.05$, $p=0.09$). PTH was not associated with trabecular vBMD of either the radius or tibia.

Our results demonstrate that PTH levels are associated with adult stature due to affected length of the long bones. Furthermore, PTH levels are clear independent predictors of both periosteal and endosteal circumference, suggesting that physiological levels of PTH play a significant role in the determining cortical bone dimensions in young men.

Effect of Ovariectomy and Low Calcium Diet on Bone Properties in Female Mice. A. Minematsu. Physical Therapy, Health Science, Nara, Japan.

Aim: This study was investigated the effects of ovariectomy (OVX) and low calcium (Ca) diet on bone properties in female mice.

Subjects and Methods: Forty female ICR mice aged 3 months divided into 4 groups randomly. Two groups were sham-operated, and remain of two were ovariectomized. They were fed standard laboratory diet (Ca: 1.1g/100g) or special low Ca diet at libitum for 100 days. After this experiment, maximum load (ML) of the femur and tibia were measured by the three-point bending test, and calculated maximum stress (MS), elastic modulus (EM), and energy absorption (EA). The bones were measured bone length (BL) and bone width (BW), weighted dry bone mass (BM), and burned to ash, and measured ash contents (AC). Data were analyzed by two-way ANOVA and Scheffé's procedure to find the effects of OVX and low Ca diet on bone properties. A significance level of $p=0.05$ was set. This study was carried out in accordance with the Guide for Animal Experimentation, Hiroshima University and the Committee of Research Facilities of Laboratory Animal Science, Hiroshima University school of Medicine.

Results: OVX decreased EM, EA, BM, and AC of the femur and tibia significantly. BL was longer by OVX. Low Ca diet significantly influenced all bone properties of the both bones except for EM and BM of tibia. Bone properties were reduced by OVX and low Ca diet, and those of combined these factors showed the lowest. Alterations were found BW of both bones. **Conclusions:** OVX and low Ca diet decreased bone properties and combination of these factors affected bone properties further. It was considered that OVX influenced EM and bone shape (BL), and low Ca diet influenced structural and material properties (ML, MS, EA), especially.

Group	Results of Bone Properties of Femur and Tibia			
	SHAM (Femur / Tibia)	OVX (Femur / Tibia)	SHAM+L.Ca (Femur / Tibia)	OVX+L.Ca (Femur / Tibia)

PTH Upregulates Placental Calcium Transfer in Response to Fetal Hypocalcemia While PTHrP Does Not. C. S. Noseworthy^{*1}, G. Karsenty², A. C. Karaplis³, C. S. Kovacs¹. ¹Memorial University of Newfoundland, St. John's, NF, Canada, ²Columbia University, New York, NY, USA, ³McGill University, Montreal, PQ, Canada.

Previous studies in mice and sheep have shown that PTHrP stimulates placental 45Ca transfer but PTH does not. Specifically in Pthrp null fetuses, placental 45Ca transfer was reduced by ~25% vs. WT but was stimulated by exogenous PTHrP 1-86 or 67-86, while PTH 1-34 and 1-84 were without effect. However, endogenous PTH levels were upregulated 7-fold in Pthrp null mice, which may have obliterated a detectable response to exogenous PTH.

We have been examining the role of fetal PTH with two models, Pth null (which lack PTH), and Gcm2 null (which lack parathyroids but retain thymic PTH). We have previously found that Pth and Gcm2 null fetuses are hypocalcemic compared to respective WTs (~1.30 vs 1.75 mmol/l), and that placental 45Ca transfer was normal in Pth null but increased to 119% of normal in Gcm2 nulls. As well, PTH was reduced to 5.03 pg/ml in Gcm2 null, but was undetectable (<1.6 pg/ml) in Pth null fetuses.

We now report that the presence of PTH, and not upregulation of PTHrP, may explain the increased placental 45Ca transfer in Gcm2 nulls v. Pth nulls.

Plasma PTHrP was assessed using a rodent PTHrP 1-34 RIA and (in pmol/l) was 8.1±0.4 in Pth null and 7.8±0.4 in Gcm2 null, no different than corresponding WTs (8.4±0.4 and 7.8±0.4, respectively). RNA was extracted from anterior neck sections (to include parathyroids) and intact placentas, and no difference in PTHrP expression (by quantitative real time RT-PCR) was observed in Pth or Gcm2 nulls versus respective WTs (placental values 0.98±0.07 in Pth null and 0.95±0.07 in Gcm2 null versus 1.00±0.07 in respective WT).

The effect of exogenous PTH 1-84 was then tested with 1 nmol of PTH 1-84, which is equimolar to the amount of PTHrP 1-86 that was effective in Pthrp nulls. On day 17.5 pc, all fetuses were injected in utero with either PTH 1-84 or saline, 85 minutes prior to administration of 45Ca/51Cr-EDTA to the mother. Accumulation of isotopes in the fetuses was measured after 5 minutes. By this standard method, placental 45Ca transfer was increased to 124±6.4 vs 106±7.9% in PTH-injected vs. saline-injected Pth nulls ($p<0.04$), while WT and Pth+/− fetuses showed no response.

Thus, we have demonstrated that PTH was detectable in Gcm2 nulls (in which placental 45Ca transfer was upregulated) but not Pth nulls, that placental and circulating PTHrP was not upregulated in either Pth or Gcm2 nulls, and that exogenous PTH administration increased placental 45Ca transfer in Pth nulls. We conclude that PTH likely stimulated placental 45Ca transfer in response to fetal hypocalcemia (Gcm2 nulls) while PTHrP was not upregulated in response to hypocalcemia; the factors that regulate PTHrP remain undetermined.

The PTH/PTHrP Receptor Modulates the Pool of Bone Marrow Stromal Cells: Implications for the Anabolic Action of PTH. M. Ohishi¹, L. E. Purton^{*2}, W. L. Stanford^{*3}, D. T. Scadden^{*2}, H. M. Kronenberg¹, E. Schipani¹.

¹Endocrine unit, Massachusetts General Hospital, Boston, MA, USA, ²Center for Regenerative Medicine, Massachusetts General Hospital, Boston, MA, USA, ³Institute of Biomaterials and Biomedical Engineering, University of Toronto, Toronto, ON, Canada.

Transgenic mice expressing constitutively active PTH/PTHrP receptors (PPR) in osteoblasts (Tg) show an increase in trabecular bone with a concomitant expansion of the bone marrow (BM) stromal cell population, and increased number of osteoblasts and hematopoietic stem cells. The goal of this study was to investigate whether PPR signaling in osteoblasts has an effect on mesenchymal stem cells (MSCs)/progenitors. It has been previously reported that the BM pool of Scf1(+) CD45(-) CD31(-) cells is enriched in MSCs/progenitors. In addition, Scf1 deficient mice (Scf1-/- mice) show an osteoporotic phenotype by 7 months of age, which is due to a decrease of MSCs/progenitors. Flow cytometry analysis of BM cells revealed that the percentage of Scf1(+) CD45(-)CD31(-) cells is at least 50% higher in Tg BM than in wild-type (Wt). Immunohistochemistry for Scf1 showed that osteoblasts do not express Scf1, which indicates that the pool of Scf1(+) CD45(-)CD31(-) cells does not contain osteoblasts. Collectively, our data thus suggest that the number of MSCs/progenitors could be indeed expanded in Tg mice. Interestingly, in vitro colony forming unit fibroblast (CFU-F) assay did not confirm this increase of MSCs/progenitors. We believe that the discrepancy is secondary, at least in part, to the high degree of heterogeneity of the CFU-F cultures. To investigate whether the MSCs/progenitors contribute to the phenotype of the Tg mice, we have then generated Tg mice lacking Scf1 (TgScf1-/- mice). Preliminary data showed a partial attenuation of the Tg phenotype in TgScf1-/- mice at an age when there is no observed osteoporosis in Scf1-/- mice. We are also investigating whether intermittent PTH treatment expands the pool of MSCs/progenitors in vivo. For this purpose, we are treating Wt mice with intermittent PTH(1-34) daily for 4 weeks; flow cytometry analysis of BM cells will be performed at the end of the treatment. Finally, in order to investigate whether the anabolic action of intermittent PTH is preserved in mice that are depleted of MSCs/progenitors, Scf1-/- mice are being injected with intermittent PTH (1-34) daily for 4 weeks. Bone density will be measured at the end of the treatment and presented together with the histological findings. To study whether intermittent PTH modulates the pool of MSCs/progenitors and whether the anabolic action of PTH is affected in a setting in which the pool of MSCs/progenitors is depleted could have important therapeutic implications for the treatment of osteoporosis.

Targeted Overexpression of Parathyroid Hormone Type 2 Receptor in Chondrocytes Impairs Cartilage Differentiation and Trabecular Bone Growth. D. K. Panda^{*}, H. Su^{*}, D. Goltzman, A. C. Karaplis. Department of Medicine, McGill University, Montreal, PQ, Canada.

Members of the parathyroid hormone (PTH) family of ligands and receptors play a pivotal role in the maintenance of calcium and phosphorus homeostasis as well as in the regulation of skeletal growth and development. TIP39 is the newest member of the family and exerts its function by binding and activating its cognate receptor, the PTH type 2 receptor (PTH2R). Experimental evidence suggests that TIP39 and PTH2R form a neuromodulator system in the CNS. However, there is very little indication that this signaling pathway partakes in the regulation of skeletal development. Using CFK2 chondrocytic cells stably transfected with human PTH2R cDNA, we have reported that treatment with TIP39 inhibited both the proliferation and differentiation of these cells and was associated with down regulation of the expression of the cartilage-associated transcription factor Sox9.

In the present study, we investigated in vivo the potential role of TIP39/PTH2R signaling in chondrocyte biology. First, using immunohistochemistry, we determined that PTH2R is highly expressed in growth plate chondrocytes in long bones from young mice but restricted to cells in the subarticular region. On the other hand, immunostaining for the ligand TIP39 was localized in hypertrophic chondrocytes.

To further explore the role of TIP39/PTH2R signaling in the growth plate, we generated transgenic mice expressing PTH2R under the control of the rat type II collagen promoter/enhancer. In mice expressing the transgene, there was a marked reduction of type II collagen expression in differentiating growth plate chondrocytes. Moreover, trabecular bone content was diminished. Employing quantitative microcomputed tomography analysis we confirmed the reduction of trabecular bone meshwork in 5 week-old PTH2R transgenic mice compared to control litter mates. Bone volume/total volume (11.55 vs. 9.34 %), trabecular number (1.86 vs. 1.54 per mm), trabecular separation (0.35 vs 0.31 mm), and degree of anisotropy (2.94 vs. 2.68) were decreased while structure model index (2.04 vs. 2.19) was increased in bones from PTH2R transgenic mice compared to wild type controls.

In summary, we have investigated in vivo the potential physiologic role of PTH2R in chondrocyte biology. In conformity with our in vitro findings, studies with PTH2R transgenic mice indicate that overexpression of the receptor impairs chondrocyte differentiation and impacts negatively on subsequent trabecular bone development.

Identification of Distinct, Functional Domains in the Hyperplastic Rat Parathyroid Gland. C. S. Ritter*, J. L. Finch*, E. Slatopolsky, A. J. Brown. Internal Medicine, Washington University School of Medicine, St Louis, MO, USA.

Secondary hyperparathyroidism (2°HPT) due to chronic kidney disease is characterized by hypersecretion of parathyroid hormone and enlargement of the parathyroid gland (PTG). We have previously shown that heterogeneous growth in uremic rat PTGs is associated with differential expression of the calcium-sensing receptor (CaR) (Kidney Int, vol 55:1282, 1999). To better understand the nature of this heterogeneity, we examined PTGs of rats in response to 5/6 nephrectomy and a high phosphate (HP) diet. Immunostaining was used to examine expression of CaR, vitamin D receptor (VDR), 1 α -hydroxylase (1 α -OHase), parathyroid hormone (PTH), glial cells missing 2 (Gcm2), E-cadherin, N-cadherin, β -catenin, p120, and proliferating cell nuclear antigen (PCNA). 2°HPT produced a heterogeneous growth of parathyroid tissue consisting of at least three functionally distinct domains. 1) Normal, non-proliferating areas, in which cells express cytoplasmic VDR and high levels of plasma membrane localized CaR, E-cadherin, β -catenin and p120, comparable to that observed in non-uremic control rats. 2) Areas of proliferating cells (PCNA positive) which express nuclear VDR, possibly attributable to local 1,25(OH) $_2$ D $_3$ produced by the elevated 1 α -OHase found in the same areas. Also found in the areas of proliferation were increased levels of PTH and Gcm2, and decreased levels of CaR. Proteins important for cell:cell adhesion, E-cadherin, β -catenin and p120, were also decreased in areas of proliferation. 3) A unique subset of cells exhibiting a distinct morphology. These nests of cells form whorl-like structures (~20-50 cells each), and are located within the proliferating areas of the gland, although the whorls themselves contain no PCNA. Cells in the whorls have smaller, darker nuclei than the surrounding proliferating cells. The whorls are readily identified by their exceptionally low levels of VDR, 1 α -OHase, Gcm2 and PTH. In addition, the whorls express N-cadherin, as well as aberrant (non-membranous) forms of β -catenin, E-cadherin and CaR. Surprisingly, the whorls appeared as early as 1 day after uremic rats were placed on a HP diet, indicating a rapid transformation of normal cells. In some glands, the whorls comprised ~25% of the tissue section. In conclusion, the uremic rat hyperplastic PTG is composed of at least three distinct functional domains, each identifiable by specific protein expression. Of particular interest is the finding of aberrant β -catenin in a previously unreported subset of whorl-like cells, suggesting the involvement of Wnt signaling. The role of these non-proliferating whorls in the progression of the hyperplasia is under investigation.

Phosphate Stimulates Greater PTH Release and Parathyroid Cell Proliferation in Organ Cultures of Parathyroid Tissue from Patients with Secondary Hyperparathyroidism than with Primary Hyperparathyroidism: Microarray Analyses of Phosphate-induced Genes. K. Sato*, K. Nakajima*, K. Takano*, S. Kosaka*, T. Obara*, K. Umino*, Y. Azuma*. ¹Institute of Clinical Endocrinology, Tokyo Women's Medical University, Tokyo, Japan, ²Central Research Laboratory, Tokyo Women's Medical University, Tokyo, Japan, ³Institute of Clinical Endocrinology, Department of Surgery, Tokyo Women's Medical University, Tokyo, Japan, ⁴Teijin Institute for Bio-medical Research, Teijin Ltd., Tokyo, Japan.

To elucidate the mechanism by which hyperphosphatemia stimulates parathyroid cell proliferation, we developed a method for organ culture of parathyroid tissues obtained from patients with primary (I-HPT) and secondary hyperparathyroidism (II-HPT), and studied the effects of calcium and phosphate on cell proliferation and PTH release, using oligo-DNA microarray. When parathyroid cells were cultured in a monolayer, calcium and phosphate elicited no significant effects on cell proliferation or PTH release. However, when parathyroid tissue was cultured in small pieces on a collagen-coated membrane, calcium decreased the release of PTH in a concentration-dependent manner but did not modulate cell proliferation during short (for 1 day) or prolonged culture (for 1-3 weeks). When parathyroid tissues were cultured in high phosphate medium (8-10 mg/dl), cell proliferation and PTH release were significantly increased (for up to 4 weeks) compared with those cultured in low phosphate medium (3 mg/dl). Both PTH-induced effects were significantly greater in tissue from patients with II-HPT than in those from patients with I-HPT. Microarray analyses capable of analyzing the whole human genome in a single run (Agilent) revealed that humanin, DRD4, BBC3, prion, and PTH were expressed most abundantly and that high calcium decreased the mRNA levels of PTH and chromogranin A, whereas high phosphate increased constantly the mRNA levels of PTH. Growth factors reported to be involved in parathyroid cell proliferation, such as the TGF- α /EGFR, TGF- β , EGF, and FGF-1&2 were expressed to the same level as those in human thyroid follicles. Although mRNA expression levels of PRKAR1A, FGF-3, and TGFBI (beta IGH3) were much increased in II-HPT (compared to those in cultured human thyroid follicles), they were not responsive to phosphate. In summary, using organ culture of hyperplastic or adenomatous parathyroid tissues, we have demonstrated that parathyroid cells from patients with II-HPT are more responsive to high phosphate concentration. Furthermore, our microarray analyses revealed that there may be unknown pathway(s) through which phosphate stimulates parathyroid cell proliferation.

Disclosures: K. Sato, None.

Dynamic Bone Changes in PTH(1-34) Treated Ovariectomized Rats, Evaluated by In-Vivo Micro-CT Scanning. O. P. Van der Jagt*, J. H. Waarsing*, J. A. N. Verhaar*, J. C. Van der Linden*, H. Weinans. Orthopaedic Research Lab, Erasmus Medical Center, Rotterdam, The Netherlands.

PTH and Teriparatide have strong anabolic effects on bone. Whether new bone is formed by thickening of trabeculae and later will transform, or new bone can also arise in the marrow is under debate. With in vivo uCT-scanning we can follow bone changes of a single rat in time in a very detailed manner (spatial resolution 18 μ m). By a registration procedure we can match the 3-dimensional scans of different time points and in this way evaluate the exact trabecular and cortical bone changes of a single rat. Morphological bone parameters of the cortex and cancellous bone were also calculated. Female Wistar rats were ovariectomized at 20 weeks of age. Ten weeks of bone depletion was allowed, thereafter subcutaneous injections with PTH(1-34); Teriparatide, 30 μ g/kg were given 5 times a week for ten weeks. At 0, 3, 6 and 10 weeks after ovariectomy and after 3, and 6 weeks after start of the treatment in-vivo micro-CT scans were made. Trabecular volume fraction increased as a consequence of Teriparatide with more than 50% at 3 weeks, but after 6 weeks trabecular resorption had occurred. Connectivity showed the same pattern. Trabecular thickness was increased but between 3 and 6 weeks it decreased in all rats with 1-3%. Trabecular structures changed from rod-like to plate-like but after 6 weeks there was a shift towards rod-like again. Cortical bone volume did not increase the first 3 weeks of treatment, between 3 and 6 weeks cortical volume increased with more than 10%. New bone formation was seen only at already existing bone structures. Trabecular thickening but also loss of trabeculae was seen. At start of the treatment there were no trabecular structures in the central proximal metaphysis, but during treatment trabeculae tended to migrate towards it. Remarkable is the different effect of PTH(1-34) between cortical and trabecular bone. A large increase in trabecular volume occurred the first 3 weeks of treatment whereas the cortical volume did not change. Between 3 and 6 weeks on the other hand trabecular bone resorption had occurred whereas cortical bone volume increased. We hypothesize that this is due to the large difference in available surface between cancellous and cortical bone. Once the cortical bone becomes thicker it can take a higher portion of the loading and thereby stress-shields the cancellous bone that as consequence becomes resorbed again. Longer follow up studies with in-vivo micro-CT scanning are needed to evaluate if migration of trabeculae are the result of resorption and transformation or the result of repetitive thickening and osteoclastic tunneling of trabecular structures.

Rapid Site-Specific Bone Growth by a Combination of Bone Marrow Ablation, PTH and Biphosphonate Therapy. Q. Zhang¹, J. Carlson^{*1}, E. Cuartas^{*1}, M. Kim^{*1}, N. Mehta², J. Gilligan², M. Kotas^{*1}, M. Ma^{*3}, S. Rajan^{*3}, M. W. Saltzman^{*3}, C. Chalouhi^{*1}, A. Vignery¹. ¹Yale School of Medicine, New Haven, CT, USA, ²Unigene Laboratories, Inc., Fairfield, NJ, USA, ³Yale University, New Haven, CT, USA.

During development and repair of bone, two distinct yet complementary mechanisms, intramembranous and endochondral, mediate new bone formation via osteoblasts. Mechanical bone marrow ablation leads to differentiation of osteoblasts, and formation of cancellous bone. The intramembranous bone-formation phase that follows bone marrow ablation is complete by day 7 at which time osteoclasts differentiate in synchrony and resorb the newly formed bone to re-create the marrow cavity into which bone marrow cells return. This transient induction of bone formation in response to marrow ablation has been used as an in vivo model to discover new genes, and to investigate the role of known genes, in the process of bone formation. We initially questioned whether parathyroid hormone (PTH) could promote the formation of new bone that occurs after marrow ablation. We subjected the left femur of rats to marrow ablation, and injected the animals daily with the PTH analog PTH(1-34)NH $_2$ for one, two or three weeks. Both femurs from each rat were analyzed by soft X-ray, pQCT, microCT and histology, and serum osteocalcin concentration was determined. Bone progressively filled the marrow cavity of the ablated femoral shafts in animals treated with PTH. The newly formed bone endowed femoral shafts with improved biomechanical properties when compared to those of contra lateral femurs as well as left femurs from control, sham operated and vehicle-treated rats. To ask whether this new bone could be maintained for extended times, we subjected the left femurs of rats to marrow ablation, and injected the animals daily with PTH(1-34)NH $_2$ for three weeks followed by treatment with alendronate or PBS for two months. Both femurs from each rat were analyzed as before. The bone that had formed in response to marrow ablation and daily PTH for 3 weeks was resorbed after two months in the PBS treated controls. By contrast, bone was maintained in the ablated marrow cavity following daily alendronate treatment for two months. These findings might potentially be useful for investigations on the molecular mechanisms of intramembranous bone formation, and for preferential site-directed bone growth in areas of high bone loss, for fracture repair, and for reinforcing the implantation of prosthetic devices.

Vilardaga^{*2}. ¹Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, ²Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Fluorescence resonance energy transfer (FRET) technology can now be used to monitor with high temporal resolution conformational changes that occur in a receptor upon ligand binding. The binding of a PTH ligand to the PTH/PTHrP receptor (PTHrP) and the subsequent activation of the bimolecular complex is likely to involve a cascade of conformational changes that occur in both the ligand and receptor. Furthermore, different PTH or PTHrP ligands may bind via different mechanisms so as to induce or stabilize distinct receptor conformations. We tested these hypotheses using the FRET approach to record kinetics of ligand association and dissociation, as well as kinetics of receptor activation and deactivation. Our data show that ligand binding, studied with PTH, occurs as a biphasic process and that the second phase co-incides with a conformational change in the PTH-receptor. This conformational change, reflecting transition into an active receptor signaling conformation, is dependent on the nature of the ligand; we showed that PTH and PTHrP as well as long- and short-acting PTH(1-28) analogs stabilize distinct PTH receptor conformations.

Parathyroid Hormone Levels Are Associated with Carotid Plaque Thickness and Number. M. D. Walker, J. Fleischer, D. J. McMahon, T. Rundek^{*}, J. DeRosa^{*}, J. Udesky^{*}, A. Tineo^{*}, R. Sacco^{*}, S. J. Silverberg. Columbia University, New York, NY, USA.

Elevated serum calcium concentrations are associated with vascular calcification and cardiovascular (CV) disease. We have previously published that serum calcium levels in a multi-ethnic population of older men and women were positively associated with mean carotid plaque thickness (MCPT), a powerful early predictor of clinical coronary and cerebrovascular events. This study was designed to pursue this observation. In particular, we assessed whether such relationships can be explained by the calcium-phosphate product (Ca x PO₄), as in renal disease, or by calciotropic hormones that may affect the vascular system.

To date, we have enrolled 113 consecutive community-dwelling stroke free adults from the Northern Manhattan Stroke Study (NOMAS; age: 68±10 SD, 50-93 yrs). Carotid ultrasound determined the presence/absence and number of plaques (plaque #), MCPT and intima-medial thickness (IMT), another marker of CV disease. As expected, these variables were highly correlated with age (IMT R= .435 P<.0001; plaque # R= .425 P<.001; MCPT R= .408 P<.0001). In a mixed model including demographic and known CV risk factors, age and male sex emerged as the strongest predictors of increased IMT, while age and diabetes emerged in the model of MCPT. No association was found between plaque #, MCPT or IMT and serum calcium or Ca x PO₄ product. 63 subjects had measurable plaque (56%). Carotid plaque # and plaque thickness were associated with PTH levels (plaque # R=0.331 P= .008; MCPT R=0.225 P=.076). There was no association between PTH and IMT. Conversely, an inverse relationship was found between IMT and levels of 25(OH)-vitamin D (R= -.217 P= .08). When controlling for age and sex, only the relationship between PTH and carotid plaque persisted. Calcitriol levels did not correlate with any CV measure.

In summary, in a small group of older adults, PTH levels were associated with carotid plaque and 25(OH)-vitamin D levels inversely related to IMT. PTH has known CV effects, including vasodilation and alterations in heart rate, coronary blood flow, peak pressure, and rate of rise of left ventricular pressure. Vascular calcification may also be accelerated in vitamin D deficiency states. If confirmed, these preliminary data suggest an association between circulating levels of calciotropic hormones and subclinical markers of CV disease, and support the hypothesis that the complex effect of mineral metabolism on vascular biology varies in different parts of the vasculature.

Disclosures: M.D. Walker, None.

Neurocognitive Changes in Mild Primary Hyperparathyroidism. M. D. Walker¹, S. B. Vardy^{*2}, W. B. Inabnet^{*1}, A. Tineo^{*1}, D. J. McMahon¹, F. Cosman², S. J. Silverberg¹. ¹College of Physicians and Surgeons, Columbia University, New York, NY, USA, ²Helen Hayes Hospital, West Haverstraw, NY, USA.

Although patients with primary hyperparathyroidism (PHPT) often report non-specific neuropsychiatric symptoms, these symptoms are not considered an indication for parathyroidectomy (PTX) because of conflicting data on their nature and reversibility. To date, most studies have investigated psychiatric but not cognitive defects. We examine both in this prospective study of mild PHPT. 29 postmenopausal women with PHPT and 95 healthy age-matched women (CTL) have been studied to date, using 10 standardized, validated cognitive and psychiatric tests, at baseline and 5-6 months later (or post-PTX). Differences between PHPT and controls, and association between cognitive dysfunction and serum calcium, parathyroid hormone, and vitamin D levels were investigated. PHPT and CTL subjects were similar in IQ (115 ± 8 vs. 112 ± 8), but those with PHPT were slightly older (62 ± 6 vs. 56 ± 4 yrs; p<0.05) and better educated (17 ± 2 vs. 15 ± 3 yrs; p<0.05) than controls. There were no differences between PHPT and CTL on tests

measuring anxiety (Spielberger State-Trait Anxiety Inventory: 49.9 ± 13.3 vs. 46.2 ± 11.3), visual learning (Rey Visual Design Learning test) or non-verbal abstraction (Booklet Category Test - Victoria Revision). PHPT subjects had more symptoms of depression (Beck Depression Inventory: 8.38 ± 5.9 vs. 5.2 ± 6.7; p=0.03) although both groups measured in the non-depressed range (0-13). Those with PHPT performed worse on tests of verbal memory (Wechsler Memory Scale: Z-score -0.92 ± 0.71 vs. -0.34 ± 0.94; p<0.01) and tended to have worse auditory memory (Bushke Selective Reminding Test: Z-score -0.47 ± 1.27 vs. -0.07 ± 1.20; p=0.09). PHPT subjects also did less well in tests measuring attention & response speed [Rosen Target Detection (RTD) test (47.5 ± 15.6 vs. 39.0 ± 8.9; p<0.01) & Wechsler Adult Intelligence Scale - Revised Digit Symbol (WAIS-R DSY) subtest (12.7 ± 2.1 vs. 12.8 ± 2.2; NS)]. Depressive symptoms and verbal memory improved with PTX, while RTD performance did not. PHPT patients performed better than CTL on tests of mental manipulation (WAIS-R digit span). Decreased attention and response speed was related to serum calcium level (r=0.35; p=0.05).

In summary, in addition to having more symptoms of depression, these PHPT patients performed less well on tests of attention, response speed and verbal memory than did age-matched healthy women. Some cognitive alterations improved with PTX, but those involving attention and response speed did not. While previous investigation has focused on psychiatric features of the disease, this prospective study suggests that neurocognitive function may be altered in mild PHPT.

Distance Restraints and Resolution Limit in Molecular Modeling of G Protein-coupled Receptor-Peptide Ligand Interactions. A. Wittelsberger¹, D. F. Mierke², M. Rosenblatt¹. ¹Physiology, Tufts University School of Medicine, Boston, MA, USA, ²Chemistry and Molecular Pharmacology, Brown University, Providence, RI, USA.

Photoaffinity crosslinking studies in combination with molecular modeling are often the only means of gaining insight into the three-dimensional structure of a G protein-coupled receptor-peptide ligand complex. Typically, a contact site identified by photoaffinity crosslinking is used as a distance restraint in molecular dynamics simulations. A ligand analog containing a photoreactive group (e.g. p-benzoylphenylalanine, Bpa) is used in the crosslinking experiment, whereas the simulations are carried out with the native ligand sequence.

We compare models of the parathyroid hormone ligand-receptor complex obtained using distance restraints of different lengths. Our study suggests that a Bpa residue in position 11 of PTH-(1-34) precludes the mid-region of the hormone from entering its binding groove on top of the seven helical bundle, resulting in a crosslinking site outside the bundle at the C-terminal end of the N-terminal extracellular domain. We conclude that a distance around 14 Å corresponds to the resolution limit obtainable with the Bpa-based photoaffinity crosslinking methodology.

The Nuclear Interactions of the VDR and Lef1 Are Ligand Independent. C. Luisella, M. B. Demay. Endocrine Unit, Massachusetts General Hospital Harvard Medical School, Boston, MA, USA.

Studies investigating the molecular basis for alopecia in VDR null mice have demonstrated that the expression of the VDR in keratinocytes is essential for postmorphogenic hair cycling and that the actions of the VDR that mediate these effects are ligand independent. Vitamin D receptor ablation leads to a gradual decrease in keratinocyte stem cells, associated with an increase in sebaceous differentiation analogous to the differentiation defect seen in the skin of mice with impaired Lef1-βcatenin interactions. Investigations in primary keratinocytes demonstrate that the absence of the VDR impairs the cooperative transcriptional effects of βcatenin and Lef1, however, the nuclear localization of βcatenin in the hair follicle stem cells is not impaired by the absence of the VDR. Studies were, therefore, performed to address whether the VDR could participate in the formation of a complex with βcatenin and/or Lef1 in the absence or presence of ligand. COS-7 cells were transfected with expression vectors for βcatenin, HA-tagged Lef1 and the VDR. Cells were treated with 10⁻⁸M 1,25(OH)₂D₃ or vehicle in charcoal-stripped serum 16 hours prior to harvesting. Nuclei were obtained by mechanical separation and homogenized in lysis buffer containing 0.5% NP-40 and 1% Triton. Immunoprecipitation was performed using a mouse α-HA antibody and protein G sepharose beads. Immunoprecipitated proteins were subjected to Western analyses. Immunoprecipitation of Lef1 resulted in coimmunoprecipitation of the VDR and of βcatenin, both in the presence and the absence of ligand. Thus, in the nuclei of intact cells, the interactions of the VDR with these effectors of the canonical Wnt signaling pathway are not dependent upon the presence of ligand. These results suggest that the ligand-independent interactions of the VDR with one or both of these key effectors of the canonical Wnt signaling are essential for the maintenance of post-morphogenetic hair cycling.

Disclosures: C. Luisella, None.

Prevalence of Hypovitaminosis D and its Correlation with Different PTH Values in a Sample of Postmenopausal Women in Buenos Aires. Z. Man, M. S. Larroude*, M. S. Moggia*, R. D. Diaz*, J. C. Morgenstern*, M. P. D. Yantorno*, M. G. Torres Cerino*, G. A. Macías*, M. Pérez Sáinz*, Centro TIEMPO, C.A. Buenos Aires, Argentina.

Vitamin D (VD) has multiple biological effects, as it plays a key role in the serum calcium homeostasis. The definition of normal values was based on Gaussian distributions of the concentrations seen in apparently healthy subjects, but it did not take into account race, age, latitude, poor dietary VD intake, use of sunscreens. The optimal value would be the one that, below that point, PTH levels starts to increase.

Objective: To evaluate the levels of 25-hydroxyvitamin D [25(OH)D] in a sample of postmenopausal women and its correlation with four groups of PTH levels using two different 25(OH)D cutoff values considered as desirable by two different classifications.

Material and method: 196 postmenopausal women from Buenos Aires and its metropolitan area (Lat: 35°S), mean age: 65 y.(51-85), were evaluated between October and December 2005. Women with thyroid, liver or renal diseases or those treated with corticosteroids, antiepileptic and anticoagulants were excluded. 25(OH)D levels were measured by a RIA assay using the Diasorin® kit, and PTH levels by chemiluminescence. VD status was sorted using the Hollis and McKenna classifications and were correlated with different cut off points for PTH values. The prevalence of secondary hyperparathyroidism (PTH levels > 65pg/ml) was evaluated.

Bruce Hollis classification: 25(OH)D deficiency <10ng/ml; insufficiency 10-20ng/ml; hypovitaminosis 20-30ng/ml; desirable >30ng/ml.

McKenna classification: 25(OH)D deficiency <10ng/ml; insufficiency 10-20ng/ml; hypovitaminosis 20-40ng/ml; desirable >40ng/ml.

We divided PTH values into four categories > 65 pg/ml, > 60 pg/ml, > 55pg/ml, and > 50 pg/ml. **Results:** No VD deficiency was detected. With Hollis classification: 70 women (35.7%) had VD insufficiency; 90 (46%) had hypovitaminosis D; and only 36 (18.3%) had desirable values. And with McKenna classification: 121 women (61.8%) had hypovitaminosis D, and 2,6% had desirable values.

Valor de PTH N=196	VD Hollis < 10 ng/ml	10-20 ng/ml	20-30 ng/ml	> 30 ng/ml
> 65 pg/ml	0	19 (9,7%)	15 (7,7%)	3 (1,5%)
> 60 pg/ml	0	27 (13,8%)	22 (11,22%)	4 (2%)
> 55 pg/ml	0	32 (16,3%)	31 (15,8%)	5 (2,55%)
> 50 pg/ml	0	36 (18,3%)	37 (18,9%)	7 (3,6%)
Valor de PTH N=196	VD McKenna < 10 ng/ml	10-20 ng/ml	20-40 ng/ml	> 40 ng/ml
> 65 pg/ml	0	19 (9,7%)	18 (9,2%)	0
> 60 pg/ml	0	27 (13,8%)	26 (13,2%)	0
> 55 pg/ml	0	32 (16,3%)	36 (18,3%)	0
> 50 pg/ml	0	36 (18,3%)	44 (22,4%)	0

Conclusions: We found that the prevalence of secondary hyperparathyroidism was 1.5% and 0% by using a cut off value for sufficiency of 30 ng/ml and 40 ng/ml. Using values > 40 ng/ml of vitamin D doesn't registered PTH values > 50 pg/ml. Therefore, we recommend a 25 (OH) D cut off value higher than 40 ng/ml.

Calcium-Independent and 1,25-Dihydroxyvitamin D₃-Dependent Regulation of the Renin-Angiotension System in 25(OH)D 1 α -Hydroxylase Knockout Mice. C. Zhou*¹, F. Lu*², D. Goltzman³, D. Miao¹. ¹The Research Center for Bone and Stem Cells, Nanjing Medical University, Nanjing, China, ²Department of Cardiology, Nanjing Medical University, Nanjing, China, ³Department of Medicine, McGill University, Montreal, PQ, Canada.

Previous studies have demonstrated that genetic disruption of the VDR results in overstimulation of the renin-angiotension system (RAS), leading to high blood pressure and cardiac hypertrophy. We employed mice with targeted deletion of the 25(OH)D 1 α -hydroxylase [1 α (OH)ase^{-/-}] gene to determine whether the effect of 1,25(OH)₂D₃ is calcium-dependent or independent. At 6 weeks of age, sex-matched wild-type and 1 α (OH)ase^{-/-} mice were fed a normal diet or a "rescue diet" diet containing 2% calcium, 1.25% phosphorus, and 20% lactose. For 4 subsequent weeks, animals on the normal diet received vehicle or 62.5ng 1,25(OH)₂D₃, intraperitoneally daily while animals on the rescue diet received vehicle, 100mg/Kg captopril, an inhibitor of angiotensin converting enzyme, or 30mg/Kg losartan, an angiotensin II (Ang II) type I receptor antagonist. At the end of this time period, in vehicle-treated 1 α (OH)ase^{-/-} mice, plasma levels of renin, Ang II and aldosterone were raised, and renal renin mRNA and protein levels and renal Ang II mRNA levels were up-regulated. Heart weight relative to body weight (BW), interventricular septum thickness diastolic (IVSD) and left ventricular mass (LVM)/BW were increased, however, indices of cardiac systolic function including fractional shortening (FS) and ejection fraction (EF) were reduced in vehicle-treated 1 α (OH)ase^{-/-} mice compared with their wild-type mice. Although the serum calcium and phosphorus levels were normalized in 1 α (OH)ase^{-/-} mice on the "rescue diet", alterations in blood pressure, RAS and cardiac hypertrophy remained abnormal. In contrast, 1,25(OH)₂D₃ administration not only normalized serum calcium and phosphorus levels, but also normalized the blood pressure, RAS, and cardiac hypertrophy. After administration of either captopril and losartan to 1 α (OH)ase^{-/-} mice, although renin expression remained up-regulated, the blood pressure, cardiac histology and function all normalized. This study demonstrates that 1,25(OH)₂D₃ plays a protective role on the cardiovascular system through repression of RAS and that this action is calcium-independent.

Postpartum Vitamin D Insufficiency and Secondary Hyperparathyroidism in Healthy Danish Women. U. Möller Liendgaard*¹, C. H. Ramlau-Hansen*², L. Rejnmark*³, L. Heickendorff*⁴, T. Brink Henriksen*⁵, L. Mosekilde*¹.

¹Department of Endocrinology and Metabolism C, Aarhus University Hospital, Aarhus, Denmark, ²Department of Occupational medicine, Aarhus University Hospital, Aarhus, Denmark, ³Department of Endocrinology and Metabolism C., Aarhus University Hospital, Aarhus, Denmark, ⁴Department of Clinical Biochemistry, Aarhus University Hospital, Aarhus, Denmark, ⁵Perinatal Epidemiology Research Unit, Department of Obstetrics and Paediatrics, Aarhus University Hospital, Aarhus, Denmark.

Objective: To examine vitamin D status and parathyroid function in normal Danish women postpartum.

Design: Three cross sectional measures during follow-up of 89 women postpartum.

Subjects and intervention: We assessed vitamin D status by measuring plasma 25-hydroxyvitamin D (P-25OHD) and the degree of secondary hyperparathyroidism by measuring plasma parathyroid hormone (P-PTH) in 89 Caucasian women at three consecutive visits: (mean (range)) 23 (10-37) days (spring), 117 (95-140) days (late summer) and 274 (254-323) days (winter) postpartum.

Results: P-25OHD showed seasonal variations with higher values in late summer than in the other periods (p<0.001). At the first visit 65% received vitamin D supplements. At the following visits almost 50% were supplemented. Vitamin D insufficiency (P-25OHD<50 nmol/l) occurred more often during winter (28%) than in spring (14%) (Fishers exact test, p=0.02) or late summer (7%) (p=0.0001). Irrespective of season, vitamin D insufficiency occurred most frequent in women who did not take vitamin D supplements (Fishers exact test, p<0.02). Frank vitamin D deficiency (P-25OHD<25 nmol/l) was observed during winter in 6%. At all three periods P-25OHD correlated inversely with P-PTH indicating secondary hyperparathyroidism at deficient vitamin D status. During spring, late summer and winter three, one, and four females, respectively, had elevated plasma PTH.

Conclusion: Vitamin D-insufficiency with secondary hyperparathyroidism is a frequent finding in healthy Danish women postpartum and especially during winter. Vitamin D supplements reduced the risk of vitamin D insufficiency, especially during winter. Our results support the importance of increased alertness regarding information of pregnant and lactating women about vitamin D supplements. Furthermore, it has to be studied whether the present recommendations of an intake of 5-10 µg vitamin D per day are sufficient, especially during winter months.

Disclosures: U. Möller Liendgaard, None.

Changes in VDR Coregulator Recruitment Result in 1 α ,25(OH)₂D₃ Hypersensitivity in MVNP Expressing Cells. A. Hidalgo*¹, J. Florea*¹, G. D. Roodman², N. Kurihara³, S. Onate*⁴. ¹Urologic Oncology, Roswell Park Cancer Institute, Buffalo, NY, USA, ²Medicine, University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA, USA, ³Medicine, University of Pittsburgh, Pittsburgh, PA, USA, ⁴Pharmacology & Therapeutic, Roswell Park Cancer Institute, Buffalo, NY, USA.

Osteoclast precursors (OCLP) in Paget's disease (PD) are characterized by expression of measles virus nucleocapsid protein (MVNP) and changes in the 1 α ,25(OH)₂D₃ signaling axis that result in their hypersensitivity to 1 α ,25(OH)₂D₃ and abnormal bone remodeling. The effects of 1 α ,25(OH)₂D₃ are mediated by the intracellular 1 α ,25(OH)₂D₃ receptor (VDR). In the absence of ligand, VDR is in the nucleus bound to chromatin loci and associated with the corepressors SMRT and NCoR. This complex represses the transcriptional activity of 1 α ,25(OH)₂D₃ regulated genes by recruitment of histone deacetylases (HDACs) through the corepressors. Ligand activates transcription through recruitment of coactivators SRC-1/p160, CBP/p300, and the DRIP/TRAP mediator complex. Consequently, changes in the VDR coregulator profile may be a mechanism for 1 α ,25(OH)₂D₃ hypersensitivity of PD OCLP. In support of this hypothesis, we reported that TAFII-17, a VDR coactivator, is increased in PD OCLP. To test this hypothesis, 1 α ,25(OH)₂D₃-mediated gene transcription in MVNP transduced cells was analyzed using adenoviral luciferase expression reporter assays linked to the 25-hydroxyvitamin D₃-24-hydroxylase (CYP24) gene promoter. MVNP transduced cells contained similar levels of functional VDR, as control cells. However, 1 α ,25(OH)₂D₃ was much more efficient in promoting VDR-mediated reporter activity in MVNP cells than in controls. Chromatin immunoprecipitation (ChIP) assays showed that the VDR corepressor, SMRT, was released from the CYP24 promoter when MVNP was expressed in the absence of 1 α ,25(OH)₂D₃. Further, immunohistochemistry and confocal analyses showed that the SMRT corepressor was excluded from the nucleus and translocated to the cytosol in MVNP transduced cells, while VDR continued to translocate to the nuclei in the absence or presence of ligand. These results indicate that MVNP alters 1 α ,25(OH)₂D₃ cellular signaling by changing the cellular localization of the SMRT corepressor and decreasing its recruitment to the promoter of VDR regulated genes, thereby increasing their sensitivity to ligand. Taken together, these results suggest that transactivation of 1 α ,25(OH)₂D₃ regulated genes is increased in PD OCLP, in part, due to altered recruitment of coregulators required for VDR-mediated gene transcription.

Vitamin D Status and Infection Frequency in Diabetic Patients. J. Park, S. Jung*, J. Rho*, M. Kim*, H. Jin*, T. Park*, H. Baek*. Division of Endocrinology and Metabolism, Department of Internal Medicine, Chonbuk National University Medical School, Jeonju, Chonbuk, Republic of Korea.

The active metabolite of vitamin D, 1,25-dihydroxyvitamin D₃, is an important immunomodulatory hormone which enhances phagocytosis via the activation of macrophages and influences immune response. Serum 25-hydroxyvitamin D₃ [25(OH)D₃] is a good indicator of vitamin D nutritional status. Increasing susceptibility to infection in diabetes mellitus is support by altered immunity. Polymorphonuclear leukocyte function is depressed, particularly when acidosis is also present. The aim of this study is to determine that 25(OH)D₃ status is associated with infectious disease frequency, together with quantification of factors related to vitamin D status in diabetic patients. Subjects were selected among diabetic patients living in their own homes and spending at least 3 hours per week outdoors. 296 diabetes subjects including 149 case and 147 controls, aged 20 to 80 years were enrolled. Subjects who experience at least one acute infectious disease from 1998 to 2006 were used for cases. We divided the participants into five groups depending in their infectious disease incidences. 25(OH)D₃ was analyzed for the infectious disease frequency and parathyroid hormone, corrected calcium, phosphorus. Subjects with medication that could interfere with vitamin D metabolism or bone mineralization and autoimmune disease as multiple sclerosis, SLE, RA, inflammatory bowel disease, Psoriasis were excluded from study. The mean concentration of 25(OH)D₃ and PTH and corrected calcium were 63.35 ± 35.67 nmol/L and 29.92 ± 31 pg/mL and 2.28 ± 0.17 mmol/L, respectively. The overall prevalence of vitamin D insufficiency (25(OH)D₃ < 80 nmol/L) was 73.3%. In one-way anova analyses, there were significant differences 25(OH)D₃ and corrected calcium by infectious disease frequency. 25(OH)D₃ levels of subjects with at least four recurrent infections were below 50 nmol/L. In multiple linear regression analyses 25(OH)D was negatively and independently associated with PTH levels ($p=0.04$). Serum 25(OH)D concentration at baseline varied cyclically with season, with the solar cycle ($p<0.05$). Approximately 70% of diabetes patients fell below 80 nmol/L, a value considered to be the lower end of the optimal range. Serum 25(OH)D₃ concentration was association with the frequency of infectious diseases in diabetic patients. Experimentally, vitamin D deficiency and host resistance to infectious diseases have not been studied extensively. Further studies are needed to explain the association of the vitamin D status and infection frequency in diabetic patients.

Transgenic Expression of the Human Vitamin D Receptor (VDR) in the Proximal Small Intestine of VDR-Null Mice Improves the Utilization of Calcium- and Lactose-Rich (Rescue) Diet in Young Mice. S. Peleg, H. D. Marks*. Endocrine Neoplasia & Hormonal Disorders, M. D. Anderson Cancer Center, Houston, TX, USA.

The hormone 1,25(OH)₂D₃ (1,25D₃) regulates active calcium absorption in the proximal small intestine through binding to its nuclear receptor (VDR). The inactivation of VDR in humans or its ablation in mice causes severe hypocalcaemia and rickets. We have previously shown that transgenic expression of the human VDR (hVDR) in the proximal small intestine of VDR-null mice (hVDR+/mVDR-/-) was insufficient to restore calcium homeostasis and bone mineralization if the mice were fed a normal rodent diet (containing 1% calcium and 0.65% phosphorus). However when 3 months old rachitic mice were fed a rescue diet (2% calcium, 1.25% phosphorus, 20% lactose), the hVDR+/mVDR-/- responded by normalizing bone mineralization and serum calcium, whereas the mVDR-/- mice did not respond. In the present study we investigated whether the hVDR in the proximal small intestine had an effect on mineral utilization even in young mice. To that end, mVDR-/- and hVDR+/mVDR-/- mice were fed a rescue diet starting at weaning (21 day-old) and calcium homeostasis was assessed when they were 60-days old. We found that total serum calcium was normalized in both groups of mice and its levels were not distinguishable from serum calcium in WT mice. In contrast, serum levels of intact PTH were normalized in the hVDR+/mVDR-/- mice but not in the mVDR-/- mice. When femurs were analyzed, we found that bone mineralization improved in the mVDR-/- mice on rescue diet compared to mVDR-/- on normal diet. However, bone mineral density and bone mineral content in these mice were slightly but significantly lower than these values in hVDR+/mVDR-/- mice on rescue diet or WT mice. Furthermore, significant structural abnormalities (thinner cortical bone, and high trabecular density) were detected in the mVDR-/- mice but not in the hVDR+/mVDR-/- mice. We propose that transgenic expression of the hVDR in the proximal small intestine improves calcium homeostasis by correcting fluxes in ionized serum calcium, which prevents excess PTH secretion and abnormal bone mineralization.

Combination of Vitamin D and BADGE Potentiates their Pharmacological Inhibition of PPARgamma and Increases Osteogenic Differentiation of Adipocyte Precursors. D. Rivas¹, G. Duque². ¹Lady Davis Institute for Medical Research, Montreal, PQ, Canada, ²Medicine/Geriatrics, McGill University, Montreal, PQ, Canada.

Peroxisome proliferator activator gamma 2 (PPARγ2) is one of the main factors involved in the pathogenesis of age-related bone marrow adipogenesis. Although knock out mice for PPARγ2 have shown increased bone mass and lower adipogenesis the pharmacological inhibition of PPARγ2 has shown contradictory results. Studies in diabetic rodents have shown that pharmacological inhibition of PPARγ with bisphenol-A-diglycidyl ether (BADGE) prevents bone marrow adiposity but not bone loss. In this study, we hypothesize that the combination of 1,25(OH)₂D₃ and BADGE would revert the inhibitory effect of BADGE on osteoblastogenesis and therefore facilitate the differentiation of adipocyte precursors into osteoblasts. Human mesenchymal stem cells (MSC) were induced to differentiate into adipocytes for one week. Subsequently, the media was replaced with osteogenesis induction media with either BADGE (5-10 μM), 1,25(OH)₂D₃ (10⁻⁸ M) or both. Untreated cells were used as a control. Cells were treated for two weeks and then stained with alizarin red and alkaline phosphatase (ALP). Additionally, changes in the expression of PPARγ2, cbfa1 and osteocalcin were determined by RT-PCR and western blot. We found that expression of cbfa1 and osteocalcin was significantly affected by BADGE alone while addition of 1,25(OH)₂D₃ reverted this effect. In addition, the reduction in mineralization and ALP activity seen after treatment with BADGE was reverted by 1,25(OH)₂D₃ inducing significantly higher mineralization and ALP activity than untreated cells ($p<0.01$). To further examine the mechanism involved, changes in both PPARγ2 and cbfa1 nuclear complex activation were assessed using ELISA TransAM kit. We found that whereas BADGE inhibited both nuclear complexes activation, addition of 1,25(OH)₂D₃ reverted its inhibitory effect on the cbfa1 complex and potentiate its inhibitory effect on the PPARγ2 nuclear complex. In summary, although the pharmacological inhibition of PPARγ2 could become an alternative for the treatment of age-related bone loss, the combination of an inhibitor plus vitamin D would be required in order to inhibit adipogenesis and stimulate osteoblastogenesis.

Development of an Assay for 25-Hydroxyvitamin-D on the Abbott ARCHITECT Analyzer. M. Martens^{*1}, C. van Duren^{*1}, S. Peters-Gdanitz^{*1}, F. Rosmalen¹, W. Krack^{*2}, J. Dhein^{*2}, J. Schultess^{*2}, M. Eppinger^{*2}, M. Hausmann^{*2}. ¹R&D, Future Diagnostics, Wijchen, The Netherlands, ²R&D, Abbott Diagnostics, Delkenheim, Germany.

Background and objective. The concentration of 25-Hydroxyvitamin-D (25-OH Vitamin D), in serum, is considered to be the most reliable determination of the overall vitamin D status.

The purpose of our study was to evaluate a prototype assay for the measurement of 25-OH Vitamin D on the Abbott ARCHITECT instrument.

Methods and results. The ARCHITECT 25-OH Vitamin D assay is a delayed one-step competitive immunoassay that utilizes direct, chemiluminescence technology in combination with paramagnetic particles. The assay utilizes a sheep polyclonal antibody specific for 25-OH-D in combination with biotinylated 25-OH Vitamin D and an anti-biotin monoclonal conjugate. The assay has a reportable range of up to 400 nmol/L (160 ng/mL), and has a time to first result of 36 minutes. Analytical sensitivity for the assay (95% confidence method) was < 3.5 nmol/L. Functional sensitivity (inter-assay imprecision <20%) was < 10 nmol/L. Preliminary assay imprecision, with serum panels, was evaluated based on guidance from CLSI, testing different levels on 1 reagent lot and 1 instrument at 2 separate times per day over 5 days. Imprecision at approximate levels of 25, 150 and 225 nmol/L were < 6%, < 4% and < 6%, respectively. A preliminary method comparison, on a relative small number of samples (n = 21), versus another commercially available diagnostic kit gave a correlation coefficient of 0.97 (Pearson).

Conclusions. Based on our data, we conclude that the ARCHITECT 25-OH Vitamin D assay is a rapid, accurate, and precise automated method for the measurement of 25-Hydroxyvitamin-D.

Calcitriol and its Analog Successfully Elongate Survival Period and Improve the Skeletal Growth via Independent Pathway of Vitamin D Receptor. K. Shiizaki¹, I. Hatamura², T. Sakaguchi³, I. Imazeki⁴, S. Kato⁵, T. Akizawa⁶, E. Kusano¹. ¹Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Japan, ²The First Department of Pathology, Wakayama Medical University, Wakayama, Japan, ³Division of Nephrology and Blood Purification Medicine, Wakayama Medical University, Wakayama, Japan, ⁴Product Research Department, Chugai Pharmaceutical Co., Ltd, Gotemba, Japan, ⁵Institute of Molecular and Cellular Biosciences, The University of Tokyo, Tokyo, Japan, ⁶Department of Nephrology, Showa University School of Medicine, Tokyo, Japan.

It is well known that vitamin D plays a major role in skeletal and mineral homeostasis through the interaction with nuclear vitamin D receptor (VDR) of target cell. For the investigation of VDR-independent effects of calcitriol (CAL) and maxacalcitol (OCT) on these, VDR knockout (VDR^{-/-}) mice treated by the high dose of CAL and OCT were analyzed.

VDR^{-/-} mice were fed normal or high calcium diet containing 20% lactose (rescue diet) immediately after weaning. These rats were intraperitoneally administered by CAL (20 µg/kg), OCT (20 µg/kg) or control solution (CONT) at three times a week for eight weeks. The differences in survival status among these treatments were investigated in mice fed normal diet. The measurements of serum ionized Ca (iCa), phosphorus (P) and intact-PTH levels and histopathological examinations of femur were performed 24 hours after the final administration in mice fed rescue diet.

The survival periods of mice administered by both CAL and OCT were significantly longer than that with control treatment (about three and two folds in mice treated by CAL and OCT, respectively). The significant differences in serum iCa, P, and intact-PTH levels among the treatments in mice fed rescue diet were not observed. However, the enlarged and distorted cartilaginous growth plates and the irregular disposition of chondrocytes were observed in mice administered by CONT, and the treatments with CAL and OCT normalized these deformities.

These results suggest that CAL and OCT elongate the survival period and improve skeletal growth via independent pathway of VDR without significant changes in serum iCa, P, and intact-PTH levels. Vitamin D may exert discreet effects on survival, skeletal growth and mineral metabolism via VDR-dependent or -independent manner.

The Vitamin D Receptor, Hedgehog Signaling and Epidermal Carcinogenesis. A. E. Teichert¹, J. J. Welsh², D. D. Bikle¹. ¹Endocrine Unit, UCSF-NCIRE, San Francisco, CA, USA, ²Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, USA.

Over 1 million skin cancers occur annually in the United States, 80% of which are basal cell carcinomas (BCC) (16% squamous cell carcinomas, 4% melanomas), making it by far the most common cancer. Extensive epidemiologic data support the concept that the incidence of a number of epithelial malignancies (e.g. breast, prostate, colon) is reduced by increasing 25OHD levels. 1,25(OH)₂D₃, produced by the kidney from 25OHD or locally produced, reduces proliferation and enhances differentiation and thus has been investigated for a role in preventing or treating cancer. However, UVB exposure, which increases 1,25(OH)₂D₃ production in the keratinocyte, causes skin cancer. Conceivably, the 1,25(OH)₂D₃ produced by the skin provides at least partial protection from UVB induced skin cancer such that lack of 1,25(OH)₂D₃ or its receptor would make the skin even more sensitive to UVB induced malignancy.

We have chosen UVB epidermal carcinogenesis as a model to directly address the issue of the balance between the increased risk of UVB exposure as an inducer of carcinogenesis with the benefit of promoting vitamin D and thus 1,25(OH)₂D₃ production in the epidermis as a chemopreventive measure.

Mice deficient for the vitamin D receptor (VDR null mice), for which 1,25(OH)₂D₃ is a ligand, have a marked hyperproliferative response in the hair follicle and epidermis and decreased epidermal differentiation. These mice, when treated with 7,12 dimethylbenzanthracene (DMBA), unlike their wildtype littermates, develop skin tumors containing hair follicle elements and/or are of basal cell origin, tumors characteristic of overexpression of the hedgehog (HH) signaling pathway in keratinocytes. We found that the epidermis and hair follicles of the VDR null animals, as well as the DMBA induced tumors in VDR null mice, overexpress elements of the HH signaling pathway [Sonic Hedgehog (Shh), Patched 1 (Ptc1), Smoothened (Smoh), Gli 1, and Gli 2]. Moreover, keratinocytes in which the VDR has been knocked down with siRNA directed against the VDR show increased expression of Shh.

Interestingly, mice overexpressing Gli1, Gli2, or Shh in their basal keratinocytes or grafted with human keratinocytes overexpressing Shh develop BCC like lesions. Furthermore, BCC show overexpression of Ptc1, Smoh, Gli1 and Gli2, raising the question of a link between the vitamin D system, HH signaling and skin cancer predisposition.

These results suggest then that increased expression of Shh in the keratinocytes of the VDR null animal activates the HH signaling pathway, predisposing the skin to the development of BCC.

Effect of Plasma 1,25-Dihydroxyvitamin D Concentration or Calcium Intake on Negative Correlation between Plasma 25-Hydroxyvitamin D and PTH Concentrations in Japanese Adolescents. N. Tsugawa¹, K. Uenishi², H. Ishida³, R. Ozaki¹, M. Kamao¹, Y. Suhara¹, T. Okano¹. ¹Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, ²Laboratory of Administrative Dietetics, Kagawa Nutrition University, Sakado, Japan, ³Laboratory of Physiological Nutrition, Kagawa Nutrition University, Sakado, Japan.

It is known that vitamin D insufficiency leads to secondary hyperparathyroidism, which has a negative effect on bone metabolism in the elderly. However, little is known about the effect of the vitamin D status on PTH concentration in Japanese adolescents. Plasma PTH concentration is also known to be regulated by dietary calcium (Ca) intake or 1,25-dihydroxyvitamin D (1,25D). The aim of this study is to examine the association between vitamin D status and PTH concentration in healthy Japanese adolescents and the effect of dietary Ca intake and plasma 1,25D concentration on the negative correlation between 25D and PTH concentrations. A total of 324 healthy Japanese adolescents aged 12-18 years (boys: 158, girls: 166) had enrolled in this study. Plasma PTH concentration was negatively correlated with 25D concentration or dietary Ca intake, and positively correlated with 1,25D. If 25D and 1,25D concentrations and dietary Ca and vitamin D intakes were included in the original model of stepwise multiple linear regression analyses, 25D and 1,25D concentrations and dietary Ca intake were independently associated with plasma PTH concentration. When subjects were divided into two groups (high and low Ca groups) by median of dietary Ca intake (462 mg/d), slope and intercept of equation obtained from negative correlation between 25D and PTH concentrations in low Ca group were higher than those in high Ca group. On the other hand, when subjects were divided into two groups (high and low 25D groups) by 20 ng/mL of plasma 25D concentration, slope and intercept of equation obtained from negative correlation between dietary Ca intake and PTH concentrations in low 25D group were higher than those in high 25D group. Plasma 1,25D concentration associated with only PTH concentration. However, when subjects were divided into high and low 25D groups, slope of equation obtained from positive correlation between PTH and 1,25D concentrations in high 25D group were higher than those in low 25D group. These results suggest that increases of 25D concentration and dietary Ca intake could independently decrease plasma PTH concentration. Moreover, although plasma 1,25D concentration did not directly associate with plasma 25D concentration, it was confirmed that the increase rate of 1,25D concentration which depends on PTH concentration was associated with plasma 25D concentration in adolescents.

Global Vitamin D Levels in Relation to Age, Gender, Ethnicity, and Latitude: an Ecologic Metaregression Analysis. T. Hagenau¹, R. Vest¹, T. Gissel¹, C. S. Poulsen¹, M. Erlandsen², L. Mosekilde³, P. Vestergaard¹. ¹The Osteoporosis Clinic, Aarhus Amtssygehus, Aarhus, Denmark, ²Department of Biostatistics, Aarhus University, Aarhus, Denmark, ³Department of Endocrinology and Metabolism C, Aarhus Amtssygehus, Aarhus, Denmark.

Aim: To study vitamin D status (serum 25-hydroxy-vitamin D (25OHD)) in native subjects in all regions to assess deficiency by latitude.

Subjects and methods: We retrieved 5,855 papers from January 1, 1970 to November 1, 2004 by searching PubMed, Embase, and Web of Science using terms: "serum", "25-hydroxy-vitamin D", "cholecalciferol", and "human". Inclusion criteria were studies on serum 25OHD levels in healthy subjects around the world.

Results: A total of 393 studies including 33,332 subjects from all over the world were included in the study. The mean serum 25OHD level was 54 nmol/l (95% CI: 51-57 nmol/l). Women had significantly higher 25OHD levels than men (p=0.02), and Caucasians had higher levels than non-Caucasians (p<0.01). Serum 25-OHD levels were higher in subjects aged >15 years than in younger subjects (p<0.01).

Unadjusted there was a small non-significant decrease in serum 25OHD with latitude (-0.11±0.10 nmol/l per degree latitude north or south of equator, p=0.27). There was a significant decline with latitude for Caucasians (-0.69±0.30 nmol/l per degree, p=0.02), but not for non-Caucasians (0.03±0.39 nmol/l per degree, p=0.94). After adjustment for age, gender, and ethnicity, no overall correlation was present between serum 25OHD and latitude (-0.29±0.24 nmol/l per degree, p=0.23).

Conclusion: The present analysis has shown that vitamin D status globally depend on age, gender, and ethnicity. There was no overall influence of latitude. However, in separate analyses plasma 25-OHD decreased with latitude in Caucasians but not in non-Caucasians. The study indicates a widespread global vitamin D insufficiency compared with proposed threshold levels.

Identification of cEts1 and STAT1 as Potential Primary Targets in the Secondary Gene Regulation of the Human Fibroblast Growth Factor-23 Gene by 1,25-dihydroxyvitamin D₃. A. Hsieh^{*1}, M. Gurevich^{*1}, D. Mathern^{*1}, M. J. Kaczmarek^{*1}, C. A. Haussler², G. K. Whitfield², M. R. Haussler². ¹Biochemistry & Molecular Biophysics, University of Arizona College of Medicine, Tucson, AZ, USA, ²Basic Medical Sciences, University of Arizona College of Medicine, Phoenix, AZ, USA.

The mammalian fibroblast growth factor-23 (FGF23) gene encodes a protein hormone, produced in osteoblasts, that serves as a potent inhibitor of kidney phosphate reabsorption. The hormonal form of vitamin D, 1,25-dihydroxyvitamin D₃ (1,25D), has a reciprocal role to that of FGF23, promoting both kidney reabsorption and intestinal absorption of phosphate. Recent findings have revealed that FGF23 and 1,25D form an endocrine loop, with 1,25D upregulating FGF23 and the resulting FGF23 inhibiting production of 1,25D to close the loop. The stimulatory effect of 1,25D was previously shown in rat osteoblast-like UMR-106 cells to involve a substantial increase in FGF23 mRNA. Transactivation by 1,25D is typically mediated by the vitamin D receptor (VDR), which binds to vitamin D response elements (VDREs) in the vicinity of regulated genes. However, conserved VDREs of the DR3 or ER6 type have not been found near the FGF23 locus; also, previous cycloheximide experiments indicated that 1,25D regulates FGF23 likely via a secondary mechanism. Utilizing a bioinformatics approach to seek potential secondary regulators, we first located segments of sequence conservation within 130 kb upstream and 20 kb downstream of the FGF23 gene using the UC Santa Cruz genomic browser, which compares sequences among 14 vertebrate genomes. Within these conserved sequences, we then sought consensus binding sites for known transcriptional regulators. This search yielded several candidates, notably members of the STAT and GATA families, as well as cEts1. As an initial screen, regulation of the relevant mRNAs by 1,25D was examined in rat UMR-106 cells. Two nuclear factors, cEts1 and STAT1, were found to be both well expressed in UMR-106 cells and also reproducibly (~2-fold) upregulated by 1,25D. Examination of the cEts1 promoter revealed two conserved VDREs of the DR3 type located at -24 and -26 kb upstream of the rat cEts1 promoter. These two VDREs were shown to bind VDR in a gel mobility shift and are currently being evaluated for their ability to confer 1,25D responsiveness onto a heterologous luciferase reporter gene. We will also evaluate if VDR binding to these sequences actually takes place in vivo via a chromatin immunoprecipitation assay. Elucidation of the molecular details whereby 1,25D regulates FGF23 will significantly enhance our overall understanding of bone mineral homeostasis in mammals.

Co-stimulation of 1,25-(OH)₂D₃ and BMP-2 Enhances the Expression of VDR and RANKL mRNA in Osteoblasts. Y. Yoshikawa, A. Kamada, E. Domae*, S. Goda*, I. Tamura*, A. Kawamoto*, J. Okazaki*, Y. Komasa*, T. Ikeo. Osaka Dental University, Hirakata, Japan.

1,25-(OH)₂D₃ (1,25-(OH)₂D₃) appears to indirectly induce osteoclast formation by up-regulating RANKL expression and down-regulating OPG expression in marrow stromal cells. A recent study has shown that BMP-2 enhances the induction of osteoclast formation by 1,25-(OH)₂D₃, but little is known about the mechanism of the promoting effect of 1,25-(OH)₂D₃ and BMP-2 co-stimulation on osteoblast-osteoclast interaction. In this study, we investigated the time-dependent expression of RANKL, OPG and vitamin D receptor (VDR) mRNA in osteoblasts co-stimulated with 1,25-(OH)₂D₃ and BMP-2.

Osteoblastic MC3T3-E1 cells were grown in culture medium with 1,25-(OH)₂D₃ and BMP-2 for 3, 6, 12 and 24 hours. Total RNA was extracted from cells and first-strand cDNA was synthesized from total RNA using reverse transcriptase. The mRNA expression level was assessed using real-time PCR.

The mRNA expression of VDR in osteoblasts increased significantly 3 hours after co-stimulation with 1,25-(OH)₂D₃ and BMP-2 compared with that stimulated with 1,25-(OH)₂D₃ only ($p < 0.01$). RANKL mRNA expression also increased significantly 6 hours after co-stimulation ($p < 0.01$), while OPG mRNA expression showed no significant difference at any time course.

These results suggested that BMP-2 may accelerate the 1,25-(OH)₂D₃-induced osteoclast formation by through enhance the expression of VDR and following RANKL in osteoblast.

Plasminogen Activator Inhibitor (PAI-1) Deficiency Enhances Fracture Callus Size but Reduces Cartilage Remodeling During Fracture Repair. C. H. Rundle, X. Wang*, R. M. Porte*, J. E. Wergedal, S. Mohan, K. H. W. Lau. Research (151), J.L. Pettis VAMC, Loma Linda, CA, USA.

The plasmin system, which functions in extracellular matrix remodeling, plays a critical role in tissue healing, including bone repair. Plasminogen activators (PAs), key activators of the plasmin system, are regulated by plasminogen activator inhibitors (PAIs). Consistent with a regulatory role of PAI-1 in bone, we have found that femur size parameters of adult male PAI-1 knockout (KO) mice [C57BL/6 (B6) background] were reduced relative to adult male B6 mice (periosteal circumference: 14 % less, 4.51 ± 0.13 vs 5.23 ± 0.14 mm, $p < 0.0001$; endosteal circumference: 19% less, 3.10 ± 0.12 vs 3.82 ± 0.15 mm, $p < 0.0001$; femur length: 4% less, 15.3 ± 0.31 vs 16.01 ± 0.47 mm, $p < 0.02$). Because we have also found PAI-1 gene expression to be reduced during fracture healing, we evaluated fracture healing in PAI-1 KO mice to determine

its functional role in bone repair. Adult male PAI-1 KO mice and B6 mice (12 weeks, $n=6$ per group) underwent femoral fracture, and fracture healing was followed by pQCT and histomorphometry at 7, 10, 14, 21 and 28 days post-fracture. When compared with B6 mice, PAI-1 KO fractures displayed increased woven bone area at 10 days (1.66 ± 0.11 vs 1.30 ± 0.36 mm², $p < 0.05$) and 14 days healing (4.77 ± 1.34 vs 2.48 ± 0.86 mm², $p < 0.002$) and increased bone mineral content (BMC) at 10 days (0.43 ± 0.03 vs 0.28 ± 0.13 mg, $p < 0.03$), 14 days (1.27 ± 0.37 vs 0.54 ± 0.29 mg, $p < 0.001$) and 28 days healing (0.57 ± 0.18 vs 0.35 ± 0.08 mg, $p < 0.04$). These results are consistent with increased callus size and bone. Histomorphometry ($n=3$ to 5 mice per group) at 7, 14 and 21 days healing showed that the relative cartilage area:total callus area at 14 days healing was greater in PAI-1 KO mice than in B6 mice ($38 \pm 8\%$ vs $11 \pm 4\%$, respectively, $p < 0.0003$). The augmented callus cartilage and bone were even greater in PAI-1 KO mice than in B6 mice when normalized for the smaller femur size in PAI-1 KO mice. At 28 days, the callus bone remained elevated in PAI-1 KO mice, but was remodeled to cortical bone in B6 mice, suggesting that callus remodeling in PAI-1 KO mice was less effective than in B6 mice. Histology revealed that PAI-1 deficiency not only failed to accelerate bony union of the fracture, but also yielded an abnormal pattern of callus remodeling by 14 days healing in which the surface of the fracture callus cartilage ossified prior to its interior. Conclusions: 1) PAI-1 is an important regulator of bone, since PAI-1 deficiency reduced bone size and marrow space and reduced bone length in KO mice, 2) PAI-1 deficiency may impede fracture cartilage remodeling, resulting in an enlarged callus, and 3) because PAI-1 deficiency yielded an abnormal pattern of bony bridging, the PAI/PA system may have a regulatory role in bony union of the fracture.

Disclosures: C.H. Rundle, None.

Modeling Bone Morphogenetic Protein and Bisphosphonate Combination Therapy in Wild Type and Nf1 Haploinsufficient Mice. A. Schindeler*, M. Ramachandran*, C. Godfrey*, A. Morse*, M. M. McDonald*, K. Mikulec*, D. G. Little*. Orthopaedic Research & Biotechnology, The Children's Hospital at Westmead, Westmead, Australia.

Recombinant bone morphogenetic proteins (BMPs) show promise in treating the orthopaedic complications associated with neurofibromatosis type 1 (NF1), such as congenital pseudarthrosis of the tibia. Minimal scientific data is available regarding the effects of BMPs in the context of NF1. We hypothesized that as abnormalities in both bone formation and resorption have been documented in Nf1-deficient mice, co-treatment with the bisphosphonate zoledronic acid (ZA) could be used to augment the effects of BMP-induced bone formation.

First, primary osteoblasts isolated from wild type (Nf1^{+/+}) and Nf1-deficient (Nf1^{-/-}) mice were cultured in the presence and absence of BMP-2. While Nf1^{-/-} cells exhibited significantly less alkaline phosphatase (ALP) expression than Nf1^{+/+} cells ($P < 0.01$), addition of 100ng/ml BMP-2 for 1 week increased ALP by 2-fold in cells of both genotypes ($P < 0.01$). Analogous results were obtained for matrix mineralization at 3 weeks. To model this response in vivo, 20µg BMP-2 was implanted intramuscularly into the quadriceps of 12 week old mice to induce heterotopic bone. When examined radiographically, less heterotopic bone was present in Nf1^{-/-} mice than in Nf1^{+/+} controls at both 3 weeks ($P < 0.03$) and 6 weeks ($P < 0.01$). Mice of an Nf1^{-/-} genotype also showed an increase in osteoclast number relative to bone surface (Oc.N/BS) suggesting a greater potential for the resorption of BMP-2 induced bone.

To test the effect of an anti-resorptive agent, BMP-2 implanted mice were co-treated twice weekly for 3 weeks with 0.02mg/kg ZA or with saline. ZA treatment led to a synergistic increase in the amount of heterotopic bone in both Nf1^{+/+} and Nf1^{-/-} mice compared with saline controls, as measured by dual-energy X-ray absorptiometry ($P < 0.03$) and histomorphometry (BV/TV, $P < 0.01$). However, significantly less net bone was still observed in Nf1^{-/-} mice ($P < 0.03$) indicating that despite suppressing bone catabolism with ZA, bone anabolism remained impaired.

BMP-2 induced heterotopic bone

Thus, the anabolic deficiency noted in *Nf1*^{+/−} mice is amenable to stimulation by BMP-2, but mineralized tissue formation remains below that of *Nf1*^{+/+} controls in vitro and in vivo. Bisphosphonate combination therapy is superior to BMP therapy alone in terms of net bone production in vivo in both wild type and *Nf1*-deficient mice.

Identification of Novel Dentin Matrix Protein-1 (DMP1) Mutations in Two Unrelated Kindreds with Autosomal Recessive Hypophosphatemia. S. Turan¹, M. Bastepe¹, A. Bereket^{*2}, T. Akcay^{*2}, T. Güran^{*2}, O. Mäkitie^{*3}, H. Jüppner¹. ¹Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA, ²Pediatric Endocrinology, Marmara University, Istanbul, Turkey, ³Hospital for Children and Adolescents, University of Helsinki, Helsinki, Finland.

DMP1, a non-collagenous bone matrix protein, is thought to play an important role in bone mineralization. Homozygous DMP1 mutations have recently been identified as a cause of an autosomal recessive form of hypophosphatemia (ARHP). Here, we report two new unrelated ARHP kindreds in whom the affected individuals carry novel homozygous DMP1 mutations. The index case in the first kindred was 3 years old when he presented with short stature and bowing of the legs that had become apparent during late infancy after he started to walk. Laboratory investigations revealed hypophosphatemia (2.8 mg/dl) due to renal phosphate-wasting, elevated serum alkaline phosphatase activity (964 U/L) and normal serum PTH levels (47.6 pg/ml). Similar clinical and biochemical findings were observed for his 16 month-old brother and his 12.5 year-old female cousin; the parents of all three affected children are first-degree cousins. In the second family, the index case and his sister are now 78 and 66 years old respectively. Both patients presented in early childhood with bone pain and bowing of their legs, and later in life, developed severe joint pain and contractures, calcifications of paraspinal ligaments leading to complete immobilization of the cervical, thoracic and lumbar spine, and significant cranial hyperostosis. Laboratory studies revealed hypophosphatemia due to renal phosphate-wasting as well as increased markers of bone turnover. Nucleotide sequence analysis of the PCR-amplified exons encoding DMP1 and the flanking intronic regions lead, in the first kindred, to the identification of a novel homozygous frame-shift mutation (485Tdel) in exon 6 resulting in a premature stop codon. The parents and available unaffected siblings were heterozygous for 485Tdel. In the second kindred, a novel homozygous missense mutation was identified that changes a conserved serine located in exon 6 to cysteine (S69C). The identified genetic mutations underscore the importance of DMP1 in the pathogenesis of ARHP and for the normal regulation of phosphate homeostasis.

Bone Formation Rate Falls After Puberty in *Brtl* OI Mouse Due to Cellular Uncoupling. T. E. Uveges^{*1}, W. A. Cabral^{*1}, C. Bergwitz^{*2}, F. Legard^{*3}, P. Collin-Osdoby^{*4}, A. Forlino^{*5}, P. Osdoby^{*4}, G. A. Gronowicz^{*3}, J. C. Marini¹. ¹BEMB, NIH/NICHD, Bethesda, MD, USA, ²Endo Unit, Mass Gen/Harvard Med, Boston, MA, USA, ³U Conn Health Ctr, Farmington, CT, USA, ⁴Dept Biology/Bone&Min Metab, Washington U, St. Louis, MO, USA, ⁵Dept Biochem, U of Pavia, Pavia, Italy.

The *Brtl* mouse is a knock-in model for moderately severe (type IV) osteogenesis imperfecta (OI); it carries a mutation causing a classical glycine substitution on one *col1a1* allele (Gly349Cys) and models the molecular, biochemical and phenotypic changes (small size, reduced BMD) of OI. We have previously shown that 2-month *Brtl* femurs have reduced cortical thickness and cross-sectional area and fracture at a lower maximum load. Geometric parameters remain reduced while load to fracture normalizes after puberty, implying that *Brtl* pubertal adaptation increases material strength and elastic modulus.

We have now examined *Brtl* long bone histomorphometry, cellular function and bone formation and resorption at 2 and 6 months of age to further understand the pathophysiology of OI. Both cortical and trabecular bone are reduced in *Brtl* before and after puberty; *Brtl* BV/TV is reduced 40-45%. An uncoupling of cellular number develops after puberty, favoring osteoclast number and function. *Brtl* ObS/BS is comparable to that of wt littermates at both ages. ObS decreases about 40% in both genotypes with age, although *Brtl* marrow can replenish osteoblasts as efficiently as wt marrow, as demonstrated by normal numbers of CFU at both ages. In contrast, OcS/BS is increased in *Brtl* compared to wt at both ages (35-45%), as are the number of TRAP positive cells (50-35%). Interestingly, OcS falls only modestly (~ 1/5) after puberty. Noc is stable and TRAP positive cells decline substantially (~ 4/5). *Brtl* MAR and BFR are comparable to wt at 2 months of age, declining to half of wt values only at 6 months. These data suggest that both (1) uncoupling of cellular numbers, with a greater decline in ObS than OcS at 6 months, and (2) a decline in production of bone matrix by *Brtl* osteoblasts occur as *Brtl* mice age. Normal levels of urinary DPD crosslinks were detected in *Brtl*, as in many OI patients with structural defects of collagen; the lack of elevation of bone resorption in spite of increased osteoclasts may reflect the matrix insufficiency of *Brtl* or resistance of abnormal matrix to resorption. Finally, although *Brtl* osteoblasts in culture deposit normal amounts of mineral, as detected by alizarin red staining, mineralized *Brtl* bone has reduced levels and organization of birefringence under polarized light, suggesting that mineral deposited on the abnormal *Brtl* matrix is improperly aligned. Changes in the composition of bone matrix or mineral may underlie the improved mechanical properties of post-pubertal *Brtl* bone.

Double KO of the Huntingtin Interacting Protein-1 (HIP1) Family Members, HIP1 and HIP1r, Lead to an Osteopenic Phenotype with Severe Spinal Defects. E. I. Waldorff^{*1}, T. S. Hyun^{*2}, K. I. Oravec-Wilson^{*2}, T. S. Ross^{*2}, S. A. Goldstein¹. ¹Orthopaedic Surgery, University of Michigan, Ann Arbor, MI, USA, ²Internal Medicine, University of Michigan, Ann Arbor, MI, USA.

Endocytic protein HIP1 has been shown to be over-expressed in a variety of cancers and both HIP1 and HIP1-related (HIP1r) prolong the half-life of multiple growth factor receptors. Previously generated double HIP1/HIP1r KO (DKO) mice surprisingly demonstrated a dramatic skeletal phenotype distinguished by dwarfism and severe kypholordosis. Single HIP1 KO mice have less severe kypholordosis while HIP1r KO mice have no spinal defects.

To investigate the effect of the HIP1 family on skeletal development; closed, internally-stabilized transverse fractures were created in left tibiae of 3 WT, 7 Het (HIP1r^{-/-};HIP1^{+/+}), and 3 DKO female 3.5 month old mice. Fractures were examined 4 wks post-fracture using microCT and histology. The spine and right tibiae were examined using microCT, while marrow from both femora was used for protein analysis using Western blots.

Compared to Het and WT, DKO mice have smaller spine angle; larger vertebral bodies, smaller vertebral foramen and smaller posterior spinous processes; a trend for decreased TMD of the vertebral body; increased vascularity in the thoracic vertebrae; shorter tibiae, lower tibial cortical and trabecular TMD; smaller cortical thickness; a trend toward decreased BVF of tibial trabecular bone and thinner trabeculae, while trabecular number were similar.

RANK expression of the femoral marrow was similar between groups, but the transcription factor, NFATc1, which acts downstream of RANK, was more highly expressed for DKO mice. Previous studies have shown no change in osteoclast numbers or differentiation, and normal TRAP5b serum levels for DKO mice.

DKO fracture callus was smaller than the other groups, with a trend toward higher BMD within the callus. Histological examinations showed that DKO mice had higher cartilage to callus ratio, and higher ratio of TRAP positive surface to total surface within the callus. Red blood cell numbers in the callus were increased for DKO mice, indicating a possible increase in vascularity.

The interpretation of the data suggests several possible underlying mechanisms that might explain the skeletal phenotype of the DKO mouse. Deletion of the HIP1 family may affect primary bone formation in the long bones through the influence on cartilage matrix formation, or direct bone matrix formation. Results from the fracture study in combination with the vertebral defects, suggest that progenitor cell availability, tissue maintenance and remodeling might also be compromised in this phenotype. Further longitudinal studies will examine the fracture repair over time.

Aromatase Deficiency in an Adult Chinese Male Caused by Heterozygote for Two New Point Mutations in the CYP19 Gene. O. Wang^{*}, X. Xing^{*}, X. Meng^{*}, M. Nie^{*}, Z. Chen^{*}, M. Li^{*}, W. Xia^{*}, Y. Jiang^{*}. Endocrinology, Peking Union Medical College Hospital, Beijing, China.

The aromatase enzyme encoded by CYP19 gene catalyzes the conversion of androgens to estrogens. Deficiency of aromatase causes estrogen deficiency which may affect bone growth and metabolism. The purpose of this study was to report the first Chinese male with aromatase deficiency and the genetic mutations in his CYP19 gene.

The 24-year-old male was admitted in Peking Union Medical College Hospital for continuing linear growth for 24 years and malformation in his legs for 2 years. He had no growth spurt. Sexual function was normal. When he was 22-year-old he got genua valga which deteriorated gradually. His parents and brother were phenotypically normal. His mother was 165cm, father 172cm and brother 175cm in height. The patient was 182.5cm and the ratio of the upper segment to the lower segment was 0.92. Physical examinations showed genua valga, acanthosis nigricans and enlarged liver. The secondary male characteristics and testicular size were normal. The biochemical markers and BMD were measured. Genomic DNA was extracted from WBC of peripheral blood from the patient and his family members. Ten exons of CYP19 gene were amplified by PCR and sequenced directly.

His serum testosterone levels were 14.6 to 20.5nmol/l while estrogen level was undetectable. FSH and LH levels were elevated. Bone age was 16 years old. Epiphyses were unfused in lower extremities, phalange and wings of iliac bones. BMD was reduced at lumbar spine (Z score = -2.9) and femoral neck (Z score = -0.9). Semen analysis was normal. OGTT suggested type 2 diabetes mellitus. Serum cholesterol level was elevated with increased ALT levels and severe liver steatohepatitis identified by ultrasound. Genetic analysis showed two heterozygous point mutations in CYP19 gene, one was Tyr81Cys in exon 3 (from his mother), the other was Leu451Pro in exon 10 (from his father). This new case of aromatase deficiency confirmed previous studies that estrogen plays an important role on bone growth and gain of peak bone mass in males. Estrogen may also affect glucose and lipid metabolism in males. In this patient, two new point mutations in CYP 19 gene are likely to be the molecular basis of his estrogen deficiency.

Osteoprotegerin Deficiency (Juvenile Paget's Disease): Responses to Oral and IV Bisphosphonates in 3 Children. D. Wenkert¹, M. Natter^{2*}, M. Otsuka^{3*}, N. Fish^{4*}, J. Lopez-Benitez^{5*}, M. Markowitz^{6*}, W. McAlister^{7*}, S. Mumm⁸, M. Whyte⁵. ¹Shriners Hospt Children, St Louis, MO, USA, ²Tufts-New Eng Med Ctr, Boston, MA, USA, ³N. Navajo Med Ctr, Shiprock, NM, USA, ⁴Montefiore Hospt, Bronx, NY, USA, ⁵Wash U Sch Med, St Louis, MO, USA.

Osteoprotegerin (OPG) deficiency, the principal variant of juvenile Paget's disease, is a rare, autosomal recessive osteopathy featuring markedly accelerated bone turnover. Here, we assess responses of 3 affected, unrelated children to bisphosphonate (BP) therapy (Table).

Pt #1: A 4 yr old boy of Cypriot descent suffered leg swelling, periosteal elevation, and ESR=74 from "Caffey disease" diagnosed at age 1 mo. Alkaline phosphatase (ALP) reached 2470 U/L. Hearing (normal at birth) was lost by 21 mo (cochleas absent on CT). Three fxs and warm, bony expansions deformed all limbs. Growth, except head size (OFC), was stunted. On referral, he had weakness, torticollis, chest and limb deformity, could not sit, and cried when moving. X-rays showed markedly expanded bones, "bowtie" vertebrae, thickened diploic space, and marked coxa vara.

One wk after 1/3 mg/kg pamidronate (PAM), he sat; 3 weeks after the first 3-dose cycle (total ~2 mg/kg), he crawled. After 3 cycles, he stood. Stamina, appetite, mood, torticollis, and mobility remarkably improved.

Pt #2: A 7 yr old girl of Puerto Rican descent seemed well until an atraumatic femoral fx at age 2. X-rays showed limb deformities from "Engelmann disease" (ALP 1963 U/L). By referral, she had 4 fxs (25% ht, 20% wt, 5% arm span, <5% sitting ht, and >95% OFC), mild deafness, and arm pain; leg pain limited walking. Femurs and tibias were bowed. X-rays showed periosteal elevation, osteopenia, and expanded bones. At age 10, after 1.5 yrs of alendronate, knee pain was minimal.

Pt #3: An 11 yr old, dwarfed, deaf, Navajo boy (NEJM 2002; 347:175) had macrocephaly, and chest and limb deformity. He became poorly compliant for calcitonin, and declined risedronate. At age 7, PAM was begun (ALP max 2716) with symptom and x-ray improvement.

Pt 1 and 2 had different, homozygous, loss-of-function defects in exon 2 of TNFRSF11B encoding OPG. Pt #1 had a frame-shift, single base deletion (c.278delT), likely forming no functional protein, consistent with severe disease. Pt #2 had a missense mutation (c.T349C, p.Phe117Leu) causing a less severe phenotype. Pt #3 is deleted for OPG.

Children with OPG deficiency show varying responsivity to BPs, reflecting the underlying OPG mutation.

Biochemical and DXA response to Bisphosphonates in 3 children with OPG deficiency

	Pt 1		Pt 2		Pt 3	
	Pamidronate (i.v.) (6 mo of 8 mg/kg/6 mo)		Alendronate (p.o.) (1.5 yr of 35 mg twice/wk)		Pamidronate (i.v.) (3.5 yr of ~8 mg/kg/yr)	
	Before	After	Before	After	Before	After
ALP (IU/L)	720	247 (nl)	1232	303 (nl)	1927	436 (nl)
Osteocalcin (mg/g)	31	79	53	97	197	142
Urine Ca/Cr (mg/g)	488	615	373	85	489	715
ESR (mm/hr)	61	17	37	11	57	15
CRP (mg/dL)	2.5	<0.5	<0.8	<0.5	<0.1	-
L1-L4 DXA (Z-score)	-6.8	-2.7	-3.1	+0.1	-3.1	+0.4

Three Novel Mutations of the PheX in Three Chinese Families with X-linked Hypophosphatemic Rickets. W. Xia^{1*}, X. Meng¹, Y. Jiang^{1*}, X. Xing^{1*}, M. Li^{1*}, O. Wang^{1*}, Y. Pei^{2*}, L. Yu^{1*}, L. Pang^{1*}, Y. Sun^{1*}, Y. Hu^{1*}, X. Zhou^{1*}. ¹Endocrinology, Peking Union Medical College Hospital, Beijing, China, ²Endocrinology, Second Artillery Forces General Hospital, Beijing, China.

X-linked hypophosphatemia (XLH), the most prevalent form of inherited rickets in humans, is a dominant disorder of phosphate homeostasis characterized by growth retardation, rachitic and osteomalacic bone disease, hypophosphatemia, and renal phosphate wasting. The gene responsible for XLH was identified by positional cloning and designated PHEX (formerly PEX) to depict a phosphate regulating gene with homology to endopeptidases on the X chromosome. Recently, extensive mutation analysis of the PHEX gene has revealed a wide variety of gene defects in XLH. The ethnic distribution of the mutations is very broad. Only a few mutations in Chinese were reported previously. To analyze the molecular basis of three unrelated Chinese families with XLH, we determined the nucleotide sequence of the PHEX gene and fibroblast growth factor 23 (FGF-23) gene of affected members. The serum FGF-23 concentrations of these patients with XLH were also measured. Three different types of novel mutations were observed in three families respectively from our study: one deletion mutation c.264delG causing p.W88 X; one missense mutation c.1673C>G causing p.P558A; one non-sense mutation c.1809G>A causing p.W603 X. Serum concentration of FGF-23 in XLH patients of these three families was significantly higher than normal range. These results suggest that PHEX gene mutations were responsible for XLH in these Chinese patients. And these mutations may contribute to higher serum FGF-23 level.

Identification of Sex-specific QTL for Femoral Neck Density and Strength in Inbred COP and DA Rats. I. Alam¹, Q. Sun¹, L. Liu^{2*}, D. L. Koller², L. G. Carr^{3*}, M. J. Econs³, T. Foroud², C. H. Turner¹. ¹Biomedical Engineering, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA, ²Medical and Molecular Genetics, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA, ³Medicine, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA.

Hip fracture is one of the most common osteoporotic fractures with significant morbidity and mortality. Several studies in humans identified potential chromosomal regions linked to hip size and bone mass. Animal models, particularly the inbred rat, serve as a potential complementary model for studying the genetic influences on hip fragility. Previously we demonstrated that, despite similar body size, Copenhagen 2331 (COP) rats had greater femoral neck biomechanical properties compared with Dark Agouti (DA) rats. To identify genes regulating fracture risk at the femoral neck, we mapped quantitative trait loci (QTL) for femoral neck density, structure and strength phenotypes using 828 (405 males and 423 females) F2 progeny derived from the inbred COP and DA rats. Skeletal phenotypes were measured by peripheral quantitative computed tomography (pQCT) and biomechanical testing. Femoral neck phenotypes included volumetric bone mineral density (vBMD), cross-sectional area, polar moment of inertia (Ip), neck width, ultimate force, and energy to break. We performed a whole-genome screen using 93 microsatellite markers with an average intermarker distance of 20 cM. Genetic marker maps were generated using MAPMAKER/EXP from the COP x DA F2 data and compared with published Rat Genome Database (RGD) maps. These recombination based maps were then employed for genome-wide linkage analyses to detect sex-specific and sex-independent QTLs. Permutation testing was employed to obtain the thresholds for genome-wide significance (p<0.01). Strong evidence of linkage for femoral neck vBMD QTLs was observed on chromosomes (Chrs) 1, 2, 10, 17 and 18 when both males and females F2 were included in the analyses. In addition, QTLs affecting femoral neck structure were found on Chrs 7, 10 and 17 and QTLs for biomechanical properties were detected on Chrs 1, 4, and 15. Sex-specific QTL analyses revealed several QTLs that have male-specific effects: total vBMD on Chrs 2 and 18, cortical vBMD on Chr 2, trabecular vBMD on Chr 17 and biomechanics on Chr 15. Female-specific QTLs were found on Chr 10 for total and cortical vBMD, and on Chr 1 for trabecular vBMD and biomechanics. Several QTL regions identified in this study are homologous to human chromosomal regions previously linked to QTLs contributing to femoral neck and related phenotypes. In summary, we detected evidence that sex-specific QTL contribute to hip fragility in the rat.

Heritability of the Principal Components of a Statistical Shape Model Describing Baboon Midshaft Femur Geometry. T. L. Bredbenner¹, L. M. Havill², M. C. Mahaney², D. P. Nicoletta¹. ¹Materials Engineering, Southwest Research Institute, San Antonio, TX, USA, ²Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA.

Cross-sectional geometry is an important contributor to bone strength. Studies in humans and inbred rodents suggest that bone shape is under partial genetic control. It is less clear, however, that genes contribute substantially to normal population-level variation in bone geometry. Using the pedigreed baboon, an established nonhuman primate model for the genetics of bone strength-related traits, we previously established that geometric properties of the midshaft femur are significantly heritable. In the present study, we developed a statistical shape model to efficiently describe the complex geometry of a set of midshaft transverse sections from 110 pedigreed baboons (30 male, 80 female; 5-33 yrs) and investigated the heritability of principal components of the statistical shape model. Midshaft sections were digitized, the images were segmented, and cubic splines were fit to inner and outer cortical boundaries. Parameter vectors were defined for each section using spline point coordinates and a statistical shape model (SSM) representation of all cross-sections was developed using the minimum description length (MDL) method. A Principal Component Analysis of the statistical shape model showed that 90% of the variability in bone cross-section geometry can be described using 6 independent components (Table 1). Shape component scores were determined to reconstruct individual cross-sectional boundaries from the statistical shape model. Maximum likelihood-based variance decomposition methods were used to estimate the mean effects of age and sex covariates and the additive effects of genes on the variability of the first 6 shape factors (Table 1). Covariate effects accounted for ~10-55% of the variability in shape factor values (p_{age} , p_{sex} , and/or $p_{age \times sex}$ < 0.005). The additive effects of genes significantly influence ($p < 0.1$) the normal variation in the 2 dominant shape factors that described 77% of the variability in baboon midshaft femur geometry. The statistical shape model retains significant dependence on the additive effects of genes and potentially can be used to efficiently quantify the contribution of bone geometry to an individual's risk of fracture.

Factor	Results of Principal Component Analysis and Variance Decomposition		
	Principal Component Analysis	Heritability	Covariate Effects
	% SSM Variability Explained	$h^2 \pm \text{Std.Err. (p value)}$	% Factor Variability Explained
b ₁	41.9	0.24 \pm 0.20 (0.07)	55.2
b ₂	35.0	0.41 \pm 0.28 (0.036)	27.7
b ₃	5.4	0 (0.5)	36.4
b ₄	3.2	0.13 \pm 0.21 (0.245)	9.5

Single Chromosome Substitutions Alter Functional Interactions Among Femoral Morphological Traits and Mineral Density in Inbred Mice. H. C. Courtland¹, B. Hu^{*1}, A. Hill^{*2}, J. B. Singer^{*3}, E. S. Lander^{*3}, J. H. Nadeau^{*2}, K. J. Jepsen¹. ¹Orthopaedics, Mount Sinai School of Medicine, New York, NY, USA, ²Case Western Reserve University, Cleveland, OH, USA, ³The Broad Institute of MIT and Harvard University, Cambridge, MA, USA.

Prior work established a hierarchical relationship between heritable whole bone traits (morphology, ash content) and mechanical properties that define fracture susceptibility in inbred mice. Functional interactions among these traits were then determined using Path Analysis on a panel of adult AXB/BXA Recombinant Inbred (RI) strains (Fig. 1)[1]. To test if genetic manipulation can perturb these functional interactions, we examined whole chromosome substitutions of 21 B6-Chr^A strains (C57BL/6J background with one chromosome replaced by the corresponding A/J chromosome), many of which demonstrate a significant alteration of whole bone traits. 16 week B6-Chr^A femoral length (Le), total area (TtAr), cortical thickness (CtTh) and tissue mineral density (TMDn) values were measured. The expected TMDn value for each B6-Chr^A strain was calculated using the AXB/BXA RI structural equation for TMDn. Significant differences between the expected TMDn and actual TMDn were calculated using genome-wide corrected t-tests ($p \leq 0.003$). Results showed that four female B6-Chr^A (2, 6, 16, and X) and male B6-Chr^A (2, 3, 4, and 18) strains had observed TMDn values significantly different than expected. For both female and male B6-Chr² mice and male B6-Chr² mice, TMDn was significantly lower than expected based on values for Le, CtTh, and TtAr which were similar to B6. Female B6-Chr^{6,16,X} mice had Le, CtTh, and TtAr values significantly larger than B6 and yet their observed TMDn values were not different than B6. The observed decrease in TMDn in male B6-Chr⁴ mice was not expected based on an increase in CtTh and in male B6-Chr¹⁸ mice a large increase in TMDn was not expected with a small increase in femoral length. Thus, eight chromosomes alter the functional relationship between femoral morphology and TMDn in inbred mice, suggesting that one or more genes present have a role in maintaining the biological control mechanisms that establish mechanically functional combinations of femoral TMDn, Le, CtTh, and TtAr. Future studies are needed to determine if these chromosomes disrupt functional interactions during growth.

Genome-wide Scan for QTL Influencing Bone Mineral Density: The Southwest Ohio Family Study. S. A. Czerwinski^{*1}, M. Lee¹, A. C. Choh^{*1}, E. W. Demerath^{*1}, B. Towne^{*1}, R. J. Sherwood^{*1}, D. L. Duren^{*1}, J. Blangero^{*2}, S. A. Cole^{*2}, R. M. Siervogel¹. ¹Community Health, Wright State University Boonshoft School of Medicine, Kettering, OH, USA, ²Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA.

In order to identify QTL influencing susceptibility to osteoporosis, we performed genome-wide quantitative trait linkage analysis on bone mineral density (BMD) phenotypes collected in a sample of individuals from five large extended families participating in the Southwest Ohio Family Study. A total of 581 (265 males, 316 females) individuals ranging in age from 8-86 years had at least one BMD phenotype and genetic marker data. These individuals were genotyped for 395 autosomal markers spaced approximately every 10 cM along the genome. Our analyses focused on three BMD phenotypes- total body, femoral neck and lumbar spine collected using the Hologic QDR 4500 bone densitometer (Hologic, Inc., Waltham, MA). Using a variance-components based maximum likelihood method (SOLAR) for pedigree data, we calculated initial heritability estimates (h^2) and identified quantitative trait loci (QTL) influencing variation in the three BMD phenotypes. In this sample, each of the BMD traits measured was highly heritable ranging from $h^2 = 0.31$ to 0.56 ($p < 0.000001$) after adjusting for the effects of age, sex, age², age-by-sex, age²-by-sex, ethnicity, and height. Preliminary results of the quantitative trait linkage screen revealed significant evidence for linkage on chromosome 3 (82cM) near marker D3S1300 with a maximum LOD of 3.6. Evidence of suggestive linkage was also found on chromosome 6 (165 cM) near marker D6S441 with a maximum LOD of 2.8, and on chromosome 2 (51 cM) near marker D2S165 with a maximum LOD of 2.0. These results provide preliminary evidence of replication of linkage signals between our study and other previous studies.

Disclosures: S.A. Czerwinski, None.

Positional Cloning Identified ESR2, ESRRB, BMP4 and LTBP2 as the Candidate Genes for the Quantitative Trait Locus in Chromosome 14 for BMD Variation. Z. J. Dai¹, C. L. Cheung¹, P. C. Sham^{*2}, V. Chan^{*1}, K. D. K. Luk^{*3}, A. Paterson^{*4}, A. W. C. Kung¹. ¹Department of Medicine, The University of Hong Kong, Hong Kong, China, ²Genome Research Centre, The University of Hong Kong, Hong Kong, China, ³Department of Orthopaedics and Traumatology, The University of Hong Kong, Hong Kong, China, ⁴Hospital for Sick Children, University of Toronto, Toronto, ON, Canada.

Chromosome 14 has previously been linked to BMD variation in several genome-wide linkage studies. To replicate and fine-map the quantitative trait locus (QTL) influencing BMD in southern Chinese, a high-density linkage and association screen of chromosome 14q13-32 was performed using high-density microsatellite markers in 306 extended southern Chinese families having a proband with BMD Z score < -1.28 (equivalent to lowest 10th percentile of the population) at either hip or spine. Candidate genes were identified within the QTL with gene prioritization using the Endeavour programme. Genotyping of the candidate genes was performed with Tag SNPs in another cohort of 600 pairs of unrelated high (Z score $> +1$) and low BMD (Z score < -1.28) subjects. Maximum LOD score of 1.89 was detected at 69.2cM (14q23) for total hip BMD. LOD scores greater than 1.2 were detected at 14q21 for femoral neck BMD, 14q12-13 and 14q23 for trochanter BMD. Five candidate genes were identified within these regions, namely estrogen receptor β (ESR2), bone morphometric protein 4 (BMP4), estrogen-related receptor β (ESRRB), latent transforming growth factor beta binding protein 2 (LTBP2), and transforming growth factor beta 3 (TGFB3). Significant association was detected with the following SNPs: T1213C, A110732G of ESR2, rs762642 and rs2071047 of BMP4, rs2980896, rs4903413 and rs12436385 of ESR2, rs2359141, rs3825709, rs2286411, rs2043948 and rs7569 of LTBP2, rs3917201 of TGFB3. Epistasis revealed significant gene-gene interaction between these genes which may be the underlying mechanism explaining the linkage peak. Our results identified multiple genes within the QTL in chromosome 14 that contribute to BMD variation in the general population. These results help in understanding the pathophysiology of low bone mass and osteoporosis.

Heritability of Lumbar Trabecular Bone Mechanical Properties in Baboons. L. M. Havill¹, M. R. Allen², T. L. Bredbenner³, D. P. Nicoletta³, D. B. Burr², C. H. Turner⁴, M. C. Mahaney¹. ¹Southwest Foundation for Biomedical Research, San Antonio, TX, USA, ²Indiana University School of Medicine, Indianapolis, IN, USA, ³Southwest Research Institute, San Antonio, TX, USA, ⁴Indiana University Purdue University, Indianapolis, IN, USA.

Mechanical properties of bone provide a direct and inclusive measure of bone's fracture resistance. Genetic effects on these properties have been demonstrated in rodents but not in primates, and the degree to which these genes contribute to population level normal variation in mechanical properties is unknown. In this study we 1) characterize normal variation, including age and sex effects, on vertebral trabecular bone mechanical properties in a non-human primate model, and 2) detect and quantify the proportion of variation in these properties that is due to the additive effects of genes (heritability (h^2)). Cranio-caudally oriented trabecular bone cores (6 mm x 8 mm) were obtained from the L3 vertebral body of 156 baboons (110 females, 46 males; 6-32 years) from a single extended pedigree. Cross-sectional area and bone volume/tissue volume for each core were obtained via microCT (uCT-20; SCANCO USA, Inc.). Each core was then tested to failure in monotonic compression (0.5 mm/min) using a servohydraulic testing machine (Model 858 Mini Bionix II, MTS Corp.). Ultimate stress, modulus, and toughness were determined from load vs displacement data (10Hz). Age, sex, and additive genetic effects were assessed using maximum likelihood-based variance components methods. After accounting for relatively small but significant age and sex effects, a substantial amount of the residual variation in ultimate stress (0.58 ± 0.20 ($p=0.0005$)), modulus (0.29 ± 0.24 ($p=0.0855$)) and toughness (0.64 ± 0.22 ($p=0.0003$)) is attributable to genes. Subsequent analyses in which bone volume ($h^2=0.55 \pm 0.20$ ($p=0.0009$)) is accounted for yield non-significant heritability estimates for ultimate stress (0.15 ± 0.14 ($p=0.1042$)) and modulus (0.02 ± 0.13 ($p=0.4413$)), suggesting that much of the genetic effect detected in the first analyses acts through bone volume. Interestingly, the results for toughness differ. When bone volume is accounted for, a significant genetic effect on toughness (0.29 ± 0.23 ($p=0.0389$)) remains. This indicates that variation in toughness is due, in part, to genes that affect bone volume, but also to genetic effects that are independent of bone volume. These results clearly demonstrate that mechanical properties of vertebral trabecular bone are strongly heritable in the baboon and that these genetic effects are largely, but not entirely, due to genetic effects on bone volume.

Disclosures: L.M. Havill, None.

A Genome-Wide Scan of Metacarpal Bone Geometric Strength Indices in the Framingham Study. N. Shimabuku¹, S. Menn², S. Demissie³, L. A. Cupples³, D. P. Kiel², D. Karasik². ¹Creighton U Med Sch, Omaha, NE, USA, ²IFAR, Hebrew SeniorLife, Boston, MA, USA, ³Biostatistics, BU Sch Public Health, Boston, MA, USA.

Bone geometry, which has a substantial genetic component, contributes to a bone's ability to resist fracture. Metacarpal bones have the same characteristic geometry of other long bones in the body and have been routinely measured in previous research studies to predict fractures and quantify bone loss. Thus, to identify chromosomal regions governing bone geometry and strength, we performed linkage analysis of metacarpal bone geometry indices.

In this study, a genome-wide scan (with a set of 615 markers with an average spacing of 5.7 cM) was performed on 1,702 individuals from 330 extended families of the Framingham study. Metacarpal strength indices, namely Metacarpal Cortical Thickness (MCT), Cortical Index (MCI), and Section Modulus (MZ), were obtained at the midshaft, from the digitized x-rays of 1,412 men and women (mean age, 56.6 yrs parents ($n=638$), 47.3 yrs offspring ($n=774$)). Data for metacarpals 2, 3 and 4 were averaged. All indices were adjusted for age and age² in each sex. Two-point and multipoint linkage analysis was performed using SOLAR, to determine regions of excess chromosomal sharing.

Heritability (h^2) was significant for all indices, ranging from 0.53 and 0.62 (Table). Both two-point and multipoint linkage identified several chromosomal regions with the maximum log10 of the odds ratio (LOD) scores >2.0. Thus, MCI and MCT were linked to chr. 7 (149 cM) with multipoint LOD>2.0. MZ was linked with chr. 9 (49 cM) (multipoint LOD=2.4). Highest LOD scores (both two- and multipoint) were obtained at chr. 11 (between 101 and 106 cM) with MZ. Additional adjustment for height and weight did not change h^2 but generally reduced the LOD scores, especially multipoint.

In conclusion, in this preliminary study, we have identified excess allelic sharing at the genomic markers D11S2000 and D11S1986 on chr.11q21-q22, as demonstrated by the section modulus, which reflects bending resistance. Linkage to this and other regions may be in some part due to effects on body size. Identification and subsequent characterization of loci for bone strength of the appendicular skeleton can further elucidate the genetic contributions to bone geometry and resistance to stress.

Linkage Screen for Bone Mineral Density Phenotypes in Male and Female COP and DA Rat Strains. D. L. Koller¹, I. Alam², Q. Sun², L. Liu³, M. J. Econs³, T. Foroud⁴, C. H. Turner⁴. ¹Medical and Molecular Genetics, Indiana University School of Medicine, Indianapolis, IN, USA, ²Biomedical Engineering, Indiana University School of Medicine, Indianapolis, IN, USA, ³Medicine, Indiana University School of Medicine, Indianapolis, IN, USA, ⁴Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA.

Studies attempting to localize and identify genes contributing to variation in BMD in both humans and model organisms have demonstrated that multiple genes of modest effect may be involved. Since inbred strains of experimental animals may be informative for only a subset of these genes, we undertook a genome screen to identify BMD QTLs in F2 progeny derived from the inbred Copenhagen 2331 (COP) and dark agouti (DA) strains of rats to complement our previous study in inbred Fisher 344 and Lewis rats. Phenotyping of areal BMD (aBMD) and volumetric BMD (vBMD) at the lumbar spine and femur was completed in 828 animals (405 male and 423 female). Microsatellite marker typing was performed using 93 markers at an average density of 20 cM. Skeletal phenotypes were measured by peripheral quantitative computed tomography (pQCT) and DEXA. Genetic marker maps were generated using Mapmaker/EXP from the genotype data and compared with published maps (RGD). These genotype, phenotype, and mapping data were then employed in the R/qtl software package to perform genome-wide linkage analyses to detect QTLs acting in both sexes as well as those that have sex-specific effects. Permutation tests were conducted to determine genome-wide significance thresholds. A major QTL was detected in both sexes on chromosome 18 for vBMD at midfemur (genome-wide $p<0.01$). On distal chromosome 1, a QTL was found in both sexes affecting femur and lumbar aBMD as well as vBMD at distal femur, and this QTL appears distinct from the proximal chromosome 1 QTL impacting BMD in our previous Fisher 344xLewis F2 cross. Additional aBMD and vBMD QTLs on chromosomes 2, 6, and 10 were also detected in both sexes of the COPxDA F2. Several sex-specific QTL were also detected, notably for the distal femur vBMD phenotype. These included a male-specific QTL ($p<0.01$) on chromosome 8 and female-specific QTL on chromosomes 7 and 14 ($p<0.01$). Interestingly, few of the QTL identified demonstrated overlap with the significant QTLs from the Fisher/Lewis cross. These results confirm the presence of QTL which act in both sexes, as well as some which are gender specific. In addition, unique QTL appear to influence different measures of BMD. Thus, the genetic architecture of BMD in the rat model is quite complex and would appear to be influenced by a number of different genes.

Evidence for QTL Underlying Normal Variation in Calcaneal Quantitative Ultrasound Measures: The Southwest Ohio Family Study. M. Lee¹, A. C. Choh², E. W. Demerath¹, B. Towne¹, R. J. Sherwood¹, D. L. Duren¹, J. Blangero², R. M. Siervogel¹, S. A. Cole², S. A. Czerwinski¹. ¹Community Health, Wright State University Boonshoft School of Medicine, Kettering, OH, USA, ²Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA.

Research in the the genetics of osteoporosis has steadily increased in recent years, but the identification of specific genes that influence osteoporosis risk factors such as calcaneal quantitative ultrasound (QUS) measures is still not well established. Quantitative ultrasound traits are correlated with bone mineral density (BMD), but are useful independently from BMD, as they predict risk for future fracture. The purpose of this study is to conduct a whole genome scan to search for quantitative trait loci influencing normal variation in QUS traits. QUS measures were collected from a subset of 555 individuals (255 males and 300 females) from the Southwest Ohio Family Study who were genotyped and had at least one QUS measurement. Participants ranged in age from 8 to 86 years and were distributed across 5 large extended families. Using the Sahara @ bone sonometer (Hologic, Inc., Waltham, MA), speed of sound (SOS), broadband ultrasound attenuation (BUA), and quantitative ultrasound index (QUI) were collected in each heel (right and left). Variance components based linkage analysis was performed on all six traits using 395 polymorphic genetic markers spaced approximately 10 cM apart across the whole genome to identify quantitative trait loci (QTL) influencing the QUS traits. Age, sex, race and weight effects were simultaneously estimated in all models. Initial heritability estimates (h^2) for the 6 QUS traits ranged from 0.54 to 0.68. Suggestive evidence for a QTL influencing SOS was found on chromosome 5p15 (LOD = 2.00) near marker D5S1953, while a suggestive QTL on chromosome 5q32 (LOD = 2.23) near marker D5S436 was found for QUI. An additional suggestive linkage was observed on chromosome 15q21 for both SOS (LOD = 2.27) and QUI (LOD=2.23) near marker D15S978. Additionally, QTL with LOD scores > 1.5 were observed on chromosomes 1, 3, and 16.

A Quantitative Trait Locus Mapping to Chromosome 2p Influences Variation in Bending Resistance of Bone: The Framingham Osteoporosis Study. M. C. Mahaney¹, L. M. Havill¹, S. Demissie², L. A. Cupples², D. P. Kiel³, D. Karasik³. ¹Genetics, Southwest Foundation for Biomedical Research, San Antonio, TX, USA, ²School of Public Health, Boston University, Boston, MA, USA, ³Hebrew SeniorLife, Institute for Aging Research, Boston, MA, USA.

Genes influencing geometric bone indices at the hip have not been clearly identified in previous studies. Thus we used maximum likelihood based variance decomposition methods to detect, characterize, and localize to specific chromosomal regions the effects of genes influencing variation in average buckling ratio (ABR), cross sectional moment of inertia (CSMI), and section modulus (Z) at the femoral neck (FN) and proximal femoral shaft (FS) measured in more than 1350 Framingham Osteoporosis Study participants from 323 nuclear and small extended families. Initial analyses of age- and sex-adjusted residuals following inverse-Gaussian normalization detected significant ($P \leq 1.72 \times 10^{-15}$) additive genetic effects; with heritability estimates (h^2) ranging from $h^2 = 0.34$ (FN-ABR) to $h^2 = 0.61$ (FS-Z). Univariate whole genome linkage screens detected genome-wide significant evidence (at $\alpha = 0.05$, LOD=3.01) for a quantitative trait locus (QTL) for two bending resistance traits (FS-CSMI and FS-Z) at the same genomic location: 80 cM from 2pter. Bivariate statistical genetic analyses revealed that nearly all (94%; $\rho_G = 0.97$, $P < 5.23 \times 10^{-37}$) additive genetic variance in these two measures was due to the shared effects of the same gene(s). Follow-up bivariate linkage analyses focusing on chromosome 2 supported a pleiotropic QTL at this same location (QTL-specific genetic correlation, $\rho_Q = 1.0$, $P < 0.0001$). Although univariate evidence for an FS-ABR QTL on 2p was only suggestive, a subsequent trivariate linkage analysis that included this measure in addition to FS-CSMI and FS-Z found significant ($P < 0.0001$), complete ($\rho_Q^2 = 1$), and negative (i.e., $\rho_Q = -1$) QTL-specific pleiotropy between it and both FS-CSMI and FS-Z. These observations are consistent with known differences in the relationships of the variables to fracture resistance: i.e., both CSMI and Z are positively correlated with bone strength while increased ABR is associated with higher fracture risk. Additionally, bivariate whole genome linkage screens localized pleiotropic QTLs influencing CSMI and Z at both the FS and FN sites (respectively, maximum bivariate LOD=3.19 and LOD=2.81) at this same location on 2p. Peak evidence places all the QTLs detected in this study just qter of the midpoint of a 16.4 mb region bounded by D2S1352 and D2S1772 and within which no bone related QTLs or obvious candidate genes have been mapped previously. We conclude that this QTL contributes to variation in bending resistance-related traits at both proximal femur sites.

Disclosures: M.C. Mahaney, None.

QTL on Chr 11 Regulates Bone Shape in SAMP6 Mice. B. Otsuki¹, M. Shimizu², M. Mori³, S. Okudaira², R. Nakanishi², K. Higuchi³, T. Tsuboyama², T. Nakamura². ¹Orthopaedic Surgery, Kishiwada City Hospital, Kishiwada, Japan, ²Orthopaedic Surgery, Kyoto University, Kyoto, Japan, ³Aging Angiology, Shinsyu University, Matsumoto, Japan.

In our previous study using SAM strains, we reported a QTL (Pbd1) on Chr11 with significant linkage to cortical thickness index (CTI, Fig. 1A). The aim of this study was to clarify the effects of Pbd1 and narrow the QTL region. All mice were handled according to the Guideline for Animal Experiments of Kyoto University.

We first generated a congenic strain named P6.P2-Pbd1b that carried a 39 cM SAMP2-derived Chr11 interval onto a SAMP6 background, and the CTI of P6.P2-Pbd1b was significantly higher than that of SAMP6 (Fig. 2). To narrow the interval, sixteen sub-congenic strains that have smaller overlapping intervals were generated (Fig. 2). From the CTI or BA/TA values, the Pbd1 locus should be seated on the region between D11Mit10 and D11Mit184.

In the morphological analyses of femora using μ CT at 16 weeks (Fig.1B and 1C), the cross-sectional shape of S5 at midshaft was more compressed than that of SAMP6 in the anteroposterior direction (Fig.1D). We then examined the time-course change of OBL between SAMP6 and S5 (Fig.1E). OBL was not different at 5 days of age. However, the difference in OBL became remarkable as they grew, indicating that the difference was formed in the process of bone modeling. The shape of epiphyseal growth plate of SAMP6 and S5 was not different; however, dynamic histomorphometrical analysis at 8 weeks revealed that rates of endocortical and periosteal bone formation were different between SAMP6 and S5 (Table 1).

In conclusion, the Pbd1 locus that was seated between D11Mit10 and D11Mit184 alters the cross-sectional shape of the femur.

Dynamic histomorphometrical parameters at the midshaft (n=9).			
Parameters	SAMP6	S5	p
Ps.MAR (μ m/day)	4.07 (1.35)	2.39 (0.59)	0.0058
Ps.BFR/BS (μ m/day)	1.83 (0.67)	1.60 (0.28)	0.38
Ec.MAR (μ m/day)	3.16 (0.76)	5.25 (1.02)	0.0002
Ec.BFR/BS (μ m/day)	1.62 (0.51)	2.34 (0.68)	0.025

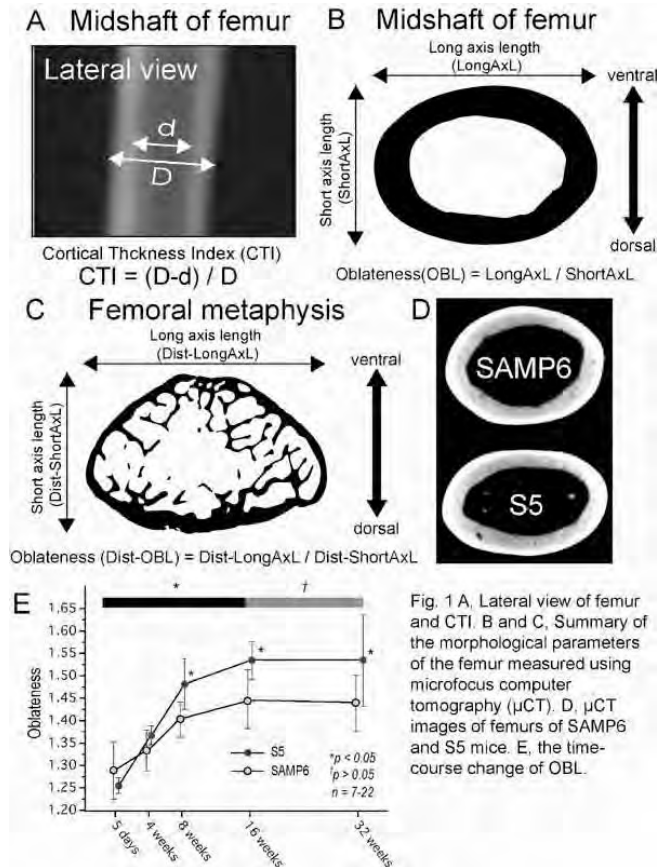

Fig. 1 A, Lateral view of femur and CTI. B and C, Summary of the morphological parameters of the femur measured using microfocus computer tomography (μ CT). D, μ CT images of femurs of SAMP6 and S5 mice. E, the time-course change of OBL.

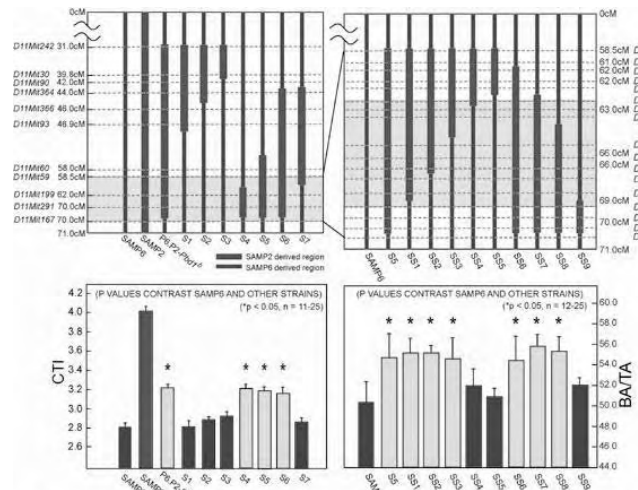

Fig. 2 Characteristics of initial seven subcongenic strains and second-generation nine-subcongenic strains. We used CTI and BA/TA for the index of relative bone mass because these values are quite well correlated ($R = 0.929$, $p < 0.0001$).

QTLs for Femoral BMD Identified in Two Separate Chicken Intercrosses Are Syntenic to Loci Controlling Human BMD. C. Rubin^{*1}, D. Wright^{*2}, A. Sahlqvist^{*1}, S. Kerje^{*1}, P. Jensen^{*3}, C. Ohlsson⁴, H. Mallmin⁵, S. Larsson^{*5}, O. Ekval^{*1}, O. Kämpe^{*1}, K. Johnsson⁶, L. Andersson^{*2}, A. Kindmark¹. ¹Dept. Med. Sciences, Uppsala University, Uppsala, Sweden, ²Dept. of Medical Biochemistry and Microbiology, Uppsala University, Uppsala, Sweden, ³IFM Biology, Linköping University, Linköping, Sweden, ⁴Dept. of Internal Medicine, The Sahlgrenska University Hospital, Gothenburg, Sweden, ⁵Department of Surgical Sciences, Uppsala University Hospital, Uppsala, Sweden, ⁶Department of Surgical Sciences, Uppsala University, Uppsala, Sweden.

We have previously conducted QTL-analysis for femoral bone traits in an intercross between the Red Junglefowl (RJ), the wild ancestor of domestic chicken, and White Leghorn (WL) strain L13 (L13), a breed heavily selected for egg-production. We have now performed QTL-analyses in a replicate intercross where RJ was intercrossed to another strain of White Leghorn (the OS-strain). The two WL-strains have been reproductively separated for approximately 50 years, during which genetic recombination has taken place within each strain. QTL-analyses in the OS/RJ-intercross may therefore considerably confine confidence intervals for shared QTLs.

From the RJ/L13-intercross, 337 F2-individuals were genotyped for 548 informative genetic markers and pQCT and DXA were used to measure femoral BMD and bone structure. From the RJ/OS-intercross, 700 F2-individuals were genotyped for 384 informative SNP-markers and were subjected to femoral bone phenotyping by pQCT. QTLs were mapped in the software QTL-express using forward selection for loci with significant marginal effects with bodyweight included as a covariate.

In the RJ/L13 intercross eight QTLs were identified as significant on the 5% genome-wide level. Six QTLs were identified in the RJ/OS intercross, three of whose confidence intervals overlap with RJ/L13 QTLs. The three QTLs which overlap are situated on chicken chromosomes 1, 2 and 3 and affect total and cortical BMD (chr. 1), BMD (chr. 2) and bone size as well as BMD (chr. 3). The three overlapping QTL-regions are syntenic to human Xp22 (chr. 1), 18p11 and 18q11-q12 (chr. 2), and 6q21-q26 (chr. 3). A QTL for BMD on human Xp22 has previously been reported, as have murine QTLs in the region syntenic to Xp22. Similarly, a human QTL for BMD of lumbar spine has previously been identified on 18p11. A QTL affecting BMD and biomechanical strength in mice is located in a region syntenic to human 6p22-23. The three chicken loci will be fine-mapped, mapped further for interspecies synteny to mouse and man and will be searched for presence of selective sweeps, the latter of which could help confine QTL-intervals greatly. Furthermore, 500 femoral bone RNA-samples collected from RJ/OS F2-individuals will be used for upcoming eQTL-studies.

Mouse Chromosome 4 Homologous with Human 1p36: Fine Mapping Femoral vBMD and Trabecular Microstructure. K. L. Shultz, L. G. Horton, H. F. Coombs^{*}, V. E. DeMambro, C. J. Rosen, W. G. Beamer. The Jackson Laboratory, Bar Harbor, ME, USA.

We previously reported (28th ASBMR Mtng) that B6.C3H-4-7 congenic mice carried 15 Mb of C3H alleles from Chr 4 that regulate femoral volumetric (v)BMD and trabecular BV/TV. Ten sublines were developed from B6.C3H-4-7 mice to fine map this bone genetic regulation. Isolated femurs from groups (4 mo old) of female and male mice (B6 controls + new sublines) were phenotyped by pQCT for total femoral vBMD and by Micro CT40 for distal trabecular microstructure (BV/TV, trabecular no., thickness). A haplotype map with 11 chromosomal markers made from genotyping the 10 sublines revealed C3H Chr 4 segments of 0.8 to 12 Mb in size. This genetic map was correlated with bone phenotypes to find patterns of segregation indicative of C3H alleles with bone regulation.

vBMD increased in females from 6 sublines that share a region from 135.00-136.42 Mb, while 4 sublines were B6-like. Males from these 6 sublines also increased vBMD, indicating the presence of a gene(s) that regulates vBMD in both sexes. Males of two sublines with C3H alleles in the 126.86-132.69 Mb region also increased vBMD in male but not female femurs, indicating a second region with male-specific regulation.

Data for female distal trabecular microstructure did not reveal a clear segregation pattern indicative of BV/TV, trabecular number, or thickness regulation. However, B6.C3H-4-19 subline females showed a consistent negative effect for all three phenotypes when compared to B6 controls, suggesting C3H alleles in this subline represent a third regulatory locus. Males carrying C3H alleles in the 126.86-132.69 Mb region showed increased BV/TV and trabecular thickness, while males carrying C3H alleles in the 135.00-136.42 Mb region had increased BV/TV and trabecular number.

The Chr 4 region from 135.00-136.42 Mb carries ~28 known or predicted genes. Examination of the Novartis gene expression database for tissue specific expression showed strong expression of 3 genes (Cnr2, E2f2, Zbtb40) and weak expression for 2 genes (Luxp1, Aof2) in bone/bone marrow. Cnr2 ^{-/-} mice have reduced osteoclast activity and low bone mass (Ofek et al 2006). Akp2 (Klein et al, 27th ASBMR Mtng) reported as a candidate for B6.DBA/2 congenic is distal to this region identified by our B6.C3H-4 congenic sublines. The larger proximal region is 5.85 Mbp and contains ~100 known or predicted genes.

In summary, 1) congenic sublines partitioned a major QTL into components affecting bone density and microstructure; 2) Chr 4 has at least two distinct bone QTLs: A, 1.41 Mb, females & males, vBMD & trabeculae; B, 5.85 Mb, males, vBMD & trabeculae; and 3) gene expression databases suggest several candidate genes in region A; while the male-specific region, B, requires further mapping.

Heritability of Serum 25-hydroxyvitamin D Suggests Genetic Factors Contribute to Endogenous Vitamin D Production. E. A. Streeten, K. Hairston^{*}, K. A. Ryan^{*}, B. D. Mitchell, A. R. Shuldiner^{*}. Endocrinology, Diabetes and Nutrition, University of Maryland School of Medicine, Baltimore, MD, USA.

Vitamin D deficiency is an important contributor to poor bone health and fractures. The main source of Vitamin D is skin production responding to UVB sunlight, converting 7-dehydrocholesterol precursors to Vitamin D3. With similar occupational sun exposure in the summer, individual serum 25(OH)D levels have been shown to vary widely. Possible explanations for this variability include genetic factors. We hypothesize that genetic factors play a role in endogenous production of Vitamin D and its metabolites.

In 1151 participants of the Amish Family Osteoporosis Study (AFOS), 25(OH)D was measured by Diasorin RIA, intact PTH (iPTH) was measured by RIA and serum calcium (Ca), phosphorus (P), alkaline phosphatase (AP) were measured by multichannel analysis. BMD was measured at the hip, spine, forearm and whole body by DXA (Hologic). Clinical information collected included over-the-counter supplements. All participants had normal values of serum calcium (8.5-10 mg/dl) and creatinine (<1.3 mg/dl) and were not on chronic glucocorticoids. The heritability (h²) of these measures was estimated using a pedigree-based likelihood approach. Associations of BMD (corrected for age, sex and BMI) with 25(OH)D and iPTH (both corrected for season) was estimated by regression analysis.

The mean age (±SD) of AFOS participants was 50.5 ± 15.6 (range 18-91); 481 men and 680 women. The mean 25(OH)D was 22.4 ± 7.3 ng/ml (range <5 to 51.2); higher in summer (June-Aug) 25.5 ± 6.9, than in winter (Dec-Feb), 18.9 ± 6.3 (p<0.0001). PTH was higher in winter (58.7 ± 18.1 pg/ml) than in summer (53.9 ± 18.5) (p=0.01). 25(OH)D levels were in the deficiency range (<15 ng/ml) in 17%, insufficiency range (16-29 ng/ml) in 69% and sufficiency range (>30 ng/ml) in 14%. Of those with 25(OH)D<30 ng/ml, 24% had secondary hyperparathyroidism (iPTH >65 pg/ml). Heritability (h²) was 0.35 ± 0.06 for 25(OH)D, 0.32 ± 0.06 for iPTH, 0.34 ± 0.06 for Ca, 0.25 ± 0.06 for P, 0.35 ± 0.06 for AP and 0.22 ± 0.06 for ln PTH/25(OH)D. BMD (corrected for age, sex, BMI) at total hip (but not other sites) was correlated with 25(OH)D (corrected for season), but only in those with 25(OH)D >30 ng/ml (p=0.03). BMD (corrected for age, BMI) was correlated with iPTH (corrected for season) for spine and hip in women (p=0.04, 0.02) but not in men (p=0.78, 0.48). Vitamin D supplements were taken in 41% (136/329); daily dose mean 398 IU, median 400 IU).

Vitamin D insufficiency and deficiency are common in the Amish and the serum level of 25(OH)D is heritable. The moderate heritability of 25(OH)D and other factors involved in Vitamin D homeostasis (Ca, P, iPTH) suggest that genetic factors may be important to endogenous Vitamin D production.

Genetic Loci for Bone Structure and Strength Identified in Inbred COP and DA Rats. Q. Sun¹, I. Alam¹, L. Liu^{*2}, D. L. Koller², L. G. Carr^{*3}, M. J. Econs³, T. M. Foroud², C. H. Turner¹. ¹Biomedical Engineering, Indiana University, Indianapolis, IN, USA, ²Medical and Molecular Genetics, Indiana University, Indianapolis, IN, USA, ³Medicine, Indiana University, Indianapolis, IN, USA.

Bone strength and structure are major determinants of osteoporotic fracture. These two phenotypes are under substantial genetic regulation and the identification of the genes contributing to their observed phenotypic variation may provide important insight regarding the genetics of osteoporosis and fracture risk. Previous studies have shown that the Copenhagen 2331 (COP) and Dark Agouti (DA) rats have significant differences in bone strength despite their similar body mass. Thus, these inbred rat strains may provide a unique resource to identify the genetics underlying the phenotypic variation in bone strength and structure. A sample of 828 (405 males and 423 females) COP x DA F2 progeny had extensive phenotyping for bone structure measures including cortical bone area and polar moment of inertia at the femur midshaft and total, cortical and trabecular bone areas at the distal femur, and lumbar vertebra 5 (LV5). Bone strength phenotypes included ultimate force of femur and LV5. These skeletal phenotypes were measured using peripheral quantitative computed tomography (pQCT) and mechanical testing. A whole-genome 20 cM screen was conducted in the F2 rats. Genetic marker maps were generated using MARMAKER/EXP from the F2 data and compared with maps from the Rat Genome Database (RGD). The recombination-based maps were then used for genome-wide linkage analyses to detect linkage to the bone structure and strength phenotypes. Permutation testing was employed to obtain the thresholds for genome-wide significance (p<0.01). A very significant QTL for femur midshaft cortical structure and strength was identified on the distal part of chromosome (Chr) 1 with a LOD score of 33; evidence of linkage was found with both the male and female F2. In addition, Chrs 6, 7, 10, 13, and 15 were linked to femur midshaft structure. Linkage for femur trabecular structure was detected on the proximal part of Chr 1 and Chr 14. Additional QTL for femur strength were identified on Chrs 6 and 15. For LV5, Chrs 2, 16, and 18 harbored QTL for cortical structure. Trabecular structure for LV5 was linked to Chrs 1, 7, 12, and 18. Our study demonstrates genetic linkage for bone structure and strength on several rat chromosomes. The strongest linkage was discovered for several femoral phenotypes on chromosome 1 harboring two distinct QTLs, one at each end.

Oral Bisphosphonate Treatment Prevents the Changes of Bone Mineral Density and Bone Biomarkers in Postmenopausal Japanese Women with Early Breast Cancer Treated with Aromatase Inhibitor. O. Chaki, K. Kurasawa*, T. Ishikawa*, Y. Nomura*, H. Yoshikata*, R. Kikuchi, F. Hirahara*. Yokohama City University, School of Medicine, Yokohama, Japan.

Many clinical trials have demonstrated the efficacy and safety of long-term adjuvant treatment with aromatase inhibitors (AIs) in women with breast cancer. Whereas aromatase inhibitors are generally well tolerated and, compared with tamoxifen, offer superior efficacy and safety, in certain other respects they are associated with the loss of bone mineral density and an increased risk of fracture. Bisphosphonates are effective inhibitors of osteoclast activity and bone resorption, and are standard treatments for osteoporosis. Bisphosphonates are now being incorporated into breast cancer treatment regimens in order to combat osteoporosis caused by ovarian suppression, chemotherapy treatment, aromatase inhibitors and the postmenopausal state itself.

The aim of our study was to investigate changes in bone loss and bone turnover associated with aromatase inhibitor treatment and the effectiveness of oral bisphosphonate treatment. We conducted an open prospective study in 34 postmenopausal women treated with anastrozole for an early breast cancer. Fourteen patients were treated with alendronate (5mg/day). Bone mineral density (BMD) was measured using DXA at baseline and one year later. The bone turnover markers bone alkaline phosphatase (BAP) and urinary NTX were measured at baseline and 1,3 and 6 months later. In the aromatase inhibitor group, there was a marked bone loss at the lumbar spine by -2.8% ($p < 0.001$) and hip by -1.3% ($p < 0.05$), but there was no significant increase in bone turnover (+16.4% for BAP and +5.3% for uNTX). BMD of bisphosphonate treatment group was increased at the lumbar spine by 2.3% and hip by 7.8%.

In conclusion, anastrozole treatment of breast cancer induces an accelerated bone loss but doesn't induce an increased bone turnover in Japanese postmenopausal women with breast cancer. This bone loss is suppressed by oral bisphosphonate treatment completely.

Dynamic Genomic and Proteomic Patterns of Osteosarcoma Metastasis to Lung: Implication of Macrophage Migration Inhibitory Factor and Tumor Necrosis Factor for Lung Metastasis. B. White¹*, C. Wilburn²*, G. Holt¹*, H. Schwartz¹*, R. Caprioli³*, L. Gerstenfeld⁴, R. Caldwell¹. ¹Department of Orthopaedics and Rehabilitation, Vanderbilt University School of Medicine, Nashville, TN, USA, ²Department of Medicine/Clinical Pharmacology, Vanderbilt University School of Medicine, Nashville, TN, USA, ³Department of Biochemistry, Mass Spectrometry Research Center, Vanderbilt University School of Medicine, Nashville, TN, USA, ⁴Department of Orthopaedic Surgery, Boston University Medical Center, Boston, MA, USA.

Despite successful treatment of osteosarcoma (OSA), death from lung metastasis occurs in >30% of patients. Novel molecules permissive for OSA metastasis to lung may improve treatment outcome by existing as prognostic markers or therapeutic targets. The rationale of this study was to examine differences in common osteoblastic gene expression between high and low metastatic OSA and mine the proteome for differences in protein expression. We focused on transcript and protein profiles from an established OSA model using northern blotting analyses, 2-dimensional difference gel electrophoresis (2D-DIGE) and MALDI-TOF mass spectrometry. This balb/c murine model of OSA is characterized by orthotopic primary tumor growth, a period of minimal residual disease, spontaneous pulmonary metastasis, and clonally related variants (K7M2 and K12). K7M2 cells are aggressive and highly metastatic, whereas K12 cells are less aggressive with infrequent pulmonary metastases. Analysis of gene expression during mineralization assays revealed dynamic differences in mRNA levels of COLA1, APase, and OC between the K7M2 and K12 OSA cells in both the proliferative and extracellular matrix deposition stages. 2D-DIGE and MALDI protein profiling demonstrated a comprehensive proteomic evaluation between the K12 and K7M2 OSA cells, revealing several differentially expressed proteins such as macrophage migration inhibitory factor (MIF), ubiquitin, and thymosin beta-4. Computer modeling algorithms further implicated VEGF, TNF, and IL-1B as key mediators in OSA metastasis to lung. Western blotting and IHC validated these findings as we observed increased TNF and MIF expression in the metastatic cells. Taken together, decreased levels of osteoblast markers in K7M2 cells demonstrate dedifferentiation, while up-regulation of MIF and TNF in highly invasive K7M2 cells represent molecular mechanisms to compromise host immunosurveillance during metastasis. These studies are among the first to implicate MIF and TNF as potential biomarkers and therapeutic targets for OSA lung metastasis. These data also represent a rational, comprehensive approach to evaluate the cellular proteome to identify proteins that may be causally associated with metastasis.

Melanoma Bone Metastasis: Osteoclasts Cannot Be Excluded. L. C. Dumitrescu, J. R. Edwards, J. A. Sterling, G. R. Mundy. Center for Bone Biology, Vanderbilt University Medical Center, Nashville, TN, USA.

Recently, there has been much controversy on the role of osteoclasts in bone metastasis in melanoma. Jones et al (2006) have suggested that melanoma bone metastases are not mediated by osteoclasts. Since we have been unable to find convincing evidence that bone osteolysis in cancer ever occurs independent of osteoclasts, we employed the melanoma cell lines B16F10 and Mel A along with primary bone marrow-derived cells to investigate and characterize the effect of this aggressive tumor on osteoclast formation and function, using bone resorption assays, enzymatic and immunohistochemical analysis and RT-PCR for melanoma-derived osteolytic factors. Treatment of primary bone marrow-derived osteoclast-precursors with M-CSF (30ng/ml), RANKL (50ng/ml) and media conditioned by B16F10 or Mel A cells showed a significant dose-dependent increase in the formation of TRAP+ multinucleated cells. These cells were also vitronectin receptor and calcitonin receptor positive. Addition of only 5% B16F10 conditioned media to bone marrow cultures stimulated the formation of 47 ± 1 TRAP+ cells/well, compared to 5.5 ± 2.5 in control treated cultures ($p < 0.05$). A similar significant response was observed with media conditioned by Mel A cells, with 49.5 ± 10.5 TRAP+ cells/well seen in treated cultures compared to 8.5 ± 0.5 in control cultures ($p < 0.01$). The quantity of TRAP+ cells formed correlated with a dose-dependent increase in bone resorption and lacunae pit formation on dentine discs. RT-PCR analysis showed clear expression of PTHrP on B16F10 and Mel A cells, although RANKL was not expressed in either cell type. These studies demonstrate a clear interaction between melanoma cells and osteoclast precursors through the release of potent soluble factors, and indicate that melanoma cells are capable of stimulating osteoclast activity. These findings are consistent with a central role for osteoclasts in the extensive osteolysis observed in melanoma bone metastases.

A Phase II Pilot Study of Safety and Effects on Bone Resorption of AZD0530 in Prostate or Breast Cancer Patients with Bone Metastases. R. D. Finkelman¹, F. M. Torti²*, A. Lipton³*, R. A. Hannon⁴, A. Hussain⁵*, C. Evans⁶*, M. Akilu²*, R. Iacona¹*, A. Swaisland⁷*, M. Stuart⁷*. ¹AstraZeneca, Wilmington, DE, USA, ²Wake Forest University Comprehensive Cancer Center, Winston Salem, NC, USA, ³Hershey Medical Center, Hershey, PA, USA, ⁴Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom, ⁵Greenebaum Cancer Center, University of Maryland School of Medicine, Baltimore, MD, USA, ⁶University of California, Davis, Sacramento, CA, USA, ⁷AstraZeneca, Alderley Park, Macclesfield, United Kingdom.

We have reported previously that once daily dosing for 14 days with AZD0530, a highly selective and orally available Src kinase inhibitor with Bcr-Abl activity, resulted in a dose-dependent reduction of bone resorption markers β CTx and NTx in healthy male volunteers (Hannon et al, ASBMR 2005). A similar outcome was evident in preliminary, unvalidated data from cancer patients with advanced disease. The present study is the first to investigate AZD0530 in cancer patients specifically with metastatic bone disease, and is due to start enrollment in September 2007. Patients with prostate or breast cancer and at least one radiographically confirmed metastatic bone lesion will be randomized to one of two treatment arms: (1) AZD0530, 175 mg once daily; or (2) zoledronic acid, 4 mg iv infusion, every 4 weeks. Patients must have been on stable therapy for their cancer for at least 8 weeks with no anticipated change of therapy for 4 weeks after randomization. Patients will continue on their present therapy during the study. Patients must have had no previous exposure to bisphosphonates. Concomitant chemotherapy with cytotoxic or novel molecularly targeted agents is not allowed on study or within 4 weeks prior to study entry. Concomitant therapy with bisphosphonates is not allowed on study for patients randomized to the AZD0530 treatment arm. Fasted serum and urine samples for assessment of bone turnover biomarkers β CTx, NTx, bone ALP, PINP, ICTP, and TRAP 5b will be collected at baseline and at 1, 2, and 4 weeks. PTH, PTHrP, calcium, phosphate, and total ALP will also be assessed in serum at the same timepoints. Serum PSA will be assessed in patients with prostate cancer at baseline and at 4 weeks. Changes from baseline will be compared between treatment arms. Data from this study will be used to determine the future development of AZD0530 in the treatment of metastatic bone disease.

Zoledronic Acid Decreases Serum Low-density Lipoprotein Cholesterol in Multiple Myeloma Patients. G. Martini¹, A. Gozzetti^{*2}, L. Gennari¹, S. Salvadori^{*1}, D. Merlotti¹, A. Avanzati^{*1}, B. Franci^{*1}, M. Campagna^{*1}, E. Lauria^{*2}, R. Nuti¹. ¹Metabolic Disease Unit, University of Siena, Siena, Italy, ²Hematology and Transplants Division, University of Siena, Siena, Italy.

Nitrogen-containing bisphosphonates (N-BPs) have been designed to inhibit osteoclast-mediated bone resorption and therefore they are the most widely used and effective anti-resorptive agent for the treatment of diseases in which there is an increase of osteoclastic resorption as postmenopausal osteoporosis, Paget's disease and tumor-associated osteolysis. The mechanism of action of these drugs has not been completely clarified but it has been observed that N-BPs may inhibit squalene synthase, as ibandronate, or farnesyl pyrophosphate synthase, as alendronate or pamidronate, inducing also a reduction of cholesterol biosynthesis. Zoledronic acid (ZA) represents a novel N-BPs which has also antitumor activity. "In vitro" studies suggest that ZA can inhibit cholesterol production, but 90% of the biosynthesis was rescued after 48 hours.

To explore the effects of ZA on serum lipids "in vivo", we studied 26 patients with smoldering myeloma at diagnosis. Sixteen patients were treated with ZA (4 mg ev) at baseline and at months 1, 2, 4 and 6. The remaining 10 served as controls. At baseline and after 1, 3 and 6 months, a blood sample was drawn from each patient to evaluate total cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C) and C-terminal telopeptide of Type I collagen (CTX). In the control group no significant changes were observed throughout the study period for any of the biochemical variables. As expected, CTX decreased significantly by 40-50% after ZA administration. In treated patients, we observed a progressive and significant reduction of TC with a maximum decrease of 13% at 6 months; moreover LDL-C decreased by 21% at 6 months while no significant differences were appreciated as regards HDL-C and TG. Also the indexes of cardiovascular risk improved after ZA administration: TC/HDL-C ratio progressively decreased by 18% and HDL-C/LDL-C ratio increased by 35% showing an effect that appears to be cumulative.

In conclusion we demonstrated that ZA, a third class of N-BPs, is able to alter lipid profile more than older N-BPs as pamidronate or neridronate. This effect can be due to the potency of ZA to inhibit FPP synthase that is about 70-fold than pamidronate.

Characterization of Leupaxin as a Focal Adhesion-associated Protein in Prostate Cancer Cells. A. Gupta. Biomedical Sciences, Dental School, University of Maryland, Baltimore, Baltimore, MD, USA.

We have identified the presence of leupaxin (LPXN), which belongs to the paxillin extended family of focal adhesion-associated adaptor proteins, in prostate cancer (PC) cells. Previous studies have demonstrated that LPXN is a component of the podosomal signaling complex found in osteoclasts, where LPXN was found to associate with the protein tyrosine kinases Pyk2 and c-Src, and the protein-tyrosine phosphatase-PEST (PTP-PEST). In the current study, LPXN was detectable as a 50 kDa protein in PC-3 cells, a bone-derived metastatic androgen-independent prostate cancer cell line. Second, we demonstrate that the subcellular localization of LPXN is both cytoplasmic and nuclear, suggesting the possibility of nucleo-cytoplasmic shuttling in PC-3 cells. Third, in PC-3 cells, LPXN was also found to associate with Pyk2, c-Src, and PTP-PEST. Fourth, a siRNA-mediated inhibition of LPXN expression resulted in decreased in vitro PC-3 cell migration. Fifth, a recombinant adenoviral-mediated overexpression of LPXN resulted in an increased association of Pyk2 with LPXN, whereas a similar adenoviral-mediated overexpression of PTP-PEST resulted in decreased association of Pyk2 and c-Src with LPXN. Sixth, the overexpression of LPXN in PC-3 cells resulted in increased migration, as assessed by in vitro Transwell migration assays. On the contrary, the overexpression of PTP-PEST in PC-3 cells resulted in decreased migration. Finally, overexpression of LPXN resulted in increased activity of Rho GTPase, which was decreased in PTP-PEST-overexpressing cells. Our data demonstrates that LPXN forms a signaling complex that may play a role in PC-3 cell function.

Effects on Bone Turnover of the Potent, Once-Daily, Oral Src Inhibitor AZD0530 in Patients with Advanced Solid Malignancies. R. A. Hannon¹, R. D. Finkelman², G. Clack³, R. B. Iacona^{*2}, P. Baker^{*3}, M. Rimmer^{*3}, F. Gossiel^{*1}, I. C. Smith^{*3}, A. Robinson^{*3}, R. Eastell^{*1}. ¹Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom, ²AstraZeneca, Wilmington, DE, USA, ³AstraZeneca, Alderley Park, Macclesfield, United Kingdom.

AZD0530 is a potent, orally active, once-daily Src inhibitor with Bcr-Abl activity that modulates multiple key signaling pathways in cancer and has potential activity in many different tumor types. We have previously demonstrated significant AZD0530 dose-dependent reduction in bone resorption in healthy males. In the present Phase I study, we assessed the effect of AZD0530 on bone resorption in adult patients with advanced solid malignancies resistant to standard therapy.

Patients were randomized into three parallel groups to receive AZD0530 50, 125, or 175 mg/day. After a single dose on day 1 followed by 6 days washout, patients received once-daily doses for 21 consecutive days. Fasted serum and second-morning void urine were collected on

day 1 predose and on days 2, 3, 17, and 28. Serum cross-linked C-terminal telopeptide of type I collagen (sCTX) and urinary cross-linked N-terminal telopeptide expressed as a ratio to urinary creatinine (uNTX) were assessed as markers of bone resorption. An analysis of covariance model was fitted to the log-transformed baseline-scaled ratio data at day 28, with treatment as a fixed-effect factor and log-transformed baseline (predose day 1) as a covariate.

There were significant reductions in sCTX in all treatment groups and in uNTX at 125 and 175 mg. Percent changes from baseline at day 28, derived from the adjusted geometric mean baseline-scaled ratios, were 36.3% (95% CI 57.6%, 4.4%; P=0.030; n=12), 61.7% (95% CI 73.6%, 44.5%; P<0.001; n=14), and 74.5% (95% CI 83.3%, 61.3%; P<0.001; n=11) for sCTX in the 50, 125, and 175 mg treatment groups, respectively; and 12.7% (95% CI 32.6%, 13.1%; P=0.293; n=12), 48.3% (95% CI 59.2%, 34.4%; P<0.001; n=14), and 50.1% (95% CI 61.8%, 34.7%; P<0.001; n=11) for uNTX, respectively. There was a dose-response trend for reductions in biomarkers.

The significant reductions in the biomarkers are in accordance with inhibition of osteoclast-mediated bone resorption by suppression of Src activity. The reduction (>60%) in sCTX at 125 and 175 mg of AZD0530 is similar to reductions reported with bisphosphonate therapy. These data suggest that AZD0530 may have therapeutic benefit in osteoclast-driven metastatic bone disease in addition to its inhibitory activity on Src in tumor cells. The trend for dose-dependent changes in biomarkers indicates that the maximum tolerated dose should be taken forward in further development.

A New Urine Assay for Sensitive Detection and Assessment of Cancer-induced Skeletal Perturbations. D. J. Hillegonds¹, D. W. Burton^{*2}, J. S. Vogel¹, E. Denk^{*3}, T. R. Walczyk³, M. Yang^{*4}, S. Vijayakumar^{*5}, D. A. Herold^{*2}, L. J. Deftos², R. L. Fitzgerald². ¹Center for Accelerator Mass Spectrometry, Lawrence Livermore National Laboratory, Livermore, CA, USA, ²University of California, San Diego, San Diego, CA, USA, ³Laboratory of Human Nutrition, ETH Zurich, Zurich, Switzerland, ⁴Anticancer, Inc., San Diego, CA, USA, ⁵Davis Cancer Center, University of California, Davis, Sacramento, CA, USA.

The need for earlier detection and improved management of metastatic bone disease has driven the search for new bone remodeling biomarkers, but existing techniques are insufficiently sensitive for reliable use in individuals. We report on a novel tracer technology for bone health wherein one calcium-41 (41Ca) dose fully equilibrates with the living skeleton and remains measurable in urine and blood for many years. Urinary 41Ca/Ca is dominated by tracer incorporation and re-release from mineralized bone. In healthy humans, intra-individual urinary variability averaged 3.3+/-0.2% diurnally and 6+/-3% over 200 days. In a preclinical prostate cancer metastasis model, serum 41Ca/Ca directly and significantly correlated with bone disruption, tumor size, serum calcium, osteoprotegerin, and parathyroid hormone-related protein. We posit that longitudinal urinary 41Ca/Ca measurements may sensitively reveal skeletal perturbations, enabling improved clinical management through rapid identification of therapeutic success and non-invasive detection of the earliest stages of cancer growth in bone.

Five Years Results of Bisphosphonate Treatment in Long-term Survivors of Highly-Malignant Osteosarcoma. G. Holzer, M. Dominkus^{*}, R. Kotz^{*}. Department of Orthopaedics, Medical University of Vienna, Vienna, Austria.

Purpose: Two thirds of long-term survivors of highly-malignant osteosarcoma treated with chemotherapy protocols including high-dose methotrexate (MTX) have low bone mineral density (BMD) and one third report about fractures after completion of chemotherapy.

Methods: Ten patients with BMD < 2.5 STD (6 male, 4 female; mean age: 33 {plusmn} 1.4 years) participated in this study. Patients received risendronate orally once daily (5 mg) or weekly (35 mg) plus a calcium / vitamin D combination daily. BMD of lumbar spine (LS) and proximal femur of the non-operated side (PF) were measured by dual energy X-ray absorptiometry at twelve months after beginning of the treatment (mean time after chemotherapy at beginning of oral bisphosphonate treatment: 13.8 {plusmn} 2.3 years).

Results: After five years of oral bisphosphonate treatment BMD increased at a mean by 2.28 % in the LS, whereas in the PF no changes were seen. No fracture occurred during the study time. Conclusions: It was shown that even in long-term survivors of highly-malignant osteosarcoma treated with chemotherapy protocols including MTX increases in BMD values are possible.

Activity of the Akt Inhibitor Perifosine and Heat Shock Protein (HSP)-90 Inhibitor 17-(Dimethylaminoethylamino)-17-Demethoxygeldanamycin (17-DMAG) in Modulating Osteoclastogenesis and the Bone Marrow Microenvironment (BMM) in Multiple Myeloma (MM). A. Huston¹, X. Leleu², X. Jia², J. Anderson³, S. Vallet², A. Roccaro², A. Moreau², J. Runnels², H. Ngo², E. Hatjiharissi², G. D. Roodman³, Y. Tai², P. Sportelli⁴, T. Hideshima², P. Richardson², K. Anderson², I. Ghobrial². ¹Hematology/Oncology, James P. Wilmot Cancer Center, Rochester, NY, USA, ²Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, USA, ³Medicine-Hematology/Oncology, University of Pittsburgh, Pittsburgh, PA, USA, ⁴Keryx Biopharmaceuticals, New York, NY, USA.

Alterations in the BMM are thought to be critical to MM pathogenesis. The PI3K/Akt and HSP-90 pathways have previously been shown to be dysregulated in MM. We hypothesize that combining two agents that interact at the level of Akt will lead to synergistic cytotoxic activity among MM cells, osteoclastogenesis and the BMM. Effects of treatment with perifosine (5-10µM; Keryx, NY) and 17-DMAG (50nM; NCI) upon the BMM were evaluated through osteoclastogenesis and osteoclast (OCL) precursor development assays, co-culture of MM cells with bone marrow stromal cell (BMSC) and endothelial cells, in vitro capillary formation, and migration/adhesion assays in the presence/absence of stromal derived factor-1 (SDF-1) and vascular endothelial growth factor (VEGF).

Perifosine and 17-DMAG induced a near complete inhibition of OCL formation. Effects were observed regardless of perifosine treatment timing (100% inhibition first vs. final week), vs. 17-DMAG (100% inhibition first vs. 60% final week). CFC assays for CFU-GM development resulted in significant inhibition after 17-DMAG treatment, as compared to perifosine or control (mean 2 ± 0.5 colonies/well vs. 18 ± 3 vs. 20 ± 3 ; $p=0.01$ 17-DMAG vs. control). Treatment with perifosine, 17-DMAG and the combination resulted in significant inhibition in MM cell growth following co-culture with BMSCs ($p<0.001$). Addition of IL-6 or IGF-1 resulted in MM cell proliferation, which was blocked by perifosine, 17-DMAG or the combination ($p=0.013$). Co-culture of HUVEC endothelial cells with MM cells or addition of VEGF to MM cells resulted in increased proliferation, which was blocked by the combination of agents ($p=0.02$ in HUVEC co-culture system; $p=0.024$ with VEGF). Similarly, perifosine, 17-DMAG and the combination significantly inhibited MM.1S cell migration (2.5-fold inhibition) and adhesion in the presence of SDF-1 or VEGF.

The PI3K/Akt and HSP-90 pathways play a critical role in regulating the BMM in MM, including OCL formation, angiogenesis and MM cell migration and adhesion. Targeting these pathways with perifosine and 17-DMAG represents an attractive approach for modulating the BMM in MM.

Prostaglandin E2 (PGE2) Receptor EP4 Antagonist Attenuates Osteolysis Due to Cancer Metastasis. M. Takita¹, M. Inada¹, M. Hirata¹, T. Maruyama², C. Miyaure¹. ¹Department of Biotechnology and Life Science, Tokyo University of Agriculture and Technology, Koganei, Tokyo, Japan, ²Discovery Research Laboratory, Minase Research Institute, Ono Pharmaceutical, Co., Ltd., Osaka, Japan.

Bone metastasis of cancer is accompanied by severe bone destruction with increased bone resorption. We recently identified that prostaglandin E2 (PGE2)-induced osteoclast formation was mediated by RANKL expression in osteoblasts, EP4 is the major PGE receptor than in the other EP subtypes (EP1-EP3). Recent studies suggest a possible role of EP4 receptor on cancer growth, but the roles of PGE2 and EP4 on host osteoblast in bone metastasis is still unclear. Here we examine the effects of EP4 antagonist, a selective inhibitor of EP4 signaling in bone destruction due to malignant melanoma. When mice were injected with B16 cells from the left heart ventricle, metastasis was detected as black spots in distal femurs on day12 after injection. In the B16 injected group, RANKL and cyclooxygenase-2 mRNA expression was elevated in the femur associated with B16 metastasis. PGE2 production was also elevated in B16 metastatic femur. Bone mineral density (BMD) measured by DEXA showed significant decrease of BMD in femur with B16 metastasis. Histomorphometry indicated that increased bone resorption at the site of B16 metastatic region, BV/TV and Tb.Th were significantly reduced, whereas Tb.Sp and ES/BS were increased, that was compared with femur of control mice. When EP4 antagonist was orally administered to mice injected with B16 cells, the osteolysis due to bone metastasis in femurs was suppressed, and the morphometric parameters were restored to the levels of femur of control mice. To know further mechanisms of B16 induced bone resorption, B16 cells were cultured with bone marrow cells and osteoblasts to evaluate the capacities of osteoclast formation. Contact with un-viable B16 cells fixed with formalin induced RANKL expression and PGE2 production in osteoblasts in the absence of bone-resorbing factors, and RANKL-dependent osteoclast formation was seen in the co-culture of bone marrow cells, fixed-B16 and osteoblasts. In the co-culture, EP4 antagonist completely inhibited osteoclast formation. These results suggest that cell-to-cell interaction between B16 and osteoblasts elicits PGE2 production by osteoblasts, and EP4 signaling induces RANKL expression in osteoblasts to form osteoclasts. Therefore, EP4 antagonist may be a possible candidate for the therapy of bone metastasis due to cancers.

Vitamin D Deficiency in Oncologic Patients - an Ignored and Potentially Life Threatening Condition, Possible Role of Increased Osteoblastic Activity in Induction of Hypocalcemia. S. Ish-Shalom¹, E. Segal^{*1}, S. Felder^{*2}, H. Yoffe⁻ Sheinman^{*2}, M. Volner^{*2}, E. Gez^{*2}, B. Raz^{*3}, Z. Shen-Or^{*3}, N. Haim^{*3}. ¹Bone and Mineral Metabolism Unit, Rambam Medical Center, Haifa, Israel, ²Department of Oncology, Rambam Medical Center, Haifa, Israel, ³Endocrine Laboratory, Rambam Medical Center, Haifa, Israel.

Introduction: Monthly administration of bisphosphonates to oncologic patients with skeletal involvement decreases bone turnover and in combination with poor vitamin D status and consequent decrease in calcium absorption may lead to life threatening hypocalcemia.

Routine or sporadic (based on medical history) evaluation of vitamin D status and subsequent vitamin D supplementation is not included in the national or international guidelines for bisphosphonate treatment for metastatic bone diseases.

The aim of this study was to assess vitamin D status and bone turnover in oncologic patients and their impact on the risk of hypocalcemia

Patients / Methods: Following IRB approval, we have assessed serum calcium, phosphate, albumin, 25(OH)D3, alkaline phosphatase and plasma PTH, procollagen type1 nitrogenous propeptide (PINP), C-terminal telopeptide of collagen (CTX) in 41 consecutive patients with metastatic bone disease, aged 58.2 ± 12.4 years, range 39- 86. The patients were treated with intravenous bisphosphonates, pamidronate or zoledronate, every 3-4 weeks.

Results: Serum albumin corrected calcium was $9.26 \text{ mg/dl} \pm 0.66$, range 6.7- 10.72. 25(OH)D3 serum concentration was $12.3 \pm 7.04 \text{ ng/ml}$ (max. value 27.6) ; vitamin D deficiency 25(OH)D3 $< 10 \text{ ng/ml}$ was observed in 17 pt (41.5%); vitamin D insufficiency 10 - 15 ng/ml in 10 pt (24.5%), vitamin D inadequacy $< 30 \text{ ng/ml}$ in 14 pt (35%). Plasma PINP was $115.686 \pm 192.6 \text{ ng/ml}$

Albumin corrected calcium strongly negatively correlated with PINP (R(- 0.517) ;P = 0.001) and with serum alkaline phosphatase (R(- 0.562), P< 0.001). Plasma CTX level was 0.265 ± 0.3 (within premenopausal range of 0.14 - 0.299 ng/ml) and has not correlated with albumin corrected calcium.

Conclusions: Vitamin D deficiency is common in oncologic patients; they are prone to hypocalcemia due to bisphosphonate treatment and absence of supplementation with calcium and vitamin D, especially in presence of increased osteoblastic activity.

Hypocalcemia and vitamin D deficiency are a preventable conditions; evaluation of vitamin D status and adequate calcium and vitamin D supplementation should be part of management of oncologic patients.

Microarray Analysis of Craniofacial and Appendicular Osteosarcoma. C. Kong^{*}, M. F. Hansen. Center For Molecular Medicine, University of Connecticut, Farmington, CT, USA.

Although both primary craniofacial and appendicular osteosarcoma are classified under the rubric of osteosarcoma, their clinical phenotypes are actually quite distinct. Most significantly, chemotherapy treatment leads to vastly different morbidity outcomes; craniofacial patients have a 40% survival rate compared to an 80% survival rate for appendicular osteosarcoma. Given the differences in outcome with conventional chemotherapeutic agents for this disease, there is a clear need to identify differentially expressed genes in these two tumor types as potential new targets for therapy. We have used the Illumina Human Cancer Panel microarray platform to compare craniofacial and appendicular osteosarcoma tumor cell lines to identify quantitative and qualitative alterations in gene expression that distinguish these two diseases. Our comparison of seven osteosarcoma tumor cell lines (1 craniofacial OS tumor cell line, USAC1, and 6 appendicular OS tumor cell lines: SAOS2, U2OS, MG63, HOS, SJSA1, OHS50) revealed distinct differences in gene expression with a bias towards alteration of expression of genes involved in cell DNA damage response and repair and bone signaling. Genes known to be involved in bone signaling such as FGF8, WNT2, WNT1, BMP4, WNT8B, and WNT5A were significantly overexpressed in the craniofacial osteosarcoma cell line when compared to the appendicular osteosarcoma cell lines. In contrast, genes involved in DNA repair such as MSH6, WRN, MSH3, FANCA, RECQL, XPA, PCNA, and BRCA2 were significantly underexpressed in the craniofacial osteosarcoma cell line when compared to the appendicular osteosarcoma cell lines. It is possible that at least some of the differences in phenotype between craniofacial and appendicular osteosarcomas are the result of the developmental pathways by which the bones of craniofacial and appendicular skeleton arise; the craniofacial bones arise from cranial neural crest cells while the appendicular skeleton arises from mesenchymal-derived cells. Our results indicate that craniofacial and appendicular osteosarcoma tumor cell lines show distinct patterns of gene expression. These patterns may provide insight into the molecular basis of these two diseases and possible targets for chemotherapeutic intervention.

A Comparative Study of Anti-resorptive and Anti-cancer Treatments in the Geometrical and Biomechanical Properties of Rat Femurs with Tumor-induced Osteolysis. T. Lee*, X. Wang*, L. Li*, K. Si-hoe*. Division of Bioengineering, National University of Singapore, Singapore, Singapore.

While much has been learned about the mechanisms of metastatic spread of cancer to bone, there has been little headway in establishing guidelines for monitoring the response of metastases to treatment. The objective of this study was to investigate the efficacy of two different treatments (Anti-Resorptive:Ibandronate and Anti-Cancer:Paclitaxel) of tumor induced osteolysis in terms of geometrical and biomechanical parameters.

A rat femur model for tumor-induced osteolysis using W256 cancer cells was adapted from a previous study. Of the 30 rats implanted with cancer cells, 12 were untreated (CANCER), 9 received Ibandronate (IBAN), and 9 received Paclitaxel (PAC). Another 12 underwent a sham operation (CONTROL). Micro-computer tomography (μ CT) scans of the femurs extracted post-mortem were used to quantify standard geometrical parameters such as bone volume (BV) and cross-sectional area (CSA). A 3-point bending test was used to assess the femurs' mechanical stiffness. Finally, serum levels of deoxypyridinoline (Dpd) were measured to obtain the degree of bone resorption, which in turn gave an indication of cancer activity.

A summary of the data recorded 30 days post-surgery (20 days for PAC group) are shown in Table 1. CSA data - taken at 25% of the total femur length from the distal end - from the CANCER group had the largest % difference between the left and right femurs (corresponding with a 13.4% increase in Dpd levels). IBAN rats showed the least % difference in CSA (38.1% drop in Dpd levels), followed by PAC rats. This pattern is repeated in the % differences in BV. The anti-cancer effect of PAC can be inferred from the lower Dpd levels of the PAC group (8.86% increase) as compared to the CANCER group. Both IBAN (2.85%) and PAC (-3.86%) maintained the stiffness properties of the operated femurs, with PAC being marginally more effective.

The initial results suggest the viability of this rat model for bone metastasis, and that IBAN was most effective in maintaining skeletal geometry. Interestingly, PAC seemed to be more capable of preserving the biomechanical properties of the femur, despite deterioration in its geometrical properties. A subsequent full scale study, with additional bone mineral content and histomorphological analysis, is in progress to confirm these results.

Group	Summary of Geometrical data and Dpd levels after 30 days			
	CSA Group %	BV Group %	Stiffness Group %	Dpd levels Group %
	Differences between Left (INTACT) and Right (TUMOR) Femurs	Differences between Left (INTACT) and Right (TUMOR) Femurs	Differences between Left (INTACT) and Right (TUMOR) Femurs	Differences between 0 and 30 day levels
CONTRO L	10.19	0.08	2.68	-13.9
CANCER	16.18	10.80	10.27	13.4
IBAN	3.63	-0.13	2.85	-38.1
PAC	12.54	5.35	-3.86	8.86

Wwox Knockout Mice Reveal Impaired Steroidogenesis, Defects in Bone Metabolism, and Formation of Osteosarcomas. R. I. Aqeilan*, M. Q. Hassan*, A. de Bruin*, S. Hussain*, S. Lee*, J. P. Hagan*, S. Volinia*, G. S. Stein*, J. B. Lian*, C. M. Croce*. ¹Department of Molecular Virology, Immunology and Medical Genetics, Comprehensive Cancer Center, Ohio State University, Columbus, OH, USA, ²Department of Cell Biology and Cancer Center, University of Massachusetts Medical School, Worcester, MA, USA.

The WW domain-containing oxidoreductase (WWOX) gene encodes a 46kDa tumor suppressor that is not present in the majority of cancer cell lines. The bona fide *in vivo* tumor suppressor activity was recently reported (Proc.Natl.Acad.Sci. 104:3949, 2007). Loss of both alleles of Wwox resulted in the formation of frequent juvenile osteosarcomas, while loss of one allele increased the incidence of spontaneous and chemically-induced tumors. In the present study we investigated WWOX function *in vivo* by examining Wwox deficient (Wwox^{-/-}) mice for phenotypical abnormalities. Wwox^{-/-} mice are significantly reduced in size and die between 3 and 4 weeks. Mutant homozygous mice are born with gonadal abnormalities, displayed impaired steroidogenesis and suffer of a metabolic disorder. Wwox^{-/-} mice exhibit a delay in bone formation and develop metabolic bone disease. LacZ staining of whole embryos revealed Wwox expression in the axial skeleton, craniofacial bones and limbs. An osteopenic phenotype was observed histologically and by μ CT, suggesting a high rate of bone resorption, particularly given the serum values of 50% lower calcium and 20% increased phosphate in the KO mouse. Higher acid phosphatase activity was observed in femur bone sections of KO mice compared to the WT, indicating increased osteoclast activity in KO mice. Gene expression in calvaria and femur bone was examined. A 30-40% reduction in Runx2 and alkaline phosphatase (Alkp) suggested a decrease in cells recruited into the osteoblast lineage. The mechanism for these findings was addressed. WWOX protein, via its first WW domain, interacts with several transcriptional activators containing proline-tyrosine motifs and suppresses their function. We find WWOX physically associates with Runx2, the principal transcriptional regulator of osteoblast differentiation, and functionally suppresses Runx2 transactivation ability in osteoblasts. Expression of Wwox in MDA-MB-231 breast cancer cells reduces the mRNA

levels of all Runx2 target genes related to metastasis to bone including MMP9, VEGF, and osteocalcin. These results reveal a vital requirement for WWOX in postnatal survival, steroidogenesis and suggest a central role of WWOX in bone metabolism and repression of tumor growth in bone in part coupled to regulation of Runx2 transcriptional activity.

Computed Microtomography of Bone Specimens in the Diagnosis of Bone Metastases. H. Libouban*, M. Audran*, E. Legrand*, N. Ifrah*, M. F. Basle*, D. Chappard*. ¹Faculté de Médecine, INSERM EMI 0335 - LHEA, Angers, France, ²CHU d'Angers, INSERM EMI 0335 - Service de Rhumatologie, Angers, France, ³CHU d'Angers, Service d'Hématologie, Angers, France.

Bone metastases occur in more than half the patients with advanced cancer. Breast and prostate cancers are specially metastasizing to bone. When anchored in the bone marrow, malignant cells release soluble factors which interact with bone cell metabolism. Bone metastases from breast or lung cancer usually exhibit a mixed osteolytic and osteosclerotic, with osteolysis usually predominating. Osteosclerosis is a common finding in prostatic cancer although lytic areas can be identified by computed tomography within the sclerotic lesions. Pathological examination of bone biopsies performed in metastatic areas plays a key role in the diagnosis of malignancies. However, histological analysis often needs several days. The recent development of microCT has allowed non-destructive and fast examination of bones.

118 patients who presented at least one bone metastasis (identified by scintigraphy), an overt myeloma or lymphoma or a monoclonal gammopathy of undetermined significance (MGUS) were studied. All patients had a bone biopsy studied by histomorphometry for the diagnosis of the malignant invasion. During the fixation time, the bone cores (7mm in diameter) were analyzed on a Skyscan microCT (resolution 11 μ m/pixel). On the 3D reconstructed models, signs of metastasis were searched: excess of bone resorption, focal disorganization of microarchitecture, plexiform bone apposition (woven bone), osteosclerosis. Results were compared with data obtained by histomorphometry using kappa test. Excellent agreement was obtained for bone metastases and overt myeloma or lymphoma. MicroCT identified excess bone resorption on trabecular surfaces when ES/BS were >11%. MicroCT failed to identify patients with smoldering myeloma (with little tumor mass) or some lymphomas with microresorption. MicroCT data are rapidly obtained (< one day) and can confirm the malignant invasion of bone marrow when excess of bone resorption/formation is obtained. However, these signs are not specific and must be confirmed by histopathological analysis.

Development of a Highly Sensitive High-throughput Mass Spectrometry-based Assay for Rat Procollagen Type I Propeptide (PINP). J. E. Hale*, B. Han*, L. V. Hale*, M. Sato*, J. You*, M. Copeland*. ¹Lilly Research Laboratories, Greenfield, IN, USA, ²Lilly Research Laboratories, Indianapolis, IN, USA, ³Indiana Center for Applied Protein Sciences, Indianapolis, IN, USA.

Type I procollagen aminoterminal propeptide (PINP) is a reliable marker of osteoblastic bone formation activity, and is routinely used in clinical trials. PINP has also recently been shown to be a reliable early bone formation marker in the rat. PINP is proteolytically derived from the type I procollagen molecule. Thus, serum level of PINP reflects new collagen matrix synthesis, the majority of which subsequently become newly mineralized bone. Currently the only commercially available assay for PINP is a radioimmunoassay for human PINP, which may not cross react with PINP from other species. It is important to have PINP assay for non-primate species to investigate the mechanism of bone formation and for preclinical development of drugs that can enhance bone formation.

We developed a highly sensitive, high-throughput mass spectrometry-based assay for PINP in rat plasma or serum that does not rely on antibody reagents. Cysteine sulphydryl groups in plasma or serum proteins were reduced and alkylated then digested with trypsin. The resulting peptides were separated by HPLC and the N-terminal tryptic fragment of the PINP was detected and quantified using tandem mass spectrometry by monitoring selected ion transitions upon high-energy fragmentation. The N-terminal glutamine residue was found to have quantitatively converted to pyroglutamate and an internal Asn residue was found to be deamidated to Asp.

Enrichment of PINP prior to HPLC-MS was necessary due to low levels of PINP in adult rats. This was achieved by combining reduction-alkylation of the serum proteins with a one-step precipitation of the majority of the serum proteins using acetonitrile. By optimizing the sample preparation method and HPLC conditions, up to 1000 samples could be processed in duplicates by a single person in one week. Circulating levels of PINP showed an age-dependent decrease in concentration. While PINP concentration in the 5 week-old rats was 200-250 nM, it dropped to 10-20 nM in the 9 month-old rats. Ovariectomy of adult female rats initially increased PINP, consistent with increased remodeling of the bone, which includes increased formation and resorption activities. Daily treatment of rats with parathyroid hormone (PTH) showed a statistically significant increase in PINP as has been observed in humans.

C-Reactive Protein, a Marker of Inflammation, in Patients with Osteoporotic Non-Traumatic Fractures. L. A. Holzer^{*1}, U. Willinger^{*2}, G. Holzer¹. ¹Department of Orthopaedics, Medical University of Vienna, Vienna, Austria, ²ENT Clinic, Medical University of Vienna, Vienna, Austria.

Purpose: Inflammation could be partially responsible for the aetiology of osteoporosis. C-reactive protein (CRP) is a sensitive marker of inflammation, tissue damage, and infection. The purpose of this study was to investigate the inflammatory status expressed by levels of high-sensitive CRP in patients with osteoporosis to assess a possible role of inflammation in the development of osteoporosis.

Methods: Eight hundred twenty-four individuals (495 female and 329 male, mean age: 63.2 ± 14.0 years) were examined at our institution. All individuals answered a questionnaire concerning history, had x-ray and densitometry of the lumbar spine, and, if possible, of the proximal femur. Individuals were classified semi-quantitatively due to the spine fracture status and due to the bone mineral density (BMD) (t-score) of the lumbar spine (LS) and the proximal femur (PF). Laboratory examinations, sexual and thyroid hormone levels and, more specifically, bone turn-over markers were done routinely. Serum high-sensitive CRP was measured using an ultrasensitive immuno-nephelometry (N Latex CRP mono, Behringwerke AG, Marburg, Germany) on a BNA Behring nephelometer. Statistical analysis was done using Pearson correlation, t-tests (unpaired), discriminant analysis, and analysis of variance (ONEWAY). For data handling and analyses SPSS for Windows, Version 10.0 was used.

Results: Group differences between individuals without fractures (mean: 0.32 ± 0.38) and such with multiple non-traumatic fractures (mean: 0.56 ± 0.70) in respect to CRP were statistically significant (t=-2.3, df=100, p=0.026), as were group differences between controls (mean: 0.25 ± 0.18) and patients with osteoporosis (mean: 0.47 ± 0.57) (t=-2.8, df=53.5, p<0.0008).

Conclusions: The relationship between high-sensitive CRP serum levels and low BMD and multiple non-traumatic fractures in otherwise healthy individuals, is confirming the possible role of inflammation in the development of osteoporosis.

Optimum Testing Strategy for Urinary N-Telopeptide. S. R. Johnson, I. Gioni^{*}, K. Lehan^{*}, J. Ellis^{*}. R&D, Unipath, Bedford, United Kingdom.

Effective therapies exist to treat osteoporosis, such as bisphosphonates. However, non-compliance and persistence mean that many women do not receive the full benefit of their treatment. Bone markers, such as urinary N-Telopeptide (uNTx) can be used to track response to therapy. This can help improve compliance and enable clinicians to identify poor or non-responders, so therapies can be optimised. The aim of this study was to ascertain the best testing strategy for uNTx to enable an accurate determination of levels, whilst providing a method that is practicable for both patients and clinicians.

Twenty women were recruited into each of three age-related cohorts, 31-40, 41-50, 51-60 years. The volunteers provided a second morning void urine sample following an overnight fast, for 30 consecutive days. The Osteomark uNTx ELISA was then used to measure NTx, adjusted for creatinine.

The effect of using 1, 2, 3, 4, 5 or 6 days worth of tests to provide a summary level for uNTx was compared to the weekly mean. Using only 1 or 2 tests produced uNTx estimates that could be greater than 20% different from the weekly mean. However, using 3 or more days worth of testing provided a good estimate of uNTx level, with more tests providing increased accuracy. A 3 day strategy was selected for further analysis because it provided sufficient accuracy, with less effort than 4+ day testing.

The effect of testing on consecutive days, testing every other day and random testing over a week was examined to determine the best 3 test regime. Testing strategies beginning at the start of the week produced the lowest variability, with consecutive measurements providing the most accurate result. Although random testing produced standard deviations higher than testing strategies starting on a Monday, it was no worse than consecutive or alternate measurements made later in the week.

As the influence of testing strategies on providing an accurate level was so small, the recommended testing strategy would be to use any 3 samples within a week. With no rigidity on providing a sample on particular days, more emphasis can be placed on ensuring the sample is second void after fasting. This relaxed strategy also enables sampling to fit in with clinic visits and is more achievable by the patients.

	Std. Mean	Std. Median
Consecutive Days (All start days)	12.4	11.9
Consecutive Days (Monday start)	11.5	11.8
Alternate Days (All start days)	12.8	12.1
Alternate Days (Monday start)	11.3	11.4
Random Testing	12.2	12.3

Some but not all Estrogen-Like Molecules Have Both Bone and Cartilage Protective Effects: Evidence for Complete Uncoupling of Bone and Cartilage Effects. M. A. Karsdal, I. Byrjalsen, D. Leeming, P. Qvist, C. Christiansen. Nordic Bioscience, Herlev, Denmark.

Postmenopausal osteoporosis is associated with increased bone resorption and increased cartilage degradation. Previous investigators have found chondroprotective effects of compounds with estrogenic properties in both preclinical and clinical settings, in which bone and cartilage degradation seemed to be closely coupled.

The objective of the present study was to determine whether Tibolone, a synthetic steroid with estrogenic, androgenic, and progestogenic properties, would have similar dual actions on both bone and cartilage turnover.

Methods: Ninety-one healthy postmenopausal women aged 52-75 yrs entered a 2-yr double blind, randomized, placebo-controlled study of treatment with either 1.25 mg/day (n=36), or 2.5 mg/day Tibolone (n=35), or placebo (n=20). Second void morning urine samples were collected at baseline, and at 3, 6, 12, and 24 months. The biochemical markers CTX-I and CTX-II were measured in Urine CrossLaps™ ELISA and Urine CartiLaps™ ELISA (Nordic Bioscience A/S) as markers of bone resorption and cartilage degradation, respectively.

Results: Bone and cartilage turnover was evaluated as the mean relative change from baseline during the 2-yr study period, corrected for placebo. Tibolone strongly and highly significantly (P<0.001) suppressed bone resorption as measured by CTX-I, figure 1A. In contrast, an increase rather than a decrease on cartilage degradation was observed, figure 1B.

Discussion: Previous studies have demonstrated positive effects of estrogens and various SERMs on both cartilage and bone degradation. In the present study we demonstrate a complete uncoupling of the bone and cartilage effects of the synthetic steroid, Tibolone. Bone resorption was highly significantly decreased as expected, whereas cartilage degradation was elevated. These effects are in direct contrast to those observed and published for other SERMs e.g. raloxifene and levormeloxifene decreasing both bone and cartilage degradation. In conclusion, these results may have important implications for the development of improved SERMs with additional effects on cartilage health supplementary to that of the primary endpoint, bone health. Interestingly these data clearly demonstrate that only some estrogen-like substances but not all have dual actions on both bone and cartilage

Development of Multiplex Immunoassay Panels for Simultaneous Quantification of Bone Metabolism Markers using Luminex xMAP Technology. W. Lie*, H. Hwang*, J. Wang*, J. Mistry*. MILLIPORE, St Charles, MO, USA.

Biochemical markers of bone metabolism play an important role in the assessment of bone diseases such as osteoporosis, arthritis, chronic inflammatory disorders, and bone metastasis with cancers. Millipore has developed various multiplexed immunoassay panels for the simultaneous measurement of multiple bone metabolism markers in mouse, rat, and human, using the Luminex xMAP platform. These bead-based sandwich assays are rapid, sensitive, and reproducible and require $\leq 25 \mu\text{L}$ of serum/plasma sample or tissue culture supernatants per well in 96-well plates. The mouse bone panels allow simultaneous quantitation of the following biomarkers in any combinations in the same sample well: Mouse Panel 1 - OPG, Osteocalcin, ACTH, Insulin, Leptin, TNF α , IL-6, and IL-1 β and Mouse Panel 2 - RANKL, Osteocalcin, ACTH, Insulin, Leptin, TNF α , IL-6, and IL-1 β . The dynamic ranges for the mouse analytes are 10-40,000 pg/mL (OPG, Osteocalcin, RANKL, and Leptin), 24-100,000 pg/mL (Insulin), and 2-10,000 pg/mL (ACTH, TNF α , IL-6, and IL-1 β). The rat bone panels allow simultaneous measurement of the following biomarkers: Rat Panel 1 - OPG, ACTH, Insulin, and Leptin, Rat Panel 2 - RANKL, ACTH, Insulin, and Leptin, and Rat Panel 3 - Osteocalcin and PTH. The dynamic ranges for the rat analytes are 10-40,000 pg/mL (OPG, PTH, Leptin), 5-20,000 pg/mL (Osteocalcin), 4-15,000 pg/mL (RANKL), 24-100,000 pg/mL (Insulin), and 2-10,000 pg/mL (ACTH). The human bone metabolism panels allow for simultaneous measurement of the following biomarkers in any combinations: Human Panel A (serum samples) - OPG, Osteocalcin, Osteopontin, and PTH and Human Panel B (tissue culture samples) - OPG, Osteocalcin, Osteopontin, PTH, Leptin, Adiponectin, Insulin, ACTH, TNF α , IL-6, IL-1 β , and VEGF. We have also developed a sensitive immunoassay for measuring the serum levels of human RANKL. The dynamic range for this Human RANKL Single-plex assay is 5-20,000 pg/mL. The above bone metabolism panels exhibited acceptable analytical performance characteristics in terms of sensitivity, intra- and inter-assay precision, linearity of dilution, spike recovery, and antibody pair specificity. In conclusion, various multiplexed assay panels were developed and validated for the measurement of multiple bone metabolism markers in mouse, rat, and human samples. The availability of these multiplexed Bone Metabolism Panels and the RANKL, OPG, and Osteocalcin Single-plex assays may provide a powerful tool in studying biological functions of these biomarkers as well as the pathological roles of these molecules.

Increased Bone Resorption in Knee Osteoarthritis with Severe Joint Surface Wear. T. Mashiba, S. Mori, Y. Kaji*, K. Iwata*, S. Komatsubara*, T. Manabe*, T. Yamamoto*. Orthopedic Surgery, Kagawa University Faculty of Medicine, Kagawa, Japan.

It has been known that the patients with knee osteoarthritis (OA) have little higher bone mineral density (BMD) when compared with normal controls. Recently, however, it has been suggested that subchondral bone metabolism is associated with the progression of osteoarthritis of the knee. The objective of this study is to examine the relationship of bone mineral density and bone metabolic markers to radiological progression of knee OA. One hundred sixty-six postmenopausal women (55-89 y.o.) with radiographic knee OA were enrolled in this study. Weight-bearing antero-posterior knee radiograph with the patellae in central position were taken in all women. They were divided into 5 groups based on Koshino's grading system of knee OA (Grade1: sclerosis or osteophyte formation, Grade2: joint space narrowing $< 3\text{mm}$, Grade 3: joint space disappearance, Grade 4: subchondral bony wear $< 5\text{mm}$, Grade 5: subchondral bony wear $> 5\text{mm}$). All women underwent bone mineral density (BMD) measurements of lumbar spine and hip. Serum osteocalcin (OC) and urinary deoxypyridinoline (DPD) were measured. There were no significant differences among groups in body mass index or BMD at any site. DPD was significantly higher in grade 5 group than in others, and Spearman's rank correlation analysis showed significant association between elevated OA grade and increased DPD value. However, no significant differences were found in OC among all groups. In this study, bone resorption expressed by DPD was elevated especially in women knee OA with the severest joint surface wear. Our results indicate that increased bone resorption was associated with the progression of subchondral bony wear in knee OA although it is not clear whether increased bone resorption is cause or results of joint surface wear.

Fluctuation of the Normal Values of the Biochemical Markers of Bone Turnover in Greek Premenopausal Women. E. Metania*¹, P. Dimou*², P. Katsimbri*¹, T. Kaplanoglou*¹, I. Koulouris*¹, P. N. Soucacos*¹, G. Skarantavos*¹. ¹1st Department of Orthopaedic Surgery, Metabolic Bone Diseases Unit, General University Hospital 'ATTIKON', Athens, Greece, ²Biochemical Department, Asclepion Hospital, Voulas, Athens, Greece.

Aim: In clinical practice, normal values of the biochemical markers of bone turnover are considered the values defined by the manufactory companies of the various reagent kits used universally. The fact that the abnormal rate of bone turnover in Greek women is based on normal values of the biochemical bone markers of women of a different nationality, has led to the need to create a data base based in normal values in Greek premenopausal women. Material-Methods: A detailed medical history was recorded and blood samples were collected from 100 healthy, Greek premenopausal women, between 30 to 54 years, with normal physical

activity. Women in pregnancy, or women who had diseases, or taking pharmacological agents affecting bone metabolism were excluded. In all participants detailed information was given regarding the purpose of the study, and written consent was obtained. Blood samples were collected and, after centrifuging, the values of 3 bone formation markers [osteocalcin, bone alkaline phosphatase, PINP], and 2 bone resorption markers [serum NTX and CTX] were determined. Osteocalcin, PINP (Roche Diagnostics GmbH Mannheim) and serum CTX (Roche Diagnostics GmbH Mannheim) was measured with an electrochemiluminescence immunoassay. Bone alkaline phosphatase (Quidel Corporation, San Diego, CA USA) and serum NTX (Osteomark NTx Serum, Wampole Laboratories, NJ USA) was measured with an ELISA. The participants were categorized in three groups according to their age and statistical analysis of the results was performed.

Results: According to our study the normal values for premenopausal Greek women are: 1) Osteocalcin: 3,56 to 33,8 ng/ml (Mean: 18,68, SD:7,56. 2) Bone Alkaline Phosphatase: 4,52 to 27,08 U/L (Mean: 15,80, SD:5,64). 3) PINP: 12,01 to 58,49 $\mu\text{g/L}$ (Mean: 35,25, SD:11,62). 4) NTX: 5,18 to 21,98 ng/ml (Mean: 13,58, SD:4,20). 5) CTX: $< 0,531\text{ng/ml}$, (Mean: 0,265, SD:0,133). The reproducibility of our measurements was 5-8%.

Conclusion: 1. The present study reflects the reference values for the biochemical bone markers that determine the normal rate of bone turnover in the Greek women. 2. Thereby, it is feasible to more accurately determine high or low bone turnover in postmenopausal Greek women. 3. In all bone markers that were examined, we observed difference in the values of the Greek population compared with the reference values, especially for osteocalcin and bone alkaline phosphatase. 4. Our results suggest that, during the premenopausal period, the biochemical bone markers show no age variability.

Disclosures: E. Metania, None.

Comparison of Serum Tartrate-resistant Acid Phosphatase Type 5b Assays and Other Bone Resorption Markers for Monitoring Raloxifene Therapy. Y. Mochizuki*¹, A. Oishi*¹, Y. Igarashi*², N. Inaba*¹. ¹Department of Obstetrics and Gynecology, Dokkyo Medical University, Tochigi, Japan,

²Department of Basic Medicine, Dokkyo Medical University, Tochigi, Japan.

Objectives: Tartrate-resistant acid phosphatase type 5b (TRACP 5b) is a reliable bone marker derived specifically from osteoclasts and its serum levels are not affected by feeding, renal or hepatic function. The purpose of this study was to compare the clinical performance of two different TRACP 5b assays and other markers of bone resorption for monitoring raloxifene therapy. Methods: Twenty five postmenopausal women with osteoporosis/osteopenia were treated raloxifene 60mg daily. Serum TRACP 5b, serum and urinary N-terminal telopeptides of type I collagen (S-NTX and U-NTX), urinary deoxypyridinoline (DPD) were measured at baseline and 1, 3 and 6 months after treatment. Lumbar bone mineral density (LBMD) was determined at baseline and six months. The TRACP 5b assays and other markers were as follows: A novel assay system for TRACP 5b called fragments absorbed immunocapture enzymatic assay (FAICEA) (Nitto Boseki Co., Ltd., Fukushima, Japan), A pH-selective immunoassay measuring TRACP 5b activity (BoneTRAP[®] Assay, IDS Ltd., NE, UK), S-NTX and U-NTX (Mochida Pharmaceutical Co., Ltd., Osaka, Japan) and DPD (DS Pharma Biomedical Co., Ltd., Osaka, Japan). Results: Serum TRACP 5b values were reduced significantly by raloxifene on 1 month using 2 assay kits. The reduction rates on 1, 3 and 6 months were 22.7%, 26.9% and 28.3% (FAICEA), 13.7%, 18.6% and 22.7% (BoneTRAP[®]), respectively. On the other hand, the reduction rates of other markers on 1, 3 and 6 months were 16.9%, 14.3% and 17.2% (S-NTX), 18.7%, 31.0% and 25.8% (U-NTX), 15.6%, 22.6% and 18.9% (DPD), respectively. Serum TRACP 5b change exceeded the least significant change (LSC) on 6 month in 66.7% (FAICEA; LSC 31.6%) and 33.3% (Bone TRAP[®]; LSC 29.5%) of the subjects. The changes of LBMD at 6 months only correlated significantly with the changes of TRACP 5b with FAICEA ($r^2=0.190$, $p<0.05$) at 3 months. Conclusions: These results suggest that serum TRACP 5b with FAICEA is an excellent bone resorption marker for monitoring raloxifene treatment.

Disclosures: Y. Mochizuki, None.

Serum PINP Is a Useful Marker of Bone Formation in Rat Ovariectomy

Model. J. Morko*¹, J. P. Rissanen*¹, M. I. Suominen*¹, Z. Peng*¹, S. Rasi*², J. Risteli*³, J. M. Halleen*¹. ¹Pharmatest Services Ltd, Turku, Finland, ²SBA-Sciences, Oulu, Finland, ³Department of Clinical Chemistry, University of Oulu, Oulu, Finland.

Serum procollagen I N-terminal propeptide (PINP) is a useful marker of bone formation in humans. We report here the development and characterization of a non-radioactive immunoassay for rat PINP, and the use of PINP as a bone formation marker in rat ovariectomy (OVX) model. A polyclonal PINP antiserum was developed in rabbits using a synthetic peptide QEDIPEVS as antigen, corresponding to the first amino acids of the N-terminal propeptide of rat type I procollagen $\alpha 1$ chain. Intra- and inter-assay coefficients of variation (CVs) were calculated from a panel of rat serum samples in three different PINP levels ($n=10$ in each level). Two OVX studies were performed, both with 3-month old rats. A pilot 14-day study contained a sham-operated control group and an OVX group, and included measurement of serum PINP and other bone turnover markers before the operation and at days 2, 4, 7, 10 and 14. An extensive 8-week study included a sham-operated control group, an OVX group receiving vehicle, and an OVX group receiving 17 β -estradiol (E2, 10 $\mu\text{g/kg/day}$ s.c.). PINP and other bone turnover markers, including serum osteocalcin, C-terminal cross-linked telopeptides of type I collagen (CTX) and tartrate-resistant acid phosphatase 5b (TRACP 5b), were measured before the operations and at 2 and 8 weeks. Trabecular bone parameters were determined from tibial metaphysis using pQCT analysis and histomorphometry at 8 weeks. The PINP immunoassay had an intra-assay CV of 2.8%, inter-assay CV of 7.5%, dilution linearity of 95%

and recovery of 107%. PINP increased during the first 2 weeks after OVX, and returned to sham-level at 8 weeks. Osteocalcin and CTX were increased at 2 weeks, but they were also increased at 8 weeks. TRACP 5b was decreased at 2 and 8 weeks, and the values at 8 weeks correlated strongly with the histomorphometrically determined absolute number of osteoclasts (N.Oc/T.Ar). E2 prevented the increase of PINP, as well as the changes of the other bone turnover markers caused by OVX. Changes in PINP showed a strong correlation with changes in other bone turnover markers at 2 weeks, and PINP values at 2 weeks correlated significantly with trabecular bone parameters at 8 weeks. These results demonstrate that rat serum PINP is a useful marker of bone formation, and short-term changes in PINP predict long-term changes in trabecular bone parameters in rat OVX model. Osteocalcin behaved similarly than CTX and differently than PINP at 8 weeks, suggesting that a substantial amount of rat serum osteocalcin may be derived from bone resorption rather than bone formation.

Automated Measurement of 1,25 Dihydroxyvitamin D on the LIAISON® Analyzer. D. M. Heldman*, D. L. Ersfeld*, C. L. Ross*, P. J. Krohn*, G. T. Olson, J. A. Schmidt, Research & Development, DiaSorin Inc, Stillwater, MN, USA.

1,25-dihydroxyvitamin D (1,25-Vit-D) is the metabolically active, most potent form of vitamin D. Its production in the kidneys is tightly regulated by serum calcium, phosphorus, and PTH concentrations. However, numerous disorders exist that can disrupt this carefully controlled system. These include renal failure, type I and II vitamin D dependent rickets, as well as extra-renal disorders such as sarcoidosis and rheumatoid arthritis. Because of these and similar conditions it is becoming increasingly important to have an accurate measurement of 1,25-Vit-D. Therefore, we have developed a sensitive and precise automated assay for the measurement of 1,25-Vit-D on the LIAISON® Analyzer. Using a competitive inhibition, chemiluminescent immunoassay and a solvent based C-18 column extraction, we were able to demonstrate the following performance parameters over a range of 4-200 pg/mL. Analytical and functional sensitivity were <4 pg/mL and <15 pg/mL respectively. Recovery ranged from 96-112%, with an average of 103%. The coefficient of variance (CV) for intra-assay precision was <13% and inter-assay precision was <15%. Linear regression for dilution linearity yielded a slope of 0.95 and r-value of 0.99. Linear regression for the method comparison of 51 patient samples compared to the DiaSorin 1,25 Dihydroxyvitamin D RIA kit was LIAISON® = 0.91(RIA) + 2.1, r = 0.94. Results obtained during development demonstrate that the LIAISON® 1,25 Dihydroxyvitamin D Assay is an accurate and precise means of measuring serum 1,25-Vit-D levels. This product significantly enhances the expanding DiaSorin LIAISON® bone and mineral product line.

Product availability subject to required regulatory approvals.

Analytical and Clinical Performance of an Automated Assay for the Measurement of Osteocalcin on the LIAISON® Analyzer. A. L. Podgorski*, D. L. Vaught*, J. J. Body*, F. Vertongen*, G. T. Olson, F. A. Blocki, J. A. Schmidt. ¹Research and Development, DiaSorin Inc., Stillwater, MN, USA, ²Department of Medicine, Institut J. Bordet, Université Libre de Bruxelles, Brussels, Belgium, ³CHU Saint Pierre, Université Libre de Bruxelles, Brussels, Belgium.

Osteocalcin (OC) is a small bone matrix protein (Mr 5800) produced by osteoblasts (OB). Three of OC's 49 amino acids are calcium binding gamma-carboxyglutamic acids. OC comprises nearly 1% of bone's organic matrix: smaller amounts are synthesized in dentine by odontoblasts. Expression of OC is vitamin K-dependent and under the control of 1,25-dihydroxyvitamin D. OC is a marker of bone formation reflecting increased or decreased bone turnover in patients with altered bone metabolism. Although OC serum levels are broadly accepted as reflecting increased OB activity, intact OC and OC fragments from the resorption of bone matrix have recently been reported as contributing to serum OC levels.

The LIAISON® Osteocalcin Assay utilizes a 25 µL serum sample, 20 µL magnetic particles coated with a monoclonal anti-OC (directed to residues 20-43) and 175 µL tracer, a second Mab anti-OC (directed to residues 1-19) labeled with an isoluminol derivative. Following a 10-min incubation, wash, and chemical trigger addition, light is measured that is proportionate to the amount of OC in the sample. Results are available in 20 minutes with a throughput of 180 tests/hour. Performance was established following standard CLSI protocols. Analytical and functional sensitivities are ≤0.3 ng/mL and ≤3 ng/mL, respectively. Intra- and inter-assay imprecision with samples throughout the range is ≤9%, following a 20 day precision protocol. Mean recovery is 93% and dilution linearity is (observed) = 1.05(expected) + 0.12, R = 1.00. A correlation using 249 serum samples across the range is: LIAISON = 0.99(commercial assay) - 1.01, R = 0.98.

In a clinical laboratory samples from patients with osteoporosis or metastatic breast cancer were tested using the LIAISON® Osteocalcin Assay to demonstrate the clinical utility of this assay for treatment evaluation. The results of the LIAISON® Osteocalcin assay corresponded well with another approved automated assay.

The accurate, precise LIAISON® Osteocalcin Assay enhances the expanding LIAISON® bone and mineral product line.

Product availability is subject to required regulatory approvals.

A Comparison Between Gene Expression in Skeletal Muscle and Bone of Postmenopausal Osteoporotic Females and Their Controls. S. Reppe*, O. K. Olstad*, V. T. Gautvik*, S. Nygård*, L. S. Nissen-Meyer*, P. I. Høvring*, R. Jemtland*, K. M. Gautvik*. ¹Medical Biochemistry, University of Oslo, Oslo, Norway, ²Dept. of Clinical Chemistry, Ullevaal University Hospital, Oslo, Norway, ³Mathematics, University of Oslo, Oslo, Norway, ⁴Section of Endocrinology, Rikshospitalet University Hospital, Oslo, Norway.

It is well known that patients with osteoporosis also have reduced muscle strength and show increased tendency to falls, thereby increasing the fracture risk. There is a question whether the entire musculo-skeletal system is affected in postmenopausal osteoporosis or only the skeleton. Maximum bone density and muscle mass are both 60 % - 80 % genetically determined. In this study we have assessed the global gene expression patterns in trans-iliac bone and in muscle biopsies from the same individuals from osteoporotic females (n=12,) and healthy controls (n=12), using total RNA (pooled two by two) and Affymetrix HG U133 Plus 2.0 arrays. The osteoporotic group had T-scores < -2.5 in vertebrae and hips and low impact fractures. The MAS 5.0 software was used to identify and filter out absent genes, while signal values were obtained using PLIER. Students t-test were used for significant differences (p<0.05). 310 mRNAs (genes) showed significantly changed expression between healthy and osteoporotic women in the bone biopsies while the corresponding number in muscle biopsies were 130 at the level of significance of p < 0.05. Using Ingenuity Pathway Analysis we found that the top canonical pathways involving more than 5 genes associated with the altered gene expression in bone were: calcium signaling (p<0.000), Cardiac β-adrenergic signaling (p<0.000) and actin cytoskeletal signaling (p < 0.001), represented by 12, 9 and 9 genes, respectively. In muscle no pathway with more than 3 genes was found to be affected in osteoporotic women as compared to healthy controls. The major physiological systems and functions affected in bone were "skeletal and muscular system development and function" and "tissue morphology" involving 62 and 42 genes, respectively, while the corresponding top systems in muscle were "hematological system development and function" and "Immune response" both with 4 genes. Thus, the osteoporotic phenotype is reflected by altered gene expression in bone. The present study also indicate abnormal gene expression in skeletal muscle, in support of the hypothesis of musculo-skeletal disorder in female osteoporosis.

A Non-radioactive Immunoassay for Mouse PINP. J. P. Rissanen¹, M. I. Suominen¹, J. Morko¹, S. Rasi², J. Risteli³, J. M. Hallee¹. ¹Pharmatest Services Ltd, Turku, Finland, ²SBA-Sciences, Oulu, Finland, ³Department of Clinical Chemistry, University of Oulu, Oulu, Finland.

Serum procollagen I N-terminal propeptide (PINP) is a useful marker of bone formation in humans. We have reported the development and characterization of a non-radioactive immunoassay for rat PINP. Here we demonstrate that the assay can also be used for measuring PINP from mouse serum samples. We used the PINP immunoassay to study the use of PINP as a bone formation marker in a mouse model of glucocorticoid-induced osteoporosis. PINP was measured from mouse serum samples with a polyclonal PINP antiserum developed in rabbits using a synthetic peptide QEDIPEVS as antigen, corresponding to the first amino acids of the N-terminal propeptide of rat type I procollagen α1 chain. Twelve weeks old Balb/c male mice (n=8/group) were given either vehicle (control group) or 3, 10 or 30 mg/kg/d of prednisolone orally for 4 weeks. Serum osteocalcin and PINP were measured from fasting blood samples before the start of treatment, and at 2 and 4 weeks. For dynamic histomorphometry, tetracycline labelling was performed at day 10 and calcein labelling at day 2 before termination. Parameters of dynamic histomorphometry were determined from trabecular bone and cortical bone at the end of the study. Statistical analysis was performed with ANCOVA for follow-up measurements and either ANOVA or Kruskal-Wallis test for end-point measurements after checking the assumptions for normality and homogeneity of variances. Linear contrasts of means or Mann-Whitney test were utilized for pairwise comparisons. Parameters of dynamic histomorphometry were dramatically decreased by prednisolone. The decrease was dose-dependent in trabecular bone parameters, whereas maximal reduction was observed already with the lowest dose of prednisolone in cortical bone parameters. PINP values were dose-dependently decreased by prednisolone treatment at both 2 and 4 weeks. The values were decreased by more than 50% already with the lowest dose of prednisolone at 2 weeks. Similar, although not as dramatic changes were observed for serum osteocalcin values. These results demonstrate that PINP is a useful marker of bone formation in this mouse model of glucocorticoid-induced osteoporosis. Prednisolone changes PINP values in a similar pattern than it changes parameters of dynamic histomorphometry, particularly in trabecular bone.

Reproducibility of Biochemical Markers of Bone Turnover in Clinical Practice. A. L. Schafer^{*1}, E. Vittinghoff^{*2}, R. Ramachandran^{*3}, N. Mahmoudi^{*4}, D. C. Bauer¹. ¹Medicine, University of California, San Francisco, San Francisco, CA, USA, ²Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, USA, ³Laboratory Medicine, University of California, San Francisco, San Francisco, CA, USA, ⁴Hospital Medicine, Kaiser Permanente, Oakland, CA, USA.

Recent investigation has shown that biochemical markers of bone turnover may be useful to predict fracture risk and to assess response to osteoporosis therapy. Although several bone turnover markers are FDA-approved, there is little information about reproducibility of marker measurements in clinical practice. This study aimed to determine the laboratory reproducibility of two markers: urine N-telopeptide (NTX) and serum bone-specific alkaline phosphatase (BSAP). Fasting morning serum and urine were collected from 5 postmenopausal women (mean \pm SD age 65 \pm 6.3 years) not taking osteoporosis therapy. The serum and the urine were pooled, divided into identical aliquots, and stored at -80°C. An identical specimen was sent to each of 6 high-volume US commercial labs on 5 dates over an 8-month period. On the fifth date, 5 identical specimens were sent to each lab. Fictional identifiers were used, and specimens were sent by the authors' institutional lab, so that the commercial labs were unaware of the investigation. Means, SDs, and coefficients of variation (CVs) with 95% confidence intervals (CIs) were calculated. Longitudinal reproducibility was evaluated as one specimen was sent to each lab on each of 5 dates. For urine NTX (Table), CVs varied from 5.4% to 37.6%. Longitudinal variation was significantly higher for labs using the Osteomark assay (CV 40.2%, CI 26.6-86.9) than for those using the Vitros ECI assay (CV 7.0%, CI 5.3-10.4). For BSAP, CVs ranged from 3.1% (CI 1.9-9.1) for Esoterix to 23.6% (CI 13.9-77.2) for LabCorp.

Lab (Assay)	Longitudinal Reproducibility for NTX			Within-Run Reproducibility for NTX		
	Mean \pm SD	CV, % (95% CI)		Mean \pm SD	CV, % (95% CI)	
ARUP (Vitros ECI)	35.8 \pm 1.9	5.4 (3.2-15.5)		36.4 \pm 0.5	1.5 (0.9-4.3)	
Quest (Vitros ECI)	34.0 \pm 2.2	6.6 (3.9-19.1)		34.0 \pm 1.2	3.6 (2.2-10.4)	
Esoterix (Vitros ECI)	35.8 \pm 2.9	8.0 (4.5-30.4)		34.0 \pm 1.4	4.2 (2.5-12.0)	
Mayo (Vitros ECI)	35.0 \pm 3.0	8.6 (5.1-25.0)		40.0 \pm 1.6	4.0 (2.4-11.4)	
LabCorp (Osteomark)	74.2 \pm 19.3	25.9 (15.2-87.9)		59.0 \pm 4.2	7.1 (4.2-20.6)	
Specialty (Osteomark)	42.8 \pm 16.0	37.6 (21.6-168.0)		52.8 \pm 9.1	17.2 (10.2-52.9)	
Units for means and SDs: nM BCE/mM Cr						

Within-run reproducibility was evaluated as each lab was sent 5 identical specimens on one date. For urine NTX, see Table. For BSAP, Esoterix produced 5 identical measurements, and CVs for the other labs ranged from 2.2% (CI 1.3-6.3) for Quest to 15.5% (CI 9.2-47.1) for LabCorp.

We conclude that the reproducibility of urine NTX and serum BSAP is highly variable at US commercial labs. Poor reproducibility is a barrier to the use of biochemical markers of bone turnover in clinical practice, particularly if clinicians do not consistently use the same assay and laboratory.

Measurement of 25-OH Vitamin D₂ by the LIAISON[®] 25 OH Vitamin D TOTAL Assay. J. A. Schmidt, E. M. Frenzel*, M. A. Friedberg*, A. L. Podgorski*, J. S. Fenske*. Research & Development, DiaSorin Inc, Stillwater, MN, USA.

The role of vitamin D in bone and mineral metabolism was recognized from its first identification as a factor that could cure rickets. However, vitamin D is now recognized as a prohormone with multiple roles in maintaining optimal health. Vitamin D₃ (cholecalciferol) is the form of vitamin D that occurs naturally in humans, but vitamin D deficiency is commonly treated in the United States with vitamin D₂ (ergocalciferol). Fortified foods or supplements may contain either form. Thus, it is important that an assay for use world-wide measure both D₂ and D₃ forms of 25 OH vitamin D.

We compared the results obtained for 25 OH vitamin D in 110 serum samples by a validated liquid chromatography-tandem mass spectrometry (LC-TMS) method and by LIAISON[®] 25 OH Vitamin D TOTAL, a chemiluminescent immunoassay. LC-TMS gives separate results for 25OH D₂ and 25OH D₃, but there is no clinical utility in separate values; the LIAISON[®] assay gives a single result. Of 110 samples tested, 46 were found to contain detectable amounts of 25OH D₂. Actual values were 4-45 ng/mL 25OH D₂ and 6-53 ng/mL total 25OH D. Regression equations were similar:

LIAISON[®] = 0.83(LC-TMS) + 2.7; R = 0.87 for all samples; and

LIAISON[®] = 0.80(LC-TMS) + 3.6; R = 0.78 for samples containing 25OH D₂.

Furthermore, there was no trend to higher or lower bias with increasing 25OH D₂.

These results demonstrate that the LIAISON[®] 25 OH Vitamin D TOTAL assay measures both the D₃ and D₂ forms of the vitamin equally.

Product availability subject to required regulatory approvals.

Development of a Bone Specific Alkaline Phosphatase Assay for the LIAISON[®] Analyzer. K. E. Paulsen, C. M. Klatt*, F. A. Blocki, P. J. Krohn*, G. T. Olson, M. A. Friedberg*, J. A. Schmidt. R&D, DiaSorin Inc, Stillwater, MN, USA.

Bone Specific Alkaline Phosphatase (BAP) is a serum marker for osteoblastic bone formation. Measurement of BAP is useful in diagnosing Paget's disease and osteoporosis and in monitoring the response to antiresorptive therapy in these patients, and for assessing bone turnover in patients with chronic kidney disease - mineral and bone disorders (CKD-MBD). BAP is also an emerging marker of bone formation within the context of reversing adynamic bone disease. We report here the development of a chemiluminescent immunoassay for BAP on the LIAISON[®] Analyzer.

Approximately 95% of total alkaline phosphatase activity in normal human serum is due to the presence of the liver and bone isoforms present in approximately equal quantities. BAP and Liver Alkaline Phosphatase (LAP), alternatively known as TNALP, tissue non-specific alkaline phosphatase, share a common primary sequence and differ structurally solely due to post-translational glycosylation. Antibody with specificity toward the carbohydrate portion of the BAP enzyme is needed in order to minimize cross reactivity to the LAP isoform in the assay.

The BAP assay uses 50 μ L of serum sample mixed with paramagnetic particles coated with monoclonal antibody to BAP in a 20 minute incubation. A tracer of a second monoclonal antibody labeled with an isoluminol derivative is then added followed by a 15 minute incubation. Particles are washed and a chemiluminescent reaction produces a signal proportionate to the quantity of BAP in the sample.

The LIAISON[®] Bone Specific Alkaline Phosphatase assay measures in the range of 0.1 to 120 ng/mL with analytical sensitivity < 0.1 ng/mL, functional sensitivity < 0.4 ng/mL, and inter-assay imprecision \leq 8%. The assay demonstrates good correlation to a predicate device, LIAISON[®] = 0.94x + 1.78 ng/mL, R = 0.90. Dilution Linearity yields a regression equation of y = 1.04 (expected) - 4.0, R = 0.98. Cross reactivity to the LAP isoform in this two-site mass based assay is comparable to or better than other methods which use phosphatase activity for detection.

The LIAISON[®] Bone Specific Alkaline Phosphatase assay is an accurate and precise assay, with minimal cross reactivity toward liver alkaline phosphatase, significantly enhancing DiaSorin's expanding bone and mineral product line. Product availability subject to required regulatory approvals.

Age-Related Changes in Bone Turnover in Men: Evidence for Impairments in Both Osteoblast and Osteoclast Function. B. Srinivasan, B. L. Riggs, E. J. Atkinson*, L. J. Melton III, S. Khosla. Mayo Clinic, Rochester, MN, USA.

While bone turnover generally increases after menopause and with aging in women, age-related changes in bone remodeling in men have been less clearly defined. Most studies have found decreases in biochemical markers of bone formation with age in men, consistent with an age-related defect in bone formation. Results with bone resorption markers have been more variable; some studies have found an increase and others report no clear changes. Serum CTx is a well established marker of bone resorption, reflecting the net effects of osteoclast number and activity on bone. By contrast, data from in vitro, animal, and human studies indicate that measurement of serum tartrate-resistant acid phosphatase (TRAP) 5b (which is specific for TRAP derived from osteoclasts) principally reflects osteoclast numbers. To dissociate possible age-related changes in osteoclast numbers versus activity, we measured serum CTx and TRAP 5b levels using highly sensitive and specific immunoassays in a large, population-based sample of men (n = 313) age 22 to 91 yrs. We also calculated the ratio of CTx:TRAP 5b as an index of resorptive activity per osteoclast. As a measure of bone formation, we assessed serum PINP levels. Panel A shows the age-related changes (mean \pm SE, expressed as T-scores relative to men age 20-29 yrs) in serum PINP levels, demonstrating a 45% decrease in bone formation between age 20 to 90 yrs (P < 0.0001). Panel B shows the changes in serum CTx and TRAP 5b; as is evident, while serum CTx decreased over life by 40% (P < 0.001), serum TRAP 5b levels increased by 32% (P < 0.001), suggesting that despite an apparent age-related increase in osteoclast numbers, net bone resorption decreased with age in men. Panel C shows the ratio of CTx: TRAP 5b, representing an index of activity per osteoclast, which decreased in men over life by 36% (P < 0.001).

These findings thus demonstrate that bone formation clearly decreases with age in men. While TRAP 5b (an index of osteoclast numbers) increases, CTx (an index of net bone resorption) decreases with age in men, consistent with an age-related defect in osteoclast function. Since there is increasing evidence that osteoclasts directly regulate osteoblastic activity, the observed deficit in osteoclast function with aging in men may contribute to the age-related impairment in bone formation in men.

Utilize of s-RANKL, s-FREE RANKL and Osteoprotegerin Serum Levels for Prediction of Bone Density. D. Stejskal^{1*}, M. Karpisek^{2*}, P. Solichova^{1*}, R. Ochmanova^{3*}. ¹Department of Laboratory Medicine, Sternberk hospital, Sternberk, Czech Republic, ²Department of Toxicology, University of Veterinary and Pharmacology Sciences, Brno, Brno, Czech Republic, ³Department of Internal Medicine, Sternberk hospital, Sternberk, Czech Republic.

Background: RANKL and its inhibitor OPG are decisive for osteoclast differentiation and osteoresorption function so that they became the aim of an intensive research. Recently, there are some informations about importance of free RANKL for BMD prediction.

Aim: to determine OPG, s-RANKL, s-RANKL free concentrations in persons with various degree of reduced bone density and to find correlations between BMD and listed markers. **Methods:** We examined 69 patients who under the follow-up for osteopathy. All individuals were examined for OPG (Biovendor), s-RANKL (Biovendor), s-RANKL free (Immunodiagnostic), osteocalcin, b-ALP, DPD/creatinine index. We performed DXA of the skeleton. Patients were divided into the subgroup of persons with normal bone density (T score>-1 "N") and individuals with reduced bone density (T score<-1, "OP"). **Results:** 27 patients had normal bone density and 42 probands had osteopenia or osteoporosis. OPG: individuals "N" had median values 2.9 vs 3.7 pmol/l in probands "OP" (p<0.05). S-RANKL-free: values didn't differ significantly in "OP" versus "N" patients (0.1 vs 0.09 pmol/l). S-RANKL: individuals "N" had median 311 vs 127 pmol/l in probands "OP" (p<0.05). OPG strongly correlated with s-RANKL (r = -0.35; p<0.01) and BMD (r = -0.4; p<0.01). Index s-RANKL/OPG had sufficient efficacy for reduced BMD. Discrimination analysis revealed that the known s-RANKL/OPG index allows a correct prediction into given groups in 83 % of cases.

Conclusions: The negative correlation between OPG and s-RANKL was detected. S-RANKL/OPG index discriminates probands with significant BMD decrease. S-RANKL-free cannot be used for mathematical assessment of bone density.

Clinical Significance of Pentsidine in Glucocorticoid-induced Osteoporosis (GIO). I. Tanaka¹, H. Oshima². ¹Department of Laboratory Medicine, Fujita Health University School of Medicine, Toyoake, Japan, ²Department of Internal Medicine, National Hospital Organization Tokyo Medical Center, Tokyo, Japan.

[Objective] In GIO, bone fractures are often seen even at high bone mineral density. This suggests bone quality is an important factor in GIO for bone strength. Recently, it is reported that Pentsidine(PEN) reflects bone quality. In this study, we tried to clarify the clinical usefulness of PEN in predicting the bone quality in GIO. **[Subjects & Methods]** Fifty nine patients (47 females and 12 males) with collagen diseases under glucocorticoid treatment were enrolled in this prospective study. An incidence of the vertebral

compression fracture in two years after the start of glucocorticoid therapy was evaluated in 37 patients among those. The mean of age, daily glucocorticoid dosage (prednisolone equivalent), and total glucocorticoid dosage were 46 years old, 20.3mg/day, and 6.3g, respectively. NTX in the urine (uNTX) and Pentosidine (PEN) were measured by the ELISA methods. Vertebral compression fractures were evaluated with X-ray photography. **[Results]** 1) After the start of glucocorticoid therapy, PEN increased significantly. 2) Doses of glucocorticoids, were significantly correlated with PEN positively. 3) PEN were significantly correlated with uNTX positively. 4) PEN was lower in patients without incident fractures in 2 years than in those with the fractures. 5) Incident fractures in 2 years was high in patients over 180ug/mgCr. **[Conclusion]** 1) These results suggested that PEN was an important risk factor for incident fracture in patients with glucocorticoid-induced osteoporosis. 2) Fracture risk in patients over 180ug/mgCr of PEN was high.

Effect of Food Intake on Bone Resorption in Cynomolgus Monkeys: A Preliminary Study. F. Vlasseros^{1*}, A. Varella¹, S. Y. Smith¹, D. Henriksen². ¹Charles River Laboratories, Preclinical Services Montreal, Senneville, PQ, Canada, ²Sanos Bioscience A/S, Roedovne, Denmark.

The objective of this preliminary study was to monitor the effect of food intake on biochemical markers of bone turnover in young adult cynomolgus monkeys. Food (Rhesus liquid diet) was provided via oral gavage in the morning (approximately 8 to 10 a.m.) following a minimum period of 12 hours fasting and blood samples collected (n=2 to 4 per time-point) prior to feeding and at 10, 15, 20, 30 and 60 minutes, and 4, 6 and 8 hours post feeding. Samples were analyzed for serum N-telopeptide, TRAP5b, osteocalcin and GLP-2. GLP-2 (glucagon-like-peptide-2) is a gut hormone released following food intake, and has been associated with significant decreases in bone resorption markers with no effect on bone formation markers in humans (Henriksen D.B, et al. 2003, JBMR 18 (12):2180-89).

Relative to baseline levels (pre-feeding), NTx showed postprandial decreases of approximately 52% and 25% at 4 and 6 hours, respectively. NTx levels showed no meaningful changes up to 60 minutes following food intake. At 8 hours post feeding NTx was similar to pre-prandial fasting levels. There were no consistent changes in TRAP5b or osteocalcin levels. Relative to baseline levels, GLP-2 plasma levels showed increases 20 to 30 minutes following food ingestion for all animals, although the magnitude of the response was variable and ranged from 20% to 3-fold.

These preliminary data suggest bone resorption activity as measured by serum NTx levels may be decreased 1 to 4 hours following food intake with values rising to fasting levels >8 hours later. This may be related to transient increases in GLP-2 levels 20 to 30 minutes following food intake. A similar spatial and causal relationship has been reported in humans. Importantly, these data suggest measurement of bone resorption activity in samples collected 1 to 8 hours after feeding may be lower than at any other timepoints. Samples can be collected early morning following overnight fasting and later the same day more than 8 hours after feeding. These preliminary data warrant further investigation into the effects of food intake on biochemical markers of bone turnover and the possible role of gastrointestinal hormones in Cynomolgus monkeys.

Disclosures: F. Vlasseros, None.

Specificity of Mouse and Rat Circulating Serological Osteocalcin Values Using a Novel Immunoassay. C. D. Wisherd^{1*}, N. E. Nasser^{1*}. Specialty Products Group (SPG), Quidel Corporation, San Diego, CA, USA.

Osteocalcin (OC) or BGP (bone gla protein) is a 5800 molecular weight extrahepatic vitamin K dependent protein produced by osteoblasts found exclusively in bone tissue. It contains three gamma-carboxyglutamic acid residues that are thought to be involved in calcium ion and hydroxyapatite binding and accounts for 10-20% of the noncollagenous protein in bone. While the in vivo function of osteocalcin is unknown, its affinity for bone mineral constituents implies a role in bone turnover.

Many current enzyme immunoassay (EIA) methods used to detect intact human osteocalcin (hOC) show negligible cross reactivity with mouse osteocalcin (mOC) and rat osteocalcin (rOC). This can be explained by current anti-human osteocalcin antibodies' inability to recognize mouse and rat proteins. Development was performed to establish an EIA with the ability to recognize these proteins while maintaining intact hOC detection. Monoclonal antibodies were developed to capture mOC and rOC in addition to hOC. EIA detection is achieved using hOC-coated plates competing with hOC calibrators and neat serum samples to capture a horseradish peroxidase (HRP) conjugated monoclonal antibody. Tetramethylbenzidine (TMB) substrate is subsequently used to detect the enzyme. The reaction is quenched with 2N H₂SO₄ and read at an absorbance wavelength of 450 nm. The total assay time is 45 minutes.

Specificity studies were run using purified mOC and rOC. mOC was prepared via extraction from mouse bone and purification via G75 gel filtration, DEAE 52 and HPLC. rOC was prepared with rat bone utilizing the mOC extraction method. Balb-C, C57BL6 and CD-1 mouse sera were spiked with 6.7 ng/mL of mOC and tested in the EIA. Average spike recovery of mouse sera was 116% (n=13, range: 86 - 135%). Sprague-Dawley and Wistar rat sera were spiked with 34.3 ng/mL of rOC. Average spike recovery of rat sera was 109% (n=7, range: 102 - 115%).

The results of this study indicate that this novel osteocalcin EIA overcomes shortcomings of the previous methods including: limited species cross reactivity, additional secondary antibody steps, and provides improved sensitivity and short overall assay time.

Disclosures: C.D. Wisherd, None.

Comparison of alpha CTX Levels in Healthy Prepubertal Children, Adolescent, Pre And Postmenopausal Women. S. N. Zeni¹, G. G. Pellegrini^{*1}, M. Linari^{*2}, N. Piazza^{*2}, J. Somoza^{*1}, M. E. Rio^{*3}. ¹Sección Osteopatías Médicas, Hospital de Clínicas, Universidad de Buenos Aires, Buenos Aires, Argentina, ²Public Health Secretary of Vicente López, Epidemiology. Infantil Nutrition., Buenos Aires, Argentina, ³National Council of Scientific and Technical Research, School of Pharmacy and Biochemistry, UBA., Buenos Aires, Argentina.

Collagen type I fragments are formed by osteoclasts and some of them can be determined using a specific immunoassays. The CTX epitope EKAHDGGR comprises a DG-motif susceptible to post-translational modifications. In newly synthesised collagen this motif is in the α -CTX form, but during aging of bone it is isomerized to β -CTX form. The α -CTX form can be determined in urine using a new sandwich ELISA. The aim of the present study was to assess the ability of this marker to discriminate the degradation of new bone in different stage of aging. A total of 243 healthy subjects were included. The distribution of the subjects were: 173 prepubertal children (70 girls and 103 boys) and 30 adolescent (12 girls and 18 boys) attending public schools of Vicente Lopez, Buenos Aires and 20 premenopausal and 20 postmenopausal women. The α -CTX (Alpha CTX ELISA; Nordic Bioscience) was assessed in the second void urine. Results of α -CTX/creatinine levels (ug/mCreatinine) as mean \pm SD were: Prepubertal children: 20 ± 7.2 (6 to <7 years); 15.7 ± 4.5 (7 to <8 years); 14.9 ± 6.7 (8 to <9 years) and 15.3 ± 6.3 (9 to <10 years); adolescents: 4.2 ± 1.9 (11-12 years); premenopausal women: 0.61 ± 0.26 (36.9 \pm 7.5) and postmenopausal women: 0.93 ± 0.58 (58.0 \pm 5.3 years). There was a significant differences among all groups however the levels of significance between postmenopausal vs. premenopausal women ($p < 0.05$) was the lowest. The present results suggest that α -CTX marker reflects well the increase of bone resorption associated with bone modeling at childhood and with high bone turnover after menopause.

Hip Geometry and Density Parameters Derived from Volumetric DXA (VXA) Correlate Strongly with 3D QCT. O. M. Ahmad^{*1}, K. Ramamurthi^{*2}, E. Thrall^{*3}, D. Karasik³, M. Boussein³, K. E. Wilson², K. Engelke⁴, R. H. Taylor^{*1}. ¹CISST, Johns Hopkins University, Baltimore, MD, USA, ²Hologic, Inc., Bedford, MA, USA, ³Orthopaedic Biomechanics Laboratory, BIDMC, Boston, MA, USA, ⁴Institute of Medical Physics, University of Erlangen, Erlangen, Germany.

3D assessment of hip geometry and density using volumetric DXA (VXA) may improve assessment of skeletal fragility. In this study we tested the correlation between structural parameters and volumetric density of the proximal femur derived from VXA and those derived from 3D QCT.

Methods: Male and female statistical models of the proximal femur, capturing both the 3D geometry and density variation, were created using in vivo CT scans from 62 Caucasian men and 57 Caucasian women. Each statistical model comprises a mean-shape and a set of modes of variation. The mean-shape represents the average 3D geometry and density, and consists of a tetrahedral mesh with density functions for each tetrahedron in the mesh. The modes of variation are vectors, derived from principal component analysis on the set of femurs which comprise the statistical models. The modes of variation allow the mean-shape to geometrically vary to match a particular subject's femur. A particular instance of the statistical model can be transformed into a voxel-volume and projections can be calculated to simulate DXA scans. To achieve a 3D model from DXA, 4 DXA scans are acquired at different projection angles (chosen to minimize pelvic overlap in vivo), and an iterative process is performed wherein the DXA projections are compared to projections of the statistical model and the modes of variation are varied to minimize the error between these simulated DXA projections of the model and the actual DXA images acquired. To test the fidelity of this approach, we performed 3D QCT (1 mm slice thickness, GE Lightspeed) and VXA in 20 human cadaveric femora (11 F, 9 M, age 62 to 95). Each resulting model was then voxelized and aligned to the QCT. We examined the association between VXA and QCT-derived femoral neck length (FNL), volumetric density of the total proximal femur (vBMD), as well as the area of bone mineral in the cross section (CSA_b), the mass-weighted polar moment of inertia (CSMI_p) computed at a corresponding VXA and QCT slice at the mid-neck, perpendicular to the neck axis.

Results: We found very strong linear correlation between VXA and QCT for all parameters: FNL ($r=0.97$), vBMD ($r=0.96$), CSA_b ($r=0.94$), and CSMI_p ($r=0.96$). In conclusion, reconstructions that contain both volumetric shape and density information can be made from four DXA views that can be obtained readily in vivo with limited radiation exposure. These VXA reconstructions are highly correlated with structural parameters and volumetric density measured with 3D QCT.

A Technique for Calculating Area Moment of Inertia of Long Bones Using Computed Tomography (CT) Data. A. K. Aiyangar^{*}, H. Ploeg^{*}. Mechanical Engineering, University of Wisconsin, Madison, Madison, WI, USA.

A technique to compute the Area Moment of Inertia (MI) of long bones is presented. In problems related to bending of beams and beam-like structures, there are two main parameters that are indicative of the resistance of the structure to bending: Young's Modulus (E), and MI. While Young's Modulus is a material property, MI is, essentially, a geometrical property of the long bone and depends on a reference axis and the distribution of the material around that axis at every cross-section along the bone. There is not yet a significant appreciation of the effect of ignoring the deviations from standard symmetric beam bending theories as applied to homogeneous materials, while interpreting data from bending tests. As a consequence, there is a strong requirement for a standard method to accurately compute the MI, taking into account the heterogeneities in the bone structure and irregular geometrical shape. Accurate calculation of MI for bone is further complicated as a composite materials model needs to be employed, wherein the different constituent materials are given weighting factors according to their respective elastic moduli. This can be accomplished by using the grayscale variations in computed tomography (CT) images, which is linearly dependent on the density distribution in the bone. The density distribution, in turn, correlates with the elastic modulus. Segmented CT data of a porcine femur bone was used for the study. A porcine femur bone was scanned in a CT scanner (GE Lightspeed. 120kV, 0.352mm pixel size, 0.625mm slice thickness, bone algorithm). The images from the scanning procedure were processed and segmented using Mimics 10.0 software (Materialise, Ann Arbor MI) to obtain the density distribution of the bone. The data for each cross-section was digitized and mapped in the form of pixels (0.125mm²). A custom-written MATLAB function using a composite materials model was used to compute the MI. The equations are shown below.

Where:

x, y = x and y coordinates of centroid respectively

I_{xx}, I_{yy} = MI about the x - and y - axes respectively

R = density ratio for each material

r = constant correlating density to the stiffness

gr = density given as hounsfield units

x_i, y_i = x and y coordinates respectively of pixel "i" in a given cross-sectional slice

The weighted and un-weighted moments of inertia (the difference between a homogeneous versus a composite materials model) differed by 20%. Details of the technique will be presented.

In Vivo Comparison of CT and DXA Methods of Proximal Femur Cross-sectional Geometry Measurement Using HSA. T. J. Beck¹, J. K. Brown², S. Gustafsson^{*3}, K. Zhu³, I. Dick⁴, S. Hentzell^{*5}, V. H. Low⁶, K. E. Wilson⁷, R. L. Prince³. ¹Radiology, Johns Hopkins University, Baltimore, MD, USA, ²Mindways Software Inc., Austin, TX, USA, ³Endocrinology and Diabetes, University of Western Australia, Perth, Australia, ⁴Medicine, University of Western Australia, Nedlands, Australia, ⁵Endocrinology and Diabetes, University of Western Australia, Baltimore, Australia, ⁶Radiology, Sir Charles Gairdner Hospital, Nedlands, Australia, ⁷Hologic Inc., Bedford, MA, USA.

The Hip Structure Analysis (HSA) method for measuring femur geometry from 2D DXA scans needs in vivo 3D validation, but methods for comparison with QCT are lacking. In this ongoing study 54 elderly post-menopausal women from the longitudinal CAIFOS/CARES study of ageing, had standard hip DXA (Hologic Discovery A) and CT scans (Phillips 64 slice) of the pelvis/hips. CT axial images were acquired with 0.78 mm pixels and 1 mm slices at 1 mm intervals. Results were analyzed with CTHSA, a collaborative development between Mindways Software Inc. and Johns Hopkins University. The software extracts cross-sections at DXA HSA femur locations: narrow neck (NN), intertrochanter (IT) and femur shaft (FS) and reformatted them to 0.78 mm pixel spacing. The method then measures the geometry for ultimate use in an automated 3D engineering analysis under development. For the present work, we compared CTHSA geometry and bending properties corresponding to frontal plane DXA with those from DXA HSA. In pooled comparisons of all three regions, bone cross sectional area, outer diameter, cross-sectional moment of inertia, section moduli and buckling ratio showed R^2 values of 0.91, 0.81, 0.95, 0.93 and 0.49, respectively. Within HSA regions, section moduli R^2 values for FN, IT and FS regions were 0.66, 0.67 and 0.47 respectively. Neck values corresponded to the line of identity but shaft and intertrochanter values were shifted upward (Fig). Overall, results correlate well between frontal plane geometry measurements measured by DXA and QCT in elderly women and with prior ex vivo studies. These preliminary results show a small dimensional error in CTHSA integrals which appear to explain the shift and should be correctable. Although work remains, results show that CTHSA may provide an in vivo geometry gold standard for DXA as well as a stand-alone method for automated engineering analysis of the hip for use with recent generation multi-slice CT scan data.

Automated Assessment of Vertebral Shape by Statistical Shape Modelling on Lateral Radiographs. A. D. Brett^{*1}, J. Krasnow^{*2}, C. Miller³, J. Haslam^{*1}, T. Ozanian^{*1}, C. van Kuijk^{*4}, K. Abrams^{*5}, R. Cope^{*3}, M. Beke^{*5}, C. Hayes^{*6}.

¹Optasia Medical Ltd, Manchester, United Kingdom, ²Roche Pharmaceuticals, Nutley, NJ, USA, ³Bio-Imaging Technologies Inc, Newtown, PA, USA, ⁴VU University Medical Center, Amsterdam, The Netherlands, ⁵Novartis Pharmaceuticals, East Hanover, NJ, USA, ⁶VCU Medical Center, Medical College of Virginia, VA, USA.

We describe the construction methodology, accuracy and reproducibility of a statistical model for the automated annotation and characterisation of vertebral shape from lateral radiographs.

Prevalent vertebral fractures are important predictors of future osteoporotic fractures in the spine and hip. Accurate computerized vertebral fracture detection and classification may benefit from capture of vertebral shape information beyond standard 6-point morphometry, similar to the visual cues that characterize semi-quantitative vertebral assessment. Accurate and reproducible acquisition of vertebral shape may also enhance the prediction of subsequent osteoporotic fractures.

Using a statistical learning technique, a vertebral model that can be altered in its shape and appearance was constructed from lateral radiographs. The model was trained on a set of manually-annotated radiographs (165 subjects from the Canadian Multicentre Osteoporosis Study [CaMos], enriched for prevalent deformities). Each vertebra, from T4-L4, was described using 95 points representing the circumferential vertebral borders, including right/left/central endplate margins, anterior/posterior margins, and osteophytes when present. Radiographs of 100 randomly chosen subjects were used to build the model; the remaining 65 subjects were used for accuracy and reproducibility testing. The resulting model may be used in the annotation of a previously unseen image; vertebral landmarks are searched for automatically after manual initialisation.

Accuracy was assessed by measuring the mean absolute distance between manually placed vertebral contours and automatically fitted points on the 65 test subjects. 79895 points were assessed on 841 individual vertebrae. The mean accuracy calculated over each vertebra in each test image was 1.11 +/- 0.94 mm. Inter-operator reproducibility was simulated by varying the placement of model initialisation points by adding random offsets of up to 4 mm and running 10 searches on each test image. The observed mean standard deviation per vertebra of the resulting annotations is 0.31 +/- 0.24 mm.

These results indicate that statistical modelling can provide a robust tool for the accurate and reproducible automated annotation of vertebral body shape. This method may prove useful as a workflow tool to aid the physician in vertebral fracture assessment.

HR-pQCT Assessment of Cortical Bone: Correlations to FE Derived Mechanical Properties. A. J. Burghardt, K. Davis*, T. M. Link, S. Majumdar. Radiology, University of California, San Francisco, San Francisco, CA, USA.

High-resolution peripheral quantitative computed tomography (HR-pQCT) is a promising new tool for longitudinal evaluation of bone quality. Cortical bone geometry is known to be an important factor in whole bone strength. Various methods, which rely on specific assumptions of cortical structure, exist to quantify cortical thickness. In this study, two common definitions of cortical thickness were evaluated using correlations to micro Finite Element (μFE) derived mechanical properties as a measure of significance.

The distal radius and tibia (n=28 and n=24, respectively) from normal volunteers (age 23-76) were imaged using HR-pQCT (Scanco XtremeCT, 82 μm isotropic nominal resolution). The cortical bone compartment was segmented using the standard clinical routines provided by the manufacturer: a strong Gaussian blurring filter (σ=1.5, kernel=7) to wash out the trabecular structure, followed by a fixed global threshold to define the

cortical bone phase. Ct.Th was calculated in 2 ways: 1) as the ratio of the cortical area to the perimeter of a semi-automatically defined periosteal contour, and 2) using a direct 3D sphere filling technique. As a standard of reference, a 1% uniaxial compressive strain (in the direction of the long axis of the radius) was simulated in the complete structure using a voxel based finite element technique. The total reaction force and the estimated failure load were determined [1].

Visually, the use of a large blurring filter clearly eliminated thinner cortical components, particularly in the ultra-distal radius. The area-to-perimeter estimate of cortical thickness included these regions as segments with zero thickness. In contrast, the direct 3D measure only considered the cortical volume that survives the segmentation step. No significant difference in tibial cortical thickness was found between methods. In the radius, the direct 3D method yielded thickness values that, on average, were 0.2 mm larger than the area-to-perimeter method (p < 0.0001). Both methods were positively correlated to μFE derived reaction force (R²=0.72 and R²=0.48 respectively) and to the estimated failure load (R²=0.70 and R²=0.46 respectively).

In conclusion, the results suggest that there is significant site dependence in the agreement between different definitions of cortical thickness in limited resolution scenarios. The μFE results indicate that, for HR-pQCT, the area-to-perimeter definition is a better predictor of mechanical competence, likely due to its inherent incorporation of thin segments lost during the segmentation process.

Topological Analysis and Spatial Distribution of Apparent Trabecular Bone in Radiographs Correlate to Biomechanical Bone Properties: An In Vitro Study of the Proximal Femur. J. Carballido-Gamio^{*1}, M. B. Huber^{*1}, K. Fritscher^{*2}, R. Schubert^{*2}, M. Haenni^{*3}, C. Hengg^{*4}, S. Majumdar¹, T. M. Link¹.

Analysis of the trabecular bone (Tb) pattern observed in radiographs has recently received more attention as significant correlations to different biomechanical bone properties have been found. Most of the analyses however have been based on Fourier, fractal, or morphological approaches trying to characterize texture.

The purpose of this study was therefore to develop an image analysis technique to characterize the apparent (App) Tb architecture observed in radiographs and evaluate it based on biomechanical bone properties.

Radiographs of 13 specimens of the proximal femur were obtained and digitized. Bone mineral density values (BMD) were measured at the femoral neck, and biomechanical testing was performed based on failure load (FL). Five regions of interest (ROI) were automatically positioned in each specimen (head, upper and lower neck, and trochanteric and inter-trochanteric compartment). Regions were normalized for contrast variations and an App Tb map was computed automatically by using soft fuzzy c-means clustering. The skeletons of these maps were computed and their junctions and terminations automatically identified. Voronoi diagrams were constructed using the junctions as nodes, and 1st and 2nd order moments of area of the cell polygons, as well as the distribution of App Tb based on the Voronoi cells were computed and correlated to FL.

Significant correlations were found for the lower neck and inter-trochanteric ROI for different moments of area and App Tb distributions. Correlation values to FL went from 0.577 (p<0.039) for the mean area of the polygons normalized by the mean distance of the nodes of the polygons to their corresponding centroids, up to -0.866 (p<0.0001) for the standard deviation of the distributions of App Tb normalized in a similar manner. When significant correlations were found to FL, no significant correlations were found to BMD. However, the mean elongations of the cell polygons of the upper neck ROI showed significant correlations to BMD (r = -0.568; p<0.042). Similar analysis was performed for the terminations of the skeletons yielding additional significant correlations. The correlation between BMD and FL was 0.695 (p<0.008).

Results suggest that the topology of the App Tb architecture and the distribution of the App Tb observed in radiographs can be quantified and that they are closely related to the biomechanical properties of the Tb in the proximal femur.

Hereditability studies show that genetic factors may contribute to the variability in bone mineral density (BMD), metabolism and microarchitectural deterioration leading to bone fragility. Several candidate genes, identified since their mutations cause severe Mendelian bone phenotypes, exhibit nucleotide sequence variants with modest effects on bone structure and remodeling. Mutations in the LRP5 gene have been associated with rare inherited syndromes characterized by extremely low (loss of function) or high (gain of function) BMD; but little is known about the contribution of this gene to the development of osteoporosis and determination of BMD in a normal population. A recent large population-based study showed that distinct genetic polymorphisms of LRP5 are associated to BMD and to fracture risk namely in elderly men. No data have been published on the relationships between LRP5 polymorphisms and structural parameters of bone as assessed by pQCT. The aim of the present study was to investigate the possible association of Ala1330Val polymorphism in LRP5 gene with volumetric BMD and structural parameters of bone in men and women. We studied 959 subjects (451 men and 508 women), participating to the InCHIANTI study. In all subjects we performed pQCT (XCT 2000, Stratec, Germany) at the tibia level obtaining the following parameters: trabecular vBMD (vBMDt, mg/cm³), cortical vBMD (vBMDc, mg/cm³), cortical bone area (tCSA mm²) and cortical thickness (Ct.Th, mm). Ala1330Val genotypes were determined by polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP).

In men and women, the LRP5 1330-valine variant was associated with decreased values of all pQCT parameters, reaching the statistical significance ($p < 0.05$) for vBMDt in men and in women and for Ct.Th and tCSA in women. These results show that Ala1330Val polymorphism may contribute to the determination of BMD and geometric parameters of bone in the male and female populations.

Texture Analysis and Geometry Measurements on Plain Radiographic Femurs: Correlation with Ultimate Load. C. Chappard¹, V. Bousson², C. Bergot³, A. Marchadier¹, T. Moser³, D. Mitton⁴, C. Benhamou¹, J. Larédo³.
¹U 658 Inserm, Inserm, Orleans, France, ²Laboratoire Radiologie Expérimentale, Université Paris VII, Paris, France, ³Laboratoire Radiologie Expérimentale, Université Paris VII, Paris, France, ⁴Laboratoire Biomécanique UMR 8005, ENSAM CNRS, Paris, France.

Osteoporosis diagnosis and fracture risk at the upper femur are usually assessed by Bone Mineral Density (BMD) measurements with Dual X-ray Absorptiometry (DXA). We propose a new method combining texture analysis and geometrical measurements, obtained from plain femur radiographs. Forty pairs of excised femurs were obtained in 18 males and 22 females (mean age: 81.5±12.3 years). Total femur BMD was measured by DXA. Film radiographs (GE Prestilix 1600x) were digitized with a Fonction Transfert Modulation of 166 µm. We selected 3 square Regions of Interest (ROIs) of 3.2*3.2cm in Femoral Neck (FN), Greater Trochanter (GT) and in Inter-Trochanteric regions (IntT) and finally a ROI of 3.6*3.6 cm in the Femoral Head (FH). We calculated texture parameters derived from the cooccurrence matrix such as Correlation (COR), Contrast (CON), Entropy (ENT), Homogeneity (HOM), Dissymmetry (DIS), Inverse of Differential Moment (IDM), Angular Second Moment (ASM) and Maximum (MAX). Geometrical parameters were directly measured on the radiographs: the total length of femoral neck (FNL), from the base of the greater trochanter to the medial limit of the femoral head, and the neck-shaft angle. All femurs were randomly assigned for axial or lateral compression testing to measure ultimate load (N), axial compression mimicking femoral neck fracture and lateral compression peritrochanteric fracture. All textural parameters were significantly correlated with total femur BMD at FH and GT and few of them were marginally significant at FN and IntT. After checking Gaussian distribution, we combined textural and geometrical parameters to obtain the best fit with ultimate load. The best results were obtained with 3 parameters, more parameters in the regression calculation did not improve the results.

	Axial Compression	r ²	Lateral Compression	r ²
Total Femur	BMD	0.74	BMD	0.78
FN	ENT+ASM	0.55	ENT+MAX	0.55
	FNL+ENT+ASM	0.66	FNL+ENT+MAX	0.70
GT	FNL+ENT	0.64	FNL+ENT	0.67
	FLN+ENT+HOM	0.67	FNL+ENT+MAX	0.69
IntT	FLN+ENT	0.49	FNL+ENT	0.48
	FLN+ENT+HOM	0.67	FNL+ENT+HOM	0.64
FH	HOM+MAX	0.76	HOM+MAX	0.76
	FLN+HOM+MAX	0.77	FNL+HOM+MAX	0.77

In term of prediction of ultimate load, the combination of textural parameters with geometry was close to BMD alone. Except for Femoral head ROI, the addition of FNL measurements in the model substantially improved the prediction of ultimate load. These results show the potential of measurements on plain radiographs to predict bone strength at the upper femur.

Disclosures: C. Chappard, None.

Comparison of Femur Structure Measurements Derived from DXA and QCT. X. Cheng¹, H. Barden², J. K. Brown³, Q. Zhou⁴.
¹Radiology Department, Beijing University Beijing Jishuitan Hospital, Beijing, China, ²GE Healthcare, Madison, WI, USA, ³Mindways Software Inc., Austin, TX, USA, ⁴GE Healthcare Asia, Shanghai, China.

The strength of the proximal femur is a function of both bone mineral density (BMD) and spatial distribution of bone mass determined from structural measurements such as cross-sectional moment of inertia (CSMI), cross-sectional area (CSA) and hip axis length (HAL). These measurements, which assist in estimating hip fracture risk, are made by both dual-energy X-ray absorptiometry (DXA) and quantitative computed tomography (QCT). Because of the ability to control the projection plane, three-dimensional measurement of femur geometry with QCT can be used for evaluating accuracy of other techniques. We compared CSMI, CSA and HAL measured with DXA (Prodigy, GE Healthcare, software version 10.5) and CT (Toshiba 64-slice, 1.0 mm slices). We measured the left femur in 14 healthy subjects, aged 35 to 78 years (64.7 ± 3.01 yrs) with total femur DXA BMD from 0.729 to 1.179 g/cm³ (0.921 ± 0.126 g/cm³). The DXA automatically measures CSMI (mm⁴) as the minimum CSMI within the neck region of interest (ROI), and CSA of the minimum CSMI section within the neck ROI. These DXA measurements usually occur in the section with the minimal neck diameter. A commercial QCT application (QCT PRO version 4.1, Mindways Software Inc.) was used to generate CSMI, CSA and HAL values from the QCT data. The QCT cross-sectional image at the narrowest portion of the femoral neck that most closely approximated the DXA CSMI measurement site was chosen for comparison purposes. QCT values were adjusted by the ratio of the DXA/QCT reference for average physical density of bone (1.85/1.05 g/cm³). Results showed very high correlations for CSMI (r=0.99), CSA (r=0.98), and HAL (r=0.86), with regression slopes not significantly different from identity. We also found high correlations (r=0.95) between DXA and QCT BMD values at the hip. We conclude that DXA structural measurements at the proximal femur had very high correlation and agreement with similar QCT measurements.

Comparison of DXA and QCT measurements of proximal femur structure and BMD				
Measurement	Regression Equation	SEE	r	
CSMI (cm ⁴)	CSMI (QCT) = 0.9689 CSMI (DXA) - 0.0241	0.0329	0.99	
CSA (cm ²)	CSA (QCT) = 0.9475 (DXA) - 0.0503	0.0555	0.98	
HAL (mm)	HAL (QCT) = 0.8278 HAL (DXA) + 23.8343	3.2308	0.86	
Femur Neck BMD	BMD (QCT) = 0.8306 BMD (DXA) - 0.0338	0.0381	0.96	
Total Femur BMD	BMD (QCT) = 0.9740 BMD (DXA) - 0.1204	0.0395	0.95

Trends in Femur Structural Strength with Aging in Canadian Adults: Canadian Multicentre Osteoporosis Study. K. S. Davison¹, T. J. Beck², J. D. Adachi³, D. Goltzman⁴, J. P. Brown¹.
¹U. of Laval, Quebec, PQ, Canada, ²Johns Hopkins U., Baltimore, MD, USA, ³McMaster U., Hamilton, ON, Canada, ⁴McGill U., Montreal, PQ, Canada.

This study details changes in hip structural strength parameters during aging in a large sample of randomly-selected community-based individuals from the Canadian Multicentre Osteoporosis Study (CaMos). Hip Structural Analysis (HSA) was performed on all CaMos baseline DXA hip scans at sites with HSA calibration data. A total of 5334 scans, 3724 women, and 1610 men were used. At the narrow neck (NN), inter-trochanter (IT), and shaft (FS) regions, BMD, outer diameter (OD), bone cross-sectional area (CSA), section modulus (SM) and estimates of cortical thickness (CT) and buckling ratio (BR) were computed. All eligible CaMos participants were separated by sex and grouped according to age: <30y, 30-39 y, 40-49y, 50-59y, 60-69y, 70-79y, and 80+y. Percent differences relative to the <30y group were used to approximate the age trend. The mean (SD, range) age was 61.0y (12.44, 25-92) for women and 57.6y (14.30, 25-90) for men. Structural and strength values provided in parentheses below represent the range in the parameter between men and women from the 80+y age group, unless otherwise noted. At the NN structural trends were similar in men and women with small almost linear increases in OD (3-9%) and large decreases in CSA and CW (21-28%). At the NN there were large

near-linear decreases in SM (12-18%) and exponential increases in BR (44-59%) with aging in both sexes. The structural changes with aging at the IT region were similar to the NN for both sexes. The IT region showed an exponential increase in BR for both sexes (30-50%) while the SM increased moderately at the 60-69y group (6-12%) and then slowly decreased in the oldest group of women. At the FS, there were small increases in OD (8-9%), moderate decreases in CSA (4-13%), and large decreases in CT (13-24%) with aging in both sexes. The FS strength changes were similar to those of the IT region. The BR for the FS region increased exponentially with aging (31-49%). In general, with age there was a slow transformation toward a wider, thin-walled bone. With regards to strength, there were relatively steady losses of CSMI and SM at the NN with aging after 40-49y; however, at the other regions there were small to moderate increases in CSMI and SM during a large portion of adulthood and generally small losses later in life resulting in a preservation of strength in comparison with the reference group. For all regions and for both sexes there was an exponential increase in BR with age which may suggest this as being one of the mechanisms of fracture in old age.

Association Between DXA-Assessed Muscle-Bone Proportionality and Fractures in Pre- and Post-Menopausal Women. R. Capozza^{*1}, C. Cure Cure^{*2}, G. Cointry^{*1}, M. Meta³, P. Cure Ramirez^{*2}, L. Plantalech⁴, J. Rittweger^{*5}, J. L. Ferretti¹. ¹Centro de Estudios de Metabolismo Fosfocálcico, Faculty of Medicine, UNR, Rosario, Argentina, ²Universidad de Barranquilla, Barranquilla, Colombia, ³UCSF, San Francisco, CA, USA, ⁴Hospital Italiano, Buenos Aires, Argentina, ⁵Manchester Metropolitan University, Manchester, United Kingdom.

This study aimed to evaluate the DXA-assessed bone mass (BMC) / muscle mass (lean mass, LM) relationship as an indicator of nonmechanical (i.e. "systemic") disturbances of the bone-muscle relationships in women in relation with the presence of fractures in different sites. Graphs of the BMC(y)/LM(x) proportionality showing CIs for ± 1 , 2, and 3 SDs from the regression line were obtained from the whole body and lower limbs (HB,LL) of 1,035 pre-MP and 1,556 post-MP healthy women as normal references (No-Fx group). Other 614 pre-MP and post-MP women with fractures in "osteoporotic" sites (hip, spine, long-bone metaphyses; Type-II Fx, n=386) or in other sites (Type-I Fx, n=228) were studied the same way. Individual SD-scores of the BMC/LM relationship (BMC/LM SD-scores) were calculated for all pre- and post-MP women as per the determined CIs of the regression curves of the healthy controls. The BMC/LM SD-scores of all Type-I-Fx women and of the pre-MP women with Type-II Fx were similar to those of their normal references, but lower than that in the post-MP women with Type-II Fx, especially in those with hip fractures. While the BMC-LBM curves were linear and similar in all the other groups, Type-II-Fx post-MP women showed nonlinear relationships, with progressively decreasing BMC and BMC/LBM SD-score values as their LBM decreased. Results were similar in WB and LL. Age and body weight and height were discarded as significant sources of variation for the studied relationships. Results show that the BMC/LM relationship may predispose somehow to Type-II Fx in post-MP women. They also suggest that both LBM and BMC/LBM SD-score determinations, either in the WB or in the LL, can help to differentiate between osteopenias/osteoporoses that ought to receive different treatments. Low BMC/LM SD-scores would define "metabolic" osteopenias which should be treated pharmacologically. Normal BMC/LM SD-scores would indicate a "mechanical" nature of the osteopenia for which only a physical or perhaps no other treatment should be indicated. The SD-scores would allow also to optimize monitoring following biomechanical criteria at low cost

Reference Graphs of Age-Related Changes in Bone Mass, Volumetric Density, Design and Strength and of Muscle-Bone Interactions in Normal Men and Women. S. Feldman^{*}, R. F. Capozza^{*}, G. R. Cointry^{*}, S. E. Ferretti^{*}, P. S. Reina^{*}, B. Homse^{*}, M. Zapata^{*}, J. L. Mansur, J. L. Ferretti. Centro de Estudios de Metabolismo Fosfocálcico, Faculty of Medicine, UNR, Rosario, Argentina.

Tomographic scans of forearms and legs (pQCT, 6 different sites) of normal, unfractured men and pre- and post-MP women (n = 60, 80, 120) aged 25-85 yr were performed to describe the variations and interrelationships of indicators of bone "mass" (BMC, cortical area, trabecular vBMD), bone material "quality" (cortical vBMD, vCtD), and bone design (moments of inertia, MIs), and of muscle strength (muscle cross-sectional area, mCSA). Three different patterns of variation were shown: 1. Bone "mass" indicators were higher in males than females and decayed slightly after MP. 2. Bone material "quality" (as assessed by vCtD) was higher in pre-MP women than men and decayed dramatically after MP. 3. Bone design was better in men than women but did not decay after MP. Calculated Bone Strength Indices (BSIs = MIs . vCtD) varied similarly to bone mass indicators. Bone mass, design and strength indicators (not so the vCtD) were linearly correlated with mCSA in all 3 groups, with parallel slopes for men and pre-MP women and lower slopes for post-MP women. The SD-scoring of the relationships between bone mass, design or strength indicators and the mCSA for men and pre-MP women allowed calculation of individual SD-scores of every relationship for post-MP women. The SD-scores for the relationships between bone mass and strength (not MIs or vCtD) and mCSA correlated negatively with time since MP (TSMP). Results show that

women would tend conveniently to maintain bone design after MP, with an independent variation of bone mass, material quality, design and strength. From a practical point of view, 1. the SD-score charts of the correlations between the different bone indicators, and of these with TSMP, provided normal references suitable for evaluation of the two true determinants of "bone quality", namely, bone material quality and design, and 2. the reference charts of the bone-muscle relationships allowed a non-invasive distinction between "disuse" and "systemic" osteopenias (with normal or reduced bone-muscle SD-scores, respectively) requiring substantially different treatments

Disclosures: J.L. Ferretti, None.

W236

Relationships Between Diaphyseal Geometry and Cortical Mineral Density as Assessed by pQCT in the Human Tibia. R. Capozza^{*1}, P. Reina^{*1}, G. Cointry^{*1}, S. Feldman^{*1}, S. Castellini^{*1}, J. Rittweger^{*2}, J. L. Ferretti¹. ¹Centro de Estudios de Metabolismo Fosfocálcico, Faculty of Medicine, UNR, Rosario, Argentina, ²Manchester Metropolitan University, Manchester, United Kingdom.

Indicators of tibial cortical bone "mass" (cortical BMC, CtC, g), mineral density (cortical vBMD adjusted for the partial-volume effect, Rho-vCtD, g/cm³) and design (cross-sectional moments of inertia, CSMIs, mm⁴) were determined in calf pQCT scans of normal men, and pre- and post-MP women (n = 60, 80, 120) aged 25-85 yr to evaluate the mechanical efficiency of the distribution of the available compact tissue as a function of its intrinsic properties.

The CSMIs (y) and Rho-vCtD (x) values correlated negatively ("distribution/quality", d/q hyperboles) showing high-CSMI / low-Rho-vCtD values for men; low-CSMI / high-Rho-vCtD values for pre-MP women, and low-CSMI / low-Rho-vCtD values for post-MP women. Parallel, linear correlations between the CSMIs and the CtCs of the same scans from every group ("distribution/mass" curves) were observed, with a common slope (b = 11,796 mm⁴/gm.cm⁻¹, p<0.001). Statistical adjustment of all CSMI values (Adj-CSMIs) to a common CtC value (3.5 mg/cm) according to that slope allowed expression of the mechanical ability of the diaphyseal design (CSMIs) achieved as a function of the available mineralized mass in every individual. Re-built d/q graphs after substituting Adj-CSMIs for the raw CSMI values showed a substantially reduced but still significant difference between curves for men and pre-MP women, and similar curves for pre- and post-MP women.

Results suggest that cortical density has an effect upon the geometrical design of the tibia diaphysis. As far as the reduced density may reflect a reduced Young's modulus of the tissue, the d/q curves can be regarded as expressing the bone ability to self-distribute the available cortical tissue (as assessed by the CSMIs) as a function of its intrinsic stiffness (as approached by its Rho-vCtD) according to the "Mechanostat" Theory. The gender-related differences between curves can be attributed to sex-hormone influences on that system.

Trabecular Bone Mass Evaluation as Related to Cortical Mass in the Human Leg: A pQCT Study. G. R. Cointry^{*}, R. F. Capozza^{*}, S. Feldman^{*}, P. Mortarino^{*}, L. Maffei, A. Alvarisqueta, J. L. Ferretti. Centro de Estudios de Metabolismo Fosfocálcico, Faculty of Medicine, UNR, Rosario, Argentina.

In uniaxial compression, the relevant factors to bone strength are the amount and material properties rather than the distribution of bone mass, and the nature of bone structure.

The distal 38% of the tibial length undergoes chiefly uniaxial compression. Toward the mid-diaphysis, an increasing proportion of bending and torsion is combined. At 4% of bone length from the heel, tibial structure is mostly trabecular. At 14% distal, almost exclusively cortical, the diameter is minimal and the section is closely rounded, with a fairly homogeneous cortical thickness. At 38% distal the shape departs from circularity.

We have determined the total BMC (TC) by pQCT at the 4%, 14% and 38% sites in the leg in normal men and pre- and post-MP women (n = 60,80,120) in order to determine 1. the proportion between total bone mass at the 4%, 14% and 38% sites in the different groups; 2. the functions describing those relationships[3], and 3. whether gender and estrogen status have any impact on these associations.

The TC at the 4% site (y) correlated linearly with that at the 14% site in all men, pre-MP and post-MP women, either separately or taken together (whole group, y = -0.45 + 1.54 x; r=0.938, R²=0.881, p<0.001, SEE=0.25) and at the 38% site (whole group, y = -0.31 + 1.08 x, r=0.903, R²=0.815, p<0.001, SEE=0.33) with similar intercepts for each group.

Results indicate that 1. the mechanical efficiency of the combined bone structure at the 4% site in compression would approximate 66% of that of the cortical structure at the 14% site, and 2. the mechanical solicitations of cortical structure at the 38% site would require the same amount of cortical mass than that of the combined structure at the 4% site, regardless of gender and reproductive status. SD-scored graphs of both relationships studied might provide normal references of the biomechanical proportionality between trabecular and cortical masses. As far as trabecular bone mass is usually more sensitive than cortical mass to metabolic changes, this may provide a diagnosis of metabolic bone diseases as based on data from the same individuals, obviating any comparison with references taken from different populations.

Evaluation of Bone Microarchitecture with High Resolution-pQCT in Patients with Thalassemia. I. M. Frieling^{*1}, R. Grosse^{*2}, E. B. Fung^{*3}, R. Fischer^{*2}, H. Kruse^{*1}, G. E. Janka^{*2}. ¹Osteoporosis Center, Hamburg, Germany, ²Pediatric Hematology, University Medical Center, Hamburg, Germany, ³Children's Hospital & Research Center, Oakland, CA, USA.

Thalassemia is a genetic disorder of hemoglobin synthesis. Due to improved blood transfusion and chelation therapy, survival has been increased with the consequence of complications like osteoporosis not seen during childhood and adolescence. The obvious shortcomings of conventional BMD methods like dual energy x-ray absorptiometry (DXA), can be overcome by simultaneously assessing the microarchitecture of the bone using high-resolution peripheral quantitative computed tomography (HR-pQCT), which may improve the estimation of the fracture risk in patients with thalassemia. In 17 regularly transfused patients (age: 13 - 43 y, 9/17 female) with beta-thalassemia major (n = 10), -intermedia (n = 6), and CDA-II (n = 1), the BMD of lumbar spine (LS) and total hip was measured by DXA (Hologic QDR1000+, Bedford, USA). Age, gender and ethnic specific BMD Z-scores were calculated. In addition, we assessed the volumetric BMD and the trabecular architecture of the non-dominant distal radius and tibia by HR-pQCT (XtremeCT[®], SCANCO Medical AG, Bassersdorf, Schweiz). Liver iron concentration and endocrinological parameters were also determined. In 15/17 patients low BMD values (LS Z-score range: -1.1 to -3.1) measured by DXA were significantly correlated with total volumetric density (range: 91 - 388 mg/cm³, p = 0.002) measured by HR-pQCT at the distal radius. In 6/17 patients (> 28 y), all with latent hypogonadism, the spongiosa was porous or nearly dissolved. Patients with hypogonadism (n = 9) were significantly different from normals with respect to radial trabecular inhomogeneity parameter TbSp SD (p = 0.02), but not to LS Z-score. Patients with fractures (n = 5) had lower total densities (p = 0.02) and trabecular TbSp SD (p = 0.02) at the tibia and started blood transfusions at a higher age (p = 0.023). However, Z-scores did not reflect the fracture risk in this patient group (p = 0.11). Liver iron was mainly correlated with tibial TbSp SD (Rs = 0.54, p = 0.025).

In patients with thalassemia BMD Z-scores seem to underestimate fracture risk because a normal cortical thickness and density may conceal a porous trabecular structure. Endocrinological failures, especially hypogonadism, were responsible for the pathological microarchitecture of distal radius and tibia, while bone marrow expansion as in thalassemia intermedia and liver iron concentration seem to play a minor role. These initial results from bone microarchitecture measurements in thalassemia should be confirmed in a larger sample of patients with greater age range.

Trabecular Microarchitecture Assessed by MicroMRI in Postmenopausal Women with Osteoporosis on Therapy. P. Greeley^{*1}, J. M. Wagner^{*1}, P. Seaman^{*2}, S. Perera^{*3}, B. R. Gomberg^{*2}, O. Ganel^{*2}, M. Kleerekoper², S. L. Greenspan¹. ¹Medicine, University of Pittsburgh, Pittsburgh, PA, USA, ²MicroMRI Inc., Philadelphia, PA, USA, ³Medicine/ Biostatistics, University of Pittsburgh, Pittsburgh, PA, USA.

Although bone mineral density (BMD) is the gold standard to diagnose patients with osteoporosis prior to fracture, and to follow response to therapy, changes in BMD may only account for 30% of the reduction in fracture risk following therapy. Other factors such as trabecular micro-architecture contribute to fracture risk. A novel, noninvasive technique based on high resolution MRI (MicroMRI), examines trabecular microstructure and provides an index of the trabecular rods and plates. In order to examine the associations between standard measures of BMD by DXA at the wrist, hip and spine and distal radius micro-architecture by MRI in women on treatment, we recruited 20 postmenopausal women (mean age 70 years). Ten women had previously been on a bisphosphonate and 10 women, previously on a bisphosphonate short term, had just initiated treatment with teriparatide. Outcomes included bone mineral density by DXA (Hologic Discovery A) of the right wrist, PA spine, and hip (total, femoral neck,). MicroMRI was examined using a right bird cage wrist coil with a Sigma 1.5 Tesla MRI scanner and analyzed by MicroMRI Inc. (Philadelphia, PA). MicroMRI indices included: BV/TV (bone volume/total volume), Surf (topological surface density), Curv (topological curve density), Surf/Curv (surface to curve ratio, number of platelike to rodlike trabeculae, higher values indicate intact trabeculae); Erosion Index =(ratio of parameters that increase with deterioration). Table Pearson Correlation Coefficients, *p<0.05, ** p<0.01

	BV/TV	Surf	Curv	Surf/Curv	Erosion Index
Age	-.763*	-.719**	.242	-.601**	.574**
Femoral Neck	.446*	.476*	-.211	.396	-.458*
Spine	.036	.044	-.005	.022	-.029
Ultra Distal Radius	.838**	.800**	-.569**	.785**	-.744**
1/3 Distal Radius	.552*	.522*	-.200	.460*	-.456*

Indices of MRI micro-architecture at the radius had the greatest association with BMD at the ultra distal radius but was also associated with BMD at the 1/3 distal radius and femoral neck sites. Correlation at the spine was poor. Older age was associated with fewer plates, lower plate to rod ratio and greater deterioration as assessed by the erosion index.

We conclude that measures of microMRI at the wrist are associated with the wrist and hip BMD and demonstrate a deterioration in architecture in postmenopausal women with osteoporosis on therapy. Additional studies are needed to examine these changes prospectively.

Bone Strength and Toughness Are Reduced by Loss of Architecture - A Non-linear FE Analysis. G. J. Gross^{*}, H. Hong^{*}, B. Borah^{*}, R. J. Phipps, T. E. Dufresne^{*}. Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Reductions in bone volume and deterioration in bone architecture occur in osteoporosis. We performed non-linear computational modeling to understand the effect of architectural changes and bone loss on bone strength and toughness.

MicroCT scanning was performed on iliac crest biopsies collected from a placebo-controlled clinical study in postmenopausal osteoporosis. Finite element models were created directly from these microCT data over a wide range of bone volumes (11-29% BV). The volume of interest was maximized to include the largest number of bone elements possible. A custom program was written to simulate bone loss, which used a 3D Euclidian distance map for each sample to randomly select bone erosion sites. A 26% loss of BV was used to match the 3-yr placebo-treated results from the clinical study. This 26% simulated bone loss resulted in architectural changes comparable to those observed experimentally in clinical biopsies. The plasticity of bone was represented using a non-linear constitutive model with apparent properties measured by compression loading each FE model.

With a 26% loss of BV, reductions in bone strength and toughness were similar, but depended on initial bone volumes.

	Sample (% BV)		
	29	19	11
% Change from baseline			
Bone Strength	-57	-61	-82
Toughness	-56	-73	-81

To understand the "dose response" of strength and toughness to bone loss better, a single sample (19% BV) was analyzed at five levels of bone loss (10, 15, 20, 26 and 35%). Both strength and toughness were reduced across all bone loss levels even after only 10% loss. Strength and toughness reductions followed similar trends.

	% of Bone Loss in 19% BV Sample				
	10	15	20	26	35
% Change from baseline:					
Bone Strength	-25	-38	-40	-55	-67
Toughness	-23	-35	-44	-52	-65

Use of non-linear tissue properties made these predictions in bone toughness possible and is a valuable technique in assessing bone fragility. Our results show that deterioration of trabecular architecture directly effects both strength and bone toughness. Toughness, the ability to absorb energy and prevent crack propagation, is important in bone fragility and will be further investigated in larger sample groups.

Trabecular Bone Microstructure Assessments of the Distal Radius Using a Compact MRI. S. Handa^{*1}, B. R. Gomberg^{*2}, T. Haishi^{*3}, K. Kose^{*1}. ¹Institute of Applied Physics, Tsukuba, Japan, ²MicroMRI Inc., Philadelphia, PA, USA, ³MRTechnology Inc., Tsukuba, Japan.

Trabecular bone (TB) microstructure measurements have shown promise for estimation of bone strength and evaluation of drug therapies for osteoporosis. Up to now, several groups have studied this extensively using whole body MRI (wbMRI) system, however the wbMRI systems are expensive and heavily utilized for other clinical indications. A compact peripheral MRI (cpMRI) system dedicated to measure TB microstructure would offer a solution to overcome these disadvantages.

In this study, we have evaluated a cpMRI system (MRTechnology Inc. Tsukuba, Ibaraki, Japan) for TB microstructure measurements of the distal radius.

The cpMRI consists of a 1.0 T permanent magnet (100 mm gap, homogeneous volume: 60 mm diameter sphere), gradient coil set, radio frequency probes, and an MRI console[1]. To acquired data, we developed 3D driven equilibrium spin-echo pulse sequence (matrix size: 512 X 384 X 32, voxel size: 150 X 150 X 500 micron cube, data-acquisition time: 17 minutes) for the distal radius imaging of five healthy male volunteers.

Ages ranged from 21 to 25 years (mean 22.4 years) and volunteers were scanned three times independently over two weeks.

Image data processing and analysis was performed semi-automatically using digital topological analysis (DTA - MicroMRI Inc., Philadelphia, PA, USA). Table 1 shows the reproducibility of BV/TV and selected DTA structural parameters in the distal radius. The root mean square CV (RMS-CV) values range from 2.9 % to 14 %. These values are close to those previously reported for the distal radius and tibia using a wbMRI system[2].

In conclusion, the 1.0 T permanent magnet cpMRI system was found to be capable of performing trabecular bone micro-architectural assessment of the distal radius consistent with the results from wbMRI systems, showing great promise of our system for evaluating bone quality in clinical settings.

Vertebral Fracture Risk: Is Size More Important than BMD. A. Hoiseth*. Sentrum Røntgeninstitute, Oslo, Norway.

Size is a major (bio)mechanical parameter, strongly associated to structural strength; compressive strength thus being associated to radius² and bending strength to radius⁴. BMD, often defined as a gold standard for fracture risk assessment, was constructed to eliminate the size factor, being the best approximation to bone density as measured by a two-dimensional projection. A dimension-less parameter, however, may not adequately reflect structure and thus strength. By DXA, however, also assessment of size as projectional area and bone mass (BMC) are derived. PURPOSE: To report the association for DXA parameters with fractures and with clinical and social consequences of fractures. MATERIAL: DXA parameters were measured in a total of 41,217 women aged >40 years. Fracture history was obtained in two cohorts of these, respectively 8,584 and 5,138 large. METHOD: After correcting for age, using the total material, the DXA parameters were ranked from high to low values into 10 equally large groups. Identical, but separate fracture analyses were then performed in the two cohorts. Fractures were classified as a) those having at least one vertebral fracture but without femoral fractures and b) those having at least one femoral fracture. Risk ratio (RR) was calculated for each tenth using the average number of fractures in the cohorts as RR=1. Only consistent results between the two cohorts were considered as "significant". RESULTS: For the femoral fracture group there was an exponential increase in RR from high to low BMC and BMD in "total femur". RR for the lower tenths being respectively 2.5 and 2.8. For area there was no difference in RR between the tenths. For the vertebral fracture group there was a linear increase in RR from high to low vertebral BMC and BMD, RR in the lowest tenth being respectively 1.5 and 1.4. For spine area there was an exponential increase in RR to 1.8 in the lowest tenth. The RR for having fractures with clinical or social consequences also increased exponentially with lower BMD and BMC in the femur, and with spine area. DISCUSSION: The results indicate a need for giving attention to bone as a structure, not merely as a material. Exploring different mechanically relevant parameters may help us to more correct predictions of the risk of vertebral fractures, a fracture that to a large degree is independent of BMD.

Age, Gender and Region Related Changes in Bone Mineral Density of Korean Adult. W. Choi, S. Hong*. Internal Medicine, Hanyang University, College of Medicine, Seoul, Korea, Seoul, Republic of Korea.

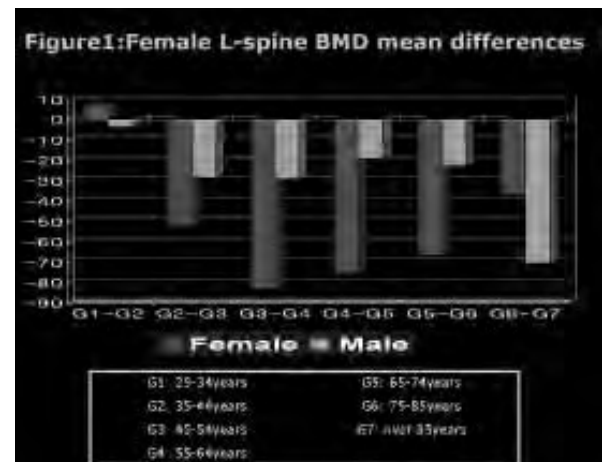

Background: Early diagnosis by measurement of bone mineral density(BMD) and treatment can reduce osteoporosis complications. But we had no large population data & Korean specific reference value in diagnosis of osteoporosis.

Method: we performed cross sectional study involving 50208 people(lumbar BMD / M:4,810, F:45,398), and 50026 people (femur neck BMD /M:4745, F:44,700) from Seoul, Gyeonggi,

Daegu, jeonbuk. BMD was measured by using DEXA (HOLOGIC, QDR 4500 system) Result: Female peak BMD was obtained at 35-45 years (lumbar: n=2224, 0.985±0.129 and femur: n=6800, 0.864±0.114 mg/cm2). Male peak BMD was obtained at 25-35years (lumbar: n=458, 1.010±0.118, femur: n=489 0.960±0.113 mg/cm2). And BMD was decreased with age. But decrease of BMD was more prominent with female and other regions than with male and Seoul. Especially female lumbar and femur wards BMD decrease was accentuated at menopause period.(figure1) The reference value in diagnosis of osteoporosis from our data was lower than the previous used reference data (Japanese data) except female femur.(figure2) Conclusion: Korea is racially homogeneous and not large nation. But there was regional difference in the BMD change. Also the diagnosis of osteoporosis may be overestimated. So further research is needed considering with social factors and fractures.

Figure2: T-score in this study

	Mean±SD	1.0 SD	2.0 SD	3.0 SD	4.0 SD
Female(35-45, n=2735)	0.992±0.124	0.868	0.744	0.620	0.715
Male(25-34, n=458)	1.008±0.127	0.881	0.754	0.631	0.729
Female(35-44, n=5500)	0.853±0.117	0.748	0.631	0.515	0.589

In Vivo Proteomic Analysis of Circulating Monocytes in Chinese Pre-menopausal Females with Extremely Discordant Bone Mineral Density. E. Y. Deng*, Y. Z. Liu*, C. Jiang*, L. M. Li*, S. Wu*, Y. Chen*, H. Jiang*, F. Yang*, P. Xiao*, S. M. Xiao*, L. J. Tan*, X. Sun*, J. X. Xiong*, X. Z. Zhu*, M. Y. Liu*, S. F. Lei*, X. D. Chen*, J. Y. Xie*, G. G. Xiao*, S. P. Liang*, H. W. Deng*. ¹Departments of Basic Medical Science and Orthopaedic Surgery, University of Missouri - Kansas City, Kansas City, MO, USA, ²Hunan Normal University, Changsha, China, ³Osteoporosis Research Center, Creighton University, Omaha, NE, USA, ⁴Department of Pediatrics, Harbor University of California, Los Angeles, Torrance, CA, USA.

Osteoporosis (OP) is a major public health problem and bone mineral density (BMD) is an important determinant of OP. Circulating monocytes (CMCs) may serve as progenitors of osteoclasts and produce a wide variety of factors important to bone metabolism. However, little is known about the specific roles of CMCs in the pathogenesis of OP. Using proteomics techniques of 2-Dimensional Gel Electrophoresis (2-DE) coupled with Matrix Assisted Laser Desorption and Ionization Time-of-Flight/ Time-of-Flight Mass Spectrometry (MALDI-TOF/TOF-MS), we performed a comparative protein expression profiling study of CMCs in Chinese pre-menopausal females with extremely high or low BMD. A total of 38 differentially expressed proteins on 2-DE gels were identified. We confirmed with western blotting five proteins that potentially might have important roles in osteoclastogenesis: up-regulation of ras suppressor protein 1 (RSU1), gelsolin (GSN), and manganese-containing superoxide dismutase (SOD2), and down-regulation of glutathione peroxidase 1 (GPX1) and prolyl 4-hydroxylase beta subunit (P4HB) in low vs. high BMD group. RSU1, GSN, SOD2 and GPX1 might affect monocyte trans-endothelium (via regulating its adhesion, morphological changes, or locomotion), differentiation, and/or downstream osteoclast function (via regulating osteoclast podosome formation, adhesion, motility, or activity). Thus, these proteins may contribute to differential osteoclastogenesis and finally lead to BMD variation. This is the first in vivo proteomics study of OP in humans and the five identified proteins may serve as biomarkers for early prevention and novel targets for clinical intervention of this debilitating disease.

The Loss of Follow up After Fragility Hip Fractures in Some Regions in Czech Republic. T. Hala¹, F. Senk^{*2}, P. Zivny^{*3}, B. Skyvarova^{*4}, M. Carda^{*5}, T. Dedek^{*6}. ¹SYNARC/CCBR Czech, Pardubice, Czech Republic, ²Osteocentre, Hospital Havlickuv Brod, Czech Republic, ³Osteocentre, Teaching Hospital Hradec Králové, Czech Republic, ⁴Osteocentre, Hospital Jablonec nad Nisou, Czech Republic, ⁵Traumatology, Regional Hospital Pardubice, Czech Republic, ⁶Traumatology, Teaching Hospital Hradec Kralove, Czech Republic.

Fragility fracture is a major risk for osteoporosis and has been identified as the only clinically relevant marker of bone quality. It is important to identify whether patients who experienced fragility fractures are being assessed and treated for osteoporosis in order to reduce the risk of future fracture. The patients with fractures should be managed in accordance with evidence-based clinical guidelines for osteoporosis.

Objective: The main objective of this study was to establish the BMD testing rate in osteoporosis management for people over 50 years of age who had already suffered a hip fracture. This is the first study in Czech Republic conducted for this purpose.

Methods: We conducted a retrospective cohort study using data from 5 fracture clinics and bone disease centres. Study population consisted of all individuals over 50 years of age who sustained hip fracture between January 1, 2004 and December 31, 2005 from regional hospitals where one fracture clinic and one bone disease centre are in house, for accurate data analysis. We used Czech classification system for fractures: hip (S 72.0), pertrochanteric fracture (S 72.1) and subtrochanteric fracture (S 72.2). We included patients with osteoporotic fractures and with DXA measurements of L1-L4 and hip. We excluded those with high-energy trauma fractures.

Results: We analyzed data from 1465 patients, 1054 (71.95%) women and 411 (28.05%) men with proximal femur fractures. We have documented that 99 patients (6.75%) with fractures underwent densitometric evaluation. The number of women and men was 86 (5.87%) and 13 (0.88%), respectively. Out of those 99 patients, 67.3% were over 70 years of age.

Patients	women	men	assessed by DXA	women	men
1465	1054	411	99	86	13
%	71,95	28,05	6,75	5,87	0,88

Conclusions: There is evidence of a care gap between the occurrence of fragility fractures and the diagnosis of osteoporosis in some regions in Czech Republic. This study provides evidence that many Czechs who experienced fragility fracture are not being diagnosed and treated for prevention of future fractures. The prevalence of bone mass measurements or physician follow-up is enormously low.

Disclosures: T. Hala, None.

Skeletal and Vitamin D Status in Two Indigenous North American Populations. I. V. Haller¹, W. D. Leslie², J. Jaakola^{*3}, H. A. Weiler^{*4}, D. Krueger⁵, N. Binkley⁵. ¹Education and Research, SMDC Health System, Duluth, MN, USA, ²Faculty of Medicine, University of Manitoba, Winnipeg, MB, Canada, ³Human Services Division, Fond du Lac Band of Lake Superior Chippewa, Cloquet, MN, USA, ⁴School of Dietetics and Human Nutrition, McGill University, Montreal, PQ, Canada, ⁵Osteoporosis Clinical Research Program, University of Wisconsin, Madison, WI, USA.

Bone health and vitamin D status have received only limited study among North American indigenous populations. To explore potential geographic differences in peripheral BMD and wintertime 25OHD levels, we conducted a secondary analysis of data from studies of two indigenous North American populations of women: First Nations (FN) in Canada and American Indian/Alaska Native (AI/AN) in the US. The FN group was comprised of 96 women from the First Nations Bone Health Study (FNBHS); the second group included 78 AI/AN women from the Great Lakes region. All participants had weight, height, and calcaneal BMD measurements (Lunar PIXI) performed. Serum calcium, PTH, and 25OHD were evaluated during winter months (January-March). In the FNBHS study, the Diasorin RIA and DPC EIA were used to measure 25OHD and PTH, respectively, while in the AI/AN cohort, HPLC and the DPC IRMA were utilized for these measurements.

In this analysis, the FN women were on average younger than their AI/AN counterparts (42.4±11.3SD vs. 50.3±9.9SD years old). There were no differences between the two groups in weight (82.7±18.9SD vs. 86.4±18.7SD kg) or BMI (30.8±6.3SD vs. 32.2±6.6SD kg/m²). Due to the effects of age and weight on peripheral BMD, we used general linear modeling (GLM) to test the difference in absolute values of calcaneal BMD between the two groups adjusted for weight and age. Adjusted BMD values in FN and AI/AN women did not differ (0.515±0.009SEM vs. 0.542±0.010SEM g/cm², respectively, P=0.052).

In bivariate analysis, the FN group had lower serum calcium (9.0±0.4SD vs. 9.4±0.3SD mg/dl, P<0.001), higher PTH (55.1±22.2SD vs. 42.5±23.6SD pg/ml, P<0.001) and higher 25OHD (21.2±10.0SD vs. 18.1±8.9SD ng/ml, P=0.032). Serum 25OHD was negatively correlated with PTH in the overall sample (r=-0.19, P=0.014); no correlation between 25OHD and BMI was observed. Similar proportions of women in both groups had serum 25OHD concentrations below 30 ng/ml (82.1% in FN vs. 89.7% in AI/AN group). There was a significant effect of group on serum 25OHD concentrations after adjustment for age, BMI and PTH levels using GLM: 22.0±1.0SEM ng/ml in FN group vs. 17.1±1.2SEM ng/ml in AI/AN group (P<0.001). In conclusion, low vitamin D status is common in these two populations of indigenous North American women. Investigation of approaches to optimize vitamin D status in FN and AI/AN women is indicated.

Low Bone Mass Is Common in Premenopausal Black Women with Systemic Lupus Erythematosus on Prednisone: High BMI Is Protective. J. K. Jenkins, I. Srivastava-Hadley*, K. Demoruelle*. Division of Rheumatology, University of Mississippi Medical Center, Jackson, MS, USA.

The purpose of this study was to examine a premenopausal black female systemic lupus erythematosus (SLE) population on prednisone to determine the prevalence of low bone density (LBD) and osteoporosis (OP) and identify modifying clinical factors.

We performed a retrospective chart evaluation to examine factors affecting bone mass in premenopausal black women with SLE on steroids. Protected by ethnicity, this population has a higher SLE disease burden that may affect the development of low bone mass (LBM, i.e., LBD and OP). We identified patients from our lupus specialty clinic in 2004-2006 who also had a bone density assessment in the Division of Rheumatology. All patients were on daily prednisone >2 mg/d. Clinical information was collected from the DXA records and clinic charts. ACR criteria were used for the classification of SLE.

Sixty-one women met our criteria. Nine others were excluded because of incomplete data. Average age at the time of the DXA scan was 32.9 yrs. Average disease duration was 7.1 yr. Prednisone was first used 7.1 yrs prior to DXA. Average prednisone dose was 11.9 mg/d at the time of DXA. Patients took: 0.7 other medications that may be associated with LBM (anticonvulsants, furosemide, anti-ulcer drugs, warfarin); 1.2 steroid sparing drugs (hydroxychloroquine, azathioprine, methotrexate, and mycophenolate); and 0.7 drugs that were potentially protective (calcium, HCTZ, bisphosphonates). Average BMI was 30.3. There were 3 non-vertebral fractures including one hip fracture.

DXA results were (WHO classification): 41% normal, 39% LBD, 20% OP. Regression analysis was performed to identify modifying factors. Duration of steroids, number of steroid sparing drugs, and the number of LBM-associated drugs or -protective drugs used were not associated with LBM. Bone density was strongly positively correlated (p<0.01, r=0.7) with BMI at all sites. Frank obesity (BMI>30, n=32) was protective, and was associated with a higher BMD (p<0.003) at all sites by 12-17%. In contrast to one report in which non-white SLE patients had a higher prevalence of hip OP, we find the usual higher prevalence of vertebral OP (20%, vs. 3% hip) with steroids in the black SLE population. This is a large study of black women with SLE on prednisone examining multiple factors affecting the development of low bone mass. Low bone density and osteoporosis appear to be as common in young premenopausal black women with SLE on steroids as in white women in previous reports (23%). This may be due to a greater disease burden and steroid use. Obesity is a significant protective factor against prednisone-associated osteoporosis in SLE in black women.

Disclosures: J.K. Jenkins, None.

What Are the Characteristics of Postmenopausal Women with the T-score of the Total Hip that Is Lower than that of the Lumbar Spine? M. Kang*, M. Kim*, D. Lim*, S. Lee*, K. Baek*, J. Han*, H. Kim*, K. Lee*. Department of Internal Medicine, The Catholic University of Korea, College of Medicine, Seoul, Republic of Korea.

Background. Generally, T-score of the lumbar spine is lower than that of the total hip in postmenopausal women because of an accelerated loss of trabecular bone after menopause. However, some women had the reversed T-score which meant that the T-score of the total hip was lower than that of the lumbar spine. It is well known that PTH and thyroid hormone preferentially involve cortical bone rather than trabecular bone. Thus, we aimed to investigate the characteristics of postmenopausal women with T-score of the total hip that is lower than that of lumbar spine.

Methods. We enrolled 246 postmenopausal women (mean age: 55.87±6.99 years) in our study. Serum levels of TSH, free T4, PTH, FSH, Estradiol, Alkaline phosphatase, Calcium, Phosphorus were measured by the standard methods. BMD at the lumbar spine and femur were measured by dual energy X-ray absorptiometry.

Results. Among 246 postmenopausal women, there were 25 cases in which the T-score of the total hip were lower than that of the lumbar spine (low hip T-score group). Body weight and BMI were significantly lower in the low hip T-score group, when compared to group that had similar lumbar BMD (55.41±6.13 vs. 60.51±7.84, p=0.011, 22.83±2.63 vs. 24.57±3.17, p=0.034). Age, YSM (years since menopause), free T4, TSH, PTH, FSH and Estradiol showed no differences between the two groups.

Conclusions. We have found that postmenopausal women, having the lower T-score of the total hip than that of the lumbar spine, have low body weight and low BMI. But, we could not detect any statistically significant differences in PTH and thyroid hormone levels. Additional studies are required to find the characteristics of postmenopausal women having the lower T-score of the total hip than that of the lumbar spine.

The Effect of Home Parenteral Nutrition on Bone Mineral Density. H. Karakelides*, J. L. Burnes*, J. M. Nadeau*, D. G. Kelly*, D. L. Hurley*, K. A. Kennel*. ¹Endocrinology, Mayo Clinic College of Medicine, Rochester, MN, USA, ²Gastroenterology, Mayo Clinic College of Medicine, Rochester, MN, USA.

Home parenteral nutrition (HPN) or long-term parenteral nutrition has been associated with poor bone health. Altered nutrition, components of parenteral nutrition formulations (e.g., aluminum) and underlying gastrointestinal (GI) disorders have been suggested as reasons for reduced bone density in this population. In addition to changing nutrition

support practices, there have been advances in pharmacotherapies for metabolic bone disorders. However, there is little data on the effects of bone active drugs in patients who are on long-term parenteral nutrition. We conducted a retrospective study of patients on HPN to assess risk factors for bone loss and effects of bone active drugs on bone mineral density (BMD). Subjects studied had been treated by the Mayo Clinic Rochester HPN team since 1994 and had been on HPN for at least 1 year and had at least 2 BMD measurements performed at least 1 year apart. 52 subjects were included with a mean age 59.8 ± 2.0 years, mean duration of HPN 115.1 ± 14.2 months, mean body mass index (BMI) 23.0 ± 0.5 kg/m². There was no association between gender, age, BMI, duration of HPN or underlying GI pathology (inflammatory vs non-inflammatory disorders) and change in BMD during follow-up. The subjects were then divided into those who had been treated (tx, n=31) with bone active drugs versus those who had not been treated (untx, n=21). There was no difference in time on HPN, time between BMDs, underlying GI pathology, BMI or age between the two groups. As may have been expected, subjects in the tx group had a lower baseline BMD of the lumbar spine (LS) (0.92 ± 0.03 in tx vs 1.03 ± 0.04 g/cm² in untx, $p < 0.05$) and femoral neck (FN) (0.76 ± 0.03 in tx vs 0.87 ± 0.03 g/cm² in untx, $p = 0.01$). However, there was no significant impact of treatment with bone active drugs on the change in LS or FN BMD from baseline to final observation. In conclusion, in subjects on HPN, gender, age, BMI, duration on HPN and underlying GI disorder were not good predictors of BMD. Subjects with lower BMD were more likely to be treated with bone active medications.

Gonadotropins Associated with Bone Mineral Density in Males. A. Kåss*, H. Gulseth*. Department of Rheumatology, Betanien Hospital, Skien, Norway.

It has been recently suggested that FSH regulates bone mass (1,2) independent of the action of oestrogen. FSH was shown to stimulate osteoclastogenesis and bone resorption by acting on $G_{i\alpha}$ -coupled FSH receptors, which are localised on the surface of mouse and human osteoclasts and their precursors. We wanted to examine the levels of FSH, LH in men and explore their relationship to bone mineral density (BMD). One hundred and eighteen males (age range 49-90 years) with low impact forearm fractures were included. Lumbar spine BMD was measured according to standard procedures with Lunar DXA equipment. Serum FSH, luteinizing hormone (LH) and testosterone were measured using fluoroimmunoassay. Multiple linear regression was used to assess the relationship between BMD and these hormones controlling for age and BMI. Of males with established osteoporosis (defined as a T score below 2.5 SD), 28.6% had above normal (>12.0 IE/L) FSH levels, 21.4% had above normal (>12.0 IE/L) LH levels and 33.3% had below normal (<8.0 IE/L) testosterone levels. FSH and LH were significantly associated ($\beta = -0.775$, $p = 0.021$, $\beta = -0.751$, $p = 0.013$ respectively) with BMD after controlling for age and BMI. To our knowledge this association has only been previously reported in women (3). Further studies are required to assess the oestrogen-independent role of FSH in osteoclastogenesis. It is unknown whether the associations observed between LH and BMD are confounded by FSH or gonadal hormones, or whether LH itself might have oestrogen-independent effects on bone mass; this remains to be studied. Spine Bone Mineral Density Predicted Incident New Vertebral Fractures in Postmenopausal Korean Women. S. Kim¹, Y. Rhee¹, H. Choi^{*1}, Y. Kim², E. Kang^{*1}, B. Cha^{*1}, E. Lee^{*1}, H. Lee^{*1}, S. Lim¹. ¹Internal Medicine, Yonsei University, Seoul, Republic of Korea, ²Internal Medicine, NHIC Ilsan Hospital, Goyang, Republic of Korea.

The identification of individuals at risk for osteoporotic fracture is essential for prevention. Low bone mineral density has been shown to be an important predictor of increased fracture risk. However, it is not known whether bone mineral density (BMD) in the axial skeleton is related to fractures in postmenopausal Korean women. We examined the relationship between BMD measured by dual energy x-ray absorptiometry (DXA) and incident vertebral fractures in postmenopausal Korean women. Baseline data collected from 2000 to 2002 (670 Korean women aged 49-87 years) at Severance Hospital, Seoul, Korea; mean follow-up of 3.2 years. Of the 670 subjects included in the study, 514 had no vertebral fractures and 156 had at least one. The women with vertebral fractures were older, smaller, and lower BMD compared to those without. In a binary logistic regression model with multivariate adjustment, age ($p < 0.001$), spine BMD ($p < 0.01$), and total hip BMD ($p = 0.001$) were independent risk factor for prevalent vertebral fractures. During follow up period, 77 women (34 in 156 women with prevalent vertebral fractures and 43 in 514 women without) developed new incident vertebral fractures. In women without prevalent vertebral fractures, age (OR=1.070; 95% CI, 1.005-1.140) and spine BMD (OR=0.559; 95% CI, 0.332-0.940) were independent risk factor for incident new vertebral fractures in a binary logistic regression model with multivariate adjustment. In models adjusted for age, Spine BMD was associated with increased risk of incident new vertebral fractures ($p < 0.05$) in women with baseline vertebral fractures. Decreased spine BMD was associated with an increased risk of incident new vertebral fractures in postmenopausal Korean women.

Longitudinal Study of Changes in Bone Mineral Density in Women Undergoing Screening for Osteoporosis. K. Kurasawa*, K. Katayama*, Y. Nomura*, R. Kikuchi, O. Chaki, F. Hirahara*. Obstetrics and Gynecology, Yokohama City University, Yokohama, Japan.

Objective: Measurements of bone mineral density (BMD) are an important tool for the diagnosis and treatment of osteoporosis. Low BMD is an independent risk factor for fracture. However, longitudinal studies of BMD are few. Longitudinal studies and analyses of the time course of BMD are essential. **Methods:** The study group comprised 69 women free of diseases potentially affecting bone metabolism who presented at our department from 1993 through 2006 to undergo measurement of BMD. Their mean age was 58.8 years (range, 43 to 71). The subjects were classified into 3 groups according to status: perimenopausal women, early postmenopausal women, and late postmenopausal women. Height, body weight, lumbar-spine bone mineral density, and femoral BMD were measured over time. The percent changes in these values were compared. Lumbar-spine radiography was performed in 1998 and 2006. The presence or absence of new fractures was examined. **Results:** At the beginning of the study, lumbar-spine bone mineral density (0.954 ± 0.04 mg/cm²), femoral BMD (total, 0.710 ± 0.05 mg/cm²; neck, 0.801 ± 0.06 mg/cm²), radial bone mineral density (0.447 ± 0.04 mg/cm²), and calcaneal bone mineral density ($91.54\% \pm 13.42\%$) were significantly higher in perimenopausal women than in early and late postmenopausal women ($p < 0.01$). In perimenopausal women, lumbar-spine BMD significantly decreased by 7.71% at 5 years, by 10.29% at 7 years, and by 13.49% at 13 years. BMD at all other sites also significantly decreased during follow-up. In early and late postmenopausal women, lumbar-spine and femoral BMD did not decrease significantly. In contrast, calcaneal BMD significantly decreased in all groups, suggesting that calcaneal BMD may not reflect the estrogen-deficiency-related decrease in BMD after menopause. Height did not significantly decrease in any group, and there were no new fractures. **Conclusions:** The age-related decrease in BMD seen in women differs depending on the site examined. Early after menopause, BMD decreases rapidly at all sites. Subsequently, longitudinal monitoring confirmed that the percent decreases in BMD gradually converged. When screening for osteoporosis, the BMD of sites other than the calcaneus should be measured mainly during the perimenopausal period. In women with no decrease in height, bone density can be measured at intervals of 1 year or longer.

No-vertebral Fracture Rates Are Lower in Hong Kong Chinese Men than American Caucasians but Bone Mineral Density Predicts Fracture Risk Similarly in the 2 groups-Results from Mr Os International. E. M. C. Lau¹, J. Lapidus², P. C. Leung³, T. Kwok³, D. Bauer⁴, J. Cauley⁵, S. R. Cummings⁶, E. S. Orwoll, for the Mr Os Study group⁷. ¹Hong Kong Orthopaedic and Osteoporosis Center, Hong Kong, China, ²Oregon Health and Science University, Portland, OR, USA, ³Chinese University of Hong Kong, Hong Kong, China, ⁴California Medical Center, San Francisco, CA, USA, ⁵University of Pittsburgh, Pittsburgh, PA, USA, ⁶San Francisco Co-ordinating Center, California Pacific Medical Center, San Francisco, CA, USA, ⁷Oregon Health and Science University, Portland, OR, USA.

The purpose of this study is to compare fracture rates in Hong Kong (HK) Chinese and American (US) Caucasian men and to study the relationship between BMD and fracture risk in these 2 groups by a cohort method.

The Mr Os cohort consists of 5,995 ambulatory men recruited from 6 communities in the US, plus 2000 men recruited from a single site in Hong Kong. Protocols in the two countries are comparable. BMD was measured with DXA, and standardized to account for equipment differences. Age and body mass index (BMI) were collected at baseline examination. Fractures were ascertained using standardized country-specific protocols, and all were confirmed by physician adjudication. Numbers and rates of fracture were compiled for each country individually. Data from the two countries were pooled, and Cox regression models used to compare associations with fracture in HK vs. US. Regression models were adjusted for age, BMI and clinical site in US.

There were 70 non-spine fractures in 69 Hong Kong participants; 500 fractures in 413 US participants. Rates of all non-spine fractures were significantly lower among HK Chinese (967.1 per 100,000) than among US Caucasians (1818.3 per 100,000) (RR = 0.53, 95% CI for RR 0.41 - 0.68). Rates of hip fractures were also lower (218.5 per 100,000) in Hong Kong than in US (281.3 per 100,000), but not significantly so (RR=0.78, 95% CI: 0.45 - 1.33).

Hong Kong participants, on average, were younger (72.4 vs. 73.8 years), had lower BMI (23.4 vs. 27.4), and lower femoral neck BMD (0.79 vs. 0.84) (all $p < 0.0001$). We adjusted for age and BMI. The relative hazard of non-spine fracture per 0.1 gm/cm² decrease in femoral neck BMD did not significantly differ in Hong Kong, 1.39 (95% CI: 1.10 - 1.76) and US, 1.48 (95% CI: 1.36 - 1.62), $p = 0.63$. The relative hazard of hip fracture per 0.1 gm/cm² also did not differ between the countries (Hong Kong RH: 2.23, 95% CI 1.30 - 3.85; US RH: 2.76, 95% CI 2.13 - 3.59), $p = 0.49$.

In conclusion, the rates of non-spine fracture were lower among HK Chinese than among US Caucasians, but the relationship between femoral neck BMD, and fracture was similar in the two countries.

Bone Mineral Density in Hispanic Lupus Patients. I. Moldovan. Loma Linda University, Loma Linda, CA, USA.

The purpose of this study is to examine the bone mineral density (BMD) and its clinical determinants in a cohort of Hispanic women with systemic lupus erythematosus (SLE). The charts of one hundred consecutive Hispanic SLE patients were reviewed and twenty women who had BMD assessment by dual X-ray absorptiometry (DXA) were identified. Ten patients were premenopausal and ten were postmenopausal. The student t-test was used to assess statistical differences between the two groups. Clinical determinants of BMD were evaluated, including age, height, weight, body mass index (BMI), smoking and alcohol use, duration of SLE, steroid treatment, SLE disease activity index (SLEDAI) at the time of the DXA scan, SLE damage index (SLICC), as well as use of immunosuppressives and osteoporosis medications. The mean age was 34.3 in the premenopausal group and 52.6 in the postmenopausal group. The mean duration of SLE was 6.55 years in the premenopausal women and 19.1 years in the postmenopausal group. The disease activity score trended towards more active disease in the younger patients, however, the average doses of prednisone were comparable. BMI results were also comparable in both groups and were in the range of overweight. Four patients in the younger group and five in the postmenopausal ones had a BMI consistent with obesity. Overall, seventeen patients (85%) were taking glucocorticoids, but only five (25%) were taking medications for osteoporosis, including bisphosphonates, calcium and vitamin D. None of them were drinking alcohol and only one was an active smoker. The results showed that 35% of patients had osteopenia at the spine, 40% at the femoral neck and 10% at the total hip. Osteoporosis was present in 10% of the patients at both femoral neck and spine. One patient had a vertebral compression fracture. When comparing BMD in the pre- and postmenopausal groups, there was a trend towards lower BMD at the spine in the postmenopausal patients, and no statistical significant difference was detected for the total hip and the femoral neck. In conclusion, this study is one of the first ones looking at Hispanic lupus patients in terms of the prevalence of low BMD. In this small retrospective study, the prevalence of low BMD in the studied Hispanic SLE patients was comparable to reports from the literature in other ethnic groups. The small number of patients taking osteoporosis medications, despite widespread use of glucocorticoids underscores the importance of educating both physicians and patients regarding this matter. Somewhat surprising was the fact that there was no statistical difference in BMD, regardless of menopausal status. One explanation can be the small sample of patients analyzed. Another possibility could be that the higher BMI of the patients analyzed confers a protection against bone loss. Further, larger, prospective studies in this ethnic group are needed.

Lower Hip BMD Among Ethnically Diverse Postmenopausal Women with Anemia--Results from a Subgroup of the Women's Health Initiative. J. S. Nicholas, T. Bassford*, Z. Chen. University of Arizona, Tucson, AZ, USA.

Previously, we reported a significantly increased risk for hip fracture but not total fracture among anemic women in the Women's Health Initiative (WHI) Observational Study (OS). Additionally, a relationship between anemia and bone density was reported in a population of older community-dwelling anemic Italians, as well as among a variety of groups with specific conditions (thalassemia, hemodialysis, sickle cell anemia). Our aim was to investigate whether this relationship was evident among an ethnically diverse subcohort (n = 5,874) of postmenopausal women, age 50-79 at baseline from three clinical centers that performed bone density assessments in the WHI observational study. Questionnaires were used to collect demographic, medical, and lifestyle information. Bone mineral density (BMD) was measured by dual-energy x-ray absorptiometry. Anemia was defined using the WHO criteria of hemoglobin <12 g/dl in women using baseline measurements. Multivariate regression analysis was used to assess the relationship between whole body and total hip BMD with anemia after adjusting for age, ethnicity, body mass index (BMI), physical activity, total calcium (Ca) intake, and hormone use. Participants were 63.7 (SD=7.4) years old at baseline, 22.4% non-White minority and had a mean hemoglobin level of 13.5 (SD1.1) g/dl. There were 393 (6.7%) participants with anemia (mean hemoglobin level 11.3 g/dl SD=1.02) of whom 47.8% were non-White minority. No statistically significant (at a p=0.1 level) ethnic interactions with anemia on BMD were found with one exception for the Native American group in which only 6 women were anemic. The ethnic stratified results were similar across all the ethnic groups in the direction of the association, so the combined results for the relationship between anemia and BMD are presented in Table 1. Results from this analysis suggest that anemia is associated with a reduced hip BMD, which may explain the increased hip fracture risk we found previously among anemic women in the entire WHI-OS cohort. The relationship between whole body BMD and anemia is much weaker, which is also inline with our previous findings of no statistical significant association between total fracture and anemia.

	Hip BMD (g/cm ²)		Whole body BMD (g/cm ²)	
	β (SE)	P	β (SE)	P
Model 1 ^a	-0.02 (0.01)	<0.001	-0.004 (0.01)	0.5
Model 2 ^b	-0.01 (0.01)	0.03	-0.001 (0.01)	0.8

^a adjusted for age & ethnicity

^b adjusted for age, BMI, physical activity, total Ca intake, hormone use

Impact of Birth Weight and Age at Menarche on Skeletal Growth in Young Women. H. Ohta, T. Kuroda*, S. Orito*, Y. Onoe, Y. Miyabara*, R. Yoshikata*, M. Ohara*, K. Ishitani*, H. Okano. Dept. of Obstetrics and Gynecology, Tokyo Women's Medical University, Tokyo, Japan.

Objectives: Skeletal growth is assumed to occur under the influence of congenital genetic as well as acquired environmental factors. In recent years, fetal programming as developmental origins of health and disease (DOHaD) has drawn attention as a factor affecting lifestyle related disease.

However, it has also been suggested that birth weight and age at menarche, as well as lifestyle factors such as nutritional intake and physical activity, may affect skeletal growth. In this study, therefore, we investigated how these factors might affect skeletal growth in young women.

Subjects and Methods: Following approval of the study protocol by the institutional ethics committee at Tokyo Women's Medical University, birth weight and age at menarche, as well as lifestyle habits were surveyed in a total of 315 healthy young female volunteers aged 19 to 29 years old who were nursing school students at the institution and who gave informed consent to participate in the current study.

Results: The subjects' mean age was 22.1 \pm 3.0 (mean \pm SD); their mean birth weight, 3,143 \pm 45 g; their birth week, 39.3 \pm 1.8 weeks; their age at menarche, 12.0 \pm 1.2 years of age; their height, 158.8 \pm 4.8 cm; their body weight, 53.4 \pm 7.3 kg; and their BMI, 21.1 \pm 2.6 kg/m².

Birth weight was found to be significantly positively correlated with current BMI and BMD, and current BMI and L₂₋₄ BMD were found to be significantly higher in those who weighed 3,500 g or greater at birth, while there was no correlation seen between birth week and current BMI or L₂₋₄ BMD.

In those with normal menarche occurring between 10 to 15 years of age, age at menarche was found to be negatively correlated with current BMI and L₂₋₄ BMD, and positively correlated with body height.

Conclusions: The study results demonstrated that the greater the birth weight, the greater the current BMI and L₂₋₄ BMD, thus suggesting a role for birth weight in skeletal growth.

It was also suggested that the earlier the age at menarche, the shorter the body height, likely due to the resulting early closure of the epiphyseal space, and, as a consequence, the greater the BMI and the BMD in these young women.

It was therefore concluded that birth weight and age at menarche are independent factors affecting skeletal growth.

Association Study of IL-15 Polymorphisms with Bone Mineral Density and Fracture Risk in Postmenopausal Korean Women. J. Koh*¹, B. Oh*², J. Lee*², J. Lee*¹, K. Kimm*³, J. Kim*⁴, J. Lim*⁴, T. Kim*³, J. Hong*⁵, G. Kim*¹, S. Kim*⁶, E. Park*⁴. ¹University of Ulsan College of Medicine, Seoul, Republic of Korea, ²National Genome Research Institute, Seoul, Republic of Korea, ³Eulgi University School of Medicine, Daejeon, Republic of Korea, ⁴School of Dentistry, BK21, Kyungpook National University, Daegu, Republic of Korea, ⁵Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea, ⁶Kyungpook National University Hospital, Daegu, Republic of Korea.

Interleukin-15 (IL-15) has been implicated in both inflammation and bone destruction. In the present study, we investigated the genetic effect of IL-15 polymorphism on bone mineral density (BMD) in postmenopausal women. IL-15 polymorphisms were genotyped in study participants (n = 728). BMD at the lumbar spine and proximal femur was measured using dual-energy X-ray absorptiometry. We found that IL-15+13815A>T polymorphism was significantly associated with BMD of various bone sites. IL-15+13815A>T polymorphism was associated with high BMD of the lumbar spine (p=0.006-0.01), femoral neck (p=0.001-0.02), trochanter (p=0.009-0.05), femoral shaft (p=0.008-0.009), and total femur (p=0.008-0.04). Haplotype (ht) analyses showed that ht1 and ht2 were also significantly associated with high BMD at various sites (p=0.001-0.05). Moreover, IL-15+13815A>T polymorphism, ht1, and ht2 showed an association with risk of fracture (OR (95%CI) = 0.62(0.39-0.99), P = 0.04). These findings indicate that the +13815A>T polymorphism, ht1, and ht2 of IL-15 may be useful genetic markers for bone metabolism and risk of vertebral fracture.

Percutaneous Injection of Allantoin Accelerates Fracture Repair. A. A. Selim*¹, K. Mezghani*², A. Abou-Samra*³, D. Al-Tamimi*⁴. ¹Biotechnology Center, KFUPM, Dhahran, Saudi Arabia, ²Mechanical Engineering, KFUPM, Dhahran, Saudi Arabia, ³Wayne State University School of Medicine, Detroit, MI, USA, ⁴Pathology Department, College of Medicine, King Faisal University, Al-Khobar, Saudi Arabia.

Allantoin is a botanical extract of the comfrey plant and is used for its healing, soothing, and anti-irritating properties. Allantoin helps to heal wounds and skin irritations and stimulate growth of healthy tissue. Its chemical formula is C₄H₆N₄O₃. It is also called 5-ureidohydantoin or glyoxyldiureide. In this study, we examined the effects of allantoin on the proliferation of the osteoblastic cell lines, MC3T3 and ROS17/2.8, in vitro; and on fracture repair in vivo. Cell cultures were treated with allantoin (1, 10 and 100 nM) for seven days (From Day 1 of culture to Day 7). On day 7, MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide) and cell counting assays were performed to examine the effect of

allantoin on osteoblast proliferation. Allantoin significantly induced osteoblast proliferation in a dose dependent manner as compared to control cultures (35% and 56% increase for 10 and 100 nM, respectively, $p < 0.05$). It is important to mention that Carcinogenic Potency Project (CPP) studies demonstrated that allantoin has no carcinogenic effects on male or female rats and mice. We further examined the effect of allantoin on fracture repair. Experimental fractures were performed on 8-week Sprague-Dawley rats under anesthesia as follows: from an anterior incision we performed a transverse osteotomy at the mid tibia with a bone saw. The animals were then treated with vehicle or allantoin (weekly percutaneous injections; 10 mg/kg) for up to 4 weeks. Torsional biomechanical testing indicated that the stiffness of the allantoin-treated fractures was 2 fold higher than that of control groups at the two, three, and four-week time-points. The strength of the allantoin-treated fractures was 34%, 60% and 77% greater than that of controls at 2 ($p < 0.05$), 3 ($p < 0.005$) and 4 weeks ($p < 0.005$), respectively. At 4 weeks, the stiffness and strength of the allantoin-treated fractures were equal to those of the intact contralateral tibia, whereas the buffer-treated and untreated fractures were significantly weaker than the intact tibiae. These data demonstrate that percutaneous injections of allantoin accelerate fracture repair in this fracture repair model. Our data on osteoblastic cell lines in-vitro suggest the possibility that the beneficial effects of allantoin on bone may result from increasing osteoblast proliferation and thereby bone formation at the fracture site.

Threshold Associations between Aspects of Body Composition and Bone Mineral Mass. T. G. Travison, A. B. Araujo, G. R. Esche*, J. B. McKinlay. New England Research Institutes, Watertown, MA, USA.

Reduced weight is associated with decreased bone mineral content and density (BMC and BMD). It is unclear, however, whether lean mass (LM), fat mass (FM), or the combination of both (expressed through weight or BMI) is most important in stimulating osteogenesis and therefore bone strength. Using data from a racially/ethnically diverse sample of 1,209 men enrolled in the Boston Area Community Health / Bone study, we examined BMC and BMD at the hip, spine and forearm as a function of weight, body mass index (BMI), waist circumference, total body FM, and total body LM. Data were obtained on 363 non-Hispanic black, 397 Hispanic, and 449 non-Hispanic white randomly-chosen male residents of Boston, MA, USA. Subjects' ages ranged from 30 to 79 y. BMC and BMD were determined by dual x-ray absorptiometry. Analyses indicated that weight, BMI, waist circumference and FM displayed strong positive associations with BMC or BMD up to certain threshold values, beyond which associations were attenuated. LM, by contrast, displayed a strong and consistent association over all values (Figure); for instance, models controlling for fat mass and other covariates indicated a 12.8% and 9.2% increase in femoral neck BMC and BMD, respectively, per 10 kg unit in LM ($p < 0.001$). Once the effect of LM was accounted for, the magnitude and significance of associations between other parameters and BMC or BMD were sharply reduced. Percent increases in BMC or BMD corresponding to increased body size were greater in magnitude at load-bearing sites (hip and spine) than at the wrist; for instance, percent difference in BMD per 10kg difference in LM was significantly ($p < 0.001$) greater at the lumbar spine (6.9%) than the wrist (3.4%). Results were similar for all race/ethnicity groups. These results indicate that decreased body size parameters are strongly associated with decreased BMD, conferring increased risk of fracture at all sites and among all race/ethnicity groups. However, the protective effect of increased weight, BMI, waist circumference or fat mass on BMC and BMD manifests only within certain ranges of body size, beyond which the effect is diminished. On the other hand, it appears that increased LM is positively associated with BMD over the entire range of values, indicating that the protective influence of body composition on BMC or BMD is largely mediated by total lean mass.

Correlations Between Bone and Body Composition in Post-pubertal Daughters and Their Premenopausal Mothers. K. Uenishi¹, H. Ishida², M. Konishi³, Q. Zhou³. ¹Kagawa Nutrition University, Laboratory of Physiological Nutrition, Saitama, Japan, ²Kagawa Nutrition University, Laboratory of Administrative Diets, Saitama, Japan, ³GE Healthcare Asia, Shanghai, China.

Evidence suggests that both environmental and genetic factors play important roles in the development of osteoporosis. A strong correlation between lean mass (LM) and bone

mineral density (BMD) as well as bone mineral content (BMC) has been repeatedly demonstrated in individuals. However, studies of the relationships of bone and body composition values in families are lacking. Dual-energy X-ray absorptiometry (DXA) provides accurate, precise measurements of regional and total body composition. We measured total body BMD, BMC, LM, fat mass (FM), and %fat in 104 post-pubertal healthy Japanese girls (aged 19.6±1.3 years) and their healthy premenopausal mothers (aged 48.0±2.5 years) with DXA (Lunar DPX-IQ, GE-Healthcare). Pearson's correlation coefficients were calculated to examine the relationship between mothers and daughters. Weight, height, BMI, BMD, BMC, FM, LM, and %Fat showed low-to-moderate similarity between the girls and their mothers ($r = 0.23-0.47$, $p < 0.01$). Significant heritability ($h^2 \pm SE$) was detected for BMD (0.506 ± 0.03 , $P < 0.001$) and BMC measured with DXA (0.658 ± 0.04 , $P < 0.001$). Among the girls, BMD was moderately correlated with weight, BMI, FM and LM ($r = 0.34-0.49$, $p < 0.01$). While among their mother, correlations of BMD with weight, BMI and FM were slightly lower ($r = 0.26-0.31$, $p < 0.01$), and there was no significant relationship between BMD and LM ($p > 0.05$). We conclude that the bone and body composition values of these post-pubertal daughters are significantly related to their premenopausal mothers. The relationship between BMD and LM in these Japanese girls was stronger than in their mothers.

Table 1. Correlations between bone mineral and body composition in daughters

	BMD Correlation	P value	BMC Correlation	P value
FM	0.41	<0.001	0.553	<0.001
LM	0.392	<0.001	0.729	<0.001
%Fat	0.336	<0.001	0.39	<0.001
Height	0.162	0.1	0.522	<0.001

Racial Differences in Skeletal Health. M. D. Walker¹, R. Babbar^{2*}, J. Vargas-Jerez¹, J. Udesky¹, C. Gagel¹, D. J. McMahon¹, R. Lantigua¹, G. Liu^{2*}, J. P. Bilezikian¹. ¹College of Physicians and Surgeons, Columbia University, New York, NY, USA, ²New York Downtown Hospital, New York, NY, USA.

Although there are racial differences in bone mineral density (BMD) and fracture risk, little data are available regarding racial differences in bone mass accrual, peak bone mass (PBMD) achieved and bone loss. We compared changes in BMD between Chinese American, Hispanic and Caucasian women across all decades of adult life. In this cross-sectional study, 1120 Chinese American and Hispanic American women, 80 per decade from age 20 to 90 in each racial group, are being recruited. Along with DXA of the total hip (TH), femoral neck (FN) lumbar spine (LS) and forearm, demographic, familial, medical, nutritional and behavioral information is being obtained. To date, 743 subjects (411 Chinese American and 332 Hispanic women) have been recruited. BMD data for these cohorts were compared to Caucasian referent values. BMD means and standard deviations for each decade were calculated. Decade means were used to approximate longitudinal changes in bone density. These preliminary data suggest that Chinese American women achieve peak bone at the LS later (age 40-49) than Caucasian or Hispanic women (age 30-39). Chinese American women achieved 96.7% of the Caucasian PBMD at the LS ($p = 0.1$), while the Hispanic group reached 99.3% of the Caucasian PBMD ($p = 0.74$). Elderly Caucasian women (age 80-89) lost 28.2% of their bone mass at the LS from peak BMD compared to 22.2% ($p < 0.01$) for Chinese American and 25.8% for Hispanic American women ($p = 0.2$). Chinese and Hispanic American women achieved peak TH BMD later (age 40-49) than Caucasian women (30-39). TH peak BMD for Chinese American women was 96.2% of the Caucasian TH PBMD value ($p = 0.1$) while TH peak BMD for Hispanic women was 104.5% of the Caucasian TH PBMD ($p = 0.04$). Aged Caucasian women (age 80-89) lost 26.6% of their bone mass at the TH from peak BMD compared to 20.7% for Chinese American ($p < 0.01$) and 20.5% for Hispanic American women ($p < 0.01$). Hispanic American women achieve peak FN BMD later (age 40-49) than Caucasian and Chinese American women (age 30-39). Chinese American women reached 93.8% of the Caucasian PBMD at the FN ($P = 0.01$). Hispanic American peak FN BMD was similar to that of Caucasian women (101.8% of Caucasian PBMD; $p = 0.51$). Elderly Caucasian women (age 80-89) lost 32.9% of their bone mass at the FN from peak BMD compared to 25.8% for Chinese American and 27.5% for Hispanic American women ($p < 0.01$). The differences we have shown in the rate of bone mass accrual and decline among these 3 groups may contribute to racial and ethnic disparities in fracture rate.

Peak Spine and Hip Bone Mass in Korean Women. Y. Won¹, H. Kim^{*1}, Y. Shin^{*2}. ¹Endocrinology and Metabolism, Kwandong University College of Medicine, Goyang, Republic of Korea, ²Clinical Nutrition Research Center, Kwandong University College of Medicine, Goyang, Republic of Korea.

The achievement of maximal peak bone mass early on in life is one of the most important strategies for prevention of osteoporosis in women. The aim of this study was to clarify the correlation between body morphometry and bone mineral density. Bone mineral density (BMD) of the spine, femoral neck, total hip, and bone mineral content (BMC) of spine, femoral neck, total hip were assessed by dual energy x-ray absorptiometry in 322 healthy women (age 20-84 years).

The peak lumbar spine BMC was gained during fifth decades (40s) of life. However, peak BMD in lumbar spine was gained during fourth decades (30s) of life. The femur neck and total hip peak BMC were gained during third decades (20s) of life. However, peak BMD of femur neck and total hip were gained during fourth decades (30s). The age was all negative significant correlation of all these bone measurements. The weight and height were all positive significant correlation of all these bone measurements. In multiple stepwise regression analysis, age and weight were independent variable on spine BMD ($R^2 = 0.305$), femur neck BMD ($R^2 = 0.294$), total hip BMD ($R^2 = 0.283$). The weight was a stronger predictor than height for all sites.

We conclude that age of attaining peak bone mass at the hip is younger than at the spine, and age and weight were most important predictor on achievement of peak bone mass in Korean women.

In Vivo Genome-wide Expression Study of Human Blood B Cells Suggests a Novel ESR1 and MAPK3 Network for Postmenopausal Osteoporosis. P. Xiao¹, Y. Chen^{*1}, H. Jiang^{*1}, T. L. Yang^{*1}, F. Pan^{*1}, Z. H. Tang^{*1}, Y. Z. Liu², R. R. Recker¹, H. W. Deng². ¹Osteoporosis Research Center, Creighton University, Omaha, NE, USA, ²Department of Orthopedic Surgery and Basic Medical Sciences, University of Missouri-Kansas City, Kansas City, MO, USA.

Osteoporosis is characterized by low BMD resulting from bone resorption (by osteoclasts) exceeding bone formation (by osteoblasts). Estrogen deficiency evokes increased osteoclastic activity and bone loss.

Studies showed that B cells may participate in osteoclastogenesis via expression of osteoclast-related factors, such as NF-kappaB ligand (RANKL), transforming growth factor beta (TGFB), and osteoprotegerin (OPG). However, the role of B cells in bone metabolism and osteoporosis is still largely unknown, particularly at the systematic expression level in vivo.

In this study, we recruited 20 unrelated postmenopausal Caucasian females aged 54 - 60, 10 with high (spine or hip Z-score > 0.84) and 10 with low BMD (spine or hip Z-score < -0.84). Total RNA of the freshly isolated blood B cells from those subjects were extracted and hybridized individually to Affymetrix HG-U133A GeneChip[®] arrays to identify genes differentially expressed between low and high BMD subjects. Significance of differential expression was tested by t-test and adjusted with Benjamini and Hochberg (BH) procedure for multiple-testing.

Twenty-nine genes were down-regulated in the low vs. high BMD group. Those genes were further analyzed using Ingenuity Pathways Analysis (Ingenuity[®] Systems, www.ingenuity.com) and a network involving estrogen receptor 1 (ESR1) and mitogen-activated protein kinase 3 (MAPK3) was identified (Fig. 1). Real-time RT-PCR confirmed the differential expression of 8 genes, including ESR1 ($p = 0.044$) and MAPK3 ($p = 0.002$).

This is the first in vivo genome-wide expression study on human B cells for osteoporosis. Our results suggest a novel mechanism for postmenopausal bone loss that downregulation of ESR1 and MAPK3 in B cells further regulates the secretion of factors leading to increased osteoclastogenesis or decreased osteoblastogenesis.

Sarcopenia in Ageing Men with Osteopenia, Osteoporosis and Normal Bone Mineral Density. C. A. Zerbini, M. G. Pippa*. Rheumatology, Hospital Heliopolis, Sao Paulo, Brazil.

Ageing men is accompanied by a loss of muscle mass. Sarcopenia, the decrease of muscle mass with age has been widely studied because of its relation to impaired gait, disability and falls. Aimed to evaluate sarcopenia, we measured body composition (BC) in 220 men at 50 years and older by dual X-ray absorptiometry (DXA). Sarcopenia was defined as a relative skeletal muscle index (RSMI) (appendicular skeletal muscle mass divided by height) below 7.26 kg/m², according to Baumgartner classification. Osteoporosis and Osteopenia prevalence were studied as well as its occurrence in sarcopenic subjects. L1-L4 bone mineral density (BMD), femoral (FNBMD) and total body BMD (TBBMD) were also measured by DXA. Total Lean mass (TLM), Total Fat Mass (TFM), percentage of adiposity (% adp), arms lean mass (ALM), legs lean mass (LLM), and body fat distribution (BFD) were also determined. Sample was gathered in different groups according to age: 50-60y, 61-70y and 71 or older. The adherence to normal curve was evaluated by Kolmogorov Smirnov test. Cochran-Armitage Trend Test was used to test proportion linear trend. To compare the difference of quantitative variables the Student t test was used. The effective P value to be considered significant was < 0.05. Data were analysed using the statistical computer program Minitab version 15.0% and SAS version 9.1.3. The average age was 61.8 years (SD = 8.15), average weight 72.9 Kg (SD = 12.0), average L1-L4 BMD 1.146 g/cm² (SD = 0.17), FNBMD 1.366 g/cm² (SD = 0.10) and TBBMD was 1.145 g/cm² (SD = 0.10). A hundred ninety five men were not sarcopenic (88.6%) and 25 men presented sarcopenia (11.36%). Sarcopenia prevalence presented a linear decrease according to BMI increase ($p < 0.0001$). Ageing showed a linear increase in sarcopenia prevalence ($p = 0.0305$). According to FNBMD T-score, 38.8% of sarcopenic showed osteoporosis (OP); 10.5% osteopenia and 9.58% normal BMD. Using L1-L4 BMD T - score 31.5% had OP, 12.7% osteopenia and 13.12% had normal BMD. According to TBBMD T - score, 40.9% had OP, 10.5% osteopenia and 12.1% normal BMD. There was a statistic significant difference between sarcopenic group (SG) and non sarcopenic group (NSG) second these variables: age (66.3 ± 9.50 SG), (61.24 ± 7.80 NSG), p value = 0.016; BMI (21.7 ± 2.0 SG), (27.3 NSG), p value < 0.0001; TBBMD (1.041 g/cm² SG), (1.158 g/cm² NSG) $p < 0.0001$; T - score L1-L4 BMD (-1.5 SG), (-0.5 NSG), p value = 0.001; T-score FNBMD (-1.8 SG), (-1.0 NSG), $p = 0.000$. Our data confirm higher prevalence of OP in Sarcopenic as well as negative influence of ageing and lower BMI in muscle mass loss.

Measures of Fitness and Body Composition in Childhood Are associated with Calcaneal Quantitative Ultrasound in Adulthood: A 20 Year Prospective Study. S. J. Foley¹, S. Quinn^{*1}, T. Dwyer^{*2}, A. Venn^{*1}, G. Jones¹. ¹Menzies Research Institute, Hobart, Australia, ²Murdoch Children's Research Institute, Melbourne, Australia.

Peak bone mass is a major determinant of fracture risk later in life. Weight-bearing exercise during growth is generally accepted as one factor that can influence bone mass, however the long-term effects of childhood exercise and body composition on bone mass remain uncertain as many studies have been retrospective in design. The aim of this inception cohort study was to describe the associations between childhood physical performance measures and body mass index (BMI), and adult bone mass. We measured an Australia wide representative random sample of 1,434 children, aged 7 to 15 yrs, originally included as part of the Australian Schools Health and Fitness Survey in 1985 and approximately 20 yrs later (mean age 31). Measures included 1.6 km run and 50 meter sprint (childhood only) and leg strength, standing long jump and physical work capacity at 170 beats/min (PWC₁₇₀) (in both childhood and adulthood). Body composition was assessed at both time points by BMI. A single Sahara bone ultrasound densitometer was used at follow-up to determine heel bone mass (CV = 1%). In females, there were modest but significant beneficial relationships between physical measures and adult bone mass (1.6 km run: $r = +0.08$ to $+0.10$, $p = 0.02-0.049$; 50 m sprint: $r = +0.08$ to $+0.11$, $p = 0.03-0.10$; standing long jump: $r = +0.06$ to $+0.08$, $p = 0.20-0.33$; PWC₁₇₀: $r = +0.12$ to $+0.21$, $p = 0.004-0.09$), of which the last was independent of adult performance ($R^2 = 1-4\%$). In males, childhood BMI (but no performance measures) was positively associated with all adult QUS parameters after adjustment for adult BMI ($r = +0.11$ to $+0.12$, $p = 0.001-0.003$) ($R^2 = 1-2\%$). An age-PWC₁₇₀ interaction was documented with PWC₁₇₀ at age nine, in both sexes, having a greater influence on adult bone mass ($r = +0.25$ to $+0.32$, $p = 0.002-0.01$) ($R^2 = 5-8\%$) than it did at ages 12 and 15 ($r = -0.01$ to $+0.02$, $p = 0.80-0.97$). On further examination, a sex-PWC₁₇₀ interaction was also observed in the 12 yr olds, with childhood PWC₁₇₀ also having a positive effect on female adult bone mass ($r = +0.19$ to $+0.25$, $p = 0.045-0.13$), but not male adult bone mass ($r = -0.19$ to -0.24 , $p = 0.06-0.13$). In conclusion, childhood fitness levels, particularly in females and in the prepubertal years, are predictive of adult skeletal status as measured by QUS, explaining up to 8% of the variation in adult bone mass. Furthermore, childhood BMI in males was predictive of all adult QUS parameters. These results strongly suggest that increased skeletal loading in childhood (especially in the prepubertal years) leads to an increase in peak bone mass which is maintained many years later independent of current fitness or body mass index.

Dietary Protein and Bone Mineral Density (BMD) in the Presence of Low vs High Calcium in Men and Women of the Framingham Study. C. E. McLennan^{*1}, K. B. Broe^{*1}, K. L. Tucker^{*2}, R. R. McLean^{*1}, D. P. Kiel¹, L. A. Cupples³, M. T. Hannan¹. ¹HSL, Boston, MA, USA, ²HNRC-Tufts, Boston, MA, USA, ³BUSPH, Boston, MA, USA.

Short-term metabolic studies show that increasing dietary protein creates negative calcium balance, yet epidemiologic studies support a beneficial effect of protein on bone. However, long-term influences of typical protein intake may rely upon concurrent calcium. We examined the cross-sectional association of dietary protein on BMD in presence of low calcium in Framingham Offspring and Original Cohort members. We hypothesized that protein intake would be positively associated with BMD only in those with low calcium.

3,988 participants (2919 Offspring members with BMD obtained in 1996-2000, and 1069 Original Cohort members with BMD from 1988-89 or 1992-93) had BMD obtained at femoral neck (FN), trochanter (TR) and lumbar spine (LS). Dietary protein and calcium intakes were estimated via 126-item Willett food frequency questionnaire. At each BMD site, by sex and by cohort, we used multivariable linear regression to examine the association of BMD with %protein (% of total energy from protein) adjusted for calcium intake (mg/d), indicator of calcium < 800 mg/d, total energy, age, weight, height, current smoking, vitamin D, supplement use of calcium or vitamin D, and in women menopause and estrogen use. Further models adjusted for physical activity, caffeine and alcohol. We then stratified by low calcium (< 800 mg/d) adjusting for calcium intake within strata.

Mean age of Original Cohort members was 75 (SD 5) and of Offspring cohort was 60 (SD 9). Mean %protein intake was 16% and 17% respectively. Over 60% of both groups had calcium intake < 800 mg/d. No associations were seen between protein and BMD in either men or women of elderly Original Cohort (all p>0.30). In Offspring cohort, no associations were seen in men but there was positive effect between protein and all 3 BMD sites in 1639 women. Adjusting for physical activity, caffeine or alcohol did not change results. Upon stratifying (table), similar though not significant results were seen for 1006 women with low calcium while no association was seen for 633 women with calcium ≥ 800.

Calcium intake modified the cross-sectional effect of dietary protein on BMD but only for middle-aged Offspring cohort women. Our findings suggest that protein and BMD studies may also need to consider concurrent calcium intake.

Table: Framingham Offspring Women, Protein coefficient

	All Women Beta (SE), p-value	Calcium<800mg/d Beta (SE), p-value	Calcium>800mg/d Beta (SE), p-value
FN	.00194 (.0009), 0.03	.00173 (.0011), 0.11	.00133 (.0017), 0.44
TR	.00199 (.0008), 0.01	.00187 (.0008), 0.057	.00120 (.0016), 0.45

Clusters of Dietary Protein and Relation to Bone Mineral Density (BMD) in Men and Women of the Framingham Offspring Study. K. L. Tucker^{*1}, N. Qiao^{*1}, C. E. McLennan^{*2}, K. E. Broe^{*2}, R. R. McLean^{*2}, D. P. Kiel², L. A. Cupples^{*3}, M. T. Hannan². ¹HNRC, Tufts University, JM USDA, Boston, MA, USA, ²HSL Institute for Aging Research, Boston, MA, USA, ³BUSPH, Boston, MA, USA.

Several studies have shown that dietary protein intake may be protective of BMD rather than contributing to calcium loss. We have previously shown a positive relation between BMD and protein in the elderly Framingham Original Cohort. As protein-rich foods are also rich sources of other nutrients, we now further examined this relation by food source of dietary protein in the primarily middle-aged members of the Framingham Offspring cohort.

We evaluated the cross-sectional relation between food sources of protein and BMD in 2919 Framingham Offspring Study participants (mean age 61y) with BMD at femoral neck (FN), trochanter (TR) and lumbar spine (LS) obtained by Lunar DPX-L in 1996-2000. Dietary intakes were estimated using the Willett 126-item food frequency questionnaire and we used cluster analysis to classify individuals into 5 groups determined by major source of protein (table). Multivariable linear regression was used to compare least-squares adjusted mean BMD among protein clusters, adjusting for: total energy, sex, age, weight, height, smoking, total protein intake, calcium, vitamin D, physical activity, caffeine, alcohol and in women, menopause status and estrogen use. We further adjusted for fruit and vegetable servings, an indicator of overall healthy diet also associated with higher BMD.

The dietary cluster for which the primary source of protein was low-fat milk had significantly greater FN and TR BMD than the other clusters (this cluster also tended to have greater LS BMD, p<0.10). Associations remained after further adjustment for fruit and vegetable servings.

In summary, increased protein intake continues to be associated with higher BMD, but a dietary pattern with primary protein sources of low-fat milk and breakfast cereal appears to have the greatest effect, even after adjusting for calcium, vitamin D and fruit and vegetable intakes. These findings show that the beneficial effect of protein on BMD may depend upon the source from which protein is obtained.

Least Squares Mean BMD ± SE across protein clusters for Framingham Offspring Participants					
	Cluster 1: Low-fat milk cereal, etc. (N=337)	Cluster 2: Fish, beans, rice, other grain, etc. (N=561)	Cluster 3: Poultry (N=551)	Cluster 4: Meat, whole milk, etc. (N=690)	Cluster 5: Bread, egg, other dairy, processed meat, pasta, etc. (N=598)

Vitamin D status and Bone Health in Adolescents: The Northern Ireland Young Heart's Project. T. R. Hill^{*1}, J. Wallace^{*2}, P. J. Robson^{*2}, W. Dubitzky^{*2}, L. Murray^{*3}, J. Strain^{*2}, A. Flynn^{*1}, M. Kiely^{*1}, K. D. Cashman¹.

¹Department of Food and Nutritional Sciences, University College Cork, Cork, Ireland, ²Northern Ireland Centre for Food and Health, University of Ulster, Coleraine, United Kingdom, ³Department of Epidemiology and Public Health, Queens University, Belfast, United Kingdom.

Our objective was to investigate the relationship between vitamin D status {as measured by serum 25-hydroxyvitamin D [25(OH)D]} and adolescent bone health.

The present cross-sectional study used data from the Northern Ireland Young Heart's Project cohort of adolescents, which included 468 girls and 458 boys, aged either 12 or 15 yr who were sampled throughout the year. Bone mineral density (BMD) was measured by DXA at the non-dominant forearm and dominant heel. Stored serums were analysed for 25(OH)D, parathyroid hormone (PTH), osteocalcin (OC) and C-telopeptide of collagen metabolism (CTX) using enzyme-immunoassays. Multivariate models were used to examine the relationship between bone parameters and tertiles of serum 25(OH)D.

Significant age × gender interactions (p<0.05) were evident in the bone parameters, which justified analysing each age-gender group separately. After adjustment for physical, lifestyle and dietary variables, there was no significant association between tertiles of serum 25(OH)D on heel BMD in any of the age-gender groups. In addition, no significant associations were observed between tertiles of serum 25(OH)D and forearm BMD in boys. However, after adjustment for physical, lifestyle and dietary variables, girls in the highest tertile of serum 25(OH)D had significantly (p<0.05) higher forearm BMD than did the girls in the lowest tertile (β = 0.018; 95% CI: 0.003, 0.033; and β = 0.018; 95% CI: 0.001, 0.034, for 12 and 15-y old girls, respectively). Mean serum 25(OH)D levels for the lowest, middle and highest tertile of serum 25(OH)D in girls were 35.1, 58.7 and 94.6 nmol/l. In general, biochemical bone indices (PTH, OC, CTX), after adjustment for covariates, were significantly (p<0.001-0.082) higher in girls (aged 12 and 15-y olds) in the lowest tertile compared to those in the highest tertile of serum 25(OH)D. When limiting the female subjects to only those sampled in winter (December to February), when vitamin D status is at its lowest, girls in the lowest tertile of serum 25(OH)D (mean: 33.5 nmol/l) had significantly (p = 0.05) lower forearm BMD (β = 0.016; 95% CI: -0.00005, 0.033) compared to those in the highest tertile (mean: 81.0 nmol/l). In conclusion, low vitamin D status appeared to be related to lower bone mass and higher bone turnover in adolescent girls, but not in boys. This may have an impact on peak bone mass development in girls.

Higher Dietary Calcium Intake along with Higher Vitamin D Status Could Suppress Bone Turnover and BMD Decrease in Asian Osteoporotic Patients. T. Hirota¹, H. Ikeda^{*1}, K. Hirota^{*2}. ¹Research Laboratory, Tsuji Academy of Nutrition, Osaka, Japan, ²Department of Obstetrics and Gynecology, Nissay Hospital, Osaka, Japan.

Recently some data failed to prove that calcium and vitamin D supplementation reduces the risk of fractures in Caucasian population. The purpose of this study was to evaluate the effects of dietary calcium intake and vitamin D status on bone turnover and BMD in osteoporotic Asian women whose habitual intake of calcium is thought to be much lower and vitamin D is higher than that of Western people.

We evaluated 215 postmenopausal Japanese women (aged 49-87 yrs, median 67 yrs) diagnosed as osteoporotic by L2-4 BMD or vertebral fractures. They had not taken any medicines affecting endocrine systems and bone turnover for 2 months nor bisphosphonates for a year. Subjects could walk and visit the physicians as out patients. Their calcium intakes were evaluated by food frequency questionnaires and vitamin D status was determined from serum 25-hydroxyvitamin D [25(OH)D] measured by RIA. Markers of bone turnover, including serum bone-specific alkaline phosphatase (BAP), osteocalcin (OC), procollagen type I N-propeptide (PINP) for bone formation, and urinary deoxypyridinoline (DPD), type I collagen N-telopeptide (NTX) for bone resorption, along with serum PTH and 1,25(OH)₂D were determined. The BMD of the lumbar spine and the total hip was measured by DXA.

The mean calcium intake in the patients was 814±307 mg/day, which was much higher than non-osteoporotic postmenopausal controls (548±257 mg/day, n=158 aged 45-74 yrs), probably due to an improvement in diet following awareness of a previous calcium shortage. However, their mean serum 25(OH)D was 43±13 nM, which was still low compared with that reported for healthy, elderly, Japanese women. Calcium intakes in patients were negatively associated with all bone turnover markers (BAP, OC, PINP, DPD and NTX). Serum 25(OH)D was negatively associated with OC and DPD, as well as PTH. The association of 25(OH)D with bone resorption markers (DPD, NTX) was clearly observed in younger patients (aged 49-66 yrs). These associations were independently observed after adjustment for 25(OH)D and calcium intake. Higher calcium intake (more than 800 mg/day), together with higher 25(OH)D status (more than 50 nM) showed not only a significant additive decrease in NTX and BAP, but also a significantly higher hip BMD.

We suggested that many osteoporotic patients could improve their diets and succeed in calcium intake but not vitamin D. Higher dietary calcium intake and vitamin D status could suppress bone turnover and BMD decrease in Asian osteoporotic patients. We recommend therapy for osteoporotic patients should include dietary calcium intake greater than 800 mg/day and serum 25(OH)D status of more than 50 nM.

Little is known about the spatial distribution of the toxic element lead (Pb) and other trace elements in normal and osteoarthritic articular cartilage and subchondral bone. We assessed the elemental distribution of lead (Pb), zinc (Zn), strontium (Sr) and calcium (Ca) using synchrotron radiation induced micro X-ray fluorescence (SR μ -XRF) in the chondral and subchondral bone region of 4 normal, 4 osteoarthritic femoral heads and 3 normal patellae from adults with no history of work-related exposure to Pb. SR μ -XRF line and area scans in confocal geometry were correlated to backscattered electron images visualizing mineralized tissue. We found a highly specific accumulation of Pb in the tidemark, the transition zone between calcified and non-calcified articular cartilage. Pb fluorescence intensities in single tidemarks of normal samples were 13-fold higher when compared to subchondral bone and were strongly correlated with Zn, but were distinctly different from Ca and Sr. However, in the double tidemarks of osteoarthritic samples, Pb fluorescence intensities in the inner tidemark were 3-fold higher than in the outer and were approximately 36.1-fold higher when compared to subchondral bone. Interestingly, Zn-intensities did not correlate with Pb-intensities in double tidemarks. Zn-intensities were approximately 5-fold higher in both, the inner and outer tidemark, when compared to subchondral bone. Our data showed a very specific spatial accumulation of Pb in the tidemark of articular cartilage in normal and osteoarthritic samples. Temporal differences in the accumulation of Zn and Pb in the mineralization front of calcified articular cartilage suggest different mechanisms in Pb and Zn accumulation in the mineralization front.

Effect of Four Weeks of Vitamin D3 Supplementation During Late Winter on Markers of the Vitamin D Endocrine System and Bone Turnover. K. Holvik¹, A. A. Madar^{*1}, H. E. Meyer¹, C. M. Lofthus^{*2}, L. C. Stene^{*3}. ¹Institute of General Practice and Community Medicine, University of Oslo, Oslo, Norway, ²The Hormone Laboratory, Center of Endocrinology, Aker University Hospital, Oslo, Norway, ³Division of Epidemiology, Norwegian Institute of Public Health, Oslo, Norway.

A seasonal variation in vitamin D status is commonly observed at northern latitudes with a drop in serum 25(OH)D and a corresponding increase in serum PTH and bone turnover during late winter, which is most evident in non-supplement users. We investigated the effect of four weeks' daily supplementation with 10 μ g (400 IU) vitamin D3 on vitamin D metabolites, PTH, and bone turnover in healthy young adults during late winter.

In a trial designed to compare the effect of two common types of vitamin D supplement on vitamin D status⁽¹⁾, 55 men and women aged 19-48 y recruited in the community received a daily dose of 10 μ g vitamin D3 during a 4-week period in late winter 2005. Venous serum samples were drawn at baseline and after 28 days for the analysis of serum concentration of 25-hydroxyvitamin D (s-25(OH)D), 1,25-dihydroxyvitamin D (s-1,25(OH)₂D), intact parathyroid hormone (s-iPTH), and osteoclast-specific tartrate-resistant acid phosphatase (s-TRAP). As previously reported, mean s-25(OH)D increased from 44 (95% CI 38, 51) nmol/l to 78 (95% CI 72, 85) nmol/l during the period (p<0.001), and the increase did not differ according to type of vitamin D3 supplement.⁽¹⁾ Mean s-iPTH decreased from 5.85 (95% CI 5.14, 6.57) pmol/l to 4.70 (95% CI 4.14, 5.26) pmol/l; p=0.001. Mean s-1,25(OH)₂D increased slightly during the period; from 120 (95% CI 109, 131) pmol/l to 134 (95% CI 124, 144) pmol/l; p=0.057. Mean s-TRAP was 2.65 (95% CI 2.46, 2.84) U/l at baseline, and it increased to 3.03 (95% CI 2.84, 3.21) U/l; p<0.001.

We conclude that four weeks of supplementation with 10 μ g vitamin D3 led to a decrease in s-iPTH, a tendency to an increase in s-1,25(OH)₂D, and an increase in s-TRAP concentration. The suggested increase in osteoclast activity in spite of the improvement in vitamin D status and corresponding PTH suppression is surprising.

Comparison of iDXA Measurements of Mid-Body Fat Mass and Tape-Measured Circumferences in Overweight Women. P. Liu^{*}, H. Shin^{*}, S. Pounds^{*}, J. Folkert^{*}, A. P. Crombie^{*}, J. Z. Ilich. Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA.

Studies show mid-body fat is more predictive of cardiovascular risk factors than total body fat. New bone densitometers have ability to measure body fat in android (abdominal) and gynoid (hip) regions utilizing total body scans. The data comparing those values obtained by iDXA series (GE Healthcare, Madison, WI) with tape-measured circumferences in overweight women are not available. Our objective was to compare android and gynoid measurements from iDXA with tape-measured circumferences in abdominal and hip regions. Tape measurements were performed according to the USDHHS guidelines (PHS, NHANES III, 1996). Participants were 37 postmenopausal women aged 56.3±3.7 y, BMI 31.7±4.8 kg/m² (mean±SD). Results showed high correlation (Pearson's r ranging from 0.7 to 0.9) between corresponding tape-measured and iDXA-analyzed regions, all p's<0.0001. In multiple regression models with android fat (g) as dependent variable and controlled for weight and age, tape-measured abdominal circumference remained significant predictor, t-ratio=2.55, p<0.05. In models with gynoid fat (g), controlled for weight and age, tape-measured hip circumference remained significant predictor t-ratio=2.23, p<0.05. We conclude that fat mass measured by iDXA in android and gynoid regions corresponds well with tape-measured circumference values and could be utilized during the total body scan and particularly rendered useful if there is no trained personnel to perform tape measurements in overweight women.

Influence of Overweight/Obesity on BMD of Various Skeletal Sites in Early-Postmenopausal Women. P. Liu^{*}, J. Folkert^{*}, S. Pounds^{*}, H. Shin^{*}, A. Crombie^{*}, J. Z. Ilich. Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA.

We reported earlier that higher body weight was associated with higher BMD in women of wide age range. However, excess weight beyond BMI of 30 kg/m² was not associated with additional increase in BMD. The objective of this study was to examine closer the relationship between weight and BMD in either overweight or obese postmenopausal women. Participants included 37 early (from 2-10y) postmenopausal women aged 56.3±3.7 y who were classified according to their BMI as either overweight (BMI=25-29 kg/m², n=17), or obese (BMI>30 kg/m², n=20). BMD of the whole body, femur (neck, Ward's triangle, shaft, trochanter and total femur), lumbar spine and forearm were measured with iDXA (GE Healthcare, Madison, WI). Non-parametric statistics was used

and based on Mann-Whitney tests, obese women did have statistically higher BMD at radius, total forearm, Ward's, trochanter, shaft and total femur (all $p < 0.05$). There was no statistical difference in spine, femoral neck and total body BMD between overweight and obese women. Based on this preliminary study focused on overweight/obese postmenopausal women only, it appears that weight status classified as obesity might lead to higher BMD in some skeletal sites compared to just overweight. More studies with larger sample size are necessary to gain better understanding of the influence of overweight/obesity on BMD.

Isoflavone and Soya Foods Intakes in Brazilian Population: Data from the BRAZOS Study. N. O. Jacques^{*1}, J. P. Roque^{*1}, M. M. Pinheiro², R. M. Ciconelli^{*3}, M. B. Ferraz^{*3}, L. A. Martini¹. ¹Nutrition, Universidade de Sao Paulo, Sao Paulo, Brazil, ²Reumatology, UNIFESP, Sao Paulo, Brazil, ³Paulista Center of Economy in Health, CPES, UNIFESP, Sao Paulo, Brazil.

Epidemiological studies have been demonstrated a positive association between dietary isoflavones and/or soy foods and bone mineral density. The purpose of present study was to evaluate the mean isoflavone and soy foods intake in men and women older than 40 years. This study was part of the Brazilian Osteoporosis Study (BRAZOS). A total of 2392 subjects (1693 women) were enrolled in the nutritional evaluation at the BRAZOS Osteoporosis Study - BRAZOS, undertaken in 120 cities across 5 regions (North, Northeast, Central, Southeast and South) of the country, and included people from five categories of economical level (from A to E). The sampling was based in the census data from IBGE (Brazilian Institute of Statistics and Geographic) 2000 and PNAD (National Research of Home Sampling) 2003 and it was calculated accordingly with the probabilistic and representative sample of Brazilian population. Dietary intakes were evaluated by a 24h Food Record. For the nutrient analysis the Nutrition Data System software (Minneapolis, MN 2005) was used. The use of supplements was not considered in the present analysis. Statistical analysis was performed by SPSS (v 12.0). Student T test was used for gender comparison and One way ANOVA for comparisons between regions and economical level. Data was log-transformed since there are no normal distribution in isoflavone intakes. Significance was considered as $p < 0.05$. Data is presented as median (min-max). The isoflavone/soy intake in the population evaluated was very low, only 1% of the sample presented an isoflavone intake higher than 1 mg/day. Considering the isoflavone intake in all participants, the mean daidzein was 0.08 mg/d (0.01-69.5) and the mean genistein was 0.03 mg/d (0.01-64.8). The mean genistein intake in men was 0.02 mg/d (0.01-15.78) and in women was 0.13 mg/d (0.01-69.54). For daidzein the mean intake in men was 0.03 mg/d (0.01-11.93) and in women 0.03 mg/d (0.01-69.54). No significant differences were observed between gender and between regions of the country. The major contributors to isoflavone intake were soy milk and soy grains, 52% and 28%, respectively. Besides soy milk and soy-grains, there was others foods that contributed to isoflavones intake, as such as: wholemeal bread, meat-substitute foods containing textured vegetable protein, soy protein isolate and toasted soy beans. Considering the benefits of isoflavones intake for bone health, the nutritional advice for osteoporosis patients, besides calcium and vitamin D, should include an increase in soy products.

Low-Level Radiation Can Enhance Trabecular Bone Quantity and Architecture. L. Karim^{*1}, M. Vazquez^{*2}, S. Judex¹. ¹Stony Brook University, Stony Brook, NY, USA, ²NSRL, Upton, NY, USA.

Detrimental effects of high-level radiation exposure to the skeleton range from cell death to cancer and may be strongly catabolic to the skeleton, in particular to trabecular bone. Charged particle radiation such as iron ions and its secondary fragmentation products are of particular concern due to their high charge and energy deposition. However, little is known about the long-term effects of these particles, applied at relatively low-levels, on trabecular and cortical bone morphology. Here, it was hypothesized that even low-level charged particle radiation can deteriorate bone quantity and architecture. Adult male C57BL/6J mice were exposed to full-head FE ion radiation (56-Fe, 1 GeV/n) with only 14% exposure for the appendicular skeleton at 120 cGy (16.8 cGy to the extremities), 60 cGy (8.4 cGy to the extremities), or 0.0 cGy (age-matched controls) for 11.5 months (n=11 per group). The metaphysis, epiphysis, and mid-diaphysis of the femurs were analyzed for differences in bone quantity and architecture by microCT. Three-point bending tests evaluated cortical bone mechanical properties. In the metaphysis, 8.4 cGy radiated femurs had significantly greater ($p < 0.05$) bone volume fraction (+61%) and trabecular number (+17%) than controls. In the epiphysis, the same mice showed a 31% greater bone volume fraction and a 31% smaller structural model index (a smaller structural model index is typically associated with greater bone strength). Bones radiated at 16.8 cGy showed a similar trend as 8.4 cGy mice but morphological indices were not significantly different from controls. There were no significant differences in cortical bone morphology between any radiated group and control mice. The mechanical tests revealed that bone's material properties did not deteriorate upon radiation at either level. In contrast to our original hypothesis, this data indicated that low-level iron radiation may enhance, rather than deteriorate, trabecular bone in the femoral metaphysis and epiphysis of mice. Mice receiving the smallest dosage showed the greatest beneficial response. The mechanisms by which these anabolic and/or anti-catabolic effects were induced remain to be determined but may be related to processes involving cell differentiation and proliferation, in particular for cells of the more radio-sensitive osteoclast lineage.

Disclosures: S. Judex, None.

Does Pre- or Post-menopausal Soy Consumption Affect Postmenopausal Bone Loss? C. J. Lees, H. Chen^{*}, J. R. Kaplan^{*}. Wake Forest University School of Medicine, Winston-Salem, NC, USA.

Chronic soy consumption has been associated with a decreased incidence of hip fracture in Asian women, an effect often attributed to the estrogen-like compounds (isoflavones) found in soy. However, it is not known whether pre- or post-menopausal soy exposure initiated in fully adult individuals will affect postmenopausal bone loss.

Ninety-six female *Macaca fascicularis* were randomized into 2 dietary treatments that differed only in major protein source, casein/lactalbumin or isoflavone-enriched soy. The animals consumed these diets for 30 months and then all were ovariectomized (OVX). Post-OVX, one half of monkeys in each diet treatment switched to the opposing diet while the remainder continued to consume their original diet, resulting in 4 pre and postmenopausal treatment conditions (casein-casein [CC], casein-soy [CS], soy-casein [SC], soy-soy [SS]). Bone mass was determined throughout the pre-menopausal phase and six months after OVX. Percent change was calculated from 30 month pre-menopausal and 6 postmenopausal measurements.

All groups had a significant decrease in whole body (WB, $p < 0.04$) and lumbar vertebral bone mineral content (LVBMC, $p < 0.03$).

	% Change in WBBMC	% Change in LVBMC
CC	-11.9	-9.1
CS	-5.2	-4.2
SC	-9.9	-10.7
SS	-9.9	-7.5

In the immediate postmenopausal period, consumption of soy significantly slowed the rate of bone loss, but only in animals that had consumed casein diet in the pre-menopausal period. Pre-menopausal consumption of soy did not affect the rate of bone loss during the first 6 months after OVX.

Disclosures: C.J. Lees, None.

Use of a Web-Based Fracture Risk Assessment Tool. B. Ettinger¹, C. Gross¹, K. Cody^{*2}, R. Walker^{*3}. ¹Medicine, University of California, San Francisco, CA, USA, ²Foundation for Osteoporosis Research and Education, Oakland, CA, USA, ³Walker Associates, Long Beach, CA, USA.

Current methods for interpretation of bone densitometry results are inadequate. Reporting of T-score has been the standard for many years, but experts throughout the world have called for a more accurate and clinically useful report format. We modified an existing fracture risk model that was developed at Kaiser Permanente's Division of Research* and made it available to providers through the Foundation for Osteoporosis Research and Education (FORE) website. The model calculates 10-year fracture risk and portrays patient risk graphically, categorized into 3 zones: "low-green" 20%. The interactive model will be available at the poster site for ASBMR attendees and for general use at <http://riskcalculator.fore.org>.

Physicians who had referred at least one patient to FORE's densitometry service during 2004-2006 were mailed invitations to use the fracture assessment tool on a special FORE-sponsored password-protected website. We assessed the percentages of invitees who logged on to the site and who performed a patient calculation using the tool.

Of 241 providers who received the mailed invitation 11 (4.9%) logged on to the fracture risk assessment website within 8 weeks. Of those logging on, 10 (91%) completed the necessary quantitative data entry fields (age, height, weight, total hip Z-score, spine Z-score), answered 7 yes/no clinical questions (prior osteoporotic fracture, mother/sister with hip fracture, current smoking, alcohol intake >2 drinks/day, exposure to glucocorticoids, rheumatoid arthritis), and submitted these data for risk calculation. The median usage of the risk calculator among those with any usage was 3 times. When invitees were categorized into 4 quartiles based on number of prior DXA referrals, there was a trend for greater likelihood of using the tool with greater prior referral: 1 referral (n=60) 3.3% use; 2-5 (n=69) 1.4%; 6-20 (n=56) 5.4%; >20 (n=56) 7.1%.

We conclude that, based on a mailed outreach and web-based practicum, only a small percentage of providers referring patients to a well-recognized center of bone densitometry excellence appear to be interested in learning about fracture risk assessment. In the near future, fracture risk assessment is expected to become a key element of densitometry reporting and would likely become the standard method for osteoporosis counseling/decision-making. More efforts will be necessary to reach providers and teach them how to interpret and use fracture risk assessment.

Progression of Vertebral Deformities but no Change in Bone Mineral Density in Patients with Sarcoidosis: A 4 Year Follow-up Study. A. Heijckmann¹, M. Drent^{*2}, A. Nieuwenhuijzen Kruseman^{*3}, P. Geusens³, M. Huijberts^{*3}. ¹Internal Medicine, Hospital Bernhoven, Veghel/Oss, The Netherlands, ²Sarcoidosis Management Center, University Hospital, Maastricht, The Netherlands, ³Internal Medicine, University Hospital, Maastricht, The Netherlands.

Introduction: Several disease related factors may influence bone mineral density (BMD) and bone quality in sarcoidosis. We have previously demonstrated in a cross-sectional study that BMD is unaffected in a large cohort of individuals with sarcoidosis. Nevertheless, increased bone turnover and a high prevalence of vertebral deformities (20%) were found in these patients. This may imply that bone strength rather than BMD is decreased in sarcoidosis. The aim of this study was to determine whether this may have consequences for the incidence of new or progressive vertebral deformities during follow up.

Methods: BMD of the hip (DXA) and vertebral fracture assessment (VFA) with a lateral single energy densitometry was performed at baseline and follow-up (45 months, range 35-49) in 66 patients with sarcoidosis. In addition, clinical risk factors and glucocorticoid use were assessed. Potential predictors of new or progressive vertebral deformities were assessed using logistic regression analysis.

Results: The BMD of the total group was unchanged after follow up, even in the groups with current or previous glucocorticoid use. The prevalence of vertebral deformities increased from 20 to 32% of all subjects, and in 17 subjects one or more new or progressive vertebral deformities were diagnosed (26%). 84% of the subjects with a new or progressive deformity had a BMD in the low normal range (T-score \leq -0.5). Logistic regression analysis revealed that a lower T-score of the femoral neck at baseline (OR=2.5 (CI: 1.0-5.9), p=0.04) and a mother with a hip fracture (OR=14.1 (CI: 1.4-142.6), p=0.02) were determinants for new or progressive vertebral deformities.

Conclusions: Our study shows that in subjects with sarcoidosis the number of vertebral deformities increases in the course of this disease, despite unchanged BMD. The combination of a low normal bone mass in combination with a family history of fragility fractures contributes to an increased risk of the incidence of these deformities.

To What Extent do Vertebral Fractures, Disc Height Loss, Low Bone Density, and Poor Muscle Strength Contribute to Hyperkyphosis in Older Women? D. M. Kado¹, K. Prenovost^{*1}, L. Palermo², K. Stone³, T. A. Hillier⁴, S. R. Cummings³. ¹Medicine, UCLA, Los Angeles, CA, USA, ²UCSF, San Francisco, CA, USA, ³California Pacific Medical Center Research Institute, San Francisco, CA, USA, ⁴Center for Health Research, Kaiser Permanente, Portland, OR, USA.

Thoracic hyperkyphosis has been traditionally attributed to underlying fractures of the thoracic spine, but only 36-38% of those with the worst kyphosis have underlying fractures. Since thoracic hyperkyphosis is associated with adverse health outcomes including poor pulmonary and physical function, and increased mortality, we sought to determine other important, and possibly modifiable causes. Using baseline data from the Study of Osteoporotic Fractures, we randomly sampled 1196 women, aged 65 or older who had baseline radiographs available to measure Cobb angle kyphosis (T4-T12), disc heights (T4-T12), and prevalent vertebral deformities (3SD definition, from T4-L5). Participants also underwent baseline calcaneal bone mineral density and hip abduction strength testing, and answered questions regarding their medical history and health behaviors. Because vertebral fractures represent a continuous rather than discrete break in bone, we examined both a dichotomous vertebral fracture index and anterior to posterior vertebral height ratios from T4 to T12. We hypothesized that even if not classifiable as a vertebral fracture, vertebral wedging may substantially contribute to degree of kyphosis. In multivariable regression, the vertebral height ratio (averaged over T4-T12) independently explained 60% (consistent with previous literature), average disc height ratio explained 22%, and a paternal history of stooped posture explained 0.2% of Cobb angle variance. All reported values are squared semi-partial correlations that factor out inter-correlations among predictors, that in this case also included prevalent vertebral fractures, calcaneal bone mineral density, and hip abduction strength (each explaining less than 0.1% of Cobb angle variance). The overall total adjusted R² for this model was 74.2%. Whether osteoporosis treatments can decrease vertebral wedging and improve kyphosis is unknown.

Disclosures: D.M. Kado, None.

5 Year Incidence of Fractures in Patients with Severe Osteoporosis: The Canadian Multicentre Osteoporosis Study (CaMos). S. M. Kaiser¹, G. Ioannidis², J. Lorraine³, W. P. Olszynski⁴, J. C. Prior⁵, D. A. Hanley⁶, J. P. Brown⁷, A. Papaioannou², R. G. Josse⁸, T. Anastassiades⁹, K. Siminoski¹⁰, S. Kirkland¹, C. Joyce^{*11}, D. Goltzman¹², J. D. Adachi². ¹Dalhousie University, Halifax, NS, Canada, ²McMaster University, Hamilton, ON, Canada, ³Eli Lilly and Company, Toronto, ON, Canada, ⁴University of Saskatchewan, Saskatoon, SK, Canada, ⁵University of British Columbia, Vancouver, BC, Canada, ⁶University of Calgary, Calgary, AB, Canada, ⁷Laval University, Sainte-Foy, PQ, Canada, ⁸University of Toronto, Toronto, ON, Canada, ⁹Queen's University, Kingston, ON, Canada, ¹⁰University of Alberta, Edmonton, AB, Canada, ¹¹Memorial University, St. John's, NF, Canada, ¹²McGill University, Montreal, PQ, Canada.

WHO defines patients with severe osteoporosis as those with a bone mineral density (BMD) T-score of < -2.5 and one or more fragility fractures. Patients with multiple fragility fractures also have severe bone disease. To assess future fracture risk, we classified CaMos participants 50 years and older, into two "severe" groups, and two comparator groups, according to their prevalent fracture status and BMD T-scores: (1) Severe Group 1: patients defined by the WHO classification (SG1, n=372, 91.4% women); (2) Severe Group 2: patients with 2 or more prevalent fragility fractures irrespective of their BMD T-score (SG2, n=390, 78.5% women); (3) Low BMD group (LG): patients with BMD T-scores ≥ -2.5 and no prevalent fragility fractures (n=3498, 67.7% women); and (4) Normal BMD group (NG): patients with T-scores > -1 and no prevalent fragility fractures (n=1437, 58.7% women). Multivariable logistic regression analyses were conducted to examine differences between the "severe" groups, and the two comparator groups, in the likelihood of developing a new fracture. Subclinical vertebral fractures were not examined, and fractures of the fingers, toes and face were excluded. Odds ratios (OR) and 95% confidence intervals (CI) were calculated. Over the 5 year period, 25.7% (80/331), 24.2% (80/315), 7.1% (221/3096), and 5.2% (66/1272) of the SG1, SG2, LG and NG developed new fractures. The likelihoods of developing a new fracture are summarized in the table below.

Group	OR vs NG (95% CI)	OR vs LG (95% CI)
SG1 men and women	3.86 (1.12,13.35)	2.47 (1.05, 5.85)
SG1 women only	7.53 (0.80, 70.7)	2.58 (0.81, 8.22)
SG2 men and women	3.35 (1.12, 10.08)	2.49 (1.06, 5.84)
SG2 women only	15.69 (1.87, 131.60)	4.00 (1.26, 12.70)

Subjects with severe osteoporosis, either as defined by WHO or as defined by having 2 or more fragility fractures, are more likely to develop a new fracture as compared with participants with no prevalent fragility fractures and normal or osteopenic BMD T-scores.

An Epidemiological Study of Hip Fractures in Korean Women: Estimated from a National Health Insurance Claims Database. H. Kang^{*1}, K. Yang^{*2}, S. Moon³, S. Kwon^{*4}, J. Park^{*5}, D. Kang^{*6}, S. Park^{*7}. ¹School of Public Health, Yonsei University, Seoul, Republic of Korea, ²Orthopaedics, Yonsei University, Seoul, Republic of Korea, ³Orthopedics, Yonsei University, Seoul, Republic of Korea, ⁴Orthopaedics, Catholic University, Seoul, Republic of Korea, ⁵Orthopedics, Konkuk University, Seoul, Republic of Korea, ⁶Severance Hospital Clinical Trial Center, Yonsei University, Seoul, Republic of Korea, ⁷Health Insurance Review Agency, Seoul, Republic of Korea.

Purpose: Previous epidemiologic studies in Korea were limited because the incidence rate was derived from the population in a single region and they require extrapolation from small populations to the national level. Thus, this study was conducted to provide a national estimate of population incidence rates of hip fracture in Korean women over the age of 50 using the Korean National Health Insurance (NHI) claims database. **Methods:** All claims records of visits or admissions of female patients aged 50 or older, containing a diagnosis of hip fracture (fracture of femur (ICD-10 code: S72), fracture of neck of femur (S72.0, S72.00), perthrochanteric fracture (S72.1, S72.10), fracture of pubis (S32.5, S32.50), osteoporosis with pathological fracture (M80.05, M80.55, M80.85, M80.95)) from 2002 to 2004 were identified from the NHI claims database. The first 6-month period (January - June, 2002) was set to be a 'window period,' such that patients were defined as incident cases only if their first records of fracture visit or admission was observed after June 30, 2002. Among the incidence cases identified, we excluded traumatic fractures and those with multi-fracture. **Results:** Average annual incidence was 17,826 fractures. Age-standardized annual incidence rates adjusted to Korean population of 2000 and to US non-Hispanic population of 1990 were 305.0 and 459.2 per 100,000 women, respectively. The incidence rate of hip fracture increased with age, ranging from 22.0 per 100,000 for 50-54 years old to 1,988.5 for 85 or older. Mortality rate within 1 year following hip fracture was 177.3 per 1,000 patients, with an increase in an exponential fashion after age 65. **Conclusion:** Our results support a high incidence rate of hip fracture for women living in Korea. The high incidence rate is a sentinel signal of the impact of hip fracture in Korea, in terms of high mortality, morbidity, and health care costs to treat hip fracture. It is hoped that this national epidemiological study contributes to raising the awareness of hip fractures among elderly population and to motivating the adoption of effective treatment options for osteoporosis needed to prevent the increase in hip fracture.

Risk Factors for Osteoporotic Fractures in Brazilian Men and Women - The Brazilian Osteoporosis Study (BRAZOS). M. M. Pinheiro¹, R. M. Ciconelli^{*1}, L. A. Martini², M. B. Ferraz^{*1}. ¹Rheumatology, Unifesp, Escola Paulista de Medicina, Sao Paulo, Brazil, ²Nutrition, Faculdade de Saude Publica, Universidade de Sao Paulo, Sao Paulo, Brazil.

Background/ Aims: Osteoporotic fractures are an important public health problem in worldwide. Several European, North American and Asian studies have demonstrated that the identification of risk factors for osteoporosis has a relevant role to early diagnosis and for treating people at high risk. The BRAZOS is the first epidemiological study performed in a representative sampling of the Brazilian population. The purpose of the present study was to evaluate the risk factors for osteoporotic fractures in Brazilian men and women older than 40 years. **Patients and Methods:** A total of 2420 subjects (1695 women) were enrolled in the BRAZOS study - BRAZOS, undertaken in 120 cities across 5 regions (North, Northeast, Central, Southeast and South) of the country, and included people from five categories of economical level (from A to E). This study evaluated aspects on lifestyle, fractures, dietary intake, physical activity, falls, quality of life, willingness to pay and knowledge on osteoporosis by quantitative and personal research that was applied in a face-to-face way. The sampling was based in the census data from IBGE (Brazilian Institute of Statistics and Geographic) 2000 and PNAD (National Research of Home Sampling) 2003 and it was calculated accordingly with to the probabilistic and representative sample of Brazilian population. The coefficient of variation is 2.2% with 95% confidence interval. After that, the data were slanted to total Brazilian population. **Results:** Subjects were classified as White (50%), Mixed Race (35%), Black (13%), Asian (1%) and Indian (1%) race. Mean age, height and weight for men and women were 58.4±12.8 and 60.1±13.7 years, 1.67±0.08 and 1.56±0.07 m and 73.3±14.7 and 64.7±13.7 kg, respectively. Men (56%) and women (51%) had BMI > 25.1 kg/ m2. Menopause's mean age was 47 years and 39% of them were at postmenopausal and 15% was currently taking hormone therapy. Osteoporotic fracture was reported by 5.29% of the subjects and the main skeletal sites were forearm, femur, ribs, spine and humerus. Osteoporosis was observed in 6% of this population. **Conclusions:** Our results have demonstrated that main risk factors for osteoporotic fractures in Brazilian men and women were age, sedentary, familial history of hip fracture, smoking and low intake of calcium and vitamin D. This study suggests that a better comprehension of clinical risk factors in our population could be an important tool to identify men and women with higher risk for osteoporotic fractures.

National Differences in the Risk for Falls and Fractures. L. Dukas^{*1}, M. Runge^{*2}, E. Schacht³. ¹Acute Geriatric University Clinic, Kantonsspital Basel, Basel, Switzerland, ²Center for Muscle and Bone Research, Aerpah Klinikum, Esslingen, Germany, ³Zurich Osteoporosis Research Group ZORG, Zurich, Switzerland.

A Creatinine clearance (CrCl) of <65ml/min. was described in multiple national studies from Germany, Switzerland and the USA as a significant risk factor for falls and fractures. In a multinational study in 7 different European countries including Russia we investigated this association. We also investigated if there are national differences in the risk for falls and fractures. For this cross-sectional study data we included 1190 women and 127 men aged 60 years and older with a mean BMI of 27.2kg/m2 and a mean CrCl of 58.6ml/min., newly diagnosed and therefore untreated osteoporosis. Patients with a CrCl of <65ml/min. had in multivariate controlled analyses a 72% significantly increased risk for falls (RR 1.72, 95%CI 1.30-2.29, p<.001) and a 47% significantly increased risk for fractures (RR 1.47, 95%CI 1.05-2.07, p=.02) compared to patients with a CrCl of >65ml/min. Interestingly we found a multivariate-controlled significant difference in fall incidence according to the country of origin: Within the past 12 months we found in patients from Russia, Lithuania, Hungary, Romania and Slovenia a 40-70% higher incidence of falls and fractures compared to patients from the Czech Republic and Latvia (p=0.04 res. p<.0001). In this study we found that a CrCl of <65ml/min is a significant risk factor for falls and fractures and are thereby inline with the results of other studies. We also found that the country of origin is also a significant risk factor for falls and fractures in elderly people. This result might be explained by the well-known national differences in the health and nutritional status of elderly people.

Detection of Prevalent Vertebral Fractures Using a Combination of Physical Examination Maneuvers. K. Siminoski¹, K. Lee^{*2}, H. Jen^{*2}, R. Warshawski^{*2}. ¹Radiology and Internal Medicine, University of Alberta, Edmonton, AB, Canada, ²Radiology, University of Alberta, Edmonton, AB, Canada.

Studies of several physical examination maneuvers have shown that they can be used to detect prevalent vertebral fractures when used individually. In this study, we have assessed the accuracy of vertebral fracture detection when the results of three such maneuvers are combined into a single spinal evaluation. Subjects were women referred for specialist assessment of osteoporosis (n=241; average age 53.5 yrs; range: 18-92 years). Vertebral morphometry was performed on all subjects from T4 to L4. Prevalent vertebral fracture was defined as a vertebral height ratio < 0.80. One or more fractures were present in 24.7%; the average number of fractures among those with fractures was 2.2. Three physical parameters were determined: HHL (historical height loss, tallest recalled height minus current measured height using a wall-mounted stadiometer), WOD (wall-occiput distance, the distance between the back of the head and the wall, with the patient standing erect and with feet and buttocks touching the wall, facing forward in the Frankfort plane, quantified using a tape measure); and RPD (rib-pelvis distance, the distance between the top of the pelvis and the lowest rib in the mid-axillary line, in fingerbreadths). Points were assigned to each of the physical findings as follows: HHL: ≤ 2.0 cm = 0 points, 2.1 to 4 cm = 1 point, 4.1 to 6.0 cm = 2 points, 6.1 to 8.0 cm = 3 points, > 8 cm = 4 points; WOD: ≤ 3 cm = 1 point, 3.1 to 6.0 cm = 2 points, ≥ 6 cm = 3 points; RPD: 0 fb = 4 points, 1 fb = 3 points, 2 fb = 2 points, 3 fb = 1 point, 4 fb = 0 points. The values for the three maneuvers were added to produce a score for each patient (referred to as the Combined Score) and the accuracy of the Combined Score for vertebral fracture detection was assessed. The area under the receiver operating characteristics curve was 0.78 (95% confidence interval, 0.72-0.85; p<0.001). Accuracy results are shown in the table. A Combined Score < 3 rules out the presence of vertebral fracture with moderate accuracy (negative predictive value of 84% in this population) while a Combined Score ≥ 6 rules in the presence of vertebral fracture with moderate accuracy (positive predictive value of 82%). Combining physical exam maneuvers that assess spinal deformity may lead to enhanced detection of prevalent vertebral fractures.

Score	Accuracy of Combined Physical Exam Score			
	LR	OR	Sens	Spec
>7	15.4	55.0	19	99
6-7	7.0	24.9	41	96
4-5	1.3	4.8	62	80
3	0.9	3.1	73	67
2	0.6	2.1	89	41
0-1	0.3	1.0	100	0

LR= likelihood ratio; OR = odds ratio; Sens = sensitivity; Spec = specificity

Prognostic Factor on MRI Findings Inducing Prolonged Intractable Pain due to Pseudoarthrosis Following Osteoporotic Vertebral Fracture. T. Tsujio^{*1}, H. Nakamura^{*2}, H. Terai^{*1}, A. Matsumura^{*1}, M. Hoshino^{*1}, A. Suzuki^{*1}, K. Takayama^{*1}, K. Takaoka¹. ¹Orthopaedic Surgery, Osaka City University Medical School, Osaka, Japan, ²Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan.

Severe pain following osteoporotic vertebral fracture usually subsides in accordance with bony union of the fracture. In some cases, however, severe pain continues due to delayed union of the fracture site in the vertebral body. The purpose of this study was to evaluate the prognostic factor of osteoporotic vertebral fracture on MRI in the early stage after the injury.

Fifty-eight patients, 62 vertebrae, with fresh osteoporotic vertebral fracture were enrolled in the study. Seven were men and 51 were women. The age at the time of injury was 73.7 years in average. Those cases were followed for six months prospectively and were judged whether bony union was obtained based on vertebral cleft within the vertebral body. In those cases, MRI findings at the time of injury both on T1 and T2 weighted image were evaluated.

Bony union was obtained in 52 cases and pseudoarthrosis was observed in 10 cases. On plain X-ray, the collapsing ratio of vertebral body at the time of injury was not different each other, but the posterior wall of vertebral body was frequently involved in the pseudoarthrosis group. Cases showing wide low intensity change in the vertebral body both on T1 and T2 weighted MRI tended to become pseudoarthrosis. Also cases having local high intensity change on T2-weighted MRI had a tendency to become pseudoarthrosis.

Recently vertebroplasty has been a treatment option for pseudoarthrosis following osteoporotic vertebral fracture. If we can estimate the prognosis of the fracture at the time of injury, we can utilize this procedure in the early stage following the fracture and prevent the prolonged pain and disability of the patients. Based on the present study, involvement of posterior wall of vertebral body, large low intensity change both on T1- and T2-weighted MRI and partial high intensity change on T2-weighted MRI seems to be prognostic factors for pseudoarthrosis.

Osteoporotic Fragility Fractures in Older Adults Admitted in a French Primary Care Department: A Prospective Population-based Study. M. Rancier^{*1}, S. Petit^{*1}, A. Bellou^{*2}, V. Pascal-Vigneron^{*1}, N. de Talancé^{*1}, I. Chary-Valckenaire^{*3}, H. Coudane^{*4}, D. Mainard^{*5}, G. Weryha¹. ¹Department of Endocrinology, CHU de Nancy, Vandoeuvre, France, ²Department of Endocrinology, Service d'Accueil des Urgences, Nancy, France, ³Department of Rheumatology, CHU de Nancy, Vandoeuvre, France, ⁴Department of Endocrinology, ATOL-Orthopedy, Nancy, France, ⁵Department of Endocrinology, COT- Orthopedy, Nancy, France

Primary care units diagnose most osteoporotic fractures. During one year we have recorded all low energy fractures in patients attending the primary care department of the University Hospital of Nancy (France). Patients are 45 years old and over.

Population: 929 women (73.8 years \pm 13.5), 365 men (65.4 years \pm 14.3).

28 died in the first month; 100 patients were already followed by a rheumatologist.

Complete exploration of osteoporosis was performed in 170 women and 72 men.

Fractures:

Women: 150 wrist; 283 femoral neck; 52 vertebra; 120 humerus; 19 pelvis; 302 other.

Men: 32 wrist; 99 femoral neck; 20 vertebra; 46 humerus; 14 pelvis; 133 other.

Fourteen double fractures; 2 triple fractures.

72% of patients experienced their first osteoporotic fracture.

Age distribution of fractures: Data are summarized in table 2. In men, fracture distribution has a bimodal shape with higher incidence in younger and older patients. In all age groups, only femoral neck fractures show the expected sharp increase in elderly.

DEXA (Z-score \pm SD): Performed in 170 women and 72 men.

Conclusion: Less than 8% of our patients are usually followed by a medical specialist of osteoporosis. Primary care units are the best place to record and patients with a recent osteoporotic fracture. The population profile is different from patient detected by DEXA in primary prevention. This assessment strongly supports the necessity of a multidisciplinary cooperation

		DEXA distribution by age		
Age		45 to 65 years	65 to 80 years	80 years and over
Femoral neck	Women	-1.266 \pm 1.013	-1.936 \pm 1.089	-2.237 \pm 1.241
	Men	-1.163 \pm 0.993	-1.338 \pm 1.328	-3.425 \pm 0.460
Lumbar spine	Women	-1.536 \pm 1.313	-2.160 \pm 1.193	-1.832 \pm 1.398
	Men	-1.660 \pm 1.517	-1.318 \pm 1.026	-2.850 \pm 0.948

		Fracture site distribution by age and sex

High Leisure Time Physical Activity and High BMI Protect Against Fractures, but Heavy Work and Smoking Increase Risk - A 30-Year Follow-up of 7202 Men. L. W. Wilhelmsen^{*1}, K. L. L. Landin-Wilhelmsen², P. Timpou^{*1}, A. Odén^{*1}. ¹Department of Medicine, Sahlgrenska University Hospital, Institution of Medicine, Göteborg, Sweden, ²Department of Medicine, Sahlgrenska University Hospital, Section for Endocrinology, Göteborg, Sweden.

The purpose was to study life style factors for fracture risk in a random population of 7202 men aged 46-56 years at start and followed for > 30 years (203 051 person-years). Physical activity graded from low (1) to heavy work or regular training (4). Stress was coded from never experienced stress (1) to continuous stress during last year (5) or last 5 years (6). Never smoked was coded (1), stopped smoking (2), smoking 1-14 cig:s/day (3), 15-24 cig:s/day (4) and 25 or more (5). Coffee in cups/day.

Osteoporotic fractures, n=1031, were retrieved from the hospital registers.

All variables were of significant importance for fractures except stress and coffee consumption. Fracture risk decreased with higher level of physical activity during leisure time, but increased with higher level at work (unexpected) and with increasing age. By use of Poisson regression, which included interaction between the predictor and follow up time, we could estimate how the importance of the predictor changed by time (age not included)

Variable	Hazard rate for 1 unit increase (95% CI)		
	Mean of entire follow-up period	At start	At 10 years
BMI (continuous)	0.96 (0.94-0.99)	0.94 (0.88-1.01)	0.96 (0.93-0.98)
Physical activity, leisure	0.85 (0.78-0.93)	0.67 (0.49-0.92)	0.81 (0.72-0.91)
Physical activity, work	1.08 (1.01-1.15)	1.24 (1.00-1.53)	1.11 (1.03-1.20)
Smoking	1.09 (1.03-1.15)	1.14 (0.96-1.36)	1.10 (1.03-1.17)

The effect of changes for the entire population was calculated. At the beginning of follow-up the hazard rate (HR) for previous smokers versus never smoked was 1.05, and after 15 years 1.0. Thus the 15-year horizon was selected. 49.7% were smokers, and the calculated reduction of HR after 15 years if all smokers stopped smoking was 6.9%. Low physical activity was reported by 84.2%, and if they were assumed to train regularly the estimated reduction of HR after 15 years was 6.9%. Men with BMI lower than the three cut offs 24, 25 and 26 kg/m², were 43.0%, 57.3% and 70.0%. The calculated reductions after 15 years if they instead had BMI = 24, 25 and 26 kg/m² would be 3.1%, 4.9% and 7.3%, respectively.

In summary, leisure time physical activity and high BMI protect against fractures, but heavy work activity and smoking increase fracture risk among men between age 50 and 80 years.

Disclosures: L.W. Wilhelmsen, None.

Physical Impact of Morphometric Vertebral Fractures in Men: Geelong Osteoporosis Study. J. A. Pasco, M. J. Henry^{*}, S. Korn^{*}, G. C. Nicholson, M. A. Kotowicz. Clinical & Biomedical Sciences, Barwon Health, The University of Melbourne, Geelong, Australia.

This cross-sectional study compared physical functioning in elderly men with and without morphometric vertebral fractures (MVFs). Using vertebral morphometry from lateral scans of the spine (Lunar Prodigy Pro, T10-12 and L1-4), moderate and severe wedge, biconcave or compression deformities (>25% reduction in any height and accompanying area) were identified in a population-based, age-stratified, random sample of 556 men (median age 75.0yr, range 60-93; 99% white) enrolled in the Geelong Osteoporosis Study.

The timed 'Up-&Go'¹ and functional reach² tests were performed as clinical measures of functional mobility and balance, respectively. Physical activity scores, incorporating household, sport and leisure activities, were determined by questionnaire³ and categorised into tertiles representing high, medium and low levels. All statistical analyses were age-adjusted.

Fifty-five men had MVFs, 26 lumbar and 35 thoracic. Age-stratified prevalence was 4.7% for 60-69yr, 10.0% for 70-79yr, 14.6% for 80+yr and prevalence for the entire group was 8.1% (age-standardised, Australia 2001). Ninety-three percent were unaware of their vertebral deformity. MVFs were associated with longer 'Up-&Go' times (10.0 (95%CI 9.3, 10.7) vs 9.2 (9.0, 9.5) secs, P=0.03) and lower height-adjusted functional reach on the non-dominant side (31.0 (28.8, 33.2) vs 34.1 (33.4, 34.7) cm, P=0.008). No difference was detected on the dominant side. Using high physical activity scores as the referent group, there were increased odds for MVF in the medium [OR=2.45 (95%CI 1.04, 5.77)] and low [OR=2.69 (1.16, 6.27)] groups.

Despite most men being unaware of their condition, MVFs were associated with compromised functional mobility, balance and reduced levels of physical activity.

Fracture and Sway Analyzed by Computed Posturography. T. Fujita¹, M. Ohue^{*2}, Y. Fujii³, A. Miyauchi³, Y. Takagi⁴, T. Sugishita^{*3}. ¹Medicine, Calcium Research Institute, Katsturagi Hospital, Kishiwada, Japan, ²Orthopedic Surgery, Katsturagi Hospital, Osaka, Japan, ³Medicine, Calcium Research Institute, Kishiwada, Japan, ⁴Medicine, National Hospital System Hyogo Chuo Hospital, Hyogo, Japan, ⁵First Division, The Tazuke Kofukai Medical Research Institute, Osaka, Japan.

In a preliminary study comparing spinal and non-spinal fracture in 723 patients consulting Osteoporosis and Osteoarthritis Clinic of Katsuragi Hospital, augmented sway was suggested in spinal but not in non-spinal fracture patients. In order to define the role of sway in each sway factor more precisely, fracture state in 420 patients with complete BMD and sway analysis were classified into 4 groups; 271 (64 %) had no fracture (O), 63 (15 %) only non-spinal fracture, 58 (14 %) only spinal fracture, and 288 (7%) both spinal and non-spinal fracture. Lumbar bone mineral density (LBMD) was measured by DXA (DPX) and distal radial trabecular bone density (t), midradial cortical bone density (c) and midradial cortical bone volume relative to the whole bone (cv) by pQCT (Norland-Stratec). Sway parameters; total length of gravity center track (LNG), track density per unit area indicating postural controlling efficiency (LNGA) and rectangular area covered by the track (REC) were measured by computed posturography (Anima) with eyes open and then closed. The difference among each group was analyzed by analysis of variance followed by multiple comparison using PLSD, Scheffe and Bonferroni-Dunn method. LMD was found to be significantly lower in B 0.810 \pm 0.03 gm/cm² (p=0.0075 and 0.0005) and S 0.851 \pm 0.02 gm/cm² (p=0.0075 and 0.0007) than in O 0.953 \pm 0.01 gm/cm² (Scheffe and Bonferroni-Dunn). LNG expressing the degree of sway was also significantly larger in B 105 \pm 11 (p=0.0046) than O, but not significantly different from O in S, 88 \pm 5 (p=0.1973), suggesting a close association of the increase of sway with spinal fracture. On eye closure, insufficient postural control efficiency in the group with spinal fracture alone became

clearer, compared with the group with both spinal and non-spinal fracture. Persistently significant negative regression was noted on pQCT-measured bone factors LNG, REC and LNG on eye closure suggesting sway aggravation on decrease of these pQCT-measured factors, whereas no significant regression of sway factors except for REC on eye closure suggesting a decreases sway on decreasing LBMD was noted, indicating different influence on sway. Computed posturography appears to be useful in evaluating sway as a risk factor for fall and fracture.

Disclosures: T. Fujita, None.

W291

Does Low Subjective Well-Being Predict Falls and Fractures in Postmenopausal Women? R. J. Honkanen¹, H. T. Koivumaa-Honkanen^{*2}, M. T. Tuppurainen¹, H. P. Kröger³. ¹BCRU, Clinical Research Center, University of Kuopio, Kuopio, Finland, ²Psychiatry, Kuopio University Hospital, Kuopio, Finland, ³Surgery, Kuopio University Hospital, Kuopio, Finland.

Some studies suggest that depression might be associated with osteoporosis. A 4-item life satisfaction (LS) scale is strongly correlated with depressive symptoms ($r=0.7$). It is associated with and predicts morbidity, mortality and health behaviour. The purpose was to examine if subjective well-being as measured with LS scale predicts falls and fractures in postmenopausal women.

The study population was formed of the 9403 OSTPRE cohort women (born in 1932-41) who responded to all the four OSTPRE enquiries in 1989, 1994, 1999 and 2004. The follow-up time was 5 years: 1999-2004. Self-reported follow-up fractures were validated by perusal of patient records: the number of women with fractures was 835, including 322 women with distal forearm fracture (DFF) and 28 women with hip fracture. A total of 3312 women reported a fall during the past 12 months in 2004. LS scale (range 4-20, mean 7.95 (SD 2.7) categorized as satisfied 4-6, intermediate 7-11, dissatisfied 12-20) was formed with four questions about happiness, interest in life, loneliness and ease of living. Logistic regression was used as the statistical method.

At baseline, the strongest correlate of LS was self-rated health ($r=0.336$ ($p<0.001$)). Also work disability and number of health disorders were associated with LS ($p<0.001$). Old fractures before year 1989 were a correlate of dissatisfaction ($r=0.035$, $p=0.001$), whereas fractures in 1989-99 were not and former DFF correlated with satisfaction $r=-0.024$, $p=0.022$.

Life dissatisfaction predicted falls: falling risk was 19 % higher in the intermediate group and 56 % higher in the dissatisfied than in the satisfied ($p<0.001$). After adjusting for weight, height, calcium intake, fracture history, time of menopause, HRT and number of health disorder (or self-rated health) these risk estimates were only slightly reduced. Life dissatisfaction did not predict fractures in general or any specific fracture type except hip fracture. As a continuous (but not categorized) variable it predicted hip fracture ($p=0.005$) with a 16.5 % increase in risk for a unit increment of LS scale. This prediction weakened but did not vanish after adjusting for weight, height, fracture and falling history, HRT, time of menopause, calcium intake and number of health disorders. Adding self-rated health to the model changed the association non-significant ($p=0.119$).

The results suggest that low subjective well-being (as an indicator of depression) predicts falls and hip fracture but not fractures in general in late postmenopausal women before old age.

Low-Dose Estrogen Oral Contraceptive Use and Bone Mineral Density in Adolescents and Young Adult Women. L. Ichikawa^{*1}, D. Scholes¹, A. Z. LaCroix², S. M. Ott³. ¹Group Health Cooperative, Seattle, WA, USA, ²Fred Hutchinson Cancer Research Ctr, Seattle, WA, USA, ³Univ of WA, Seattle, WA, USA.

Oral contraceptive (OC) use may adversely impact bone mineral density (BMD) in young women. Use of low-estrogen dose OC has recently been increasing, but few studies have examined the association of these OC formulations and BMD in young women. We report results from a cross-sectional study of OC use and BMD, comparing adolescents 14-18 years old and young adult women 19-30 years old. Study invitation letters were sent to potential study participants who were selected from the computerized databases of Group Health, a Washington state HMO, based on age and OC prescriptions. We enrolled 606 women who were 20 mcg ethinyl estradiol (EE) OC users ($n=148$), 30-35 mcg EE OC users ($n=241$), or OC non-users ($n=217$) at the time of their visit. OC non-users may have had some past OC use but it was limited to no use in the last 2 years and less than 8 years lifetime use. BMD (DEXA) was measured at the hip, spine, and whole body. Women were asked about their contraceptive history and OC brand and start and stop dates were collected. Data on factors related to bone health were collected using health and food frequency questionnaires. OC users were more likely to be White and smokers. Young adult women had less calcium intake and physical activity and more smokers compared to adolescent women. Average current, continuous OC use was 6 months (range 0.1-37) among adolescents and 13 months (range 0.1-135) among young adults. OC use is often intermittent and life-time exposure was 8 months (range 0.3-53) in adolescents and 42 months (range 0.3-172) in young adults. We found no association between OC group and BMD at any anatomic site among adolescents after adjusting for age, race, BMI, calcium intake, physical activity, period regularity, and current smoking status. For young adults, the adjusted mean spine BMD by OC group was significantly different with the 20 mcg EE OC users 3.5% lower compared to 30-35 mcg EE OC users ($p=0.03$) and 3.3% lower compared to OC non-users ($p=0.04$) (Table). Patterns were similar but non-significant for the hip and whole body. Results did not differ when OC non-users were restricted to those who never used in the past and the amount of past OC use of a different formulation was restricted to less than one year. Our data suggest the use of 20 mcg EE OC may suppress

bone mass accrual in young adult women.

Age Group (years)	Adjusted Mean BMD by Age Group and OC Group			
	OC Group (n)	Total hip BMD, g/cm ² (s.e.)	Spine BMD, g/cm ² (s.e.)	Whole body BMD, g/cm ² (s.e.)
Age 14-18, Adolescent women	20 mcg EE OC (n=74)	1.012 (0.012)	1.016 (0.011)	1.094 (0.009)
	30-35 mcg EE OC (n=124)	0.997 (0.010)	1.016 (0.008)	1.089 (0.007)
	OC Non-user (n=111)	0.992 (0.010)	1.003 (0.009)	1.084 (0.007)
Age 19-30, Young adult women	20 mcg EE OC (n=74)	0.960 (0.013)	1.005 (0.013)	1.098 (0.010)
	30-35 mcg EE OC (n=117)	0.988 (0.010)	1.041 (0.010)	1.120 (0.008)
	OC Non-user (n=106)	0.985 (0.011)	1.039 (0.011)	1.108 (0.008)

The Association of Pulse Wave Velocity and Bone Mineral Density. Y. Kim, Y. Kim^{*}, S. Lee^{*}. Family Medicine, Pusan National University Hospital, Busan, Republic of Korea.

Background: Increased arterial stiffness and decreased bone mass is age-related disease. So we investigated association of arterial pulse wave velocity (PWV) and bone mineral density (BMD).

Subjects and Methods: In this study, 304 postmenopausal women who underwent annual physical health check-ups recruited. Brachial-ankle PWV were measured using automated device. The BMD was measured using dual-energy X-ray absorptiometry.

Results: The mean age of the subjects was 57.3 ± 6.0 years. 202 subjects who have normal BMD and 102 subjects who have osteopenic and osteoporotic BMD. There were no significant difference of PWV between subjects with normal BMD and with osteopenic and osteoporotic BMD ($P>0.05$, 1452.6 ± 228.0 cm/sec, 1495.3 ± 247.1 cm/sec). But after adjusting for age, subjects with osteopenic and osteoporotic BMD had a significantly higher PWV ($R = 0.270$, $P<0.01$).

Conclusions: Postmenopausal women with normal BMD had a lower arterial stiffness than with osteopenic and osteoporotic BMD. This result suggest normal BMD postmenopausal women may have a lower cardiovascular disease with osteopenic and osteoporotic BMD.

Key words: postmenopausal women, BMD, PWV

Clinical Risk Factors for Fracture Are Additive in Postmenopausal Women Who Are at Risk for Fracture in a Primary Care Setting. J. LaFleur^{*1}, C. McAdam-Marx^{*1}, C. V. Asche^{*1}, S. Alder^{*2}, X. Sheng^{*2}, D. I. Brixner^{*1}, S. Silverman^{*3}. ¹Department of Pharmacotherapy, University of Utah, Salt Lake City, UT, USA, ²Department of Family and Preventive Medicine, University of Utah, Salt Lake City, UT, USA, ³Cedars-Sinai/University of California, Los Angeles, CA, USA.

Background: Increasing number of clinical risk factors (CRFs) has been linked to higher fracture risk in postmenopausal (PM) patients. We characterized hip fracture (HF) risk associated with combining multiple CRFs among at-risk patients in a primary care setting.

Methods: A historical cohort study of primary care health records from 1995-2005 was conducted to identify PM patients at risk of fracture. Patients had a 395-day run-in period and an average follow-up of 29 months. CRFs of interest during run-in were age, body mass index (BMI), bone mineral density (BMD), fracture since age 50, and maternal osteoporosis history. Other CRFs including race, drug exposures, and comorbid diseases were also evaluated. Cox models were used to estimate the risks of HF over time for each CRF in univariate and multivariable models. Risks for patients with combined CRFs were calculated.

Results: We identified 50,783 patients. Mean age was 66.8 years (SD 8.6). BMD T-scores were present in 6.8% of which 52.4% and 25.9% had T-scores in the osteopenia and osteoporosis ranges, respectively. Most patients were overweight or obese (55.8% with BMI ≥ 25); 2.8% of the population was underweight (BMI < 18.5). A prior fracture since age 50 was identified in 3.5% of which 41.9% and 21.1% had a prior vertebral fracture (VF) and HF, respectively. Maternal history was not available. Race was identified for 30.9% of which 82.8% were Caucasian.

Incident HFs occurred in 0.76% with a mean time-to-event of 23 months. In univariate analyses, increasing 5-year age increments, lower BMI, prior fracture, and race were statistically significant predictors of HF risk. BMD was not significant, but the number of patients with BMD data was small. Of the primary CRFs, only age, BMI, and prior fracture were used in the multivariable models due to a lack of univariate significance or missing data.

Risks for HF were markedly higher for older patients with both low BMI and prior fractures versus younger patients with higher BMI and no fracture. Underweight patients age 70-74 with no prior fracture, a prior VF, or a prior HF had 42, 143, and 155 times the risk, respectively, compared to a younger obese woman with no fracture. These risks increased to 86, 290, and 315 for patients age 80 and above.

Conclusion: We studied the utility of CRFs for predicting HF risk in a primary care setting using historical data. CRFs for HF included age, BMI, and prior fragility fracture. The CRFs were additive, thus combinations of CRFs could be useful for identifying PM women at high risk for HF.

Factors Associated with Lack of Osteoporosis Care at the Time of Fragility Fracture. J. J. Laughren*, B. G. Escott, S. E. Ward*, V. Elliot-Gibson*, D. E. Beaton*, E. R. Bogoch. Mobility Research, St. Michael's Hospital, Toronto, ON, Canada.

Purpose: Previous work has identified low rates of preventive OP care when people arrive for treatment of an OP related fracture. Identification of those least likely to be on care could help streamline or prioritize care in a busy fracture clinic. The purpose of this study is to identify the factors associated with not being on OP care at the time of presentation with a fragility fracture.

Methods: Cross sectional survey of women >40 years and men >50 years presenting to fracture clinic with a fragility fracture. Data collected at baseline via a self-reported survey included socio-demographics, previous osteoporosis diagnosis, treatment and risk factors as well as self-reported osteoporosis awareness and health beliefs. A patient was identified as receiving treatment for osteoporosis if they were taking any anti-resorptive or anabolic bone agent at the time of presentation. Potential predictors were evaluated first at a univariate, unadjusted odd-ratios of being on care and then in a multivariable logistic regression. The data was randomly split in two prior to analysis, and with the modeling rerun in a the validation set of data. Results were compared for stability between multivariable models. Adjusted odds ratios are reported from the validation model.

Results: 508 people participated in this study. The average age was 68.5 years and there were 111 (21.9%) males. 165 patients (32.5%) were on care for OP at the time of presentation. Multivariable analysis revealed that being male (adjusted OR: 3.39; 95% CI: 1.22-9.43), not perceiving that OP could have caused the fracture (adjusted OR: 6.39; 95% CI: 2.96-13.81) and not perceiving that one has low bone mass (adjusted OR: 10.78; 95% CI: 4.10-28.36) were predictive of a lack of osteoporosis care in both design and validation multivariable models. While the effect of age <60 and previous history of a fracture were not stable in both design and validation models, their effect was in the same direction. After multivariable modeling, fracture site was not predictive of being on osteoporosis care.

Conclusions: Male patients and patients with poor awareness of osteoporosis and its risks are less likely to be receiving treatment for osteoporosis at the time of fracture. While men are at lower risk of osteoporosis than women, our findings may suggest that care should be exercised not to overlook these patients should be screened at time of presentation. Patients' poor awareness of OP and its risks may be both a cause and effect of their lower rates of treatment. While patients already on treatment may be more aware of OP and its risks as a result of exposure and education, patients with poor beliefs may render them less willing to accept treatment if offered by GP or professional.

Age Increases the Risk of Subsequent Fractures Following an Initial Fracture among Women in Managed Care Population. R. Lindsay¹, N. N. Borisov², M. Steinbuch². ¹Helen Hayes Hospital, West Haverstraw, NY, USA, ²Procter & Gamble Pharmaceuticals, Mason, OH, USA.

The study objective was to assess the risk of subsequent fracture with age among women 65 years and older utilizing integrated administrative medical claims databases (Ingenix Lab/Rx™ and Medstat MarketScan®).

A retrospective cohort study was conducted among women who presented with a new fracture between July 1, 2000 and December 31, 2003. The study included non-traumatic closed fractures at nine sites: hip, femur, tibia/fibula, humerus, clavicle, pelvis, forearm, wrist, and spine. The cohort was followed for at least 12 months after the initial fracture to identify subsequent fractures and to evaluate the proportion of women who received treatment for osteoporosis (nasal calcitonin, raloxifene, alendronate, or risendronate). From a total of 448,769 eligible women, 19,554 women were identified with a new fragility fracture during the study period. Nonvertebral fractures represented 77% of the all index fragility fractures in this population. The average follow-up time after the index fracture was 24 months (range 12 months to 54 months). During this period, 72% did not receive any treatment for osteoporosis. The occurrence of subsequent fragility fractures increased from the youngest to oldest age cohorts, peaking at 4% vertebral and 10% nonvertebral fractures.

Subsequent fractures and treatment pattern after a fragility fracture by age groups

Age groups	65-74	75-84	85+	Total
Women, N	6,138	8,679	4,737	19,554
Nonvertebral Fractures, n (%)	4,836 (79)	6,549 (75)	3,607 (76)	14,992 (77)
Subsequent Fractures, n (%)	590 (10)	991 (11)*	650 (14)**	2,231 (11)
Nonvertebral	414 (7)	697 (8)*	457 (10)**	1,568 (8)
Vertebral	180 (3)	296 (3)	196 (4)**	672 (3)
Women who did not receive osteoporosis treatment, n (%)	4,449 (72)	6,221 (72)	3,499 (74)**	14,169 (72)

*significantly different from age group 65-74 at p < 0.05

**significantly different from age groups 65-74 and 75-84 at p < 0.05

In this study, age was observed to have a significant effect on risk of a subsequent fracture after the initial fracture. The risk of subsequent fractures (vertebral and nonvertebral) increased with age. The majority of women remained untreated after their initial fracture.

Association of Self-Reported Frailty with Bone Mineral Density (BMD) and Incident Fractures in an Elderly Population. S. Ma, J. Oyler*, T. J. Vokes. Medicine, University of Chicago, Chicago, IL, USA.

Although BMD declines with chronological age, little is known about the association between BMD and "biological age" or frailty. The Vulnerable Elders Survey (VES-13) measures self-reported functional impairment and is widely used to assess frailty. We examined whether the VES-13 can predict low calcaneal BMD and incident fractures in the elderly.

207 elderly community subjects (age 65-95 yrs, mean 77±7 yrs, 170 women, 37 men, 127 African-Americans[AA], 80 Caucasians[CA]) had calcaneal BMD measured by the PIXI densitometer, and frailty assessed by the VES-13. Besides the VES-13 score (range 0-10), a modified score was developed that excluded age, a known strong predictor of BMD. The modified total score (range 12-60) was the sum of the points for general health, 6 functional activities and 5 activities of daily living (ADL), with higher scores reflecting greater impairment. Functional and ADL subscores were created by adding the points for the respective functional and ADL items. The two subscores were added to create a Physical subscore reflecting physical impairment without age or general health. Six years after the initial assessment, each subject or relative was contacted by phone to ascertain incident fractures and/or death. 114 of the 207 subjects completed the follow-up.

At the initial evaluation, BMD significantly correlated with age (r=-0.32), weight (r=0.56) and height (r=0.42), was higher in men and in AA. In multivariate linear regression with BMD as the outcome, only the modified total score (p=0.013) and subscores (p=0.007 for Physical) remained significant after controlling for age, weight, sex and race. Based on the model, the difference in BMD between subjects with the lowest and highest Physical subscores was 0.102 g/cm², corresponding to 1.275 T-score units and a doubling of the fracture risk.

At the follow-up evaluation, 13 of 114 subjects were deceased and 17 had incident fractures. Death was associated with higher baseline frailty using the VES-13 score (p=0.01) and even more significantly with the Physical subscore (p=0.001), providing validation for both scoring methods. Fractures were associated with lower baseline heel BMD (OR=1.65 for fracture per 1 unit T-score decrease, p=0.02). The positive association between fractures and Physical subscore was not statistically significant (p=0.06), likely due to small numbers.

We conclude that frail elderly subjects have lower calcaneal BMD than expected for their age, sex, race and weight. Assessing frailty with an easily-obtained, self-reported measure like the VES-13 can identify elderly community subjects with lower BMD who would benefit most from an aggressive approach to the diagnosis and treatment of osteoporosis.

Epidemiology of Chronic Obstructive Pulmonary Disease and Osteoporosis: The E.O.L.O. Study. S. Maggi¹, P. Siviore¹, S. Gonnelli², S. Battucci³, D. De Feo³, G. Guglielmi⁴, L. Sartori⁵, R. Nuti², G. Crepaldi².

¹Aging, National Research Council, Padova, Italy, ²Internal Medicine, University of Siena, Siena, Italy, ³Procter & Gamble, Rome, Italy, ⁴Department of Radiology and Division of Endocrinology, Scientific Institute Hospital "Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy, ⁵Internal Medicine, University of Padua, Padova, Italy.

Chronic obstructive pulmonary disease (COPD) is a complex disease and a major cause of morbidity and mortality worldwide. In the last few years a link has been identified between COPD and other systemic diseases, such as cardiovascular disease, diabetes and osteoporosis. Several factors contribute to the development of osteoporosis in COPD patients, such as smoking, Vit. D deficiency, low BMI, decreased free fatty mass, hypogonadism, immobility, use of glucocorticoids. (Iqbal et al., Chest 1999)

E.O.L.O. (Evaluation of Obstructive Lung disease and Osteoporosis) is a study aimed at evaluating the prevalence of osteopenia, osteoporosis and vertebral fractures in a sample of patients affected by COPD treated or not with GCs. Fifty-nine Teaching and General Hospitals in Italy participated in the study. A total of 3030 outpatients with COPD, aged 50+ yrs, were enrolled. All subjects had undergone a BMD evaluation (QUS) and a latero-lateral chest X-ray for thoracic spine evaluation.

The results of this study showed:

- The prevalence rates of osteopenia and osteoporosis in COPD patients are higher than in the general population of same age and sex (Figure)

- The frequency of osteoporosis is associated with COPD severity, even after adjusting for age, sex, BMI, smoking and GCs use (Table)

Sex-specific multivariate analyses did not show differences between men and women in the association of predictors and outcomes.

This study confirms that COPD patients are at higher risk of osteoporosis compared to the general population.

Logistic Regression Model for Osteopenia/Osteoporosis (N=2106: normal=538, osteopenia=857, osteoporosis=711)*

	OSTEOPENIA vs NO			OSTEOPOROSIS vs NO		
	OR	95% C.I.		OR	95% C.I.	
GENDER (Men)	0,395	0,307	0,508	0,136	0,103	0,178
AGE (year)	1,013	0,999	1,027	1,062	1,046	1,078
BMI (<26.6)	1,189	0,952	1,484	1,483	1,163	1,892
COPD (Severe+Much Severe)	0,851	0,667	1,087	1,405	1,079	1,830

Effects of Doxorubicin on Bone Mineral Content and Density in Rats. M. A. McNulty^{*1}, L. C. Sharkey^{*1}, C. C. Curran^{*2}, C. S. Carlson^{*1}. ¹Veterinary Population Medicine, University of Minnesota, Saint Paul, MN, USA, ²Biostatistics Design and Analysis Center, University of Minnesota, Minneapolis, MN, USA.

Doxorubicin (DOX) is a chemotherapeutic agent commonly used to treat a variety of cancers. This agent has known cardiotoxic effects and DOX treatment has been reported to be toxic to osteoblasts in vitro; however, little work has examined its effects on bone in vivo. The purposes of this study were 1) to evaluate the effects of 6 or 8 weeks of treatment with DOX on bone mineral content (BMC) and density (BMD) in rats; and 2) to determine if these effects were influenced by strain or gender. Six- to eight-week old male and female rats of 3 different strains (SHHF, SHR, and WKY) were treated with saline (Controls) or were injected subcutaneously with 2mg/kg of DOX once per week for 6 (DOX6) or 8 (DOX8) weeks. Each group contained 6 or 7 rats for a total of 120 animals. The rats were euthanized 12 weeks after the end of the treatment period and post-mortem dorsoventral whole body bone scans were taken using a GE Lunar Prodigy Densitometer. The spine of each animal (T2-L6) was analyzed using the GE Small Animal software to determine BMC & BMD values for this site. BMC and BMD data for treatment and strain were evaluated by ANOVA, and for gender, strain, and treatment after adjusting for pretreatment body weight using ANCOVA. BMC and BMD were significantly decreased by treatment in a dose dependent manner ($P < 0.001$ for both BMC & BMD) and also were significantly affected by strain ($P < 0.001$ for both BMC & BMD). The SHHF strain had significantly higher BMC & BMD values than both the SHR & WKY strains, and the SHR strain had slightly higher BMC values and significantly higher BMD values than the WKY strain. After adjusting for all other factors, the following were observed: 1) There was a significant effect of DOX treatment on BMC & BMD ($p < 0.001$). The control group had a significantly higher mean BMC & BMD than the DOX6 group ($P < 0.05$), but not the DOX8 group; 2) There was a significant association between strain and mean BMC & BMD ($P < 0.001$), with SHHF & SHR strains having higher mean values for both than the WKY strain ($P < 0.001$); and 3) There was a significant gender by strain interaction ($P < 0.001$). Specifically, males had on average significantly higher mean BMC & BMD values than females within strains SHHF ($P < 0.001$ for both BMC & BMD) and SHR ($P = 0.001$ for BMC, $P < 0.001$ for BMD). Within strain WKY, males had slightly lower mean BMC & BMD values, but these differences were not significant ($P = 0.316$ for BMC, $P = 0.05$ for BMD). These results demonstrate that DOX treatment in young rats results in significant reductions in BMC and BMD compared with saline-treated control rats and that the choice of rat strain and gender are important considerations.

Long-term Use of Oral Anticoagulants and Risk for Osteoporosis. E. Stenova^{*1}, J. Payer², Z. Killinger^{*2}, L. Baqi^{*2}. ¹1st Department of Internal Medicine, University Hospital In Bratislava, Bratislava, Slovakia, ²5th Department of Internal Medicine, University Hospital In Bratislava, Bratislava, Slovakia.

Introduction: Vitamin K allows for gamma-carboxylation of glutamyl residues, a conversion that activates clotting factors and bone proteins, including osteocalcin, which is a marker of osteoblastic activity. Vitamin K antagonists such as warfarin inhibit this process. Studies of oral anticoagulant use and BMD have produced conflicting results. There were usually retrospective, limited by small sample sizes with very short follow-up period and no control group.

Aim: The presented prospective study was conducted to demonstrate the effect of long-term oral anticoagulation therapy on bone mass.

Material and Methods: 54 patients / postmenopausal female 23, male 31/ of age 50 years or older treated with warfarin of mean dosage 4,5mg per day were enrolled in this study. The

mean INR was 2-2, 5. 62 age- and sex-matched volunteers were also randomized according to same exclusion and inclusion criteria as healthy controls, without warfarin treatment. Hip and spine bone density was measured by dual X-ray absorptiometry with Hologic Delphi scanner. Sera were analyzed for osteocalcin /OSC-S/, C-terminal cross-linking telopeptide of type I collagen /CTx-S/, alkaline phosphatase /ALP-S/ and calcium /Ca-S/. 24-hour urine samples were collected for detection of urinary calcium loss /Ca-dU/. The BMD and the concentrations of laboratory markers were measured at baseline and after 12 months.

Results: No differences between warfarin-treated and control groups in markers of calcium metabolism /Ca-S, Ca-dU/, ALP-S and BMD at baseline were observed. After 12 month there was also no significant difference of these markers between treated and untreated groups. The concentrations of CTx-S / $p < 0,05$ / and OSC-S / $p < 0,001$ / were significantly lower in warfarin-treated group. We determined a significant elevation of Ca-S / $p < 0,05$ / and Ca-dU / $p < 0,05$ / after 12 month in warfarin-group. These results were not recognized in controls. There were no significant changes of BMD after 12 month in either group.

Conclusion: There were no changes of bone mineral density in both warfarin-treated and control group after 12 month. The significantly lower OSC and CTx serum levels suggest that vitamin K has an influence on bone turnover, but this effect is probably modest. The long-term anticoagulant treatment is associated with higher urinary calcium loss and elevation of calcium serum level. The mechanism of these laboratory findings is unclear and should be confirmed by other investigations including determination of vitamin D level.

Disclosures: J. Payer, None.

The Osteoporosis Self-Assessment Tool vs. Alternative Triage Tests: a Comparative Systematic Review of Accuracy. B. Rud¹, J. Hilden^{*2}, L. Hyldstrup¹, A. Hróbjartsson^{*3}. ¹Osteoporosis Unit 545, Hvidovre University Hospital, Copenhagen, Denmark, ²Department of Biostatistics, Faculty of Health Sciences, University of Copenhagen, Copenhagen, Denmark, ³The Nordic Cochrane Centre, Rigshospitalet, Copenhagen, Denmark.

Previous studies have suggested that the Osteoporosis Self-Assessment Tool (OST), which is an index based on age and weight, may be as accurate as alternative triage tests in selecting postmenopausal women with low BMD for assessment by DXA. Our aim was to systematically compare the accuracy of OST and alternative triage tests in postmenopausal women.

We searched PubMed, Embase, Web of Science, citation lists and conference proceedings for studies that compare the accuracy of OST and alternative triage tests using a paired design. Our main measure of accuracy was the diagnostic odds ratio (DOR). By using the Moses-Littenberg method we summarised DOR in pair wise meta-analyses for OST and alternative triage tests when three or more studies were available, otherwise we performed qualitative summaries. We evaluated methodological quality by using the QUADAS checklist.

We identified 21 relevant studies of which 16 provided data for the pair wise meta-analyses. In whites, regardless of measurement regions and threshold for low BMD, summary estimates of DOR (sDOR) for OST were consistently at least as high as sDOR for the clinical decision rules SCORE, ORAI and SOFSURF (p -values > 0.02). By contrast, sDOR was almost twice as high for Stiffness Index assessed by quantitative ultrasonography using Achilles devices (GE-lunar) than for OST with respect to lumbar spine T-score ≤ -2.5 ($p = 0.005$). Similar results were found across measurement regions and thresholds for low BMD, although meta-analyses were unfeasible because studies were few. A few studies in whites suggested that weight is only slightly less accurate than OST regardless of how low BMD is defined. Between-study heterogeneity in estimates of DOR varied considerably between triage tests, measurement regions and thresholds for low BMD. Studies were few in Asian and black women and meta-analyses were unfeasible, but OST and alternative triage test were in general equally accurate. Methodological quality was generally low; no studies compared the accuracy of the triage tests prospectively as used by clinicians in settings where decisions about DXA referral are common.

Only the QUS variable Stiffness Index was consistently more accurate than OST in white women; however the transferability of our findings to clinical settings is uncertain due to low methodological study quality.

Dental Status, Low Bone Mass, and other Osteoporosis-related Conditions as Predictors of Adverse Outcomes in an Elderly Population. E. Musacchio^{*1}, E. Perissinotto^{*2}, P. Binotto^{*2}, F. Silva-Netto^{*1}, M. C. Corti^{*3}, G. Baggio^{*4}, S. Zambon^{*1}, E. Manzato^{*1}, G. Crepaldi⁵, L. Sartori¹. ¹Clinica Medica 1, Dpt of Medical and Surgical Sciences, University of Padova, Padova, Italy, ²Dpt of Environmental Medicine and Public Health, University of Padova, Padova, Italy, ³Direzione Sanitaria, ULSS 16, Padova, Italy, ⁴Azienda Ospedaliera, Padova, Italy, ⁵Institute of Neurosciences, CNR, Padova, Italy.

We have previously reported that, in an aging (65+ years old) Italian population of both sexes cross-sectionally evaluated (ProVA Study cohort), the condition of low remaining number of teeth alone identified a larger proportion of impaired subjects as compared to the presence of osteoporosis alone. We now further investigated this issue through the data resulting from the longitudinal phase of ProVA consisting of two follow up at 5 (F1) and 7 (F2) years. The prevalence of edentulism in our population was 43.7% at baseline (n=3058), 46.2% at F1 (n=2176), and 44.9% at F2 (n=160), while the prevalence of subjects with 20+ teeth was 15.8%, 13.0% and 13.1% respectively. Logistic regression analyses with stepwise forward selection were performed in order to estimate the independent contribution of number of teeth, low bone mass and other osteoporosis-related conditions - after adjustment for confounders and including in the model variables hypothesized to be in the causal pathway - at baseline, in predicting physical impairment (PI), mortality, femoral fracture and institutionalization at follow up. With respect to PI, a low basal T-score was not critical, while edentulism appeared to be an independent risk factor with an OR=1.65 (CI 95%: 1.19-2.27). A stronger significant association (OR=3.38) was found considering separately edentulous subjects that did not wear prosthesis. Interestingly, analysis at F2, which was in general consistent with that F1, revealed an effect of low vitamin D levels (OR=3.69) not present at F1. With respect to mortality, low T-score and vitamin D levels had OR=1.38 and 1.99 respectively, while for low functional remaining teeth, OR was 1.45. Incident femoral fractures were associated with low T-score (OR=2.35) and previous femoral fracture (OR=3.39), but not with the number of teeth. Institutionalization was associated with previous falls (OR=2.85). Our data support the hypothesis that, in the elderly, oral status is a more reliable tool than osteoporosis in predicting impaired physical activity and mortality. Oral condition assessment could then have a role in the daily clinical practice for the identification of subjects at risk.

The Direct Assessment of Non-vertebral Fracture in Community Experience (DANCE) Study: Baseline Demographics and Reasons for Initiating Teriparatide Therapy. A. Sebba^{*1}, R. Sierra-Zorita^{*2}, P. Miller^{*3}, P. Chen^{*4}, K. Taylor^{*4}, M. Wong^{*4}, K. Krohn^{*4}. ¹Arthritis Associates, Palm Harbor, FL, USA, ²Univ of Puerto Rico School of Medicine, Hato Rey, PR, USA, ³Colorado Center for Bone Research, Lakewood, CO, USA, ⁴Eli Lilly and Company, Indianapolis, IN, USA.

Randomized, placebo-controlled clinical trials have shown the efficacy of teriparatide (TPTD) in treating osteoporosis (OP) and preventing fractures, but therapeutic decisions may differ in community practice. The ongoing, prospective, observational DANCE study examines the long-term effectiveness, safety, and tolerability of TPTD in a heterogeneous "real world" population of patients with co-morbidities, severe OP, and/or prior OP therapy, in a community setting. Study investigators prescribe TPTD 20 µg/d for up to 24 months to patients, and follow them for another 24 months. For the 4057 patients enrolled in DANCE, baseline demographics (Table) and reasons for initiating TPTD are described here.

Physicians cited reasons for initiating TPTD therapy in 4010 patients, of which 3335 (83.2%) had ≥1 fracture risk factors. The most frequent reasons included very low BMD (61.2%), previous self-reported osteoporotic fracture (33.8%), general frailty (20.7%), advanced age (18.8%), propensity to fall (17.7%), and family history of OP fractures (17.3%). In 2938 patients who previously used OP therapies, 596 patients (20.3%) had intolerance, and 2041 (69.5%) had an inadequate response, which included a decline (44.5%) or no change (10.9%) in BMD, or occurrence of new fractures (20.8%). It appears that in addition to BMD, several other clinical risk factors are important in the physicians' decisions to initiate TPTD therapy. Data from DANCE may clarify the rationale used by physicians in the community for assessing antiresorptive therapy and initiating TPTD therapy, to facilitate an evidence-based method of patient management.

Table. Baseline Demographics of DANCE Study Cohort (Mean ± SD)

Characteristic (*P<0.05 between genders)	Women (N=3653)	Men (N=404)	Overall (N=4057)
Age (years)*	68.2 ± 11.6	64.9 ± 13.3	67.9 ± 11.8
Caucasian (%)*	88.1	92.1	88.5
Lumbar Spine Bone Mineral Density (BMD) T-score*	-2.50 ± 1.40	-2.25 ± 1.48	-2.48 ± 1.41

Peripheral Artery Disease and Osteoporosis in Older Adults. D. von Mühlen^{*}, M. A. Allison^{*}, S. K. Jassal^{*}, E. Barrett-Connor. Family and Preventive Medicine, UCSD, La Jolla, CA, USA.

Increased rates of bone loss, osteoporosis and osteoporotic fractures have been reported in patients with cardiovascular disease, suggesting a relationship between osteoporosis and atherosclerosis. Limited information is available on whether low bone mass is associated with vascular disease. We examined the cross-sectional and longitudinal association between peripheral artery disease (PAD) and bone health in a sample of community-dwelling older adults. We studied 525 men and 806 women, aged 30 to 97 (mean age=73.8, SD=9.2) who attended a baseline clinic visit in 1992-1996, when ankle-brachial index (ABI) and BMD were measured, and spine x-rays were taken. In 1999-2002, 321 men and 517 women attended a follow-up visit, when BMD was re-assessed and incident OP fractures were queried. PAD defined by an ABI ≤ 0.90 was present in 15.4% of the women and 13.3% of the men. Compared to those without PAD, participants with PAD were older (77 vs. 73 years old, p<0.001), leaner (BMI = 24.5 vs. 25.3, p=0.02), and more likely to have hypertension (77% vs. 70% p=0.05), diabetes (12% vs. 7%, p=0.02) and to be current smokers (12% vs. 6%, p=0.002). They were also more sedentary (38% vs. 25%, p<0.001) and reported less frequent alcohol intake (38% vs. 47%, p=0.01) than participants without PAD. Among those with PAD, the prevalence of osteoporosis by T score at the femoral neck and hip was significantly higher in women (59% vs. 49% and 25% vs. 17% respectively, p<0.05), but not men. Women with PAD also had a significantly higher rate of bone loss at the hip (-0.85%/year vs. -0.52%/year, p=0.05). However, the associations between PAD and bone mass did not persist after adjusting analyses for age and/or body mass index. At baseline more women than men had a vertebral and/or non-vertebral osteoporotic fractures (13% vs. 8% and 12% vs. 7% respectively, all p's<0.01). After a mean follow up of 3.7 (SD=0.9) years there were no sex differences in the incidence of non-vertebral fractures (8.3% in women and 8.9% in men). PAD was not associated with prevalent or incident osteoporotic fractures in either men or women. In conclusion, we found an association between PAD with osteoporosis and bone loss in women, but not men. However, the associations were not independent of age, body weight or other confounders.

High Prevalence of Abnormal Lumbar Spinal DXA Scans in Men Receiving Methadone Maintenance Therapy for Opiate Dependence. K. M. Wesa^{*1}, L. S. Hafner^{*2}, D. P. McGuire^{*3}, C. L. Smith¹, J. J. Monk^{*4}, G. A. Carlson^{*1}, K. E. Ensrud^{*5}, R. H. Grimm^{*1}. ¹Department of Medicine, Hennepin County Medical Center, Minneapolis, MN, USA, ²Department of Experimental and Clinical Pharmacology, University of Minnesota, Minneapolis, MN, USA, ³Thomson West, Eagan, MN, USA, ⁴Bone & Mineral Metabolism, Davita, Minneapolis, MN, USA, ⁵VA Medical Center & University of Minnesota, Minneapolis, MN, USA.

One area of chronic opiate use that has not been extensively examined is the correlation between narcotic-induced hypogonadism and associated side effects such as osteoporosis in men receiving methadone maintenance therapy (MMT). This is a case-control study comparing lumbar spine densitometry by DXA scan and sex-hormone levels in 29 men receiving MMT for opiate dependence and 28 age-matched controls not on MMT.

Serum testosterone (T), estradiol (E), luteinizing hormone (LH), sex-hormone binding globulin, albumin, 25(OH)vitamin D, 1,25(OH)²vitamin D and lumbar spinal bone mineral density (BMD) were measured in all participants. Serum samples were obtained 24 hours post methadone dosing for those on MMT.

Both groups were similar regarding age, physical activity, calcium intake and BMI. Mean length of time on MMT was 5.4 years (1 - 25, ± 5.6) with a mean daily methadone dose of 92 mg (13 - 150, ± 29).

Test	Cases mean (SD)	Controls mean (SD)	p value
Total Testosterone	339.45 (164.79)	556.71 (204.89)	0.000
Estradiol	16.86 (7.68)	27.21 (10.53)	0.000
25(OH)vit D	20.93 (12.23)	17.32(10.21)	0.232
DXA L2-4 BMD	1.159 (0.143)	1.261 (0.195)	0.029
DXA L2-4 T score	-0.679 (1.186)	0.175 (1.635)	0.029
Tobacco pack-yr	19.6 (10.57)	10.8 (15.17)	0.014
Alcohol #drinks/wk	0.62 (1.9)	8.11 (13.7)	0.008

For the cases length of time receiving MMT was negatively correlated with serum T (p=0.035). Across all subjects there was a significant negative correlation between T level and both length of time receiving MMT (p=0.001) and daily methadone dose (p=0.001). Serum T was positively correlated with E (p=0.003) across all subjects as was E level and L2-4 BMD (p=0.014). The cases had 9% lower BMD compared with the controls (p=0.029). Vitamin D deficiency was present in 25 (86%) of the cases and 25 (89%) of the controls. Controlling for tobacco exposure, daily methadone dose strongly predicts E (p=0.001) but not T (p=0.092) or BMD (p=0.068); and years of MMT strongly predicts T (p=0.000) but not E (0.261) or BMD (0.446). Controlling for alcohol use, daily methadone dose strongly predicts E (p=0.001) but not T (p=0.065) or BMD (p=0.198); and years of MMT strongly predicts T (p=0.000) but not E (p=0.339) or BMD (p=0.668).

There are many osteoporosis risk factors which are amenable to modification in the MMT population. Routine screening of sex-hormone levels, Vitamin D status and bone densitometry should be strongly considered and smoking cessation encouraged.

Hip Geometry and Bone Fragility Among Postmenopausal Women with Rheumatoid Arthritis. N. C. Wright¹, J. Lisse^{*1}, T. J. Beck², T. Bassford^{*1}, A. Z. LaCroix^{*3}, J. A. Cauley⁴, C. E. Lewis⁵, S. B. Going^{*1}, Z. Chen¹. ¹Univ. of Arizona, Tucson, AZ, USA, ²Johns Hopkins University, Baltimore, MD, USA, ³Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ⁴Univ. of Pittsburgh, Pittsburgh, PA, USA, ⁵Univ. of Alabama-Birmingham, Birmingham, AL, USA.

Bone strength, comprised of bone mineral properties and bone geometry, is one of the primary determinants of osteoporotic fractures. Rheumatoid Arthritis (RA) has also been shown to be an independent risk factor for osteoporotic fractures. The overall goal of this analysis is to investigate the impact of hip geometry on bone fragility of postmenopausal women with RA. Participants of the Women's Health Initiative Observational Study (WHI-OS) from the BMD clinical centers were included in the analysis. Arthritis status was self-reported at baseline, identifying 335 (5.8%) women with RA and 2,701 (47.1%) women without any form of arthritis. BMD and hip geometry parameters (cross sectional area (CSA), outer diameter, section modulus (SM), cortical thickness, and buckling ratio (BR)) at three hip regions (narrow neck, intertrochanter, and shaft) were derived from baseline and follow-up dual energy x-ray absorptiometry scans using hip structural analysis programs developed by Beck and colleagues. After adjusting for age, height, and weight, white women with RA (n=220) had significantly higher mean CSA, outer diameter, and SM at the narrow neck, and higher mean CSA and SM at the shaft compared to white women without arthritis (n=2,105) at baseline. No statistically significant differences by RA status were seen in African American women at baseline (RA n=69, non n=310), although having RA was associated with lower mean BMD, CSA, and SM in the narrow neck and intertrochanter, and higher means at the shaft. After adjusting for age, height, weight, and the baseline parameter, RA was associated with decreases in hip strength from baseline to year 3 in African American but not white women (Table 1: coefficients and 95% confidence intervals (CI)). Though decreases were seen in both groups, the findings suggest that RA may play a larger role in hip strength in African American women. Further investigation is needed to examine how variables such as hormone use, physical activity, and medication usage affect the relationships between hip geometry and RA.

Table 1: Associations between RA and changes in narrow neck hip strength from baseline to year 3

	White		African American	
	Coeff.	(95% CI)	Coeff.	(95% CI)

Is Osteoporosis Related to Future Incidence of Osteoarthritis Over 10 Years, or Vice-Versa? N. Yoshimura, S. Muraki, H. Oka*, A. Mabuchi*, H. Kawaguchi, K. Nakamura. 22nd Century Medical Center, Univ. of Tokyo, Tokyo, Japan.

To learn the contribution of the presence of osteoporosis (OP) or osteoarthritis (OA), two major disorders causing disability of the elderly, to future incidence of the other disorder, a 10-year population-based epidemiological study was conducted in a cohort of a mountain area. Among the entire 1,543 participants (716 men, 827 women), 400 subjects (200 men, 200 women) were selected randomly but evenly from each generation, and evaluations of OP and OA were performed by BMD and X-ray examinations, respectively, in 1990 as the baseline study. BMD measurement was performed by DXA (Lunar DPX) at the antero-posterior projection of lumbar vertebrae (L2-4) and the proximal femur, and was repeated after 3, 7, and 10 years. The presence of OP was diagnosed by the WHO criteria. X-ray examination was performed on antero-posterior and lateral images of thoracolumbar vertebrae (Th5-L5), and was repeated after 10 years. The presence of OA was determined according to the Kellgren/Lawrence (KL) grade (0-4) at intervertebral spaces from Th5/6 to L5/S1, and those with at least one space of KL \geq 3 were diagnosed as OA. The cumulative incidences of OA at intervertebral spaces during 10 years for the subjects without OA at the baseline in their 40s, 50s, 60s and 70s were 15.6%, 24.1%, 24.2% and 34.4% for men, and 27.1%, 32.6%, 38.5% and 58.3% for women, respectively. A logistic regression analysis was carried out utilizing the incidence of OA (1: Yes, 0: No) as an objective factor and the presence of OP at the lumbar spine or the femoral neck (1: OP, 0: osteopenia or normal range) as an explanatory factor after adjustment for age. There was no significant relationship between the presence of OP at the baseline and the incidence of OA in men or women (OP at the lumbar spine; men: odds ratio [OR]=2.52, 95% confidential interval [CI]=0.57-11.3, P=0.22; women: OR=0.56, 95% CI=0.23-1.35, P=0.19), (OP at the femoral neck; men: OR=0.72, 95% CI=0.29-1.79, P=0.48; women: OR=0.95, 95% CI=0.37-2.41, P=0.91). Similarly, the presence of OA at the baseline was not significantly related to the incidence of OP during a 10 year period. In conclusion, based on the observation over 10 years of a population-based cohort, the presence of OP did not predict the future incidence of OA, or vice-versa, suggesting that these disorders have independent backgrounds.

Effects of Treatment of Ovariectomized Adult Rhesus Monkeys with Parathyroid Hormone 1-84 on Trabecular and Cortical Bone Structure and Biomechanical Properties of the Proximal Femur. J. Fox¹, M. A. Miller¹, R. R. Recker², C. H. Turner³, S. Y. Smith⁴. ¹NPS Pharmaceuticals, Salt Lake City, UT, USA, ²Creighton University, Omaha, NE, USA, ³Indiana-Purdue University, Indianapolis, IN, USA, ⁴Charles River Laboratories, Montreal, PQ, Canada.

Treatment of monkeys and humans with parathyroid hormone 1-84 (PTH) stimulates skeletal remodeling which increases trabecular (Tb) BMD and decreases cortical (Ct) BMD at locations where these bone types predominate. We have also previously reported that daily PTH treatment (5, 10 or 25 μ g/kg) of ovariectomized (OVX) rhesus monkeys for 16 months increased bone stiffness at a lumbar vertebra, and decreased stiffness at the femoral diaphysis which led to increased work-to-failure (the energy required to fracture). We now report the effects of PTH treatment on bone structure and biomechanical properties at the proximal femur, a mixed trabecular and cortical bone site, in these monkeys. PTH reversed the OVX-induced decrease in DXA BMD within 3 to 7 months at the proximal femur, femoral neck, and distal femur. pQCT confirmed a significant dose-related decrease in Ct.BMD and increase in Tb.BMD at the total proximal femur, and proximal and distal femoral metaphyses of PTH-treated monkeys. The decrease in Ct.BMD resulted primarily from increased cortical area, because cortical bone mineral content was unaffected by PTH. Histomorphometry revealed significant dose-related increases in trabecular bone formation rate, volume, and number at the proximal femur. Trabecular thickness was unaffected by PTH. Osteoblast and osteoid surface were increased by PTH, but osteoid thickness was unaffected. Activation frequency and eroded surface were increased significantly by PTH, but osteoclast surface was unchanged. PTH did not affect periosteal or Haversian BFR at the femoral neck; however, cortical porosity was slightly, but statistically significantly higher in the 25 μ g/kg group (2.7% vs 1.5% in OVX controls). PTH treatment had no significant effects on stiffness or peak load measured using a shear test, but work-to-failure was significantly higher. Thus, PTH 1-84 treatment induced changes in trabecular and cortical bone at the proximal femur that were similar to those that occur at skeletal sites where each bone type predominates and ultimately increased the total energy required to break the proximal femur.

Pharmacokinetics and Pharmacodynamics of Human Parathyroid Hormone 1-84 in Adult Ovariectomized Rhesus Monkeys. J. Fox¹, S. Y. Smith², D. S. Wells^{*1}. ¹NPS Pharmaceuticals, Salt Lake City, UT, USA, ²Charles River Laboratories, Montreal, PQ, Canada.

When administered by daily injection, human parathyroid hormone 1-84 (PTH) acts as a potent anabolic agent in bone of animals and humans, and also markedly decreases the incidence of vertebral fractures in postmenopausal women with osteoporosis. We have previously reported that daily PTH administration (5, 10 or 25 μ g/kg) for 16 months increases bone formation and BMD and improves the biomechanical properties of vertebral bodies of ovariectomized adult rhesus monkeys. We now report the pharmacokinetics of PTH and the pharmacodynamic responses that result from PTH exposure in these animals. Blood samples were collected before and for 24 hours after PTH injection on day 1, and again during months 3, 6, 12, and 16 of the study, and analyzed for PTH and Ca levels. Predose serum 25(OH)D and 1,25(OH)₂D levels and urine Ca (normalized to creatinine levels) were also measured. A dose-related linear increase in PTH C_{max} and exposure (area under the concentration-time curve) occurred. PTH doses of 5, 10 or 25 μ g/kg produced plasma PTH exposures that were 2.1-, 4.1- and 13.2-fold greater than occurred in women given a 100 μ g dose. T_{max} occurred later with the high dose (1.1 vs. 0.6 hr). Predose PTH levels were restored by \leq 6 hr with the 5 and 10 μ g/kg doses but remained elevated at 6 hr with the 25 μ g/kg dose. Serum Ca levels increased acutely in a dose-related and consistent manner following PTH administration at each time point throughout the study. When averaged across all time points, the serum Ca T_{max} occurred at 3.7, 4.8, and 7.3 hr after dosing, with a C_{max} increase of 0.6, 1.0 and 1.8 mg/dL with the 5, 10, and 25 μ g/kg doses, respectively. No sustained increases in predose Ca occurred with the 5 and 10 μ g/kg doses whereas an increase of \sim 0.6 mg/dL occurred with the 25 μ g/kg dose. Serum 25(OH)D levels were variable but tended to be lower in PTH-treated animals; the decrease was significant with the 25 μ g/kg dose at months 6 and 12. Serum 1,25(OH)₂D levels were also variable but tended to be higher in PTH-treated animals, particularly with the 25 μ g/kg dose at month 6. There were no increases in fasting predose urine Ca levels with the 5 and 10 μ g/kg PTH doses, but sustained increases occurred with the 25 μ g/kg dose. In summary, PTH exposures 4-fold those observed in women did not result in sustained increases in serum or urinary Ca in adult rhesus monkeys.

Intrabone Tunneling Increases Trabecular Number at Multiple Skeletal Locations in Ovariectomized Rhesus Monkeys Treated with Parathyroid Hormone 1-84. M. A. Miller¹, S. P. Bare^{*2}, R. R. Recker², S. Y. Smith³, J. Fox¹. ¹NPS Pharmaceuticals, Salt Lake City, UT, USA, ²Creighton University, Omaha, NE, USA, ³Charles River Laboratories, Montreal, PQ, Canada.

We have reported that daily treatment of ovariectomized (OVX) adult rhesus monkeys with human parathyroid hormone 1-84 (PTH) (5, 10, or 25 µg/kg) for 16 months increased trabecular bone volume (BV/TV), number (Tb.N) and connectivity at lumbar vertebra-3 (L3) and thoracic vertebra-10. We proposed that the increased Tb.N and connectivity was achieved by stimulation of intrabone tunneling, a remodeling event orientated parallel to the long axis of a trabecula at a non-nodal location. Bone formation followed resorption thus maintaining normal trabecular thickness (Tb.Th). Collectively, these features are important determinants of bone strength. Using histomorphometry to determine frequency of events, we have now quantified intrabone tunneling at L3 and extended it to investigate the effects of PTH treatment on trabecular bone at the proximal femur, distal radius and iliac crest of these animals. At L3, tunneling frequency was low in control sham and OVX animals (~0.05/mm²) but increased significantly in PTH-treated animals (0.27, 0.49 and 0.95/mm² with 5, 10 and 25 µg/kg doses, respectively). Very similar tunneling frequencies were observed at the other 3 trabecular bone sites in all treatment groups. Iliac crest biopsies were also collected at baseline and after 6 months of treatment and showed significant time- and dose-related increases in tunnels. For example, in the 10 µg/kg PTH dose group the tunneling frequency was 0.03, 0.36 and 0.64/mm² at baseline, month 6 and month 16, respectively. Although the pattern and magnitude of response varied slightly from site to site, the PTH-induced intrabone tunneling significantly increased Tb.N, as well as BV/TV and bone formation rate at all sites. A modest but statistically significant increase in Tb.Th occurred only at the iliac crest. In summary, intrabone tunneling is rare in control monkeys, but increased substantially with PTH 1-84 treatment. This phenomenon provides a plausible explanation for the PTH-induced increase in Tb.N observed at all trabecular bone locations in OVX monkeys.

The Skeletal Effects of Teriparatide in Glucocorticoid-Treated Mice. K. S. Howe¹, J. H. Long^{*1}, T. J. Wronski², U. T. Iwaniec³, R. T. Turner³, R. W. Braith^{*1}. ¹Applied Physiology and Kinesiology, University of Florida, Gainesville, FL, USA, ²Department of Physiological Sciences, University of Florida, Gainesville, FL, USA, ³Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA.

Synthetic analogs of glucocorticoids (GC) are widely used in treating many inflammatory diseases. However, they result in serious side effects, including osteoporosis. The purpose of this study was to determine whether treatment with teriparatide (PTH 1-34) can prevent or reverse the detrimental effects of GC on bone. Seven month old male Swiss-Webster mice were randomized by weight into 4 groups: (1) vehicle only (8 w CNTL); (2) GC for 8 w (GC8); (3) simultaneous GC and teriparatide administration for 8 w (GC+PTH8); or (4) GC for 4 w followed by GC+ teriparatide for 4 w (GC4/GC+PTH4). Either vehicle, prednisolone (2.1 mg/kg/d), or prednisolone and teriparatide (40µg/kg/d) were administered subcutaneously 6 d/w. Fluorochrome markers, demeclocycline (15 mg/kg) and calcein (15 mg/kg), were injected prior to sacrifice to label mineralizing bone. Femurs and lumbar vertebrae were harvested at the end of the 8-week study and processed for cancellous bone histomorphometry. Data were analyzed using the Kruskal-Wallis test followed by a non-parametric posthoc test.

GC treatment did not induce cancellous bone loss in adult male mice. However, GC inhibited and teriparatide increased osteoblast surface (Ob. S) and mineralizing surface (MS). Teriparatide prevented bone changes associated with GC exposure (Table). Although 8 weeks of teriparatide treatment increased BV/TV in the distal femur and lumbar vertebrae (data not shown), the relative effects were greater in the distal femur (+100%, p = 0.02) than in the lumbar spine (+42%, p = 0.01). Four and 8 w of teriparatide significantly increased Ob. S, MS, mineral apposition rate (MAR), and bone formation rate/bone surface (BFR/BS). In conclusion, teriparatide effectively prevented the inhibitory effects of GC on cancellous bone formation in the distal femur.

Changes in Distal Femur Cancellous Bone Parameters Based on Treatment with Vehicle, GC, or GC-PTH

	8 w CNTL	GC8	GC4/GC-PTH4	GC-PTH8
BV/TV	2.6 ± 1.9	3.1 ± 1.6	4.5 ± 1.7	5.2 ± 2.9 a

RAP-011 (a Soluble Activin Receptor Type IIA) Increases Bone Mineral Density in Combination with Prior Antiresorptive Therapy. M. Mangini^{*}, M. Cornwall-Brady^{*}, A. Pullen^{*}, K. Halley^{*}, T. Monnell^{*}, J. Milling^{*}, B. Haigis^{*}, R. Kumar^{*}, K. Underwood^{*}, R. S. Pearsall. Acceleron Pharma, Cambridge, MA, USA.

RAP-011 is a soluble activin receptor type IIA (ActRIIA) fused to a murine IgG1-Fc region. Previously, we demonstrated that treatment with RAP-011, an activin antagonist, reversed bone loss in ovariectomized mice (Pearsall et al, J Bone Min. Res. 21(S1) 2006). We have further investigated the use of RAP-011 in combination with bisphosphonate treatment in ovariectomized mice.

To investigate the bone effects of RAP-011, 8 week old female C57BL/6 mice (N=40) were ovariectomized and allowed to lose bone for 8 weeks prior to treatment. When the mice were 16 weeks old half the mice were given a single dose of zoledronic acid (ZOL, IP, 20 µg/kg). Three days later, mice began RAP-011 (IP, 1 or 10 mg/kg, biw) treatment for 8 weeks either individually or after the initial ZOL injection. Whole body DXA and pQCT scanning was performed at baseline, 4 weeks and at the conclusion of the study.

In the ovariectomized mice, treatment with RAP-011 showed a significant (p≤0.01) increase in BMD (+11%) than either ZOL (+5%) or PBS treated mice (+1%). In addition, pre-treatment with ZOL followed by RAP-011 increased BMD to a greater extent than either treatment by itself (+15%).

This data show that RAP-011 able to act as a bone anabolic agent regardless of the presence of a previously administered bisphosphonate. The data provide support for the use of soluble ActRIIA fusion proteins for the treatment of skeletal fragility regardless of prior treatment history.

Protective Role of Green Tea Polyphenols in Bone Microarchitecture in Aged Female Rats. C. Shen¹, P. Wang^{*2}, J. Guerrieri^{*1}, J. Hoefler^{*3}, J. K. Yeh⁴, B. J. Stoecker³, J. Wang^{*2}. ¹Pathology, Texas Tech University Health Sciences Center, Lubbock, TX, USA, ²The Institute of Environmental and Human Health, Texas Tech University, Lubbock, TX, USA, ³Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, ⁴Medicine, Winthrop-University Hospital, Mineola, NY, USA.

Human epidemiological and laboratory studies strongly suggested that green tea polyphenols (GTP), extracted from green tea, are promising agents for preventing bone loss in women due to currently unclear mechanisms. This study was to explore the bioavailability, molecular mechanism, and efficacy of GTP in preventing bone loss in aged rats with and without ovariectomy (OVX). A 2 (Sham vs. OVX) × 3 (no GTP, 0.1% GTP, and 0.5% GTP in drinking water) factorial design using 60 aged female rats (14-mo-old) assigned to 6 groups (n=10/group): Sham, Sham+0.1% GTP, Sham+0.5% GTP, OVX, OVX+0.1% GTP, and OVX+0.5% GTP for 16 wks. Concentrations of urinary GTP ingredients and 8-hydroxydeoxyguanosine were determined by high-pressure liquid chromatography-coularray detection. Efficacy was evaluated in tibia and lumbar vertebra microarchitecture by histomorphometric and µCT analysis, respectively. GTP supplementation in drinking water increased concentrations of epigallocatechin and epicatechin in urine of rats (0, 27.8, and 46.9 µg/mg creatinine for no GTP, 0.1% and 0.5% GTP, respectively), but decreased urinary 8-hydroxydeoxyguanosine level (32.5, 27.3, and 21.8 µg/mg creatinine for no GTP, 0.1%, and 0.5% GTP, respectively). OVX resulted in lower values for trabecular bone volume, number and thickness in proximal tibia, and stiffness and force for compression of lumbar vertebra, but higher values for bone formation rates in cancellous proximal tibia as well as periosteum and endocortical tibial shaft. The results of two-way ANOVA show that GTP treatment resulted in significantly increased trabecular bone volume (F value=7.5, P<0.001), thickness (F value = 9.4, P<0.001), and bone formation rates in both proximal tibia (F value=5.4, P=0.008) and endocortical tibial shaft (F value=9.9, P<0.001), but lower values for eroded surface in both proximal tibia (F value=10.4, P<0.001) and endocortical tibial shaft (F value=20.3, P<0.001). This study demonstrates that GTP administered in drinking water for 16 weeks prevents trabecular bone loss through increasing bone formation while suppressing bone resorption. Such a protective role of GTP may, in part, be attributed to a decrease in oxidative stress DNA damage. The results merit investigation of a potentially significant prophylactic role of green tea in bone health of premenopausal and postmenopausal women.

Low Serum IGF-I Levels Results in Cortical Osteopenia but Increased Life Span in Elderly Mice. J. Svensson^{*}, K. Sjögren^{*}, N. Andersson^{*}, J. Jansson^{*}, O. Isaksson^{*}, C. Ohlsson^{*}. Department of Internal Medicine, Center for Bone Research, Göteborg, Sweden.

Background. It is unknown whether circulating IGF-I regulates cortical bone mass and life span in old mice.

Methods. Transgenic mice with adult, liver-specific IGF-I inactivation (LI-IGF-I^{-/-} mice) were used. These mice have an approximately 80 % reduction in serum IGF-I level. Body composition was measured using dual energy X-ray absorptiometry (DEXA). Bone mass and density was measured using peripheral quantitative computed tomography (pQCT). In addition, the life span was determined.

Results: Two-year old female mice with inactivation of liver derived IGF-I at one month of

age displayed a 25% reduction in femur cortical cross-sectional bone area at the middiaphyseal level ($p<0.05$ vs. control using pQCT). This was mainly due to a decrease in the periosteal circumference ($p<0.001$) whereas there was no significant difference in femur length. Experiments in 18-month old male LI-IGF-I^{-/-} mice with inactivation of liver derived IGF-I at one year of age demonstrated reduced body weight ($p<0.01$ vs. control) due to decreased fat mass ($p<0.01$) as measured using DEXA. In addition, in the 18-month old male LI-IGF-I^{-/-} mice, there was a 13% reduction femur cortical cross-sectional bone area at the middiaphyseal level ($p<0.05$ vs. control using pQCT), confirming that liver-derived circulating IGF-I is of importance for cortical bone mass in late life. The trabecular volumetric BMD was unaffected in all experiments. Importantly, the life span was increased in the LI-IGF-I^{-/-} mice (LI-IGF-I^{-/-} mice (n=84): 24.2 months vs. control (n=137): 22.5 months, $p<0.05$). This was mainly due to increased life span in the female LI-IGF-I^{-/-} mice (LI-IGF-I^{-/-} mice 26.7 vs. control 23.0 months, $p<0.001$). Conclusion. Deficiency of liver derived, circulating IGF-I in old mice results in decreased body weight due to decreased fat mass and markedly reduced cortical bone mass but increased life span. Thus, low serum IGF-I levels results in cortical osteopenia but increased life span in elderly mice.

Dual-Action Cathepsin K Inhibitors: Regulation of Human Mesenchymal Stem Cell (MSC) Lineage Commitment. T. Twomey*, D. Chagnovich, J. Zielinski*, M. W. Long. Velcura Therapeutics, Inc., Ann Arbor, MI, USA.

Cathepsin K (CTSK), a cysteine protease secreted by osteoclasts (OC), is an attractive target for therapies aimed at osteoporosis and other bone diseases. Moreover, the recent demonstration of CTSK's expression in osteoblasts (OB) suggests that other functions exist for this enzyme. VEL-0230 is a dual-action, orally available CTSK inhibitor that has an anabolic effect on OBs (stimulation of ex vivo and in vivo bone formation) while also inhibiting osteoclast bone resorption. The effects of VEL-0230 on MSC Lineage commitment and differentiation were investigated and compared to TGF- β and BMP-6. Culture of human MSC in serum-free media containing TGF- β (200 pM), BMP-6 (2 nM), or Vel-0230 (1uM) results in OB lineage commitment and differentiation. In particular, cells so-treated undergo a process of ex vivo bone formation (a process previously described by us (Nat. Biotech 18, 954, 2000)) in which growth factor-induced OBs form tissue-like aggregates and produce microcrystalline bone. We next used transcriptional analysis to discover the molecular events underlying MSC cell-fate determination. Interestingly, comparison of induced cells to uninduced indicate a very small number of genes (60 -150) are significantly ($p<0.05$) modulated during this process. Non-supervised hierarchical clustering of TGF- β , BMP-6 and VEL-0230 expression profiles show distinct but related patterns of gene modulation suggesting different, but convergent, cellular pathways regulate OB commitment and/or differentiation. This also was illustrated in analysis of individual genes, e.g., TGF- β induction up-regulates collagen X and COMP, but down-regulates BSP; BMP-6 up-regulates the expression of Collagen X, COMP, and BSP, but Vel-0230 up-regulates BSP, and down-regulates COMP. None of these three regulators modulate myogenic or adipogenic markers. Cell pathway-mapping reveals that the canonical Wnt, BMP, and TGF- β signaling pathways play a role in MCS fate decision and that the TGF- β , BMP-6, and VEL-0230 pathways converge at Smad 2. However, siRNA-mediated knockdown of SMAD2 does not block osteoblastic commitment or differentiation of human MSC. We conclude that VEL-0230 functions in a similar fashion to the biological regulators TGF- β and BMP-6 and that these molecules function through an as yet unknown final common pathway. Importantly, they seemingly signal via a SMAD2- independent pathway suggesting either redundant or novel signaling molecules translocate osteogenic signals to the nucleus. Finally, VEL-0230 may serve as a useful therapeutic by promoting both OB recruitment from MSC, as well as OB differentiation into bone-forming cells.

Recombinant Human Platelet-Derived Growth Factor BB (rhPDGF-BB) and Beta-Tricalcium Phosphate (β TCP) Accelerate Fracture Healing in Aged-Osteoporotic Rats. J. O. Hollinger*, A. O. Onikepe*, J. MacKrell*, T. Einhorn*, G. Bradica*, C. S. Young*, S. E. Lynch*, C. E. Hart*. ¹Carnegie Mellon University, Pittsburgh, PA, USA, ²Boston University, Boston, MA, USA, ³Kensley-Nash Corporation, Exton, PA, USA, ⁴BioMimetic Therapeutics Inc., Franklin, TN, USA.

Aged individuals with osteoporosis exhibit impaired fracture healing, and rhPDGF-BB may provide therapeutic benefit for these people. PDGF-BB released from platelets initiates wound healing by supporting neovascularization, and stimulating chemotaxis and mitosis in mesenchymal progenitor cells that differentiate to osteoblasts, chondrocytes, and vascular smooth muscle cells. The clinical efficacy of rhPDGF-BB in wound healing has been underscored in patients for periodontal applications (GEM 21S[®]) and rhPDGF-BB (GEM OS[™]) is currently in clinical trials for orthopaedic indications. The goal of this study was to demonstrate that rhPDGF-BB delivered in a collagen/ β TCP matrix accelerates fracture healing in an osteoporotic, geriatric rat model. Eighty six-week old virgin female Sprague Dawley rats were ovariectomized and placed on a 30% caloric reduced diet for 4 months to ensure osteopenia and then housed for 2 years. Transverse, mid-diaphyseal tibial osteotomies were surgically prepared and stabilized with a K-wire. Ten animals were included per treatment group as follows: fracture alone, fracture + buffer + collagen/ β TCP, fracture + 0.3 mg/ml rhPDGF-BB + collagen/ β TCP, and fracture + 1.0 mg/ml rhPDGF-BB + collagen/ β TCP and the time of sacrifice was either 3 or 5 weeks post-surgery. At each time, treated and contralateral untreated tibiae were harvested, and the bones were processed for analyses by torsional biomechanics, or microCT and

histology. MicroCT analysis indicated that β TCP particles remained around the fracture sites at both 3 and 5 weeks, but there was less material at 5 weeks compared to 3 weeks. For both rhPDGF-BB-treated groups, histology demonstrated that fracture healing was accelerated compared to either non-treated fractures or fractures treated with collagen/ β TCP alone. Torsional biomechanical testing indicated that at 5 weeks in both groups of rhPDGF-BB-treated animals there was no significant difference in torsional strength between rhPDGF-BB-treated and contralateral unfractured tibiae. In contrast, the torsional strength of the untreated and buffer-treated fractures were statistically weaker than the contralateral unfractured tibiae. In conclusion, the combination of rhPDGF-BB and a collagen/ β TCP matrix significantly accelerated fracture healing versus untreated fractures and the effect was a time-dependent increase in torsional strength.

Patients Treated with Risedronate Have a Fracture Risk Similar to Patients 20 Years Younger in Age. S. Boonen¹, A. Klemes², X. Zhou^{*2}, S. Pack^{*3}, P. D. Delmas⁴. ¹Universiteit Leuven, Leuven, Belgium, ²Procter & Gamble Pharmaceuticals, Mason, OH, USA, ³Procter & Gamble Pharmaceuticals, Egham, United Kingdom, ⁴INSERM Unit 403, Lyon, France.

Age is a well recognized independent risk factor for fracture. Generally, older patients have lower BMD T-scores and greater risks for fracture. It has been recently reported that, for every 1 decade increase in age, osteoporotic fracture risk for an untreated patient increases by 46% (Klemes et al. 2007 IBMS abstract). In this research, the objective was to examine the effect of risedronate on fracture risk as patients' age. 3229 osteoporotic PMO women in clinical trials (VERT, RON & ROE) who took at least one dose of placebo or risedronate 5mg pill were included in the analysis. Patients ranged from 38 to 85 years in age and had a mean FN T-score of -2.2 SD. The fracture endpoint was the incidence of a new morphometric vertebral fracture over a three year period, as previously described. The impact of age on fracture risk was examined using Cox regression models with age and treatment as explanatory variables. Both treatment and age had a statistically significant impact on fracture risk. The interaction between treatment and age was included in the initial model but removed from the final model as it was not statistically significant ($p>0.05$). The association of the increased risk for fracture and age did not differ significantly by treatment groups ($p>0.05$ for the interaction term). Regardless of treatment group, for every 1 decade increase in age, patient risk for any osteoporotic fracture increased by 37% on average. It also suggested that the magnitude of the treatment benefit was consistent regardless of age, i.e. risedronate reduced the fracture risk by 46% with $p<0.001$ after adjusting for age. When comparing 3-year fracture risk between risedronate and placebo patients, we found that fracture risk for patients who had been treated with risedronate 5 mg was estimated to be similar to the placebo patients who were 19.8 (95% CI: 10.8, 42.7) years younger in age. 70-year-old patients in the risedronate 5 mg group had a risk of fracture similar to 50-year-old patients in the placebo group. In conclusion, fracture risk increases with age. Patients who had been treated with risedronate had a similar osteoporotic fracture risk to the patients in the placebo group who were 20 years younger in age.

Evaluation of Cell Apoptosis and Cox-2 expression in Glucocorticoid-induced Osteoporosis in Rats Treated with Risedronate. L. Dalle Carbonare^{*1}, M. T. Valenti^{*1}, F. Bertoldo^{*1}, L. Donatelli^{*1}, S. Sella^{*2}, S. Giannini², G. Realdi^{*2}, V. Lo Cascio¹. ¹Dpt. of Biomedical and Surgical Sciences, Medicina Interna D, Verona, Italy, ²Dpt. of Medical and Surgical Sciences, Clinica Medica I, Padova, Italy.

Osteoporosis is a severe complication of the glucocorticoid (GC) treatment and bisphosphonates are a powerful therapeutic option to prevent osteoporotic fractures by inhibiting bone resorption. Recent findings demonstrated that bisphosphonates are also able to prevent osteoblastic and osteocytic apoptosis induced by glucocorticoids. More recently, it has been suggested that endogenous prostaglandins are involved in modulation of bone formation in vivo by COX-2 modulated BMP synthesis.

To confirm the effects of bisphosphonates, in particular risedronate (Ris), in the prevention of apoptosis of osteoblasts and osteocytes induced by GC and to explore a possible role of COX-2 in this pattern, we evaluate apoptosis and COX-2 expression in 40 female Sprague-Dawley rats randomly divided into 4 groups of treatment, and administered 3 times a week subcutaneously as follows:

1. Control: vehicle of methylprednisolone (GC) + vehicle of risedronate (Ris); 2. Ris: Ris 5 μ g/Kg body weight vehicle of GC; 3. GC: GC 7 mg/Kg + vehicle of Ris; 4. GC+Ris: GC 7 mg/Kg, Ris 5 μ g/Kg. Animals were treated for 30 days and then were sacrificed.

The apoptosis was quantified by TUNEL method, whereas the COX-2 expression was performed by immunohistochemistry and the data were expressed by German Immunoreactive score (IHS).

Preliminary results confirm that GC induces apoptosis of osteocytes (88%, $p<0.0001$ vs controls). This effect is reduced by risedronate (44%, $p<0.0001$ vs GC). Concerning COX-2, Ris seems to increase their expression in osteocyte with respect to controls (IHS: 8.75 vs 1.00, $p<0.0001$). The last suggests a possible positive effect of Ris in bone formation, by enhancing COX-2 expression.

Daily and Monthly Ibandronate Restores Bone Loss in Androgen Deficient Male Rats. M. Montero^{*1}, I. Quiroga^{*2}, M. Rubert^{*1}, M. Diaz-Curiel³, F. Bausa⁴, C. De la Piedra¹. ¹Biochemistry, Osteoarticular Pathology Laboratory, Fundacion Jimenez Diaz, Madrid, Spain, ²Endocrinology, Hospital Puerta de Hierro, Madrid, Spain, ³Internal Medicine, Fundacion Jimenez Diaz, Madrid, Spain, ⁴Pharma Research Penzberg, Roche Diagnostics GmbH, Penzberg, Germany.

Ibandronate (IBN) is a highly potent bisphosphonate which is approved in many countries for the treatment of postmenopausal osteoporosis and metastatic bone disease. However, little is known about the effect of IBN in male osteoporosis due to androgen deficiency. In particular, the clinically attractive mode of intermittent administration of IBN has not yet been investigated in male osteoporosis.

The aim of this work was to study the ability of IBN, administered daily (d) or monthly (m), to revert the deleterious effects on bone produced by orchidectomy. Forty, 9 month-old, male Wistar rats were sham-operated (SHAM) or orchidectomized (OQX). All animals were left untreated for 6 months after surgery, and subsequently submitted to 4 groups, which were administered subcutaneously over a duration of 20 weeks with either placebo (SHAM; n=10) and (OQX; n=10) or with two regimens of ibandronate (Roche Diagnostics GmbH, Germany): 1 microg/Kg/day (OQX+IBNd (n=10) or 28 microg/Kg/28 days (OQX+IBNm (n=10)).

After sacrifice, bone mineral density (BMD) was determined in the lumbar spine and in the whole left femur by DEXA in situ. Also, the following biochemical markers of bone remodelling were determined by ELISA at the end of the study: rat 5b isoenzyme of serum tartrate resistant acid phosphatase (IDS, UK) and rat osteocalcin (BGP, Nordic Bioscience, Denmark).

When compared to the sham group, lumbar spine and femoral BMD were significantly lower in the OQX-controls (p=0.07 and p<0.01 respectively). Both treatment regimens, IBNd and IBNm restored the BMD levels observed in orchidectomized rats to those of the SHAM group, with equivalent data for both regimens. OQX rats presented significantly higher levels of BGP than those in the SHAM group (p<0.01), while no difference was observed for TRAP. IBNd or IBNm treatment decreased BGP and TRAP levels in OQX rats to levels significantly lower than those of the SHAM group (p<0.01). The above results in androgen-deficient rat suggest that daily treatment with ibandronate is as effective as monthly treatment to revert the changes in bone mass and remodelling, provided the same cumulative total dose per animal is administered. Any numerical difference in any parameter between the two regimens did not reach statistical significance.

The Mode of Binding of Nitrogen Containing Bisphosphonates in Farnesyl Pyrophosphate Synthase. F. H. Ebetino^{*1}, J. E. Dunford^{*2}, M. W. Lundy^{*1}, X. Dao^{*2}, R. Dobson^{*1}, J. T. Triffitt^{*2}, M. Quijano^{*1}, X. Song^{*3}, R. K. Boeckman^{*3}, R. G. G. Russell^{*2}, B. L. Barnett^{*4}. ¹Procter & Gamble Pharmaceuticals, Mason, OH, USA, ²Oxford Univ., Oxford, United Kingdom, ³Chemistry, Univ. of Rochester, Rochester, NY, USA, ⁴Chemistry, Univ. of Cincinnati, Cincinnati, OH, USA.

Enzyme inhibitory potency of Farnesyl Pyrophosphate Synthase (FPPS) is one of the key components of the mechanism of antiresorptive action of nitrogen containing bisphosphonates (NBPs). In vivo, subsequent to binding at the bone surface, NBPs are taken up by osteoclasts where they inhibit FPPS & interfere with multiple cellular functions. Each NBP possesses a different combination of these properties, which may lead to differences in clinical performance. From crystal structures of human FPPS ligated with NBPs, it is clear that differences in inhibitory potency are based on key interactions of the NBPs within the geranyl pyrophosphate (GPP) binding site. The most potent FPPS inhibitors seem to form strong hydrogen bonds between the BP nitrogen & the hydroxyl of T 201-OH and the backbone carbonyl (C=O) of K 200. Following this concept, we used protein crystallography to study a mirror image pair of conformationally restricted NBPs within the GPP binding site of FPPS & noted that only one, the IR 6S version of cis-2-azabicyclo[4.3.0]nonane-8,8-diphosphonic (PG-1014491) could orient its nitrogen in the region of the binding site necessary for such hydrogen bonding.

Previously, the racemic mixture demonstrated good antiresorptive activity in acute models in vivo. PG-1014491 should be the more potent inhibitor of FPPS and resorption. Using a unique chemical synthesis, stereochemically pure versions of each enantiomer were prepared. Enzyme inhibition studies with hFPPS confirmed that PG-1014491 was the more potent inhibitor with an IC₅₀ of 15 nM vs. 359 nM for the poorly oriented enantiomer PG-1014493. The IC₅₀ of the racemic mixture was consistent with a 50:50 mixture of these two isomers (42 nM). In vivo studies to further relate this IC₅₀ difference to overall antiresorptive performance have also shown that in growing rats, BMD increases of 20% vis-à-vis controls occur at lower doses with PG-1014491 (9 µg P/kg) than with PG-1014493 (600 µg P/kg). These results confirm the key role of the Lys 201 & Thr 200 hydrogen bonding site in NBP inhibition of FPPS & further confirms the role of FPPS as the key biochemical target in the bisphosphonate mechanism of action on bone.

Novel Effects of High Doses of Olpadronate on Cortical Bone and Mechanism of Fracture in Young-Rat Femurs. G. R. Cointy^{*1}, R. F. Capozza^{*1}, M. Meta², N. Mondelo^{*3}, E. Piccini^{*3}, J. L. Ferretti¹. ¹Centro de Estudios de Metabolismo Fosforológico, Faculty of Medicine, UNR, Rosario, Argentina, ²David Geffen Med Sch, UCSF, San Francisco, CA, USA, ³Gador S.A., Buenos Aires, Argentina.

This study aimed to determine whether the administration of high doses of OPD affect bone mass, design and mineralization, simultaneously impairing, maintaining or improving bone pre- and post-yield properties of young rat femurs (an almost only-modeling model). Twenty male and 22 female 4-5-week-old rats received orally 45 or 90 mg/kg/d olpadronate (dimethyl-pamidronate) over 3 months (8/9 male/female controls). Periosteal perimeter, cortical vBMD, cross-sectional area (CSA), moment of inertia (xCSMI), cortical bone elastic modulus (E), stiffness and strength of femur diaphyses were determined by pQCT and bending tests.

Treatment proportionally enhanced periosteal perimeter, CSA and xCSMI with no change in vBMD and E. While yielding stiffness and strength were mildly improved, post-yield strength was strikingly increased (males +385%; females +80%). Ultimate strength was enhanced mainly as a consequence of post-yield properties rather than pre-yield or geometric properties. No dose-related effects were observed. The expected improvement in pre-yield properties suggests a mild anabolic effect. The large effect on post-yield properties (bone toughness) suggests a role for microstructural factors unrelated to mineralization. Sex-related differences were attributed to a better bioavailability of the drug and a much larger body weight in males, perhaps in connection with the mechanical stimulation of bone structure. Results reveal novel effects of OPD on bone strength and mechanism of fracture unrelated to tissue mineralization and stiffness, possibly associated with a positive interaction on the bone mechanostat, with little or no involvement of bone remodeling. No deterioration of any material, geometric or mechanical property was observed, despite the high doses employed.

Cost-Effectiveness of Risedronate vs. Ibandronate: Impact of Discounts. D. Grima^{*1}, N. N. Borisov^{*2}. ¹Cornerstone Research Group Inc, Burlington, ON, Canada, ²Procter & Gamble Pharmaceuticals, Mason, OH, USA.

This study uses a Markov model of postmenopausal osteoporosis (PMO) to compare the clinical- and cost-effectiveness of risedronate and ibandronate at a range of rebate discounts of wholesale acquisition cost (WAC). The Markov model simulated a cohort of women aged 65+, with previous vertebral fracture and BMD T-score <-2.5, under a one-year time horizon. Fracture rates were derived from US clinical studies. Vertebral and nonvertebral risk reduction measures are 58% and 0% for ibandronate respectively (Chesnut, Skag, Christiansen, et al., 2004), and 65% and 74% for risedronate, respectively (Harris, Watts, Genant, et al., 1999 and Harrington JT, Ste-Marie LG, Brandt ML, et al., 2004). Annual WAC before rebate discounts was \$924.69 for risedronate and \$853.56 for ibandronate.

At equal levels of discounts, treatment with risedronate results in lower fracture costs and lower total costs of treating fractures than treatment with ibandronate. Total medical costs for risedronate at 0% discount were still lower than total costs for ibandronate up to 60% discount (figure 1).

The costs per fracture avoided versus no treatment were consistently lower for risedronate than for ibandronate. Discount at 40% or above for risedronate resulted in cost savings compared to no treatment (figure 2). The cost per fracture avoided for ibandronate at 80% rebate discount approaches the cost per fracture avoided for risedronate at 0% discount. Ibandronate treatment did not achieve any savings even with 90% discount. In this analysis, overall cost-effectiveness is more dependent on efficacy than rebate discounts.

The Efficacy and Safety of Intravenous Ibandronate for Chinese Primary Osteoporotic Women. M. Li^{*1}, X. Xing^{*1}, X. Meng^{*1}, Z. Zhang^{*2}, J. Liu^{*3}, W. Xia^{*1}, D. Liu^{*1}. ¹Endocrinology, Peking Union Medical College Hospital, Beijing, China, ²Endocrinology, 6th People Hospital of Shanghai, Shanghai, China, ³Obstetrics and Gynecology Endocrinology, General Hospital of Chinese PLA, Beijing, China.

Objective Antiresorptive agents are widely used to treat osteoporosis. We observe a new kind of bisphosphonate, ibandronate in a multicenter randomized, positive controlled open study, to evaluate its efficacy and safety on postmenopausal osteoporosis women in China. Methods 158 postmenopausal osteoporosis women, aged 49 to 75 years, were randomized as two groups in this one year phase study. Women in ibandronate group intravenously received 2mg Ibandronate every three months. Women in control group took 70mg alendronate weekly. All women also received supplemental calcium (500 mg) and vitamin D (200 IU) daily. The primary end point was mean relative change from baseline in lumbar spine, femoral neck, trochanter BMD after one year. The secondary end points were relative changes in biochemical bone turnover markers (AKP, a bone formation marker; CTX, a bone resorption marker) and stature after one year. Safety was suggested by adverse events, new fractures liver and kidney function.

Results 151 cases completed the observation. Treatment with ibandronate for 1 years produced mean increases in BMD of 4.27% at the lumbar spine (95 %CI, 12.0 to 15.5 percent), 3.48% at the femoral neck (95 %CI, 8.1 to 12.4 percent), 2.03% at the trochanter (95 %CI, 3.5 to 7.4 percent) as compared with baseline values. Mean increases in BMD of 4.24% at the lumbar spine (95 %CI, 12.0 to 15.5 percent), 2.72% at the femoral neck (95 %CI, 8.1 to 12.4 percent), 2.99% at the trochanter (95 %CI, 3.5 to 7.4 percent) as compared with baseline values were observed in alendronate group. No difference of mean relative change from baseline was found between two groups. Significant decrease in serum CTX value and ALP level were found in two groups after one and three month of treatment respectively, then they were maintained in low level during the whole study. Decrease of ALP was significantly less and later than that of CTX. No change of stature was found in two groups. Except ibandronate group had more cases with mild muscle pain in the first month of treatment than alendronate group ($P < 0.001$), ibandronate and alendronate also had good tolerance and compliance.

Conclusions Treatment with Ibandronate 2mg once three-monthly intravenous dosing significantly reduced bone resorption and increased bone mineral density with good tolerance in Chinese postmenopausal osteoporotic women, therefore it had potency to improve adherence and avoid peptic side effects of oral bisphosphonate.

Osteotropic Cyclodextrins as Novel Bone Anabolic Agents. X. Liu¹, J. Rutledge^{*2}, A. Wiswall^{*2}, R. A. Reinhardt^{*2}, D. Wang¹. ¹Department of Pharmaceutical Sciences, University of Nebraska Medical Center, Omaha, NE, USA, ²Department of Surgical Specialties, University of Nebraska Medical Center, Lincoln, NE, USA.

Alendronate-cyclodextrin conjugate (ALN-CD) was evaluated as an osteotropic delivery system for prostaglandin E1 (PGE1).

A bilateral rat mandible local injection model was used for this study. Mandibles were isolated 24 days post injection of the drug formulations and analyzed histomorphometrically.

Initial study with ALN-CD/PGE1 complex shows that it generates significantly higher amount of new bone than the non-osteotropic cyclodextrin (CD)/PGE1 complex. Surprisingly, as a control, ALN-CD was found with strong bone anabolic effect (Table 1). To investigate this observation, following groups were added: ALN-CD/PGE1 vs. ALN-CD; PGE1 in ethanol vs. ethanol; ALN in saline vs. saline and saline vs. no treatment. The histomorphometry data show that ALN-CD generates more bone than ALN-CD/PGE1 complex (equivalent dose to ALN-CD). ALN stimulates moderate bone formation, but mostly on the opposite side of the injection (Figure 1). All other formulations show minimal anabolic effect.

Evidently, the anabolic effect of ALN-CD is independent of the effects of PGE1 and ALN. Since the cyclodextrins could form strong inclusion complexes with many lipophilic compounds, such as PGEs, lipids, steroids, etc., one may speculate that the immobilization of ALN-CD on bone surface would cause local enrichment of the certain endogenous anabolic factors and lead to the observed bone anabolic effect.

Table 1. Histomorphometry analysis of rat mandibles 24 days post single injection of different formulations. New Bone Width-1, injection site; New Bone Width-3, non-injection site.

Groups	New Bone Area (mm ² ± SEM)	New Bone Width-1 (mm ± SEM)	New Bone Width-3 (mm ± SEM)
ALN-CD/PGE ₁	0.97 ± 0.23	0.50 ± 0.14	0.17 ± 0.06
CD/PGE ₁	0.18 ± 0.09	0.14 ± 0.06	0.16 ± 0.06

Bisphosphonate Affinity to Hydroxyapatite and Farnesyl Pyrophosphate Inhibitory Potency, Together, Drive In Vivo Efficacy. M. W. Lundy¹, F. H. Ebetino¹, L. Fei^{*1}, Z. Xia^{*1}, M. Pozzi^{*1}, D. Trokhan^{*1}, R. Phipps¹, J. Dunford^{*2}, J. T. Triffitt^{*2}, R. G. G. Russell². ¹Procter & Gamble Pharmaceuticals, Mason, OH, USA, ²Oxford University, Oxford, United Kingdom.

The nitrogen containing bisphosphonates (N-BPs) are believed to exert their clinical antiresorptive effects via two fundamental mechanistic properties, bone mineral affinity and enzyme inhibitory potency. In vivo, N-BPs are targeted to the bone surface and site of osteoclastic activity due to binding of the 2 phosphonate groups to hydroxyapatite (HAP). Subsequently, N-BPs are taken up by osteoclasts where they diminish osteoclastic activity by inhibiting farnesyl pyrophosphate synthase (FPPS). It is well documented in vitro that the relative mineral affinity and FPPS inhibitory potencies among N-BPs can vary broadly over a range from weak to strong. To determine the relative influence of mineral binding and enzyme inhibitory potency on efficacy in vivo, we used the growing rat model (Schenk model) to investigate N-BPs with a range of mineral affinities and FPPS inhibitory potencies.

Male Sprague-Dawley rats 6 weeks old were treated for 7 days, over a range of doses, with 17 N-BPs. BMD of the proximal tibial metaphysis was measured ex vivo using a Hologic QDR-4500 densitometer, with the effect of each dose expressed as a percent change from the vehicle control. The efficacy of each compound was identified as the dose which increased BMD 20 percent higher than control (D20). The relationship between in vivo efficacy, FPPS IC₅₀ (inhibition of isolated human enzyme) and HAP affinity (minutes to elution from an HAP column) was determined using multiple regression analysis, with FPPS and D20 log transformed.

Bisphosphonate inhibition of hFPPS correlated poorly with HAP affinity ($r^2 = 0.03$). Bisphosphonate inhibition of FPPS predicted in vivo efficacy expressed as D20 with an $r^2 = 0.66$. HAP affinity also correlated poorly with D20 ($r^2 = 0.12$). However when antiresorptive potency was predicted using both HAP affinity and hFPPS inhibition; the combination improved the prediction of D20 ($r^2 = 0.91$).

The in vivo efficacy predicted by inhibition of FPPS can be increased or decreased by how avidly the N-BP binds to bone mineral as measured by HAP affinity. A better correlation of in vivo anti-resorptive activity is therefore derived from measurements that include both FPPS inhibition and bone affinity than data from either alone. These results also illustrate that each N-BP has a unique combination of these two properties, which may help explain clinical differences such as onset of efficacy, relative efficacy at different skeletal sites, and the rate at which their inhibitory activity recovers after stopping treatment.

Statins Decrease Bone Turnover Markers in Postmenopausal Women. J. Martínez^{*1}, J. L. Hernández^{*1}, J. M. Olmos¹, E. Pariente^{*2}, C. Valero^{*1}, P. García^{*2}, D. Nan^{*1}, G. Pinedo^{*2}, J. González-Macías¹. ¹Medicina Interna, Hospital Universitario M. Valdecilla. Universidad de Cantabria, Santander, Spain, ²Centro de Salud "José Barros". Camargo. Universidad de Cantabria, Santander, Spain.

The aim of the present study was to evaluate the effects of treatment with statins on calcium homeostasis, bone turnover and bone mineral density in a population of postmenopausal women from Cantabria, Spain. We present preliminary results of the first 258 women included in the Camargo Cohort Study, a community-based study designed to evaluate the prevalence of metabolic bone diseases and disorders of mineral metabolism, as well as the prevalence of fractures and risk factors for osteoporosis and fragility fractures, in postmenopausal women and men older than 50 attended in a primary care centre from Northern Spain. Serum levels of aminoterminal propeptide of type I collagen (PINP), C-terminal telopeptide of type I collagen (β -CrossLaps, CTX), parathyroid hormone (iPTH), bone mineral density at the lumbar spine and hip by DXA (BDM) and quantitative ultrasound at the calcaneus (QUS), were measured in 49 postmenopausal women who had been treated with statins for more than one year, and compared with 209 age- and gender-matched controls. Women who were receiving treatment with bisphosphonates, oestrogen, raloxifene, or glucocorticoids were excluded. The mean (\pm SD) age of subjects was 65 \pm 8 years in treated women and 62 \pm 8 in controls. The statin-treated subjects had lower plasma levels of PINP (38.9 \pm 14.8 vs. 46.8 \pm 20.5 ng/ml; $p=0.03$) and CTX (0.298 \pm 0.162 vs. 0.374 \pm 0.194 ng/ml; $p=0.01$). However, serum iPTH levels (57 \pm 16 vs. 53 \pm 17 pg/ml), BMD at lumbar spine (0.916 \pm 0.13 vs. 0.919 \pm 0.132 g/cm²), femoral neck (0.722 \pm 0.098 vs. 0.726 \pm 0.120 g/cm²), and total hip (0.870 \pm 0.119 vs. 0.870 \pm 0.125 g/cm²), and QUS did not differ between groups. Once adjusted by age, BMI, serum cholesterol levels and presence of diabetes, this association remain statistically significant only for serum CTX ($p=0.04$) but not for PINP. This fact was confirmed in a stepwise multiple regression analysis. Treatment with statins was associated with a reduction in serum markers of bone resorption. However, no changes were observed in either BMD or QUS.

Essential Mechanistic Studies of the Esophagogastric Transit of Oral Bisphosphonates. A. C. Perkins^{*1}, P. E. Blacckshaw^{*1}, R. J. Dansereau^{*2}. ¹Academic Medical Physics Medical School University of Nottingham, Nottingham, United Kingdom, ²Procter & Gamble Pharmaceuticals, Mason, OH, USA.

The incomplete swallowing of oral bisphosphonate tablets has potential iatrogenic implications for patients on long-term treatment. The major risk factors for "pill-induced esophagitis" are tablet size, shape and coating, esophageal dysmotility factors, patient posture and water volume for dosing. The pharmaceutical design of oral formulations influences the site of drug release, rate of dispersal and absorption within the gastrointestinal tract. We have extensive in vivo evidence of the swallowing of tablets and capsules labeled with ^{99m}Tc and ¹⁵³Sm. In general, these studies have shown more rapid transit of tablets compared with similar sized capsules. We have observed the slow esophageal release of contents from a lodged capsule over a period of 90min with the subject not aware of any dysmotility.

Our studies have shown short transit times of commercially available, film-coated 35 mg risedronate tablets ingested with 2 separate water volumes (50 ml and 120 ml) in elderly patients with postmenopausal osteoporosis, gastroesophageal reflux disease and postural kyphosis where mean transit times of 12 and 16s were measured for 50ml and 120ml water respectively. The severity of kyphosis did not affect the esophageal transit time. We have also examined the effect of posture on tablet swallowing, this being important for bed-ridden patients in long term care facilities.

There is now increased worldwide availability of generic alendronate formulations that have yet to show proven gastrointestinal acceptability. A previous report of in vitro disintegration times of generic 70mg alendronate formulations ranged between 7 seconds to 31 minutes indicating quite different pharmaceutical properties¹. It is therefore important to demonstrate the swallowing exposure and esophageal exposure of these generic tablets is minimal if equivalent safety is to be assumed. Our current work is examining the transit of generic formulations and data will be presented.

Scintigraphic studies have proven value in the design and selection of oral pharmaceutical dosage forms and in assessing their physiological characteristics. Such studies provide essential data for the physician prescribing to osteoporotic patients.

Effect of Combined Treatment of Alendronate and Vitamin K₂ on Bone Mineral Density and Strength in Ovariectomized Mice. H. Sasaki, N. Miyakoshi, Y. Kasukawa, S. Maekawa, H. Noguchi, K. Kamo, Y. Shimada. Orthopedic surgery, Akita University School of Medicine, Akita, Japan.

Bisphosphonates increase bone mineral density (BMD) in an indirect manner by reducing the remodeling space and by prolonging the duration of mineralization; however, the effects of bisphosphonates on bone quality have not been fully evaluated. On the other hand, menatetrenone (vitamin K₂) has been considered to reduce the incidence of fractures by improving bone quality more than BMD in patients with osteoporosis. The purpose of this study was therefore to investigate the effects of combined treatment of menatetrenone and alendronate (ALN) on BMD and bone strength in ovariectomized (OVX) mice. OVX was performed at 16 weeks of age, and treatment was started 4 weeks after surgery. OVX mice were randomized into following four groups: 1) OVX-control group, treated with normal diet and administered with the vehicle of ALN; 2) K₂ group, treated with menatetrenone (30mg/kg p.o., daily); 3) ALN group, treated with ALN (56µg/kg s.c., once a week); and 4) K₂ + ALN group, treated with menatetrenone plus ALN. At the end of the 8-week treatment period, the femur was harvested, and BMD and mechanical strength of distal metaphysis were evaluated. BMD was measured by peripheral quantitative computed tomography (pQCT), and mechanical strength was evaluated by failure energy of the compression test. Total-BMD at the distal metaphysis of the femur in the K₂ group showed no significant difference from that in the OVX-control group. The total BMD in the ALN group and K₂+ALN group was significantly higher than that in the OVX-control group (20% and 15% respectively, $p<0.0001$). No significant difference was observed in failure energy of the distal femur between the ALN and OVX-control groups; however, failure energy was significantly higher in the K₂+ALN group compared to the OVX-control group (25%, $p<0.01$). These results suggest that ALN alone or in combination with menatetrenone showed significant improvement on BMD but combined treatment of ALN and menatetrenone was more effective than ALN alone for improving bone strength in OVX mice. Using menatetrenone with bisphosphonates might have a more positive effect on bone quality in patients with osteoporosis.

VDR, ESR1, and COL1A1 Associations with Osteoporosis Phenotypes at Baseline and after Risedronate Treatment in the IMPACT Trial. A. Uitterlinden¹, J. van Meurs¹, D. Contopoulos-Ioannidis^{*2}, R. Eastell³, P. Delmas⁴, H. Pols¹, L. van de Langerijt⁵, J. Ioannidis^{*2}. ¹Internal Medicine, Erasmus MC, Rotterdam, The Netherlands, ²Hygiene & Epidemiology, University of Ioannina, Ioannina, Greece, ³Metabolic Bone Centre, Sheffield University, Sheffield, United Kingdom, ⁴Internal Medicine, Université de Lyon & INSERM unit 831, Lyon, France, ⁵Sanofi-Aventis, Gouda, The Netherlands.

Purpose: To examine the association of 6 single nucleotide polymorphisms (SNPs) of the COL1A1 (-1997 promoter G/T and Sp1 G/T), ESR1 (XbaI and PvuII), and VDR (308 and 464 3'UTR SNPs) genes, with bone mineral density (BMD) at hip and lumbar spine and bone turnover markers (N- and C-terminal telopeptides of type I collagen (NTx, CTx), and with changes of BMD and bone turnover markers during therapy with risedronate for osteoporosis.

Methods: We performed genotyping (Taqman) on DNA from a large cohort of 5412 women participating in the IMPACT trial for COL1A1 SNPs; 3742 (69%) women were also evaluated for the ESR1 and VDR SNPs. Changes in indices upon treatment were evaluated in women who had additional follow-up data during their participation in the trial ($n=2048$; 38%).

Results: Genotype and allele frequencies were consistent with previous data and followed Hardy-Weinberg equilibrium.

For both hip and spine BMD, allele-based models showed no nominally statistically significant effects with any SNP, for baseline values and changes during treatment: all p -values were >0.05 except for one $p=0.036$ unadjusted for multiple comparisons. No associations were seen for haplotype analyses of both SNPs at each gene.

Similarly, no associations were seen for any SNP with bone turnover markers, except for VDR 464 and change in CTx during follow-up ($p=0.003$), also seen in VDR haplotype analyses ($p=0.013$). However, the recessive effect was limited to 26 and 17 subjects, respectively, and the meaning of this isolated finding is unclear given the multiplicity of performed analyses. Other genetic contrasts and adjusted analysis did not yield more significant results.

Point estimates were entirely consistent with prior large-scale evidence (in GENOMOS) on the impact of these genetic markers on BMD, e.g., COL1A1 Sp1 TT had 0.15 SD lower BMD on a standardized scale, although this was far from being nominally statistically significant.

Conclusions: COL1A1, ESR1 and VDR SNPs do not have a major impact on BMD and bone turnover markers at baseline, and no genotype-dependent response to risedronate treatment was observed. We cannot exclude small effects of these polymorphisms by these data. Our results support the requirement of large databases and genome-wide approaches to delineate the genetics of osteoporosis, including response to treatment.

Effects of Alendronate-induced Bone Matrix Changes on Resorption and Turnover. D. Vashishth¹, B. Merle², E. Gineyts², G. Boivin², M. Allen³, D. B. Burr³, P. D. Delmas². ¹INSERM Unite 831 Université de Lyon, France & Rensselaer Polytechnic Institute, Troy, NY, USA, ²INSERM Unite 831 Université de Lyon, Lyon, France, ³Anatomy & Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

Bisphosphonates (BP) including alendronate (ALN), used for treatment of osteoporosis, increase osteoclast apoptosis and reduce bone turnover. The reduction in bone turnover preserves bone mass but alters bone matrix. At the bone matrix level, the mean degree of tissue mineralization (DMB) increases [1] and the collagen accumulates crosslinks by non-enzymatic glycation (NEG) [2]. Because mineralization increases resorption and NEG-crosslinks decrease resorption [3], matrix changes may alter resorption and the efficacy of drug therapy. Here, using an in vitro cell-tissue culture approach, we have investigated the role of ALN-induced bone matrix changes on bone resorption. 100 ± 5 µm thick bone sections were obtained from ribs of 12 skeletally mature female beagles treated either with ALN at the clinical dose of osteoporosis (0.20 mg/kg/day) or vehicle (1 mL/kg/day of saline) for 1 year. The sections were microradiographed for the measurement of DMB and subjected to in vitro bone resorption caused by rabbit osteoclasts for 8 days under standard cell culture conditions. Additional sections from the same anatomical site were harvested to measure enzymatic (mmol pyridinoline or deypyridinoline /mol of collagen) and non-enzymatic crosslink content (mmol pentosidine /mol of collagen). The frequency and area of resorption pits were compared between groups and tested for correlation with DMB and crosslink content. Similar to in vivo reports, this in vitro model showed that the resorption pit area was smaller in ALN-treated than in the vehicle-treated group (p<0.01) and there were no differences in the pit frequency between the groups (p=0.52). NEG-crosslinks were significantly higher in ALN-treated than in vehicle-treated controls (p<0.05) and were inversely correlated with the mean resorption area ($r = -0.9$; p<0.05). Enzymatic crosslinks were not different between the groups but pyridinoline showed an inverse trend with resorption pit frequency ($r = -0.9$; p = 0.08). DMB was not different between the groups and showed a weak and non-significant correlation with resorption parameters. In conclusion, this study demonstrates for the first time that bone matrix changes, particularly the accumulation of NEG crosslinks with BP therapy, reduce bone resorption and may consequently affect bone quality by a further reduction in turnover. PTH and Risedronate Prevented Glucocorticoid Induced Reduction in Bone Mineralization Through Different Mechanisms. W. Yao, C. Busse*, Z. Cheng, S. Rao*, N. Lane. Center for Healthy Aging, UC Davis Medical Center, Sacramento, CA, USA.

Glucocorticoids (GC) excess inhibits bone mineralization which leads to reduced bone strength. Both anabolic (PTH) and anti-resorptive agents (Risedronate) are used to prevent and treat GC induced bone loss. The purpose of this study was to further evaluate how PTH and Risedronate (Ris) may modulate GC induced bone loss through alteration of bone mineralization in vivo and at the transcriptional levels. Five-month-old Swiss-Webster male mice were treated with prednisolone [2 mg/kg 28-day slow-release pellet (GC), or placebo (PL)] or with GC+ Vehicle, GC+PTH (20µg/kg, 5x/wk) or GC+Ris (5µg/kg, 3x/wk) for 28 days. X-ray tomography microscopy (XTM) was used to determine the DBM in lumbar vertebral body, and real-time PCR were used to monitor the expression of several key genes regulating bone mineralization, including Dmp1, Phex, OPN, Akp2, Enpp1 and Ank. In addition, microCT and biochemistry were used to determine bone microarchitecture and bone turnover. Results. Compared to the placebo treated mice, 28 days of GC treatment decreased trabecular bone volume (BV/TV) by 20%, osteocalcin (OSC) by 60% and increased TRAP5b by 18% (p<0.05). On the other hand, GC+PTH and GC+Ris increased BV/TV by 15% and 7%, respectively with OSC and TRAP5b similar to the PL levels. Average DBM was lowered after GC treatment (-15%). Both PTH and Ris treatments maintained DBM while PTH increased (+18%) and Ris decreased (-10%) the heterogeneity of mineral distribution (half maximum width of the mineral distribution). At day 28, whole bone gene expression by RT-PCR done in triplicate revealed that continuous exposure to GCs increased the expression of gene that inhibit bone mineralization (Spp1, Enpp1, Dmp1). GC+PTH further increased OPN and Dmp1 gene expressions while GC+Ris decrease their expression (Table) compared to the PL group. These results suggest that GC induced inhibition of bone mineralization is in part through the expression of gene that inhibit mineralization. Both GC+PTH and GC+Ris increase the global degree of bone mineralization (DBM) but PTH increases heterogeneity of mineral distribution while Ris improves mineral homogeneity. Differential expression of genes regulating mineralization (phosphate metabolism) may explain the in vivo changes in degree of mineralization observed with GC treatment.

Table: Fold changes from placebo

Treatment Groups	Ank	Enpp1	Spp1	Dmp1	Phex
PL + Vehicle	1	1	1	1	1
GC + Vehicle	1.71*	1.56*	3.01*	1.89*	1.05
GC+PTH	1.10	-2.14*	3.84*	2.21*	-2.65*
GC+Ris	1.33	-2.70*	1.23	1.25	-1.89*

Note: Fold changes = 2^{-ΔΔCt}; *, p < 0.01 vs. PL.

One Week Evaluation of Pharmaceuticals in sRANKL-injected Osteopenia Model Mice. H. Yasuda¹, K. Mori¹, Y. Nakamichi², M. Koide³, N. Udagawa³, Y. Tomimori¹. ¹Nagahama Institute for Biochemical Science, Oriental Yeast Co., Ltd., Shiga, Japan, ²Institute for Oral Science, Matsumoto Dental University, Shiojiri, Japan, ³Department of Biochemistry, Matsumoto Dental University, Shiojiri, Japan.

There are several osteopenia or osteoporosis models such as OVX, tail-suspension and low Ca diet. However, they require skills in animal testing and it takes at least a couple of weeks for the models to establish. Here we report the establishment of a novel and rapid osteopenia model mice and the evaluation of pharmaceuticals using this model. Receptor activator of NF-κB ligand (RANKL) is the membrane-bound protein essential for osteoclast development. We prepared a fusion protein of Gultathione S-transferase and extracellular domain of RANKL (GST-RANKL) for this study. GST-RANKL showed much higher activity than commercially available sRANKLs in in vitro osteoclastogenesis assay. GST-RANKL (10ug, 20ug and 40ug/ mouse) was injected intraperitoneally every 24 hours for 3 days into 7 week-old female C57/B6 mice. One and half hours later the third injection, mice were sacrificed and the blood and tissue samples were taken. Bone resorption markers (serum Ca, CTx and TRAP-5b) were increased in GST-RANKL-injected groups in a dose dependent manner. In contrast, bone synthetic markers (serum osteocalcin and ALP) were not changed. BMD of femurs was measured by pQCT and their 3D-images were made by µCT. Compared with the control group, bone mass of the GST-RANKL injected mice was decreased in a dose dependent manner. Especially the mice injected with the highest dose of GST-RANKL showed 43% decrease in BMD compared with the control mice. These results suggested that severity of osteopenia could be controlled by selecting the dose of GST-RANKL. Next, we tested whether sRANKL-injected model mice were useful for evaluation of pharmaceuticals. Risedronate (Actonel) was injected subcutaneously (0.01mg/kg/day) for 3 days before RANKL injection and was further injected for 3 days with GST-RANKL injections as described above. CTx and TRAP-5b were increased in GST-RANKL-injected mice, but the treatment of RANKL-injected mice with risedronate completely inhibited the increases of bone resorption makers. Bone synthetic markers were decreased in risedronate/RANKL injected mice. The risedronate treatment also completely inhibited the decrease of BMD of femurs in RANKL-injected mice. The in vivo evaluation of risedronate was successfully done within a week. In conclusion, we established the 50 hour-osteopenia model. This model would be useful for and applicable to the rapid evaluation of drugs for osteopenia and osteoporosis. Evaluation of bone anabolic factors in this model is underway.

Role of Prostaglandins in Strontium Ranelate Effects on Osteoblastic Differentiation and Growth Factor Production. S. Choudhary¹, P. Halbout², C. Alander¹, C. Pilbeam¹, L. Raisz¹. ¹Musculoskeletal Institute, University of Connecticut Health Center, Farmington, CT, USA, ²Institute De Recherches Internationales Servier, Coubevoise, Cedex, France.

Strontium ranelate is a new treatment for osteoporosis that has both antiresorptive and anabolic effects. Strontium ranelate increases osteoblastic differentiation and induces cyclooxygenase (COX-2) and prostaglandin E₂ (PGE₂) production in murine marrow stromal cells (MSCs), and differentiation is diminished in cultures treated with COX-2 inhibitors or derived from COX-2 knockout animals. To further investigate the hypothesis that strontium ranelate exerts some of its anabolic effects on osteoblasts via prostaglandin production, we examined the ability of strontium ranelate to stimulate gene expression of growth factors in MSCs cultured from COX-2 knockout (KO) and wild type (WT) mice. A dose-dependent increase in PGE₂ production was seen after treatment of cells from COX-2 WT mice with 1 or 3 mM strontium ranelate for 7 days. COX-2 KO MSCs showed minimal PGE₂ production. MSCs from COX-2 WT and KO mice were cultured up to 21 days. Gene expression was determined by real time PCR. After 14 and 21 days of culture, strontium ranelate (1 or 3 mM) significantly and dose-dependently increased alkaline phosphatase (ALP) and osteocalcin (OCN) mRNA expression in WT cultures. These effects were associated with an increase insulin-like growth factor 1 (IGF-1) and vascular endothelial growth factor (VEGF) mRNA expression by 1.4-1.5 fold (p<0.01) and 1.4-1.7 fold (p<0.01), respectively. In COX-2 KO cultures, ALP and OCN mRNA levels were decreased 50% (p<0.05) and 60% (p<0.01), respectively, compared to WT cultures, and there was no increase in ALP and OCN mRNA expression or in IGF-1 and VEGF mRNA expression with strontium ranelate. In summary, strontium ranelate increased osteoblastic differentiation and IGF-1 and VEGF mRNA expression in a COX-2 dependent manner in murine MSCs. Coupled with previous data, this study indicates that strontium ranelate effects on bone formation may involve the local production and action of prostaglandins on osteoblasts, and that strontium ranelate-induced prostaglandin synthesis may increase production of growth factors that are implicated in stimulation of bone formation.

MK-0822 Is a Potent and Selective Cathepsin K Inhibitor that Maintains Its High Selectivity in Whole Cell Assays. W. C. Black^{*1}, S. Desmarais^{*1}, L. T. Duong², J. Falgoutyret^{*1}, J. Gauthier^{*1}, S. Lamontagne^{*1}, C. Li^{*1}, F. Masse^{*1}, V. Truong^{*1}, G. Wesolowski², M. Percival^{*1}. ¹Merck Research Laboratories, Pointe-Claire-Dorval, PQ, Canada, ²Merck Research Laboratories, West Point, PA, USA.

Cathepsin K (Cat K) is a lysosomal cysteine protease that is highly expressed in osteoclasts and plays a critical role in the degradation of bone collagen. It has been demonstrated that Cat K inhibitors are effective anti-resorptive agents for the treatment of osteoporosis. Several inhibitors of Cat K, including balicatib and L-006235, contain a basic substituent that results in lysosomotropism - the physical property in which the drug accumulates in the acidic lysosomes of the cell. Since off-target cathepsins reside in lysosomes, this resulted in a dramatic loss of selectivity of these inhibitors when tested in whole cell assays.

To address this problem, we have identified a neutral Cat K inhibitor, MK-0822, which has an IC₅₀ of 0.2 nM against human Cat K and is 300-fold selective versus Cat S and >5000-fold selective versus Cat B and Cat L. The potency and selectivity of MK-0822 against isolated enzymes are similar to those of the basic inhibitors, but its high selectivity is maintained in whole cell assays.

	Cat K		Cat B		Cat L		Cat S	
	IC ₅₀ (nM)	enzyme	IC ₅₀ (nM)	enzyme	IC ₅₀ (nM)	enzyme	IC ₅₀ (nM)	enzyme
balicatib	0.6	4800	61	503	48	65000	2900	
MK-0822	0.2	1034	1050	2995	4843	60	45	

In a functional bone resorption assay using rabbit osteoclasts, MK-0822 has an IC₅₀ of 23 ± 14 nM as compared to balicatib with an IC₅₀ of 89 ± 29 nM. Since MK-0822 is 5-fold less potent against rabbit Cat K compared to human Cat K, this value likely under represents its true potency.

MK-0822 has an excellent pharmacokinetic profile in preclinical species with terminal half-lives of 6h in rat, 57h in dog and 18h in monkey. The observed volumes of distribution are near unity, distinguishing this compound from analogous basic inhibitors, which have large volumes of distribution. In conclusion, MK-0822 is a potent and selective Cat K inhibitor that is non-lysosomotropic and maintains its high selectivity in whole cell assays.

Cathepsin K Inhibitors Prevent Matrix-Derived Growth Factor Degradation by Human Osteoclasts. K. Fuller¹, K. M. Lawrence^{*1}, J. L. Ross^{*1}, U. B. Grabowska^{*2}, M. Shiroo^{*2}, B. Samuelsson^{*2}, T. J. Chambers¹. ¹St George's, University of London, London, United Kingdom, ²Medivir UK, Little Chesterford, United Kingdom.

Under normal circumstances, bone resorption and bone formation are coupled in such a way that, if bone resorption is inhibited, then so is bone formation. This coupling between bone formation and resorption creates therapeutic difficulties in osteoporosis: further bone loss can be prevented using antiresorptive therapy, but because suppression of resorption also inhibits bone formation, the condition is not reversed. Surprisingly, inhibition of resorption by cathepsin K inhibitors has recently been found to augment bone formation. Uniquely amongst resorption-inhibitors, inhibitors of cathepsin K suppress degradation of the organic matrix while allowing demineralisation. We hypothesised that these characteristics might explain the unexpected capacity of cathepsin K inhibitors to enhance bone formation: they might prevent degradation not only of matrix collagen, but also other matrix-embedded proteins, including the growth factors that are known to be embedded in bone matrix. We tested this hypothesis using osteocalcin and IGF-I as examples of matrix-embedded proteins. We found that, when osteoclasts were incubated on bone, inhibitors of cathepsin K dramatically increased the concentrations of these matrix-derived proteins in supernatants. Other resorption-inhibitors did not do this. Inhibition of cathepsin K appeared to act by protecting the proteins against intracellular degradation, rather than against their degradation in supernatant. We also found that protons are both necessary and sufficient to release IGF-I from bone matrix, and that recombinant cathepsin K is capable of the degradation of both marker proteins. In the presence of a cathepsin K-inhibitor, the amount of IGF-I released from matrix by osteoclasts substantially exceeded the amount they secreted. Cathepsin K-inhibition similarly augmented release of bone morphogenetic protein (BMP)-2. Moreover, the numbers of osteoblastic MC3T3-E1 were greater after co-culture with osteoclasts on bone with versus without cathepsin K-inhibitor, showing that osteoclasts release biologically-significant quantities of growth factors from bone, and that the biological activity of the released growth factors is preserved by inhibition of cathepsin K. These results suggest a model in which cathepsin K inhibitors prevent degradation of growth factors released from bone matrix by osteoclast-derived protons, thus augmenting the anabolic component of the coupling between bone resorption and bone formation.

Elcatonin Injections after Drill-hole Injury in Mice Inhibits Osteoclast Differentiation and Prevents the Decrease of Bone Mineral Density in Non-injured Bones with Promotion of Repair in the Cortical Bone Defect. Y. Katae^{*1}, S. Tanaka¹, A. Sakai¹, M. Nagashima^{*2}, H. Hirasawa^{*1}, N. Nakura^{*1}, K. Sabanai^{*1}, K. Menuki^{*1}, H. Yamane^{*1}, K. Tanaka^{*1}, Y. Shimizu^{*1}, T. Nakamura¹. ¹Orthopaedic Surgery, School of Medicine, University of Occupational and Environmental Health, Kitakyushu, Japan, ²Orthopaedic Surgery, Moji Rosai Hospital, Kitakyushu, Japan.

We evaluated the effects of elcatonin on the bone repair of drilled bones and non-injured bones in mice. Twelve-week-old male C57BL/6J mice were treated with a subcutaneous injection of elcatonin 3 times a week in three doses (0.2mg/kg body weight (BW); ELL, 2.0mg/kg BW; ELM, and 20mg/kg BW; ELH), or the vehicle (VC) from 12 weeks of age until sacrifice. Base-control animals at 12 weeks of age were sacrificed before drilling (day 0), and the specimens were obtained. At 12 weeks of age (day 0), a drill-hole was made in the diaphysis of the left femur and tibia. Twelve-week-old sham operated mice were used as the Control. Specimens were obtained at days 0, 5, 7, 9, 14, 21 and 28 after surgery.

The mean bone mineral density (BMD) values of the vertebral bodies in the VC group decreased at days 7, 14 and 21, and those of one-third of the non-injured distal femoral in the VC group decreased at day 28. Elcatonin injection inhibited the reduction of those values. In the non-injured femur of the VC group, the values of the osteoclast surface of the distal metaphysis and the number of osteoclasts derived from bone marrow increased, but did not increase in the ELM and ELH groups at day 14. In the elcatonin-treated groups, regenerating bone was filled up earlier than in the VC group. The BFR values of the regenerating bone at the drill-hole in the ELM and ELH groups tended to increase compared with those in the VC group at day 21, but did not at day 28. In the ELH group, the number of alkaline phosphatase-positive colony forming unit-fibroblasts in the bone marrow cell culture was higher than in the VC group at day 7. In the elcatonin-treated groups, the osteoblastic mRNAs expression levels of bmp2, osterix, colla1, and osteocalcin were significantly increased compared to those in the VC group at day 5. The expression levels of rankl/opg and trapc mRNA were similar among all groups.

These data indicate that injection of elcatonin after a drill-hole injury in mice inhibited osteoclast differentiation and prevented the decrease of BMD in non-injured bone without retardation of the filling up with regenerating bone in the drill-hole.

Icariin, an Active Ingredient in Herba Epimedii, Exerts Bone Protective Effects In Vivo and In Vitro. W. P. Lai^{*1}, S. K. Mok^{*1}, W. Y. Pang^{*1}, X. L. Wang^{*2}, X. S. Yao^{*2}, M. J. Favus³, M. S. Wong¹. ¹Applied Biology and Chemical Technology, The Hong Kong Polytechnic University, Hong Kong, China, ²School of Pharmacy, Shenyang Pharmaceutical University, Shenyang, China, ³Pritzker School of Medicine, The University of Chicago, Chicago, IL, USA.

Icariin is an active compound identified in Herba Epimedii (HEP), a Chinese medicinal herb frequently used for treatment of osteoporosis. The present study aims to determine the osteoprotective effect of Icariin in vivo and in vitro.

Four-week-old sham-operated or ovariectomized C57BL/6J mice were pair-fed and treated with icariin (300ug/g/day), E₂ (4ug/g/day) or its vehicle by tube-feeding for 6 weeks. Body weight and uterus weight were recorded. Blood sample were collected for Ca and P detection, while bone tissues were for BMD measurement by pQCT. Icariin treatment did not alter serum Ca and P in OVX mice. Unlike E₂ treatment (OVX vs. E₂, p<0.01), icariin feeding did not alter the uterus to body weight ratio (OVX vs. Icariin, p=NS) in OVX mice. Six weeks of icariin treatment increased trabecular BMD (Icariin vs. OVX, p<0.05) in distal end of femur and cortical BMD (Icariin vs. OVX, p<0.05) in mid-shaft of tibia as well as its cortical thickness (Icariin vs. OVX, p<0.05) significantly. The results indicated that icariin is effective in maintaining BMD in OVX mice.

The in vitro effect of icariin (10⁻¹⁴ to 10⁻⁶M) on bone cell proliferation and differentiation were determined by MTS and alkaline phosphatase (ALP) activity assay using rat osteoblast-like UMR 106 cells, respectively. In addition, the effects of icariin on osteoprotegerin (OPG) and RANKL mRNA expression were determined by real time reverse-transcriptase polymerase chain reaction (RT-PCR). Icariin could increase proliferation (at 10⁻¹⁰M to 10⁻⁶M, p<0.05) and differentiation (at 10⁻¹⁴M to 10⁻⁶M, p<0.05; maximal at 10⁻¹²M) of UMR-106 cell. OPG and RANKL mRNA expression in UMR 106 cells increased significantly in response to treatment with icariin. However, the degree of up-regulation was generally higher for OPG than RANKL at all dosages, resulting in a higher OPG to RANKL gene expression ratio in all icariin treated groups, suggesting that icariin might inhibit the process of osteoclastogenesis.

The results clearly demonstrated that icariin, a major active ingredient in Herba Epimedii, could exert bone protective both in vivo and in vitro. The study provides the mechanistic basis for the use of Herba Epimedii in treatment of postmenopausal osteoporosis.

The Approach for Screening Natural Plant Ingredients for Development of Nutraceutical Supplements to Support Bone Health. Y. Lin^{*1}, M. A. Murray^{*1}, D. Krempin^{*1}, K. Gellenbeck^{*1}, H. Roh-Schmidt^{*1}, L. Wilkins^{*2}, J. F. Rehman^{*1}, R. K. Randolph^{*1}. ¹Nutrilit Health Institute, Buena Park, CA, USA, ²Interleukin Genetics Incorporated, Waltham, MA, USA.

Preformulation research towards development of efficacious nutraceutical supplements was conducted to identify natural plant ingredients that have positive effects on reducing bone resorption and stimulating bone formation. A systematic screening strategy included mechanism of action specific bio-assays and neonatal murine calvarial organ culture systems. Natural ingredient extracts were first screened for the ability to inhibit the receptor activator of NFκB ligand (RANKL) expression via inhibition of IL-1 production by T cells. The ingredients that exhibited the best inhibition of RANKL expression were further assessed for their ability to reduce 45Ca release in a murine calvarial organ culture system. A similar screening strategy was also conducted for identifying bone formation ingredients where ingredients were first assessed for their ability to trigger osteoblast cell differentiation by the activation of bone morphogenic protein (BMP) expression by BMP-2 gene expression. Ingredients with positive outcome were also screened for their ability to induce BMP-2 promoter activity and BMP-2 protein expression. The ingredients that exhibited the best induction in BMP-2 assays were further assessed for their ability to increase new bone formation in a neonatal murine calvaria organ culture system. More than 50 natural ingredients screened by RANKL assay and BMP-2 gene expression assay. Nine ingredients found to inhibit RANKL expression were evaluated for inhibition of bone resorption in the calvarial system. Pomegranate extract was found to be the most efficacious ingredient to reduce bone resorption and compared favorably to alendronate in the calvarial system. Grape seed extract also exhibited a reduction in bone resorption similar to alendronate in the calvarial system. Eight of 50 natural ingredients were found to induce BMP-2 gene expression, and further screened for induction of BMP-2 promoter activity, BMP-2 protein expression, and bone formation in the calvarial system. Natural quercetin was found to be the most effective to induce both BMP-2 activity, and was comparable to drug control in increasing new bone formation in the calvarial system. Ethanolic licorice extract also exhibited a positive effect on bone formation in both BMP-2 assays and the calvarial system. This screening strategy was successful in preliminary identification of potentially efficacious ingredients towards the development of nutraceutical formulas to support bone health.

Role of Nitric Oxide in the Preventive Effects of Electrical Stimulation on Ovariectomy-induced Bone Loss in Rats. A. P. R. Lirani-Galvão^{*1}, C. Bergamaschi^{*2}, O. L. Silva^{*3}, N. Portero-Muzy^{*4}, A. B. Carvalho^{*5}, V. Jorgetti^{*5}, P. Chavassieux^{*4}, M. Lazaretti-Castro^{*1}, P. D. Delmas^{*4}. ¹Departamento de Medicina, Universidade Federal de São Paulo, São Paulo, Brazil, ²Departamento de Ciências da Saúde, Universidade Federal de São Paulo, Santos, Brazil, ³Bioengenharia, Universidade de São Paulo, São Carlos, Brazil, ⁴INSERM Unité 831, Université de Lyon, Lyon, France, ⁵Departamento de Medicina, Universidade de São Paulo, São Paulo, Brazil.

Electrical stimulation (ES) is able to stimulate osteogenesis probably through the production of nitric oxide (NO). The aim of the present study was to evaluate the effects of ES and the potential role of NO on bone structure, microarchitecture and remodelling in ovariectomized (OVX) rats. Sixty rats (200-220g) were divided into 6 groups: sham; treated with 6mg/d of L-NAME, an inhibitor of NO synthase (sham-L); ovariectomized (OVX); treated with L-NAME (OVX-L) or subjected to an electrical stimulation (OVX-ES) or both (OVX-L-ES) for 12 weeks. After double tetracycline labelling, rats were sacrificed and the tibias were collected for histomorphometric analysis. The decreased bone mass and increased remodeling with an augmentation of eroded surface (ES/BS) induced by OVX were prevented by ES. In sham-L, the significant increases in bone volume (BV/TV), trabecular number (TbN) and node number (NdN/TV) associated with decreases of mineralizing surface (MS/BS) and bone formation rate (BFR/BS) suggested a possible biphasic effect of L-NAME on the bone formation with a possible initial stimulation followed by a diminution of the osteoblast activity. In contrast, in OVX-L, this initial increased formation was not observed. In presence of L-NAME, ES did not induce significant increases in BV/TV and TbN. But ES seemed to partly prevent the negative effect of L-NAME on bone formation after 12 weeks.

Groups	BV/TV (%)	TbN (/mm ²)	NdN/TV (/mm ²)	ES/BS (%)	MS/BS (%)	BFR/BS (μm ² /μm/d)
sham	24.8±8	3.9±0.9	9.6±4	3.2±1.8	7.7±2.9	0.15±0.1
OVX	10.2±2 ^{ab}	1.7±0.3 ^{ab}	3.65±1 ^{ab}	4.7±1.7 ^a	15.9±7.9 ^{ab}	0.47±0.4 ^{ab}
OVX-ES	22±11	3.69±1.8	4.27±2	3.3±2	7.7±6	0.12±0.1
sham-L	37±7 ^{ad}	5.8±0.6 ^{ad}	19.1±3 ^{ad}	4.14±1.8	3.80±2 ^a	0.04±0.03 ^a
OVX-L	14±7	2.3±1	3.52±2	6.24±2	5.8±3.7	0.06±0.05
OVX-L-ES	15.8±9 ^c	2.4±1 ^c	6.84±7 ^c	2.65±1.4 ^{cd}	12.1±3.7 ^c	0.205±0.1 ^c

P<0.05^a vs sham; ^b vs OVX-ES; ^c vs sham-L; ^d vs OVX-L

In conclusion, ES may prevent OVX-induced bone loss. These effects may be mediated through NO. However, L-NAME appeared to directly modulate bone formation. The initial increase in bone formation under L-NAME may be due to the augmented blood pressure which may act as a mechanical stimulation on osteoblasts (Turner et al., Bone 1997, 21:487-90) but after long-term, L-NAME inhibited osteoblastic activity.

Knowledge of Osteoporosis Among Tertiary Students in Vietnam. H. T. T. Nguyen^{*1}, N. D. Nguyen^{*2}, T. T. H. Ha^{*3}, C. K. T. Nguyen^{*3}, B. H. Nguyen^{*3}, T. V. Nguyen^{*2}. ¹Medical University, Karolinska Institute, Stockholm, Sweden, ²Bone and Mineral Research Program, Garvan Institute of Medical Research, Sydney, Australia, ³Hanoi Medical University, Hanoi, Viet Nam.

Osteoporosis has emerged as one of the most significant public health problems in the world, especially in developing countries. Prevention is recognized as an ideal approach to reduce the burden of osteoporosis. Knowledge is considered as important component in any preventative program; however, assessment of osteoporosis knowledge has not been well studied. The aim of this study was to assess the knowledge about osteoporosis among tertiary students in Vietnam.

Three hundred and five students were randomly invited from 5 universities/colleges (Medicine, 40%; Pharmacy, 12%; Poly-techniques, 17%; Journalism, 17%; and Pedagogy, 14%). The median age of the students was 23y. Each student was administered a Vietnamese version of the OPQ questionnaire, which consists of 20 items with four components: general knowledge (GK), risk factors (RF), nutrition and exercise (N&E) and treatment (T). Each question was scored as 1 for correct answer and 0 for incorrect answer. Therefore, the maximum score for a participant was 20 and the minimum score was 0. The proportion of correct answers was then estimated for each participant. A log-binomial regression was used to estimate the association between factors and the likelihood of correct answers.

The median proportion of correct answers (for 20 items) was 65% (inter-quartile range, IQR: 45-75). The median of proportion of correct answers for GK was 80% (IQR: 60-100), RF 63% (IQR: 50-75), N&E 75% (IQR: 50-100) and T 33% (IQR: 0-67%). Results from a multivariable analysis suggested that medical and pharmacy students were more knowledgeable than other students, with the proportion of >75% correct answers being 55% vs. 7%. The multivariable log-binomial regression analysis suggested that the degree of osteoporosis knowledge among medical and pharmacy students was 7.3 times (95% CI: 3.7-14.6) higher than non-medical and pharmacy students. Moreover, students spending more than 2 hours in reading and listening to radio were 1.41 times (95% CI: 1.1-1.9) more likely to answer >75% correct questions compared to those with limited time (< 2hrs).

In summary, university/college students in Vietnam had good knowledge of osteoporosis, including general knowledge, nutrition and exercise and risk factors for osteoporosis. However, they had poor knowledge of treatment. These findings imply that there is a need for educational program via newspapers and radio to impart the osteoporosis knowledge in the general public and university students.

Disclosures: H.T.T. Nguyen, None.

Local Delivery of Lovastatin by a Biodegradable Polymer Increases Callus Strength in Rats. J. S. Nyman¹, G. Gutierrez², I. R. Garret^{*3}, G. Rossini^{*3}, G. R. Mundy². ¹Orthopaedics, Vanderbilt University, Nashville, TN, USA, ²Medicine, Vanderbilt University, Nashville, TN, USA, ³Osteoscreen, San Antonio, TX, USA.

The one-time administration of BMP-2 at the site of a recent fracture has been found to enhance the strength of the callus and thus hasten fracture repair. However, BMP-2 is expensive to manufacture, and delivery of peptides to fracture sites can be problematic. Therefore, we have been investigating fracture repair with lovastatin, a small molecule that stimulates BMP-2 transcription when it reaches the bone microenvironment. Being insoluble, its release into the fracture site must be controlled in order to be effective. Therefore, we encapsulated the drug into nano-sized beads made of a biodegradable polymer (nanobeads in PGLA). Upon establishing the release kinetics and osteoinductive potential of lovastatin nanobeads, we investigated their effect on fracture repair. Mixing poly-DL-lactide (DURECT Corp.) with lovastatin in acetone produced nanobeads after dripping 1% PVA under continuous stirring. Following centrifugation, the encapsulated lovastatin was re-suspended in saline. An in vitro release assay determined the concentrations in which nanobeads could deliver doses of 0, 0.2, 1, 1.5, or 7.5 μg of lovastatin per day. These doses were assessed in a closed-pin, transverse fracture model involving male Sprague Dawley rats. Weight matched rats were divided into 5 groups, one for each nanobead dose. A single injection of 50 μl was administered directly into the fracture site immediately following the femoral break. After four weeks of healing, rats were sacrificed, and then the fractured femur was excised for micro-CT analysis (at 36 micron resolution) and biomechanical testing. The former involved measuring the fracture gap in sagittal images of the callus, while the latter involved three point bending at 3 mm/min about the medial-lateral plane. Results showed that when compared to vehicle-treated rats, the local delivery of lovastatin using biodegradable nanobeads reduced the fracture gap between the cortices by 125%, 160%, 219%, and 207% in a dose-dependent manner. Likewise, structural strength improved as the release rate increased, peaking at 1.5 μg/day. At this dose, there was a 39% and 94% increase in strength and work-to-fracture of the callus, respectively. For comparison, a single injection of rhBMP-2 has been found to increase the torsional strength of the callus by 60% at 4 weeks using similar rat model (Einhorn et al. JBJS 2003). Thus, a single injection of lovastatin that is released into the fracture in a controlled-manner also significantly increased the structural strength of the callus. Creating a stronger callus increases the likelihood that the fractured femur returns to functionality sooner than without treatment.

Total Flavonoid Fraction of Rhizoma Drynaria and Its Active Ingredient, Naringin, Exert Bone Protective Effect In Vivo and In Vitro. W. Pang^{*1}, X. Wang^{*2}, S. Mok^{*1}, W. Lai^{*1}, X. Yao^{*2}, M. Wong¹. ¹Applied Biology and Chemical Technology, The Hong Kong Polytechnic University, Hong Kong, Hong Kong, ²School of Pharmacy, Shenyang Pharmaceutical University, Shenyang, China.

Rhizoma Drynaria (RD) is a Chinese medicinal herb commonly used for treatment of bone fracture in China. Naringin, a major flavonoid isolated from RD, was previously reported to stimulate bone cell proliferation and thus might be useful for treatment of osteoporosis. The present study aims to determine if the total flavonoid fractions of RD as well as naringin could exert bone protective effects in vivo and in vitro, respectively. Six-weeks old sham-operated or ovariectomized young C57 BL/6J mice were orally administered with either the total flavonoid fractions (ex-low: 0.03875, low: 0.0775, mid: 0.155, high: 0.31 mg/g/day) of RD, 17 β -estradiol (4 μ g/g/day) or its vehicle for 6 weeks. Serum and urine were collected for biochemical marker determination while femur were collected bone mineral density (BMD) determination using peripheral quantitative computed tomography (pQCT). Total flavonoid fractions of RD did not alter serum Ca, P and uterus weight in OVX mice. The increase in urinary Ca excretion by OVX was reduced in rats treated with RD fractions. Treatment of OVX-mice with RD flavonoids increased trabecular BMD in femur in a dose-dependent manner with the optimal dosage at 0.155 mg/g/day. The in vitro effects of total flavonoid fraction (0.02 to 200 μ g/ml) and naringin (10^{-8} to 10^{-5} M) on bone cell proliferation and differentiation were determined by MTS and alkaline phosphatase activity assay using rat osteoblastic-like cell, UMR 106 cells, respectively. Total flavonoid fraction of RD increased cell proliferation in dose-dependent manner. At 2 μ g/ml, it significantly increased cell proliferation by 79% ($p < 0.001$). Naringin also increased cell proliferation and differentiation in a dose-dependent manner. At 10^{-8} M, it significantly increased cell proliferation by 50% ($p < 0.001$) and differentiation by 60% ($p < 0.001$). Our studies demonstrated that total flavonoid fraction of RD and its isolated flavonoid compound, naringin, could exert bone protective effects in vivo and in vitro. Our results suggest that RD and naringin might be an effective therapeutic agent for treatment of osteoporosis.

Interactive Effects of Milk Basic Protein Supplementation and Habitual Physical Activity on Bone Health in Older Women: A 1-Year Randomized Controlled Trial from the Nakanojo Study. H. Park¹, A. Yasunaga^{*1}, E. Watanabe^{*1}, F. Togo^{*1}, S. Park^{*1}, K. Yoshiuchi^{*2}, H. Kikuchi^{*2}, H. Kawakami^{*3}, Y. Morita^{*3}, A. Ono^{*3}, R. J. Shephard^{*4}, Y. Aoyagi^{*1}. ¹Exercise Sciences Research Group, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan, ²Department of Psychosomatic Medicine, The University of Tokyo, Tokyo, Japan, ³Technology and Research Institute, Snow Brand Milk Products Co., Ltd., Saitama, Japan, ⁴Faculty of Physical Education and Health, University of Toronto, Toronto, ON, Canada.

Milk basic protein (MBP) has been reported as improving bone health in healthy adults (aged <50 years). However, findings were not controlled for possible differences of habitual physical activity between control and experimental subjects. Thus, we examined possible interactive effects of MBP and habitual physical activity in the elderly. 79 Japanese female volunteers aged 65-86 years completed a randomized controlled study. Serum and urinary indices of bone metabolism, a forearm dual X-ray absorptiometric measure of bone mineral density (BMD), and a calcaneal osteosonic index (OSI) were measured at 0, 6, and 12 months. Step count and activity intensity (metabolic equivalents, METs) were measured by accelerometer every 4 s throughout one year. MBP (40 mg/day) had no effects on serum osteocalcin (OC) or bone-specific alkaline phosphatase (BALP). Urinary deoxypridinoline (Dpd) and cross-linked N-telopeptides of type-I collagen (NTx) also showed no MBP effect at 6 months, but at 12 months excretion was significantly less than in controls. Forearm BMD and calcaneal OSI scores tended to decrease in controls, but experimental subjects maintained BMD and had a statistically significant 1.5% increase of OSI at 12 months. After adjustments for age and baseline values of bone-related parameters, OC, NTx, Dpd, and/or OSI at 12 months were significantly related to step count and/or activity >3 METs, with no significant treatment x activity interactions for other parameters (BALP and BMD). MBP supplementation appears to prevent bone loss in older women, particularly in the lower extremities. However, a longer trial is needed to establish the clinical significance of the observed changes. Reduced resorption of bone is favored by moderate habitual physical activity.

The Long Term Effect of 2-Arachidonoyl Glyceryl (AG) Ether on Body Weight and Bone Mass. S. Park, C. Hwang^{*}, H. Kwak^{*}, M. Jung^{*}, Y. Kang^{*}, H. Yoon, C. Yim^{*}, K. Han^{*}. Division of Endocrinology, Department of Internal Medicine, Cheil General Hospital & Women's Healthcare Center, Kwandong University College of Medicine, Seoul, Republic of Korea.

The CB1 cannabinoid receptor, one of the cannabinoid receptors has been known to regulate appetite, bone remodeling and bone mass. CB1 receptor-related researches have revealed discrepancies for body weight and bone mass according to murine phenotype and methodology. We investigated the effect of prolonged use of CB1 receptor agonist on body weight, behavioral activity and bone mass in mice. 6-week female Balb/c mice were received noladin ether (2-AG ether) known as a CB1 specific agonist or placebo intraperitoneally with ad libitum food for 10 weeks and injections were performed 6 times per week. There was a significant increase in body weight following administration of noladin ether (0.1 and 1 mg/kg), which was pronounced since 5-week treatments with noladin ether. The examinations for pharmacological activity of noladin ether showed a significant dose-dependent decrease in intestinal motility reflected by rate of defecation, however, showed no specific change in other tests for locomotor activity and antinociception. For bone mass, 0.1 mg/kg of noladin ether resulted in increased bone mineral density in femur. In conclusion, the chronic study with CB1 receptor agonist suggests that the body weight enhancement effect of 2-AG ether could be maintained throughout prolonged use for a long period and additional bone-protective effect might be obtained with 2-AG ether. Further study to delineate mechanism of noladin ether on bone would be needed.

P2X₇ Agonist Reduce Ovariectomy-induced Bone Loss in a Murine Model. S. Syberg^{*1}, S. Petersen^{*1}, J. Teilmann^{*1}, J. B. Jensen¹, P. Schwarz², N. R. Jørgensen¹. ¹Endocrinology and Clinical Biochemistry, Copenhagen University Hospital Hvidovre, Hvidovre, Denmark, ²Research Center of Aging and Osteoporosis, Copenhagen University Hospital Glostrup, Glostrup, Denmark.

The purinergic P2X₇ receptor mediates intercellular signaling between osteoblasts and osteoclasts, and it is involved in the regulation of osteoclast activity. Knockout models for this receptor have been established, but conflicting results have been reported for the different models. We have reported earlier, that deletion of the P2X₇ receptor in C57BL/6N.CrlBR mice results in increasing BMD. BzATP is a P2X₇ agonist that has been reported to increase mineralization in osteoblasts in vitro. In this study ovariectomized BALB/cJ mice were treated with BzATP for a month, to investigate the effect of the agonist in vivo. Female mice were, at the age of 4 months, DEXA scanned on a Piximus scanner (Lunar Corp.) to determine bone mineral density (BMD) and bone mineral content (BMC). One group were sham operated, the rest were ovariectomized. After a period of 4 weeks to resituate, the animals were again DEXA scanned, and treatment were initiated. 85 ovariectomized mice were treated with BzATP in two concentrations or positive (PTH) and negative controls (vehicle) for 4 weeks. At sacrifice serum was collected from animals to measure in vivo markers of bone formation and resorption (Osteocalcin, C-telopeptide collagen and Alkaline phosphatase). All animal procedures were approved by the Danish Animalcare Society. The ability of the femurs to resist mechanical forces ex vivo was quantified. After treatment lumbar spine, femur and tibia were collected for histomorphometric analysis and the other femur and tibia was saved for bone strength measurements and μ CT scanning respectively. Four weeks after the ovariectomy the animals had lost 9% of their bone mineral density (BMD). Subcutaneous injection of low doses of BzATP every other day reduced the loss of BMD to 5%. Compared to the positive control group, that were treated with PTH, the BzATP treated animals had higher BMDs. In the femur region the PTH treated group did not differ significantly from the vehicle treated group, but the effect of BzATP were maintained. In this study we have shown that BzATP in vivo is capable of increasing BMD in animals that have lost BMD in response to estrogen depletion by ovariectomy, further results will be presented to confirm the results.

Unfocused Extracorporeal Shockwave Therapy Diminishes Bone Loss in Ovariectomized Rats. O. P. Van der Jagt^{*1}, W. Schaden^{*2}, H. T. Van Schie^{*1}, T. M. Piscoer^{*1}, J. A. N. Verhaar^{*1}, J. C. Van der Linden^{*1}, H. Weinans¹. ¹Orthopaedic research lab, Erasmus MC, Rotterdam, The Netherlands, ²Orthopaedics, Unfallkrankenhaus Meidling, Vienna, Austria.

Extracorporeal Shockwave (ESW) therapy has shown to be effective in the treatment of non-unions and fracture healing. Other studies also show enhanced proliferation and differentiation of osteoprogenitor cells in rats after a single ESW treatment. Therefore ESW therapy might play a role in the treatment of osteoporosis. We evaluated if unfocused electro-hydraulically driven ESW could influence the bone architecture and the fracture healing in ovariectomized rats.

To induce bone depletion ovariectomy was performed, 3 or 10 weeks before the first ESW treatment. To evaluate the effects on fracture healing in the same animals a bilateral fibula osteotomy was performed two days before the first treatment. Also a sham-ovariectomy

with fibula-osteotomy was treated, to evaluate architectural changes in healthy bone. A control group to exclude influences of the osteotomy and ovariectomy was also evaluated. N=6 for all groups.

ESW therapy was given to the right leg, 3 or 10 weeks after OVX. Two treatments regimes were evaluated: a single treatment with 2000 pulses, 0.13 mJ/mm², or two treatments with three weeks in between with 1000 pulses, 0.13 mJ/mm².

In vivo micro-CT scans of the treated and non-treated leg were made before ESW treatment as well as 3, 6 and 10 weeks thereafter.

With in vivo micro-CT scanning we can longitudinally evaluate the bone architecture of a single rat in a highly detailed manner (voxelsize of 18 microns). The proximal metaphysis of the tibia and the osteotomy site of the fibula were analyzed. Bone morphologic parameters of both the cortex and cancellous bone were calculated.

3 Weeks after ESW treatment of shamOVX rats, 10% higher trabecular volume fraction (TBV), 8% higher connectivity and 3% higher trabecular thickness was seen. Cortical volume and thickness were 3 % lower in all treated legs. TBV of the treated legs of rats ovariectomized 3 weeks prior to treatment was 5% more than contralateral non-ESW legs and mean trabecular thickness was lower in all treated legs (3%). Also effects on cortical bone of OVX were diminished. These effects but smaller were also seen in rats ovariectomized 10 weeks prior to treatment but only in the group which received 2000 pulses.

These data suggest that electro-hydraulically driven unfocused shockwaves can influence bone architecture in healthy and osteoporotic bone. The number of shocks seems to be important in more progressed bone loss. How long a single treatment has its anabolic effect on the bone must be further investigated. Because these unfocused shockwaves are not painful, ESW can become a clinically relevant treatment for osteoporosis.

Extracorporeal Shockwave Therapy Stimulates Bone Remodeling in the Rat, Evaluated with In-vivo Micro-SPECT Scanning. O. P. Van der Jagt^{*1}, T. M. Piscoer^{*1}, M. Bijster^{*2}, W. Schaden^{*3}, J. A. N. Verhaar^{*1}, J. C. Van der Linden^{*1}, M. De Jong^{*2}, H. Weinans¹. ¹Orthopaedic Research Lab, Erasmus MC, Rotterdam, The Netherlands, ²Nuclear Medicine, Erasmus MC, Rotterdam, The Netherlands, ³Orthopaedics, Unfallkrankenhaus Meidling, Vienna, Austria.

It is known that Extracorporeal Shockwave therapy (ESWT) can stimulate fresh fracture repair and healing of non-union, in animal models as well as in humans. There are indications that ESWT may stimulate normal bone remodeling as well. By labeling the radioisotope 99m-Tc-methylene diphosphonate (Tc-99m-MDP) we can image bone remodeling with in vivo multi pinhole micro-SPECT scanning of a single rat in a longitudinal manner. In this way we can observe effects of the treatment on bone remodeling and evaluate these in time with a resolution of less than 0.5 mm.

Male Wistar rats 13 weeks of age received one ESW treatment on the tibia with 1000 pulses of 0.13 mJ/mm² or 1000 pulses with 0.30 mJ/mm², both with n=6. Only the right tibia was treated, the contra-lateral left tibia served as control. At 48 hours and 1 week after treatment micro-SPECT scanning was performed. 6 hours before scanning rats got an injection with Technetium-99m-MDP. Both lower legs were scanned in the same session, using gas anesthesia.

Follow-up scans of the rats treated with 0.13 mJ/mm² did not show an enhancement of the bone remodeling of the treated leg compared to the control leg at both 48 hours and 1 week.

The higher dose of 0.30 mJ/mm² on the other hand did show a 20% higher activity in the treated leg compared to the non-treated contralateral left leg at after 1 week after shockwave therapy.

Unfocused electro-hydraulic generated shockwave therapy can alter bone remodeling in rats, but this is highly dependent on the energy level of the shockwaves. It is likely that this alteration will influence the bone architecture, but how long the enhanced effects remain after a single treatment is not known yet. An explanation for the enhanced turnover cannot be concluded from these data, though the dependency of energy level and the resemblance with fracture healing may suggest that micro damage can be the trigger for enhanced bone remodeling. More work (e.g. histology for microdamage) is needed to reveal the underlying mechanisms of the described phenomena.

Restoration of Regenerative Osteoblastogenesis in Aged Mice: Modulation of TNF. E. C. Wahl^{*1}, J. Aronson^{*1}, L. Liu^{*1}, R. A. Skinner^{*1}, M. J. Miller^{*1}, J. L. Fowlkes¹, K. M. Thraill¹, T. M. Badger^{*1}, M. J. J. Ronis^{*1}, J. Sims^{*2}, C. K. Lumpkin¹. ¹University of Arkansas for Medical Sciences, Little Rock, AR, USA, ²Amgen, Seattle, WA, USA.

Studies have demonstrated that skeletal changes accompanying aging (type 2 osteoporosis) are associated with decreased bone mass, increased risk of fractures, impaired fracture healing, and increased serum levels of pro-inflammatory cytokines: tumor necrosis factor alpha (TNF) and interleukin 6 (IL-6). Previous studies utilizing a mouse distraction osteogenesis (DO, tibial lengthening) model demonstrate that aging is associated with elevated serum TNF levels and inhibition of direct bone formation and that treatment of young mice with recombinant mouse tumor necrosis factor α (rmTNF) inhibits bone formation. Here we report the results of studies on aged mice undergoing DO and treatment with TNF blockers (Pegsunercept-soluble TNF receptor 1 derivative [sTNFR1] or Enbrel-soluble TNF receptor 2 derivative [sTNFR2]).

1) To study the effects of a TNF antagonist on direct bone formation 24 (22 month old) male C57BL/6 mice underwent the DO protocol. After the three day latency period, half the mice were treated (sq injection) with either vehicle or sTNFR1 (8 mg/kg/every two days) over the 14 day distraction period. Histological analysis demonstrated an increase in bone formation (also observed in the radiographs) of the treated mice (76.1% \pm 7.6) versus the vehicle controls (31.2% \pm 12.4; P<0.01). In fact, 86% of the treated mice "bridged" (osteoid from both cortices meet and overlap) the gap during distraction, while none of the controls exhibited bridging. Serum analyses confirmed high levels of sTNFR1 in treated mice only and further demonstrated increased serum levels of TNF α , IL -6, and insulin in 22 month old mice as compared to 3 month old male C57BL/6 mice from a contemporary study. No differences were noted in serum mIGF-1 levels in aged mice.

2) A study comparing the effects of sTNFR1 and Enbrel (FDA approved derivative of sTNFR2) in 21 month old mice was performed. Mice were divided into three equal groups: vehicle, sTNF-R2, and sTNF-R1 treated. The mice received subcutaneous injections of vehicle (PBS pH 7.4), Enbrel (8.0 mg/kg), or sTNF-R1 (8.0 mg/kg) every other day for the 14 day distraction period. Histological analysis demonstrated an increase in bone formation in the treated aged mice (sTNFR1:70.5% \pm 4.9; sTNFR2:75.7% \pm 6.3) versus the aged vehicle controls (45.7% \pm 12.8; P<0.05).

These studies provide proof of concept that age-related deficits in direct bone repair are reversible.

Turmeric Extracts for Postmenopausal Osteoporosis Treatment: An Initial Evaluation. L. E. Wright^{*1}, J. B. Frye^{*1}, T. Henderson^{*1}, M. L. Bouxsein^{*2}, S. L. Marion^{*1}, P. Hoyer^{*1}, J. L. Funk¹. ¹Physiological Sciences Graduate Program, University of Arizona, Tucson, AZ, USA, ²Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA.

In previous studies, curcuminoid-containing turmeric extracts were remarkably protective in preventing bone loss in an animal model of rheumatoid arthritis (RA), preventing up to 50% of bone resorption as measured by increases in bone mineral density (BMD), normalization of the local ratio of RANK/OPG, and inhibition of osteoclast formation in the distal femur. To determine whether turmeric might also prevent bone resorption in postmenopausal osteoporosis, its effects on bone were examined in ovariectomized (OVX) rats. In prevention (daily turmeric begun 4 days after OVX) or treatment studies (turmeric begun 1 month after OVX), 3 month old female Sprague Dawley rats were placed in the following treatment groups: (1) sham operated + vehicle; (2) OVX + vehicle; (3) OVX + turmeric extract (purified curcuminoid extract, 25 mg/kg/d ip); (4) OVX + turmeric extract (purified curcuminoids, 50 mg/kg/d ip). Effects of 2 months of in vivo extract treatment on bone were monitored by BMD analysis of the distal femur using dual-energy x-ray absorptiometry (DXA), serum markers for bone turnover, and assessment of bone microarchitecture of the distal femur by microCT. In the prevention study, OVX animals treated with vehicle lost bone mass relative to sham animals, had an 40% increase in serum C-telopeptide fragments of type I collagen (CTX-1), and had decreased trabecular number and increased structure model index (SMI) by microCT. Turmeric-treated OVX animals maintained on average higher BMD than OVX animals treated with vehicle, however this trend was not statistically significant. Trabecular microarchitecture in OVX animals was not changed after 2 months of turmeric extract treatment relative to vehicle-treated OVX animals, except for a decrease in trabecular thickness in animals treated with high dose turmeric. Turmeric treatment also did not alter serum markers of bone resorption except at day 10 with high dose turmeric treatment where levels were actually higher than in the OVX/vehicle group. In contrast, in the treatment study, turmeric-treated rats maintained significantly higher BMD relative to OVX animals treated with vehicle that continued to lose bone. However, at the end of treatment, serum CTX-1 levels in OVX animals remained increased relative to sham animals and were unchanged by turmeric treatment. From these studies we can conclude that despite similarities in the pathway of bone loss in RA and postmenopausal osteoporosis, the active components of turmeric extract may act differently on bone resorption in each disease.

Phenotypic Variations of Fluoride Responses Between Inbred Strains of Mice. D. Yan^{*1}, X. Gu², E. Everett³. ¹Dental Research, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, ²Oral Biology Curriculum, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, ³Pediatric Dentistry, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA.

Excessive exposure to fluoride (F) can lead to disturbances of bone homeostasis and tooth enamel development. We have previously shown (J Dent Res. 2002 Nov;81(11):794-8.) differences in dental fluorosis (DF) susceptibility between inbred strains of mice. The current study was undertaken to investigate F responsive variations in bone metabolism and to determine possible relationships with DF susceptibility. Seven-week-old male mice (n=6 for each strain and treatment/control group) from FVB/NJ, C57BL/6J, C3H/HeJ, A/J, 129S1/SvImJ, AKR/J, DBA/2J and BALB/cByJ strains were exposed to F (0 or 50ppm as F ion) in their drinking water for 60 days. Sera were collected for Ca, Mg, P04 and ALP levels. Bone marrow cells were harvested for ex vivo osteoclast potential, hematopoietic colony-forming cell (CFC), and fibroblast-colony-forming unit (CFU-f) assays. The DF severity in mandibular incisors was evaluated by quantitative light-induced fluorescence (QLF) and clinical criteria. Strain specific responses to fluoride were observed for DF, serum chemistries and ex vivo cell culture studies. For each strain examined total serum Ca was not significantly affected. Serum P04 was elevated in A/J mice (34%, p=0.001) and decreased in C57BL/6J (12%, p=0.008). Serum Mg was elevated in FVB/NJ (13%, p=0.004) and decreased in AKR/J and DBA/2J (12%, p=0.003 and 19%, p=0.006, respectively). Total ALKP increased in AKR/J (13%, p=0.032), C3H/HeJ (16%, p=0.005), FVB/NJ (40%, p=0.007) and 129S1/SvImJ (43%, p=0.002), whereas ALKP decreased in A/J (38%, p=0.008). Osteoclast potential increased in A/J (13%, p=0.003) and 129S1/SvImJ (84%, p<0.001). CFU-f (AKLP positive) colonies increased only in FVB/NJ (48%, p=0.026). DF severity (QLF) showed the greatest increase in A/J (417%, p<0.001) and C57BL/6J (157%, p<0.001); modest increase in FVB/NJ (76%, p<0.001), DBA/2J (62%, p=0.001), and C3H/HeJ (47%, p=0.017); and no significant changes in 129S1/SvImJ, AKR/J, and BALB/cByJ. Among the strains investigated there were no patterns or significant correlations between DF severity and any of the serum chemistries or ex vivo assays. Prolonged fluoride exposure lead to variable phenotypic responses between inbred strains involving bone metabolism, osteoclast potential and osteoprogenitor potential. Risedronate Efficacy for Non-vertebral Fractures Is Consistent Across Age Groups. J. P. Bilezikian¹, X. Zhou^{*2}, A. B. Klemes², S. Boonen^{*3}. ¹Columbia University, New York, NY, USA, ²Procter & Gamble Pharmaceuticals, Mason, OH, USA, ³University Hospital Leuven, Leuven, Belgium.

Age is one of the most important risk factors for fracture among untreated patients. With age, fracture risk increases. In this study, we examined relationships between age and fracture risk using data from randomized, placebo-controlled clinical trials. Risedronate anti-fracture efficacy (5 mg daily vs. placebo) was examined among and across a wide range of age groups.

The analysis population included 3229 post-menopausal women from 4 risedronate phase III randomized placebo-controlled clinical trials. Average age was 68 yrs and Femoral Neck (FN) T-score was -2.2. Fracture was defined as any osteoporosis-related radiographically confirmed non-vertebral fracture.

The impact of age was estimated using a Cox regression model, adjusted for FN T-score and treatment group and stratified by clinical trial in order to take into account different underlying hazard functions. Interactions among treatment, age and FN T-score were included in the initial model but then removed because it was not statistically significant (p>0.05).

The association between increased fracture risk and age did not differ significantly by treatment groups (p>0.05, for the interaction terms). For every decade increase in age, patient risk for any osteoporotic fracture increased by 49% (95% CI: 21%, 88%) among patients in the same treatment group with similar baseline FN T-score.

Overall, risedronate reduced non-vertebral fracture risk by 43% (33%, 58%) relative to placebo after adjusting for age and BMD. The relative risk reductions for patients with age <=65, 66-75 and >=76 were 51%, 39% and 45% with p-values < 0.03. The therapy is well tolerated in the treatment of women with established postmenopausal osteoporosis (Harris et al. JAMA 1999).

Age is an important risk factor for fracture. Risedronate demonstrated consistent efficacy for non-vertebral fractures across a wide range of age groups.

Osteoporotic Non-vertebral Fracture Incidence Over 0-3 Years by Age Group				
	<=65	66-75	>=76	OVERALL
Number of Patients	1197	1480	552	3229
Non-vertebral Fracture incidence				
Placebo	7.5%	9.4%	19.5%	10.5%
Ris 5 mg	3.8%	6.3%	11.3%	6.4%
RR (95% CI)	0.49 (0.26, 0.92)	0.61 (0.39, 0.96)	0.54 (0.31, 0.94)	0.57 (0.42, 0.77)

Tolerability of Once-Monthly Ibandronate Across Different Age Groups of Women Switched From Once-Weekly Bisphosphonates. N. Binkley¹, M. G. Martens^{*2}, J. D. Kohles³, R. Civitelli⁴. ¹University of Wisconsin, Madison, WI, USA, ²Oklahoma University, Tulsa, OK, USA, ³Roche, Nutley, NJ, USA, ⁴Washington University, St Louis, MO, USA.

CURRENT, an open-label, 6-month, multicenter study, was designed to identify satisfaction levels and tolerability with once-monthly oral ibandronate in women switched from once-weekly bisphosphonates (BPs). Since drug tolerability is often a concern for older adults, tolerance to ibandronate was compared between women in younger and older age groups.

Postmenopausal women currently taking a weekly BP for ≥3 months for the treatment or prevention of osteoporosis or osteopenia were eligible to participate. Enrolled participants received 150-mg monthly oral ibandronate for 6 months. Adverse events (AEs) were monitored throughout the study.

The intent-to-treat population (n=1678) was grouped by age: <60 years of age (n=496); ≥60 to <70 (n=574); ≥70 to <80 (n=459); and ≥80 (n=149). The prevalence of osteoporosis in each age group was 49.2%, 66.7%, 73.2%, and 80.5%, respectively. AEs in the safety population (defined as participants who had received ≥1 dose of ibandronate and had ≥1 postbaseline safety measurement) are presented in the Table. In general, numerical differences in the percentage of participants with ≥1 AE between the <60 years group and the older groups were small. Infections/infestations were the most common class of AEs followed by gastrointestinal (GI) disorders. The percentage of participants experiencing GI AEs was 9.8% in the <60 group, 14.2% in the ≥60 to <70 group, 13.3% in the ≥70 to <80 group, and 12.8% in the ≥80 group. Four women (0.8%) in the <60 group experienced a renal and urinary AE. In the older groups, the range was 0.5% (≥60 to <70 group) to 1.5% (≥70 to <80 group). Women in the <60 group had the highest rate of fracture-related AEs among all the age groups. The incidence of participants withdrawing from treatment because of an AE was low and comparable between the <60 and older groups. GI disorders were the most common class of AEs leading to withdrawal in all the age groups. One patient, in the <60 group, experienced a renal AE leading to withdrawal; the AE was considered unrelated to medication.

No clinically meaningful differences were evident in the tolerability profile of once-monthly ibandronate for women of different age groups switched from weekly BPs.

Table. Adverse events in women across different age groups in the safety population

	<60 years n=491 n (%)	≥60 to <70 years (n=570) n (%)	≥70 to <80 years (n=459) n (%)	≥80 years (n=149) n (%)
Study participants with:				
≥1 AE	180 (36.7)	234 (41.1)	210 (45.8)	65 (43.6)
≥1 serious AE	9 (1.8)	12 (2.1)	24 (5.2)	9 (6.0)
≥1 fracture-related AE	15 (3.1)	10 (1.8)	11 (2.4)	4 (2.7)
≥1 AE resulting in withdrawal	13 (2.6)	21 (3.7)	29 (6.3)	5 (3.4)

Monthly Ibandronate Is Associated with Reduced Risk of Serious GI Events Compared with Weekly Bisphosphonates: Results of an Observational Analysis. W. A. Blumentals^{*1}, S. T. Harris². ¹Roche Laboratories, Inc, Nutley, NJ, USA, ²University of California, San Francisco, CA, USA.

The use of oral bisphosphonates (BPs) has been associated with the occurrence of gastrointestinal (GI) symptoms. The objective of this study was to investigate the incidence of clinically severe GI events (including acute, bleeding, or perforation events) among patients receiving monthly ibandronate therapy compared to patients receiving weekly BPs.

Data were collected from the Medstat MarketScan® database. Eligible women were ≥45 years of age, filled a new (index) prescription for monthly ibandronate or weekly alendronate or risedronate from April 1, 2005 to December 31, 2005, and had continuous enrollment for at least 6 months prior to the index date (pre-index period). Exclusion criteria included Paget's disease and the use of any BPs during the 6 month pre-index period. Patients on weekly BPs were propensity-score matched to monthly ibandronate patients using baseline characteristics, including age and history of GI events, to ensure a well-matched patient population and reduce selection bias. Severe GI events were identified via ICD-9 and CPT codes. Incidence rates of GI events were calculated and logistic regression was used to compare odds of experiencing a serious GI event in patients receiving monthly ibandronate versus those receiving weekly BPs. Additionally, GI-related healthcare utilization rates, which included GI medication use, visits to GI specialists, and procedures such as endoscopies, were compared.

A total of 17216 patients (mean age of 63 years) were eligible for inclusion in this analysis, with 8608 patients per group. During the 6 month pre-index period, 106 (1.2%) patients in the monthly ibandronate group and 113 (1.3%) patients in the weekly BP group experienced a GI event. During the follow-up period (average of 93 days), 45 (0.52%) monthly ibandronate patients and 70 (0.81%) weekly BP patients experienced a GI event. Monthly ibandronate patients had a 36% reduction in the risk of serious GI events compared to weekly BP users (OR = 0.64, 95% CI = 0.44-0.93). In general, monthly ibandronate patients appeared to have lower GI-related healthcare service utilization but

these differences did not reach statistical significance.

Despite the low incidence of serious GI events that occurred in either group, we observed a statistically significant reduction in the risk of serious GI events for monthly ibandronate patients. Results of this analysis suggest that monthly ibandronate may be associated with a lower incidence of serious GI events compared with weekly BPs.

Clinical Comparison in BMD Gains with Monthly Oral Ibandronate (150mg) and Weekly Oral Alendronate (70mg): Results From the MOTION Study. P. D. Miller¹, C. A. F. Zerbin², R. R. Recker³, F. Sedarati⁴, C. Neate⁵, J. Y. Reginster⁶. ¹Colorado Center for Bone Research, Lakewood, CO, USA, ²Hospital Heliopolis, Sao Paulo, Brazil, ³Creighton University, Osteoporosis Research Center, Omaha, NE, USA, ⁴Hoffmann-La Roche Inc., Nutley, NJ, USA, ⁵Roche Products Ltd, Welwyn Garden City, United Kingdom, ⁶University of Liège, Liège, Belgium.

The efficacy of monthly oral ibandronate and weekly oral alendronate for the treatment of postmenopausal osteoporosis has been directly compared for the first time in the MOTION (Monthly Oral Therapy with Ibandronate for Osteoporosis INtervention) study. The primary aim was to show non-inferiority for monthly ibandronate versus weekly alendronate in increasing bone mineral density (BMD) at both the lumbar spine and total hip over 12 months.

This was a randomized, multinational, multicenter, double-blind, double-dummy, parallel-group, non-inferiority study. The study enrolled 1,760 postmenopausal women with osteoporosis (age 55-84 years, time since menopause ≥ 5 years), with mean lumbar spine BMD T-score (L2-L4) < -2.5 and ≥ -5.0 SD. Patients were randomized to receive either 150mg monthly oral ibandronate and weekly placebo (n=887), or 70mg weekly oral alendronate and monthly placebo (n=873). All patients also received supplemental vitamin D 400IU/day and calcium 500mg/day. The primary efficacy endpoint was to show non-inferiority between ibandronate and alendronate in the relative change (%) from baseline at 12 months in mean BMD of the lumbar spine (L2-L4) and total hip. Monthly ibandronate would be proven clinically comparable to weekly alendronate if the lower boundary of the one-sided 97.5% CI was ≥ -1.41 percentage points for lumbar spine and ≥ -0.87 percentage points for total hip.

The intent-to-treat (ITT) population comprised 836 patients in the ibandronate arm and 822 in the alendronate arm. The per-protocol (PP) population comprised 725 patients treated with ibandronate and 720 with alendronate. The relative change in mean lumbar spine BMD (PP) was 5.10% with ibandronate and 5.78% with alendronate (95% CI for difference, -1.13, -0.23; non-inferiority met at ≥ -1.41). The relative change in mean total hip BMD (PP) was 2.94% with ibandronate and 3.03% with alendronate (95% CI for difference, -0.38, 0.18; non-inferiority met at ≥ -0.87). The PP analyses were confirmed in the ITT population. In conclusion, the primary endpoint was met with monthly oral ibandronate shown to have essentially similar increases from baseline to weekly oral alendronate at 12 months in both lumbar spine and total hip BMD.

Clinical and Nonvertebral Fracture Risk Is Reduced with the Use of Ibandronate in Women with Postmenopausal Osteoporosis. P. D. Miller¹, S. T. Harris², W. A. Blumentals³. ¹Department of Medicine, Colorado Center for Bone Research, PC, Lakewood, CO, USA, ²Osteoporosis Clinic, University of California, San Francisco, San Francisco, CA, USA, ³Roche Laboratories, Inc, Nutley, NJ, USA.

The purpose of this study was to assess fracture efficacy of ibandronate (IBN) at increasing doses and levels of annual cumulative exposure (ACE) in women with postmenopausal osteoporosis by pooling and analyzing data from the 4 pivotal phase III clinical trials.

Patients in the intent-to-treat (ITT) population who received oral or IV doses of IBN or placebo (PBO) in 4 studies (IV dose fracture study, BONE, MOBILE, and DIVA) were included in this pooled analysis.

BONE and the IV dose fracture study were 3-year PBO-controlled fracture trials. MOBILE and DIVA were 2-year BMD active-controlled studies that examined fractures as secondary endpoints. Doses were grouped by ACE, ie, high (≥ 10.8 mg includes 150mg oral monthly, 3mg IV quarterly, and 2mg IV every 2 months [q2mo]), mid (5.5-7.2mg), and low (≤ 4.0 mg) annual doses. ACE was defined as the drug strength (mg) multiplied by the number of annual doses and an absorption factor (0.6% for oral and 100% for IV). Fracture risk with IBN vs PBO was estimated using Cox hazards models, which controlled for age, baseline BMD T-score, and clinical fracture history. Due to confounding with ACE, the analysis was not stratified by study. All clinical fractures (both vertebral and nonvertebral), nonvertebral fractures (NVFs), and a subgroup of the 6 major NVFs (clavicle, humerus, wrist, pelvis, hip, leg) were examined. Time-to-fracture for different ACE groups was compared using log-rank tests.

A total of 1924 patients received PBO, 1911 received 2.0- ≤ 4.0 mg ACE, 3585 received 5.5-7.2mg ACE, and 1290 received ≥ 10.8 mg ACE in this pooled analysis. The group that received the highest annual doses of IBN (≥ 10.8 mg) had a reduction in relative risk of 28.8% for all clinical fractures, 29.9% for NVFs, and 34.4% for the subgroup of 6 NVFs compared with PBO (Table). The high ACE group had a longer time-to-fracture vs PBO

for all clinical fractures (P=0.002), and NVFs (P=0.025) at 2 years as determined by a log-rank test.

In this pooled analysis, we observed that the risk of clinical fractures and NVFs was significantly reduced for doses of ibandronate resulting in ACEs of ≥ 10.8 mg—which includes the marketed doses of 150mg monthly oral and 3mg IV quarterly.

Table. Adjusted hazard ratios for fractures at varying dose levels relative to placebo (ITT)

Fracture type ACE group (mg)	Adjusted hazard ratio	95% CI	P value
All clinical (vertebral + nonvertebral)			
High* (≥ 10.8)	0.712	0.55-0.92	0.010 [†]

An Open Label Study on the Effects of Alendronate in Osteoporotic Patients Affected by Monoclonal Gammopathy of Undetermined Significance. S. Minisola¹, J. Pepe², C. Cipriani¹, M. T. Petrucci², M. L. Mascia¹, E. Romagnoli¹. ¹Department of Clinical Sciences, University of Rome, Rome, Italy, ²Department of Cellular Biotechnology and Haematology, University of Rome, Rome, Italy.

Patients with monoclonal gammopathy of undetermined significance (MGUS) should be considered at risk of fracture; the pathophysiological mechanism could be ascribed to the raised bone turnover rate, probably due to an altered relationship of the RANKL/OPG balance. Therefore, it seems rational that these patients could benefit by the use of drugs able to normalize the negative balance at the level of the single remodelling units.

We studied 100 patients (65 females and 35 males), divided in two groups according to the presence of vertebral fractures and/or osteoporosis. The group with skeletal fragility (group A, 50 patients) was treated with alendronate (70mg/weekly) plus calcium and cholecalciferol for 18 months. The group without skeletal fragility (group B) was treated with calcium and cholecalciferol. In each patient, BMD at lumbar and hip level together with bone turnover markers were evaluated every 6 months.

Thirty patients in group A and 29 in group B completed the study. After 18 months, the mean BMD of the lumbar spine had increased by 6.1 percent in group A and by 1.24 % in group B, an absolute difference between the two groups of 4.8 percent (p ≤ 0.001). The mean BMD of the total femur had increased by 1.5 percent in the alendronate group and decreased by 1.2 % in group B, an absolute difference between the two groups of 2.7 percent (p ≤ 0.01). After starting therapy with alendronate, there was a marked decrease in mean serum β CTX that persisted throughout the treatment period in osteoporotic MGUS patients; smaller mean decreases were observed concerning the other markers investigated. In MGUS patients without osteoporosis, we observed significant decreases of bone remodelling markers (the only exception being mean bone sialoprotein-BSP) following therapy with cholecalciferol and calcium. At 18 months, the absolute percent difference between the groups was -23.2 (p ≤ 0.01) for serum isoenzyme of bone alkaline phosphatase, -23.6 for serum osteocalcin (p ≤ 0.01), -35.1 for serum β CTX (p ≤ 0.001) and -0.47 (p = ns) for serum BSP.

These data suggest that the increase in vertebral BMD together with the reduction of bone turnover markers could lead to a significant reduction in fracture risk in MGUS patients with skeletal fragility.

Therapeutic Effects of Risedronate for Two Years, on Bone Metabolic Markers, Especially on TRACP-5b. H. Naka^{*1}, H. Masaki^{*1}, Y. Imanishi^{*2}, T. Miki¹, Y. Nishizawa². ¹Geriatric Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan, ²Department of Metabolism, Endocrinology and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan.

The prevention of treatment cessation for osteoporosis patients is important for providing protection against fractures. Assessing bone resorption in the early stage of treatment by evaluating various bone metabolic markers over time in risedronate therapy is considered useful in preventing cessation of treatment. Therefore, we conducted prospective study on the extent to which the therapeutic effect on the patient can be assessed by evaluating bone metabolic markers over time, including the new bone resorption marker TRACP-5b.

Risedronate was administered to 36 postmenopausal osteoporosis patients (mean age 66.3 years) for 2 year and the therapeutic effects on bone density and bone metabolic markers were evaluated. As a control, 8 people received Ca and were evaluated in the same manner. When bone metabolic markers (BAP, uNTX, uCTX, sNTX, TRACP-5b) were measured before treatment and in Months 1, 3 and 6, some of the bone resorption markers were significantly inhibited from Month 1 and by Month 6 mean inhibition was 15-60%. Bone formation markers were suppressed 25-35% in Months 3-6, and lumbar BMD had increased 3.7% in 6 months, 4.2% in 12 months and 4.5% in 24 months. The proportion of patients who showed an inhibition rate (S/N ratio) against the least significant change of 1 or more in Month 1 was 83.3% for TRACP-5b, 52.8% for sNTX, 66.7% for uNTX and 44.4% for uCTX. In Month 3 they were 81.1%, 70.3%, 75.7% and 51.4%, respectively. In the Ca administration controls, no long-term significant changes in TRACP-5b were observed, but fluctuations in the collagen degradation products NTX and CTX were observed. Significant correlation ($p < 0.05$) between the rate of TRACP-5b inhibition and the rate of increase in lumbar bone density in Month 12 was observed at -0.386 in Month 1 and -0.513 in Month 3. In contrast, correlation between the rate of change in BMD and the rate of uCTX inhibition was -0.335 and -0.425, respectively. There was no significant correlation between the rate of increase in BMD and uNTX, sNTX or DPD. Correlation with the rate of BAP inhibition in Months 3 and 6 was -0.492 and -0.633. Furthermore, about 28 patients who could be measured BMD in 24 months, Significant correlation ($p < 0.05$) between the rate of TRACP-5b inhibition and the rate of increase in BMD in Month 24 was observed at -0.419 in Month 6, but other bone resorption marker were not. Correlation with the rate of BAP inhibition in Months 6 was -0.536.

Some bone metabolic markers can predict the therapeutic effect for short periods like a year after. However, only fewer markers can predict the therapeutic effect for long periods.

Three-Year Effects of Bisphosphonates on Treatment of Osteoporosis and on Reducing the Risk for Vertebral Fractures of Rheumatoid Arthritis Patients.(Fracture Intervention Trial). H. Nakayama¹, F. Hagiwara^{*2}, K. Shimada^{*1}, T. Matsui^{*1}, T. Tohma^{*2}. ¹Department of Rheumatology, National Hospital Organization, Sagami-hara National Hospital, Sagami-hara-City, Kanagawa Pref., Japan, ²Department of Rheumatology, Clinical Research Center for Allergy and Rheumatology, National Hospital Organization, Sagami-hara National Hospital, Sagami-hara-City, Kanagawa Pref., Japan.

[PURPOSE]To evaluate the efficacy of alendronate, risedronate and etidronate in the change of bone mineral density (BMD), bone metabolic markers and, reducing the risk for vertebral fractures of rheumatoid arthritis(RA) patients.[METHODS]We carried out 36-month, randomized, intervention trial of five groups in 400 patients with RA(366 women and 34 men). GroupA (n=77): alendronate(ALN) 5mg, GroupR(n=80): risedronate (RIS) 2.5mg, GroupE4 (n=77): cyclical (every 3 month) etidronate (EHDP)400mg, GroupE2(n=72): cyclical EHDP200mg, and GroupD(n=90): not treated with any bisphosphonate(BP). All patients received supplemental calcium and alfacalcidol(VD) 0.5µg. Every dose of BPs was licensed in Japan. BMD was measured at lumbar spine(LS), femoral neck(FN) total hip(TH) by dual energy X-ray absorptiometry technique, and we checked thoracic and lumbar vertebral fractures by X-ray at baseline, 6, and 12 month later. BAP and urine NTX(uNTX) were measured at baseline, 3, 6, and 12 month.[RESULTS]Mean age of the patients of every group was 61-63 years. The mean percent change from baseline to 36 month in LS/FN/TH BMD was +3.7/+3.5% in GroupA, +3.3/-0.7% in GroupR, +2.0/-2.2% in GroupE4, +0.7/-1.9% in GroupE2, and +0.5/2.4% in GroupD. The mean percent change in BAP/uNTX was -25.7/-37.9% in GroupA, -23.2/-23.8% in GroupR, -8.2/-26.7% in GroupE4, -13.1/-11.2% in GroupE2, and +3.9/-7.7% in GroupD. The frequency of incidental vertebral fracture (per 100 person-year) for latter 30 months was 1.8 in GroupA, 1.9 in GroupR, 7.3 in GroupE4, 8.7 in GroupE2, and 16.8 in GroupD. Reductions in risk of vertebral fractures were 89% in GroupA, 88% in GroupR, 56% in GroupE4, 48% in GroupE2[CONCLUSIONS]ALN increased both LS and FN BMD significantly, and RIS also increased LS BMD. ALN and RIS decreased both BAP and uNTX significantly, cyclic EHDP400mg also decreased uNTX. ALN, RIS and cyclic EHDP400mg reduced the risk of vertebral fractures by less than half. These effects were superior to that with cyclic EHDP200mg or VD alone.

Prevalence of Severe Suppression of Bone Turnover Among Patients with Atypical Osteoporotic Fractures. N. Napoli¹, D. Novack¹, K. M. Diemer^{*1}, M. Watkins¹, S. L. Teitelbaum², R. C. Armamento-Villareal¹. ¹Div. of Bone and Mineral Diseases, Washington University in St Louis, St Louis, MO, USA, ²Department of Pathology, Washington University in St Louis, St Louis, MO, USA.

Recent reports of patients on long-term bisphosphonates (BPs) developing fragility fractures in sites that are not typical for osteoporosis with bone biopsy findings suggestive of severe suppression of bone turnover (SSBT), have raised important safety concerns on the prolonged use of the drug. This study is a retrospective analysis of the patients (14 women and 6 men) at the Bone Health Program at Washington University School of Medicine who underwent bone biopsy because of unusual osteoporotic fractures (femoral shaft, pelvis, rib, metatarsal, shoulder) from November 2004 to January 2007. Ten of 15 patients were found to have biopsy findings consistent with SSBT, defined as total absence of double tetracycline labels in trabecular bone. There were no significant differences in bone mineral density by DEXA, clinical and biochemical data (age, BMI, serum Ca, alkaline phosphatase, PTH, Vitamin D) between the 2 groups, except for the duration of therapy. On the average, SSBT cases took BPs for a significantly longer period of time than non-SSBT (6.1 ± 0.58 vs 3.9 ± 0.83 , $P = 0.05$). Histomorphometric analysis also demonstrated significantly lower Ob.S/BS (0.57 ± 0.28 vs 2.23 ± 0.42 , $P < 0.01$), but no difference in Oc.S/BS, in cases of SSBT. Our findings suggest that a majority of patients treated with BPs who develop fractures at sites not typical of osteoporosis have SSBT, and that duration of BP therapy is a risk factor. Further studies are needed to determine whether patients at risk for SSBT and atypical fracture can be identified clinically, without biopsy. Given the large numbers of patients who have been treated with BPs for >5 years without atypical fractures, and reports of normal turnover in a random sample of treated patients (Black DM et al., JAMA, 2006 Dec 27;296(24):2927-38) the overall risk for SSBT in all patients taking BPs is low. However, it is important to define the subpopulation at risk for these atypical fractures.

CFOS Trial: Alendronate Once Weekly for the Prevention and Treatment of Osteoporosis in Canadian Adult Cystic Fibrosis Patients. A. Papaioannou¹, C. C. Kennedy¹, G. Ioannidis¹, J. O'Neill^{*2}, C. Webber², M. Pui^{*2}, A. Freitag^{*1}, R. Josse^{*3}, A. Cheung^{*3}, Y. Berthiaume^{*4}, H. Rabin^{*5}, N. Paterson^{*6}, A. Jeanneret^{*4}, E. Matouk^{*7}, J. Villeneuve^{*8}, R. McCallum^{*1}, M. Nixon^{*1}, J. D. Adachi¹. ¹Medicine, McMaster University, Hamilton, ON, Canada, ²Radiology, McMaster University, Hamilton, ON, Canada, ³Medicine, University of Toronto, Toronto, ON, Canada, ⁴Medicine, Centre hospitalier de l'Université de Montréal, Montreal, PQ, Canada, ⁵Medicine, University of Calgary, Calgary, AB, Canada, ⁶Medicine, London Health Science Centre, London, ON, Canada, ⁷Medicine, Montreal Chest Institute, Montreal, PQ, Canada, ⁸Medicine, Le Centre hospitalier universitaire de Québec, Quebec City, PQ, Canada.

Introduction: A multicentre, randomized controlled trial (RCT) was conducted in adults with cystic fibrosis to assess the efficacy and safety of oral alendronate (FOSAMAX®). This is the only Canadian RCT to examine a bisphosphonate in this patient population. **Methods:** Patients received placebo or alendronate 70 mg once weekly for 12-months. All patients received 800 IU Vitamin D and 1000 mg calcium (500 mg supplementation, 500 mg from diet) daily. Patients age 18 years and older with cystic fibrosis (confirmed by positive sweat test or DNA analysis) with a bone mineral density (BMD) T-score <-1.0 were eligible for inclusion. Patients with a prior organ transplantation; endoscopy-proven esophagitis, gastritis, ulceration; metabolic bone disorders; severe renal disease; or using systemic corticosteroids (dose of 7.5 mg/day or greater) in previous 6-months, were excluded. The primary measure was percent change in lumbar spine (LS) BMD after 12-months. Secondary measures were percent change in total hip BMD, proximal femur (PF) BMD, and N-telopeptide after 12-months. **Results:** A total of 56 patients (34 males, 22 females) were enrolled in the study. The mean age was 29.1 (SD=8.78) years. Mean baseline 25-OHD was 60.3 (SD=27.9) nmol/L. Five patients (4 Placebo, 1 Alendronate) had a new vertebral fracture (all Grade 1) during the study. The number of withdrawals was equal between the treatment groups (4 Alendronate, 4 Placebo). Over 12-months, the active treatment group had a 4.99% (95% CI: 2.40, 7.59) greater increase in LS BMD and a 3.50% (95% CI: 1.37, 5.63) greater increase in PF BMD compared with the placebo group (adjusted for age, body mass index, baseline BMD, number of baseline vertebral fractures).

Conclusion: Patients with cystic fibrosis are at risk for early bone loss due to several factors including delayed pubertal maturation, glucocorticoid therapy, malabsorption of vitamin D, poor nutritional status, inactivity, and hypogonadism. Alendronate was well tolerated and produced a significantly greater increase in BMD over 12-months compared with placebo.

The Bisphosphonates Cause Inflammatory Response In Vivo and in Human Peripheral Blood Mononuclear and Polymorphonuclear Cells In Vitro. W. Park¹, M. Lim¹, S. Kwon¹, S. Hong¹, S. Lee². ¹Medicine/Rheumatology, IN-HA University Hospital, Incheon, Republic of Korea, ²Medicine/Rheumatology, Konkuk University Hospital, Seoul, Republic of Korea.

Bisphosphonates (BPs) are currently mainstay therapy for various clinical conditions including osteoporosis, Paget's disease, multiple myeloma, and metastatic bone disease. However BP associated osteonecrosis of jaw (ONJ) and influenza-like illness were reported mainly in patients who received intravenous (IV) BPs. Therefore we speculated that high blood concentration of BP after IV or intermittent large oral dose would cause inflammatory reaction and the reaction would be related to those side effects.

Five patients with idiopathic osteoporosis without recent bisphosphonate, glucocorticoid, or the immunosuppressant use were selected. They were given 30 mg of IV pamidronate. Acute phase reactants such as erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were measured for 3 days. The in vitro effects of BP on the mRNA expression of the pro-inflammatory cytokines was measured using the human peripheral blood mononuclear (PBMC) and polymorphonuclear (PBMNCs) cells isolated by centrifugation over Histopaque-1077 and Histopaque-1119 (Sigma, 1119-1, St. Louis, MO, USA). The isolated PBMCs and PBMNCs were incubated in RPMI-1640 containing alendronate 0, 1, 5, 25, 125 μ M for 18 hours. One million cells were harvested to extract RNA. The real-time RT-PCR quantified the expression of the interferon (IFN)- γ , TGF- β , interleukin (IL)-1 β , IL-10, IL-6, RANKL, TNF- α , TRAP, cathepsin-K (CTK).

At baseline, serum CRP level was normal but the level rose 24-72 hours after pamidronate IV infusion (0.08 \pm 0.074 vs. 0.23 \pm 0.240 mg/dL, $p=0.042$, paired T-test). The ESR at the concurrent time did not rise significantly (13.4 \pm 18.02 vs. 15.6 \pm 15.13 mm/hr). Most of the inflammatory cytokines increased after alendronate pulse dose-dependently. The expression of IFN- γ , IL-6, and TNF- α were most prominent in the PBMCs and those of IFN- γ , IL-6, and IL-1 β in the PBMNCs. (Table 1) RANKL and CTK expression were not detectable in PBMNCs.

Acute inflammation caused by BP may be due to its high blood level after intravenous infusion or large intermittent oral dose. The clinical study concerning whether the very slow IV infusion or small dose daily oral therapy would minimize those inflammatory side effects is warranted

Expression of cytokines in human PBMCs after alendronate pulse measured by real time PCR

Alendronate (μ M)	1	5	25	125
IFN- γ	2.7	17.1	73.2	818.1
TGF- β	2.4	3.0	2.2	14.7
IL-1 β	7.4	7.8	10.9	13.8
IL-6	473.8	303.5	1943.6	13934.7

Comparable Adherence and Improvement in Gastrointestinal (GI) Tolerability with Monthly Oral and Quarterly Intravenous Ibandronate in Patients Who Discontinued Previous Bisphosphonates Because of GI Intolerance. V. K. Pizlak¹, A. M. Babbitt², J. D. Kohles³, E. M. Lewiecki⁴. ¹The Children's Hospital at Scott & White, Temple, TX, USA, ²Greater Portland Bone & Joint Specialists, South Portland, ME, USA, ³Roche Laboratories, Inc, Nutley, NJ, USA, ⁴NM Clin Res & Osteoporosis Center, Albuquerque, NM, USA.

The PRIOR study evaluated adherence and gastrointestinal (GI) tolerance to monthly oral (PO) ibandronate 150 mg and quarterly intravenous (IV) ibandronate 3 mg in patients who discontinued previous daily or weekly bisphosphonate (BP) therapy because of GI intolerance.

PRIOR was a 12-month, prospective, open-label, multicenter, noninferiority study in postmenopausal women with osteoporosis or osteopenia. Patients chose either PO or IV ibandronate and could switch formulations once because of side effects. Patients were considered adherent to therapy if adherence (ratio of the actual duration of trial medication intake over the maximum duration of the trial medication intake) was $\geq 75\%$. In comparing the IV and PO groups, the between-group difference in adherence rates was adjusted by propensity score and a 2-sided 90% confidence interval (CI) was constructed. If the upper limit of the CI was $<20\%$, then noninferiority of the adherence of the PO group compared with the IV group was concluded. Patients reported GI symptoms by completing a self-administered GI Experience Survey at screening, and Months 1, 4, 7, and 10.

Of 543 patients in the intent-to-treat population, 147 (27.1%) chose PO and 396 (72.9%) chose IV as the initial therapy. Twenty-seven patients switched administration route; 11 switched to IV ibandronate because of GI intolerance (all completed the study), and 16 patients switched to PO therapy for various reasons, including bone or joint pain (n=4), influenza-like symptoms (n=3), and injection-site reactions (n=3) (5 withdrew prior to study completion). Within the per-protocol (PP) population, 69.7% of patients in the PO group and 82.9% in the IV group were adherent to their originally chosen therapy at study end. Based on the adjusted difference in adherence rates in the PP population, adherence to PO therapy was noninferior to adherence to IV therapy (12.4% difference; 90% CI, 5.1%

to 19.7%). Overall mean GI tolerance scores improved significantly from baseline to all postbaseline assessments for both the PO and IV treatment groups ($P<0.0001$ for both). Both dosing regimens were generally well tolerated.

In this population of patients who had discontinued daily or weekly BP treatment because of GI symptoms, adherence rates were similar between patients on monthly PO and quarterly IV ibandronate. Patients reported improvement of GI symptoms compared with baseline while receiving either form of ibandronate.

Quarterly Intravenous Ibandronate Injections Provide Continuing Benefits in Women with Postmenopausal Osteoporosis: DIVA Study Long-Term Extension. C. Recknor¹, M. Lilliestol², R. Grant³, C. Neate⁴, R. R. Recker⁵. ¹United Osteoporosis Centers, Gainesville, GA, USA, ²Internal Medicine Associates, Fargo, GA, USA, ³Hoffmann-La Roche Inc., Nutley, NJ, USA, ⁴Roche Products Ltd, Welwyn Garden City, United Kingdom, ⁵Creighton University, Osteoporosis Research Center, Omaha, NE, USA.

Oral and intravenous (i.v.) ibandronate are available for treatment of postmenopausal osteoporosis. The daily oral regimen (2.5mg) has proven antifracture efficacy,¹ and in the DIVA trial, i.v. injections of 2mg every 2 months (q2mo) or 3mg every 3 months (q3mo) were shown to be superior to daily oral.^{2,3} After 2 years, patients in the i.v. arms had superior gains in lumbar spine (LS) BMD (q2mo 6.4%, q3mo 6.3%) compared with daily oral (4.8%; $p<0.001$). Gains in total hip (TH) BMD were also superior ($p<0.001$) and reductions in serum CTX were comparable (53.4-59.9%).³

After completion of the 2-year, double-blind DIVA study, patients could be enrolled in a long-term extension (LTE). Eligible patients from the i.v. arms continued to receive open-label i.v. ibandronate at the same dose for a further 3 years (q2mo, n=253; q3mo, n=263), those in the oral arm were re-randomized to receive q2mo (n=128) or q3mo (n=137) i.v. according to whether they had received 2- or 3-monthly i.v. placebo during DIVA. Here we present the LTE first year results.

Further increases were seen after 1 year in LS BMD (q2mo 0.92%; q3mo 0.95%) and TH BMD (q2mo 0.48%; q3mo 0.13%). A pooled analysis evaluating only those patients who remained on the same treatment for 3 years showed 3-year gains in LS BMD of 7.6% (q2mo; $p<0.0001$) and 7.0% (q3mo; $p<0.0001$). 3-year increases in TH BMD were 3.7% (q2mo; $p<0.0001$) and 3.3% (q3mo; $p<0.0001$). The reduction of serum CTX seen in the first 2 years of DIVA was maintained in the LTE. In the pooled analysis, median reductions in peak (30 months) and trough (36 months) serum CTX were 89.0% (q2mo), 92.4% (q3mo), and 40.2% (q2mo), 41.4% (q3mo), respectively. Both i.v. regimens continued to be well tolerated, with a similar incidence of adverse events (AEs) to those seen during the 2 years of DIVA and no evidence of late or cumulative toxicity. Treatment-related AEs were reported in 14% (q2mo) and 9% (q3mo) of patients, with serious AEs in 8% (q2mo) and 9% (q3mo), of which two were considered treatment related (both GI disorders in the q2mo group). Five patients (all q2mo) were withdrawn for AEs. The continuing efficacy benefits and good tolerability seen here show that i.v. ibandronate is a valuable long-term treatment option for postmenopausal osteoporosis.

The Efficacy of Fosamax 35mg a Week for the Treatment of Osteoporosis in Postmenopausal Women with Subclinical Hyperthyroidism. L. Y. Rozhinskaya*, G. A. Melnichenko*, Z. E. Belaya*, G. S. Kolesnikova*, A. V. Iijin*, N. I. Sazonova*. Neuroendocrinology and Osteoporosis, The National Research Centre for Endocrinology, Moscow, Russian Federation.

The aim was to estimate the effects of treatment with alendronate (Fosamax 35 mg) in postmenopausal women with osteoporosis and subclinical hyperthyroidism. Thirty postmenopausal women (64 (60-69) years old) with osteoporosis and subclinical hyperthyroidism (77% with endogenous subclinical hyperthyroidism and 23% on L-thyroxine suppressive therapy after thyroidectomy due to differentiated thyroid cancer) were randomly assigned into two groups: (1) 14 women received Fosamax 35 mg a week in combination with 500 mg of calcium and 400 UI of Vitamin D3 (VD) daily; (2) 16 women received 1000 mg of calcium and 800 UI of VD daily. Euthyroidism was achieved in all women with endogenous subclinical hyperthyroidism. An increase in physical activity was recommended to all patients and a hypolipidemic diet was given to those who had had high cholesterol level. Calcium (Ca), phosphorous (P), creatinine (Cre), alkaline phosphatase (ALP), cholesterol, low density lipoprotein (LDL), high density lipoprotein (HDL), triglycerides (TG), cholesterol/HDL ratio) in fasting serum as well as calcium/creatinine ratio in fasting urine (U-Ca/U-Cre); osteocalcin (OC) and C-terminal telopeptide of type I collagen (b-CTX) serum, BMD (DXA; Prodigy, Lunar) at the lumbar spine (L1-L4), femoral neck (FN), total hip (TH) and radius total (RT) were measured at the baseline visit and after 1 year of treatment. At the baseline visit there were not found any differences between the (1) and the (2) groups. After 12 months of treatment the markers of bone metabolism as well as ALP decreased significantly in both groups, though the decreases were significantly greater ($p < 0.001$ for both OC and b-CTX) in the (1) versus the (2) group. BMD in the (1) group increased by 7.6% at L1-L4 ($p = 0.003$), 2.8% at FN ($p = 0.013$), 3.3% at TH ($p = 0.012$) and 3.2% at RT ($p = 0.047$). There was not detected any BMD loss in the (2) group. The changes were not significant between the two groups. The levels of Ca, P, Cre, U-Ca/U-Cre did not change in both groups. Significant improvements in lipid levels were found: HDL increased ($p = 0.035$ (1) $p = 0.034$ (2)), cholesterol/HDL ratio decreased ($p = 0.011$ (1); $p = 0.004$ (2)). In addition, cholesterol ($p = 0.003$); TG ($p = 0.016$) and LDL ($p = 0.006$) decreased for patients from the (1) group. Conclusion: The achievement of euthyroidism and Fosamax 35 mg a week increase BMD in all regions of the skeleton in postmenopausal women with osteoporosis and subclinical hyperthyroidism and reduce bone resorption significantly more than Calcium and VD supplementation.

Relationship Between Increasing Annual Cumulative Exposure to Ibandronate, Increases in BMD and Reductions in Clinical Fractures. A. Sebban*, R. D. Emkey*, W. A. Blumentals*, P. N. Sambrook*. ¹University of South Florida, Tampa, Palm Harbor, FL, USA, ²Emkey Arthritis and Osteoporosis Clinic, Wyomissing, PA, USA, ³Roche Laboratories, Inc, Nutley, NJ, USA, ⁴Institute of Bone & Joint Research, University of Sydney, Sydney, Australia.

Analyses of the relationship between changes in bone mineral density (BMD) and fracture reduction with bisphosphonate therapy have produced varying results, but only a limited range of doses has been examined. Data from 4 pivotal phase III clinical trials of ibandronate (2 oral and 2 intravenous [IV]) were pooled and analyzed to examine increases in BMD at various annual cumulative exposures (ACEs) in women with postmenopausal osteoporosis.

Data from the intent-to-treat populations, comprising patients who received oral or IV ibandronate or placebo in 4 studies (Study 4380 [IV fracture study], BONE, MOBILE, and DIVA), were pooled. BONE and the IV fracture study were 3-year placebo-controlled fracture trials, and MOBILE and DIVA were 2-year BMD studies that examined fractures as secondary endpoints. Oral doses included 2.5 mg daily, 20 mg intermittent, 100 mg monthly, 2x50 mg monthly, and 150 mg monthly. IV doses included 0.5 mg quarterly, 1 mg quarterly, 2 mg every 2 months, and 3 mg quarterly. ACE was computed by multiplying the drug strength in milligrams by the number of annual doses and by an absorption factor (0.6% for oral and 100% for IV). Rates of BMD increases at the lumbar spine (LS) and total hip (TH) and rates of all clinical fractures over 2 years were calculated. Linear models, weighted by the sample sizes of the trials, were constructed to examine the clinical fracture rate as a function of increases in LS BMD.

This analysis included a total of 8710 patients. Plots constructed to visually observe any potential association between clinical fractures and ACE showed a trend to decreased clinical fractures with increasing ACE. Plots of change in LS BMD vs ACE showed an increase in percentage change in LS BMD with increasing ACE. The same relationship was seen for TH BMD. There was a statistically significant inverse linear relationship between clinical fracture rates and gains in LS BMD (Figure: $\beta = -0.397$, $P = 0.0046$; $R^2 = 0.65$).

Increasing gains in BMD at the LS correlated with decreasing rate of clinical fractures. Higher ibandronate doses were associated with the highest level of BMD gain and lowest rate of clinical fracture.

Figure. Clinical fracture rates vs percent change in lumbar spine BMD at 2 years

Women Are More Persistent with Monthly Bisphosphonate Therapy Compared to Weekly Bisphosphonates: 12 Month Results from Two Retrospective Databases. S. L. Silverman¹, J. A. Cramer^{2*}, J. A. Sunycz^{3*}, C. Sarawate^{4*}, C. Harley^{5*}, W. A. Blumentals^{6*}, S. Poston^{7*}, E. M. Lewiecki⁸. ¹Cedars-Sinai Medical Center, Beverly Hills, CA, USA, ²Yale University, West Haven, CT, USA, ³Laurel Highlands Ob/Gyn, Hopwood, PA, USA, ⁴HealthCore, Inc., Wilmington, DE, USA, ⁵i3 Innovus, Eden Prairie, MN, USA, ⁶Roche, Nutley, NJ, USA, ⁷US Health Outcomes, GlaxoSmithKline, Research Triangle Park, NC, USA, ⁸NM Clin Res & Osteoporosis Ctr, Albuquerque, NM, USA.

This study evaluated medication persistence among patients receiving monthly ibandronate versus weekly bisphosphonates. The 12-month results of 2 retrospective database analyses are presented here.

Deidentified patient data were obtained from 2 large managed care claims databases (provided by i3 Innovus and HealthCore Integrated Research Network™) in parallel studies. The combined databases represent over 30 million covered lives. In both studies, eligible women were ≥ 45 years of age and filled ≥ 1 pharmacy claim(s) for a weekly or monthly bisphosphonate from April 1, 2005 to November 30, 2006 (i3 Innovus) or October 31, 2006 (HealthCore). Baseline data were collected for 6 months prior to the index date (date of first prescription filled). Persistence, defined as continuous use, was evaluated at 12 months based on a refill gap of 30 days for weekly bisphosphonates; a gap of 45 days was used for monthly ibandronate because of its longer dosing window. Persistence was assessed using Cox proportional hazard models to control for baseline characteristics and potential confounders such as patient age, co-pay amount, comorbidities, long-term prescriptions, concomitant medications, fracture history, and prior DXA scans.

The i3 Innovus database provided claims data from 3,512 women prescribed monthly ibandronate and 13,967 prescribed weekly bisphosphonates. The HealthCore database included 1,006 women receiving monthly ibandronate and 10,658 receiving weekly bisphosphonates. The analyses determined that women on monthly therapy demonstrated higher persistence than women receiving weekly therapy (Table). After adjusting for age, co-pay and comorbidities, monthly users were 25.1% and 37.7% less likely to discontinue therapy versus weekly users in the i3 Innovus and HealthCore analyses, respectively (Table).

	Monthly ibandronate (unadjusted rate)	Persistence at 12 months		Adjusted hazard ratio (95% CI)	P value
		Weekly bisphosphonates (unadjusted rate)	P value		
i3 Innovus	35.7%	24.8%	<0.0001	0.749 (0.702-0.796)	<0.0001
HealthCore	36.3%	26.9%	<0.0001	0.623 (0.575-0.676)	<0.0001

The 12 month results of these analyses suggest that women prescribed monthly ibandronate are more persistent than women on weekly bisphosphonates.

Oral Monthly Ibandronate Is Associated with Rapid Suppression of Serum CTX Within Three Days of Treatment Initiation. S. L. Silverman¹, E. Barrett-Connor^{*2}, C. Simonelli³, J. D. Kohles^{*4}, G. Dasic⁵, N. C. Binkley⁶.

¹Cedars-Sinai Medical Center/UCLA, Beverly Hills, CA, USA, ²University of California at San Diego, La Jolla, CA, USA, ³Health East Osteoporosis Care, Woodbury, MN, USA, ⁴Roche Laboratories, Inc, Nutley, NJ, USA, ⁵GlaxoSmithKline, King of Prussia, PA, USA, ⁶University of Wisconsin, Madison, WI, USA.

The purpose of the Rapid Onset study was to examine the speed of onset and pattern of suppression of the bone resorption marker serum C-terminal telopeptide of type 1 collagen (sCTX) in postmenopausal women with osteoporosis treated for 6 months with monthly ibandronate.

Rapid Onset was a randomized, double blind, placebo-controlled study of women diagnosed with postmenopausal osteoporosis within the past 12 months and with no more than 3 months exposure to daily or weekly bisphosphonate therapy for the 5 years before screening. Participants received once monthly oral ibandronate (150 mg) or placebo for 6 months. Levels of sCTX were measured at baseline and Day 3 (first month only), as well as on Day 7, 14, 21, and 28 after the doses were administered. The primary study endpoint was the relative change in median sCTX from baseline to Day 3. Responder analyses (defined as $\geq 50\%$ and $\geq 70\%$ sCTX decreases) were also performed.

An Independent Data Monitoring Committee performed the analyses. Sixty-seven women participated in this study; 1 did not take any study drug, 49 received ibandronate and 17 received placebo. Mean baseline sCTX measurements levels were the same (0.63 ng/mL) for patients receiving ibandronate and placebo. Rapid suppression of sCTX occurred in those receiving ibandronate; median sCTX was reduced by almost 70% within 3 days of ibandronate administration ($P < 0.0001$ vs placebo) and remained suppressed at day 28 (median decrease of 43% from baseline, [$P = 0.0014$ vs placebo]). In contrast, in the placebo group, the median sCTX was reduced by almost 6% on Day 3 and the maximum median percent change in sCTX from baseline was 22% on Day 14. A high proportion of women responded to ibandronate; at Day 3, 71% of patients receiving ibandronate had $\geq 50\%$ decreases in sCTX and 47% had $\geq 70\%$ decreases in sCTX. No patients receiving placebo were considered to be responders at Day 3. This study demonstrated that ibandronate treatment rapidly decreases sCTX levels within 3 days of treatment initiation.

Daily or Intermittent Oral Ibandronate Preserves Trabecular Microarchitecture: Micro-Computed Tomography Analysis of Patients in the 3-Year BONE Study. L. G. Ste-Marie¹, B. Langdahl^{*2}, D. Masanaukaite^{*3}, D. Ethgen^{*4}, R. R. Recker⁵.

¹CHUM Université de Montreal, Montreal, PQ, Canada, ²Aarhus University Hospital, Aarhus, Denmark, ³F. Hoffmann-La Roche Ltd, Basel, Switzerland, ⁴GlaxoSmithKline, Collegeville, PA, USA, ⁵Creighton University, Osteoporosis Research Center, Omaha, NE, USA.

In postmenopausal osteoporosis, trabecular bone microarchitecture contributes significantly to overall bone strength. Micro-computed tomography (microCT) is a quantitative 3D scanning procedure used to assess trabecular architecture. In the 3-year BONE study, oral ibandronate (IBN) administered daily (2.5mg) or intermittently (20mg every other day for 12 doses every 3 months) significantly reduced vertebral fracture risk (primary endpoint) by 62% ($p=0.001$) and 50% ($p=0.006$) respectively; significantly increased lumbar spine and proximal hip bone mineral density (BMD) and reduced markers of bone turnover, vs placebo (PBO).¹ 2D histomorphometric analysis of biopsies taken at months 22 and 34 of the study indicated that newly formed bone was of normal quality.² In the current analysis, biopsies have been analyzed by microCT to assess 3D trabecular microarchitecture. Biopsies were analyzed at Creighton University with a Scanco microCT 40 scanner (Scanco Medical, Bassersdorf, Switzerland) and rod and plate distribution quantified by differential analysis of the triangulated bone surface. The structural model index (SMI), was then calculated, with a lower SMI indicating an increased ratio of plates to rods and thus improved trabecular microarchitecture. Biopsies were obtained from 110 patients, with 84 evaluable by microCT (28 PBO, 56 IBN [both arms]). Median SMI was 1.001 with IBN vs 1.365 with PBO (90% CI for difference in medians: -0.626, -0.033) and connectivity density was higher in IBN-treated patients (median 3.904 vs 3.112/mm³, 90% CI for difference in medians: 0.159, 1.517). This indicates that trabecular microarchitecture was better preserved in patients receiving IBN than PBO. Additional measurements showed that IBN is consistently beneficial on multiple parameters of bone structure and architecture vs PBO. Taken together with previous results from the BONE study showing reduced fracture risk, improved BMD and decreased bone turnover as well as histomorphometric and hip structural analyses,³ these findings indicate that treatment with ibandronate preserves bone strength by maintaining good quality trabecular microarchitecture in women with postmenopausal osteoporosis.

10-Years-Follow-Up of a Pregnancy-associated Osteoporosis (PAO). A Clinical Case Report. U. C. Stumpf¹, J. Windolf^{*1}, W. J. Fassbender².

¹Department of Traumatology and Handsurgery, University Hospital, Duesseldorf, Germany, ²Department of Internal Medicine, Hospital z. Hl. Geist, Kempen, Germany.

Pregnancy-associated osteoporosis (PAO) is an uncommon condition characterized by the occurrence of painful fractures during late pregnancy or lactation. The pathophysiology of this disease is uncertain, and its therapeutical management is poorly defined. At the moment exist no guidelines for the therapy. Although rare, diagnosis of pregnancy-associated osteoporosis should be suspected when lumbar or thoracic spine pain occur during pregnancy or in the post-partum period as it can lead to multiple vertebral fractures. Case report: A 41-years-old, premenopausal, slim (BMI= 19) woman is accompanied by pain of the whole spine and the bone in general since 10 years. Within her adolescence she got traumatic fractures of the jaw, metatarsus and toes. She had two pregnancies 10 and 8 years ago. Since the first pregnancy a PAO was known, which impaired after the second one. A secondary cause is the treatment for asthma bronchiale over 12 years with inhalative, intermittent oral, corticosteroids (CS) in the range between 5-16 mg /die. Seven years ago, the first DXA-scan was performed and showed a t-score (L2-L4): -2,1 (z-score:-2,0); medication started with etidronate, calcitonin and supplementation of calcium and vitamin D3. In the DXA-scan after 1 year, a consolidation of the PAO could be observed (t-score L2-L4: -1,7; z-score:-1,6). With this medication back pain got under control. 5 years ago, the patient had a horse-riding accident with an instable burstfracture of L1, which was stabilised by internal fixator from Th12 to L2. In the actual DXA-scan an increase of bone mineral density up to a t-score L2-L4 of -1,3 (z-score:-1,3) was observed. In the first laboratory investigation an overall low turnover of bone was seen, due to CS therapy without accelerated bone resorption, PTH and vitamin D3 in normal range. Furthermore a low estradiol (24 pg/ml range: 0.0 - 270.00 female) despite regular menstrual cycle was noticed. We started a combined osteoporosis (ibandronate 3 mg iv /12 weeks) and pain treatment (level I WHO) with supplementation of 1000 mg calcium and 800 IU vitamin D3 per die.

Conclusion: As we can observe in this long time follow up the PAO accompanies the patient their whole life and should not be underestimated. We conclude that it is necessary to avoid a long course of pain and fractures in these young women in order to treat the PAO initially adequate with antiresorptive or even osteoanabolic substances to obtain a fast consolidation of BMD and to lower the risk of further fractures and chronification of pain.

The Effects of Risedronate and Raloxifene on Serum Lipid Levels in Postmenopausal Women. H. Suh^{*}, K. Lee^{*}. Family Medicine, Gachon Medical School, Gil Medical Center, Incheon, Republic of Korea.

Purpose: Some studies in other countries have reported that the intravenous injection of bisphosphonate and the oral administration of raloxifene, which are used in the prevention and treatment of osteoporosis, have the effect of lowering lipid levels. However, there have been no studies on the effect of the oral administration of bisphosphonate. Furthermore, there have been no studies on the effect of raloxifene in Korea. Thus, we studied the effect of typical bisphosphonate medication, risedronate and raloxifene, classified as SERM(Selective Estrogen Receptor Modulator) on the serum lipid levels of post-menopausal Korean women.

Methods: At a certain university hospital, each 199 postmenopausal women who had either taken 35mg of risedronate per week or 60mg of raloxifene daily for at least 1 year were selected. We followed them up and compared their baseline serum lipid levels with that of 1 year after.

Results: The risedronate group showed a valid decrease in the level of total cholesterol, LDL cholesterol, non-HDL cholesterol($P<0.05$). The raloxifene group showed a valid decrease in the level of total cholesterol, LDL cholesterol, non-HDL cholesterol($P<0.05$) and showed a valid increase in HDL cholesterol levels($P<0.05$). The raloxifene group showed a valid decrease in the level of total cholesterol, LDL cholesterol, non-HDL cholesterol compared to the risedronate group($P<0.05$)

Conclusions: In post-menopausal Korean women, the oral administration of risedronate and raloxifene reduced total cholesterol, LDL cholesterol and non-HDL cholesterol levels. As well, raloxifene showed superior effects to risedronate.

Efficacy and Safety of Alendronate for the Treatment of Glucocorticoid-induced Osteoporosis in Children: A Prospective Multicenter Study in Japan. H. Tanaka¹, Y. Seino². ¹Pediatrics, Okayama University, Okayama, Japan, ²Pediatrics, Osaka Koseinenkin Hospital, Osaka, Japan.

OBJECTIVE: Glucocorticoid-induced Osteoporosis (GIOP) is being increasingly reported even in children. And efficacy and safety of the use of oral bisphosphonate treatment have been established in adult area. But few randomized control trials have been published and its efficacy and safety are still controversial in growing children. In this preliminary study, we evaluated the effect of an oral bisphosphonate (alendronate) on bone mass in children under long-term glucocorticoid treatment. **METHODS:** Fifty six children under long-term (over 6months) glucocorticoid treatment were randomly assigned into 2 groups; 30 children (Group A) were treated with alfacalcidol and alendronate, and 26 (Group B) were treated with only alfacalcidol as a control for 2 years. We measured lumbar bone mineral density (LBMD) and metabolic bone markers (NTx and Bone specific ALP) every 6months. **RESULTS:** Mean LBMD at the start of the trial was 88.7% and 86% of the healthy Japanese children in group A and B respectively. In group A, Mean LBMD increased to 93.6 % (6 months), 98.5 % (12 months) and maintained until the end of the trial, while it decreased to 83.3 % (6 months) and 80.5 % (12 months) and then continued to decreased slowly in group B. Urinary excretion of NTx decreased by 33.7 % at 6 month while it increased by 9.6 % in group B. Considering their condition, increases in the height of all patients but one enrolled in this trial was satisfactory. No new fractures were observed in group A, but multiple vertebral fractures were observed in one case of group B. **CONCLUSION:** Bisphosphonates can be considered essential components of the treatment of GIOP, not only in adults, but also in pediatric patients. Alendronate has a positive effect on GIOP in children.

Identifying the Treatment Care Gap in Postmenopausal Women at the Southlake Regional Health Centre: The Role of a "Shared Care" Model. C. Thorne¹, G. Ioannidis², L. Fraser^{*1}, E. Ng^{*1}, J. D. Adachi². ¹Southlake Regional Health Centre, Newmarket, ON, Canada, ²McMaster University, Hamilton, ON, Canada.

Inadequate osteoporosis management in patients with fragility fractures has been well documented in Canada. We performed a patient chart audit to examine the treatment care gap in postmenopausal women 50 years of age and older with at least one fragility fracture and who were admitted to the acute musculoskeletal inpatient nursing unit in the Southlake Regional Health Centre (Newmarket, ON, CAN) in 1999 (T1), 2003 (T2) and 2005 (T3). During this time period, a "Shared Care" program was developed where by all patients with fragility fractures admitted by orthopedic surgeons were seen by one of two rheumatologists. The program began in 1999 and was fully implemented in 2005. The treatment care gap was defined as any fracture patient who was not on therapy at the time of discharge (potential therapies included bisphosphonates, calcitonin, raloxifene and parathyroid hormone). Exact multivariable logistic regression analysis was performed to determine how the treatment care gap changed from T1 to T3. Covariates included in the analysis were patients' history of osteoporosis (yes/no), past osteoporosis medications (yes/no), age of patient (years), length of hospital stay (days), and most responsible physician (orthopedic surgeon, rheumatologist, or general internal medicine physicians alone). Odds ratios (OR) and 95% confidence intervals (95% CI) were calculated. A total of 27, 43 and 44 patients with fragility fractures were evaluated at T1, T2, and T3, respectively. Of these patients, 90, 86 and 96% had a hip fracture. The mean (standard deviation) age, and length of hospital stay of the patients were 81.1 (7.7) years and 8.2 (5.8) days at T1, 79.0 (9.6) years and 10.5 (14.0) days at T2, and 84.8 (7.9) years and 9.6 (7.9) days at T3. The number (%) of patients with a history of osteoporosis and past osteoporosis drug use were 2 (7.4) and 0 (0.0) at T1, 20 (46.5) and 10 (23.3) at T2, and 26 (59.1) and 25 (56.8) at T3. A large number (%) of responsible physicians were orthopedic surgeons (T1=27 (100%), T2=36 (83.7%), T3=34 (77.3%)). The number (%) of patients on therapy at the time of discharge was 0 (0.0), 13 (30.2) and 35 (79.6) at T1, T2, and T3 respectively. As compared with treated patients at T1, the OR of patients treated in T2 and T3 was 1.6 (95% CI: 0.166,∞), and 20.3 95% CI: (2.6,∞). A patient's history of osteoporosis (OR= 12.5, 95% CI: 2.4, 128.2) and past osteoporosis medications (OR= 6.2, 95% CI: 1.2, 45.5) was associated with higher treatment rates. In conclusion, the treatment gap at the health centre has decrease from 1999 to 2005. The development of the "Shared Care" program has resulted in improved management of patients with fragility fractures.

Two-Consecutive Days-a-Month Risedronate 75 Mg (2Cd) Reduces Vertebral Fracture Risk at One Year. N. Watts¹, J. Brown^{*2}, G. Cline^{*3}, P. D. Delmas⁴. ¹University of Cincinnati, Cincinnati, OH, USA, ²Laval University, Quebec City, PQ, Canada, ³Procter & Gamble Pharmaceuticals, Mason, OH, USA, ⁴INSERM Research Unit 403, Lyon, France.

The antifracture efficacy of new osteoporosis therapies is usually based on placebo-controlled trials, but inclusion of a placebo arm in subsequent clinical trials may be limited by practical or ethical considerations. In these cases, use of historical controls can be explored as an interesting alternative. To assess the anti-fracture efficacy of this new regimen, we analyzed fracture data in an active-controlled study of risedronate dosing regimens (the 2CD study) using matched historical controls from previous placebo-controlled trials. Women in the 2CD study were matched for age, years since menopause, BMD and prevalent vertebral fractures, with placebo patients in the Vertebral Efficacy of Risedronate Therapy (VERT) trials, forming an historical placebo group. We also constructed an historical active-treatment group from the risedronate 5 mg daily arm of the VERT trials for comparison with the 5 mg daily (n=613) and 2CD (n=616) treatment groups in the 2CD study; historical control groups consisted of daily placebo patients (n=99, matched from 993) and risedronate 5 mg daily patients (n=96; matched from 990) in the VERT studies. Over 1 year of treatment, risk of new vertebral fractures in the 2CD group (1.1%) was reduced by 79% relative to the historical placebo group (5.1%) (OR 0.21; 95% CI, 0.05 to 0.88, P=0.016), similar to the 1-year risk reduction observed in the VERT trials of risedronate 5 mg daily (61-65%). The incidence of new vertebral fractures, assessed for internal validation, was similar in the three treatment groups: 1.0% in the historical risedronate 5 mg group, 1.5% in the risedronate 5 mg daily group from the 2CD study, and 1.1% in the 2CD group. The use of appropriate historical control data provides an approach to the assessment of fracture effects in osteoporosis trials for which placebo-controlled data are not available. Risedronate 75 mg for 2 consecutive days each month appears as effective as the 5 mg daily dose in reducing the risk of new vertebral fractures in the first year of treatment.

Disclosures: N. Watts, Procter & Gamble Pharmaceuticals 5.

Vertebral Fracture Efficacy with Risedronate Is Apparent Early and Is Sustained. N. B. Watts¹, C. Roux^{*2}, X. Zhou^{*3}, A. Grauer³. ¹University of Cincinnati, Cincinnati, OH, USA, ²Cochin Hospital, Rene Descartes University, Paris, France, ³Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Treatment with an agent that provides both early and sustained fracture protection can benefit patients. Superficial examination of published studies suggests that the early effect of treatment on vertebral fracture (as reflected in relative risk reduction) may lessen over time. In this study, absolute vertebral fracture risk reduction was examined in the Vertebral Efficacy with Risedronate Trials (VERT).

The population included 2442 patients from VERT-NA and VERT-MN who were treated with at least 1 dose of either placebo or risedronate (RIS) 5 mg daily. The mean age was 69 and the mean spine T-score was -2.5. Treatment groups were balanced with respect to key baseline characteristics. Fracture endpoints included clinical vertebral fracture and radiographic vertebral fractures. Difference in risk of vertebral fractures between placebo and RIS 5 mg groups was estimated using the difference of the Kaplan-Meier (KM) estimators at months 3, 6, ... and 36.

The findings for clinical vertebral fracture were consistent with the rapid onset of risk reduction with risedronate treatment; relative to placebo, RIS significantly reduced the risk for clinical vertebral fracture starting from Month 6, with significant absolute risk reduction of 1.0% (95% CI: 0.3%, 1.6%). The magnitude of the difference in fracture risk between the placebo and risedronate 5 mg groups increased over time (Figure). Relative to placebo, RIS significantly reduced the risk for radiographic vertebral fracture starting from the first scheduled radiographic visit at one year. In general, the mean magnitude of the difference in the fracture risk between the placebo and risedronate 5 mg groups increased over time (from 5.3 % at 12 months up to 8.6%, (95% CI: 5.5%, 11.6%).

In summary, the results confirmed the risedronate rapid protection against clinical vertebral fracture as early as Month 6. Further, risedronate anti-vertebral fracture efficacy as reflected in absolute fracture risk reduction increased over 3 years for both clinical and radiographic vertebral fractures

Difference and 95% CI Of Clinical Vertebral Fracture Risk Between Risedronate and Placebo Groups

Difference and 95% CI Of Radiographic Vertebral Fracture Risk Between Ris 5mg and Placebo Groups

Long-term Bisphosphonates Therapy and Increase Fracture Risks. S. J. Wimalawansa. Medicine, Div. Endocrinology, UMDNJ-RWJMS, New Brunswick, NJ, USA.

Bisphosphonate have been in the market for over 2 decades. However, no credible evidence available on fracture benefits of continuation of bisphosphonate therapy >5 years. The terminal half-life of alendronate is similar to bone mineral, ~10 years, while risedronate is ~2 years. The skeletal effects of these two bisphosphonates last for years after stopping therapy. Studies with alendronate show 5 years after discontinuation of therapy, patients bone marker levels remain below the pretreatment levels.

The patients on long-term bisphosphonate therapy continue to maintain their BMD with reduced bone remodeling markers. Once bisphosphonate therapy is discontinued, BMD is stable for about 1 to 2 years depending on bisphosphonate used. Increase in bone remodeling, as indicated by markers of bone turnover will occur before reduction of BMD begins. Therefore, bone markers are much sensitive indicators than BMD to consider starting bisphosphonate or another therapy following discontinuation of bisphosphonate.

Current data suggest that discontinuation of bisphosphonate after 4 to 5 years of therapy does not increase fracture risks, but may in fact be beneficial to patients. Whereas, patients who continue to have fractures while on therapy are non-compliant, or likely to have an underlying secondary cause of bone loss. After several years' therapy with bisphosphonates, stable BMD (with suppressed bone turnover markers) or demonstration of normal histology by biopsy does not signify that the drug protects against fractures. Not only biopsies can miss generalize trends, but also the very small sample sizes used in these studies give false sense of security of the safety of long-term bisphosphonate use. Although the optimal duration of treatment with bisphosphonate (or any therapy) for osteoporosis is uncertain. Data accumulating to suggest that there are no benefits to patients by continuation of therapy beyond five years. The only useful therapy to be continued in the long-term is calcium and vitamin D supplementation. To-date, no independent data available on fracture efficacy of long term anti-osteoporosis medications; this need to be critically evaluated. Prospective clinical trial addressing this issue is underway at this institute. It is now a decade since the first FDA approval of bisphosphonates for osteoporosis. It is time now to examine this issue seriously and to develop clinical practice guidelines (and cost-benefit analysis) for minimizing complications of long-term use of bisphosphonates. This pro-active measure may save millions of tax payer dollars and other health costs (i.e., cost of unnecessary drug therapy, management of complications, and the potential for increased fractures incidence).

Bringing Bone Health to Seniors' Communities: A Unique Approach to Help Manage Osteoporosis. M. Kloseck^{*1}, M. van Zandvoort^{*2}, R. Crilly³, M. Speechley^{*4}. ¹Faculty of Health Sciences, University of Western Ontario, London, ON, Canada, ²Department of Health and Rehabilitation Sciences, Faculty of Health Sciences, University of Western Ontario, London, ON, Canada, ³Department of Medicine, University of Western Ontario, London, ON, Canada, ⁴Department of Epidemiology and Biostatistics, University of Western Ontario, London, ON, Canada.

Osteoporosis is preventable and treatable, yet there is a significant care gap in Canada. We hypothesized that engaging seniors in raising awareness, identifying neighbours and others in their community at risk and a peer-led senior-friendly education program would increase diagnosis and treatment of osteoporosis, and that ongoing peer support would encourage compliance and persistence with medication and lifestyle change. This hypothesis is being tested in a randomized controlled trial (RCT). In Phase 1 (completed) community capacity building and participatory action research methodology was used to train seniors in a local community to act as peer educators and mentors within their community. Ten seniors (mean age=82 yrs. \pm 6.74 yrs. SD, range=71-90) participated in a 2-week training program containing 5 osteoporosis education modules and 1 session on public presentation skills delivered by local experts. Once trained, these seniors formed the Community Osteoporosis Advisory Committee which collaboratively developed a peer advisor training manual, designed a community information and recruiting program, and developed a senior-friendly education and support program which they practiced until all were comfortable. Pre- and post-knowledge surveys showed a statistically significant change ($p=.04$) in knowledge from project start to end of Phase 1. Confidence by seniors in their role as osteoporosis advisors increased significantly ($p=.02$), as did confidence in their ability to deliver information to their neighbours through community presentations ($p=.02$). Overall confidence in their role as peer educators and mentors increased significantly from project start to end of Phase 1 ($p=.01$). In Phase 2 (in progress) the senior-led education and support program is being tested in a RCT ($n=100$) in a local community of seniors ($n=2500$, mean age=79 \pm 9.53 SD). Outcomes include BMDs performed, treatments begun, appropriateness of treatment and persistence. Preliminary baseline knowledge surveys ($n=33$, mean age=81 \pm 7.18 yrs. SD, range 67-91 yrs., 97% female, 3% male) show a substantial gap in knowledge. On the 19-item osteoporosis questionnaire the mean correct minus incorrect score=6.15 \pm 4.79 SD. Scores ranged from -4 to 16 out of 19. Forty-one percent reported having fallen in the past year. This unique approach to diagnosing and treating osteoporosis may be a useful model for other communities of seniors.

Compliance with Osteoporosis Treatment and Incidence of Hip and Wrist Fracture after Forearm BMD Screening. M. W. J. Davie, T. Jones*, N. Dugard*. Charles Salt Research Centre, Robert Jones & Agnes Hunt Orthopaedic Hospital NHS Trust, Oswestry, United Kingdom.

Treatment compliance in osteoporosis may affect fracture outcome. To investigate compliance and fracture after a screening programme, we revisited 1299 women aged 50-97y screened by forearm scanning after a minimum of 3 years. Women were scanned at the request of their doctor (GP) and treatment advised if BMD values were $<0.34\text{g/cm}^2$ (osteoporosis (OP)). Treatment was decided by the woman's GP. No follow up was arranged. Women completed a detailed questionnaire at the scanning visit and again when revisited. Women lost to follow up were traced through health records and treatment details between scanning and revisit obtained from the women's own GP. 74% of women returned their questionnaires with no difference between those osteoporotic and those not. Fractures were validated with a 10% sample (and were correct within 5%).

All but 98.5% were traced of whom 14.4% had died. 254 women had osteoporosis at the first visit (aged 50-9, 2.4% had OP, 60-9 15.8%, and >69 54.3%). Of these 37.4% had never started any treatment (excluding Ca and Vit D only) - with no difference across ages. 1.3% had HRT and 98.7% Bisphosphonate (BP) of which 38% used Didronel, 43% Fosamax and 19% had had >1 BP. Compliance with BP dropped to 73.8% after 1yr (no difference across ages) with 22.9% only collecting 1 script. Fewer women with OP in institutions had ever had treatment (28%, $p<0.01$) and were also more likely to stop treatment (28.6% had only 1 script). Excluding women who were no longer available compliance at 2yr was 68.3%, 3yr 58.6%, 4yr 50% and 49.6% at 5yr. Hip fracture occurred in 1 woman with OP out of 38 (age 76.6 \pm 8.1y) who were never treated and in 7 of 55 women (73.2 \pm 7.3y (age $p<0.05$)) fully compliant for 5yr. The excess in women fully compliant occurred after >3y treatment (2 had used Didronel, 2 Fosamax, 3 both). Wrist fractures occurred in 3 women in each group.

Compliance declined early suggesting early follow up is indicated. Treatment in institutions may be overlooked. Compliance is not necessarily associated with hip fracture reduction. However the age of patients with hip fracture (75% were >80y) is consistent with BP efficacy being less in this age group. Moreover most of the hip fractures occurred >3y after treatment started when BP may be less effective at preventing hip fracture.

An Outreach Program Improved Osteoporosis Management after a Fracture. A. C. Feldstein¹, W. M. Vollmer^{*1}, D. H. Smith^{*1}, A. Petrick^{*1}, J. Schneider^{*1}, H. Glauber^{*2}, M. Herson^{*2}. ¹Center for Health Research, Kaiser Permanente Northwest, Portland, OR, USA, ²Northwest Permanente, Portland, OR, USA.

This longitudinal retrospective cohort study evaluated implementation of a 2-phase intervention to improve management of osteoporosis after a fracture. Stakeholder barriers and facilitators of osteoporosis management were also determined. The study setting was a nonprofit group model HMO in the U.S. Pacific Northwest with 15 clinics, 480,000 members, and comprehensive electronic medical record data. Study participants were women members aged 67 or older who sustained a qualifying clinical fracture(s) and who had not received a bone mineral density (BMD) measurement or osteoporosis treatment in the 12 months prior to the fracture (n=3588) and their 255 primary care providers (PCPs). Interviews/focus groups were conducted with 58 patients, health care managers, PCPs, and orthopedic clinicians. Phase 1 included outreach to clinicians and patients; Phase 2 added clinician/staff incentives. The primary outcome was "osteoporosis management" receipt of a BMD measurement or osteoporosis medication in the 6 months after an index fracture. Prior to the intervention, 13.4% (95% confidence interval [CI] = 12.0%-14.8%) of fracture patients had received osteoporosis management; the pre-intervention time trend was not significant. After the intervention, the unadjusted probability of osteoporosis management increased on average by 3.1% (95% CI = 2.6%-3.5%) every 2 months throughout both study phases. There was no significant added improvement in Phase 2. Overall, the probability of osteoporosis management increased from the baseline level to 44.0% (95% CI = 40.0%-48.0%) by the end of the study period (20 months post intervention). Adjusted models revealed that osteoporosis management was less likely in older patients and in those with dementia and was more likely in those with fractures more highly associated with osteoporosis. Improvement varied by clinic and was less likely for patients with dementia. Patient knowledge gaps and fatalism were common, especially among older patients. Common clinician barriers were lack of time, difficulty interpreting all relevant results, patient management concerns in the transition from specialty to primary care, and frustration with the side effects of and poor patient adherence to osteoporosis medications. This study found that an outreach program to clinicians and patients improved the management of osteoporosis after a fracture. More-tailored interventions may be necessary for high-risk subgroups. There is also a need for more effective patient and clinician education and a stronger role for specialists.

Adherence to Raloxifene Therapy: Assessment Methods and Relationship with Efficacy. J. Finigan¹, J. A. Clowes², M. A. Paggiosi^{*1}, D. K. Swindell^{*1}, K. E. Naylor^{*1}, N. F. A. Peel¹, R. Eastell¹. ¹Academic Unit of Bone Metabolism, University of Sheffield, Sheffield, United Kingdom, ²Mayo Clinic School of Medicine, Rochester, MN, USA.

Adherence to study medication is usually estimated by counting returned tablets. This method relies on subjects' honesty and may be inaccurate.

We aimed to assess adherence more accurately, and examine its effect on measures of bone response, by using monitoring caps on the medication bottles in two 2-year studies of osteopenic women, ages 50 to 80. Study 1: 75 women took 60 mg Raloxifene. Study 2: 50 were randomised to take 60 mg Raloxifene (n=25) or no treatment (n=25). Electronic caps (MEMS, Aardex) recorded the date and time whenever the bottle was opened. Returned tablets were also counted. We measured bone mineral density (BMD) by DXA at the lumbar spine (LS) and total hip (TH) twice, a week apart, at baseline and 2 years. Percentage changes from mean baseline to mean 2-year BMD were calculated. We measured urinary NTX from samples taken while fasting on 4 consecutive mornings at baseline, 1 and 2 years. We calculated the mean NTX for baseline and the mean for years 1 and 2 combined, and hence the mean percentage change since baseline.

Combining data from both studies, 100 women took Raloxifene, of whom 29 withdrew during the 2 years. Adherence was assessed by both methods for 71 subjects as a percentage of the total study days. The two methods correlated significantly ($p < 0.001$, Spearman's $\rho = 0.73$) but the tablet count showed a higher mean adherence than the MEMS caps (91.4% v 79.8%, $p < 0.001$), with greater divergence at lower adherence levels. Using the MEMS results for 65 subjects with complete data, adherence correlated with NTX response ($p < 0.01$, $\rho = -0.33$) but not BMD response (LS $p = 0.087$, $\rho = 0.21$, TH $p = 0.25$, $\rho = 0.15$). However there was a threshold effect, with adherence in the lowest quartile associated with poorer BMD response at LS (+0.61% v +2.10%, $p = 0.040$) and at TH (-0.66% v +0.91%, $p = 0.012$).

Monitoring caps may assess adherence more accurately than tablet counts. The degree of adherence is associated with both bone turnover and BMD responses.

Adherence and Persistence with Teriparatide Therapy in Commercial Insurance Plans and Managed Medicare. S. A. Foster¹, K. A. Foley^{*2}, E. S. Meadows^{*1}, J. A. Johnston^{*1}, S. Wang^{*2}, G. M. Pohl^{*1}, S. R. Long^{*2}. ¹Eli Lilly and Company, Indianapolis, IN, USA, ²Thomson Medstat, Ann Arbor, MI, USA.

The purpose of this study was to evaluate adherence to teriparatide (TPTD) therapy and to identify the factors that impact persistence. Beneficiaries (45 years and older) with at least one claim for teriparatide in 2003 or 2004 and continuous enrollment in the previous 12 months and subsequent 6 months were identified in a large (7.6 million covered lives) national commercial and Medicare administrative claims database (MarketScan). Adherence was assessed through the calculation of the medication possession ratio (MPR) at 6 months and 12 months. The MPR was calculated as the sum of days supply dispensed between the start of the observation period and the end of the observation period and divides that number by the total number of days being examined. Persistence was calculated as the time (days) to discontinuation (meaning the last prescription for the index drug regardless of gaps in fills - with at least 2 months remaining enrollment without the script). In addition, factors associated with time to discontinuation in treatment were assessed using Cox proportional hazards models. The average age of patients in this analysis was 70.3 and 89.7% were female. In the 12 months prior to initiating TPTD, 38% of patients had experienced a fracture. The average MPR at 6 months was 0.74 (N=2218) and 12 months was 0.66 (N=1303). At 6 months (N=2218), 64.6% of patients remained on TPTD therapy and at 12 months (N=1303), 56.7% of patients remained on TPTD. Prior use of an antiresorptive therapy, having BMD screening within the 12 months prior to starting TPTD, and lower patient copayments were associated with longer times until discontinuation. Overall, despite being an injectable, TPTD adherence was comparable with adherence rates found with other osteoporosis medications in the literature. Understanding the factors that impact persistence with therapy may allow clinicians to make informed decisions about patient selection that may improve persistence.

Patient Perceptions and Reasons for Discontinuing Teriparatide Treatment: Initial Results from the DANCE Observational Study Addendum. D. T. Gold¹, D. L. Weinstein^{*2}, G. Pohl^{*3}, K. D. Krohn³, E. Meadows^{*3}. ¹Psychiatry & Behavioral Sciences, Sociology, and Psychology, Duke University, Durham, NC, USA, ²Medicine, Washington University, St. Louis, MO, USA, ³Outcomes Research, Eli Lilly, Indianapolis, IN, USA.

Purpose: To determine the perceptions of patients who initiate and persist on treatment with teriparatide (Forteo) for osteoporosis.

Methods: The Direct Assessment of Non-vertebral Fractures in the Community Experience (DANCE) is a multi-center, prospective, observational study. The DANCE addendum includes questionnaires (Q1 and Q2) completed by the teriparatide patients. Administered at initiation of therapy, Q1 includes items related to the patient's experience with self-injection drugs, perceptions about the severity of their osteoporosis, relationships with their prescribing physician and staff, and concerns about starting treatment. The Q2 instrument (completed 2 to 6 months after initiating therapy) includes items regarding training or other support offered at therapy initiation, the patient's early experience with teriparatide treatment (including problems, adverse events, and concerns), and whether the patient is still taking treatment. If the patient has stopped teriparatide treatment when Q2 is completed, the patient is asked to choose one of 6 pre-specified reasons why they stopped treatment.

Results: As of January 2007, 700 patients had completed both Q1 and Q2. The DANCE Addendum patients were relatively homogeneous in their perceptions at initiation of teriparatide treatment. Fewer than 1 out of 4 (n=150, 22%) patients reported that they had previous experience with self-injectable medications. Many (n=409, 59%) patients believed their osteoporosis was severe or very severe. Nearly all (n=662, 95%) believed that it was extremely or very important to treat their osteoporosis. Additionally, some (n=167, 24%) patients were extremely or very concerned about their ability to pay for teriparatide. Few patients (n=50, 7%) reported discontinuing teriparatide treatment by the time Q2 was administered. The reasons for discontinuation are shown below.

Reasons for discontinuation of teriparatide therapy	n	%
concerns about treatment outweighed the benefits	18	2.6
cost issues - difficulty paying for it	14	2.0
taken as long as physician prescribed	7	1.0
problems with injecting	3	0.4
did not believe it was beneficial	2	0.3
too hard to follow all the steps necessary to use Forteo	2	0.3
unspecified	4	0.6
total	50	7.1

Conclusions: Few patients have discontinued teriparatide treatment in the DANCE Addendum before the first follow-up visit 2-6 months after initiation. The 2 most common reasons for discontinuation were (1) that treatment concerns outweighed the benefits of teriparatide and (2) concern about paying for teriparatide.

A Group-based Patient-Education Program Increases Knowledge of Osteoporosis and Adherence to Pharmacological Treatment - A Randomised Trial. D. Nielsen¹, J. Ryg^{*1}, W. Nielsen^{*2}, B. Knold^{*1}, N. Nissen^{*1}, L. Stilgren¹, A. Riis Madsen^{*1}, K. Brixen¹. ¹Endocrinology, Odense University Hospital, Odense, Denmark, ²Physiotherapy, Odense University Hospital, Odense, Denmark.

Purpose: A large number of studies have demonstrated that pharmacological therapy of osteoporosis is effective; however non-adherence to such therapy is a well recognized problem. Few studies, have examined the effect of particular patient education programs on knowledge and adherence to therapy. We hypothesised that group-based, multi-disciplinary, education program increases the patients' knowledge of osteoporosis and adherence with pharmacological therapy. **Methods:** A total of 300 patients (32 men aged 65 ± 9 yrs and 268 women aged 63 ± 8 yrs), recently diagnosed with osteoporosis and started on specific treatment, were randomised to either the "school" (n=150) or "control" (n=150) group. In the school-group, patients attended four classes with 8-12 participants during four weeks (a total of 12 hours). Teaching was performed by nurses, physiotherapists, dieticians, and doctors and was based on dialogs and situated learning. The classes covered "facts on osteoporosis", "fractures and pain", "diet", "preventive measures", "balance and exercise", and "medical treatment". Teaching was designed to increase empowerment. We assessed the patients' knowledge about osteoporosis and compliance to pharmacological treatment, using validated questionnaires. **Results:** At baseline, no significant difference was seen between the groups regarding knowledge score (20.1 ± 5.6 versus 21.0 ± 4.7). The change in knowledge at 3 months was significantly higher in the school group (3.43 ± 4.0) compared with the control group (0.33 ± 2.48) (p<0.001). Adherence with pharmacological therapy at 2 years was significantly higher in the school group (99%) compared to controls (84%) (p<0.001, Log Rank test). Neither baseline knowledge score, nor change in knowledge score, however, was significantly associated with compliance. **Conclusion:** A multidisciplinary patient education program leads to increased knowledge of osteoporosis and increased adherence to treatment. Knowledge, however, did not predict adherence. There are more issues important when it comes to adherence to treatment.

Convenience and Preference Perceptions After 1 Year of Oral Bisphosphonate Treatment in a Group of Brazilian Women. S. Ragi-Eis¹, I. F. Francischetto^{*2}, B. Albergaria^{*2}, A. A. Oliveira^{*2}, F. V. Simões^{*2}, K. Milagre^{*2}, C. Bonomo^{*2}. ¹Clinical Research Department, CEDOES, Vitoria - ES, Brazil, ²Clinical Research, CEDOES, Vitoria - ES, Brazil.

Once monthly dosing (OM) of ibandronate has been shown to provide similar efficacy in increasing BMD to once weekly dosing (OW) of alendronate for treatment of osteoporosis in postmenopausal women. Whether patients will prefer monthly dosing to weekly dosing for a chronic condition such as osteoporosis has not been well documented in a Latin American population. The aim of this study was to assess the preference as well as their perception of convenience for monthly versus weekly dosing regimens among sample of Brazilian osteoporotic postmenopausal women.

One hundred and eighty one postmenopausal women with osteoporosis were originally randomized in the Motion Study, to receive treatment with either (1) alendronate 70 mg once weekly plus once monthly placebo tablet or (2) ibandronate 150 mg once monthly plus once weekly placebo for 12 months. From this subset, 145 (One hundred and forty five) women (80.1%) were interviewed during the follow-up visits, after completion of the study. The patients were asked about the convenience as well as their preference about treatment regimens to continue their treatment.

Among those expressing preference (n=115), 69 % (79) pointed the once monthly dosing regimen as the preferred regimen to continue their treatment from that moment on. The main reasons to justify their option were "better to remember" (30 subject for the OM vs 22 for the OW) and "more favorable time interval" (22 subjects for the OM vs 0). In addition, from the patients expressing opinion about convenience (n=81) the once monthly regimen was considered by 73% (59) to be the more convenient one. The key factor to justify their opinion was "fits better in my lifestyle" (56 subjects for the OM vs 16).

After having the opportunity to try both weekly and monthly regimens for a 12 month period, the majority of the patients preferred the OM one to continue their treatment. They also considered this option the more convenient one. In conclusion, patient preference and convenience perceptions about dosing regimen should also be taken into consideration when taking the decision to prescribe an oral bisphosphonate for Brazilian Women. This could have a favorable impact on treatment compliance.

W384

Persistence with Teriparatide Therapy Among Participants in the DANCE Trial. K. Taylor^{*1}, D. Gold^{*2}, S. Silverman^{*3}, P. Chen^{*1}, M. Wong¹, K. Krohn^{*1}. ¹Eli Lilly and Company, Indianapolis, IN, USA, ²Duke University, Durham, NC, USA, ³OMC Research, Beverly Hills, CA, USA.

Despite the benefits of osteoporosis (OP) therapies shown in clinical trials, poor persistence is a common cause of reduced patient benefit in a "real world" setting [Mayo Clin Proc 2006;81:1013-22]. Overall persistence with OP therapies has been reported to be between 25-45% at 1 yr [Maturitas 2004;48:271-87; Arch Int Med 2005;165:2414-9]. Few, if any, US studies have assessed persistency with teriparatide (TPTD) in community settings. A prescription tracking database [IMS Health LRxTM] estimated persistency with TPTD (20 µg/d) to be about 30% at 12 months (Lilly data on file). The ongoing, observational DANCE study captures data on persistence with TPTD therapy. A survival model (Figure) assesses the rate of patients persisting with therapy at defined time points after their start date. This analysis included 2474 patients who were eligible to have had 12 months of TPTD therapy. The model estimated ~70% of patients persisted with therapy at 12 months.

Persistence was not significantly affected by age, co-morbidity, or baseline severity of OP, as assessed by BMD T-score, prevalent fracture status, or clinical risk factors for fracture. Of these 2474 patients, 419 completed 18-24 months of therapy, 852 discontinued therapy before completing the 18-24 month course, and 1203 remained in the study. Reasons for discontinuation were categorized as patient decision (422, 49.5%), physician decision (136 patients, 16%), serious adverse event (57, 6.7%), sponsor decision (2, 0.2%) and other unstated reasons (172, 20.2%), and 63 patients (7.4%) had no data available. For the 422 patients who listed "patient decision" as the reason for discontinuation, additional comments about their discontinuation were collected, and included insurance reimbursement, inconvenience, and concerns about injection. Persistence with TPTD in DANCE subjects at 12 months may be higher than that measured using a prescription tracking database. Different methodologies used to measure persistence may reflect some of this disparity. Further analysis of the DANCE cohort may elucidate factors affecting persistence to TPTD therapy and offer new approaches to optimize TPTD use in the community.

Safety and Tolerability of Bazedoxifene in Postmenopausal Women with Osteoporosis: Results from a 3-Year, Randomized, Placebo- and Active-Controlled Clinical Trial. J. D. Adachi¹, C. H. Chesnut², J. P. Brown³, C. Christiansen⁴, L. A. Russo⁵, C. E. Fernandes⁶, J. C. Menegoci⁷, A. Kung⁸, A. A. Chines⁹, L. Bessac⁹, D. Chakrabarti⁹. ¹St. Joseph's Hospital - McMaster University, Hamilton, ON, Canada, ²University of Washington, Seattle, WA, USA, ³CHUL Research Center, Laval University, Quebec, PQ, Canada, ⁴Center for Clinical and Basic Research (CCBR), Ballerup, Denmark, ⁵CCBR, Rio de Janeiro, Brazil, ⁶Women's Health and Wellness Institute (ISBEM), São Paulo, Brazil, ⁷San Francisco Clinic, São Paulo, Brazil, ⁸The University of Hong Kong, Hong Kong, China, ⁹Wyeth Pharmaceuticals, Collegeville, PA, USA.

Bazedoxifene (BZA) is a novel selective estrogen receptor modulator selected for clinical development based on preclinical evidence of tissue-selective estrogen agonist activity on the skeletal system and lipid metabolism and estrogen antagonist activity on breast and uterine tissues. A total of 7492 postmenopausal women with osteoporosis (mean age \pm SD, 66.4 \pm 6.7 years) were randomized to receive BZA 20 mg, BZA 40 mg, raloxifene (RLX) 60 mg, or placebo (PBO) daily and received \geq dose of study medication. At 36 months, BZA exhibited a statistically significant decrease in new vertebral fracture compared with placebo (primary efficacy endpoint to be reported elsewhere). We report here the 3-year safety and tolerability data from this study. After 3 years of treatment, BZA was overall well tolerated and exhibited a favorable safety profile. Findings of selected safety/tolerability analyses are shown below.

	No. of Women (%)			
	BZA 20 mg (n=1886)	BZA 40 mg (n=1872)	RLX 60 mg (n=1849)	PBO (n=1885)
Discontinuations	632 (33.5)	643 (34.3)	598 (32.3)	629 (33.4)
Discontinuations due to adverse events	269 (14.3)	270 (14.4)	262 (14.2)	240 (12.7)
Myocardial infarctions	8 (0.4)	8 (0.4)	6 (0.3)	8 (0.4)
Ischemic stroke	13 (0.7)	18 (1.0)	11 (0.6)	13 (0.7)
Hemorrhagic stroke	1 (0.1)	1 (0.1)	1 (0.1)	5 (0.3)
Deep vein thrombosis (DVT)	7 (0.4)	11 (0.6)	8 (0.4)	1 (0.1)
Hot flushes	238 (12.6)	243 (13.0)	222 (12.0)	118 (6.3)
Leg cramps	205 (10.9)	204 (10.9)	216 (11.7)	155 (8.2)
Breast cancer	5 (0.3)	4 (0.2)	7 (0.4)	8 (0.4)
Breast cysts/fibrocystic breast	14 (0.7)	13 (0.7)	32 (1.7)	20 (1.1)

No safety concerns related to the cardiovascular and reproductive systems, including breast, were observed in the BZA treatment groups. There was a higher incidence of DVT in the BZA groups compared with the PBO group. The incidence of breast cancer and cystic/fibrocystic breast disease was lower in women receiving BZA than in those receiving PBO. Transvaginal ultrasonography examinations revealed that BZA had no significant effects on the endometrium or ovaries.

In conclusion, BZA has a favorable safety and tolerability profile in postmenopausal women with osteoporosis. The safety and tolerability profile was similar between BZA 20 and 40 mg groups. BZA is a promising new SERM for the prevention and treatment of postmenopausal osteoporosis.

Postmenopausal Osteoporosis and Weight Gain. A. Bazarra-Fernandez*. ObGyn, Juan Canalejo University Hospital Trust. La Coruña. Spain, La Coruña, Spain.

Background: Recent studies have found weight gained during menopause increase the risk of high blood pressure, the diabetes, heart disease, and has been strongly linked to increased incidence of breast and other hormone-related postmenopausal malignancies. These healthcare concerns have led to the conception of specific products that target menopausal weight gain.

Aim: Looking over weight gain and osteoporosis treatment in climacteric. Material and methods: 20 women who were 44 to 58 years old have been recruited. BMI was increased to age. Those with an intact uterus have moderate to severe vasomotor symptoms associated with the menopause, moderate to severe symptoms of vulvar and vaginal atrophy and risk of postmenopausal osteoporosis. They were ascribed to equal two 10 women groups. One group was assigned to 2 mg drospirenone /1 mg 17 beta- estradiol hemihydrate. The other group treated with 40 mg soy bean.

Results: in the women on 2 mg drospirenone /1 mg 17 beta- estradiol hemihydrate medication decreased, moderate to severe symptoms of vulvar and vaginal atrophy vasomotor symptoms associated with the menopause in regard to the other group treated with 40 mg soy bean. They had weight main loss of 3 kg in one year, (P < 0.05).

Conclusions: Human HRT is in relation to decrease osteoporosis. Nobody noted 17 beta-estradiol is in relation to breast cancer. Estradiol is the same oestrogen produced by the ovaries before menopause. Drospirenone has the unique property of reducing water retention often associated with the use of oestrogen and other synthetic progestin hormones. The impact of obesity on hormone replacement therapy is due to many women associate hormones with weight gain. This late medication formula can be beneficial in minimizing uncomfortable symptoms, such as weight gain, hot flashes, night sweats, and

mood swings, associated with the natural progression of a woman's life cycle. So, it is due to conduct one great try to make clear and more comprehensible these points.

Safety and Tolerability of Bazedoxifene for the Prevention of Postmenopausal Osteoporosis. C. H. Chesnut¹, C. Christiansen², H. C. Hoec², H. Genant³, D. van Duren⁴, A. B. Levine⁵, A. A. Chines⁵, G. Constantine⁵. ¹University of Washington, Seattle, WA, USA, ²Center for Clinical and Basic Research, Ballerup, Denmark, ³University of California San Francisco, San Francisco, CA, USA, ⁴Menox BV, Nijmegen, The Netherlands, ⁵Wyeth Pharmaceuticals, Collegeville, PA, USA.

Bazedoxifene (BZA) is a novel selective estrogen receptor modulator (SERM) selected for its antagonist activity on endometrial and breast tissues. Here we report on the safety and tolerability of BZA for the prevention of postmenopausal osteoporosis in a randomized, double-blind, placebo- and raloxifene-controlled phase III trial. Healthy postmenopausal women (aged \geq 45 years) with lumbar spine or femoral neck bone mineral density T-scores no less than -2.5 (mean, -1.2) were enrolled if they did not have vasomotor symptoms requiring treatment, bone diseases (other than osteoporosis), previous vertebral fractures, or endometrial hyperplasia at baseline. Subjects were randomized to take BZA 10, 20, or 40 mg; raloxifene 60 mg; or placebo daily for 2 years. Efficacy assessments (bone mineral density, bone markers, and lipids) are presented in detail elsewhere. Safety was evaluated based on adverse event (AE) reporting, laboratory analyses, and physical examination. Endometrial and ovarian safety were assessed by periodic transvaginal ultrasound and endometrial biopsy. Of 1,583 women (mean age \pm standard deviation, 57.6 \pm 6.5 years) included in the safety population; 1,113 (70.3%) completed the 2-year study. The rates of treatment-emergent AEs, serious AEs, and discontinuations due to AEs were similar among treatment groups. Vasodilatation was more common with BZA 20 and 40 mg (19.9% and 22.6%, respectively) than with placebo (13.2%; P < 0.05 for both), but similar to raloxifene (18.3%). The incidence of leg cramps was similar across treatment groups (range, 9.3%-11.6%). The incidence of venous thrombotic events with BZA was low (<1%) and similar to that with RLX or placebo. No cases of endometrial hyperplasia or malignancy were diagnosed in women treated with BZA. In conclusion, BZA was well tolerated and had a safety profile similar to placebo in a population of relatively young postmenopausal women. BZA is a new promising SERM that could become an important addition to the available therapies for the prevention of postmenopausal osteoporosis.

Methods of Transition from Hormone Therapy to Raloxifene or Other Regimens Administered to Postmenopausal Women for the Prevention or Treatment of Osteoporosis: The HORTHON Study. G. Christodoulakos¹, V. Drossinos², C. Barker³, E. Korelis², G. Kreatsas¹, & the Hellenic HORTHON Study Group¹. ¹2nd Dpt of Obstetrics & Gynecology, University of Athens, Aretaion Athens Hospital, Greece, ²Dpt of Medical Research, Pharmaserve-Lilly, Athens, Greece, ³EuMIS Statistics, Eli Lilly & Company, Erl Wood, United Kingdom.

HORTHON is a Hellenic prospective observational study designed to investigate the preferred method of transition from hormone therapy (HT) to Raloxifene or other pharmaceutical agents for the prevention or treatment of osteoporosis.

The study design was non-interventional. Patients were asked to sign an informed consent document before entering the study. Inclusion criteria were a postmenopausal status for at least 2 years and continuous treatment with HT for at least 6 months prior to inclusion.

494 patients were included in the study, enrolled by 39 investigative sites. Mean age (SD) was 52.2 (5.12) years, mean (SD) age at start of menopause was 47.1 (4.94), mean (SD) time since menopause was 5.2 (4.13) and mean (SD) duration of HT was 4.0 (2.85) years. 49.0% had a history of osteoporosis in mother and 7.7% had a family history of breast cancer. 62.2% of enrolled patients were diagnosed with Osteopenia and 14.8% with Osteoporosis.

83.0% of patients received Raloxifene either as monotherapy (Raloxifene only) or combined mainly with calcium and vitamin D (Raloxifene plus Other), 11.6% received other treatment (Other Therapy) while 5.3% were not administered any therapy, as chosen in the course of normal clinical practice. The primary reason of choice was safety in the "Raloxifene only" (52.8%) and "Raloxifene plus other" (41.0%), while in the "Other therapies" was efficacy (34.5%).

Transition methods included "no wash out and no taper", "wash out only", "wash out and taper" and "taper only" (45.2%, 45.2%, 7.6% and 1.9% of patients respectively). For "Raloxifene only" group, "no wash out and no taper" method applied to 55.9% of patients. "For Raloxifene plus Other" and "Other" new therapies "wash out only" method was chosen for the majority of patients (46.0% and 49.1% respectively). Mean (SD) satisfaction from transition method (taper and/or wash out), estimated by a visual analogue scale, was 32.9 (19.30).

The main reason for discontinuation of HT was prolonged use (42.3% of patients). Mean (SD) satisfaction to previous HT treatment was 30.8 (20.16) while for patients who received no new therapy, satisfaction (SD) was 22.7 (15.48). In this study, patients who discontinue HT, mainly for prolonged use, were more likely to transition to Raloxifene rather than another pharmaceutical agent. Safety is the major reason for choosing the new

therapy. The most frequent transition methods were "no wash out and no taper" and "wash out only".

Possible Role of Equol Status in the Effects of Isoflavone on Bone and Fat Mass in Postmenopausal Japanese Women: A Double-Blind Randomized Controlled Trial. Y. Ishimi¹, J. Oka², S. Uchiyama³, T. Ueno⁴, T. Toda⁴, M. Uehara⁵, J. Ezaki¹, J. Wu⁶. ¹Nutritional Epidemiology Program, National Institute of Health and Nutrition, Tokyo, Japan, ²Home Economy, Tokyo Kasei University, Tokyo, Japan, ³Saga Nutraceuticals Research Institute, Otsuka Pharmaceutical Co. Ltd., Saga, Japan, ⁴Fujico Co. Ltd., Kobe, Japan, ⁵Nutritional Science, Tokyo University of Agriculture, Tokyo, Japan, ⁶Central Research Laboratory, Nisshin Oillio Group, Ltd., Yokosuka, Japan.

Introduction: Equol is more biologically active than its precursor daidzein, which is the principal isoflavone found in soybean. There are inter-individual differences in the ability to produce equol; this may lead to differences in the effects of isoflavone intervention on human health. This study aims to investigate whether the effects of soy isoflavones on bone and fat mass are related to an individual's equol status.

Methods: We performed a 1-year double-blind randomized trial to compare the effects of isoflavone (75 mg of isoflavone conjugates/day; equivalent to 47 mg/day of aglycone form) with those of placebo on bone mineral density (BMD), fat mass, and serum isoflavone concentrations in early postmenopausal Japanese women who were classified based on their equol-producer phenotype.

Results: After 1-year, the isoflavone intervention significantly increased serum equol concentration in the equol producers but not in the nonproducers. In the isoflavone group, the annualized changes in the BMD of the total hip and inter-trochanteric regions were -0.46% and -0.04%, respectively, in the equol producers and -2.28% and -2.61%, respectively, in the nonproducers; these values were significantly different ($p < 0.05$ for both the regions). Significant differences were observed between the equol producers and nonproducers in the isoflavone group with regard to the annualized changes in the fat mass. No significant difference in the annualized changes in the BMD and fat mass was observed between the equol producers and nonproducers in the placebo group.

Conclusions: Our data suggest that the preventive effects of isoflavones on bone loss and fat accumulation in early postmenopausal women depend on an individual's equol-producing capacity.

Success and Complication Rate of Percutaneous Vertebroplasty (PVP) in Patients with Osteoporosis (OP). M. Gaugg¹, F. Kanel², P. Breiter², W. Kump², B. Kutil¹, L. Erlacher¹. ¹Internal Medicine, Division of Rheumatology and Osteology, SMZ Süd, Vienna, Austria, ²Radiology, SMZ Süd, Vienna, Austria.

Background: Percutaneous vertebroplasty (PVP) is an evidence-based, minimally-invasive procedure to manage pain and vertebral spine deformation after vertebral compression fracture (VCF) in patients with OP^{1,2}. **Objective:** To describe success and complication rates in patients affected by VCF and treated by PVP in specialized clinical care, to evaluate their clinical and treatment characteristics. **Materials and Methods:** Data were collected retrospectively by review of examination reports. PVP was performed by two interventionists. CT fluoroscopy guided PVP with additional guidance by conventional C-arm fluoroscopy was performed as described previously^{3,4}, between October 2003 and February 2007. **Results:** A total of $n = 133$ procedures were available for analysis. PVP was performed in $n = 85$ patients [71 females/14 males, mean age 75.5 ± 9.5 a; (53-93a)]. Post-interventional cement leakage was found in 44/85 patients (51.7%) or 50/133 vertebrae (37.6%). The location of the leakage was distributed as follows: 9.7% ($n = 13$) to basivertebral veins, 5 % ($n = 7$) to paravertebral structures including paravertebral veins, 15 % ($n = 20$) to adjacent vertebral disc (upper or lower end plate), and 7% ($n = 10$) to epidural venous system. All PVP's were completed successfully with conscious sedation and local anesthesia. During treatment of 133 vertebrae (TH4-L5), no clinically evident neurologic or embolic events occurred. There was no procedure related mortality. **Conclusion:** PVP can be performed safely and effectively in patients with OP and VCF. Post-interventional cement leakage is found frequently by combination of CT and conventional fluoroscopy. However, clinically relevant neurologic and/or thromboembolic complications may be rare with careful patient selection by clinicians and appropriate radiologic imaging.

Health-related Quality Of Life 7 Years After Hip Or Vertebral Fractures. I. Hallberg¹, M. Bachrach-Lindström¹, G. Toss², A. C. Ek¹. ¹Dept of Medicine and Care, Div of Nursing Science, Faculty of Health Sciences, Linköping University, SE-581 85 Linköping, Sweden, ²Dept of Medicine and Care, Div of Internal medicine, Faculty of Health Sciences, Linköping University, SE-581 85 Linköping, Sweden.

In a previous paper we reported that women with vertebral fracture had severe reduction of health-related quality of life two years after a fracture. In order to estimate the long-term impact of osteoporotic fractures on HRQOL we examined 67 women, 7 years after a hip or vertebral fracture. Patients were otherwise attending routine primary health care. HRQOL was evaluated by the SF-36 questionnaire and compared with a local age-matched reference material ($n = 804$). High scores in SF-36 indicate better HRQOL. Bone mineral density (BMD) was measured with Hologic 4500A. Physical function was assessed by handgrip strength (Jamar dynamometer) and static balance on dominant leg with eyes open. The number of the vertebral fractures was evaluated by lateral radiographs of the spine and calculation of spinal deformity index (SDI, range 0-39), according to the Genant visual semiquantitative criteria.

At the 7 year investigation 51 women had one or more vertebral fractures (9 of which also had a hip fracture). Mean SDI was 5.7 (range 1-25). Of the women with a hip fracture 16 were without vertebral fractures. Mean age (SD) was in vertebral fracture group 76.0 (4.7) and in hip fracture group 73.6 (4.2) years ($p = 0.07$). Bisphosphonate treatment was used by 23 of 67 women (17/51 and 6/16 respectively, n.s.).

HRQOL (SF-36) was reduced in the vertebral fracture group regarding physical function ($p = 0.005$), role-physical ($p < 0.001$), bodily pain ($p < 0.001$), role-emotional ($p = 0.046$), vitality and social function ($p = 0.06$). Women with hip fracture ($n = 16$) but no vertebral fracture did not differ from the reference material.

In the total fracture group ($n = 67$) static balance showed a significant positive correlation ($p < 0.05$) to SF-36 regarding all 8 domains (range $r_s = 0.268-0.549$). Also handgrip strength correlated in all domains except role-emotional (range $r_s = 0.261-0.387$). SDI showed negative correlation to all domains except physical function, general health and mental health (range $r_s = -0.269-0.346$). Age showed negative correlation to vitality and mental health (range $r_s = -0.246-0.292$). BMD in hip or lumbar spine did not correlate with any domain in SF-36.

In conclusion women with vertebral fractures still had pronounced reduction of most HRQOL domains 7 years after fracture and treatment in routine health care. The long-term reduction of HRQOL and its correlation to static balance and handgrip strength raise questions for further investigation.

Importance of Balloon Kyphoplasty in the Management of Vertebral Fractures. J. Hamon^{*}, P. Longis^{*}. Orthopedie, Hospital, Saint-Nazaire, France.

Objectives: To show the importance of balloon kyphoplasty, in the management of vertebral compression fractures of the elderly and vertebral fractures secondary to cancer. This minimally invasive procedure is designed to reduce the fracture, correct the deformity, stabilize the lesion by injection of cement, decrease the pain, limit the hospitalization time and improve the patients' quality of life.

Methods: Retrospective study from Dec 2005 to Apr 2007. All patients older than 40 years and presenting with a vertebral compression fracture or a metastatic vertebral fracture, localized between T6 and S4 without neurological complication, were included. The procedure is performed under general anesthesia and is characterized by controlled inflation of 2 small balloons under fluoroscopic control in order to correct the vertebral deformity before injection of the cement. **Results:** 44 patients, 26 women and 18 men were included in the study, 51 vertebrae were treated. The average age is 64 years. 35 vertebral compression fractures (from T7 to L4) and 16 metastatic vertebral lesions (from T6 to S4) were treated (2 prostate, 3 pulmonary, 3 hematologic, 5 gastro-intestinal, 1 gynecologic and 2 neuro-endocrine primary cancer). For traumatic fractures, mean fracture age is 67 days. Pre-operative use of analgesics, according to the classification of the W.H.O., is of level 1 in 8 patients, level 2 in 11 patients and level 3 in 25 patients. The mean cement volume injected per vertebra is 5 cc. For the trauma lesions, height restoration of the anterior vertebral body wall is on average 15% lost height restored and the correction of the local kyphosis is 5°. Cement leakages in the adjacent discs are found in 9 patients without any clinical consequences. No post-operative complications were seen. Post-operative mobilization is on average on day 1. Hospital discharge is on average on day 2. Post-operatively prescribed analgesics, according to the classification of the W.H.O., are of level 1 in 29 patients, level 2 in 9 patients and level 3 in 6 patients. 38 patients returned home, 6 patients needed revalidation (1 because of associated traumatic lesions and 5 patients needed specialized care for their primary tumor).

Discussion: The usual treatments of this type of vertebral lesions as well as their frequent adverse events are known. The interest of Kyphoplasty is thus highlighted. The review of the literature also highlights the advantages of this technique compared to vertebroplasty. **Conclusion:** Balloon kyphoplasty is an alternative with reduced surgery time, good safety profile, early mobilization and without need for bracing. Balloon kyphoplasty allows reduction in analgesics consumption, an early hospital discharge and improvement of the patients' quality of life.

Significant Reduction of Vertebral Fractures: Comparison of Rehabilitation of Osteoporosis Program-Exercise (ROPE) versus No-ROPE, With or Without Pharmacotherapy. D. A. Kurmen Figueroa*, M. Sinaki. Physical Medicine and Rehabilitation, Mayo Clinic, Rochester, MN, USA.

The objective of this study was to determine whether patients with osteoporosis who received the Rehabilitation of Osteoporosis Program-Exercise (ROPE) had reduced risk of vertebral fracture as compared with those who did not (No-ROPE). To avoid bias in choice of treatment, none of the subjects or evaluators had knowledge of group assignment. We reviewed the medical records of 200 patients. One hundred and twelve patients with osteoporosis met the inclusion criteria, i.e. women older than age 40 with the diagnosis of osteoporosis, baseline and follow-up radiographs of spine. Patients with steroid-induced bone loss and active malignancy were excluded. Two groups were formed: 71 subjects in the ROPE group and 41 subjects in the No-ROPE group met the enrollment criteria. Follow up was the date of follow up x-rays or recurrence of fracture/back pain. The duration of follow up ranged from 3 months to 118 months with an average of 45.5 months. The results showed that fifty-six of the 71 ROPE subjects (78.9%) and 20 of the 41 No-ROPE subjects (48.8%) had no new fracture at the time of final follow up. Interestingly, 56 subjects (78.9%) of the 71 ROPE subjects had received pharmacotherapy whereas all 41 (100%) of the No-ROPE subjects had received pharmacotherapy for bone loss. The 79% of the ROPE population without new fracture were distributed as: 29.6% combination therapy, 26.8% bisphosphonates only, 9.9% calcium only, and 12.7% no pharmacotherapy. The 49% of the No-ROPE population without new fracture were distributed as: 26.8% combination therapy, 17.1% bisphosphonates only, and 4.9% calcium only. In the population taking some kind of pharmacotherapy, 21.1% had new fractures during the time to follow up in the ROPE group versus 51.2% in the No-ROPE group. The No-ROPE group was four times more susceptible to fracture during the time to follow up ($P = 0.001$), Pearson Chi Sq test. The group with the lowest incidence of fractures was the ROPE group with combination pharmacotherapy. To prevent vertebral osteoporosis fractures, we enthusiastically suggest that ROPE be mandatory for management of every woman with osteoporosis, regardless of choice of pharmacotherapy.

Relationship Between Serum 25-hydroxyvitamin D₃ Concentration and Walking Ability, Leg Strength, or Balance in Community-Dwelling Japanese Frail Elderlies. J. Okuno*, S. Tomura*, H. Yanagi*, N. Yabushita*, T. Okura*, K. Tanaka*. Graduate school of Comprehensive Human Sciences, University of Tsukuba, Tsukuba City, Japan.

The aim of this study was to evaluate the relationship between serum 25-hydroxyvitamin D₃ (25OHD) concentration and walking ability, muscle strength, or balance in community-dwelling Japanese frail elderly. The study was a longitudinal study conducted in a town near Tsukuba city (latitude 36° north) from June to September, in 2005 and 2006. Forty-five participants were community dwelling elderly aged 65 years and over who required minimum support or nursing care to maintain their ADL. Their mean age was 76.5±5.9 years (mean±SD, range: 65-90). Of the participants, 32 attended a 3-month exercise program for nursing care prevention once per week (exercise group). The remaining 13 received only advice for nursing care prevention (control group). The Ethics Committee of University of Tsukuba approved the study. An interview was conducted based on a questionnaire including score of functional capacity of ADL (Tokyo Metropolitan Institute of Gerontology (TMIG) score), experiences of fall, stumbling and body sway during the past one year, walking ability, and the frequency of going outside of the home. The serum levels of 25OHD, intact parathyroid hormone (iPTH) and calcium were measured. The following physical tests were performed at baseline and 3 months: Timed Up & Go (TUG) and a 5-meter walk for walking ability, functional reach and foot balance with open eyes for balance, trunk flexion for flexibility, and ankle strength and grip strength for muscle strength. Among 45 patients who underwent the tests, 66.7% and 40% had difficulties in standing up and in walking, respectively. 54.3% experienced falls, 73.8% experienced stumbling and body sway more than once during the past one year. The mean level of 25OHD was 62.1±13.7 nmol/L (mean±SD, range: 27.5-87.5). At baseline, the rate of 25OHD levels less than 50 nmol/L that is the cut-off point of 25OHD resulting from the significant difference of intact PTH level was 18.0%. At baseline and 3 months there were no significant differences in physical tests between the control group and the exercise group. The subjects with 25OHD levels more than 50 nmol/L at baseline improved their walking ability and ankle strength for a period of three months in both groups. On the other hand, the subjects with 25OHD levels less than 50 nmol/L did not improve their physical performance even in the exercise group. It is suggested that serum 25OHD level is related to walking ability and muscle strength in Japanese frail elderly, and that serum 25OHD level more than 50 nmol/L may be needed for maintaining their mobility or balance.

Disclosures: J. Okuno, None.

Treatment of Osteoporotic Vertebral Body Fractures by Means of Percutaneous Balloon Kyphoplasty. Long Term Results of a Prospective, Clinical Trial. T. R. Blatter*, Trauma & Reconstructive Surgery, Leipzig University, Leipzig, Germany.

Introduction: Balloon kyphoplasty is a minimally-invasive, percutaneous surgical technique for reduction and stabilization of osteoporotic vertebral body fractures. However, there is no prospective, clinical trial on long term results concerning the safety and efficacy of the method so far.

Patients and Methods: This prospective, clinical trial investigated both safety and efficacy of percutaneous Balloon kyphoplasty. All vertebrae were stabilized with Polymethylmethacrylate (PMMA). Pre- and postoperatively, the following data were acquired: subjective rating of pain (Visual Analog Scale, VAS), bisegmental endplate-angle (EA2), anterior and posterior height of vertebra. Inclusion criteria were osteoporotic fractures of vertebral bodies in the thoracolumbar spine, patient age ≥ 65 years, fracture age ≤ 4 months, and t-score ≤ -2.5 (DEXA). Exclusion criteria were tumor lesions and additional posterior instrumentation.

Results: 352 vertebrae of 314 patients suffering from acute pain could be included with a minimum-follow up of two years. The average patient age was 74 years (57-92). Average t-score was -2.7. (-3.1 to -2.5). 262 patients suffered from pain for three weeks on average, whereas 52 patients were not able to recall the onset of pain. Fractures were only localized within the thoracolumbar spine with only A type of injuries occurring. 309 of 314 patients experienced marked pain-relief as expressed on the VAS (2.1 ± 1.9 to 8.2 ± 1.5 ; 0 "worst" to 10 "best"). Average correction of EA2 was 6.2°. The anterior vertebral height could be restored by 7.4 mm on average, posterior height by 3.0 mm. There were no neurological complications. In 32 (9.1%) vertebrae, we saw intraoperative leakage of cement (6 (1.7%) out of these with epidural leakage), however, no clinical consequences had to be noted. There were 6 (1.7%) cases of intraoperative balloon-perforation, and 11 (3.1%) cases of subsequent vertebral body fractures in the adjacent level.

Conclusion: Balloon-kyphoplasty is an efficient, and minimally-invasive therapeutic option for the treatment of painful vertebral body fractures having its focus on cases with underlying osteoporosis. Depending on the age and type of fracture, this treatment can obtain a significant rate of fracture reduction that is being maintained over the course of two years minimum. Compared to current literature on vertebroplasty, this technique presents fewer leakage complications at equal long term success in reducing pain.

Disclosures: T.R. Blatter, Kyphon Europe 5.

Life Quality in Patients with Surgically Treated Vertebral Stenosis and the Relation with Bone Quality. I. D. A. Nemes*, D. V. Poenaru*, H. Vermesan*, R. Prejbeanu*, D. Vermesan*, I. Branea*, M. Dragoi*, O. Bereteu*, R. Onofrei*, E. Amarica*, D. Popa*, I. Ilia*, C. Nemes*. ¹Timisoara City University and Emergency Hospital - Rehabilitation and Rheumatology Department, Timisoara "Victor Babes" University of Medicine and Pharmacology, Timisoara, Romania, ²Timis County University and Emergency Hospital - Orthopaedic and Traumatology Department, Timisoara "Victor Babes" University of Medicine and Pharmacology, Timisoara, Romania, ³Medical Lab, Timisoara City University and Emergency Hospital, Timisoara, Romania.

Purpose: To establish the ratio of real vertebral stenosis versus those supposed to be and to assess life quality of patients with surgically treated vertebral stenosis and to the relation with bone quality.

Methods: In 3 years period from 380 patients considered to have vertebral stenosis, only 130 had the real disease. They were divided in 3 therapy groups: 25 patients with mild to moderate symptoms and a conservative treatment; 46 patients with more severe symptoms and surgically treated with decompressive laminectomy ± chypophoveroplasty; 59 patients with severe symptoms and surgically treated with decompressive laminectomy + instrumented fusion.

All patients benefit from diet, pain management, antiosteoporotic drugs in group II and III and physical therapy (local analgetic electrotherapy, biofeed-back training of the local muscle and Williams programme in group I/ biofeed-back training of the local muscle and Florida Spine Institute post-operative protocol in group II and III). All patients were evaluated, regarding their life quality, according to WOMAC scale at baseline, day 21 and at 3 month and DXA bone densitometry and lab parameters of bone metabolism were performed at 40 patients of group III.

Results: In group I and II the three months evaluation showed a clinical and functional improvement. The clinical and functional status of the third group patients was significantly improved at 3 month assessment. A "slow" evolution was seen at 40 patients after six months, despite the fact that DXA scores and lab parameters had an improvement.

Conclusion: The ratio of vertebral stenosis/ vertebral hernia is almost 1/3 in our area. If the conservative therapy applied in moderate forms has no significant result in 3 month we should consider the surgical therapy as the appropriate therapy. As a result of the protocol's applying a better life quality, related with DXA scores and lab parameters, was seen. The difference in outcomes between the post surgical evaluations in group III may be due to the type or intensity of the rehabilitation programme followed after the hospitalization period or cultural issues, patients having greater expectation from the surgical treatment than this is meant to realise.

Disclosures: I.D.A. Nemes, None.

Adjacent Fractures in the Thoracic and Lumbar Spine after the Treatment with Balloon-Kyphoplasty - 2 Years Prospective Follow-up. R. Pflugmacher*. Centrum für Muskuloskeletale Chirurgie, Charité - Universitätsmedizin Berlin, Berlin, Germany.

Purpose: To evaluate the long-term outcomes of 57 patients with 87 osteoporotic vertebral fractures, located in the thoracic and lumbar spine, treated with Balloon Kyphoplasty.

Material and Methods: 63 patients (20 males and 43 females) with 96 osteoporotic vertebral fractures were treated with Balloon Kyphoplasty. We were able to have a 2 year follow up in 57 patients with 87 vertebrae treated. Symptomatic levels were identified by correlating the clinical presentation with conventional radiographs, CT and / or MRI. During the 2 year follow-up reduction in pain was determined. The effects on pain symptoms were measured on a self-reported Visual analog Scale (VAS) and the Oswestry score was documented to assess disability. Radiographic scans were performed pre- and postoperatively and after 3, 6, 12 and 24 months. The vertebral height and kyphosis angle were measured to assess the restoration of the sagittal alignment.

Results: The median pain scores (VAS) improved significantly from pre- to post-treatment as did the Oswestry Disability Score ($p < 0.001$). This improvement was maintained at 2 year follow up. In 9 patients (15.8%) (6 female, 3 male) an adjacent fracture occurred in 12 vertebrae (13.8 %) within 2 weeks to 22 months follow-up. In four patients the adjacent fractures were asymptomatic. Five patients with symptomatic adjacent fractures were treated again with Balloon Kyphoplasty. Clinically asymptomatic cement leakage occurred in 12 of 96 vertebral bodies (12.5 %). During 2 year follow-up this surgical technique demonstrated restoration and stabilization of the height of the vertebral body.

Conclusion: Balloon Kyphoplasty is an effective minimal invasive procedure for the stabilization of osteoporotic vertebral fractures leading to a statistically significant reduction of pain status.

Disclosures: R. Pflugmacher, None.

Improving Trunk Strength and Endurance in Older Women with Vertebral Fractures. K. M. Shipp, D. T. Gold, C. F. Pieper*, K. W. Lyles. Duke University, Durham, NC, USA.

The trunk musculature is important for people with osteoporosis. First, strong, fatigue-resistant trunk muscles are necessary for erect postural alignment. Second, strong trunk extensors may prevent vertebral fractures. An observational study associated trunk extension strengthening over 2 years with decreased incidence of vertebral fractures in the next 8 years [Sinaki M et al. Bone 2002;836-841]. The relationships between trunk alignment, strength, and endurance; functional status; and fracture risk are complex and not yet fully understood.

Results will be presented from a randomized clinical trial of a group exercise intervention (3X/week for 6 months) in older women ($n=122$, mean age 81 years) with vertebral fractures (mean # 2.3) [Gold DT et al. J Am Geriatr Soc 2004;52:1471-1478]. Randomization was by site: 3 trunk exercise intervention sites ($n=53$) and 3 control sites ($n=69$). The trial was a modified cross-over design: the control sites received the exercise intervention after 6 months of health education sessions. The exercises included 1) stretches to increase trunk extension flexibility and 2) progressive resistive strengthening exercises for trunk extensors, abdominals, and posterior scapular groups.

Using mixed-model ANCOVA (intention-to-treat), we found a significant difference between groups for trunk extension strength at 6 months ($p=0.0001$; +6.6 ft-lbs. [up 24%] exercisers, -4.6 ft-lbs. controls). When the control subjects received the exercise intervention, there was a mean increase of 15.0 ft-lbs [up 45%].

An ancillary study examined the effect of the intervention on Timed Loaded Standing (TLS), a measure of combined trunk and arm endurance [Shipp KM et al. Osteoporos Int 2000;11:914-922]. Using mixed-model ANCOVA (intention-to-treat), we found a trend for difference between groups for TLS time at 6 months ($p=0.0542$; +8.8 sec exercisers, -8.9 sec controls). Among compliers (those attending 2/3s of sessions), group was significant ($p=0.035$; +14.9 sec exercisers, -10.3 sec controls). Change in TLS time, but not change in trunk extensor strength, over 6 months was significantly correlated ($p < 0.05$) with change in psychological symptoms and functional status.

These results demonstrated that trunk extension strength and combined trunk and arm endurance could be increased, in older women with vertebral fractures, by 6 months of group, physical therapist-led, trunk-specific exercise classes. Improved trunk endurance was associated with fewer psychological symptoms and better functional status.

Peak Vertical Impact Forces During Backward Falls onto the Buttocks and the Influence of Compliant Flooring. M. M. Sran, S. N. Robinovitch*. Simon Fraser University, Burnaby, BC, Canada.

Fall-related vertebral fractures are common and backward falls result in impact to the buttocks and pelvis. Compliant flooring is a promising technique for reducing impact force and risk for vertebral fracture during a fall. However, we have little knowledge of the peak forces applied to the body during a backward fall, or how floor stiffness affects this force. Our goal was to measure the peak vertical force applied to the buttocks in a backward fall from standing, and to determine whether this force is lowered by reductions in floor

stiffness. Participants included 11 males mean age 25 ± 5 (SD) yrs and body mass mean 81 ± 16 (SD) kg. A tether and electromagnet suddenly released the participant from a backward lean of 15° , causing him to fall backward onto the ground, which was covered with a layer of ethylene-vinyl acetate (EVA) foam rubber. We conducted 5 trials for each of 3 foam thicknesses [4.5 cm (Firm), 7.5 cm (Medium), and 10.5 cm (Soft)]. Participants were instructed to avoid contacting the ground with their hands until their buttocks had contacted the ground, not to squat or step. We measured peak vertical impact forces applied to the buttocks at 960 Hz with a force plate (model 4060H, Bertec Corp.). An 8-camera, 240 Hz motion measurement system (EVA-RT 4.6, Motion Analysis Corp.) was used to track peak velocity (m/s) of a skin surface marker on the sacrum. We also modeled peak vertical force for falls onto a rigid (bare) floor. We used repeated measures ANOVA and post-hoc t-tests to compare peak forces between the 3 conditions ($p = 0.016$). There was a significant difference in peak normalized vertical force (N/kg) between falls onto the Soft foam condition compared with the Medium ($p = 0.002$) and Firm ($p < 0.001$) conditions. Peak normalized vertical force (N/kg) was (mean \pm SD) 63.6 ± 6.2 , 59.9 ± 6.2 , and 56.9 ± 5.9 for Firm, Medium, and Soft respectively. Estimated peak normalized vertical force (N/kg) for the rigid (bare floor) condition was 75.3 ± 7.6 . In comparison to the rigid floor, falling onto the Firm, Medium and Soft floors provided, on average, 15, 20 and 24% force attenuation. This novel data improves our understanding of this mechanism of vertebral injury and is essential if we are to design techniques for the prevention of vertebral fractures, such as protective equipment and safe movement environments. Peak vertical forces were $5099 \text{ N} \pm 868$ (SD) for the thinnest foam condition. Studies report the compressive force required to cause fracture of elderly lumbar vertebrae to be between (mean \pm SD) 3009 ± 1505^1 and $6910 \pm 2480 \text{ N}^2$, similar to the peak loads measured in this study. A thin (4.5cm) layer of foam overlying the floor can provide 15% force attenuation during a fall onto the buttocks. ¹Burklein D et al. J Biomech 2001 ²Cheng XG et al. J Bone Miner Res 1998.

A Community-Based Program to Minimize Osteoporosis and Fractures Risks. S. J. Wimalawansa*, M. Bartello*², K. Morgan*³, M. Wagner*⁴, K. Hodapp*⁵, S. Lachenmayr*⁶. ¹Medicine, UMDNJ-RWJMS, New Brunswick, NJ, USA, ²Memorial Hospital, Morristown, NJ, USA, ³Rutgers University, New Brunswick, NJ, USA, ⁴Rutgers University, Milltown, NJ, USA, ⁵Morristown Memorial Hospital, Morristown, NJ, USA, ⁶NJ Dept. of Health, Trenton, NJ, USA.

In New Jersey (NJ), ~1 million residents have low bone mass and ~8,000 individuals over 65 fractures a hip annually. The NJ Interagency Council on Osteoporosis (ICO) oversees osteoporosis (OP) education & prevention initiatives in the state. Since 1997, Project Healthy Bones, a 24-week, comprehensive, peer-led OP exercise & education program provides a public health approach to healthy behaviors improving BMD, dietary calcium intake, balance & strength, and minimize falls and associated fracture risk.

In 2004, reduced funding resulted in creating new training at local level for community class leaders, establish program sites for local program demand, provision of resources / technical assistance and provide program oversight. This model utilizes regional, trainers-training program with community-based partnerships. ICO provides 2-day training program in volunteer Peer Leader training, evaluation protocols and oversight accountability.

Our data demonstrated improved balance, increased strength & higher bone density through this program. The impact of Project Healthy Bones was evaluated through exercise tracking forms, pre-post- knowledge tests and food diaries. With the new program, 90% of participants increased weight lifting and exercise tolerance, and 68% increased their calcium intake (~500 mg per day).

From March 05 to December 06, a network of 82 agency staff and 318 volunteer peer leaders provided >two-hundred 24-week programs to nearly 2,000 participants in every county in NJ (over 15,000 volunteer hour contributions). This is in addition to continuing of 80% regular classes beyond the initial 24-weeks. A statewide ICO listserv also provides a forum answers questions/challenges, disseminates current research and OP news, and coordinates local program offerings. Many physicians and HMOs are referring patients directly to the program based on improved DXA results (pre- and post-class) and decrease falls.

The Project Healthy Bones maintain existing community programs; create new programs based on local demand; and oversight to assure program integrity. The program is on CD-ROM, which is designed to use locally by peer leaders. Program demonstrated improve balance and nutrition; prevent falls, increased strength, morale and social well-being among participants. Despite lack of state funding, the modeled program has been strengthened and expanded with extensive community partnerships, fostered volunteerism, and has shown a positive impact in the health and quality of individuals' lives.

Overexpression of Osteoblast IGF-I Blunts the Deleterious Effects of Low Protein Intake on Bone Strength. P. Ammann¹, B. Kream², C. Rosen³, R. Rizzoli¹. ¹Department of Rehabilitation and Geriatrics, Division of Bone Diseases, Geneva, Switzerland, ²University of Connecticut Health Center, Farmington, CT, USA, ³St Josephs Hospital Maine Center for Osteoporosis Research, Bangor, ME, USA.

Isocaloric low protein intake decreases bone mass and bone strength. These alterations are associated with decreased circulating IGF-I levels. Osteoblast IGF-I expression is decreased by low amino-acids concentration. Whether circulating and/or bone locally produced IGF-I are responsible for low protein diet-induced bone damages is not established yet. We investigated 6-month adult transgenic male mice overexpressing IGF-I in osteoblasts under the control of collagen type-1 promoter (TG-IGF) and wild type mice (WT), fed a normal or an isocaloric low protein diet, for 8 weeks. After sacrifice, tibia were tested for biomechanics, size, microstructure using microcomputerized tomography, cortical histomorphometry and bony tissue nano-indentation. Blood was also collected. In WT on low protein diet, compression strength was significantly decreased and resistance to bending displays similar trend, whereas they were not changed in TG-IGF. Data in the table show a cortex thinning, and also alterations of intrinsic bone tissue quality in WT but not in TG-IGF. Outer bone diameter was higher in TG-IGF-I, irrespective of the protein intake. Endosteal BFR was reduced in WT on a low protein diet, but not in TG-IGF. Trabecular bone mass was significantly decreased in WT only. Plasma IGF-I was similar in WT and TG-IGF, and equally decreased by the low protein diet. These results in adult male mice indicate that bone local overexpression of IGF-I blunts the deleterious effects of a low protein diet, even in the presence of lower IGF-I circulating levels.

Sub-Optimal 25(OH)D₃ Levels Causes Increased Osteoclastogenesis and Bone Loss. P. H. Anderson^{*1}, R. K. Sawyer^{*1}, A. J. More^{*1}, A. Muliabrahimovic^{*1}, B. K. May^{*1}, P. D. O'Loughlin^{*1}, H. A. Morris². ¹Endocrine Bone Research, Institute of Medical and Veterinary Science, Adelaide, Australia, ²Hanson Institute, Institute of Medical and Veterinary Science, Adelaide, Australia.

The association between increased risk of hip fracture and a low vitamin D status has long been recognised. However, the level of circulating vitamin D required to maintain bone strength is controversial. To determine the circulating 25-hydroxyvitamin D (25D) level required for the maintenance of bone, we generated 6 groups of Sprague-Dawley rats with stable, mean 25D level ranging from 11 nmol/L to 118 nmol/L. Vitamin D depleted animals were fed various levels of vitamin D (0ng-500ng/d) with 0.4% Ca for 4 months before being killed at 7 months of age for serum biochemistry and bone histomorphometry analyses. Proximal femora structure was analysed by µCT and distal femora histomorphometry was analysed using sagittal 5µm undecalcified sections. Fasting serum calcium, PTH and phosphate levels were normal in animals with low 25D levels. Evidence of osteomalacia was seen only in animals with 11(±0.7) nmol/L 25D, with elevated serum ALP and cross-laps, increased osteoid surface and delayed osteoid maturation time (OMT) compared to animals fed higher levels of vitamin D. OMT was constant in animals fed between 50 and 500ng/d vitamin D and trabecular bone volume (BV/TV) was positively related to circulating 25D ($R^2=0.51$, $P<0.001$), but not to 1,25(OH)₂D₃ levels, nor PTH levels. Animals fed between 50 and 100ng/d vitamin D (mean 25D <80nmol/L) had lower BV/TV (Fig 1) and both osteoid surface and osteoclast surface (Fig 2) were elevated compared to animals fed higher vitamin D. In summary, while osteomalacia occurs at extremely low 25D levels, less severe depletion of vitamin D was associated with increased osteoclast numbers, and significant bone loss. The molecular mechanism for the changes in cellular activity due to vitamin D insufficiency are currently under investigation. In conclusion, for animals fed adequate dietary Ca, a circulating 25D above 80nmol/L is required to prevent bone loss.

A More Alkaline Diet May Enhance the Favorable Impact of Dietary Protein on Lean Tissue Mass in Older Adults. B. Dawson-Hughes, S. S. Harris*, L. Ceglia*. Bone Metabolism Laboratory, The Jean Mayer Human Nutrition Research Center on Aging at Tufts University, Boston, MA, USA.

Maintaining muscle mass in aging is important to prevent falls and fractures. Dietary protein is required to preserve muscle mass, however the acid load from diets rich in acidogenic protein foods and cereal grains relative to alkaline fruits and vegetables may contribute to loss of lean tissue mass in older adults.

This analysis was conducted to determine whether for a given protein intake, a more alkaline diet has a more favorable effect on lean body mass (LBM). Subjects were 384 men and women age 65+ who participated in a 3-yr calcium and vitamin D versus placebo trial. All subjects gave written informed consent.

Urinary nitrogen (N), an indicator of protein intake, and potassium (K) were measured at baseline in 24-hr collections. N was measured by the Dumas combustion method and K by direct-current emission spectroscopy. The N:K ratio, reflecting the ratio of acidic protein foods to alkaline fruit/vegetable intake, was calculated. LBM, defined as total body non-fat, non-bone tissue mass, was measured by DXA at baseline and 3 years. Physical activity, measured by Physical Activity Score for the Elderly (PASE) questionnaire, height, and weight were assessed at baseline and 3 years.

At baseline, the mean N:K was 5.98 ± 1.70 (SD) mmol/mmol. The N:K was inversely associated with baseline LBM (regression coefficient = -0.245, $P = 0.011$, adjusted for sex, age, weight, physical activity score, and nitrogen excretion) and with 3-yr change in LBM (regression coefficient -0.105, $P = 0.046$, adjusted in addition for treatment group and baseline LBM).

These results suggest that the effect of protein on muscle may be enhanced when the overall diet is less acidic, that is, higher in fruit and vegetable content.

Propensity to Accumulate Bone Microdamages Is Increased in Adult Female Rats Fed an Isocaloric Low Protein Diet. V. Dubois-Ferrière*, R. Rizzoli, P. Ammann, Division of Bone Diseases, Geneva, Switzerland.

Low protein intake decreases bone strength through a change in bone mass, bone microstructure and intrinsic bony tissue quality. Whether the low protein diet-induced alterations of bony tissue could favor the accumulation of bone microdamages is not known. We investigated the effects of repeated loading on humerus bone strength in 6-month-old female rats pair-fed a control (15% casein, n=10) or an isocaloric low-protein (2.5%, n=10) diet for 10 weeks. The humeri were cyclically loaded in three-point bending under load control for 2000 cycles. The peak load selected corresponded to 60% of the maximal load of the controlateral humerus. The humeri were then loaded to failure. We compared the load/displacement curve of the cyclically loaded humerus to the controlateral non-cyclically loaded humerus.

Whereas cyclic loading did not induce any deterioration in rats fed a normal protein diet, this cyclic loading regimen negatively influenced the post-yield behaviour of humerus in rats fed a low protein diet, as indicated by the significant decrease of post-yield load and plastic deflection. This suggests that bone microdamages could be more prominent in rats fed a low protein diet than in control bones submitted to the same loading regimen.

Results are mean±SEM; * p<0.05 as evaluated by a Student's t-test				
Casein Diet	15%	15% controlateral loaded	2.5%	2.5% controlateral loaded

Thin Healthy Women Have a Similar Low Bone Mass as Women with Anorexia Nervosa. D. Fernandez-García^{*1}, J. García-Aleman^{*1}, A. Sebastian Ochoa^{*2}, M. Muñoz-Torres², F. Tinahones^{*1}. ¹Department of Endocrinology, University Hospital Virgen de la Victoria, Malaga, Spain, ²Department of Endocrinology, University Hospital San Cecilio, Granada, Spain.

Association between anorexia nervosa (AN) and low bone mass has been demonstrated. Bone loss associated with AN involve hormonal and nutritional impairments, though their exact contribution is not clearly established. The aim: of our study was to compare bone mass in AN patients with women of similar weight with no criteria for anorexia nervosa, and a third group of healthy, normal-weight, age-matched women.

We studied 48 patients with AN (DSM-IV criteria), 22 healthy eumenorrheic women with low weight (LW Group; BMI <18.5 kg/m²) and 20 healthy women with BMI >18.5 kg/m² (Control Group), all of similar age. We measured by DEXA lean body mass, percentage of fat mass, total bone mineral content (tBMC) and bone mineral density in lumbar spine (BMD LS) and total (BMD T). We measured anthropometric parameters, leptin and GH.

The control group had greater BMD T and BMD LS than the other groups, with no differences between the AN and LW groups. No differences were found in BMD T, BMD LS and t BMC between the restrictive (n=25) and binge-purge type (n=23) in AN patients. In AN, minimum weight ($p=0.002$) and percent of fat mass ($p=0.02$) explained BMD LS variation ($r^2:0.48$) and minimum weight ($r^2:0.42$; $p=0.002$) for BMD T in stepwise regression analyses. In LW group, BMI explained BMD LS ($r^2:0.72$; $p=0.01$) and BMD T ($r^2:0.57$; $p=0.04$).

Conclusions: Patients with AN had similar BMD as healthy thin women. Anthropometric parameters could contribute more significantly than estrogen deficiency in achievement of peak bone mass in AN patients.

Vitamin D Insufficiency and Normal Parathyroid Function: Disease or No Disease? K. E. Hansen¹, J. Riggert^{*1}, A. N. Jones^{*1}, J. Engelke^{*1}, M. Shafer^{*2}.

¹Medicine, University of Wisconsin, Madison, WI, USA, ²Wisconsin State Lab of Hygiene, Madison, WI, USA.

Vitamin D insufficiency (VDI) is allegedly widespread. In patients with normal parathyroid hormone (PTH), the diagnosis rests upon an increase in calcium absorption (CA) following increments in serum 25(OH)D to levels >30 ng/ml. However, estimates of increased CA with correction of VDI vary dramatically, depending on methods used to measure CA. Using the increment for serum calcium as an index of CA, correction of VDI reportedly increases CA by 65% (J Am Coll Nutr 2003;22(2):142). Of concern, estimates of CA using serum calcium levels correlate poorly with estimates using calcium isotopes ($r=0.42$, Calcif Tissue Int, 1983;35(6):819). We initiated a dual stable calcium isotope study to clarify the impact of vitamin D repletion on CA in postmenopausal women with VDI and normal PTH.

Eligible women were ≥ 5 years postmenopausal with a serum 25(OH)D of 16-24 ng/ml by HPLC assay, normal PTH and an estimated calcium intake $\leq 1,100$ mg daily. Exclusion criteria included hypercalcemia, hypercalciuria, chronic intestinal disorders, use of medications known to interfere with vitamin D or calcium metabolism, osteomalacia, prior adult fragility fracture or a T-scores below -3.0 (spine or femur).

Each woman underwent inpatient dual calcium isotope studies when vitamin D insufficient and subsequently when vitamin D replete (25(OH)D > 35 ng/ml after ergocalciferol 50,000 IU/daily for 15 days). During each CA study, women consumed 18 mg of ^{44}Ca orally with breakfast and received 3 mg of ^{42}Ca intravenously. Each woman's typical diet was replicated during each CA study using 7-day diet records and Food Processor software. Urine was collected for 24 hours and analyzed for its calcium isotope content by mass spectrometry. We calculated CA using the formula by Eastell (JBMR 1989;4(4):463-468). Thus far, 6 of 22 women have completed the study. All had normal PTH at baseline (46 (9) pg/ml). Basal serum 25(OH)D was 20 (4) ng/ml, increasing to 73 (22) ng/ml with ergocalciferol. CA was 23% (8%) initially and 20% (8%) following vitamin D repletion ($p>0.05$, Wilcoxon signed-rank test).

Our observations suggest that calcium absorption does not increase in women with VDI who achieve unequivocal vitamin D repletion with ergocalciferol. Although preliminary, our data raise significant questions about whether VDI is a true disorder in patients with normal parathyroid function.

Effect of Citrus Flavanones on Bone Metabolism in Old Male Rats. V. Habauzit^{*1}, A. Trzeciakiewicz^{*1}, J. Mardon^{*1}, J. Mardon^{*1}, P. Lebecque^{*1}, M. Davicco^{*1}, C. Morand^{*1}, E. Offord^{*2}, V. Coxam¹, M. Horcajada^{*1}.

¹Human Nutrition, INRA, Saint Genès Champanelle, France, ²Nutrition and Health, NESTLE, Lausanne, Switzerland.

Currently, there is an increasing interest in fruit and vegetables as their consumption appears to be related to lower risk of metabolic disorders occurring during ageing. Polyphenols could be involved in these benefits. In this study we investigated the potency of hesperidin and naringin, their two major citrus flavonoids (flavanones), in regulating bone metabolism in senescent male rats.

Forty-eight 20-m-old male Wistar rats were divided into 4 groups. Control group received

a casein-based diet. The others were fed, for 90 days, the same diet but added with either 0.5 % hesperidin (Hp), 0.5 % naringin (Nar) or a mix of both flavanones (0.25%Hp + 0.25%Nar). Femoral mineral density and strength, bone biomarkers (deoxypyridinoline and osteocalcin) were measured. Plasma and serum analyses (leptin, cholesterol, triglycerides, insulin, glucose, IGF-1, IL-6, FRAP, NO) were performed.

During the experiment, body weights were steady in each group and flavanones intake did not affect this parameter. Besides, plasma leptin was significantly decreased in Hp and Hp+Nar groups, suggesting an effect on body composition. At necropsy, daily Hp intake improved bone mineral density compared with control group, whatever bone sites considered ($p<0.05$). While the same pattern for the animals fed with the mix of flavanones was observed, only metaphyseal density was affected by Nar consumption ($p<0.05$). However bone strength was not modified by flavanones. Bone resorption was slowed down by Hp and Nar whereas accretion remained unchanged. Flavanones induced a decrease in plasma triglycerides and total cholesterol and no changes in blood glucose and plasma insulin were detected.

The consumption of flavanones appeared to prevent serum IL-6 from increasing during aging-related inflammation. Oxidative status seemed also to be improved in animals consuming flavanones as shown by FRAP assay and decreased NO production. Finally, circulating flavanones were only detected in rat plasma receiving Hp and/or Nar.

These results suggest that both hesperidin and naringin were able to affect bone metabolism in senescent male rats, hesperidin being apparently the more efficient. This effect could be partly due to the ability of flavanones in slowing down bone resorption rate. Bone sparing effect of hesperidin and naringin observed in senescent intact male rats, a model of ageing, should also be linked with anti-inflammatory, antioxidant and also hypolipidemic capacities of these compounds.

Influence of Moderate Energy Restriction and Seafood Consumption on Bone Turnover in Overweight Young Adults. A. J. Lucey^{*1}, G. Paschos^{*1}, K. D. Cashman², J. A. Martínez^{*3}, N. Bandarra^{*4}, I. Thorsdottir^{*5}, M. Kiely^{*1}.

¹Department of Food & Nutritional Sciences, University College Cork, Cork, Ireland, ²Department of Food & Nutritional Sciences & Department of Food & Medicine, University College Cork, Cork, Ireland, ³Department of Physiology & Nutrition, University of Navarra, Pamplona, Spain, ⁴National Institute on Agriculture and Fisheries Research, Lisbon, Portugal, ⁵Unit for Nutrition Research, Landspítali University Hospital, Reykjavik, Iceland.

While weight loss may increase bone turnover, increased intakes of n-3 fatty acids (FA) may maintain skeletal health by reducing bone resorption. This study examined relationships between weight loss, changes in FA in red blood cell (RBC) membrane phospholipids (%) and bone turnover biomarkers, induced by an 8-week dietary intervention, which included fish or fish oil as part of an energy restricted diet (-30%) in 20-40 year old adults (BMI 27.5-32.5 kg/m²). Participants (n 276) were randomised to 1 of 4 groups: placebo (sunflower oil capsules; 3g/day); cod (3 x 150g/week); salmon (3 x 150g/week); fish oil capsules (3g/day). At baseline and endpoint serum levels of the biomarkers of bone formation (osteocalcin (OC) and bone specific alkaline phosphatase (BAP)) and resorption (serum crosslaps (CTx) and N-telopeptide of Type I collagen (NTx)) were measured by enzyme linked immunosorbent assay (ELISA) and the FA composition of RBC membrane phospholipids (%) was measured by gas chromatography. Using repeated measures analysis of variance, before adjusting for confounding factors, serum levels of CTx ($P < 0.001$) and NTx ($P < 0.05$) increased, BAP showed little response, while levels of OC ($P < 0.05$) decreased from baseline to end point, however, these changes were no longer present after adjusting for country, gender, sampling month, age, smoking status and % weight loss. Mean weight loss was 5.8% (range 0 to 15) over the 8-week intervention and was similar across the 4 study groups. Weight loss and changes in body composition were the main factors influencing the increases in CTx ($P < 0.001$) and NTx ($P < 0.05$), while OC was unrelated to weight loss. Increased n-3 FA consumption in the salmon and fish oil groups resulted in increases in n-3 FA in RBC membranes and decreases in n-6 FA ($P < 0.05$). After adjusting for confounding, OC was positively correlated with the % RBC n-3 FA at baseline and endpoint. However, the overall inclusion of fish or fish oil in the diet had no significant effect on bone turnover. We conclude that a nutritionally adequate energy-restricted diet over 8 weeks, which resulted in modest weight loss and changes in body composition influenced biomarkers of bone resorption in young overweight adults.

Effects of Calcium Sources and Soluble Silicate on Bone Metabolism and the Related Gene Expression in Mice. F. Maehira¹, I. Miyagi¹, Y. Eguchi².

¹Lab. Metabolic Chemistry, Faculty of Medicine, University of the Ryukyus, Okinawa, Japan, ²Research Laboratory Center, Faculty of Medicine, University of the Ryukyus, Okinawa, Japan.

Silicon has been known as an essential element for the formation of collagen and glycosaminoglycans in bone and cartilage. The effects of five calcium (Ca) sources were compared on bone biochemical and mechanical properties and the related gene expression using the control strain of senescence-accelerated mice (SAMR1), from a viewpoint of their soluble silicon (Si) content. The experimental protocols of this study were approved by our Institutional Animal Studies Committee. Weanling male SAMR1 were fed the diets containing 1% Ca supplemented with CaCO₃ as the control (CT), coral sand (CS), fossil stony coral (FSC), fish (FC), egg-shell (EC) powders, and 50 ppm Si in the CT diet for 6 months. The mRNA expression of Runx2, BMP-2, IL-11, COL1A1, PPAR- γ , OPG, RANKL, TGF- β was quantified by a real-time PCR. Soluble Si content was 9.83, 7.17, 2.48, 0.29, and 0.20 ppm for CS, FC, FSC, EC, and Ca-deficient basal diet, respectively. In bone biochemical properties, Si, CS, and FSC in order increased ($P < 0.05$) dry and ash weights, Ca and hydroxyproline (OHP) contents, and alkaline phosphatase and decreased ($P < 0.05$) tartrate resistant acid phosphatase, urinary excretion of OHP comparing with the CT group. In bone mechanical properties, Si increased ($P < 0.05$) and FC decreased ($P < 0.05$) strength and stiffness. In the mRNA expression related to osteoblastogenesis, Si increased ($P < 0.05$) Runx2, Si, CS, and FSC in order decreased ($P < 0.05$) and FC, EC increased ($P < 0.05$) PPAR- γ . In the mRNA expression related to osteoclastogenesis, Si, CS increased ($P < 0.05$) and FC, EC decreased ($P < 0.05$) OPG/RANKL ratio whereas Si, CS decreased ($P < 0.05$) TGF- β . FC in spite of its high Si content showed worst effects on bone, probably due to its high phosphorus content. The results indicated that soluble silicate and coral sand with highest soluble Si content among Ca sources improved bone biochemical and mechanical properties through stimulation of gene expression related to osteoblastogenesis and suppression of that related to osteoclastogenesis.

The Effect of a High Protein Diet on Bone and Body Composition in Young Female Rats. K. M. Pye¹, A. Wakefield², H. Aukema², J. House², M. Ogborn², H. Weiler¹. ¹School of Dietetics and Human Nutrition, McGill University, Ste-Anne de Bellevue, PQ, Canada, ²Department of Human Nutritional Sciences, University of Manitoba, Winnipeg, MB, Canada.

Long-term, high protein diets at 35% of energy may have implications in bone biology. Increased consumption of protein lowers blood pH levels which may interfere with blood calcium homeostasis leading to an increased stimulation of osteoclasts and elevated calcium losses. However, inconsistencies within the literature make it impossible to state whether this level of bone resorption, over long periods, has a negative impact on bone health. No one study within the eighty years of high protein diet research has examined all the biochemical, physical, and largely the biomechanical markers of bone health. This study will be the first to give a complete analysis and examine whether a high protein diet at the 35% energy level can be deemed safe with respect to long-term bone health. The objective of this research is to examine the effect a high protein diet at 35% of energy has on bone mass and strength in the rat model.

Eighty female Sprague-Dawley rats were randomized to receive 4, 8, 12, or 17 months of a control diet (15% of energy as protein) or the high protein diet (35% energy). Weekly food intake and weight was documented. Whole body composition and regional bone mass were measured in vivo using dual-energy x-ray absorptiometry (DXA; Hologic QDR version 11.2, Hologic, Inc.). Following termination, femurs and tibias were excised. Ex vivo, femur and tibia bone mass were measured using DXA and right femurs were tested for mechanical strength using designed 3-point bending tests (INSTRON 5544, Instron Inc.). Main effects of diet and time were detected using factorial ANOVA ($p < 0.05$). The high protein diet increased BMC (g/kg) in femur, tibia, and vertebrae as illustrated in the table below. High protein consumption also decreased whole body fat (normal diet: 165.17 ± 87.92 g, high diet: 110.60 ± 70.92 g, $p < 0.0001$), increased lean mass (normal diet: 634.68 ± 99.95 g/kg, high diet: 717.11 ± 92.75 g/kg, $p < 0.0001$), and decreased abdominal fat (normal diet: 44.56 ± 22.32 g, high diet: 31.55 ± 19.18 g, $p = 0.0006$). Diet had no effect on the biomechanical strength of femurs. Thus preliminary results suggest that high protein diets at the current upper limit of 35% of energy increase mineral content, decrease body fat content, but does not hinder the mechanical and weight bearing abilities of bone.

	Normal Protein BMC (g/kg)	High Protein BMC (g/kg)	p values
Femur	1.4555 ± 0.324	1.6125 ± 0.347	0.0046
Tibia	0.9172 ± 0.233	1.0535 ± 0.333	0.0178
Vertebrae	1.5751 ± 0.344	1.7365 ± 0.366	0.0076

Low Calcium Diet Accelerates Alveolar Bone Resorption in Rat Experimental Periodontitis. K. Tokunaga¹, C. Wada¹, H. Ohba¹, H. Seto¹, E. Takeda², T. Nagata¹. ¹Periodontology and Endodontology, Health Bioscience,

Tokushima, Japan, ²Clinical Nutrition, Health Bioscience, Tokushima, Japan.

Periodontitis is characterized by the inflammatory destruction of periodontal tissues including alveolar bone, periodontal ligament, and gingiva. Alveolar bone resorption is a major cause of tooth loss. It is possible that a decrease of general bone density may affect the pathogenesis of periodontitis. Estrogen deficiency by menopause and lack of Ca ingestion is known to be a risk factor for osteoporosis. However, it is not clear whether the lack of Ca ingestion influences alveolar bone resorption in periodontitis. In this study, we examined the effect of low Ca diet on alveolar bone resorption in rat experimental periodontitis. Male Wistar rats, 8 weeks old, were firstly divided into 2 groups: rats with low Ca diet (Ca: 0.18%), and the control (Ca: 1.08%). The diets were given for 5-20 days. Nylon ligature was placed around the cervix of maxillary lateral second molars to induce periodontitis with bone resorption. Then ligature-treated group and ligature-treated low Ca group were prepared. On days 5 and 20, maxillae was extracted and analysed using micro CT. Samples were decalcified and the thin sections were stained by tartrate-resistant acid phosphatase (TRAP). Multinuclear osteoclast-like cells were visualized under light microscopy. Micro CT images of maxillae showed that there was no change in the non-ligature group and that alveolar bone resorption was strongly induced around the second molar from days 5 to 20 in the ligature-treated groups. The ligature-treated sites in low Ca group showed a greater bone resorption than the ligature-treated control. Histological examination showed that TRAP positive cells appeared at the top of alveolar bone on day 5 in the ligature-treated groups. The number of osteoclasts in the ligature-treated low Ca group was more than that in the ligature-treated control. These osteoclast-like cells disappeared on day 20 in both groups. Taken together, low Ca diet may increase the number of osteoclasts at the top of alveolar bone and induce the greater resorption of alveolar bone in the experimental periodontitis. These findings suggest that the lack of Ca ingestion in daily life may accelerate alveolar bone resorption in periodontitis.

A Marked Abnormality in Myeloid and Mesenchymal Somatic Stem Cells Explains the Skeletal Defect in Glucagon-Like Polypeptide-2 Receptor KO Mice. J. Xiao¹, D. J. Drucker², J. A. Clowes¹. ¹Mayo Clinic, Rochester, MN, USA, ²Department of Medicine, University of Toronto, Toronto, MN, USA.

Clinical studies have established nutritional intake as a key factor regulating the marked circadian rhythm in bone turnover. In addition, at pharmacological concentrations the intestinal hormone, glucagon like peptide 2 (GLP2) which is released in response to nutrient intake acutely decreases bone resorption. Furthermore, we have established that there is a marked skeletal deficit during growth in GLP2 receptor knockout (GLP2R -/-) mice.

In addition, previous studies have established that CD11b+ myeloid precursors differentiate into mature osteoclasts (OCs) and express key surface receptors, including c-Fms (the receptor for MCSF) and RANK (the receptor for RANKL). Furthermore, cells expressing stro1 a mesenchymal stem cell (MSC) marker differentiate into osteoblast (OB) precursors following co-expression with RANKL. Finally CD133 is a marker of the most primitive somatic stem cell (SSC).

Although the importance of nutrition in bone biology has been clearly established the mechanism(s) for how GLP2 regulates bone metabolism in vivo at physiological concentrations has not yet been determined. We determined this in 6 week old GLP2R -/- mice (n = 4) compared to their wild type (WT) C57BL/6 littermates (n = 5) by examining the percentage of cells (as a fraction of bone marrow MNCs) expressing the various receptors using flow cytometry.

As shown in the Table, a defect in the GLP2R resulted in a significant increase in the % of total cells expressing RANK+ and the % of RANK+/CD34- and RANK+/cFms- cells. Furthermore, there was a significant increase in the % of total cells expressing the MSC marker stro1, the % of stro1+/CD133- and stro1+/RANKL+ cells.

	Percent positive cells			
	RANK+	Stro-1+	Stro-1+/CD133-	Stro-1+/RANKL+
WT	-0.22 ± -0.22	-0.07 ± -0.07	-0.02 ± 0.17	0.06 ± 0.09
GLP2R-/-	1.03 ± 1.04	0.13 ± 0.18	0.26 ± 0.18	0.33 ± 0.19

Data are mean \pm SD; * $P < 0.05$

These studies thus represent the first systematic examination of the effects of a nutrient-regulated hormone at physiological concentrations on OC and OB precursor populations in vivo. Collectively, these data indicate that the absence of GLP2 signaling increases the differentiation of myeloid cells towards mature osteoclasts. Since there is a profound defect in OB differentiation and mineralization in vitro it suggests the increase in MSC differentiation towards mature OBs may either represent a compensatory mechanism or an increase in OB precursors due to a distal block in OB differentiation.

Comprehensive Analysis of Bone-related Genes Expression Induced by Acute Oxidative Stress. K. Mori¹, R. Kitazawa¹, T. Kondo¹, Y. Hamada², S. Kitazawa¹. ¹Division of Pathology, Kobe University Graduate School of Medicine, Kobe, Japan, ²Division of Nephrology and Kidney Center, Kobe University Hospital, Kobe, Japan.

In the diabetic condition, accumulation of methylglyoxal (MG), an intermediate metabolite of glucose formed through glycolysis, precedes formation of advanced glycation end products (AGE), which then cause oxidative stress in various cells and organs. This oxidative stress is now regarded as a major cause of diabetic complications such as diabetic nephropathy, retinopathy, angiopathy and bone loss. In this study, we comprehensively analyzed gene expression by the DNA microarray system to identify genes in osteoblastic/ stromal cells modulated by oxidative stress. Mouse bone marrow stromal cells, ST2, were treated with MG (100 μ M) for 48hr, and RNA extracted from ST2 cells cultured with or without MG was examined. DNA microarray analysis revealed that the expression of osteoprotegerin (OPG), a decoy receptor of receptor activator of nuclear factor- κ B ligand (RANKL), was markedly reduced by MG treatment. In contrast, the expression of soluble Frizzled-related protein 4 (sFRP-4), a decoy receptor for Wnt proteins, increased by MG treatment. This reciprocal gene expression between OPG and sFRP-4 was also reproduced and confirmed by quantitative real-time RT-PCR. Since the canonical Wnt/ β -catenin signaling pathway contributes to OPG gene expression in osteoblastic cells through the transactivation of the gene, the rapid and marked decrease of OPG gene expression after MG-induced acute oxidative stress may be due to reduced Wnt/ β -catenin signaling by the upregulated expression of its antagonist, sFRP-4. Furthermore, the expression of several target genes of the Wnt/ β -catenin signaling pathway (e.g. cyclin D1, Wnt1 inducible signaling pathway protein 1 (WISP1), WISP2) also decreased in MG-treated ST2 cells. On the other hand, the expression of mesenchymal cell differentiation regulating transcription factors, such as Runx2 for osteoblasts and peroxisome proliferators-activated receptor γ (PPAR- γ) for adipocytes, did not change significantly by short-term MG treatment. In conclusion, oxidative stress induces a rapid reduction of Wnt/ β -catenin signaling and expression of its target genes. We speculate therefore that diabetic bone loss is ultimately caused by decreased Wnt/ β -catenin signaling, and that the early bone-resorption-dominant phase attributed to rapid and marked decrease of OPG gene expression may precede final low turnover osteoporosis as a late complication of diabetes.

Disclosures: K. Mori, None.

Poor Long Term Glycemic Control Is Not Associated with Decreased Bone Mineral Density in Typ 1 Diabetes. T. Neumann¹, A. Saemann², S. Lodes¹, B. Kaestner¹, S. Franke¹, C. Hemmelmann³, U. A. Mueller², G. Hein¹, G. Wolf⁴. ¹Department of Medicine III, Rheumatology/ Osteology, Friedrich-Schiller-University of Jena, Jena, Germany, ²Department of Medicine III, Endocrinology, Friedrich-Schiller-University of Jena, Jena, Germany, ³Institute of Medical Statistics, Computer Sciences and Documentation, Friedrich-Schiller-University of Jena, Jena, Germany, ⁴Department of Medicine III, Nephrology, Friedrich-Schiller-University of Jena, Jena, Germany.

It is assumed that type 1 diabetes is associated with lower bone mineral density (BMD) and increased fractures risk. The impact of duration of diabetes on BMD is controversial. In a cross-sectional study design we investigated the influence of long term glycemic control on BMD in type 1 diabetes. We studied 126 unselected patients with diabetes mellitus type 1 from our outpatient clinic, 63 premenopausal women (41 \pm 8 years) and 63 men (45 \pm 10 years), duration of diabetes was 22 \pm 10.5 years. All patients received standard questionnaire on diabetic history and risk factors for osteoporosis. History of HbA1c was obtained from medical records (mean HbA1c for each year of diabetes duration). 15 patients (10 women and 5 men) were excluded from analysis of long term glycemic control because of missing HbA1c data. BMD was measured using DXA (Lunar Prodigy Advance) at lumbar spine (LS), right femoral neck (FN) and total hip (TH). Osteoporosis (T-score $<$ -2.5 SD) at the LS (FN; TH) was found in 5 (4; 2) %. Osteopenia (T-score between -1 and -2.5 SD) at the LS (FN; TH) was found in 33 (34; 26) %. BMD was not associated with cigarette smoking or a familial history of osteoporotic fracture. Neither diabetes duration nor quartile of duration (1st, 2 to $<$ 14 years; 2nd, 14 to $<$ 21 years; 3rd, 21 to $<$ 31 years; 4th, 31-48 years) were associated with BMD. Quartiles of median HbA1c (1st, 5.4 to $<$ 6.8 %; 2nd, 6.8 to $<$ 7.4 %; 3rd, 7.4 to $<$ 8.1 %; 4th, 8.1-10.8 %) over the time of diabetes were not associated with BMD. No association was found for markers of bone turnover and median HbA1c by measuring serum C-terminal telopeptide of type I collagen (CTX).

Our data suggest that osteoporosis is a clinical significant and commonly underestimated problem in type 1 diabetes. However, the quality of long term glycemic control as well as the duration of diabetes type 1 has no impact on BMD of lumbar spine, femoral neck and total hip.

Antiepileptic Drugs Affect Bone Loss Via Reproductive Hormones. A. Pack¹, E. Shane², D. McMahon², A. Randall¹, M. Morrell³. ¹Neurology, Columbia University, New York, NY, USA, ²Medicine, Columbia University, New York, NY, USA, ³Neurology, Stanford University, Palo Alto, CA, USA.

The antiepileptic drugs (AEDs), phenytoin (PHT) and carbamazepine (CBZ), are commonly associated with low bone density (BMD) and high bone turnover markers (BTM). Traditionally they are thought to affect bone metabolism by inducing the hepatic cytochrome P450 enzyme CYP3A4 which in turn increases catabolism of vitamin D to inactive metabolites, causing lower serum calcium (SCa) and higher parathyroid hormone (PTH) secretion. Notably, however, CYP3A4 also increases metabolism of estradiol (E2) to inactive 2-OH-estradiol. Moreover, CYP enzyme inducing AEDs (EIAEDs) are associated with increased oral contraceptive failure rates, decreased serum E2 and androgens, and increased serum sex hormone binding globulin (SHBG), thus decreasing free, biologically active hormone. These effects of EIAEDs on E metabolism may also compromise bone health. We hypothesized that women with epilepsy (WWE) treated with EIAEDs have lower E levels, higher bone turnover and lower BMD than WWE treated with lamotrigine (LTG), an AED with no effect on CYP450.

WWE aged 18-40 on monotherapy with EIAEDs CBZ or PHT (n=18) or LTG (n=13) were studied during the follicular phase of the menstrual cycle. E2, estrone (E1), testosterone (T), and SHBG were measured. Free E2 and T were calculated. BMD was measured by DXA. SCa, 25-OHD, 1,25(OH)₂D, PTH, osteocalcin (OC), bone alkaline phosphatase (BSAP) and urine N-telopeptide (UNTX) were assessed.

E1, % free E2, and % free T were lower and SHBG was higher in women on EIAEDs compared to LTG. SCa was lower and UNTX was higher in women on EIAEDs, although there was no correlation between BTMs and reproductive hormones. In contrast, vitamin D metabolites and PTH did not differ. BMD did not differ between groups at any site. In the EIAED group, spine BMD correlated positively with E2 (r=0.58; p=0.02) but femoral neck BMD correlated negatively with % free E2 (r=-0.54; p=0.03). There was no relationship between BMD and calciotropic hormones or SCa in either group.

In summary, women on PHT or CBZ had lower levels of gonadal hormones and higher SHBG than those on LTG, while calciotropic hormones did not differ. Although BMD was not lower in the EIAED group, lower E exposure may lead to higher rates of bone loss over time. We conclude that adverse effects of EIAEDs on bone health may be mediated in part through effects on gonadal hormone status.

	EIAEDS		LTG		p-value

Hepatic Osteodystrophy: Expression of IGF-1 and GH Receptor (GHR) and Biomechanical Studies in Experimental Model of Cholestatic Liver. E. A. Pereira¹, I. Facincani^{*1}, L. N. Z. Ramalho^{*2}, J. B. Volpon^{*3}, F. J. A. Paula¹.

¹Internal Medicine, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, ²Pathology, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, ³Biomechanical and Rehabilitation of the Locomotor System, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil.

Hepatic osteodystrophy is an important co-morbidity of chronic liver disease. In the present study we assessed the impact of chronic cholestasis on the expression of IGF-1 and GHR in liver and in growth plate and bone resistance in rats submitted to bile-duct obstruction (BDO). Male Wistar rats were divided into two groups: Sham (n=15) and Cirrhotic (n = 15). On day 30 post-surgery, the rats were sacrificed and blood was withdrawn to determine serum liver enzymes and bilirubin. Liver and left tibia were used for immunohistochemistry and right femur for biomechanical study. Liver histology was evaluated. Immunohistochemistry semi-quantitative expression was performed according to the following criteria: (-) no stained cells; (+) less than 10% positive cells; (++) 10% -50% positive cells; (+++) more than 50% positive cells. Bilirubin (Sham =0.08 ± 0.01 mg/dl vs Cirrhotic 6.6 ± 0.1 mg/dl p<0.001), alkaline phosphatase (Sham =68.3 ± 0.3 U/L vs Cirrhotic 1864 ± 0.6 U/L p<0.001), γ GT (Sham =5.8 ± 0.2 U/L vs Cirrhotic 66.5 ± 0.2 U/L p<0.001) levels were significantly higher in Cirrhotic group. In this group, all animals showed histological evidence of cholestatic cirrhosis. Also, in liver tissue, the levels of IGF-1 expression were significantly higher in Cirrhotic group in comparison with Sham group (p<0.01), and the level of GHR expression were significantly lower in cirrhotic group (p<0.01). In growth plate cartilage the levels of IGF-1 expression was significantly lower in cirrhotic group (all animal showed no stained cells or less than 10% of positive cells) in comparison with Sham group (the majority of animals showed more than 50% IGF-1 positive cells) (p<0.01). The same pattern was observed in the growth plate cartilage in relation to GHR expression (p<0.01). The applied forces at the fracture moment were: Sham = 82.5 ± 8.6 N vs Cirrhotic = 57.1 ± 12.1 N p<0.001). Our results indicate that the bone quality is significantly impaired on chronic liver cholestasis in rats and probably the reduction of expression of growth factors on bone microenvironment is involved in this process.

An Integrated Model for Evaluation and Simulation of Therapeutic Responses to Bone-Related Therapies. M. C. Peterson¹, M. M. Riggs^{*2}.

¹Amgen Inc., Thousand Oaks, CA, USA, ²Metrum Research Group, LLC, Tariffville, CT, USA.

Calcium (Ca) homeostasis and bone remodeling are complexly integrated, highly regulated processes involving multiple organs and endocrine pathways. Published generalized models have failed to provide adequate platforms for describing multiple therapeutic class effects on the system. Our aim was to develop a model that predicts longitudinal Ca homeostasis and co-factor levels (including phosphate, PTH, and calcitriol), as well as expected rates of bone turnover due to natural progression, therapeutic intervention, or disease states.

Our approach is based on physiologic requirements to maintain Ca balance, with the general model predicated on 3 manuscripts [Raposo et. al, J Clin Endocrin Metab, 2002; Lemaire et. al, J Theor Biol, 2004; Bellido et. al, J Biological Chem, 2003]. Based on literature and Amgen clinical data, significant modifications and additional feedback mechanisms have been added to appropriately integrate the model. The model includes the RANK-RANKL-OPG system to enable characterization of osteoclast (OC) and osteoblast (OB) genesis and survival, PTH-mediated anti-apoptotic signaling in OB to allow description of anabolic and catabolic effects of PTH on bone remodeling, and TGF β -mediated feedback mechanisms to capture homeostatic observations.

The model has enabled evaluation of various affecting mechanisms, ramifications of therapeutic interventions, and disease state sequelae, including the following: (1) administration of the RANKL inhibitor, denosumab, (2) intermittent- and (3) constant-PTH infusion, and (4) progressive renal insufficiency. The integrated model appears to provide a generalizable structure with known or plausible cell signaling concepts and physiologically consistent parameters. Model predictions under conditions (1) - (4) provide results consistent with clinical observations.

In conclusion, a robust physiologic model that provides continuous descriptions of biomarkers and electrolytes including calcium, phosphate, PTH, and markers of bone turnover consistent with literature and Amgen internal data has been developed. This model may facilitate characterization of therapeutics under development, enable predictions of cytokine mediators of bone homeostasis, and provide a platform for hypothesis testing prior to clinical investigations.

Effects of Estrogen on Circulating dlk1/pref-1/FA1 Levels in Postmenopausal Women and Correlations with Bone Turnover and Volumetric BMD. B. Srinivasan¹, B. M. Abdallah^{*2}, S. Khosla¹, M. Kassem².

¹Mayo Clinic, Rochester, MN, USA, ²Odense University Hospital, Odense, Denmark.

dlk1/FA1 (Delta-like 1/fetal antigen1), also known as Pref-1, (Pre-adipocyte factor 1), is a member of the epidermal growth factor-like protein family, known to modulate differentiation of mesenchymal and hematopoietic stem cells in bone marrow in a paracrine/endocrine fashion. Studies in mice have shown that dlk1/FA1 inhibits adipogenesis and is a marker for pre-adipocytes. Recently, Dlk1/FA1 was identified as a novel paracrine/endocrine inhibitor of human bone marrow stromal (hMSC) cell differentiation. Since estrogen (E) is known to enhance osteoblast differentiation and inhibit adipocytic differentiation, we measured circulating FA1 levels by immunoassay in untreated and E-treated postmenopausal women (n = 83 per group, mean age, 63 yrs) who were matched for age and BMI. Circulating FA1 levels were significantly higher in the untreated women (mean ± SEM, 41.5 ± 1.8 ng/ml) as compared to E-treated women (29.9 ± 1.4 ng/ml, P < 0.001). Serum FA1 levels were correlated with serum osteocalcin levels in untreated (age and BMI adjusted correlation coefficient, R^{age,BMI} = 0.26, P = 0.02) and E-treated women (R^{age,BMI} = 0.27, P = 0.02), with femur neck cortical volumetric BMD (vBMD) measured by QCT in both groups (R^{age,BMI} = 0.24 and 0.26, respectively, P < 0.05), and with trabecular vBMD at the distal radius in the E-treated women (R^{age,BMI} = 0.24, P = 0.03). No significant associations with other bone turnover markers (PINP or CTx) or vertebral vBMD were noted. Collectively, these findings indicate that E suppresses circulating FA1 levels in postmenopausal women, perhaps reflecting the known effects of E in inhibiting differentiation of bone marrow stromal cells to pre-adipocytes. The positive associations with serum osteocalcin levels and with vBMD that were noted raise the possibility that higher dlk1/FA1 levels, whether in untreated or E-treated women, may suppress adipocyte differentiation of bone marrow stromal cells to a greater extent than osteoblastic differentiation, leading to a net positive effect of dlk1/FA1 on bone. Further studies are needed to test this hypothesis and to better understand the endocrine role of dlk1/FA1 in regulating bone turnover and bone mass.

To Detamine Serum Fluoride Levels in Patients with Osteoporosis Is Quite Useful for the Judgment of Effectiveness of Osteoporosis Treatment. K. Tanno^{*1}, K. Itai^{*1}, M. Ohsawa^{*1}, T. Onoda^{*1}, Y. Yaegashi^{*1}, T. Sato^{*1}, K. Sakata^{*1}, G. Murooka^{*2}, T. Shimamura^{*2}, A. Okayama^{*3}.

¹Department of Hygiene and Preventive Medicine, Iwate Medical University, Morioka, Japan, ²Department of Orthopedic Surgery, Iwate Medical University, Morioka, Japan, ³Department of Preventive Cardiology, National Cardiovascular Center, Suita, Japan.

Endogenous fluoride is mostly stored within the bone and vividly released into blood circulation along with bone resorption, therefore, serum fluoride levels may faithfully reflect resorption rates of bone metabolism. Purpose of this study is to determine serum fluoride levels in postmenopausal women with osteoporosis before and after treatment of antiresorptive agents and to examine whether serum fluoride levels faithfully reflect resorption rates represented as changes in bone mineral density (BMD) and changes in biochemical markers of bone turn over. A total of 55 postmenopausal women with osteoporosis were enrolled (mean age 69.4 years). BMD (measured by Dual energy X-ray absorptiometry), serum levels of bone alkaline phosphatase (BAP), serum levels of type I collagen cross-linked N-telopeptide (NTX), urinary levels of deoxypyridinoline (DPD), and serum fluoride levels (measured by flow injection method with ion selective electrode) were determined and compared before and after treatment with antiresorptive agents (Alendronate, Risedronate). Mean treatment period was 6.2 months (3.8 - 7.6 months). Serum fluoride levels, as well as serum BAP levels, serum NTX levels, and urinary DPD levels significantly decreased along with increases in BMD in patients with osteoporosis after antiresorptive treatment (see table). In conclusion, markedly decreased serum fluoride levels indicated attenuated resorption rates of bone metabolism, and serum fluoride should be a useful marker that faithfully reflects bone metabolism. To determine serum fluoride levels in patients with osteoporosis should become increasingly essential for the judgment of disease severity and effectiveness of osteoporosis treatment.

Levels of measurements in postmenopausal women with osteoporosis before and after treatment

Measurement	Before Tx	After Tx	p - value
BMD (g/cm ²)	0.62±0.06	0.66±0.06	p < 0.001
serum fluoride (ng/mL)	11.0±3.69	6.5±2.20	p < 0.001
serum BAP (U/L)	33.4±10.0	20.5±6.4	p < 0.001
serum NTX (nmol/BCE/L)	22.1±6.8	14.2±3.3	p < 0.001
urinary DPD (nmol/mmol Cr)	8.5±2.8	4.8±1.7	p < 0.001

Case Series: Osteomalacia Following Gastric Bypass and Biliopancreatic Diversion Surgery. A. Al-Shoha¹, R. Lakhdar^{*1}, D. S. Rao². ¹Internal Medicine, Henry Ford Hospital, Detroit, MI, USA, ²Bone & Mineral Metabolism, Henry Ford Hospital, Detroit, MI, USA.

Gastric bypass surgery (GBS) and Biliopancreatic diversion (BPD) are the most common procedures for management of morbid obesity, a disorder that is increasing in epidemic proportions in the US and world wide. Metabolic bone disease after GBS has been reported. However, to our knowledge, only two cases of post-GBS osteomalacia (OM) have been reported, but the diagnosis of OM in both cases was based solely on biochemical findings. We report 4 patients with bone biopsy confirmed OM after GBS. Three women and one man (age range 29-53y) were seen for evaluation of metabolic bone disease not responding to "usual" therapy. Two of the 4 patients had BPD; one of those 2 had gastric stapling (GS) about 9y before BPD (Case 2). The other 2 patients had Roux-en-Y GBS; one of those had GS at the time of GBS (Case 3) and the other had jejunoileal bypass 26y before GBS (Case 4). Clinical features included generalized bone pain and tenderness, muscle weakness, difficulty walking, and waddling gait, stooping posture, and fractures. Two patients (Cases 2 and 4) had history of kidney stones at presentation. Diagnoses prior to referral were varied including arthritis, gout, vitamin D deficiency and osteoporosis. Serum chemistry (Table) and radiological findings were suggestive of OM in all the 4 cases, and the diagnosis was confirmed by bone biopsies. Following high doses of Vitamin D and calcium therapy there was significant improvement in the symptoms and functional status and biochemical variables. Our experience suggests that GBS may predispose to severe vitamin D depletion and OM in the absence of high dose vitamin D and calcium supplements. The current "usual" supplements are grossly inadequate in this population and the presentation may be non-specific and misleading. Prospective long-term studies are needed to determine the appropriate vitamin D dose to prevent metabolic bone disease in this uniquely susceptible population.

	Pertinent Laboratory Data			
	Case 1	Case 2	Case 3	Case 4
Time to presentation (years)	5	2	5	5
25-hydroxyvitamin D (ng/mL)	9	6	5	7
Corrected Calcium (mg/dL)	9.5	8.8	8.9	7.3
Alkaline Phosphatase (IU/L)	249	227	1246	178

Rickets Is Associated with Failure of Epiphyseal/Metaphyseal Bone Tether Formation. J. Chen^{*1}, C. H. Lohmann^{*2}, R. Coleman^{*1}, R. E. Guldberg^{*1}, Z. Schwartz¹, B. D. Boyan¹. ¹Petit Institute of Bioengineering and Bioscience, Georgia Institute of Technology, Atlanta, GA, USA, ²University of Hamburg-Eppendorf, Hamburg, Germany.

Recently, we showed that bone bridges (tethers) connect the metaphyseal and epiphyseal trabecular bone through the rat tibial growth plate (GP); altered tether formation was highly correlated to growth disruption. We hypothesized that altered chondro-osseous morphology typical of rickets might involve changes in tether number, distribution, or structure. To test this, we imaged the GP via micro-CT and histology to assess if 8-week old VDR^{-/-} mice have changes in tether parameters compared to VDR^{+/+} littermates. GPs were isolated from micro-CT scans (resolution = 16 μ m) of right distal femurs from 15 VDR^{-/-} and 15 VDR^{+/+} mice and average thickness and volume were calculated. To define the tether area, GPs were marked with ellipses using Adobe Photoshop. The "tether probability index" was set as the fraction of samples with tethers in each area. Randomly selected GPs were processed for decalcified (8) and undecalcified (1) histomorphometry; serial sagittal sections were stained with H&E or silver nitrate, respectively. GP and tether vertical height (GP width), horizontal width and area were measured (Image-Pro Plus) and GP volume, GP projection area, tether volume and tether occupancy rate calculated; tether number was determined by reconstruction the consecutive histological images. For reconstructed 3D micro-CT images, tether number was counted directly, GP and tether projection area were measured with Image-Pro Plus software, tether volume was calculated from tether area and average GP thickness. Tethers occurred in all VDR^{+/+} femurs; in contrast, only 20% of VDR^{-/-} femurs had tethers, and their area and distribution were different. Although VDR^{-/-} GPs had greater area and thickness, tether number, area, occupancy rate and volume fraction were dramatically reduced. This was confirmed by histology of non-decalcified femurs. Statistical analysis showed that the histological results correlated with micro-CT for all tether parameters except tether volume. This study demonstrates the utility of the micro-CT method for assessing GP morphology and pathology. Tethers did form at specific sites in some VDR^{-/-} animals, suggesting that rickets does not affect all regions of the GP equally. The results indicate that failure of the GP to develop properly has consequences for establishing the appropriate interface between two mechanically dissimilar tissues.

Minimally Invasive Treatment of Oncogenic Osteomalacia by Radiofrequency Ablation. E. Hesse¹, H. Rosenthal^{*2}, G. Brabant^{*3}, F. Langer^{*4}, K. F. Gratz^{*5}, L. Bastian^{*6}. ¹Orthopaedics and Cell Biology, Yale University School of Medicine, New Haven, CT, USA, ²Diagnostic Radiology, Hannover Medical School, Hannover, Germany, ³Endocrinology, Christie's Hospital, Manchester, United Kingdom, ⁴Pathology, Hannover Medical School, Hannover, Germany, ⁵Nuclear Medicine, Hannover Medical School, Hannover, Germany, ⁶Trauma Surgery, Klinikum Leverkusen, Leverkusen, Germany.

Oncogenic osteomalacia (OOM) is a rare disorder characterized by hyperphosphaturia, hypophosphatemia, and osteomalacia. OOM is treated by surgical excision, which rapidly and permanently abrogates all symptoms. However, tumor removal can be complicated because the lesion is usually small and difficult to distinguish from the surrounding tissue. Complete excision is necessary, however, because the syndrome typically persists if any tumor tissue remains. To ensure complete excision, surgery may require wide resection margins, causing iatrogenic tissue damage that is disproportional to tumor size and to the almost always benign nature of the tumor. We report for the first time the use of minimally invasive radiofrequency ablation (RFA) to completely destroy a tumor causing OOM and thereby avoid arthroplasty. A 40-year-old woman was diagnosed for an acquired hypophosphatemic vitamin D-resistant osteomalacia due to a tumor in her right femoral head that was detected as recently described (JBMR, 2007 Jan;22(1):158-62). Laboratory analyses revealed hypophosphatemia and a diminished TmP/GFR. A complete tumor removal by an open surgical procedure would have required total hip arthroplasty. Because of her young age, we attempted to preserve the hip joint, which was healthy and not affected by the tumor. Histology revealed a benign mesenchymal tumor. We performed CT-guided RFA to destroy the lesion, thereby avoiding arthroplasty. Complete tumor ablation was achieved six days later after a second round of RFA and confirmed on the following day by magnetic resonance imaging (MRI). A few weeks after RFA, biochemical markers returned to normal and all symptoms resolved. A one year clinical follow-up was unremarkable. RFA is a well-established procedure for selectively removing small tissue volumes. In bone, RFA is an effective palliative method for treating skeletal metastases. RFA of benign primary bone tumors has been primarily used to treat osteoid osteoma. This case demonstrates that CT-guided RFA can successfully treat a tumor causing OOM. We believe that RFA may broaden the scope of treatment options in OOM and may offer an effective, less invasive technique that would be a very attractive alternative to classical surgery.

Severe Vitamin D Depletion in Arab-American Women Living in Dearborn, MI, USA. R. D. Hobbs^{*1}, Z. Habib^{*1}, D. Alromaihi^{*1}, L. Ida^{*2}, N. Parikh^{*2}, J. Schmidt^{*3}, J. Kordosky^{*3}, D. S. Rao². ¹Internal Medicine, Henry Ford Hospital, Detroit, MI, USA, ²Bone & Mineral Research Laboratory, Henry Ford Hospital, Detroit, MI, USA, ³DiaSorin, Inc, Stillwater, MN, USA.

Although vitamin supplements and dairy intake are important determinants of vitamin D nutrition, most individuals can maintain sufficient 25-OHD levels with adequate sun exposure. Secular habits, geographic location (latitudes <40°) or diminished sun exposure may lead to vitamin D depletion. European studies have documented vitamin D depletion in veiled Muslim women living in areas with decreased ambient sunlight, but no such data exist for this ethnic group living in the US. Accordingly we assessed vitamin D nutritional status by serum 25-OHD in Arab-American women living in Dearborn, MI, the largest, most concentrated Arab settlement in the US.

Serum 25-OHD and PTH were measured in 87 Arab-American women who attended an ethnic market on either April 7 or 14, 2007. Demographic variables, dress, medication use, medical history, vitamin supplementation and a food analysis were performed on each subject. A cross sectional approach with analysis using MANOVA or Fischer's exact test was used.

Three groups were formed as follows: unveiled (UV; n=22), veiled with supplementation (VS; n=45), and veiled non-supplemented (VNS; n=20).

Mean 25-OHD levels were lowest and mean PTH levels highest in the veiled non-supplemented group, and differed significantly from the other two groups and from each other (p=0.004, p=0.003 respectively). Although mean age and location did not differ, the mean time in the US was significantly different between the groups (p=0.002). Vitamin D supplementation between the veiled/supplemented (1250 \pm 1243 IU/week) and unveiled groups (1000 \pm 1276 IU/week) did not differ (p=.45).

Vitamin D depletion, as assessed by 25-OHD, is highly prevalent in a sample of Muslim women living in Dearborn, MI and probably the highest among any demographic groups studied thus far. Similar to European studies the findings are at least in part attributable to conservative dress in an area with decreased sun exposure. With increasing time spent in the United States vitamin D levels increase across all tested groups although most (61/87) had levels \leq 10 ng/ml. These findings potentially identify a problem in the largest, most concentrated Arab-American population in the United States.

Variable	Comparison Between Arab-American Women in Terms of Clothing and Vitamin Supplementation		
	UV	VS	VNS
Mean Age (yrs)	36.4 \pm 13.4	37.2 \pm 14.1	37.6 \pm 7.1
Time in the US (yrs)	18.9 \pm 14.2	9.8 \pm 9.1	9.5 \pm 7.3
25-OHD (ng/dl)	11.1 \pm 8.8	8.6 \pm 4.9	4.9 \pm 3.5
PTH (pg/ml)	72 \pm 27	62 \pm 23	88 \pm 35

Lack of Efficacy of Octreotide in the Treatment of Tumor-induced Osteomalacia. M. H. Kelly^{*1}, B. Brillante^{*1}, A. Khosravi^{*2}, M. T. Collins¹.

¹National Institute of Dental and Craniofacial Research, National Institutes of Health, Bethesda, MD, USA, ²Neurorehabilitation Department, Kennedy Krieger Institute, Johns Hopkins University, Baltimore, MD, USA.

The purpose of this study was to test the efficacy of the somatostatin analogue, octreotide, in the treatment of tumor-induced osteomalacia (TIO).

TIO is a rare, acquired disease characterized by low serum phosphate and 1,25-dihydroxyvitamin D₃ (1,25-D), and osteomalacia. It is due to mesenchymal tumors that produce the phosphate and vitamin D-regulating hormone, FGF-23. Removal of the tumor is curative, but the tumors sometimes cannot be located and medical treatment is required. Octreotide has been reported to be an effective medical therapy. We sought to confirm the efficacy of octreotide by treating six patients with TIO.

Six patients with TIO who were off phosphate and calcitriol replacement were studied. Five of the six subjects had FGF-23 secreting tumors that were localized on Indium-111-pentetreotide scans (a radiolabeled analogue of octreotide). Subjects were treated with octreotide (Sandostatin, Novartis) 100 mcg by subcutaneous injection every 8 hours for three days. Serum phosphorus, 1,25-D, and FGF-23 were measured serially for 3 days. Repeated measures ANOVA was performed to test for significant changes in serum measurements.

None of the subjects responded to the octreotide. The mean changes in serum values over the 3 day period were: phosphorus 4% (range -3 to 13), 1,25-D 10% (-5 to 14), and FGF-23 -1% (-11 to 8). There was no significant change in serum phosphorus, 1,25-D, or FGF-23 in response to treatment with octreotide.

During 3 days of treatment with relatively high doses of octreotide, there was no effect on serum phosphorus, 1,25-D, or serum FGF-23 in patients with FGF-23 secreting tumors, in spite of the fact that 5/6 tumors took up pentetreotide.

Skeletal Fluorosis from Instant Tea: A Second Case. M. P. Whyte¹, W. G. Totty^{*2}, G. M. Whitford^{*3}. ¹Division of Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA, ²Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, MO, USA, ³School of Dentistry, Medical College of Georgia, Augusta, GA, USA.

Skeletal fluorosis (SF) usually results from prolonged consumption of well water with > 4 parts per million (ppm) fluoride ion (F⁻); i.e., > 4 mg/L. Black and green teas can contain significant amounts of F⁻. In 2005, SF due to drinking 1 - 2 gallons of double-strength instant tea daily throughout adult life was reported in a 52-year-old woman (Am J Med 118:78).

A 49-year-old woman developed widespread musculoskeletal pains, considered fibromyalgia, in her mid-30's. Additionally, there was unexplained, increasing, axial osteosclerosis. She reported drinking 2 gallons (7.56 liters) of instant tea each day since age 12 years, and took fluoxetine intermittently for 5 years. Ion-selective electrode methodology quantitated F⁻ in her blood, urine, municipal tap water, beverage, and extracts of fingernail and toenail clippings.

Radiographs showed uniform osteosclerosis involving the axial skeleton, but enthesopathy was consistent with her age. DXA Z-scores were + 10.3 in the lumbar spine, and + 2.8 in the total hip. Serum F⁻ concentration was 120 µg/L (20 - 80, reference range), and a 24-hour urine specimen contained 18 mg F⁻/gm creatinine (< 3, reference range). Mean F⁻ levels were 2.2 and 2.8 times greater than for 3 age-matched controls in fingernails and toenails, respectively (p < 0.001). Her instant tea beverage, prepared extra-strength as usual and using tap water with ~ 1.14 ppm F⁻, contained 5.8 ppm F⁻. In the U.S.A., this F⁻ level exceeds the Environmental Protection Agency limit of 4.0 ppm for primary drinking water, the Food and Drug Administration limit of 1.4 - 2.4 ppm for bottled water or beverages, and the Public Health Service optimum fluoridation level in community water ranging from 0.7 - 1.2 ppm. The tea product contributed ~35 of the 44 mg daily F⁻ exposure from her beverage. Fluoxetine could have added as much as 3.3 mg F⁻ daily.

A second case of SF from habitual consumption of large volumes of extra-strength instant tea calls for recognition and better understanding of a skeletal safety limit for this modern preparation of the world's most popular beverage.

Legend to Figure:

Anteroposterior radiograph of the lower thoracic and upper lumbar spine at age 48 years shows uniformly dense, but properly shaped, vertebrae.

The Relationship between Bone Formation Rate and Bone Marrow Adipocytes in Pediatric Metabolic Bone Diseases. M. S. Cheung^{*}, F. H. Glorieux, L. M. Ward, R. Travers^{*}, F. Rauch. Genetics Unit, Shriners Hospital for Children, Montreal, PQ, Canada.

Adipocytes are derived from the same mesenchymal stem cells as osteoblasts. If mesenchymal stem cells differentiate into either adipocytes or osteoblasts depending on functional requirements, there should be an inverse relationship between the number of adipocytes in the bone marrow and bone formation rate on adjoining bone surfaces. Indeed, histomorphometric studies in adults seem to confirm this hypothesis. In the present study we examined whether a similar relationship between adipocyte numbers and bone formation rate is present in a range of pediatric metabolic bone disorders. Iliac bone samples from 71 children and adolescents with osteogenesis imperfecta (OI) -before medical treatment and after two years of pamidronate therapy (OI-PAM) - idiopathic juvenile osteoporosis (IJO), Crohn's disease and pseudohypoparathyroidism (PHP) were assessed for cancellous bone formation rate per bone surface (BFR/BS) and the presence of adipocytes. Results were compared to those of 58 controls who were individually age-matched to each disease cohort.

	N	Age (yr)	BFR/BS (µm ³ *µm ⁻² *y ⁻¹)	Samples with Adipocytes (N)
OI	24	11.4 (4.2)	71 (33)*	6*
OI-PAM	24	11.5 (3.9)	19 (17)	7*
Controls	24	11.3 (5.0)	42 (17)	0
Crohn's	8	15.5 (2.7)	46 (25)	8***
Controls	8	15.7 (3.2)	34 (11)	0
PHP	8	16.5 (3.2)	86 (43)**	8***
Controls	8	16.4 (3.0)	30 (18)	1
IJO	7	10.9 (0.9)	23 (14)*	0
Controls	7	11.1 (1.1)	57 (14)	1

*p<0.05; **p<0.01;***p<0.001 compared to controls

In untreated OI, both BFR/BS and the proportion of samples containing adipocytes were higher than in controls. Pamidronate treatment led to lower BFR/BS, but had no effect on the number of samples with adipocytes. In Crohn's disease and PHP, adipocytes were more prevalent than in controls, even though average BFR/BS was similar or higher. When all biopsy samples were examined, there was no difference in BFR/BS between samples with adipocytes present compared to those without adipocytes (p=0.40). In conclusion, no evidence for an inverse relationship between bone formation and the presence of adipocytes was found in the disease groups studied here. Factors other than bone formation rate seem to be more important determinants of adipogenesis in these conditions.

Exostoses After Pediatric Stem Cell Transplant Are Associated with Growth Hormone Treatment. K. J. Dilley¹, K. Danner-Koptik². ¹Pediatric Hematology-Oncology-Transplant, Children's Memorial Hospital, Feinberg School of Medicine, Chicago, IL, USA, ²Pediatric Hematology-Oncology-Transplant, Children's Memorial Hospital, Chicago, IL, USA.

Allogeneic hematopoietic stem cell transplant (SCT) is a curative therapy for pediatric patients with both malignant and non-malignant diseases. Single or multiple benign exostoses or osteochondromas have been reported following total body irradiation (TBI) as well as focal irradiation. Patients exposed to TBI at a young age are at highest risk of developing exostoses. The objective of this study was to look at potential factors besides radiation that may play a role in development of exostoses. All patients who have undergone SCT at a single institution between March 1992 and October 1998 and who have had an exostosis identified by clinical findings or as an incidental finding on a radiologic study were included. A case-control design matched patients with controls who had the same stem cell source. 11/13 cases were matched to controls within the same age group at SCT of <4 yrs or ≥4 yrs but 2 others were not able to be so closely matched to unique controls. Treatment-related variables as well as physical and laboratory findings were collected from medical record reviews. Of 110 eligible patients, 13 (12%) were found to have exostoses at the time of data collection, 7 male and 6 female. All but two were transplanted for malignancy. All but one received TBI, that case did receive radiation but to a site remote from the exostosis. Multiple exostoses were noted in 62% (8/13). Treatment with growth hormone was more likely in cases (n=6) than in controls (n=2), p=0.046. Also, cases had a nonsignificant trend toward more negatively skewed height Z scores (mean -2.1 vs -1.5, p=0.056) and weight Z scores (mean -1.4 vs -0.2, p=0.097) at most recent follow-up than did controls. Patients available for use as controls tended to be older than cases, anecdotally supporting other studies that have reported younger age to be a risk factor for exostoses. No other SCT treatment factors such as HLA-mismatch or the occurrence of GVHD were associated with exostosis risk. Calcium (9.8 vs 9.9, p=0.75) and IGF-1 (382 vs 331, p=0.60) values were not significantly different at latest follow-up (cases at mean age 14.6 yrs vs controls at mean age 13.5 yrs), but IGF-BP3 approached significance with a mean of 5.0 in cases compared to 3.7 in controls (p=0.066). In conclusion, allogeneic SCT patients with the most extreme growth disruption and subsequent treatment with growth hormone appear to be at highest risk for development of exostoses. All reported samples to date have been small, use of multi-institution data to further examine risk factors is warranted.

Postnatal Vitamin D Supplementation Normalized Neonatal Bone and Lean Mass Following Maternal Dietary Vitamin D Deficiency in the Guinea Pig. S. L. Finch, H. A. Weiler. School of Dietetics and Human Nutrition, McGill, Ste. Anne-de-Bellevue, PQ, Canada.

While vitamin D deficiency is common at birth, the consequences to growth and bone mass by weaning are unclear. This study was designed to determine if maternal dietary vitamin D deficiency in pregnancy has a negative impact on mineralization of full term infants and if postnatal supplementation would recover the limited bone mass using a 2-by-2 design. Forty pregnant guinea pigs were randomized to receive a diet with or without 1 IU vitamin D3/g diet. Blood was sampled in sows before mating at the start of the 3rd trimester (d42) to coincide with fetal mineralization and postpartum to measure 25(OH)D as the marker for vitamin D status. At birth pups were randomized to receive 10 IU of cholecalciferol or a placebo of equal volume until weaning at d28. Diets and supplements were blinded using letter coding. Dual energy x-ray absorptiometry (DXA) was used to measure body composition, as well as bone mineral density (BMD), bone area and bone mineral content (BMC) of the whole body, tibia, femur and lumbar spine at birth and d28 of life. Main and interaction effects were detected using factorial ANOVA and post-hoc testing using Bonferroni tests. Weight of the pups was lower in the vitamin D deficient group at birth and d28 (Birth: 169.59±97.94 vs 155.34±97.89 g, P=0.042; d28: 279.13±47.43 vs 255.91±44.19 g, P=0.024). Main effects of the maternal diet showed vitamin D deficient offspring had lower whole body BMC (5.58±2.69 vs 5.24±2.52 g, P=0.012) and lower tibia BMC (0.15±0.07 vs 0.14±0.07 g, P=0.012) than the control group. Interaction effects showed that the deficient group were lower than the control group in whole body BMD (P=0.045) and lean mass (P=0.024) unless they received supplemental vitamin D. Additionally, femur BMC was lower at d 28 in the deficient males unless they received the supplement (P=0.012). Weight and whole body BMC increased 2.5 to 3 times from birth to weaning demonstrating the magnitude of growth that this novel model is capable of in a short period of time. In summary, postnatal vitamin D supplementation normalized neonatal bone and lean mass following maternal dietary vitamin D deficiency in the guinea pig.

Hyperparathyroid Bone Disease in Two Sisters with Parathyroid Hormone Resistance (pseudohypoparathyroidism 1b). R. C. Gensure¹, M. Bastepe². ¹Pediatrics, Ochsner Clinic Foundation, New Orleans, LA, USA, ²Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Pseudohypoparathyroidism (PHP) is a disorder of hypocalcemia and elevated serum parathyroid hormone (PTH) levels caused by defective signaling via the stimulatory G protein α subunit (G α). PHP type-1a results from mutations in G α -coding GNAS exons, and is characterized by multi-hormone resistance and a bone dysplasia syndrome called Albright's hereditary osteodystrophy (AHO). PHP-1b is caused by mutations that disrupt the imprinting of GNAS and is characterized by resistance to PTH (and occasionally to TSH) with no bone dysplasia. In each subtype, hormone resistance develops only after maternal inheritance of the genetic defect, consistent with the predominantly maternal expression of G α in some tissues, including the renal proximal tubule. We report on two sisters with PHP-1b, demonstrating both PTH- and TSH-resistance in the absence of AHO, seen in consultation because of increased fractures. The genetic defect in this family, a 4.4-kb deletion in STX16, has been reported previously (Am J Hum Genet. 2005 May;76(5):804-14). The elder sister (patient A, 15 9/12 y.o.) had one pathological fracture and was found to have a low lumbar bone mineral density (BMD) (Z-score -1.7). Importantly, the BMD did not show the expected increase with age, but rather decreased 12.6% over the past year. The younger sister (patient B, 14 0/12 y.o.) had two recent fractures and had a BMD closer to the normal range (Z-score -0.7), with a slight increase (2.6%) over the past year. Each had been managed with calcium and calcitriol according to the standard practice to maintain low-normal serum calcium levels to reduce risk of kidney stones; the PTH levels were elevated in both patients (272 pg/ml for patient A, 320 pg/ml for patient B). G α is not imprinted in bone; hence, while patients with PHP-1a have a 50 percent reduction in G α signaling leading to partial PTH resistance in bone, patients with PHP-1b are predicted to have normal G α signaling in bone and could therefore develop hyperparathyroid bone disease. The patients' medications were adjusted to lower PTH levels to the normal range (57 pg/ml and 35 pg/ml, respectively). After 8 months, their bone mineral densities improved to Z=-0.9 and Z=-0.3, respectively (increased by ~0.5 S.D. in each case), and they did not have any additional fractures. Neither patient developed hypercalcaemia, likely because of the lack of imprinting of GNAS in the renal distal tubule. Given that bone is not resistant to PTH in PHP-1b, we recommend that these patients' serum PTH levels be maintained in the normal range to prevent hyperparathyroid bone disease.

Physal Closure from Chronic Vitamin A Intoxication. D. Wenkert¹, W. H. McAlister², M. P. Whyte³. ¹Res Ctr, Shriners Hospt Children, St. Louis, MO, USA, ²Mallinckrodt Inst Radiol, Wash Univ Sch Med, St. Louis, MO, USA, ³Div Bone & Miner Dis, Wash Univ Sch Med, St. Louis, MO, USA.

Vitamin A excess causes periosteal calcification, diffuse idiopathic skeletal hyperostosis, and fractures. In pediatric patients, skeletal growth, modeling, and remodeling can be disrupted. Premature growth plate fusion from vitamin A and D toxicity was first reported in animal hind limbs ("hyena disease"). Subsequently, in 1962, 3 of 7 children with growth retardation from vitamin A toxicity had early lower limb physal closure (JAMA; 182:980). Further reports concerned vitamin A derivatives used in severe pediatric dermatoses or cancers.

A 6-yr-old boy with a history of hypervitaminosis A, associated with liver fibrosis, was referred for "epimetaphyseal disease". Birth weight was 10 lbs, and he walked at 10 mo. At that time, gastroenteritis was reportedly treated by a chiropractor with a dose of 3 million units (U) of vitamin A over 16 days, followed by 60,000 U/d except when intercurrent illness prompted ~20 additional 3 million U, 16-day courses.

By age 2 ½ yrs, fingernails reportedly "bubbled up and fell off", speech regressed, and gross motor skills were lost. Hospitalization elsewhere revealed a critically ill, anorexic child with shiny, hairless, jaundiced skin, icterus, mouth sores, mucosal bleeding, pseudotumor cerebri, ataxia, and marked hepatosplenomegaly. Laboratory studies revealed a coagulopathy, hepatitis, anemia, and thrombocytopenia, but normal serum Ca, P, and Mg levels. Alkaline phosphatase was elevated at 827 IU/L. Hypervitaminosis A was diagnosed. After vitamins were stopped, he resumed walking and eating within 9 mo. Nevertheless, leg bowing, noted at age 3, worsened. Radiographs at age 5 showed physal closure within distal femurs and proximal and distal tibias.

Upon referral, he had dysphagia, dyspnea, anemia, bleeding tendency, morning stiffness, knee and ankle pain, but took only vitamin K. Height was 5%, weight 75%, sitting height 50%, arm span 75%, and head circumference >>95%. He had petechia, bruises, telangiectasias, hypertelorism, cupped optic discs, and splenomegaly (17 cm) without hepatomegaly, 30° knee contractures, enlarged warm ankles and knees, and bowed tibias. Radiographs revealed the physal closure, now with relative overgrowth of fibulae, and 1/2 yr later, closure of the proximal fibular physes. Physes elsewhere remained open.

Long-term follow-up of physal fusion from vitamin A toxicity (eg. 12 yrs: JBJS[AmJ] 1974;56:1283) suggests disproportionate, asymmetric shortening of lower limbs. Narrowing of physes from isotretinoin can resolve (Am J Dis Child 1988;142:316-8). Experience with our patient suggests that reversal of physal fusion is not possible if vitamin A toxicity has been severe and prolonged.

The Importance of Biochemical Markers of Bone and Cartilage Turnover as the Predictors of Radiographic Progression in Patients with Early Rheumatoid Arthritis. J. Hashimoto¹, P. Garnero², N. Miyasaka³, K. Yamamoto⁴, S. Kawai⁵, T. Takeuchi⁶, N. Murata⁷, H. Yoshikawa¹, N. Nishimoto⁸. ¹Orthopaedic Surgery, Osaka University Graduate School of Medicine, Suita, Japan, ²INSERM Research Unit 664 and Synarc, Lyon, France, ³Tokyo Medical and Dental University, Tokyo, Japan, ⁴The University of Tokyo, Tokyo, Japan, ⁵Toho University Omori Medical Center, Tokyo, Japan, ⁶Saitama Medical Center/School, Saitama, Japan, ⁷Orthopaedic Surgery, Kyowakai Hospital, Suita, Japan, ⁸Osaka University Graduate School of Medicine, Suita, Japan.

Background: Rheumatoid arthritis (RA) is characterized by chronic arthritis leading to joint damage due to bone and cartilage destruction. Although early intervention of RA could prevent the progression of joint damages, it is difficult to predict the radiological progression in patients with early RA.

Objectives: To evaluate the predictive value of biological, radiological and clinical parameters for the prognosis of radiographic joint damage in RA patients treated with conventional DMARDs.

Methods: Among 302 patients with active RA of less than five years duration who participated in the prospective 1-year randomized controlled trial of tocilizumab monotherapy, termed SAMURAI study, the control arms (n=145), in which the dose regimens of the conventional DMARDs therapy excluding any biologics, were analyzed. Biochemical markers (bone turnover, cartilage turnover and inflammation), clinical score (number of swollen joint, tender joint, DAS score) and body mass index were measured at baseline and radiographic joint damage were scored at baseline, week 28 and 52 by two independent blinded readers according to the van der Heijde modified Sharp method.

Results: At baseline, mean age, disease duration, DAS28 score, total Sharp score and CRP were 53 years, 2.3 years, 6.5, 29.4 and 4.8 mg/dl, respectively. Increased urinary C-terminal crosslinking telopeptide (CTX-II) levels, higher urinary pyridinoline/deoxypyridinoline ratio (PYD/DPD), higher JSN score and low BMI at baseline were associated with increased radiological progression at 1 year both for erosion and the JSN score. When categorized into two or three groups of baseline risk factors (cut-off values: 500 and 1000 ng/mmol/creatinine for CTX-II, median for PYD/DPD, 0 unit or more for JSN, 18.5 and 25 for BMI), logistic regression analysis showed that these four variables were significant independent predictors of radiological progression (+0.5 unit increase of erosion or JSN score at week 52).

Conclusion: High baseline levels of biomarkers of bone and cartilage turnover including CTX-II and PYD/DPD, JSN score and low BMI are significantly and independently associated with 1-year progression of joint destruction in early RA.

Disclosures: J. Hashimoto, None.

Tartrate-Resistant Acid Phosphatase Isoform 5a as a Marker of Disease Severity in Rheumatoid Arthritis. A. J. Janckila¹, D. H. Neustadt², L. T. Yam¹. ¹Medicine, VA Medical Center, Louisville, KY, USA, ²Medicine, University of Louisville, Louisville, KY, USA.

Objective: This study was undertaken to determine the clinical significance of tartrate-resistant acid phosphatase (TRACP) isoforms 5a and 5b as markers of chronic inflammation and cartilage/bone destruction in rheumatoid arthritis (RA).

Methods: 118 patients were recruited including 50 with RA (25 with subcutaneous nodules), 26 with osteoarthritis (OA) and 42 with other rheumatic diseases. 26 healthy adults served as controls. Serum TRACP-5a activity, TRACP-5a protein and TRACP-5b activity were determined by in-house immunoassays. C-reactive protein (CRP) was determined by in-house immunoassay using commercial antibodies and CRP. Other commercial markers included bone-specific alkaline phosphatase (bALP), C-telopeptides of type-I collagen (ICTP), cartilage glycoprotein-39 (YKL-40), and IgM rheumatoid factors (IgM-RF).

Results: TRACP-5a protein was elevated in RA and correlated only with IgM-RF. Amongst RA patients, TRACP-5a protein and IgM-RF were higher in those with nodules. TRACP-5a protein and IgM-RF tended to decline with disease duration, but not age in RA patients with nodules. In contrast, TRACP-5b activity was slightly elevated in RA and correlated with bALP and ICTP, but not with IgM-RF or CRP. TRACP-5b activity was not related to presence of nodules, however it increased with age and disease duration in RA.

Conclusion: TRACP isoforms may be useful disease markers in RA. TRACP-5a protein may be a measure of systemic inflammatory macrophage burden and a marker for disease severity. TRACP-5b activity is a marker for osteoclast number and may be useful to monitor local or systemic bone destruction in early RA.

Association of tri-nucleotide (CAG and GGC) Repeat Polymorphism of androgen Receptor Gene in Taiwanese Women with Refractory or Remission Rheumatoid Arthritis. H. Kang¹, S. Yu¹, Y. Hsu², C. Chang³.

¹Graduate Institute of Clinical Medical Sciences, Chang Gung University, Kaohsiung, Taiwan, ²Program for Population Genetics, Harvard School of Public Health, Boston, MA, USA, ³Departments of Pathology, Urology, Radiation Oncology, Rochester University, Rochester, NY, USA.

To investigate the relationship between CAG and GGC repeat polymorphism of the androgen receptor (AR) gene and rheumatoid arthritis (RA) in female patients with different disease subtypes. This case-control study enrolled 215 females in three groups: RA patients refractory to standardized therapy (n=51); RA patients at complete remission phase (n=60); and healthy controls (n=104). CAG and GGC repeat lengths were determined by automated fluorescence-based DNA fragment-sizing method. Demographic data, allele lengths, allele distribution, and zygosity status of CAG/GGC repeats were assessed for the three group. Refractory RA patients tend to have a significantly younger onset age of RA and more elevated erythrocyte sedimentation rates than do remission RA patients. Mean and median values of CAG and GGC repeat lengths are similar in both RA and control patients. However, RA patients harboring any long CAG alleles with more than 23 repeats had an increased risk of a refractory course, whereas differences in risk were not observed between these patients and RA subtypes harboring any long GGC alleles with more than 16 repeats. In addition, the homozygous frequency of CAG but not GGC alleles was lower in refractory RA than in remission RA patients or in controls (p=0.042). Neither CAG nor GGC repeat lengths had a significant relationship with rheumatoid factor reactivity. Our observations indicate that short CAG repeats of the AR gene with higher transactivation activity may have protective effects against refractory course of RA development and that homozygous frequency of CAG alleles may be involved in the disease remission subtype. In contrast, lack of association of GGC polymorphism and RA was also observed. Together, these data imply that CAG but not GGC alleles in the AR polymorphism may play an important role in modulating the disease pattern of RA among Taiwanese women.

The Effect of Etanercept on Bone Metabolism in Patients with Rheumatoid Arthritis. D. Kida^{*}, Y. Eto^{*}, M. Tsukamoto^{*}, T. Sato^{*}, A. Kaneko^{*}, G. Ishihara^{*}, H. Sugishita^{*}, K. Saito^{*}. Department of Orthopedic surgery and Rheumatology, National Hospital Organization Nagoya Medical Center, Nagoya, Japan.

Background: Recently, the discovery of the RANKL-RANK-OPG pathway contributed to a better understanding of bone diseases such as RA, osteoporosis, and bone metastasis. On the other hand, TNF has been shown to increase the expression of RANKL and act directly on osteoclasts by enhancing their resorpting activity. Furthermore, TNF enhances bone loss in RA by inducing osteoblast apoptosis. Therefore, the imbalance between bone resorption and bone formation leads to focal and systemic bone loss in RA. Although the most recent data suggest that infliximab therapy may inhibit generalized bone loss in patients with RA, it has not been studied in etanercept (ETN).

Purpose: The aim of this study was to evaluate urinary N-telopeptide of type-I collagen / creatinine (NTx) and serum bone specific alkaline phosphatase (BAP) in RA before and after treated with ETN.

Methods: Sixty postmenopausal females (mean age 62 yr; mean disease duration 14 yr) with RA who had not been treated for osteoporosis were divided into three groups: Twenty treated with bisphosphonate (BP), twenty treated without BP and twenty treated with ETN alone. To evaluate disease activity, ESR, CRP, DAS28ESR-4, modified Stanford Health Assessment Questionnaire (mHAQ) score, NTx, and BAP were measured in all patients at baseline, and after 6 months.

Results: However, ESR (p<0.01), CRP (p<0.001), DAS28ESR-4 (p<0.001), and mHAQ score (p<0.05) had decreased significantly, NTx levels did not differ significantly in 6 months after initial treatment with ETN. BAP levels (p<0.01) were significantly increased, and higher (p<0.01) in patients treated with ETN compared to others.

Conclusion: ETN therapy may not inhibit bone resorption but stimulate bone formation in patients with RA. This effect may be due to a beneficial roll of TNF-alpha blockade on bone turnover. Studies of longer duration are needed to assess the effect of ETN on bone metabolism.

Human Rheumatoid Synovial Fibroblasts Promote Osteoclastogenic Activity by Activating RANKL via TLR-2 and TLR-4 Activation. H. Kim¹, S. Lee¹, K. Kim², M. Cho², W. Park³, H. Kim². ¹Internal Medicine, Konkuk University Hospital, Seoul, Republic of Korea, ²Internal Medicine, Catholic University of Korea, Seoul, Republic of Korea, ³Internal Medicine, INHA University Hospital, Seoul, Republic of Korea.

Objective: The interplay between the innate immune system and inflammatory bone destruction in the joints of individuals with rheumatoid arthritis (RA) remains unclear. This study was undertaken to explore the effect of toll-like receptor (TLR) signaling in fibroblast-like synoviocytes (FLS) on the expression of RANKL and induction of

osteoclastogenic activity.

Methods: The levels of RANKL mRNA and protein were measured using RT-PCR, real-time PCR, and immunostaining. Monocytes were cocultured with RA-FLS that had been stimulated with TLR ligands in fresh media and subsequently stained for tartrate-resistant acid phosphatase (TRAP) activity. Osteoclast molecule markers were measured using real-time PCR.

Results: Expression of TLR-2 and TLR-4 was higher in RA-FLS than in OA-FLS and normal skin fibroblasts. TLR-2 and TLR-4 ligands induced RANKL expression in RA-FLS. TLR stimulation of RA-FLS also induced the production of IL-1 β and TNF- α to a lesser extent; however, it had no effect on IL-17 production. Inhibition of TLR induced IL-1 β production, which partially reversed the upregulation of RANKL induced by TLR ligands. RA-FLS stimulated by TLR-2 and TLR-4 ligands and cocultured with human monocytes induced high levels of expression of TRAP, RANK, cathepsin K, calcitonin receptor, and matrix metalloproteinase-9, suggesting that RA-FLS promote osteoclast differentiation. Our results suggest that the TLR signaling pathway, through TLR-2 and TLR-4, induces RANKL expression in RA-FLS and the expression of RANKL promotes the differentiation of osteoclasts in RA synovium.

Conclusion: Targeting specific TLRs may be a promising approach to prevent inflammatory bone destruction in the pathogenesis of RA.

Alpha Lipoic Acid Attenuates Vascular Smooth Muscle Calcification via the Expressional Regulation of Genes Related to Apoptosis and Oxidative Stress. E. Kim^{*1}, I. Lee^{*1}, H. Kim^{*2}, W. Jang^{*1}, I. Park¹. ¹Kyungbook National University, Daegu, Republic of Korea, ²Keimyung University, Daegu, Republic of Korea.

Vascular smooth muscle cell (VSMC) calcification is an important risk factor for cardiovascular diseases. It is reported that alpha lipoic acid (ALA) has many beneficial effects on vascular cells in atherosclerosis. The present study was designed to investigate whether ALA can prevent VSMC calcification. We explored the effects of ALA on human VSMC calcification in vitro and found that ALA attenuates VSMC calcification induced by high phosphate conditions as quantified by the o-cresolphthalein complexone method. ALA also inhibits vitamin D3-induced aortic calcification in vivo. Using DNA microarray analysis and secretome analysis using LC/MS/MS, we identified genes and proteins whose expression was changed by high phosphate conditions and ALA. Proteins up-regulated by high phosphate condition that were subsequently down-regulated in the presence of ALA were related to apoptosis and oxidative stress. Gene expression analysis using DNA microarray tools confirmed the up-regulation or down-regulation of some, but not all, of the proteins observed in ALA challenged, in high phosphate condition. The present data suggest that vascular calcification is inhibited by ALA through modulation of apoptosis and oxidative stress pathway and provide valuable information about the underlying mechanisms of atherosclerosis.

Survey on the Effect of Immunomodulatory Therapy on Bone in Multiple Sclerosis. M. J. McKenna¹, M. Shuhaiber^{*2}, K. Foy^{*2}, R. Lonergan^{*2}, M. Au-Yeong^{*1}, J. Brady^{*3}, B. Murray^{*3}, J. M. T. Redmond^{*2}. ¹DXA Unit, St. Vincent's University Hospital, Dublin 4, Ireland, ²Neurology Department, St. James' Hospital, Dublin 8, Ireland, ³Metabolism Laboratory, St. Vincent's University Hospital, Dublin 4, Ireland.

Osteoporosis is a complication of multiple sclerosis (MS) especially if corticosteroid therapy is given. Little is known about the effect on bone of immunomodulatory therapy for MS. We sought to evaluate bone mass in patients with MS on immunomodulators. We performed a cross-sectional survey and a follow-up survey.

At baseline, we studied bone mineral density (BMD) by dual energy X-ray absorptiometry (DXA) in 37 patients with MS who received immunomodulators. The BMD was measured at two sites: the lumbar spine (L1 to L4) and the left total femur site, using a Hologic QDR4000 Elite Densitometer (Bedford, MA). In our DXA unit, the least significant change at the 95% level is 3.2% at the spine and 2.5% at the femur.

Different immunomodulators were administered: Interferon beta-1a in 70%, Interferon beta-1b in 27% and Glatiramer in 3%. High-dose pulse steroid therapy (intravenous methylprednisolone 500 mg) was given to 81% ranging from one course to 17 courses. The mean age was age 38.8 \pm 8.9 years, the mean duration of MS was 5.8 \pm 3.7 years; the mean number of relapses was 4.0 \pm 0.7; and the mean disability score (EDSS) was 3.1 \pm 1.9. Both mean BMD Z-score at spine of 0.53 (CI: 0.15-0.92; p<0.001) and mean BMD Z-score at femur of 0.72 (CI: 0.42-1.01; p<0.0001) were significantly greater than zero.

A follow-up survey after nearly 4 years of continuous immunomodulatory therapy is now being conducted. BMD is being remeasured. In addition, biochemical studies are being performed including: vitamin D status; parathyroid status; and bone turnover markers (serum bone specific alkaline phosphatase, intact osteocalcin, procollagen type I aminopeptide, beta-carboxyterminal telopeptide of type I collagen; and, urine aminoterminal telopeptide of type I collagen, and deoxypyridinoline crosslinks). Preliminary analysis of DXA in 7 subjects shows no change in BMD at the spine (1.046 \pm 0.16 g/cm² vs 1.051 \pm g/cm²; p=0.58) and at the femur (1.024 \pm 0.20 g/cm² vs 1.02 \pm 0.20 g/cm²; p=0.46).

In conclusion, immunomodulatory therapy in MS does not appear to have an adverse effect on bone.

Prevalence of Radiographic Osteoarthritis of Knee and Lumbar Spine and Its Association with Pain: The Research on Osteoarthritis Against Disability (ROAD) Study. S. Muraki¹, N. Yoshimura¹, H. Oka^{*1}, A. Mabuchi^{*1}, Y. En-yo^{*2}, M. Yoshida^{*2}, T. Suzuki³, H. Yoshida³, H. Ishibashi^{*3}, S. Yamamoto³, H. Kawaguchi¹, K. Nakamura¹. ¹22nd Century Medical Ctr., Univ. of Tokyo, Tokyo, Japan, ²Wakayama Medical Univ., Wakayama, Japan, ³Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan.

Although osteoarthritis (OA) of knee and lumbar spine is a major cause of disability in the elderly, few epidemiologic studies have been performed. We established a large-scale nationwide clinical study called ROAD (Research on Osteoarthritis Against Disability) in 2005, and created a comprehensive and systemic database including clinical and genetic information in three cohorts of urban, mountainous and seacoast areas. We recruited 3,040 participants in total, from which 2,288 subjects older than 60 years (818 men & 1,470 women; mean age=74.3 yrs.) were enrolled for investigation of the prevalence of radiographic OA of knee and lumbar spine, as well as its association with the respective local pain. The radiographic severity of OA was determined according to the Kellgren/Lawrence (KL) grade (0-4) at femoral-tibial joints of bilateral knees and at intervertebral spaces from L1/2 to L5/S1 of the lumbar spine. Prevalence of radiographic OA (KL> or = 2) in either knee joint was 47.0% in men and 70.2% in women, while that in either intervertebral space was 84.1% in men and 70.7% in women. Prevalence of radiographic knee OA was higher in the female sex (odds ratio [OR]=3.28, 95% confidential interval [CI]=2.71-3.97) and mountainous residents (OR=1.62, 95%CI=1.44-1.83 compared to urban residents), whereas that of lumbar OA was higher in the male sex (OR=2.06, 95%CI=1.63-2.61) and urban residents (OR=1.43, 95%CI=1.13-1.83 compared to mountainous residents). We next compared the association between radiographic severity and local pain by logistic regression analysis after adjustment for age and BMI. The radiographic severity of knee OA was positively associated with knee pain (OR=6.7, 95%CI=4.10-11.2 in men; OR=4.3, 95%CI=3.07-6.02 in women; for KL3/4 compared to KL0/1), while that of lumbar OA was weakly associated with low back pain at all spaces in women (OR=1.6-2.1 for KL3/4 compared to KL0/1), but not in men. The initial investigation in the ROAD study using the baseline data revealed a high prevalence of radiographic OA in knee and lumbar spine among elderly people, and found that gender and community differences were distinctly associated with the knee and lumbar OA. Furthermore, the radiographic knee OA showed a strong association with knee pain in both genders. Contrarily, the radiographic lumbar OA had a moderate association with low back pain only in women. With the progress of the ROAD study, the underlying environmental and genetic backgrounds will be elucidated.

Treatment with Anti-TNF- α Antibody Recovers Osteoclast Maturation Deviated from Bone Remodeling Cycle in RA Joint Destruction. M. Nawata^{*}, Y. Okada^{*}, K. Saito^{*}, Y. Tanaka^{*}. The First Department of Internal Medicine, School of Medicine, University of Occupational and Environmental Health, Japan, Kitakyusyu, Japan.

Rheumatoid arthritis (RA) is characterized by inflammatory synovitis, erosive arthritis and joint destruction. Recent evidence indicates that TNF- α plays a pathological role in joint destruction and that infliximab (anti-TNF- α antibody) provides significant protection against the destructive process, even in patients who show no clinical improvement, suggesting the dissociation of these two disease processes. However, the mechanism of bone destruction in RA remains unknown. Here we assessed bone metabolism in RA patients before and after infliximab treatment. RA patients (n=100, mean age, 53.6 \pm 12.1 years, \pm SD) were treated with either methotrexate (MTX) or infliximab+MTX. We evaluated DAS (Disease Activity Score)-28, bone metabolism markers and bone mineral density (BMD) at 0, 6, 12 and 24 months after treatment. At enrollment, BMD was within the normal aged-adjusted level (L2-4; 0.89 \pm 0.18 g/cm², left hip; 0.67 \pm 0.14 g/cm²), as was serum bone alkaline phosphatase (BAP; 26.9 \pm 10.5 U/l), a bone formation marker, but urinary crosslinked N-telopeptide of type I collagen (u-NTx), a bone resorption marker, was notably high (76.4 \pm 37.7 nmol/mmol CRE). Treatment with infliximab resulted in the following: i) No change in BMD for 2 years (L2-4 BMD 0.90 \pm 0.22, left hip 0.68 \pm 0.11 g/cm²). ii) Decrease in u-NTx to 61.3 \pm 32.1 (p<0.05), 48.8 \pm 27.0 (p<0.01) and 42.3 \pm 18.3 nmol/mmol CRE (p<0.01) at 6, 12 and 24 months, respectively. iii) Increase in BAP to 31.6 \pm 11.5 (p<0.05), 31.9 \pm 11.7 (p<0.05) and 29.2 \pm 11.2 U/l at 6, 12 and 24 months, respectively. iv) These changes were independent of the dose of steroids or disease activity. v) Improvement of bone erosion was noticeable on the joint X-p after 24 months. BAP and u-NTx did not change in patients treated with MTX alone. Bone metabolism is normally maintained by bone remodeling, bone resorption by osteoclast and formation by osteoblasts, respectively. In contrast, we here propose that joint destruction in RA is induced by osteoclast maturation in "deviation" from the remodeling cycle in a TNF-dependent manner, based on the followings: i) increase in u-NTx with normal BMD and BAP levels, ii) TNF- α and/or sRANKL induce osteoclast maturation in the absence of osteoblasts in RA synovium, iii) joint erosion is observed within 10 weeks in TNF- α transgenic mice. Furthermore, infliximab treatment allowed recovery from the "deviation" into the remodeling cycle as evident by the decrease in u-NTx and increase in BAP. These results imply the dissociated efficacy of infliximab for joint destruction from clinical improvement, which leads to repair of RA bone erosion.

Evaluation of the Bone Mineral Density and Body Composition in Early Rheumatoid Arthritis - The Osteoporosis and Early Rheumatoid Arthritis (OPERA) Study. A. C. Azevedo^{*1}, M. M. Pinheiro¹, K. S. Sarkis^{*2}, E. T. Reis Neto^{*1}, L. A. Martini², V. L. Szejnfeld¹. ¹Rheumatology, Unifesp, Escola Paulista de Medicina, Sao Paulo, Brazil, ²Nutrition, Faculdade de Saude Publica, Universidade de Sao Paulo, Sao Paulo, Brazil.

BACKGROUND: Traditional and not traditional risk factors for osteoporotic fractures have been described in patients with rheumatoid arthritis (RA), like menopause, smoking, glucocorticoids, immobilization and bone mineral density (BMD). Recently, some authors have showed that aspects related to body composition could also be associated with bone loss. **OBJECTIVES:** To evaluate bone mineral density (BMD) and body composition in patients with early rheumatoid arthritis (ERA) before and after the treatment. **PATIENTS AND METHODS:** Thirty-two RA patients (ACR, 1987) with time of symptoms less 15 months and without previous treatment with DMARDs (disease-modifying anti-rheumatic drugs) were enrolled in this study. Patients using medications that interfered on bone mass were excluded. Details on lifestyle, demographic data, fractures, dietary intake, physical activity, quality of life were evaluated by a specific questionnaire. Disease's characteristics and activity (DAS28) and current treatment of RA were also evaluated. Moreover, it was applied SF-36 and HAQ (Health Assessment Questionnaire). All the patients underwent bone densitometry (spine and femur BMD) by DXA (GE-Lunar, DPX MD+). Body composition was measured by DXA (lean, fat and bone mass). Descriptive statistical analysis, chi-squared test and logistic regression were used. $P < 0.05$ was adopted. After 12 months, the questionnaires and DXA measurements were repeated. **RESULTS:** Mean age and BMI were 43.4 ± 11.8 years and 24.7 ± 6.5 kg/m², respectively. Women were 26 (83.9%) and mixed race were 13 (41.9%). At baseline, disease duration, DAS28 and HAQ was 7.97 ± 4.5 months, 5.41 ± 1.45 and 0.896 ± 0.605 , respectively. Corticosteroids were referred by 21 patients (67.7%) with mean dosage 7 ± 8.9 mg/day. Spine and total femur BMD was 1.068 ± 0.15 and 0.987 ± 0.12 g/cm², respectively. Total and skeletal lean mass was 37.180 ± 6.4 kg and 6.34 ± 0.9 kg/m², respectively. Fat mass was $36.8 \pm 6.9\%$. After 12 months of follow-up, we did not verify significant bone or lean loss. On the other hand, there were significant reduction of the disease's activity and significant increase of functional ability and fat mass. **CONCLUSIONS:** We observed low prevalence of osteopenia/osteoporosis and sarcopenia in patients with ERA at baseline. Although the patients were considered as euthrophic by BMI, there was higher percentage of fat mass than lean mass between 2 visits. Thus, our data suggest that health interventions may emphasize more prevention of fat mass increase than lean or bone mass loss in ERA patients.

Bone Metabolism in an Animal Model of Ankylosing Spondylitis. M. Rauner^{*1}, D. Stupphann^{*1}, J. Patsch^{*1}, M. Haas^{*2}, M. Breban^{*3}, I. Fert^{*3}, S. Glatigny^{*3}, P. Pietschmann¹. ¹Institute of Pathophysiology, Medical University of Vienna, Vienna, Austria, ²Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, ³Institut Cochin, Hôpital Cochin, Paris, France.

Ankylosing Spondylitis (AS) is a chronic inflammatory disease characterized by the main involvement of axial joints and bilateral sacroiliitis. Besides the formation of new bone leading to syndesmophytes and ankylosis, osteoporosis is a reported feature as well. Thus, AS raises the paradox of new bone formation at sites of inflammation and the association of reduced bone mass and high fracture risk. The major histocompatibility complex class I allele HLA-B27 has been found to be strongly associated with AS. HLA-B27 transgenic (tg) rats spontaneously develop a multisystemic disease with the appearance of spondylitis and syndesmophytes. However, there is no information about bone metabolism in this animal model. Hence, the aim of our study was to investigate the suitability of the HLA-B27 tg rat as a model for the bone-related alteration in AS. Therefore, bone histomorphometry was conducted for the femur, tibia and fourth vertebral body from six control rats, six healthy HLA-B27 tg rats and six HLA-B27 tg rats exhibiting the phenotype of spondyloarthropathies. Each group consisted of two male and four female rats aged between seven and ten months. Sections, stained with Goldner's trichrome, were analyzed using the Osteomeasure Software (Osteometrics, USA). Femur, tibia and the fourth vertebral body of the diseased HLA-B27 tg rats exhibited a significant reduction of bone volume over total volume compared with control rats and healthy tg rats. Moreover, trabecular thickness and trabecular number of the diseased rats were significantly reduced. The trabecular separation was significantly increased. The number of osteoblasts and osteoid volume did not show any alterations, however, the number of osteoblasts as well as osteoid volume were higher in femur and tibia than in the vertebral body. Osteoclasts tended to be more abundant in the diseased HLA-B27 tg rats. The decrease in bone volume, trabecular number and thickness as well as the increase of trabecular separation in the diseased HLA-B27 tg rats indicate an enhanced bone resorption, possibly mediated by the increased number of osteoclasts. Moreover, the indices of osteoid volume show, that the mineralization process in the diseased rats was not disturbed. Our results demonstrate that HLA-B27 tg rats is an appropriate model for the study of bone loss in AS. In further experiments, we will analyze markers of bone formation and resorption in the serum and bone of HLA-B27 tg rats to assess bone turnover on a systemic level.

Osteoporosis and Rheumatoid Arthritis, Which Nutritional Factors Are Associated? K. S. Sarkis^{*1}, R. G. Silva^{*2}, C. F. Zerbin^{*2}, M. M. Pinheiro³, L. A. Martini¹. ¹Nutrition, Universidade de Sao Paulo, Sao Paulo, Brazil, ²School of Medicine, Universidade de Sao Paulo, Sao Paulo, Brazil, ³Reumatology, UNIFESP, Sao Paulo, Brazil.

The aim of this study was investigate the association between diet, body composition and Bone Mineral Density (BMD) in women with Rheumatoid Arthritis (RA). This is a cross-sectional study performed at RA outpatient clinic and included forty-five (45) patients who fulfilled the ACR criteria for RA and agreed to participate. Mean age was 55 ± 10 y and the mean duration of disease was 7.5 ± 5.6 y. The patients were divided in two groups according to BMD status: group 1 - normal BMD ($n=24$); group 2 - patients with osteoporosis ($n=21$) (WHO 1994). Standardized questionnaires were used to ascertain demographic characteristics, medical history and use of oral glucocorticosteroids. Functional status was assessed using the Health Assessment Questionnaire (HAQ) score and the disease activity by the Disease Activity Score (DAS28). A validated food frequency questionnaire was used to assess the dietary intake. Mean daily intake, including total energy (kcal/day) and all others macronutrients, calcium, phosphorus and vitamin D was calculated and adjusted for energy. Percentage Body Fat (%BF), Total Fat Free Mass (TFFM), Appendicular Lean Mass (ALM), Relative Skeletal Muscle Index (REMI) and BMD was measured at the total femoral, femoral neck and lumbar spine (L1-L4) in g/cm² by using DXA (GE Lunar Radiation Corporation, DPX IQ, Madison, WI, USA). Statistical analysis included Student T test, Pearson correlation and multiple linear regression. BMD was considered dependent variable. Significance was adopted as $p < 0.05$. There were no significant difference in HAQ, DAS 28 and use of oral glucocorticosteroids between groups. Also no differences were observed in total energy, protein, carbohydrate, calcium, phosphorus and vitamin D intake. However both groups presented mean calcium and vitamin D intake lower than recommended values (597.3 ± 281.7 mg/day vs 692.2 ± 217.1 mg/day and 60.7 ± 56.9 vs 88.1 ± 89.6 UI/day, group 1 and 2 for calcium and vitamin D, respectively). Patients with lumbar or femoral osteoporosis were significantly older ($p < 0.01$), had a lower %BF ($p < 0.05$), FFM ($p < 0.01$), ALM ($p < 0.01$), RSMI ($p < 0.01$), longer disease duration ($p < 0.05$) and a higher lipid intake ($p < 0.05$). In the regression linear model, being older with more than 7.5 years with AR, lower %BF, fat free mass, appendicular lean mass together with higher lipid intake, were negatively associated with BMD [Femoral total = $0.637 - 0.008$ (age) - 0.009 (disease duration) + 0.073 (RSMI) + 0.006 (%BF), with $R^2=66.8$; $p < 0.001$]. The present study indicated two important modifiable factors that could improve BMD in patients with RA; the body composition and a reduction in fat intake.

Vitamin D Receptor Deficiency Aggravates TNF-Mediated Arthritis. K. Polzer^{*1}, J. Zwerina^{*1}, K. Redlich^{*2}, J. Smolen^{*2}, G. Schett^{*1}. ¹University of Erlangen-Nuremberg, Erlangen, Germany, ²Medical University of Vienna, Vienna, Austria.

Background: Vitamin D is an important hormone for calcium homeostasis and bone metabolism and may have immunomodulatory effects. The aim of this study was to investigate the role of the Vitamin D Receptors (VDR) in inflammatory arthritis.

Methods: To determine the role of the Vitamin D in TNF-mediated joint disease, we crossed mice deficient for the VDR with arthritic human TNF transgenic (hTNFtg) mice. Offsprings were analysed for clinical signs of arthritis as well as the histological degree of synovitis, cartilage damage and bone erosion. Systemic mineral bone density was evaluated by bone histomorphometry. Furthermore, serum levels of cytokines and other inflammatory mediators were determined by ELISA.

Results: hTNFtg mice with VDR deficiency showed pronounced weight loss, increased paw swelling and decreased grip strength compared to hTNFtg mice. In addition, VDR-/-hTNFtg mice showed lower bone mineral density compared to hTNFtg mice. In line, serum levels of TNF were significantly increased in VDR-/-hTNFtg mice compared to hTNFtg mice. Consequently, histological analysis showed an increase in synovial inflammation in VDR-/-hTNFtg mice compared to hTNFtg mice. The VDR-/-hTNFtg mice showed a dramatic increase in osteoclast number compared to hTNFtg mice, accompanied with strengthened bone erosions in the joints. These data were verified in osteoclast assays of the four genotypes in vitro. Cartilage proteoglycan loss was also enhanced in VDR-/-hTNFtg mice compared to hTNFtg mice.

Conclusion: These findings suggest that deficiency of the VDR leads to an increase in inflammation, cartilage destruction and bone erosion with enhanced recruitment of osteoclasts. This leads to the assumption that additional treatment with active metabolites of Vitamin D may have potentially positive effects as an additive therapy in RA.

Bone Microarchitecture as Assessed by High Resolution Peripheral Quantitative CT (HRpQCT) in HIV+ Postmenopausal Women. A. D. Shu^{*1}, M. T. Yin¹, D. J. McMahon^{*1}, S. Cabral^{*1}, H. Eisenberg^{*1}, D. Ferris^{*2}, E. Shane¹. ¹Columbia University, NY, NY, USA, ²Bronx-Lebanon, Bronx, NY, USA.

As a result of effective antiretroviral therapy (ART), more HIV+ women are surviving beyond menopause and are at increased risk for osteoporosis (OP). We previously reported lower BMD but similar rates of bone loss in HIV+ PM Hispanic women compared to HIV-controls. There are no studies on bone microarchitecture and limited fracture data in HIV+ individuals. We hypothesized that lower BMD in HIV+ women is associated with microarchitectural deterioration. Xtreme CT (Scanco Medical AG) is a new HRpQCT system with sufficiently high resolution (<100µm) to permit in vivo assessment of trabecular (Tb) architecture at the radius (RAD) and tibia (TIB). DXA and HRpQCT were performed in 32 HIV+ (75% on ART) and 38 HIV- Hispanic and African American PM women from outpatient clinics, excluding women with known OP, metabolic bone disease and serum Cr >2.5 mg/dL. HIV+ and HIV- groups were similar with regard to age (mean 60 y), prevalence of hypertension, diabetes, thyroid disease, and use of HRT, glucocorticoids and antiepileptics. HIV+ women were more likely to use tobacco. BMI was higher in HIV- women (31 v 28, p = 0.04). In contrast to our previous findings in Hispanics, mean BMD did not differ at any site. Similarly, HRpQCT measurements of 13 cortical (Cort) or Tb microstructural parameters did not differ between groups (Table). Analyses stratified by HIV status and race and adjusted for covariates of age, BMI and tobacco use were compared by repeated measures ANCOVA. No differences between HIV and race-defined groups were observed at the TIB. At the RAD, Hispanics had higher D100 (average bone density) (p<0.003) and Cort thickness (p<0.03); however, HIV status was not associated with any differences. In summary, DXA and HRpQCT parameters did not differ between HIV+ and HIV- PM women. The groups may be similar because the controls are drawn from a clinic population and many have chronic illnesses common in older minority women. The similarities in microarchitecture may also explain why retrospective studies of HIV+ patients on ART have not found that fracture rates are higher than expected.

Table: Mean HRpQCT and DXA values (± SD) with reference values^{*}

	Study		p-value	Reference values		
	HIV+ N = 32	HIV- N = 38		PreM [†]	LBM [†]	OP [†]

OPG Prevents Osteopenia in Arthritic Rats Via Different Mechanisms than Bisphosphonate Therapy. M. Stolina, D. Dwyer^{*}, S. Middleton^{*}, S. Adamu^{*}, M. S. Ominsky, D. Zack^{*}, P. J. Kostenuik. Amgen Inc., Thousand Oaks, CA, USA.

RANKL was recently suggested to be a mediator of systemic bone loss in arthritic rats (Stolina et al, JBMR 2005). The catabolic effects of RANKL are inhibited by osteoprotegerin (OPG), and the RANKL:OPG ratio may be an important determinant of bone resorption. Skeletal catabolism can also be prevented by bisphosphonates, which can exert modest changes in OPG levels in patients and in osteoblast cultures. However, local and systemic changes to the RANKL:OPG ratio have not been described with BP treatment in an osteopenia model. We therefore compared the effects of OPG versus zoledronic acid (ZA) on serum and bone proteins and BMD in a rat arthritis model.

Adjuvant arthritis (AIA) was induced in rats by heat-killed mycobacteria. AIA rats were treated with human OPG-Fc (1 mg/kg), ZA (0.1 mg/kg), or PBS (Veh) at the clinical onset of arthritis (day 0), day 3, and day 6. Non-arthritic (NA) controls were treated with Veh. BMD was assessed at the lumbar vertebrae (LV) by DXA on day 9 when serum was collected and total protein was extracted from LV for evaluation of OPG, RANKL, and the resorption marker TRAP-5b.

AIA-Veh rats had lower LV BMD compared to NA controls (P < 0.05). Histology showed no evidence of inflammation in the LV of AIA-Veh rats, so osteopenia may have been related to an 80% increase in serum RANKL (P < 0.05 vs NA controls). Osteopenia was fully prevented by OPG or ZA treatment. Whereas OPG treatment prevented the AIA-related increase in serum RANKL, ZA treatment led to a further non-significant RANKL increase (vs AIA-Veh) and had no effect on serum OPG levels. The serum RANKL:OPG ratio was markedly reduced by OPG treatment (P < 0.05, vs AIA-Veh), and non-significantly increased by ZA (vs AIA-Veh). Serum TRAP-5b was significantly reduced by both treatments (P < 0.05 vs. AIA-Veh), more so with OPG (P < 0.05 vs ZA). The RANKL:OPG ratio in LV protein extracts was significantly increased in AIA-Veh rats (P < 0.05 vs NA controls). This increase was primarily related to local suppression of OPG.

OPG treatment significantly reduced LV RANKL, whereas ZA caused a 2-fold increase in LV RANKL (P < 0.05 vs AIA-Veh). OPG treatment markedly increased LV OPG levels, while ZA caused a modest reduction in LV OPG (vs AIA-Veh). The RANKL:OPG ratio was thereby reduced with OPG treatment, while ZA led to a 5-fold increase (both P < 0.05 vs AIA-Veh). LV TRAP-5b was significantly reduced by both treatments, to a greater extent with OPG (P < 0.05 vs ZA).

In summary, two potent agents of different therapeutic classes fully prevented systemic bone loss in arthritic rats. RANKL inhibition by OPG reduced the RANKL:OPG ratio in bone whereas ZA increased this ratio, highlighting the different mechanisms of action of these therapeutics.

Increased Expression of Receptor Activator of NF-kappaB Ligand (RANKL) in Stimulated T-cells from Patients with Ankylosing Spondylitis.

D. Stupphann^{*1}, M. Rauner^{*1}, D. Krenbek^{*1}, J. Patsch^{*1}, T. Pirker^{*2}, C. Muschitz^{*2}, H. Resch^{*2}, P. Pietschmann¹. ¹Medical University of Vienna, Vienna, Austria, ²St. Vincent Hospital, Medical Department II, Vienna, Austria.

Ankylosing spondylitis (AS) is a chronic, disabling rheumatic disease, which initially mainly involves the sacroiliac joints and in later stages affects the vertebral column. Besides new bone formation leading to syndesmophytes and ankylosis, osteoporosis is a reported feature as well. Based on the hypothesis, that activated T cells are the major source of RANKL in inflammatory bone-resorptive diseases, we investigated the presence of intracellular (ic) and membrane bound (mb) RANKL on activated T cells from patients with ankylosing spondylitis (AS). Further we determined their relationship to bone mineral density (BMD), disease activity and bone metabolism markers. T-cell surface and intracellular expression of RANKL was analyzed by flow cytometry. BMD at the lumbar spine and total hip was measured by dual-energy x-ray absorptiometry (DXA) and quantitative computed tomography (QCT). Serum OPG levels were determined by ELISA. Expression of icRANKL was statistically significantly increased in patients with AS compared to the healthy volunteers (p < 0.05). In contrast expression of mbRANKL was significantly lower in the group of patients compared to the controls (p < 0.01). The cytokine expression was not associated with bone loss that was found with DXA at the total hip in 45% of all cases, and with QCT at the lumbar spine in 48 % of all cases. Spinal BMD values measured by QCT were positively correlated with age (r = - 0.630; p = 0.003) and negatively correlated with serum OPG levels (r = - 0.571; p = 0.025). We conclude that intracellular RANKL in T cells is overexpressed in patients with AS, indicating that these cells may act as a storage for soluble RANKL which rapidly can be mobilized and secreted into the circulatory system after an inflammatory stimulus. In contrast, the expression of mbRANKL is significantly decreased in the AS patients, that might be due to a different activity or prevalence of the enzymes, responsible for the ectodomain shedding of RANKL.

Advanced Glycation-end-products Induce Vascular Calcification Through the RAGE/p38 MAPK Signaling Pathway. T. Tanikawa, R. Tanikawa, Y. Okada, Y. Tanaka.

First Department of Internal Medicine, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan.

Mönckeberg's calcification in type 2 diabetes, known as medial artery calcification is a strong independent predictor of cardiovascular mortality. However, the mechanism of vascular calcification in diabetes remains to be elucidated. Advanced glycation-end-products (AGEs), long-term products of the Maillard reaction, are formed at an accelerated rate in diabetes. They are thought to contribute to the development of diabetic complications, including atherosclerosis and microvascular diseases. In our in vitro studies, AGEs induced calcification of cultured vascular smooth muscle cells by von kossa staining and also induced the expression of Runx2 mRNA by RT-PCR, known as a transcription factor in osteoblast differentiation. Furthermore, AGEs increased alkaline phosphatase (ALP) activity and osteocalcin secretion, two osteoblast differentiation markers. Finally, AGEs induced phosphorylation of p38 MAPK and the phosphorylation was inhibited by anti-RAGE blocking antibody, which was assayed by western blotting. Increased ALP activity was inhibited by a p38 MAPK inhibitor. Our findings indicate that AGEs induce vascular calcification by osteoblast-like differentiation of smooth muscle cells and through the RAGE/p38 MAPK signaling pathway and suggest that inhibition of the AGE/RAGE pathway could be potentially effective therapeutically for prevention of vascular calcification in diabetic patients.

Type 2 Diabetic Patients with Charcot Arthropathy Display Reduced Calcaneal Stiffness Despite Normal Foot BMD. K. A. Witzke¹, H. K. Parson^{*2}, A. I. Vinik^{*2}, ¹Kinesiology, California State University, San Marcos, San Marcos, CA, USA, ²Internal Medicine, Eastern Virginia Medical School, Norfolk, VA, USA.

Because bone is innervated it is subject to degradation when the nerves that innervate it lose their function. Charcot neuroarthropathy is a complication of diabetes associated with severe nerve dysfunction that often leads to unusual fractures that collapse the ankle and/or midfoot. These fractures may be caused by declines in bone mineral density (BMD), although BMD of the feet is not a common evaluation site. We believe that Charcot probably compromises the quality of bone, specifically its microarchitecture, crystallinity, and collagen properties, and these changes may not be completely explained by BMD alone. Calcaneal stiffness, measured by Quantitative Ultrasound (QUS), is a simple method of determining the stiffness of bone, an important biomechanical property related to bone quality and fracture. The purpose of this preliminary study was to determine if poor nerve function is related to reduced calcaneal stiffness and/or reduced BMD of the feet, and whether type 2 diabetics with Charcot display significantly different bone stiffness and BMD than either controls or type 2 diabetics without Charcot. We measured BMD of the whole body, hips, and feet (BMD, GE Lunar Prodigy), Calcaneal stiffness (QUS, GE Achilles Express), peroneal nerve conduction velocity (NCV), vibration detection threshold (VDT), and pressure perception (PRES), in 56 male subjects (n=22 controls; n=31 type 2 diabetic; n=3 diabetic patients with Charcot) aged 56.1 +/- 8.4 y. Diabetics averaged 127.4 +/- 80.4 months of diabetes. As expected, all nerve function measures were significantly worse in Charcot patients than the other two groups. For bone measures, Charcot patients displayed significantly lower calcaneal stiffness but similar BMD measures at all sites including the feet, compared to the diabetic and control groups. This may suggest a direct relationship between motor nerve dysfunction and the structural properties of bone in Charcot neuroarthropathy. Although the Charcot patients in this study were fairly homogeneous, these assumptions need to be tested in more patients, and a more direct measure of bone collagen would also be useful.

Nerve Function, Bone Density, and Stiffness Across Groups [mean (SD)]			
	Control (n=22)	Diabetic (n=31)	Charcot (n=3)

Morphological Texture Analysis of Radiographs of the Proximal Femur: In Vitro Study Using Biomechanical Strength as a Standard of Reference. M. B. Huber^{*1}, J. Carballido-Gamio^{*1}, K. Fritscher^{*2}, R. Schubert^{*2}, M. Haenni^{*3}, C. Hengge^{*4}, S. Majumdar^{*1}, T. M. Link^{*1}. ¹University of California, San Francisco, San Francisco, CA, USA, ²University of Health Sciences, Medical Informatics and Technology, Innsbruck, Austria, ³AO Development Institute, Davos Platz, Switzerland, ⁴Medical University Innsbruck, Innsbruck, Austria.

Texture analysis of femur radiographs may serve as a potential low cost technique to predict osteoporotic fracture risk and has received considerable attention in the last years. The goal of this in vitro study was to use automatically placed regions of interest (ROI) and morphological texture analysis methods in radiographs of proximal femur specimens to investigate their biomechanical strength.

Radiographs were obtained from 14 femoral specimens and bone mineral density (BMD) was measured in the femoral neck. Biomechanical testing in terms of failure load (FL), breakaway torque (BT) and number of cycles (NC) was performed. Five ROIs were placed automatically in the head, upper and lower neck, trochanteric and intertrochanteric compartment. In each ROI, we obtained isotropic and anisotropic morphological gradients (MG) and Minkowski Dimensions (MD), and three Minkowski Functionals [Area (MFA), Perimeter (MFP), Euler number (MFE)] and calculated coefficient of determination with parameters of biomechanical strength. In a stepwise multiregression analysis, we identified the most predictive parameters in different models.

A moderate correlation between neck BMD and FL of $R^2=0.40$ ($p<0.05$) was found and a high correlation $R^2=0.78$ ($p<0.01$) between BMD and BT. For isotropic MG-filters, correlations with FL up to $R^2=0.64$ ($p<0.001$) and with BMD, BT and NC up to $R^2=0.62$ were found. Using anisotropic MGs even higher correlations were obtained ($R^2=0.70$) for FL and NC, but no significant correlations were found with BMD. Correlations between MDs and FL were in the range $R^2=0.37$ - 0.61 *. MFA and MFP correlated significantly with FL and NC ($R^2=0.55$), and were independent of BMD. All these correlations were based on femoral head and lower neck ROIs. Our multiregression analysis showed, that BMD was not able to improve the prediction of FL using a model with three MGs ($R^2=0.85$). The model testing all parameters resulted in a high prediction of $R^2=0.97$ and included MGs, MD and MFP, however, not BMD. In conclusion morphological texture features were highly correlated with biomechanical strength and were partially independent from BMD. We showed that femoral head and lower neck ROI were best suited to estimate bone strength. Morphological information contained in trabecular bone structure visualized on radiographs may provide osteoporotic fracture risk prediction as a low-cost modality.

Micro-architectural Changes of Developing Bone in Male and Female Rats. R. J. Arends^{*1}, M. V. Beuningen - Vaan^{*1}, M. V. Boven - Nunen^{*1}, M. T. Brok - Bardoel^{*1}, D. V. Dobbela^{*2}, G. B. Janssen^{*2}, T. V. Klundert^{*1}, P. E. Langerwerf^{*1}, T. J. Robben^{*1}, M. G. Scheepers^{*1}, J. V. Vliet^{*2}, A. G. Ederveen^{*1}. ¹Pharmacology, N.V. Organon, Oss, The Netherlands, ²Toxicology & Drug Disposition, N.V. Organon, Schaijk, The Netherlands.

MicroCT measurements are extensively applied in pre-clinical research on bone and are well validated to study micro architecture in adult and aged animals. However, the number of studies on the growing skeleton is limited. In this report, we have combined the metaphyseal trabecular bone and mid-diaphyseal bone μ CT data of a number control groups of male and female Wistar rats at the age of 5, 8, 11 and 14 weeks to obtain a reference dataset of μ CT parameters in growing animals.

From week 5 to 14 bodyweight increased from 107 to 424 gram in male and from 97-228 in female rats. Cortical BMD decreased rapidly between 5 and 8 weeks in males (1441 to 1148 mg/cm³) and in females (1459 to 1187) and thereafter remained constant until week 14. Moreover, between week 5 and 14 cortical thickness increased gradually; more in males (0.30 to 0.6 mm) than in females (0.31-0.51 mm). As a result of this, polar moment of inertia increased; more pronounced in males (4.2 to 19.6 mm⁴) than in females (3.6 to 8.4).

Trabecular BMD gradually decreased between week 5 and 14 in males (283-239 mg/cm³), however it increased in females (321-378). BV/TV increased steadily in females from 26.7 to 52.8% between 5 and 14 weeks and only slightly in males (24.8-31.8). Trabecular number decreased rapidly between 5 and 8 weeks in both males and females (3.1 to 1.8 1/mm and 3.3 to 2.7 1/mm, resp.) and this was accompanied by an increase in trabecular thickness (0.079 to 0.170 mm in males, 0.082 to 0.190 in females). As a net effect of these changes, trabecular separation strongly increased between 5 and 14 weeks in males (0.19-0.54 mm) and only slightly in female rats (0.18-0.23). Between 5 and 14 weeks, the degree of anisotropy decreased gradually in both males (3.29 to 2.15) and females (3.04 to 1.80), furthermore a modest decrease in structure model index was detected in males (1.49-1.12), while in females a strong decrease was measured (1.38-0.31).

In conclusion, the cortical femur is still growing in both sexes up to 14 weeks of age; males grow more than females. In femur of growing male rats, cortical thickness and diameter are the major parameters that determine bone strength as is predicted by a high polar moment of inertia. However, the cancellous compartment showed a different profile. In female rats, during skeletal growth trabecular bone volume and trabecular thickness increase in the femur, resulting in a gain of trabecular bone and an architectural change from a rod like structure to a more plate like structure, whereas in males trabecular bone is partially lost before it reaches a plateau phase.

Correlation Between the Mechanical Properties of Trabecular Bone Assessed by Finite Element Analysis and Experimental Test. Y. Won¹, B. Min^{*2}, Y. Chung³, M. Baek^{*1}, W. Cui^{*1}, M. Hahn^{*4}. ¹Orthopaedics, Ajou University School of Medicine, Suwon, Republic of Korea, ²Orthopaedics, Keimyung University School of Medicine, Daegu, Republic of Korea, ³Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, Republic of Korea, ⁴Orthopaedics, Kwandong University School of Medicine, Gangneung, Republic of Korea.

Introduction: Following development of imaging technology, image-based finite element analysis has been commonly used to assess the mechanical properties of bone as a surrogate of experimental test. The aim of this study was to investigate the correlation between the mechanical properties of trabecular bone from the primary compressive trabecular system of human femoral head assessed by micro- finite element analysis and the experimental test.

Materials and Methods: Twenty-one human femoral heads were obtained from 11 patients undergoing total hip arthroplasty and 10 cadavers. Cylindrical trabecular bone was cored from the primary compressive trabecular system of the femoral head. The sample size was diameter of 19 mm, height of 15 mm. All samples were scanned with a high-resolution micro-computed tomography system at a spatial resolution of 21.31 μ m. Based on the serial micro-CT images, a volume of interest (VOI) was selected to be 9.50 mm of diameter and 7.50 mm of side length. Based on these micro-images of trabecular bone, the finite element model was created, and the finite element analysis and the compressive test were performed sequentially. The yield stress and Young's modulus were calculated from two methods.

Results: The average yield stress and Young's modulus from FEA and Instron system were 13.04 MPa and 1.30 GPa, 13.06 MPa and 0.11 GPa, respectively. The correlations between the yield calculated from FEA and Instron were significant ($p = 0.001$), but not for the Young's modulus ($p=0.055$).

Conclusion: The mechanical properties of trabecular bone calculated from FEA are well correlated with those from the mechanical test, suggesting that the micro-image-based finite element analysis as a substitute of the mechanical test can be a useful tool to evaluate the mechanical properties of trabecular bone, further to predict the fracture risk.

A Methodology for Bone Strength Prediction using Parametric Statistical Shape and Density Finite Element Modeling. T. L. Bredbenner*, D. P. Nicoletta. Materials Engineering, Southwest Research Institute, San Antonio, TX, USA.

Bone strength is the result of the complex combination of traits related to bone shape and bone density distribution. The use of finite element (FE) modeling methods improve the estimation of bone strength over predictions based on clinical image data alone since FE models can explicitly incorporate detailed descriptions of bone geometry and bone density distribution. However, the efficient construction of finite element models that accurately represent the complex morphology of skeletal structures is a major challenge thereby limiting their clinical use in diagnosing fracture risk. In the present study, methodology based on statistical shape modeling was developed and implemented to parametrically describe the complex geometry and bone density distribution using clinical imaging data for a set of 7 human female proximal femurs. The femurs were scanned using a clinical CT scanner (Lightspeed Ultra, GE Healthcare) along with a density calibration phantom (Mindways Software). Triangulated surfaces were created to describe the outer geometry for each femur (Amira, Mercury Computing) and a volumetric finite element mesh was mapped onto each femur using optimal point-to-point correspondence methods. Apparent ash density was estimated at each node for all femur models using the calibrated CT image data. Statistical shape and density modeling methods were then used to develop a parametric finite element model describing the set of cadaver femurs. Principal Component Analysis of the statistical shape and density FE model showed that 78% of the variability in bone geometry and density can be described using only 3 independent components. Reconstructing the FE model using each component independently and predicting bone strength under simulated fall conditions estimated the contribution of each component to proximal femur strength. Finally, individual finite element models of femurs within the training set could be accurately reconstructed, and a leave one out analysis demonstrated that a volumetric finite element model of a previously unseen femur could be reconstructed with a maximum geometry error of 1.25 mm and an average error of 0.04 mm.

Assessment of Vertebral Fracture Threshold and Alendronate Therapeutic Effects by a QCT-based Nonlinear Finite Element Model in Postmenopausal Women. K. Imai¹, I. Ohnishi^{*2}, S. Yamamoto¹, K. Nakamura². ¹Orthopaedic Surgery, Tokyo Metropolitan Geriatric Medical Center, Tokyo, Japan, ²Orthopaedic Surgery, Tokyo University, Tokyo, Japan.

A QCT-based nonlinear finite element model (CT/FEM) accurately predicts vertebral strength, fracture sites and distribution of minimum principal strain (Spine 2006; 31:1789-94). This study aimed to assess the risk of vertebral fracture and the therapeutic effects of alendronate on osteoporosis using a CT/FEM. We performed a cross-sectional analysis of L2 vertebral strength for 104 postmenopausal Japanese women (mean age, 71.3 yrs; range, 49-85; mean height, 149.7 cm; mean weight, 50.5 kg) with no history of previous L2 fracture, traumatic vertebral fracture or osteoporosis medication. Subjects comprised 75 women without vertebral fracture and 29 women with non-traumatic vertebral fracture. The optimal point on the ROC curve that was used as vertebral fracture threshold was 1950 N with 75.9% sensitivity and 73.3% specificity. We also prospectively assessed the biomechanical effects of alendronate in 33 patients (mean age, 76.5 yrs) who were treated with alendronate at a dose of 5 mg/day for 1 year. QCT scans of the L2 were obtained at baseline and 3, 6 and 12 months, and the vertebral strength and mechanical parameters for each patient were analyzed using the CT/FEM. BMD of the L2-4 was measured by DXA at baseline and 6 and 12 months. BMD tended to increase from baseline at 6 months (3.7%; $p=0.0451$), and was significantly increased at 12 months (7.5%; $p<0.0001$). Vertebral strength from the CT/FEM significantly increased by 10.2% from baseline at 3 months ($p<0.0001$), 16.7% at 6 months, and 26.9% at 12 months. The CT/FEM also revealed that the area with large negative value of minimum principal strain before medication, where a high risk of fracture exists, decreased after medication. After 1 year of medication, the density of the inner cancellous bone with a distance of more than 2 mm from the outer surface increased by 8.3% ($p=0.0013$), while the density of the peri-cortical bone with a thickness of 2mm increased by 13.6% ($p=0.0004$). The CT/FEM could assess the vertebral fracture threshold with higher sensitivity and specificity, and also assess the therapeutic effects of alendronate with higher sensitivity and earlier (at 3 months) than BMD. The increase in the vertebral strength might be attributed to the alterations in the distribution of bone density, stress, and strain within the vertebra. The alendronate treatment was more effective in the peri-cortical and cortical areas compared to the inner trabecular compartment. The CT/FEM allows us to analyze quantitatively vertebral strength and biomechanical characteristics and is useful to assess the risk of vertebral fracture and therapeutic effects on osteoporosis.

The clinical diagnosis of osteoporosis is typically based on measuring bone mineral density (BMD) with dual-energy X-ray absorptiometry (DXA). However, access to DXA is limited in many regions, while radiography is widely available. Here, we used an image processing method for assessment of trabecular structure, density and geometry from radiographs, to estimate the mechanical strength of femur.

The sample consisted of 62 femoral cadaver specimens (34 females, 81.6±10.7 yrs, and 28 males, 77.8±11.1 yrs). After radiography and DXA, the femora were mechanically tested in a side impact configuration. The fracture patterns were classified as being cervical or trochanteric. Computerized image analysis was applied to obtain several structure-related trabecular parameters, and a set of geometrical variables was also defined. Multiple linear regression analysis was performed to identify the variables that best explain variation in BMD and failure load between subjects.

In the cervical fracture cases, trabecular bone area (TBA) and calcar femoral cortex thickness (CFC) explained 68% of the variability in DXA-based femoral neck BMD ($p<0.001$). TBA and femoral neck axis length (FNAL) explained 64% of the variability in failure loads ($p<0.001$), while femoral neck BMD also explained 64%. In the trochanteric fracture cases, trabecular homogeneity index (HI) and femoral shaft cortex thickness explained as much as 87% of the variation in trochanteric BMD ($p<0.001$). Euler number (EN) and calcar femoral cortex thickness (CFC) explained 66% of the variability in failure load ($p=0.001$), while trochanteric BMD explained 72% ($p<0.001$).

In conclusion, trabecular bone structure, as determined from conventional radiographs, reflects a substantial proportion of the variability in DXA-based BMD. Structural parameters of trabecular bone and bone geometry predict in vitro failure loads of the proximal femur with quite similar accuracy as DXA, when using appropriate image analysis technology.

Evolution of the Crack-Growth Resistance and Toughening Mechanisms of Human Cortical Bone via In-Situ Electron Microscopy. K. J. Koester^{*1}, J. W. Ager^{*2}, R. O. Ritchie^{*1}. ¹Materials Science and Engineering, University of California, Berkeley, Berkeley, CA, USA, ²Lawrence Berkeley National Laboratory, Berkeley, CA, USA.

Mammalian bone has evolved to support a variety of physiologically relevant loads and also to resist fracture, which, in many cases, can have life endangering consequences. It is imperative to understand the toughening mechanisms in human bone to characterize influence of age, disease, and drug treatments on the fracture properties of bone. Previous works have established that bone "toughens" to resist crack growth. However, without looking at the fracture of human bone in situ, these studies lack the potency to elucidate the phenomenon taking place during the fracture process. Here, in-situ crack propagation measurements performed in an environmental scanning electron microscope have allowed simultaneous measurement of the crack-growth resistance curve and real-time visualization of the toughening mechanisms. This work is the first study of the evolution of toughness in the transverse and longitudinal orientations in human cortical bone (humerus). The dominant toughening mechanisms were found to be crack deflection in the transverse direction and uncracked ligament bridging in the longitudinal direction.

Compromised Fracture Healing in Lrp5 Null Mice. D. E. Komatsu¹, A. G. Robling², C. H. Turner³, S. J. Warden¹. ¹Physical Therapy, Indiana University, Indianapolis, IN, USA, ²Anatomy & Cell Biology, Indiana University, Indianapolis, IN, USA, ³Biomedical Engineering and Orthopaedic Surgery, Indiana University, Indianapolis, IN, USA.

The importance of Wnt signaling in skeletal development and regulation has been unequivocally demonstrated in recent years. However, the role of this pathway in fracture repair has been the subject to far less attention. At the cellular level, Wnt pathway activation is initiated by the binding of Wnt ligands to the Wnt co-receptor Low-Density Lipoprotein Receptor-Related Protein 5 (Lrp5). Mice with homozygous null Lrp5 mutations (Lrp5^{-/-}) demonstrate a low bone mass phenotype, concomitant with decreased mechanical properties. As Lrp5 is also known to be up-regulated during fracture repair, we hypothesized that fracture repair in Lrp5^{-/-} mice would be compromised compared to wild-type littermates (Lrp5^{+/+}). To test this hypothesis, closed fixed femoral fractures were generated in the left femurs of 4 month old male Lrp5^{-/-} (N=7) and Lrp5^{+/+} (N=6) mice. Fracture repair was qualitatively assessed by radiography, performed post-surgery and weekly until sacrifice at day 28 post-fracture. The fractured and contralateral intact femurs were harvested and quantitatively analyzed by peripheral quantitative computed tomography (pQCT), dual energy X-ray absorptiometry (DXA) and biomechanical testing (4-point bending). To correct for baseline phenotypic differences, the results obtained for the fractured femurs were normalized to those of their contralateral intact femurs. No apparent differences in callus development were seen in the weekly radiographs. Similarly, analysis by DXA showed no differences in area or BMD, though a 15% reduction in BMC was observed in fractured femurs from Lrp5^{-/-} mice, compared to Lrp5^{+/+} mice ($p < 0.02$). Likewise, the pQCT results also failed to identify substantial changes in callus morphology, with the sole significant difference being a 32% reduction in cross-sectional mature bone area in Lrp5^{-/-} fracture calluses, as compared to Lrp5^{+/+} calluses ($p < 0.05$). However, biomechanical testing revealed a gross hindrance in the mechanical properties of fractured femurs from Lrp5^{-/-} mice, compared to Lrp5^{+/+} mice, with reductions of 64-76% seen for ultimate load, stiffness, yield force, energy to yield and energy to ultimate force (all $p < 0.05$). The striking mechanical impairment in Lrp5^{-/-} calluses, combined with minimal radiographic differences, indicates that the newly formed bone is biomechanically unsound despite the fact that these calluses appear to undergo almost normal development and mineralization. We conclude that signaling through Lrp5 is critical for the establishment of biomechanical integrity in healing bone.

Biomechanical Testing in Experimental Bone Interventions - May the Power Be with You. O. Leppänen¹, H. Sievänen², T. L. N. Järvinen¹. ¹Department of Trauma, Musculoskeletal Surgery and Rehabilitation, University of Tampere, Tampere, Finland, ²Bone Research Group, UKK Institute, Tampere, Finland.

Total variation in any measured variable, in conjunction with the expected treatment effect, dictate the minimum sample size (minSS) required to detect the expected effect with statistical confidence should the effect truly exist. The objective of this study was to introduce a practical algorithm for calculating the minimum sample size needed to detect a statistically significant treatment effect in biomechanical parameters. A comprehensive literature survey comprising all 3472 original studies published in four major bone journals during 1999-2003 was carried out to identify studies in which biomechanical testing of whole bones was applied. The total variation in most commonly used biomechanical tests of various bones was statistically estimated. In addition, the average intervention effects were calculated for most common settings (ovariectomy, increased and decreased loading) in rats. Employing this data, the adequately-powered sample size for common biomechanical testing procedures was determined. According to our literature survey, the total variation in different biomechanical tests of bones from different species was similar, justifying the use of rat femur as a model for detailed calculations. Due to poorer repeatability in terms of total variation, minSS in the femoral neck compression test is considerably larger compared to the midshaft bending test. Similarly, the use of stiffness and energy absorption required substantially larger sample size than the use of breaking load. For example, minSS to show a 10% treatment effect in the femoral shaft breaking load with 80% power was 11 rats/group, while the respective minSSs for the stiffness and energy absorption were 23 and 53, respectively. For the femoral neck compression, these numbers were 16, 51, and 134, respectively. Of note, a typical ovariectomy experiment in rats resulted in ~5% decrease in femoral shaft breaking load, thus requiring a sample size of 42 rats. The present analysis underscores the need for considerably larger sample sizes in experimental bone interventions using mechanical parameters as primary outcome variables. In particular, the poor repeatability in terms of total variation and the generally small expected treatment effects appear to compromise the general utility of stiffness and energy absorption results in typically small experimental bone interventions.

Prednisolone Induces Osteocyte's Death and Erosion of Osteocytic Lacunae Walls. M. Li¹, K. Hara², Y. Akiyama², N. Amizuka¹. ¹Center for Transdisciplinary Research, Niigata University, Niigata, Japan, ²Pharmacological Evaluation Section, Eisai Co., Ltd., Tokyo, Japan.

We have examined the abnormalities in the bones of Wistar rats that received prednisolone (20mg/kg) three times per week. Four, 8 and 12 weeks after beginning the steroid administration, rats were perfused with 4% paraformaldehyde in 0.1M phosphate buffer (pH 7.4), and their femora and tibiae were processed for paraffin and epoxy-resin embedding. Bone abnormalities in prednisolone-administered rats were assessed by performing alkaline phosphatase (ALP), acid phosphatase (ACP), tartrate resistant acid phosphate (TRAP) histochemistry, TUNEL assay and transmission electron microscope (TEM) imaging. Peripheral quantitative computed tomography (pQCT) was performed for evaluating bone mineral density (BMD) and bone mineral content at the metaphyseal and diaphyseal regions of prednisolone-administered and control rats. Three-point bending test was employed for estimating bone strength. BMD and mineral contents at metaphyseal and diaphyseal regions, as well as values of maximum loading were reduced as early as 4 weeks in prednisolone-administered rats. Ratio of maximum load divided by bone mineral content was much lower in prednisolone-treated rats, so that the reduced maximum load-bearing values appear to relate not only with a decreased BMD, but also with diminished bone quality in prednisolone-administered bones. ALP and TRAP assessments did not reveal obvious difference between control and prednisolone-treated bones. When examining cortical bones, however, several empty osteocytic lacunae were seen in prednisolone-administered rats, and a statistical analysis on the number of empty lacunae showed a significant increase in the prednisolone group. TUNEL assay unveiled increased osteocytic apoptosis in prednisolone bones. However, empty lacunae seem not to be a result of apoptosis only, as the number of apoptotic cells was lower than the number of such lacunae. TEM images demonstrated disrupted osteocytes in relatively enlarged osteocytic lacunae, as well as irregularly shaped osteocytes that were embedded in lacunae featuring eroded peripheral walls. In addition, osteocytes distant from bone-resorbing osteoclasts tended to show ACP-positive granules, indicative of activated lysosomal enzymes in prednisolone-treated rats. Thus, in our study, prednisolone appears to target osteocytes, inducing their cell death and erosion of the surrounding walls of their lacunae, which might influence overall bone quality.

New Method to Determine Variation of the Elasticity of Single Trabeculae. S. Lorenzetti*, E. Stüssi. Institute for Biomechanics, ETHZ, Zürich, Switzerland.

By comparing the deflection of an experimental 3 point bending test with FE calculation, the Young's modulus of single trabeculae can be determined.

With DXA and QCT the bone mineral density (BMD) is measured. Due to this technique, variations of the calcium apatite are detectable, but changes of the collagen mesh are not visible. With the presented new method, variations of the elastic behavior of single trabeculae are accessible.

A special micro-positioning device enables sample rotation around the trabecular axis. The force was applied normal to the optical axis and the trabecular with a nylon thread, and the deflection could be measured with the microscope. Based on the image stack from microscopy, a CAD body of the trabecula can be built using Amira™ and Geomagic™. FE calculations were performed with ANSYS™. By comparing the FE modeling with the deflection of the experimental 3 point bending test, the Young's modulus can be determined.

To obtain the accuracy of the method, two types of error calculations were performed: First, a straight forward estimation according to Gauss which includes the length, the force and the deflection, and second, FE calculations with variation of the volume. The expected resulting error for the Young's modulus is <10 %.

To test the new method the collagen was removed from a set of samples. Samples from the femur of an adult sheep were treated with sodium hypochlorite (NaOCl). The treatment with NaOCl is a standard method to deproteinize bone, and therefore, to alter the Young's modulus without changing the geometric properties or the inorganic part of the bone. The analysis of a native (untreated) femoral sample resulted in a Young's modulus of 15.0 ± 1.4 GPa. This is in the upper range of the published data in the literature of 1 up to 19 GPa. The treated samples showed a reduction of the Young's modulus by a factor of 15. Broz et al (1997) observed a decrease at macroscopic samples by a factor of 2.7.

Using DXA, no variation of the BMD would have been observed in this type of samples. With the new method, changes of the organic part (collagen) of the bone become visible.

It is concluded that the new method including sample preparation, experimental 3 point bending test with optical control, determination of the volume and FE modeling is suitable to determine the Young's modulus of single trabeculae in the natural boundary conditions of the sponiosa.

Fracture Strength of the Distal Radius Can Be Estimated by Non-linear Finite Element Analysis Using 3D High Resolution Peripheral Computed Tomography. J. A. M. MacNeil*, S. K. Boyd. Mechanical Engineering, University of Calgary, Calgary, AB, Canada.

Finite element (FE) modeling based on micro-computed tomography data has the potential to provide significant insight into disease- and treatment-related bone quality changes through estimation of fracture strength. The goals of this study were to determine if linear finite element models of bone stiffness can predict bone strength, and determine if non-linear finite element models provide an improvement over linear finite element models, through a direct assessment of strength. It was also investigated whether a non-homogeneous tissue Young's modulus scaled according to attenuation values can improve bone stiffness and strength measurements.

Fresh human cadaver forearms (5 male and 5 female) with ages ranging from 55 to 93 were obtained from the Gross Anatomy Lab at the University of Calgary. The distal radius was dissected free from each forearm and four 9.1 mm sections were cut beginning at the subchondral plate. The sections were scanned with high resolution peripheral quantitative computed tomography (HR-pQCT) (XtremeCT, Scanco Medical, Switzerland; voxel size 82 μm) in saline solution. These forty samples were mechanically tested and used to determine appropriate homogeneous and non-homogeneous tissue Young's moduli for finite element analyses. Ten samples corresponding to the standard clinical measurement location for in vivo HR-pQCT measurements were used for non-linear finite element evaluation.

Bone stiffness measurements by linear FE analysis using a non-homogeneous tissue Young's modulus had a significantly higher correlation to bone ultimate strength than the homogeneous tissue Young's modulus models, likely due to implicit correction for partial volume effects ($R^2=0.983$ vs. $R^2=0.960$; $p<0.05$). For the clinical measurement samples, the non-linear FE analysis predicted the experimentally determined ultimate strength better than correlations based on apparent stiffness estimates from linear FE. This trend was true for homogeneous tissue Young's modulus models ($R^2=0.937$ vs. $R^2=0.868$) and was statistically significant for non-homogeneous tissue Young's modulus models ($R^2=0.951$ vs. $R^2=0.928$; $p>0.05$).

It was concluded that for estimation of bone strength using in vivo HR-pQCT measurements, non-homogeneous tissue Young's modulus improves estimations, and that linear finite element measurements were highly predictive of bone ultimate strength, albeit based on correlations rather than direct measurements. A non-linear finite element measurement directly estimated bone strength, and can provide improved accuracy when the increased computation is justified.

Posterior Cortical BMC in the Femoral Neck Predicts Proximal Femur Failure Load. S. L. Manske*, D. M. L. Cooper*, T. Liu-Ambrose*, P. Guy*, H. A. McKay*. ¹University of Calgary, Calgary, AB, Canada, ²University of British Columbia, Vancouver, BC, Canada.

Region-specific deterioration of the femoral neck (e.g. superoposterior) may play a key role in hip fractures. We aimed to determine the region of the femoral neck where cortical bone mineral content (CoBMC) best predicted failure load. We obtained 36 unembalmed, previously frozen human cadaveric femora (36 - 92 years), and scanned each with a 16-slice helical QCT scanner (GE LightSpeed Ultra). QCT scans were acquired axially and images ($0.5 \times 0.5 \times 0.63$ mm) were reconstructed perpendicular to the femoral neck axis ($0.5 \times 0.5 \times 2.5$ mm). We assessed total area (mm^2) and CoBMC (g) in the femoral neck cross-section with the lowest total area (i.e., narrowest-neck). We also measured cortical BMC regionally within 8 sectors (octants) radially defined about the centroid of the cross-section (Figure). The femora were then loaded to failure in an apparatus that simulated a sideways fall at a rate of 100 mm/s. Femora that fractured outside of the neck or intertrochanteric regions ($n=7$) were excluded from analyses. We performed hierarchical linear regression with failure load (N) as the dependent variable. In the regression model, we entered total area at the first level to account for differences in bone size and then utilized stepwise selection of the sector-based CoBMC values at the second level. Two additional specimens were excluded as outliers based on Cook's distance. The highest correlations between CoBMC and failure load were along the anteroinferior to superoposterior axis (R ranged from 0.63 to 0.71, Figure). The stepwise regression selected CoBMC from the posterior sector based on its association with failure load. CoBMC in the posterior region explained 65% of the variance (R^2) in failure load after accounting for total area. Our results agree with the predictions of Mayhew et al. (2005) and Lotz et al. (1995) who suggest that the superoposterior region may be critical to the strength of the femoral neck. We extend their findings by providing measurements of proximal femur strength in ex vivo specimens. Our quantitative results further correspond with our observation that most of the fracture lines propagated through the superoposterior region. We conclude that the superoposterior region requires further investigation as a key site of fracture initiation and propagation in sideways falls.

Evaluation of Vertebrae Fragility by Osteoporosis. N. Nango¹, N. Endo^{2*}, T. Yamamoto^{3*}, H. Takahashi⁴, M. Machida^{5*}, Y. Suga^{6*}, T. Asai^{6*}. ¹Ratoc System Engineering Co., Ltd., Tokyo, Japan, ²Niigata University, Niigata, Japan, ³Niigata Bone Science Institute, Niigata, Japan, ⁴Niigata University of Health and Welfare, Niigata, Japan, ⁵Murayama Medecal Center, Tokyo, Japan, ⁶Kawaguchi Municipal Medical Center, Saitama, Japan.

We developed a method to quantify the trabecula path that connects between the two endplates of the vertebrae. We consider this connecting path primarily prevent the vertebral deformation. We used in-vivo Multi Detector CT images of females aged 70 with lumbar stress fracture (a), females aged 86 without fracture(b), and males aged 57 without fracture (c). Based on the CT values of these bone images, we determined the trabecula bone (TRI/3D-BON software by RATOC), and measured the length (L) and cross section (S) of each trabecula. We define the trabecula elasticity coefficient (k) as $k \propto S/L$, and the resistance force (f) as $f = k \cdot d$ for deformation distance (d). We define the simulation model as follows: loaded surface, fixed surface and trabecula network connecting both surfaces. Using given external deformation (D), deformation (d) for each trabecula was obtained: each trabecula path connecting the two surfaces satisfy $D = \sum d$; we also calculated the resistance force (fe) of each trabecula composing the network. The resistance force of vertebrae (Fe) was calculated as the sum of (fe) of the trabeculae contacting loaded surface $Fe = \sum fe$.

This calculated Fe is the simulation of resistance force generated in vertebrae when stress deformation is applied to the loaded surface. The figure shows the results, of the connecting trabecula paths between upper and lower endplates which resistance force greater than the specified threshold. The value of the resistance force decreased in the order of young male(c), old female(b), female with stress fracture(a). The resistance force in females with stress fracture was half of that in the male.

As the images show, in the female with stress fracture, the density of trabecula bone connecting the endplates is low at the front of the vertebrae and there are few straight connecting paths, instead the paths are connected by many detours. The paths of the old female without fracture have many fragmented disconnections. The trabecula bone network of the female with stress fracture has disappeared locally and is regarded as the cause of the fragility.

This model shows the mechanical strength of vertebrae trabecula bones but also demonstrates the fragility.

Improved Analysis of Bone Nano-mechanical Properties Using a Novel Nanoindentation Technique. S. Pathak^{1*}, S. R. Kalidindi^{1*}, H. W. Courtland², K. J. Jepsen², H. M. Goldman³. ¹Materials Science and Engineering, Drexel University, Philadelphia, PA, USA, ²Orthopedics, Mount Sinai School of Medicine, New York, NY, USA, ³Neurobiology and Anatomy, Drexel University College of Medicine, Philadelphia, PA, USA.

Currently, there exists a critical need to develop better techniques to understand the relationship between bone matrix composition and organization and tissue-level mechanical properties, thereby improving our ability to predict fracture risk. To address this gap, we have developed a new technique for extracting mechanical property information at the nano-scale in bone, by translating nanoindentation generated load-displacement curves into indentation stress-strain (ISS) curves for a better representation of material deformation at the lamellar level. We applied this method to a sample of femora obtained from strains of inbred mice known to have varying whole-bone mechanical properties.

Femora from A/J, C3H/HeJ (C3H), and C57BL/6J (B6) mice (16 wks of age, n=3 each) were embedded in PMMA, sectioned transversely below the third-trochanter and surface polished to 0.05µm. Backscattered electron microscopy (BSE-SEM) was used to assess mineralization density across the postero-lateral (PL) cortex of each sample. Nanoindentations (20µm apart) were carried out across this same cortex using a nanoindenter (MTS XP[®]) with a 13.5 µm radius spherical diamond tip, and corresponding ISS curves were computed. Examination of the ISS curves taken at a 40µm distance from the actively forming periosteal surface of each strain demonstrate that all three have similar slopes during (elastic) loading, but vary in post yield behavior; A/J demonstrates the highest hardening slope, while B6 demonstrates the lowest. Obtaining the elastic modulus values from the loading portion of these ISS curves rather than the unloading portion of the load-displacement curve also helps us more readily discern the differences in modulus between bone of lower and higher mineralization density.

Our results demonstrate that this method can be used to elucidate trends in yield and post-yield behavior at the lamellar level that are consistent with findings found in macro-mechanical testing of these mouse strains. This represents a significant advancement in the characterization of mechanical behavior of bone under indentation pressure beyond the regimes of elastic limit to which it has been restricted to thus far. The additional local property information provided by our nanoindentation technique, in conjunction with compositional analyses, will help us tremendously in developing an understanding of the complex interactions between bone quality, composition and mechanical properties.

Osteoblast-specific Knockout of IGF Receptor Gene in Mice Alters Mechanical Properties of Cortical Bone. G. Ramaswamy^{1*}, X. Cao^{2*}, S. Chowdhury^{3*}, C. Wan², G. McGwin^{4*}, J. E. Lemons^{5*}, T. L. Clemens^{2*}, A. W. Eberhardt^{1*}. ¹Department of Biomedical Engineering, University of Alabama at Birmingham, Birmingham, AL, USA, ²Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, ³Department of Physics, University of Alabama at Birmingham, Birmingham, AL, USA, ⁴Department of Epidemiology, University of Alabama at Birmingham, Birmingham, AL, USA, ⁵Department of Prosthodontics and Biomaterials, University of Alabama at Birmingham, Birmingham, AL, USA.

Insulin-like growth factor-1 is essential for normal embryonic and postnatal growth. Previous studies have shown that selective disruption of the IGF receptor gene (Igflr) in mouse osteoblasts decreased bone formation and mineral apposition rates over the pubertal period.¹ The present study compared the geometric and mechanical properties of cortical bone at the mid-diaphysis of tibiae in 3 week old Igflr knockout and control mice (n = 14 per group) at the whole bone level by microCT and three-point bending and at the microstructural level using nanoindentation. MicroCT data revealed a decrease in cortical thickness (p < 0.05) which translated into a dramatic reduction in bone area (p < 0.05) and bone volume fraction (p < 0.0001) in the knockouts. Elastic modulus and toughness obtained from bending showed significant reductions (p < 0.05) in the knockouts as compared to controls while overall bending stiffness was only mildly affected. These bones showed geometric adaptation with increased mediolateral radii (p < 0.05) and moments of inertia similar to controls, which partially counteracted for the material degradation to maintain their structural integrity. Microstructural properties from nanoindentation did not show any genotype effect, which was consistent with bone mineral density measurements from microCT that were similar between controls and knockouts. Gender specific comparison demonstrated females to be smaller in size with structural properties more severely reduced following ablation of IGF signaling. In conclusion, the current study suggests that local IGF signaling in murine osteoblasts is essential for normal appositional growth of cortical bone during diaphyseal modeling and its disruption affects the mechanical properties, more severely in females, at the prepubertal stage in mice.

Txnp Deficient HcB/19 Mice Have Decreased BMD and Femoral Strength. N. Saless¹, J. Chen^{*2}, A. Shalev^{*2}, R. D. Blank². ¹Cellular and Molecular Biology, University of Wisconsin, Madison, WI, USA, ²Medicine, University of Wisconsin, Madison, WI, USA.

Thioredoxin interacting protein (Txnp) mediates the oxidative stress response. Txnp-thioredoxin interaction reduces thioredoxin activity, so that in vitro Txnp overexpression leads to increased apoptosis and decreased proliferation following exposure to oxidative stress. HcB/19 recombinant congenic mice harbor a nonsense mutation of Txnp, resulting in a metabolic profile similar to human familial combined hyperlipidemia. Mice harboring the Txnp mutation also display an increase in fat mass relative to wild-type. Hypothesizing that the observed increase in fat mass is accompanied by a concomitant decrease in bone mass, we compared bone density and biomechanical performance in HcB/19 mice and C3H/DiSn mice, their recipient progenitor, which harbor the normal Txnp allele.

Mice were studied at 4 months of age, examining BMD by DXA (PIXIMus, GE-Lunar) and femoral biomechanics by 3-point bend testing. The latter was performed under displacement control at a rate of 0.3 mm/second and post spacing of 3.75 mm. Data were analyzed for total displacement, structural stiffness, maximum load, and energy to failure. Data from the right and left femora were averaged for each individual. Data were analyzed by 2 way ANOVA with $\alpha = 0.05$.

We found that HcB/19 mice display decreased total body BMD, and decreased maximum load and stiffness, in spite of similar body mass (see table). Although energy to failure tended to be lower in HcB/19, the difference did not reach significance. There were no interactions between strain and sex. Biomechanical performance was greater in females than males.

Our data show that Txnp deficiency reduces peak bone mass and bone strength. Txnp is known to be induced by 1, 25 di-OH D and repressed by mechanical loading. Our data do not address the question of whether either of these mechanisms contributes to the observed biomechanical phenotype. Our data also do not allow us to determine whether the Txnp mutation alters the balance between the osteoblastic and adipocytic lineages during development. Our experiment is limited in that other loci also segregate between the strains. Nevertheless, the epidemiological association between atherosclerosis and osteoporosis and our biomechanical data justify further investigation of Txnp

Biomechanics and Body Size Quantitative Trait Loci in HcB/8 x HcB/23 F2 Mice. N. Saless¹, G. E. Lopez Franco^{*2}, S. J. Litscher^{*2}, K. Abdul Raheem^{*3}, K. Kozarek^{*3}, S. Sudhakaran^{*3}, M. J. Houlihan^{*3}, A. S. Ahmed^{*3}, T. K. O'Neill^{*3}, S. J. Han^{*3}, R. D. Blank². ¹Cellular and Molecular Biology, University of Wisconsin, Madison, WI, USA, ²Medicine, University of Wisconsin, Madison, WI, USA, ³University of Wisconsin, Madison, WI, USA.

Recombinant congenic mouse strains HcB/8 and HcB/23 differ in biomechanical performance in spite of similar ash percentages. To identify quantitative trait loci contributing to the differences in biomechanical performance between these strains, we performed a reciprocal F2 intercross to map the responsible QTLs. Below, the female progenitor is listed first, in accordance with convention.

F2 mice were kept to 17 ± 1 weeks under standard husbandry conditions. Following sacrifice, we performed microsatellite genotyping and measured femoral whole bone biomechanics and BMD by DXA. From 3-point bend testing performed under displacement control, post separation of 3.5 mm, and a deflection rate of 0.3 mm/sec, we extracted total and post-yield displacement, stiffness, maximum load, and energy to failure. We analyzed the data with QTL Cartographer and established experiment-wide significance levels by permutation testing. We studied 124 8x23 females, 163 23x8 females, 169 8x23 males and 147 23x8 males.

Significance thresholds ranged between LOD scores of 1.9 for stiffness to 3.7 for post-yield displacement, reflecting the reproducibility of the trait assays. In the entire F2 population, the only significant QTL is for body mass at 27 cM on chromosome 2. In the 8 x 23 arm, there is a significant QTL at 68 cM on chromosome 3 for total displacement and post-yield deflection (LOD = 4.9 and 5.7, respectively). On chromosome 10, there is a stiffness QTL (LOD = 2.6) at 28 cM. In the 23x8 arm, there are a pair of chromosome 3 QTLs for length centered at 12 cM (LOD = 3.0) and 68 cM (LOD = 3.2). Among males of both arms, there is a broad body mass QTL (LOD = 3.3) located between 18 and 72 cM on chromosome 3. Among females of both arms, there is a body mass QTL (LOD = 3.2) at 79 cM on chromosome 3. Arm and sex specific subgroups display some of these QTLs and also display additional significant QTLs not listed above. Comparison of the overall phenotypic distributions also revealed evidence of one or more X-linked QTLs.

The data show that there are both cross and sex effects, as others have found in previous bone linkage studies. Epistatic interactions between pairs of genes, genomic imprinting, and mitochondrial inheritance are all possible mechanisms underlying the observations. Future work to isolate the genes responsible for the QTLs found in this cross will be facilitated by the fact that the donor segments in the parental strains have already

undergone multiple recombination events, limiting their length and providing physical landmarks for fine structure genetic mapping.

Interrelation Between Dietary Fatty Acids and Fibers in Modulating Bone Quantity and Quality During Skeletal Growth. A. Schirmer^{*1}, S. Ferreri^{*1}, L. M. Miller^{*2}, Y. Qin^{*1}, N. Turner^{*3}, J. Lupton^{*3}, S. Judex¹. ¹Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA, ²Biomedical Engineering, Brookhaven National Laboratory, Upton, NY, USA, ³Texas A&M University, College Station, TX, USA.

Dietary factors can influence the levels of bone formation, bone resorption and impact bone quantity and quality. Increased quantities of dietary lipids may have detrimental effects on bone mass but emphasizing specific lipid sources, while maintaining the total amount of dietary fat, can be beneficial. Little is known about the interaction between dietary lipid and fiber source. The objective of this study two different lipid sources were factorially combined with two different fiber sources to investigate their skeletal impact in rapidly growing rats. Forty-nine 4wk old male rats were randomly divided and fed one of four dietary combinations for 4wk (fish oil/cellulose, fish oil/pectin, corn oil/cellulose, corn oil/pectin). At completion of the protocol, micro-computed tomography determined differences in trabecular and cortical bone morphology of the distal and diaphyseal femur. Mechanical and chemical properties of the femoral diaphysis were determined by 3-point bending and Fourier transform infrared spectroscopy. There were no significant differences between the four dietary groups for any morphological or micro-architectural parameter in the distal femoral metaphysis. In contrast, middiaphyseal cortical bone was sensitive to differences in dietary components. Rats fed a fish oil rather than a corn oil diet had a 5% (p<0.02) greater cortical bone area, a 5% (p<0.005) greater periosteal area, and a 6% (p<0.02) greater endocortical envelope area. Conversely, bones from rats on the corn oil diet showed a 26% (p<0.002) higher energy to failure. There were no significant differences in collagen structure between groups but rats fed the corn oil diet had a 16% (p<0.02) higher level of mineralization compared to rats on the fish oil diet. When comparing rats on cellulose versus pectin diets, no differences were found for any morphological, mechanical, or chemical properties. These data indicate that dietary fish oil, compared to corn oil, can moderately promote cortical, but not trabecular, bone growth but, at the same time, may decrease measures of bone quality. In the absence of effects, or interactions, of pectin and cellulose, any skeletal differences observed in this study could be attributed to differences in fatty acid content. Whether the only modest differences in bone quantity and quality are related to the relatively short experimental protocol or the genetically modulated high levels of cellular activity in the rapidly growing rat remains to be determined.

Vitamin D Deficiency: A Common Occurrence in Both High and Low Energy Fractures. B. Schreck^{*1}, A. Serota^{*1}, D. Helfet^{*1}, M. G. E. Peterson^{*1}, N. Sinha², J. M. Lane¹. ¹Hospital for Special Surgery, New York, NY, USA, ²New York Presbyterian Hospital, New York, NY, USA.

Vitamin D insufficiency is an under-recognized problem in adults in the United States. Vitamin D influences Ca homeostasis, bone mineral density, muscle strength, and bone strength and healing. This retrospective study tests the hypothesis that vitamin D deficiency is prevalent among fracture patients, regardless of high vs. low energy fracture etiology.

A retrospective analysis of the medical records for 44 in-patients with non-vertebral fractures on the orthopedic trauma service at the Hospital for Special Surgery was conducted from June 1, 2006 to February 1, 2007. The obtained data included a 25-hydroxyvitamin D level, age, gender, and reason for admission; high energy fracture vs. low energy fracture (a fall from standing height or less).

Vitamin D deficiency, 25(OH)D<32 ng/ml, was found in 59.1% of the patients and the mean 25(OH)D was 30 ng/ml ± 13. Significantly more women (75%) than men (40%) were vitamin D deficient. Significantly more women than men with high energy fractures were vitamin D deficient (p=0.01). In women, both high and low energy fractures present with vitamin D deficiency (80% of high energy fractures and 71.4% of low energy fractures). In men, the mean vitamin D level was lower for low energy fractures (16 ng/ml) compared to high energy fractures (32 ng/ml), p=0.007. In addition, men with low energy fractures were significantly older than men with high energy fractures, p=0.02, but this age difference was not significant among women, p=0.053. The mean age for women (66 years) was higher than the mean age for men (51 years), p=0.02. Women showed a significant correlation of age vs. 25(OH)D as older women actually had higher values of 25(OH)D than younger women, rho=0.46 (p=0.02). For men, there was no significant correlation of age vs. 25(OH)D, rho=-0.2 (p=0.2).

A high prevalence (59%) of vitamin D deficiency is seen among in-patients on the orthopedic trauma service. Statistically more vitamin D deficiency is seen in women and our results are consistent with the gender difference seen in the general population. The higher values of 25(OH)D in older women compared to younger women may be due to the fact that older women are more likely to be treated with calcium and vitamin D. Even among younger men who sustain a high energy fracture, 25% are vitamin D deficient. Women regardless of age or energy level causing fracture have low vitamin D levels. 25(OH)D levels should be measured in all orthopedic trauma patients and deficient patients should be treated.

Variation of the Young's Modulus of Single Trabeculae in a Sheep Femur. E. Stüssi, S. Lorenzetti*. Institute for Biomechanics, Ethz, Zürich, Switzerland.

In this work, first results of a study of the variation of the Young's modulus of single trabeculae within a femur are presented.

The fracture risk of bone is influenced by several parameters. The important factors are age, gender, mobility, type of bone, the bone mineral density (BMD) and the material properties. The mechanical properties are influenced by the architecture, the structure and the quality of the bone forming material. One of the major parameters of the material properties is the Young's (elastic) modulus E. This value describes the linear deformation under loading.

Various standard methods are known to measure the stiffness of the entire spongiosa or bone at macroscopic scale. Furthermore, indentation tests are available to determine the elastic behavior of microscopic spongiosa samples. In this work, the first results of a new method to determine the Young's modulus of single trabecula using experimental and FE simulation of a 3 point bending test are presented.

This method takes the exact 3D geometry and the behavior under loading into account. Stacks of images were taken using a laser scanning microscope (LSM) and a near infrared laser. Based on the image stack from microscopy, a CAD body of the trabecula can be built using Amira™ and Geomagic™. FE calculations were performed with ANSYS™. The experimental 3 point bending test was performed with the boundary conditions of the natural trabecular network. The force was applied normal to the optical axis with a thread, and the deflection could be measured with the microscope. By fitting the FE modeling to the deflection of the experimental 3 point bending test, the Young's modulus can be determined. The experimental error estimated by Gaussian error calculation and variation of the input parameters of the FE calculations is < 10 %.

The spongiosa samples were taken from the femur of a healthy 2.5 y old sheep. The bone was cut into cubic samples using a band saw. The bone marrow was extracted using ultrasound wave bath and pressure air.

The presented data shows variation of the Young's modulus within one femur by a factor of about 4. This is a similar range as summarized by Bayraktar et al. 2004.

Bayraktar et al. J. of Biomech. 37(11):27-35

Bone Fragility May Be Caused by Mechanostress Inequality in Transitional Period from a Steady-state Bone Metabolism to Another State. Y. Tamura, K. Nakayama, S. Katayama*. Saitama Medical University, Saitama Pref., Japan.

We have presented a computer simulation program of bone metabolism in a past ASBMR meeting. In this meeting, we want to show unloading model of bone on this program.

At first, we made a two-dimensional square bone model in computer and loaded 10 units of mechanical force to the initial bone. After dozens of simulation time, this bone became a structure like trabecular bone and reached steady-state bone metabolism. Then we reduced this force from 10 to 5 units to simulate mechanical unloading. BV/TV decreased promptly, but Tb.N decreased slowly. Dozens of simulation time later, this bone reached new steady state.

We postulated that the phase between fast and slow convergence of BV/TV and Tb.N was transient period for bone to adapt to change of external load. So we examined local mechanical stress, bone formation and resorption in this period.

Before and after transient period, local mechanical stresses were uniform and steady, and bone formation and resorption were also stable. However, during transient period, local stresses varied from place to place, causing increased and fluctuated bone metabolism. Trabecular perforation caused stress concentration to parts of residual trabecula and the places became very weak transiently.

These results suggest that bone fragility with increased bone metabolic marker may occur in transitional period from a steady state bone metabolism to another one, as shown in this unloading simulation model. If so, fractures in osteoporosis may be caused by mechanostress inequality in transient and unstable structures during adaptation processes to another environment of external load and hormones. And it may be very important that this unstable state continued for a long time after bone mass had changed. This condition may mean poor bone quality in osteoporosis.

Lean and Not Fat Mass Is Associated with Male Proximal Femur Strength. T. G. Travison¹, A. B. Araujo¹, G. R. Esche^{*1}, T. J. Beck², J. B. McKinlay¹. ¹New England Research Institutes, Watertown, MA, USA, ²Johns Hopkins University School of Medicine, Baltimore, MD, USA.

Obesity is thought to confer protection against fracture, but the mechanism driving this association is poorly understood. We hypothesized that the effect of increased weight or BMI on bone structure would be accounted for by total and/or appendicular lean mass (LM), and that once these trends were removed, fat mass (FM) would demonstrate no protective influence. To test this hypothesis, we examined body composition and geometric indices of proximal femur strength in a diverse sample of randomly-selected men, ages 30-79 y.

Data were obtained from N=1,171 community-dwelling men randomly selected for inclusion in the cross-sectional Boston Area Community Health / Bone study. Body composition was obtained by dual X-ray absorptiometry (DXA). Hip geometry parameters at the narrow neck (NN), intertrochanter, and shaft regions of the proximal femur were obtained via Hip Structural Analysis of DXA images. These measures included bone mineral density (BMD), bone material in cross sections (cross-sectional area, CSA), bending strength (section modulus, Z) and propensity to buckle under compression (average buckling ratio, ABR). Analyses controlled for age, race/ethnicity (black, Hispanic, white), height, and physical activity.

When considered individually, BMI, LM and FM were each positively associated with hip strength. However, controlling for LM removed the positive, and induced a negative, association for BMI or FM (the Figure depicts results for BMI and NN CSA). In joint models including LM, FM and covariates, NN CSA and Z increased by an estimated 12.4 percent (95% CI: 10.2, 14.6) and 15.1 percent (95% CI: 12.2, 17.9), respectively, per 10 kg increase in LM, while FM had no positive effect. Finally, LM alone was sufficient to account for a substantial proportion of racial difference in hip strength measures (≥ 50% for the majority of comparisons), while FM exhibited no explanatory power. Findings were similar whether total or appendicular mass was considered.

These results indicate that the positive association between relative weight and proximal femur strength is accounted for by lean mass, and suggest that the protective effects of BMI in preventing fracture risk is mediated not by adipose tissue but by the influence of increased muscle mass accompanying elevated BMI.

Development of a High-Resolution 3D Micro-CT Based Model to Predict Fracture Callus Histological Architecture. J. A. Weis^{*1}, F. Granero-Molto¹, L. D. O'Rear^{*1}, M. I. Miga^{*2}, A. Spagnoli¹. ¹Pediatrics, Vanderbilt University, Nashville, TN, USA, ²Biomedical Engineering, Vanderbilt University, Nashville, TN, USA.

Annually ~600,000 people in the US suffer from fracture healing failure. There is a compelling need for studies that define the dynamic mechanisms underlying the fracture healing process and predict when it fails. The purpose of this study is to determine appropriate microCT thresholds that can predict callus bone/cartilage architecture. A stabilized tibia fracture was created in FVB mice by three-point bending. The tibia was harvested after 14 days and subjected to microCT scanning at 6 micron voxel resolution for 7.4 mm length around the callus (Scanco µCT 40). The tibia was sectioned at 6 micron for 5.2 mm length around the callus. Sections were placed on 288 slides with 3 sections per slide. In-situ hybridization for collagen 1 and collagen 10 was performed for 210 sections for each probe. The collagen 1 and 10 stained sections were quantified and labeled with a defined color value and spatially reconstructed by a custom built image registration code (MATLAB). Each section was centered and rotated to align with the previous section. The reconstructions were then overlaid to produce a bone/cartilage 3-D model based on collagen 1 and 10 expressions. The 3-D model was then compared to the 3-D reconstruction from microCT. As shown in Figure 1, callus volumetric analysis demonstrated that the CT voxel based 3-D reconstruction well predicted the 3-D bone/cartilage model based of collagen 1 (A) and 10 (B) expressions. Figure 2 depicts representative sections of collagen 1 (A), collagen 10 (B), voxel based CT image (C), and predicted 3-D bone/cartilage model (D) clearly indicating the high resolution predictability of the CT model. This study provides basic information for developing a CT voxel based 3-D model that correlates with histological structure of a fractured callus. This model can potentially overcome the limitation of histological studies that can only be based on a limited number of tissue sectional analysis.

Figure 1. Volumetric analysis of bone/cartilage model vs the predicted voxel-based CT reconstruction.

Figure 2. Representative callus sections of Col 1 (A) Col 10 (B) in situ hybridization, CT imaging (C), and predicted model (D)

Unilateral Osteoarthritic Hips Have Lower Trochanteric BMD and Higher Femoral Neck BMD Compared with the Unaffected Side - An Explanation Why Trochanteric Fractures Are More Frequent Than Femoral Neck Fractures in Osteoarthritic Hips. O. Wolf*, J. Milbrink*, S. Larsson*, H. Mallmin. Surgical Sciences, Uppsala, Sweden.

Patients with osteoarthritis of the hip, OAH, are subject to trochanteric hip fractures but very seldom to femoral neck fractures. One reason might be differences in bone strength due to altered bone composition in the proximal femora. In OAH there might be a problem using DXA, as external contracture is common and this might affect BMD compared to the recommended slight inward rotation. Our aim was to compare BMD at the proximal femur and heel in OAH-affected and healthy legs as well as body composition in the lower extremities. In addition we measured the effect of differences in rotation on DXA values in patients with no hip disease.

41 patients (20 women, 54 ± 8.8 years) with unilateral OAH scheduled for arthroplasty were included. Before surgery DXA was done bilaterally at the proximal femora and heels, as well as total body. Three regions of interest (ROI) for the proximal femur (femoral neck-FN, trochanter-TR and total hip-TH) were investigated. Preoperative weight bearing (WB) was measured with the F Scan system and hip abductor strength with a dynamometer (MS). Differences in rotation on DXA images between OAH and control side were thoroughly assessed. In 21 hip-healthy patients (64.1 ± 11.5 years; 42 hips) DXA was done with the foot in a vertical position as well as the recommended inward rotation to assess the effect of rotation. OAH had 5% higher BMD_{FN} ($p < 0.007$), 8% lower BMD_{TR} ($p < 0.000002$) and 5% lower BMD_{TH} ($p < 0.001$) compared with the control side. 21/38 had no differences in rotation whereas 16 had an increased outward rotation of the OAH side. Regional analyses of the total body measurement showed significantly lower BMC and fat mass, 5% and 2%, respectively, in OAH legs but no difference in lean mass ($p < 0.67$). However, when calculated as ratios these differences did not remain significant. We found no significant differences in BMD_{HEEL} , WB or MS between OAH and controls. For the hip-healthy patients there was a significant increase in BMD_{TR} (2.5%, $p < 0.00001$) but no significant influence on BMD_{FN} and BMD_{TH} with the foot in vertical position compared with slight inward rotation.

Higher BMD_{FN} and lower BMD_{TR} in OAH compared with controls, indicates that the trochanteric region is the weakest part of the proximal femur in patients with OAH. This finding can not be explained as false low values due to external contracture. On the contrary, neutral position seems to provide higher BMD_{TR} values. In conclusion, low BMD_{TR} offers a potential explanation why OAH-patients are far more likely to suffer a trochanteric rather than a femoral neck fracture.

The Effect of Collagen Degradation on the Stiffness of Bone in an Emu Model. C. Wynnckijy^{*1}, S. Omelon^{*2}, M. D. Grynbas². ¹Materials Science Engineering, University of Toronto, Toronto, ON, Canada, ²Samuel Lunenfeld Research Institute, Mount Sinai Hospital, Toronto, ON, Canada.

Current methods of bone quality assessment, such as Dual energy X-ray Absorptiometry (DXA) and Quantitative Ultrasound (QUS) measure bone mineral content and density, while less emphasis has been devoted to collagen's role in fracture risk assessment. Neither DXA nor QUS provide a direct measurement of the mechanical properties of bone. DXA measures bone mineral density (BMD) and QUS measures speed of sound (SOS) transmitted through bone. Although these surrogate measurements are related to fracture risk, they are not sufficient to adequately predict bone fragility. Consequently, there is a need for a technique that can provide more information related to fracture than the data from DXA or QUS. A promising candidate is the Mechanical Response Tissue Analyzer (MRTA), a radiation free, non-invasive instrument developed by NASA to investigate the effect of space travel on bones. The MRTA directly measures a mechanical property of bone, the cross-sectional bending stiffness, which describes the ability of bone to resist deformation.

In order to assess the contribution of collagen on the mechanical properties of bone, the emu tibia was selected as a model due to its size and approximate cylindrical shape, making it ideal for devices designed to accommodate human long bones. The effect of deproteinization in ex-vivo emu bone was explored using DXA, QUS and MRTA. Four groups ($n=7-10$) of female emu tibiae were endocortically deproteinized in 1M KOH solution for 1, 3, 7 and 14 days, resulting in negligible mass loss (0.5%). Hydroxyproline assays were used to confirm minimal loss in collagen content. Statistical analysis of results over time and between techniques was performed. The negligible mass loss resulted in significant changes in modulus of elasticity between all time points (except between 3 and 7 days), as determined by 3-point bending and MRTA. The change in SOS and BMD varied by less than 2%. This is not surprising as both techniques measure changes in bone mineral content, which is not affected by KOH. In contrast, the MRTA reflected changes in the modulus caused by deproteinization of bone more significantly. No significant differences were seen between 3-point bending and MRTA. The significant reduction in modulus caused by the small amount of bone mass removal may be due to in situ collagen degradation rather than collagen loss.

	1 day	3 day	7 day	14 day
3-point bending - % Change Modulus	5.3±1.4	9.7±1.8	11.6±1.1	16.8±3.1
MRTA - % Change Modulus	4.8±1.4	10.9±1.5	13.2±2.8	18.3±3.3
DXA - % Change BMD	1.1±0.5	1.7±0.8	0.8±0.3	1.2±0.2
QUS - % Change SOS	0.9±0.2	1.4±0.4	0.9±0.4	1.0±0.2

A Novel Patient-Specific Finite Element Model to Predict Damage Accumulation in Vertebral Bodies under Axial Compression. Y. Chevalier*, M. Charlebois*, P. Varga*, D. Pahr*, P. K. Zysset. Institute of Lightweight Design and Structural Biomechanics, Vienna University of Technology, Vienna, Austria.

In the past years, QCT-based finite element (FE) approaches were applied to monitor the effect of anti-resorptive or anabolic treatments on vertebral body stiffness under axial compression or bending.

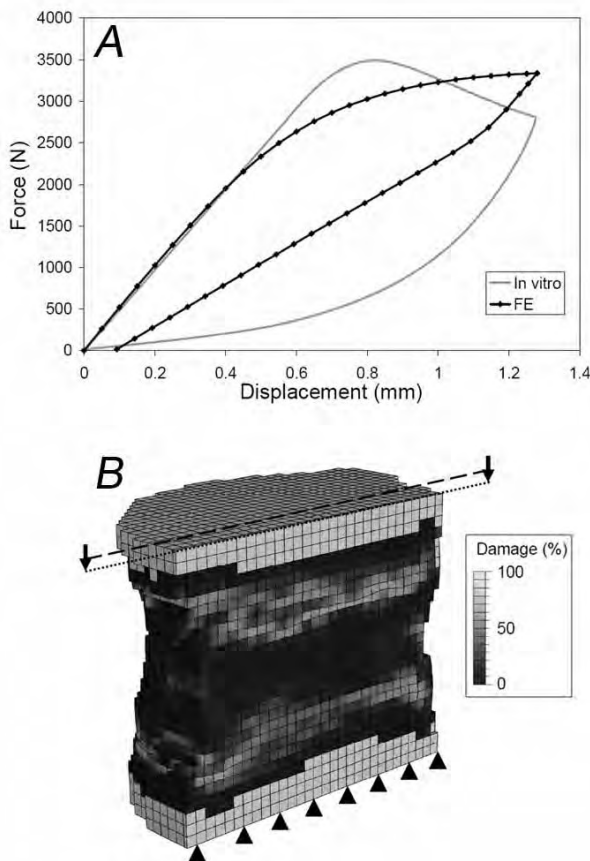

However, these FE analyses were either elastic, that is they excluded any representation of damage accumulation, or utilized constitutive laws based on metal plasticity which have limited accuracy in simulating irreversible strain and damage in bone tissue.

In this work, a novel constitutive law specifically designed for trabecular bone elasticity, plasticity and damage was applied to a collection of 12 cadaveric human vertebral bodies (L1-L5, age 47 to 83) in the framework of an automated finite element model generation software.

The vertebral bodies were scanned by pQCT at 80 microns, segmented and coarsened into 1.3mm isotropic voxels. Mineral density was converted into bone volume fraction (BV/TV) on which the elastic, yield and ultimate properties of the developed transverse isotropic constitutive law were based. Superior and inferior endplates in PMMA were added to transmit load to the vertebral bodies. Axial compression was applied to the digital meshes in the form of axial displacements on the superior endplate. Generation of the mesh and application of the boundary conditions were fully automated and a typical FE simulation took approximately 240 minutes of CPU time on 3GHz Xeon processors with 16GB RAM.

Beyond the usual compression stiffness, the yield and ultimate loads as well as the irreversible deformation of the vertebral bodies were computed. A typical force versus displacement curve is shown in Fig. 1A. While a map of the induced damage is visualized in Fig. 1B. Both vertebral stiffness and ultimate force predicted by the finite element models were linearly related to the experimental values ($r^2=0.64$ and $r^2=0.76$ respectively). The slopes and intercepts of these regressions were not significantly different from 1 and 0 respectively.

This novel finite element model of the human vertebral body was therefore properly validated by experimental data, computationally efficient and could be applied to investigate the effect of 2 years teriparatide treatment within the Eurofors study (see abstract this meeting).

A Combined Axial Compression and Flexion Loading Mode to Evaluate Strength of Vertebral Bodies using a Voxel-Based Finite Element Method. M. Charlebois*, Y. Chevalier*, P. Varga*, D. Pahr*, P. K. Zysset. Institute of Lightweight Design and Structural Biomechanics, Vienna University of Technology, Vienna, Austria.

The effect of pharmacological treatment on the mechanical properties of bone relies increasingly on finite element models. For human vertebral bodies, axial compression is the loading mode of choice to investigate stiffness or nonlinear characteristics such as yield or ultimate force. However, in daily activities, the human lumbar spine is subjected to a variety of loading modes and vertebral fractures also exhibit different morphologies. In this context, the goal of this study was to compare stiffness and ultimate mechanical properties of human vertebral bodies under axial compression, antero-posterior flexion and a combination of these two loading modes.

A group of 12 human lumbar vertebrae (age 47-83) were scanned with high-resolution pQCT and digitized to 1.3mm voxels. A novel transverse isotropic constitutive law for bone including elasticity, plasticity and damage accumulation was used for all loading cases. Superior and inferior endplates in PMMA were added to the vertebral models to apply loads in the form of axial displacements on the superior endplate and flexion angles about a transverse axis located at the most posterior voxel of the superior endplate. A combined proportional loading mode was then applied using the axial displacement and flexion angle obtained at the yield point of the individual loading modes.

Beyond the independent axial and flexion stiffnesses, the full stiffness matrix of the sagittal motion was computed. Ultimate load and moment were calculated as the maximum force and torque resisted by each vertebrae.

As a first result, the axial and flexion stiffnesses as well as their respective ultimate properties were linearly related ($r^2=0.87$, $r^2=0.74$). In all loading modes, the level of damage was substantially lower in the cortical than in the trabecular compartment where damage localization occurred preferentially (Fig. 1). As expected, the amount of damage was increased for the combined loading mode and was higher than the sum of the damage produced by the individual compression and flexion modes. In conclusion, the combined loading mode applied in voxel-based finite element analyses provides a refined insight into the damage mechanisms leading to failure of vertebral bodies.

Effects of Strontium Ranelate Therapy after Long Term Bisphosphonate Treatment. Histomorphometric and μ XRF/EDX Analysis of Paired Iliac Crest Bone Biopsies in 15 Patients. B. Busse*, M. Priemel¹, B. Jobke², M. Hahn³, J. Zustin³, J. Semler⁴, M. Amling¹. ¹Center for Biomechanics & Trauma Surgery, Univ. Med. Center Hamburg, Hamburg, Germany, ²MQIR, Radiology, UCSF, San Francisco, CA, USA, ³Bone Pathology, Univ. Med. Center, Hamburg, Germany, ⁴Internal Medicine, Immanuel Hospital, Berlin, Germany.

Several medications have proved effective in reducing the fracture risk in patients with osteoporosis. However, the optimal duration of use of these medications and the effects of changes between treatment strategies remain to be established. The latter are of special clinical

interest in patients who have been on bisphosphonate (BP) therapy for years and present with persistent high fracture risk. To gain insights into the effects of strontium ranelate (SR) therapy after long term BP treatment we studied paired transiliac crest biopsies from 15 patients. All patients had previous BP therapy (Ø 32 months) and were subjected to bone biopsy at baseline. Patients were treated with 2g SR/d and subjected to a second biopsy after 6 months (group I, n=5) and 12 months (group II, n=10), respectively. Biopsies were undecalcified histologically processed. The bone mineral density distribution was evaluated by the gray level allocation (mean GL) of backscattered signal intensities. Energy dispersive x-ray analysis (EDX) combined with μ -x-ray fluorescence analysis (μ XRF) was used to monitor Sr concentration (Sr/(Sr+Ca), Wt%). Static analysis was performed using the Osteomeasure system according to ASBMR standard and included the quantification of bone volume (BV/TV, %), trabecular interconnection (TbPF, mm-1), trabecular thickness (Tb.Th, μ m), osteoid volume (OV/BV, %), osteoid surface (OS/BS, %), as well as osteoclast number (NOC/BPm, mm-1). In group I there was an increase in Sr content while all other indices did not show significant changes as compared to baseline. In sharp contrast in group II there was not only a further increase in Sr content of bone and mean GL but also a significant increase in BV/TV (11.12 ± 3.78 vs. 8.53 ± 2.14) with an improved TbPF (0.69 ± 0.52 vs. 1.35 ± 0.63) and increased Tb.Th (99.39 ± 9.89 vs. 89.99 ± 10.96). These structural changes were explained by activated bone formation indicated by increased OS/BS (12.04 ± 6.81 vs. 7.97 ± 5.6) and OV/BV in face of persistent suppression of bone resorption and unchanged low NOC/BPm (0.011 ± 0.016 vs. 0.035 ± 0.065). These data show that Sr is present in bone in patients that have been on BP treatment previously and that one year after SR therapy active bone formation sites are increased while osteoclasts are still repressed with beneficial effects on bone quality. Therefore SR might be considered as an alternative therapeutic option in patients that have been on long term BP treatment.

Bone Turnover and Quality: How Discrepancies in BMD Changes and Fracture Risk May Be Explained. M. A. Karsdal, I. Byrjalsen, D. Leeming, P. Qvist, C. Christiansen. Nordic Bioscience, Herlev, Denmark.

Introduction: Bone matrix quality may be important for anti-fracture efficacy as the reduction in risk is only partly explained by a concomitant increase in BMD during anti-resorptive therapy. Some of these discrepancies may in part be explained by careful investigation of novel bone turnover markers.

The main protein component of the extracellular bone matrix is collagen type I of which the C-telopeptide motif is released during osteoclastic bone resorption (CTX). Newly synthesized bone matrix contains the α -form of CTX, but with aging the motif spontaneously isomerizes to the β -form. Thereby index of alpha/ beta fragments released during osteoclastic of bone resorption may be a representative for endogenous bone age, which may be related to bone quality and affected differently by different treatments regimes.

The aim of the present study was to evaluate the effect of different anti-resorptive treatments (bisphosphonates, HRT, SERMs and calcitonin) on the age profile of bone collagen degradation measured as the ratio between the degradation products of newly synthesized and mature isomerized C-telopeptides of type I collagen.

Methods: Participants were from cohorts of healthy postmenopausal women participating in double blind, placebo-controlled 2-year studies of alendronate, ibandronate, intranasal hormone replacement therapy (HRT), oral HRT, transdermal HRT, oral calcitonin or raloxifene (n = 487). The non-isomerized $\alpha\alpha$ CTX and isomerized $\beta\beta$ CTX were assessed by ALPHA CrossLaps and BETA CrossLaps ELISAs, respectively, in urine samples obtained at baseline, and after 6, 12, and 24 months of therapy. Presently only 3 months data are available for calcitonin.

Results: Bone collagen age measured as the ratio between $\alpha\alpha$ CTX and $\beta\beta$ CTX showed that bisphosphonate treatment induced a pronouncedly older age profile with a 52% (alendronate) and 38% (ibandronate) reduction in the ratio between the two CTX isoforms in face of 3% and 15% with HRT or raloxifene. Calcitonin treatment resulted in an increase of 10%, rather than a decrease.

Conclusions: The different responses of $\alpha\alpha$ CTX to $\beta\beta$ CTX ratio by the various anti-resorptive therapies reflect a treatment-dependent effect on the endogenous age profile of bone collagen. These data highlight that even though the treatments have comparable effects on BMD, the endogenous bone composition, which may be associated to bone quality, is strongly affected by the type of intervention.

Quality and Strength of Cortical Bone in Both Ovariectomized and Sham-operated Rats Are Lowered by Limiting Physical Activity. Y. Mikuni-Takagaki¹, K. Miyagawa^{*1}, Y. Kozai^{*2}, Y. Ito^{*3}, K. Naruse^{*4}, Y. Nagai^{*5}, H. Yamato⁵, I. Kashima^{*2}, K. Ohya⁶, K. Aoki⁷. ¹Functional Biology, Kanagawa Dental College, Yokosuka, Japan, ²Maxillofacial Diagnostic Science, Kanagawa Dental College, Yokosuka, Japan, ³Yokohama Training Center, Kanagawa Dental College, Yokohama, Japan, ⁴Department of Orthopedic Surgery, Kitasato University School of Medicine, Sagami-hara, Japan, ⁵Kureha Special Laboratory Co., Ltd, Tokyo, Japan, ⁶Hard Tissue Engineering, Graduate School, Tokyo Medical and Dental University, Tokyo, Japan, ⁷Department of Hard Tissue Engineering, Department of Hard Tissue Engineering, Section of Pharmacology, Tokyo, Japan.

Lack of estrogen after menopause and reduced activity (hypokinesia) are both important factors in the pathogenesis of osteoporosis in the elderly women. To compare the contribution of these two factors independently, we developed an animal model comparing

ovariectomized (OVX) or sham-operated rats, which were housed in cages with limited space or in regular institutional cages. The experimental cages restricted standing and walking, while allowing other activities such as eating, drinking and changes in position. Thirty-two Wistar rats, 14 weeks of age, were assigned to four groups of OVX-Restricted, OVX-Walking, Sham-Walking and Sham-Restricted rats. Serum samples were collected during postoperative weeks 1, 4, 8 and 12 to study metabolic bone markers. After sacrificing rats at week 12, femora and tibia were examined with peripheral quantitative computed tomography (pQCT), laser Raman spectroscopy, three point bending, and histopathology. Although significantly elevated levels of metabolic markers, CTx, and osteocalcin were recorded in OVX groups compared to the Sham groups, results of bone strength as well as structural parameters revealed significant differences only between Sham and Restricted groups. In the Restricted rat tibial cortices, both the number of empty osteocytic lacunae and lacuno-canalicular sclerostin staining were significantly increased. Osteoclast activity was not necessarily associated with the osteoporotic pathology in restrained rat bones, suggesting a predominant role of osteocytic control of osteolysis in the bone loss of individuals with restricted activity.

Changes in Dental Enamel Crystals by Bleaching. M. Ogiwara, Y. Miake*, T. Yanagisawa*. Ultrastructural Science, Tokyo Dental College, Masago 1-2-2, Mihama-ku, Chiba -city, Japan.

Recently, the number of requests for dental bleaching has been rapidly increasing for aesthetic reasons. Clinically, dental bleaching is widely performed. Bleaching is considered to occur by the decomposition of organic substances, without affecting inorganic substances. However, there have been only a few number of basic morphological studies, and no study has been conducted on changes in the crystal structure examined by ultrahigh-resolution transmission electron microscopy. We considered that crystal-morphological evaluation of the effects of dental bleaching on enamel crystals was necessary.

We observed the structural changes in the superficial layer of extracted teeth that agreed with patient and approved ethics committee, after trimming and bleaching by scanning electron microscopy (SEM,3D-SEM), and examined the radiolucency by contact microradiography (CMR). Furthermore, trabecular and crystallographic changes in the enamel were analyzed by ultrahigh-resolution transmission electron microscopy (HR-TEM).

SEM and 3D-SEM revealed trabecular capsules, indicating a change caused by bleaching. Furthermore, HR-TEM demonstrated the decalcification of enamel crystals in some samples.

It has been considered that since bleaching occurs through the action of generated reactive oxygen species (ROS) on organic substances, it does not affect inorganic substances. However, the results of this study suggested that bleaching had considerable effects on inorganic substances. The pH is reduced by a bleaching agent, suggesting that the decalcification of enamel crystals caused by bleaching was related to the pH reduction.

Image Processing for Three Dimensional Dynamic Histomorphometry. C. R. Slyfield^{*1}, R. E. Tomlinson^{*2}, E. V. Tkachenko^{*1}, G. J. Steyer^{*2}, C. G. Patthanacharoenphon^{*1}, G. J. Kazakia^{*3}, D. L. Wilson^{*2}, C. J. Hernandez¹.

¹Mechanical and Aerospace Engineering, Case Western Reserve University, Cleveland, OH, USA, ²Biomedical Engineering, Case Western Reserve University, Cleveland, OH, USA, ³Radiology, University of California, San Francisco, San Francisco, CA, USA.

Bone remodeling has been implicated as an indicator of bone quality. The manner in which bone remodeling influences bone strength independent of bone mass is not yet well understood but is believed to be influenced by cavities formed during remodeling. Cavity number and size may therefore influence bone quality and strength. Two dimensional (2D) histomorphometry is currently the only way to examine local bone remodeling. Unfortunately, 2D histomorphometry cannot quantify the number and size of remodeling events. In addition, 2D histomorphometry is very labor intensive and requires special training. Here we present methods for performing automated three dimensional dynamic histomorphometry which enable the measurement of remodeling cavity number and size. 3D images of bone and two different fluorescent formation markers are obtained using a automated serial milling technique at a resolution of five microns (Kazakia et al., 2007). A 3D model is created using an automated image pre-processing technique. Subsurface fluorescence is removed and an adaptive threshold automatically labels mineralizing bone. While 2D histomorphometry requires manual labeling of five or more bone surface traits (labeled surface, bone surface, osteoid surface, etc.), the 3D histomorphometry technique only requires eroded surfaces to be traced manually. Just as micro computed tomography led to improved precision and accuracy in trabecular microarchitecture measures, 3D dynamic histomorphometry is expected to be more precise and accurate than 2D methods. This is the first image processing technique to allow precise 3D measures of bone and fluorescent markers in cancellous bone. This technique will enable investigations of the effect of remodeling size and number on bone biomechanics and help to identify differences among osteoporosis therapies.

The Role of Dynamic Muscle Contractions on Inhibition of Bone loss and Muscle Atrophy in a Functional Disuse Mouse Model. A. M. Ali*, Y. Qin. Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA.

It is proposed that musculoskeletal disorder may be counterbalanced by understanding the relationship between muscle function and bone adaptation. Skeletal muscle dynamics and its related mechanotransduction function have been suggested as a modulator of intramedullary pressure, and may play a role in bone adaptation. The objective of this study was to evaluate optimized dynamic muscle stimulation in the therapeutic potentials in prevention of bone loss and muscle atrophy. The aims of this study were to test the role of varying the frequency and duration of repetitive muscle contractions at 1 Hz, 20 Hz, and 50 Hz on muscle mass and bone morphology in a functional hind limb disuse mouse model. Forty-four adult female BALB/c mice were randomized into 6 groups: baseline control (n=6), age-matched control (n=6), hind limb suspension non-stimulated (HLS-NS) (n=8), HLS with electrically stimulated muscle contractions at 1 Hz (n=8), 20 Hz (n=8), and 50 Hz (n=8). Pulsatile signal was delivered to the quadriceps muscle with stainless steel needle electrodes for 2 seconds, followed by a 3 second rest period, for total of 10 minutes per day, for 3 weeks. Upon sacrifice, soleus, gastrocnemius, quadriceps, and whole hind limb weights were recorded. Femoral trabecular bone was quantified using micro-CT (SCANCO) at 8 micron resolution for a 1-mm region of interest at the distal metaphysis. HLS-NS showed a decrease in the weight of soleus (-21%), gastrocnemius (-26%, p<0.01), quadriceps (-20%, p<0.01), and the whole hind limb (-15%, p<0.05). Electrically stimulated muscle contractions at all frequencies showed increasing trends in soleus (+6% to +21%), gastrocnemius (+7% to +18%), quadriceps (+3% to +12%), and the whole hind limb (+7 to +13%, p<0.05). Micro-CT revealed that HLS-NS reduced bone volume fraction (-62%, p<0.01), connectivity density (-40%, p<0.01), trabecular number (-19%, p<0.01), and increased trabecular separation (+22%, p<0.01). Muscle contractions at 1 Hz, 20 Hz, and 50 Hz significantly recovered bone volume fraction (+34% p<0.05; +47% p<0.01; +48% p<0.01), connectivity density (+50% p<0.01; +59% p<0.001; +65% p<0.001), trabecular number (+10% p<0.05; 15% p<0.001; 15% p<0.001), and decreased trabecular separation (-10% p<0.01; -14% p<0.001; -14% p<0.001), respectively. The significant recovery of muscle mass and bone structural parameters in the treatment animals suggests that the dynamic muscle contraction is a valid potential therapeutic signal for musculoskeletal disuse. Among all the applied signals, 50 Hz contraction generated the greatest response in bone morphology. These data suggest that an optimized range of physiologic signals can be responsible for prevention of bone loss and muscle atrophy noninvasively and at low magnitude.

The Long Term Macro-architectural Benefits of High Impact Exercise During Growth: A Study of Retired Gymnasts. P. Eser*, B. Hill*, S. Bass. Centre for Physical Activity and Nutrition Research, Deakin University, Burwood, Australia.

The greatest skeletal benefits from exercise occur during growth; for these benefits to be important in the primary prevention of osteoporosis they must be maintained into adulthood. Little is known however about the macro-architectural structure of bone changes in response to exercise during growth and how these changes may be maintained when exercise is ceased.

The objective of this study was to determine if retired gymnasts have greater bone strength (i.e. bigger bone size, mass and density) at both cortical and trabecular sites compared to age-matched controls. In this study we compared 30 female gymnasts (age: 23.0 ± 4.4 years, training duration: 10.5 years) who had been retired for 6.1 years, with 20 age, height and weight-matched controls (less than 2 hours of exercise per week). Volumetric BMD and bone cross-sectional area (CSA) were assessed by peripheral quantitative computed tomography (pQCT) at the epiphyses and diaphyses of the radius, humerus, tibia and femur. Polar bone strength strain index (SSIpol) and muscle CSA were assessed at the mid-shaft of each limb.

Upper Limb: At the radial and humeral shafts, cortical CSA, total CSA, BMC and SSIpol were significantly greater (15%-40%) in the retired gymnasts (p<0.01). Muscle CSA at the arm and forearm was also increased by 14% and 16%, respectively (p<0.05). At the distal radius, cortical CSA, BMC and trabecular vBMD was 19%-23% greater in the retired gymnasts (p<0.001). Lower Limb: At the tibial shaft, cortical CSA and BMC was 10% greater (p<0.05). At the femoral shaft BMC was 10% greater (p<0.08). At the distal tibia and femur, trabecular vBMD was greater by 8% and 7%, respectively (p<0.05). Muscle CSA at the upper and lower leg was not different between groups. At the lower extremity, the magnitude of the differences were approximately half that observed in the upper extremity. Between-group differences in bone geometry and vBMD paralleled the differences in muscle CSA. No significant linear relationship was found between years of retirement and any of the bone or muscle parameters.

Despite a greatly reduced level of physical activity (less than 2 hrs/week) and at least 6 years of retirement gymnasts maintained benefits that were site and region specific; at the diaphysis the macro-architectural changes were due to greater bone size and cortical CSA at the upper limb but only a greater cortical CSA at the lower limb. At the epiphysis the benefit was predominantly due to a greater trabecular vBMD at both upper and lower limbs. In conclusion, greater bone strength is maintained in gymnasts retired for up to 6 years. The macro-architectural basis of these benefits varies depending on the skeletal site and region.

The Effect of Vibration Resistance Exercise During 56 Days of Bed Rest on Different Muscle Properties. B. Buehring*, U. Gast*, I. Michaelis*, D. Belavy*, D. Felsenberg*, J. Rittweger*. ¹Internal Medicine, University of Wisconsin Hospital and Clinics, Madison, WI, USA, ²Center for Muscle and Bone Research - Charite Berlin, Berlin, Germany, ³Institute for Biophysical and Clinical Research into Human Movement, Manchester Metropolitan University, Alsager, United Kingdom.

Multiple studies have examined the effect of microgravity on muscle function. There is ongoing debate whether the observed loss of muscle function is solely correlated to loss of muscle mass. Finding the causes of muscular function loss in microgravity is important not only for future space flight missions but also for immobilized patients on earth.

Maximal voluntary contraction force (MVC) and dynamic muscle power during counter-movement jumps were examined in a 56 day bed rest setting. The effect of vibration resistance exercise (VRE) on the two tasks was also assessed. VRE, consists of a combination low frequency vibration applied to the feet and resistance training. 20 healthy male subjects participated and were divided into an exercise and a control group (CTRL). Mean MVC and surface electromyography (EMG) was measured in the plantarflexors with a dynamometer. Muscle power and jump height were used to evaluate counter-movement jumps.

After bed rest, MVC in CTRL was decreased by 17% (p<0.01), but remained unchanged in the VRE group. Maximal EMG amplitude was unaffected in both groups. Neuromuscular drive (ND) did not change in the VRE group but a trend in the decline of ND was found (p=0.052) in CTRL. Counter-movement jumps revealed a loss in peak power in both groups. Jumping ability decreased by 13% (p<0.001) in the VRE group whereas the CTRL lost 26% (p<0.001).

This study showed that bed rest without any countermeasures lead to a significant loss of MVC and a decrease in neuromuscular drive of 21% which was on the border of statistical significance. It proved that VRE was able to preserve MVC in the plantarflexors, maintain neuromuscular properties but could not prevent a decrease in the ability to perform counter-movement jumps. Mulder et al report a 14.1% loss of total quadriceps cross sectional area (CSA) in the same control group. The VRE group had a significantly smaller loss of 3.5%. We conclude that besides muscle atrophy, other factors like coordination, neuromuscular drive and changes in muscle cell function contribute to loss of certain muscle functions. VRE can preserve MVC, however it can only alleviate the loss of function in more complex tasks. Therefore it is important to add training methods like VRE to astronauts in space or immobilized patients on earth. However more research is needed to examine the effects of microgravity and immobilization on muscular functions besides maximal force.

Exercise Induced Changes in the Macro-Architectural Parameters of Cortical Bone as Boys Progress Through Puberty: A Large Window of Opportunity? G. Ducher*, J. Black*, L. Saxon*, R. Daly*, C. Turner*, S. Bass*. ¹Centre for Physical Activity and Nutrition Research, Deakin University, Burwood, Australia, ²Musculoskeletal Research Centre, La Trobe University, Heidelberg, Australia, ³Basic Sciences, The Royal Veterinary College, London, United Kingdom, ⁴Department of Orthopaedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA.

Very little is known about the macro-architectural changes in cortical bone in response to exercise during different stages of growth. In this study we compared the side-to-side differences in cortical bone parameters in pre- (n=6), peri- (n=16) and post- (n=16) pubertal boys who played tennis to determine the site- and maturation-specific changes in cortical bone parameters in response to loading. Humeral BMC was assessed by DXA and bone geometry of the mid (40-50%) and distal (60-70%) humeral diaphyses was assessed by magnetic resonance imaging. The pre-, peri, and late or post-pubertal players were aged 11.2±0.5, 12.9±0.3, and 15.3±0.3 yrs and were currently training for 9.1±1.8, 15.4±1.7, 13.0±1.7 hr/wk respectively. Relative side-to-side differences in total and cortical areas ranged from 6.9% to 33.6% at both sites for all pubertal groups (p ranging <0.09 to 0.001). The absolute side-to-side difference in cortical CSA was greater in the peri- and post pubertal boys compared with the pre-pubertal boys (p<0.05). Medullary contraction was detected at the distal site (ranging from 7.9 to 14%) in all pubertal groups. In contrast, expansion in the medullary cavity was observed at the mid site (~5%) in pre- and peripubertal boys.

Table 1. Absolute side-to-side differences in humeral bone parameters in the young male tennis players according to their pubertal status (mean ± SE).

Pubertal status	Pre-	Peri-	Post-
Humeral BMC (g)	5.1 ± 1.2*	10.9 ± 1.0*	15.3 ± 1.7*†
Mid periosteal area (mm ²)	15.6 ± 7.4*	33.4 ± 4.5*	41.9 ± 5.3*†
Mid medullary area (mm ²)	5.5 ± 2.5*	3.7 ± 1.9*	3.1 ± 2.9
Mid cortical area (mm ²)	10.2 ± 5.0*	29.8 ± 4.0*‡	38.8 ± 4.3*†
Distal periosteal area (mm ²)	12.8 ± 4.4*	30.1 ± 3.7*	41.6 ± 5.0*†
Distal medullary area (mm ²)	-7.8 ± 2.2*	-10.6 ± 1.2*	-7.4 ± 3.0*
Distal cortical area (mm ²)	20.6 ± 5.4*	40.2 ± 3.5*‡	49.0 ± 4.6*†

* Playing vs non-playing significant at p<0.09-0.001

Between groups comparison: ‡ Pre < Peri at p<0.05; † Pre < Post at p<0.01

Large absolute and relative side-to-side differences in total and cortical cross-sectional areas were detected in prepubertal boys; these differences were greater in the peri and postpubertal boys. These findings are in contrast to our previous work in girls where we report an initial response in the prepubertal players but no further increase in peri and postpubertal girls despite a longer duration of loading. These findings together suggest that males may have a larger

window of opportunity to optimize the osteogenic response to loading.

Optimising Bone Health in Pre-Pubertal Children: The Importance of Muscle Strength. R. English^{*1}, P. Eser^{*1}, A. Patchett^{*1}, R. Daly¹, G. Naughton², M. Seibel³, R. Telford^{*4}, S. Bass¹. ¹Centre for Physical Activity and Nutrition Research, Deakin University, Burwood, Australia, ²Centre of Physical Activity Across the Lifespan, Australian Catholic University, Sydney, Australia, ³ANZAC Research Institute, University of Sydney, Sydney, Australia, ⁴Australian Institute of Sport, Australian National University, Belconnen, Australia.

Peak muscle force is a determinant of bone strength; however its contribution to sex-specific differences in skeletal development remains uncertain. We investigated the role of muscle cross-sectional area (MCSA); a surrogate measure of peak muscle force on bone mineral content (BMC), geometry and strength at different skeletal sites (weight bearing and non-weight bearing) and bone compartments (trabecular versus cortical). Peripheral QCT was used to assess non-dominant tibia and radius (distal 4% and mid-shaft 66%) BMC, total and cortical CSA and MCSA in 598 pre-pubertal boys (n=302) and girls (n=296) aged 8-9 years.

No sex differences were detected in age, weight or tibial length. Compared to girls, boys were taller (1.4 cm), had greater radial length (0.4 cm) (p<0.001) and greater MCSA at the lower leg (3.5%) and arm (7.9%) (p<0.001). At the tibia and radius metaphyses boys had greater BMC (~10%) and total CSA (7%) (p<0.0001). These differences remained after adjusting for MCSA. At the diaphysis total and cortical CSA, and polar strength strain indices were 2-10% greater in boys (p<0.05). These differences were not maintained after adjusting for MCSA, which accounted for 10 to 40% of the variance in bone parameters. All results were maintained after adjusting for bone length. In conclusion, MCSA accounted for the greater bone strength at the diaphyses in boys compared to girls. Factors other than MCSA contributed to the sex-specific differences in skeletal parameters at the metaphyses. These findings highlight the importance of developing MCSA for improved bone health at the diaphysis in children.

Bone Turnover Response of Men and Women to a Strenuous Gender-Integrated Recruit Training Regimen. R. K. Evans¹, A. J. Antczak^{*1}, M. E. Lester^{*1}, R. Yanovich^{*2}, E. Israeli^{*2}, D. S. Moran^{*2}. ¹Military Performance Division, US Army Research Institute of Environmental Medicine, Natick, MA, USA, ²Sheba Medical Center, Heller Institute of Medical Research, Tel Hashomer, Israel.

Rapid onset of strenuous exercise training can lead to stress fracture, a bone overuse injury. Stress fracture susceptibility is hypothesized to result from accelerated bone remodeling and changes in bone turnover that favor resorption. Whether the bone metabolism response is different in women, who present with a five-fold greater risk for stress fracture than men, has not been studied. The purpose of this study was to assess gender disparity and changes in biomarkers of bone metabolism during a four-month recruit training program. Healthy age-matched men (n=58) and women (n=199) (19.0 ± 1.0 yr) entering a four-month gender integrated basic combat training program in the Israeli Defense Forces volunteered for this study. Blood was collected at baseline and at 2 and 4 months. Serum was analyzed for biomarkers reflecting bone formation (BAP and PINP), bone resorption (CTX and TRAP5b), nutrition (PTH, calcium, and 25-OH-D), and the cytokine response (IL-1, IL-6 and TNFalpha). A repeated measures ANOVA was used to analyze changes over time and between genders for each variable. Bone formation and resorption markers were higher in men than women (p<0.001) over the training period, though there were no gender differences in the response to training. For men and women combined, an increase in bone turnover was evident from 0 to 2 months as reflected by significant increases in BAP, PINP, CTX, and TRAP5b (see table), which decreased or stabilized from 2 to 4 months.

	Baseline		2 mos		4 mos	
	Men	Women	Men	Women	Men	Women
BAPhos (ug/L)	32.0±13.3	17.8±6.9	35.3±15.7*	21.7±8.2*	36.0±17.2	20.8±7.8
PINP (ug/L)	120.6±59.0	65.4±22.5	126.8±58.6*	78.8±32.6*	124.0±58.5*	73.6±31.5*
CTX (ng/mL)	1.3±0.5	0.9±0.4	1.4±0.6*	1.0±0.4*	1.3±0.6**	0.9±0.4**
TRAP (U/L)	4.1±1.6	3.0±0.6	4.1±1.6*	3.2±0.7*	4.2±1.7	3.1±0.8

*denotes increase for both genders 0-2 mos (p<0.001); **denotes decrease for both genders 2-4 mos (p<0.01)

Serum calcium and PTH decreased similarly in both genders from 0-2 months, returning to baseline by 4 months. 25(OH)D decreased over the study period in men, but not women. IL-1B, IL-6, and TNFalpha values did not differ between genders, and did not change over the training period. Our results show that a four-month strenuous recruit training regimen increased markers of bone formation and resorption in both men and women during the first two months of training. These data suggest that rapid onset of strenuous training initially results in acceleration of bone turnover. Whether this is related to changes in bone that predispose women to stress fracture warrants further examination.

The Functional Muscle-Bone Unit in Young Active Women. P. C. Fehling, L. Ishkanian*, K. Hawkins*, A. Lange*. Exercise Science, Skidmore College, Saratoga Springs, NY, USA.

Several authors have proposed a functional bone to muscle unit (FBMU) defined as the ratio of bone mineral content (BMC) to muscle (BMC/muscle)^{1,2,3} to characterize the relationship between bone and muscle. However, which measure of bone and muscle to use in calculating FBMU remains unclear. Therefore, this study investigated FBMU in young, healthy women, using various measures of bone and muscle to calculate FBMU.

Participants in the study were 39 women (20.1 yr ± 1.1); categorized as advanced dancers (DN; n=15), Division III volleyball players (VB; n=9) or non-athletic controls (CN; n=15). A total body (TB) DXA scan was acquired to assess total BMC and leg BMC (Lunar DPX-IQ, V4.5). A 1 RM leg press (LP; kg) and squat (kg) were used to assess leg strength. The muscle portion of FBMU (denominator) was calculated using TB fat free mass (FFM; kg), TB weight (TBW; kg), leg FFM (kg), leg mass (kg) or strength (leg press & squat; kg). Differences among groups were assessed with a 1-way ANOVA with a Tukey Post Hoc analysis. An ANCOVA was used to adjust for height and weight group differences. Significance level was set at p < .05.

The VB were significantly taller (172.2 vs. 163.3 and 163.1 cm) and heavier (65.8 vs. 59.5 and 59.0 kg) than the DN and CN groups, respectively. After adjusting for height and weight the DN and VB had significantly greater BMC than the CN in the legs; had greater TB and leg FFM; and were stronger (all measures). However, when FBMU was calculated using various measures of bone and muscle (mass or strength), no consistent FBMU pattern emerged (Table 1). For example, when FBMU was expressed as TB BMC/squat, CN had significantly greater FBMU than DN & VB. However, when FBMU was expressed as leg BMC/squat CN were significantly lower than VB. It appears that depicting the physiological relationship between bone tissue and muscle tissue using FBMU is problematic due to functional, theoretical and practical measurement issues. Several questions about FBMU remain unanswered, including, what does this variable tell us and how should it be calculated?

Characterization of Muscle Disuse Atrophy and Recovery in Mice Using an In Vivo Casting Model. L. V. Hale*, B. C. Yaden*, J. L. Andrews*, L. M. Helvering*, S. T. Estrem*, F. Lawrence*, S. Li*, S. McAhren*, G. Field*, H. A. Bullock*, V. Krishnan. Musculoskeletal, Lilly Research Laboratories, Indianapolis, IN, USA.

Atrophy of skeletal muscle is characteristic of sarcopenia, cancer cachexia, and disuse in both humans and rodents. Treatment of muscle atrophy is an unmet therapeutic need in these conditions and several preclinical models have been previously described. We have developed and characterized an in vivo model of disuse muscle atrophy in mice by immobilizing one hindlimb in the plantar flexion position by means of a cast. This model is very well-tolerated by the animals and results in no body weight changes with casting. Muscle loss is observed as a decrease in wet weight in both the gastrocnemius and soleus within one day of immobilization with an increasing gradual loss (15-20%) over a 7 day period. This loss is largely reversed after 3 weeks following removal of the cast and reloading of the hindlimb by the animal. Upon reloading, there is edema and some additional loss in gastrocnemius wet weight before noticeable improvement in muscle mass is observed. Atrophied and control gastrocnemius muscles were also subjected to microarray analysis and compared histologically. The beta-adrenergic agonist, Clenbuterol (2mg/kg/day), is able to diminish the extent to which the gastrocnemius atrophies during casting. IGF-1 mRNA is elevated in both the Clenbuterol casted and contralateral legs. We conclude that this in vivo model allows for consistent and characteristic muscle wasting and is useful for the evaluation of pharmacological agents which may prevent atrophy and/or enhance the recovery of muscles which are atrophied from disuse.

Electrically Stimulated Eccentric Muscle Contraction Benefits Bone in the Tibia of Hindlimb Unloaded Rats at Both the Mid-Diaphysis and Proximal Metaphysis. L. R. Sumner*, M. L. Nilsson*, J. M. Swift*, J. M. Jeffery*, C. J. Walthall*, J. L. Stallone*, S. A. Bloomfield*, H. A. Hogan*. ¹Mechanical Engineering, Texas A&M University, College Station, TX, USA, ²Health and Kinesiology, Texas A&M University, College Station, TX, USA.

The objective of this study was to investigate controlled electrical muscle stimulation as a countermeasure for bone degradation due to hindlimb unloading in adult male rats. The stimulation protocol uses fine wire electrodes to stimulate the sciatic nerve and induce contractions of the muscles of the lower left hindlimb. The ankle is dorsiflexed during stimulation to create eccentric contractions of the posterior muscles below the knee. In the current study, each session of this simulated resistance training (SRT) consisted of 4 sets of 5 contractions (1000ms) with ankle torques equal to 100% of peak isometric torque. Six-month old male Sprague Dawley rats were divided into 3 groups of 12 each: CC (cage control) animals were allowed normal ambulation; HU animals were hindlimb unloaded using standard protocols for 28 days; HU+RT animals were hindlimb unloaded for 28 days with SRT (every other day). The mid-diaphysis and proximal metaphysis of the tibia were assessed by peripheral computed tomography (pQCT). In addition, reduced platen compression (RPC) testing was used to evaluate the mechanical properties of the cancellous bone of the proximal metaphysis. On a separate group of animals, strain gauges were applied to the anteromedial surface of the tibial metaphysis. Values ranged from 800 to 1200 microstrain, which are levels generally expected to be osteogenic. The SRT protocol was highly effective as a countermeasure at both sites in the tibia. At mid-

diaphysis, total BMD was significantly higher for HU+RT than both CC (7.2%) and HU (7.0%). Total BMC was similarly higher in HU+RT (7.8% vs. CC; 14.2% vs. HU). Mid-diaphysis cross-sectional area was also higher in HU+RT (6.6% vs. CC; 13.2% vs. HU). Beneficial effects of SRT were even more dramatic at the proximal metaphysis. Total BMD was higher in HU+RT (13.4% vs. CC; 16.8% vs. HU), as was total BMC (2.4% vs. CC; 21.9% vs. HU). Ultimate stress of the cancellous bone of the metaphysis was 175% higher for HU+RT compared to CC and 268% higher compared to HU. To our knowledge, these data (along with those first presented by our laboratory last year; JBMR 2006 21(S1): S171) are the first to demonstrate not only effective mitigation of bone loss but absolute gains in bone mass during a simulated microgravity exposure with a physiological exercise intervention. In the earlier study, each exercise session consisted of 4 sets of 10 contractions (500ms) with ankle torques of 120% of peak isometric torque.

The Effects of Endurance Running Training on Bone Quality in Growing Rats. T. Huang¹, R. Yang², F. Chang³, S. Lin⁴, S. Liu⁴, S. S. Hsieh⁵.

¹Institute of Physical Education, Health and Leisure Studies, National Cheng-kung University, Tainan, Taiwan, ²Department of Orthopaedics, National Taiwan University, Taipei, Taiwan, ³Department of Physical Education, National Taiwan Normal University, Taipei, Taiwan, ⁴Institute of Toxicology, National Taiwan University, Taipei, Taiwan, ⁵Institute of Sports Science, National Taiwan Normal University, Taipei, Taiwan.

To investigate the effects of two different endurance-running modes on bone quality in the growing rats. Thirty-one male Wistar rats were randomly assigned into three groups: the END group (n=10), undergoing continuous endurance treadmill running; the INT group (n=11), undergoing intermittent endurance treadmill running; the CON group, served as sedentary control group (n=10). For equalizing the training volume, the daily training distance was set equal for both exercise groups through out the eight-week training period. Intensity and distance of the two training programs were progressively increased. Both exercise groups showed decreased body weight gain after 8 weeks of running training. Regarding the effects of training on aerobic capacity, both exercise groups showed significantly higher levels in citrate synthase of soleus and heart muscle ($p < .05$) after eight-week training. Densitometric analysis of femur showed a significantly lower areal bone mineral density (aBMD) in both exercise groups as compared with CON group ($p < .05$). A three-point bending test was used to measure the biomaterial properties of bone. In extrinsic biomechanical analysis, both the END and INT groups showed significantly higher energy to maximal load and fracture load ($p < .05$), whereas significantly lower in bending stiffness as compared to the CON group. In intrinsic biomechanical analysis, both exercise groups showed a significantly higher bending stress, bending toughness and Young's modulus ($p < .05$). Additionally, the INT group was even better than the END group in some of the intrinsic biomechanical parameters. In conclusion, either continuous or intermittent endurance training did benefit the biomaterial bone properties but seemed not to be necessarily associated with aBMD. In addition to conventional geometric and densitometric measurements, further study would be important to investigate the contribution of exercise-enhanced micro-architecture on bone quality.

Hypergravity Prevents Bone Loss in Rats Following Ovariectomy. A.

Kawaguchi*, T. Ninomiya*, Y. Nakamichi*, M. Nakamura*, N. Udagawa*, N. Takahashi*, H. Kato*, K. Takaoka*, S. Wakitani*. ¹Department of Orthopedic Surgery, Shinsyu University of Medicine, Matsumoto, Japan, ²Division of Hard Tissue Research, Institute for Oral Science, Matsumoto Dental University, Shiojiri, Japan, ³Department of Biochemistry, Matsumoto Dental University, Shiojiri, Japan, ⁴Department of Orthopedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan.

There are a lot of reports that characterize the negative effects of microgravity environment on the bone. However, little is known about the effects of hypergravity on bone loss, such as after ovariectomy in rats. Therefore, the purposes of this study were to examine whether hypergravity prevents bone loss after ovariectomy, and to elucidate the mechanisms of hypergravity effects on bone formation and bone resorption. Adult sixteen female Sprague-Dawley rats were randomized to four groups of four rats (sham or ovariectomized, and control or hypergravity exposed). Rats were performed ovariectomy or sham operation at 20 weeks of age, and the gravity treatment was started at the next day of operation. Hypergravity group were subjected to about 3G by centrifugation in accelerated gravity loading machine. The control group at 1G in an identical compartment on the floor of the centrifuge room experienced the same noise, temperature, and light environment as the hypergravity groups. The centrifuge was run continuously for 28 days, except for one hour stops each day for rat care. All animals were triple labeled with tetracycline hydrochloride and calcein injection. After 28 day of centrifugation, femur bones were excised and used for structural analysis by micro computed tomography, measurement of bone mineral density (BMD) by pQCT, and histomorphometric analysis. Micro computed tomography images showed that cancellous bone was greatly decreased in OVX control group, but the bone loss was prevented in OVX with hypergravity group. As a result of pQCT analysis, sham and OVX treated with hypergravity had significantly higher BMD of trabecular bone in distal femur metaphysis compared to control.

groups. In histomorphometric analysis, OVX decreased BV/TV as a result of increased bone turnover, but OVX with hypergravity group had significantly higher BV/TV, and significantly lower Ob.S/BS, BFR/BS, MAR, N.Oc/BS, OcS/BS. Sham groups had same tendency as OVX groups. These results demonstrate for the first time that hypergravity can suppress high bone turnover following Ovariectomy, and resulting in prevention of bone loss in aged OVX rats.

Association of Body Weight and Daily Walking Steps with QUS Parameters and Urinary DPD in Elderly Japanese Women. J. Kitagawa¹, Y. Nakahara². ¹Human System Science, Tokyo Institute of Technology, Tokyo, Japan, ²Health and Nutrition, Wayo Women's University, Chiba, Japan.

High levels of physical activity (PA) have positive effects on quantitative ultrasound (QUS) parameters of the calcaneus and bone resorption markers. However, it remains unclear whether the effects of PA are similar between elderly women with a high body weight and a low body weight. The aim of this study was to investigate the association of body weight and daily walking steps, as an outcome measure of PA, with QUS parameters and urinary DPD in elderly Japanese women.

The subjects were 114 elderly women aged 60 to 85 years (71.4±4.8 years). They were members of a senior citizen's club. Subjects with a history of disease known to affect bone metabolism were excluded. QUS parameters (SOS, BUA and Stiffness) in the right calcaneus were measured with an A-1000 (Lunar, USA). A pedometer (HJ-005, Omron, Japan) was given to each subject. The subjects were instructed to wear the pedometer during waking hours for 7 consecutive days.

There were significant decreases in body weight and daily walking steps with age in the simple regression analysis. Then, the subjects plotted on the upper part and lower part of the regression line were defined as a high body weight group (BW⁺) and a low body weight group (BW⁻) respectively. Similarly, the subjects were divided into a high walking steps group (WS⁺) and a low walking steps group (WS⁻) according to the regression line for daily walking steps plotted against age. Finally, the subjects were assigned to one of four groups (BW⁺WS⁺; n=17, BW⁺WS⁻; n=35, BW⁻WS⁺; n=33, BW⁻WS⁻; n=29). The associations of body weight and walking steps with QUS parameters and DPD were analyzed by two-way ANOVA in which body weight and walking steps were used as factor variables. There were no significant differences in age among the groups.

The main effects of body weight and walking steps on Stiffness were significant (p<0.001, p<0.05, respectively). Although there was no significant body weight x walking steps interaction for Stiffness (p=0.16), BW⁺WS⁺ had a significantly (p<0.05) greater Stiffness compared with BW⁺WS⁻, whereas there was no significant difference in Stiffness between BW⁻WS⁺ and BW⁻WS⁻. The main effect of walking steps on DPD was significant (p<0.05), whereas that of body weight was not significant. The body weight x walking steps interaction for DPD was not significant. BW⁺WS⁺ showed significantly (p<0.05) lower DPD compared with BW⁺WS⁻. BW⁺WS⁺ showed non-significant 16% lower DPD compared with BW⁻WS⁻. These results indicate that there may be additive effects of walking steps on QUS parameters for elderly women with a high body weight. On the other hand, higher levels of walking steps may be effective in reducing DPD irrespective of the body weight levels.

Role of the L-Type Voltage-gated Calcium Channel Cav1.3 in Bone Mechanotransduction. J. Li¹, C. H. Turner². ¹Department of Biology, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA, ²Department of Orthopedic Surgery, Indiana University School of Medicine, Indianapolis, IN, USA.

Osteoblasts respond to mechanical stimulation with a rapid increase in intracellular calcium ion that is dependent on both extracellular calcium entry and release of calcium ion from intracellular stores. Previous studies have demonstrated that extracellular calcium entry via L-type voltage sensitive calcium channels (L-VSCC) is important in osteoblast proliferation. An alpha 1 subunit forms the pore of the channel and contains the sequences for the dihydropyridine receptor and the voltage sensor. Cav1.3 (alpha 1D) is one of the four different genes that code for the L-VSCC alpha 1 subunit and has been found in osteoblastic cells. We hypothesized that Cav1.3 plays a role in bone growth and mediates mechanically induced bone formation. In order to test this hypothesis, we measured the bone length and bone mineral content in Cav1.3 knockout (KO) mice (obtained from D James Surmeier, Northwestern University, Chicago, USA). We also investigated the skeletal response to loading in Cav1.3 KO mice. The body weight of male KO mice was significant lower than the wildtype male mice (p < 0.05). There was no difference in femur length and bone mineral content of femur and tibia between KO and WT control mice. Axial loading of the ulna with a peak force of 2.5 N (2 Hz for 120 cycles) for 3 days induced new lamellar bone formation on the periosteal surface at midshaft in both KO and normal control mice. There was no difference in mechanically induced mineralizing surface and bone formation rate between KO and WT mice (p = 0.12 and p = 0.17). Others have shown that L-VSCCs are important for osteoblast signaling after mechanical loading. However, our data suggest that Cav1.3 is not necessary for bone growth and skeletal response to mechanical loading. We conclude that the Cav1.3 subtype of L-VSCC is not primarily responsible for the role of L-VSCC in bone development and mechanotransduction in osteoblasts.

Mechanical Enhancement of Bone Quality Is Paralleled by Suppression of Fat Production: Can Osteoporosis and Obesity be Countered Through the Same Mechanism? Y. K. Luu¹, E. Capilla², B. J. Lee¹, J. E. Pessin², S. Judex¹, C. T. Rubin¹. ¹Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA, ²Pharmacology, Stony Brook University, Stony Brook, NY, USA.

An inverse yet interdependent relationship between osteoblasts and adipocytes in the marrow cavity has been identified, emphasizing that both bone and fat stem from a common precursor - the mesenchymal stem cell. We posit that the introduction of a low magnitude mechanical signal that is anabolic to bone can in effect alter the balance of bone and fat development at the tissue level, and while improving bone quality could also serve as an effective preventative measure towards the onset of obesity. Twenty four C57/BL6 male mice, 7wks of age, were randomly split into two groups, VIB: 12 wks of whole body vibration (0.2g, 90Hz, 15min/d, 5d/wk), and PL: an equal number of placebo sham controls. To promote adiposity, all animals were fed a high fat diet (45 kcal % fat) through the study duration. Body mass gains and the average food intake/wk were similar for both vibrated and control groups. In vivo microCT scans at 12 wks were used to quantify bone and fat (subcutaneous and visceral) of the entire torso of each animal. Normalized to body mass, VIB showed a 6.6% increase (p = 0.015) in lean volume and 5.3% increase (p = 0.098) in bone volume over PL. Post-sacrifice, high resolution (12 µm) microCT scans of the left tibia of VIB indicated a 13.8% (p = 0.058) increase in trabecular bone volume over PL. Additionally, connectivity density (+27.1%, p = 0.058) and trabecular number (+12.1%, p = 0.060) in VIB were increased over PL, while trabecular spacing (-12.5%, p = 0.051) decreased.

In contrast to the increase in bone quantity and quality measured in VIB, these animals also had 28.5% less fat volume (p=0.030) as compared to PL. Weights of epididymal fat pads harvested at sacrifice correlated strongly with CT data (R² = 0.80), and also demonstrated a reduction in VIB animals. That the anabolic effect to bone is achieved at the "cost" of a significant reduction in adiposity, achieved without a metabolic challenge (i.e., the signal is low and the duration is short), suggests that these mechanical signals influence the skeletal and fat phenotype by preferentially driving the lineage commitment and subsequent differentiation of the mesenchymal stem cells towards bone.

Using pQCT to Assess Regional Bone Changes Resulting from Short-Term Exercise Interventions. C. H. Negus¹, R. K. Evans², W. Shen¹, H. M. Isome², M. L. Lester², D. E. Catrambone², B. A. Spiering³, D. L. Hatfield³, W. J. Kraemer³, B. C. Nindl². ¹L-3 Jaycor, San Diego, CA, USA, ²U.S. Army Research Institute of Environmental Medicine, Natick, MA, USA, ³University of Connecticut, Storrs, CT, USA.

The purpose of this randomized controlled trial was to evaluate the effect of several short term exercise interventions over 13 weeks on regional bone strength parameters of the tibia using peripheral quantitative computed tomography (pQCT). Fifty-seven female volunteers (age 20.4 ± 1.8) were assigned to one of four groups: a sedentary control group, a resistance training group, an aerobic group, or a combined aerobic-resistance group. pQCT scans were taken at sites 4%, 38% and 66% from the distal end plate of the tibia at baseline and at the end of the 13-week training period. Cross-sectional images were divided into six 60° sectors centered on the intramedullary canal. Matlab was used to register and align images and to assess geometry (4%: trabecular area; 38%, 66%: cortical area, periosteal diameter, cortical thickness, & cross-sectional moment of inertia), density (4%: trabecular density; 38%, 66%: cortical density) and overall bone strength (38%, 66%: bone strength index, Slenderness Index). A repeated-measures ANOVA compared the four training groups over time; Fisher's LSD was used to analyze significant interactions. Trabecular density increased significantly at the 4% site with exercise intervention, while the control group exhibited no change. Changes were most pronounced in the groups incorporating impact exercise, and were evident on the medial aspect of the tibia. Measures derived from the 38% and 66% site did not change significantly.

Load-specific Differences in Femoral Neck Cortical Geometry: Preliminary data from 3-D MRI Study of Proximal Femur of Athletes. R. Nikander¹, H. Sievänen¹, P. Dastidar^{*2}, A. Heinonen³, P. Kannus^{*4}. ¹Bone Research, UKK Institute for Health Promotion Research, Tampere, Finland, ²Department of Radiology, University Hospital, Tampere, Finland, ³Department of Health Science, University of Jyväskylä, Jyväskylä, Finland, ⁴Department of Trauma, Musculoskeletal Surgery and Rehabilitation, University and University Hospital, Tampere, Finland.

During normal walking, femoral neck (FN) is subjected to a large number of consecutive, low magnitude impacts from typical directions. In contrast, during sport performance, power-lifters' femoral neck experiences very high magnitude, low rate loading from unusual direction, while swimmers' femoral neck is subjected to high rate muscle activity lacking virtually the weight-bearing component. We aimed to investigate the differences in the femoral neck cortical geometry among world-class power-lifters, national level swimmers and normal exercisers serving as referents.

In this preliminary analysis of accumulating bone data from five power-lifters, five swimmers and five referents were compared. In all groups, the femoral neck cortical structure was assessed with DXA and 3-D MRI of the proximal femur. ANCOVA (age, weight and height as covariates) were used for statistical analysis.

The femoral neck BMC and BMD were 35% and 31% higher in power-lifters, but 11% and 13% lower in swimmers compared with controls ($0.02 < p < 0.07$). Interestingly, the shape of power-lifters' femoral neck appeared to be round at the narrowest section, while swimmers' and controls' FN seemed to be oval being wider in the superior-inferior direction.

Although the inter-group differences in the femoral neck cortical thickness did not reach statistical significance, a clear trend suggesting substantially thicker cortices in power-lifters in all anatomic directions (anterior 22%, posterior 52%, superior 12% and inferior 45%) was found, while the cortices between swimmers and referents were similar.

The strong femoral neck structure (more mass, denser bone, round shape and thick cortices) seemed to be characteristic of power-lifting performance. High magnitude loading produced at low rate seemed to account for strong femoral neck, while non-weight bearing, low-magnitude loading, despite large number of repetitions at relatively high rate, seems not benefit to bone structure at all.

Disclosures: R. Nikander, None.

The Effect of Resistance Exercise on In Vivo-Derived Tomography Measures and Mechanical Properties of Rodent Bone: Is More Load Always Better? M. Nilsson^{*1}, J. M. Swift^{*1}, C. J. Walthall^{*2}, J. L. Stallone^{*1}, H. A. Hogan², J. D. Fluckey^{*1}, S. A. Bloomfield¹. ¹Department of Health and Kinesiology, Texas A&M University, College Station, TX, USA, ²Department of Mechanical Engineering, Texas A&M University, College Station, TX, USA.

Weight-bearing resistance exercise and high-impact jump training have previously been shown to be particularly beneficial to skeletal growth compared to other modes of exercise. Exercising against an increased resistance, such as traditional strength training, would theoretically yield higher bone strains compared to exercise with just your own bodyweight (BW), and is expected to produce a greater anabolic response in bone. The purpose of this study was to compare the osteogenic effects of a 5-week progressive resistance exercise paradigm with a BW exercise protocol in rats. Mature male Sprague-Dawleys (mean BW of 407 ± 26.5 g) were operantly conditioned to perform a full leg extension to reach an illuminated lever (mimicking a traditional squat), and thereafter assigned to a resistance exercise group (RT; n=16), a BW exercise group (BW-EX; n=15), or a cage-control group (CC; n=7). Three training sessions were performed per week and resistance was progressively increased from 80 g during session 1 to 410 g during session 15 in the RE group. The BW-EX completed the same number squats per session as the RT group, but without added weights, resulting in many rats being able to jump off the cage floor. In vivo peripheral quantitative computed tomography scans (pQCT) of midshaft and proximal tibiae were done at baseline and after 5 weeks of training. Strength, stiffness, and toughness of mid-diaphyseal tibial bone were assessed with 3-point bending tests to failure post sacrifice. Ex vivo pQCT scans and bending/compression tests of the femoral neck were also performed. RE and BW-EX resulted in similar increases in tibial total bone mineral content (BMC) at the metaphysis (+10% and +11%, respectively) and midshaft (+19% and +18%, respectively). Diaphyseal bone area, cortical shell thickness, and polar moment of inertia increased significantly in RT (+14%, +9%, and 29%, respectively) and BW-EX (+13%, +9%, and +26%, respectively), and both groups had significantly stronger, stiffer, and tougher bone compared to CC ($p < 0.05$). Femoral neck total BMC ($p < 0.001$) and max force ($p < 0.01$) were significantly higher in exercise groups compared to CC, but there were no differences between RT and BW-EX. In summary, increasing load magnitude by up to ~100% of the animal's bodyweight in this voluntary resistance exercise paradigm did not produce additional gains in BMC, bone geometry, or mechanical properties. We speculate that the additional impact provided by jumping in the BW-EX group may account for the similar benefits.

Musculoskeletal Response to Altered Mechanical Demand Is Tissue Specific and Influenced by Genetic Make-up. E. Ozcivici¹, S. Lublinsky^{*1}, C. Rubin¹, L. Donahue², S. Judex¹. ¹Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, ²Bone Biology Group, Jackson Labs, Bar Harbor, ME, USA.

The degree of musculoskeletal devastation by the loss of functional weightbearing is heavily influenced by genetic variations. Here, we subjected genetically heterogeneous mice to 3wk of disuse (hindlimb unloading) and 3wk of subsequent reambulation to investigate: (a) if the degree of mechanosensitivity of cortical bone, trabecular bone and muscle are similar, (b) whether the amount of tissue at baseline is associated with disuse induced changes in morphology (c) to what extent the loss in tissue morphology can be recovered upon reambulation. In vivo μ CT quantified longitudinal changes in metaphyseal trabecular bone, middiaphyseal cortical bone, and muscle surrounding cortex in the femur of adult (4mo) F2 female progeny of BALB and C3H (high and low mechanosensitivity) mice (n=450). During disuse and reambulation, changes in cortical area amounted to $-1(\pm 4)\%$ and $4(\pm 4)\%$, respectively. Age-matched controls (n=29) added $3(\pm 1)\%$ and $4(\pm 1)\%$ of cortical bone in an identical time frame indicating that appositional growth was retarded with disuse. Muscle loss during disuse was $9(\pm 11)\%$, 82% of which was recovered upon reambulation. Trabecular bone was devastated during disuse as characterized by a $44(\pm 17)\%$ smaller volume fraction and a $18(\pm 8)\%$ drop in both trabecular number and thickness. Recovery of trabecular volume fraction upon reambulation reached only to 10% of the loss during disuse. Even worse, trabecular number was reduced by an additional $8(\pm 9)\%$ upon reambulation while 71% of the loss was recovered in trabecular thickness. Baseline trabecular volume fraction and muscle area were inversely related to the loss during disuse ($R^2=34\%$ and 16% , respectively), while changes in cortical area were not associated with baseline morphology ($R^2<1\%$). The relation between the loss of skeletal tissue during disuse and gain upon reambulation was weak ($R^2<10\%$) for both trabecular and cortical bone, while in muscle, a moderate correlation ($R^2=32\%$) was observed. In summary, changes in mechanical demand resulted in a very tissue- and compartment-specific response with large differences between muscle, cortical bone, and trabecular bone. The data also suggest a genetically regulated protective effect of the quantity of trabecular and muscle tissue at baseline on the preservation of tissue during disuse. In contrast to muscle that recovered most of its losses upon reambulation, the recovery of trabecular bone was minimal with some architectural aspects even continuing to deteriorate. The large variations between individuals emphasizes that the identification of the underlying molecular basis will be invaluable for the future development of tailored treatments.

Males Have an Enhanced Osteogenic Responsiveness to Loading vs. Females - A Consequence of Higher Mechanical Competence of Female Bones Relative to Locomotive Loading. I. Pajamäki^{*1}, O. Leppänen^{*1}, J. Jokihaara^{*1}, H. Sievänen^{*2}, P. Kannus^{*2}, T. L. N. Järvinen¹. ¹Orthopaedics and Traumatology, University of Tampere, Tampere, Finland, ²UKK Institute, Tampere, Finland.

Sex is considered one of the primary factors modulating the responsiveness of bone to mechanical loading. The purpose of this study was to assess whether the loading-induced bone gain (mechanoresponsiveness) differs between young male and female rats.

A total of 40 three-week old male (M) and female (F) rats were used. At entry, unilateral sciatic neurectomy was performed to remove loading from left limb (L-) while the contralateral right limb remained intact (subjected to normal physiological loading, L+). After a 6-month study period, a comprehensive structural analysis of the femoral midshaft was carried out utilizing peripheral quantitative computed tomography (pQCT) and mechanical testing. Total cross-sectional area (tCSA), cortical cross-sectional area (cCSA), cortical bone mineral content (cBMC) and fracture load (Fmax) were determined. To eliminate the inherent bias arising from comparisons between animals differing in body weight and size, all data pertaining to bone mechanical competence was equalized in terms of the animal's apparent loading environment by using the body weight and femoral length as covariates.

A clear sex-difference was observed in the mechanoresponsiveness, males exhibiting significantly higher loading-induced responses than females (Figure). However, it should be noted that the non-loaded (L-) bones of females displayed clearly higher mechanical competence relative to the animal's apparent loading. Thus, it is quite plausible that there is no need for these already "overstrengthened" female bones to adapt to mechanical loading with the same magnitude as the male bones.

In conjunction with our previous findings (Järvinen et al. Bone 2003 and JBMR 2003), the reduced mechanoresponsiveness of female bones seems to be explained by the difference in the mechanical (locomotive) competence of bones between sexes. Thus, our results emphasize the importance of acknowledging the locomotive context (existing bone characteristics) in studies evaluating the mechanoresponsiveness of bones.

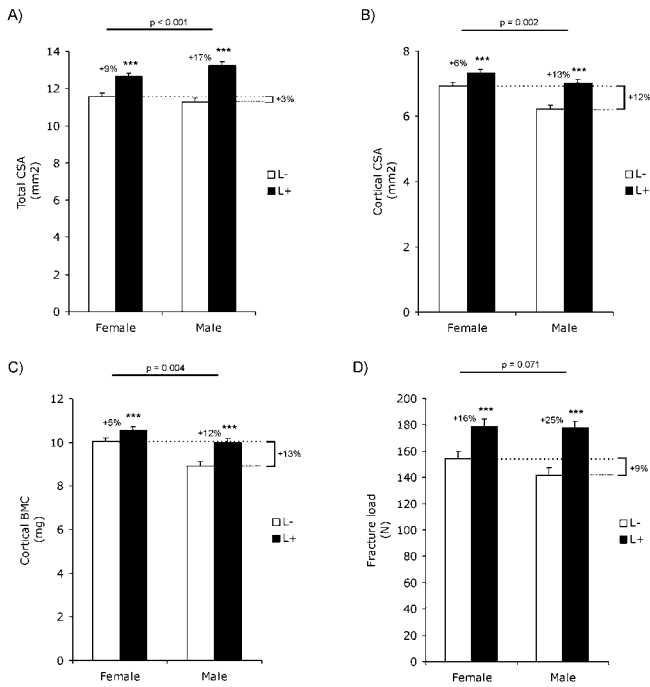

Figure. The mechanoresponsiveness of female and male bones. Bars represent mean \pm standard error of mean (SEM). Significant differences between L+ vs. L- are indicated as follows: *** p < 0.001. The p-value for interaction (sex and loading) is presented on top of each figure. □ denote the difference in the normal (control) bones between females and males.

Effects of Vibration Plus Resistance Training on Bone Metabolism in Postmenopausal Women. I. J. Palmer*, M. G. Bemben*, D. A. Bemben. Health and Exercise Science, University of Oklahoma, Norman, OK, USA.

Whole body vibration has been shown to be osteogenic in animal models, however the efficacy of vibration as an intervention for the prevention of osteoporosis in humans is not clear. The purpose of this study was to examine the effect a vibration stimulus preceding resistance exercise on bone mineral density (BMD) and bone biomarkers in healthy estrogen-deficient postmenopausal women, 55 to 75 years of age. Subjects were assigned to a control group (C, n=12), resistance training group (R, n=22), or a vibration plus resistance training group (VR, n=21). R and VR trained 3 days/week for 8 months, with 3 sets of 10 reps (80% of 1RM) on 8 exercises. VR received vibration in three different positions beginning with 1 set of 15 sec (30Hz, 2.16g) and progressing to 2 sets of 60 seconds (40Hz, 2.8g). Training loads were adjusted every 5 weeks. Daily calcium intake was estimated by a food frequency questionnaire. Bone-specific alkaline phosphatase (BAP) and C-terminal telopeptides of Type-1 collagen (CTX) were measured as indicators of bone turnover. BMD and bone mineral content (BMC) of the AP lumbar spine, dual proximal femur, radius 33%, and total body were measured by DXA (GE Lunar Prodigy, enCORE version 8.80.001). At baseline, there were no significant (p>.05) group differences in age, height, weight, strength, calcium intake, BMD, or BMC. Two-way repeated measures ANOVA (group x time) did not detect significant group or time effects for BAP, CTX, or BMD or BMC at any site. VR had significantly (p<.05) higher relative strength increases in 5 of the eight exercises, compared with R. Multiple regression analyses were used to determine significant (p<.05) predictors of absolute changes in BMD and BMC in response to training for VR and R groups. Total BMD was predicted by upper body strength change ($R^2=0.089$ p=0.031). Right and left trochanter BMD was predicted by fat mass change ($R^2=0.083$ and 0.127 , p<.05). Right femoral neck BMD was predicted by change in BAP ($R^2=0.113$, p=0.019), by fat mass change ($R^2=0.108$, p=0.021), and by weight change and calcium intake change ($R^2=0.203$, p=0.005). Right total hip BMD was predicted by change in calcium intake ($R^2=0.12$, p=0.015). Spine (L2-L4) BMD was predicted by change in lean mass ($R^2=0.079$, p=0.042). Radius 33% BMD was predicted by change in fat mass ($R^2=0.091$, p=0.028) and by group ($R^2=0.074$, p=0.045). In conclusion, the vibration plus resistance training protocol did not result in significant alterations in bone biomarkers, BMD, or BMC. Although the addition of the vibration stimulus to a traditional resistance training program significantly enhanced muscle strength, no benefits for skeletal health were evident.

Flexible Multibody Simulation Approach in The Analysis of Tibial Strains During Walking. T. Rantalainen*, R. Al Nazer*, A. Heinonen*, H. Sievänen*, A. Mikkola*. ¹Department of Biology of Physical Activity, University of Jyväskylä, Jyväskylä, Finland, ²Department of Mechanical engineering, University of Lappeenranta, Lappeenranta, Finland, ³Department of Health sciences, University of Jyväskylä, Jyväskylä, Finland, ⁴UKK-Institute, Tampere, Finland.

Strains within the bone play a major role in bone remodeling. These small deformations can be determined using experimental strain gage measurements which are challenging and invasive tasks. Further, the strain measurements are, in practise, limited to certain regions of superficial bones only, e.g. the anterior surface of tibia. In this study, tibial strains occurring during walking were estimated using a numerical approach based on the flexible multibody dynamics. A written informed consent was obtained from healthy male volunteer (25 years, 184 cm, 89 kg), who served as a subject. The study was approved by the local ethical committee. The subject was asked to walk on a level surface at a natural cadence and at a constant velocity (1.47 m/s). The walking performance was recorded using four digital video cameras (COHU High Performance CCD Camera, San Diego CA, USA). A detailed lower body musculoskeletal model was developed by employing motion analysis data obtained from the walking test. The motion analysis data was used in inverse dynamic simulation to train the muscles to replicate the motion in forward dynamics simulation using a commercial human movement modeling software (BRGLifeMOD Biomechanics Modeler®, Biomechanics Research Group, Inc, USA). The tibial strains were then estimated by applying the forward dynamic simulation to a lower body model with a flexible tibia. The maximum and minimum principal strains predicted by the model were 376 and -472 microstrains, respectively, which are in line with literature values from in vivo measurements. It is concluded that the non-invasive flexible multibody simulation approach may be used as a surrogate for experimental bone strain measurements and be of use in the detailed strain analyses of bones.

The Relationship Between Serum 25-hydroxyvitamin D and Bone Markers in the Professional Football Players. Y. Saita, H. Nakajima*, H. Ikeda*, H. Kurosawa*. Department of Orthopaedic Surgery and Sports medicine, Juntendo University, Tokyo, Japan.

Stress fractures are one of the most common types of overuse injuries in top athletes. A recent report suggested a relationship between the incidence of stress fractures and low 25-hydroxyvitamin D (25OH(D)) concentration in military recruits. However, relationships between 25OH(D) and bone markers in top athletes are not well known. Therefore, serum levels of 25OH(D) and bone markers were measured in the professional football (soccer) players in Japan (n = 32, mean age 24 years). The average values of 25OH(D) and bone markers were as follows; 25OH(D): 25.9 ± 2.8 ng/ml (mean \pm SD), bone-specific alkaline phosphatase (BAP): 31.3 ± 9.1 U/L, cross-linked N-telopeptides of type I collagen (NTX): 18.8 ± 5.2 nmolBCE/l. The levels of BAP and NTX were elevated above normal range in 28.1% and 62.5% in all players, respectively. There are significant positive correlations between BAP and NTX values ($r = 0.37$, p<.05). Then, we assessed the correlations between 25OH(D) and bone markers. The players were divided into two groups according to their 25OH(D) levels (low-vitD group: less than mean value of 25OH(D), n=15; high-vitD group; n=17), and bone markers were compared. Interestingly, low-vitD group showed higher levels of BAP compared to high-vitD group (p<.05). Similarly, low-vitD group showed relatively higher levels of NTX, though it was not statistically significant. The levels of 25OH(D) and BAP showed negative correlations ($r = -0.25$), yet it was not statistically significant. These findings indicate that football (soccer) players tend to be in a high turnover state in bone remodeling and the serum 25OH(D) concentration would negatively correlate with it. Further study may reveal whether 25OH(D) level could be a biomarker to predict the occurrence of stress fractures in athletes.

Bone Mineral Density and Bone Quality in Unilateral Lower Limb Amputees. V. D. Sherk*, M. G. Bemben*, J. T. Cramer*, D. A. Bemben. Health and Exercise Science, University of Oklahoma, Norman, OK, USA.

Bone(s) in a residual limb undergo prolonged unloading after amputation, potentially causing significant bone loss in the hip and distal bony end of the residual limb. The purpose of this study was to examine the effect of amputation on bone geometry, volumetric bone mineral density (vBMD) and areal bone mineral density (aBMD) by comparing the intact and residual limbs in unilateral transfemoral and transtibial amputees. Five above-knee and four below-knee amputee subjects (23-50 years of age) who had been ambulatory with a prosthesis for at least 6 months gave informed consent to participate in this study. Bone geometry and vBMD were assessed at the distal end of the residual limb and comparable cross-sectional slice of the intact limb using pQCT (Stratec XCT 3000). aBMD of the proximal femurs was assessed using DXA (GE Lunar Prodigy, enCORE version 8.80.001). Paired t-tests were used to determine differences in bone variables between the amputated and intact limbs. There were significant differences in the hip BMD sites ($p < .05$) with total hip aBMD for the amputated side being 32% lower than that of the intact side. Femoral neck and trochanter aBMD were 27% and 37% lower in the amputated hip, respectively. Forty-four percent of amputees had hip T-scores < -2.5 . As shown in the table below, total and cortical areas and densities were significantly lower at the end of the residual limb compared to the midshaft of the intact limb ($p < .05$), but there were no significant differences in the trabecular area and density. In conclusion, amputees had significant decrements in total bone area and density in the residual limb compared to the intact limb, which was attributed to concomitant changes in the cortical bone variables. Based on the aBMD for the hip sites, these individuals are at increased risk for osteoporosis.

Table 1. Bone Area (A) and Density (D) pQCT Variables (Means \pm SE)

Limb	Cortical A (mm ²)	Cortical D (mg/cm ³)	Trabecular A (mm ²)	Trabecular D (mg/cm ³)	Total A (mm ²)	Total D (mg/cm ³)
Intact	400.46 \pm 36.14*	1156.67 \pm 48.96*	222.81 \pm 53.09	151.74 \pm 12.31	657.87 \pm 42.12*	796.51 \pm 64.63*
Residual	139.02 \pm 29.46	970.66 \pm 27.05	238.93 \pm 38.53	209.92 \pm 51.80	465.19 \pm 61.34	489.70 \pm 61.74

Effect of Combined Strength and Speed Training on Cortical Bone Geometry and Mass Distribution in Master Athletes. H. Suominen¹, M. Korhonen¹, J. Hautakangas¹, T. Suominen¹, M. Alen¹, A. Mero².

¹Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland,

²Department of Biology of Physical Activity, University of Jyväskylä, Jyväskylä, Finland.

Cross-sectional and longitudinal observational studies have shown that athletes competing in strength and power events have superior bone mineral mass and cross-sectional geometry of long bones compared with their non-athletic counterparts. The purpose of the present study was to investigate the effects of intensive physical training on cortical bone geometry and mass distribution in master sprinters. Seventy-three male athletes aged 40-85 years with long-term experience and success in sprint events were randomly assigned into two groups. The men in the experimental group ($n=40$) participated in a periodized strength and speed training program for 6 months while the controls ($n=32$) continued their accustomed training routines. Volumetric bone mineral density (vBMD), cortical thickness (CTh), and polar mass distribution were assessed in the tibia shaft by pQCT (XCT 2000) using a Geanie 2.1. software. No significant interaction of group by time was observed in vBMD, while the mean change in CTh was 2-3% greater in the experimental group compared to controls, particularly among the older sprinters (Fig.). According to polar mass distribution, the changes were more evident in the medioanterior region of the tibia shaft. The results indicate that high-load and high-speed exercise training may improve cortical bone geometry even in elderly athletes with long-term training background.

Association of Serum Osteocalcin with Bone Gain in Pubertal Girls and Bone Loss in Postmenopausal Women. S. M. Cheng¹, K. M. Fagerlund², P. Rahkila¹, E. Helkala¹, F. Tyllavsky³, F. Tyllavsky³, H. K. Väänänen⁴, S. Cheng¹.

¹Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, ²Department of Medicine, University of Turku, Turku, Finland, ³Department of Preventive Medicine, University of Tennessee, Memphis, TN, USA, ⁴Department of Preventive Medicine, University of Turku, Turku, Finland.

Serum osteocalcin (OC) has been proposed as a specific and sensitive marker for bone formation because it is present exclusively in bone tissue and increases significantly when skeletal growth becomes boosted. Furthermore, since OC is incorporated into the bone matrix it may be released even during bone resorption. In this study we evaluate whether OC reflects bone modeling in pubertal girls, and bone loss in a group of their mothers and grandmothers. The study subjects consisted of 258 girls (mean age at baseline 11.2 yrs, menarche age 13 yrs), and 80 pre-menopausal mothers (PreM, mean age 43yrs), and 100 post-menopausal mothers and grandmothers (PostM, mean age 63yrs). Serum total OC was assessed by an in-house immunofluorometric assay. Bone mineral content (BMC) and density (BMD) of whole body (WB), total femur (TF) and lumbar spine (L2-4) were assessed by DXA (Prodigy, GE Lunar). Data for the girls were collected at baseline and 12, 24, 36, 48 and 84 months intervals. Mother and grandmother participated in the study twice at 36 and 84 months time points. The correlation between OC (not measured at 84 months) and BMC, BMD and the annual changes of BMC and BMD were calculated for successive measurement interval. In girls the mean OC concentration decreased from 45.5 \pm 12.5 ng/ml at baseline to 44.4 \pm 11.9 (12m), 42.5 \pm 12.9 (24m), 35.1 \pm 12.6 (36m), and 25.6 \pm 10.4 ng/ml (48m). The decrease was significant from 36 to 48 months. In PreM the OC concentration was lower than in PostM (6.9 \pm 2.3 vs 8.5 \pm 4.4 ng/ml $p=0.023$). In girls the OC concentrations between different time points were highly correlated ($r=0.387-0.827$). In girls a significant positive correlation was found between OC and BMC or BMD of WB, TF, and L2-4 at baseline, but significant negative correlations at 24 months and 36 months. In PostM the OC concentration was negatively correlated with BMC or BMD of the WB. Further, we found that in girls the initial OC value is associated with a positive annual BMC or BMD change during the following measurement interval. For all measured bone sites this positive relationship was strongest during 24-36 months ($r=0.447-0.595$) and 36-84 months ($r=0.701-0.771$) intervals. In PostM, the association of OC and the annual change of BMC was negative (TF $r=-0.427$, $p=0.037$ and WB $r=-0.551$, $p=0.005$). Our results indicate that in pubertal girls serum OC concentration reflects the bone gain during the bone modeling period, and bone loss by resorption in postmenopausal women.

Sexual Dimorphism in the Relationship Between Serum Leptin and Skeletal Health in Healthy Adolescents. J. Maalouf¹, N. Hwalla², Z. Mahfoud³, O. Obeid², G. El-Hajj Fuleihan¹.

¹Calcium Metabolism and Osteoporosis Program, American University of Beirut-Medical Center, Internal Medicine, Beirut, Lebanon, ²American University of Beirut, Nutrition & Food Sciences, Beirut, Lebanon, ³American University of Beirut, Epidemiology & Population Health, Beirut, Lebanon.

Serum leptin and bone mass are concordant in several respects and both increase at the initiation of puberty. Few studies have investigated the relationship between serum leptin concentrations and bone mineral in both genders in the context of other mediators of bone mineral accretion.

The purpose of this cross-sectional study is to determine the relationship between leptin and bone mass in 363 healthy adolescents (184 boys and 179 girls), 10-17 years old. Height (Ht), weight, Tanner stages (TS), dietary calcium and exercise were evaluated. Bone mineral density (BMD), content (BMC) and body composition were measured by DEXA. Serum leptin, 25-hydroxyvitamin and IGF1 were also measured.

Girls had higher leptin levels than boys at all TS and reached significance at TS3 ($p=0.025$) and TS4 ($p=0.012$). In girls, leptin levels increased substantially across TS and were two-fold higher in post-pubertal girls than pre-pubertal, while in boys the increments were negligible ($p=0.87$) (Figure). This significant sexual dimorphism persisted ($\beta = 4.75$ ng/ml, $p<0.001$) after controlling for fat mass (FM) and TS.

There was a correlation between leptin and BMD at the lumbar spine, total hip (TH), femoral neck (FN), radius and subtalar body (TB) and at FNBM in boys ($r=0.17-0.26$, $p<0.05$) and at all skeletal sites for BMD and BMC in girls ($r=0.28-0.38$, $p<0.001$). Serum leptin was correlated with lean mass (LM) in boys ($r=0.31$ $p<0.001$) and girls ($r=0.48$, $p<0.001$). It was highly correlated with FM ($r=0.78$, $p<0.001$) in boys and ($r=0.67$, $p<0.001$) in girls.

There was no independent effect of serum leptin on BMD or BMC in boys after adjusting for TS, LM, FM, Ht, exercise, dietary calcium, IGF1 and serum vitamin D. Conversely, in girls, after adjustment, leptin was a consistent predictor of BMD but not BMC at cortical sites i.e. at the TH, FN, trochanter, and TB explaining 4-4.5% of variability in BMD.

Leptin correlates with BMD in girls independent of fat and other classical bone mass predictors. The basis for the sexual dimorphism in the relationship between leptin and bone mass is unclear and deserves further investigation

Plasma leptin concentrations by gender and Tanner stages

*p<0.05 between boys and girls at the same Tanner Stage by independent T-test

Analysis and Quantification of Spontaneous Bone Regeneration. T. P. Fairbanks^{*1}, T. M. Link^{*2}, D. Ellis^{*1}, J. S. Lee¹. ¹Oral & Maxillofacial Surgery, UCSF, San Francisco, CA, USA, ²Radiology, UCSF, San Francisco, CA, USA.

Rib grafts are commonly used for reconstruction in the craniofacial region. Despite the size of the defect at the donor site, the rib will regenerate completely and can be harvested a second time. Little is known about this spontaneous regeneration. This unique ability provides an opportunity to study bone regeneration in the only known site to spontaneously and completely form bone in the postnatal setting. The purpose of this study is to use quantitative CT to analyze in vivo rib regeneration at the costochondral bone graft site. This data will provide further understanding of spontaneous bone regeneration and the effects of age on bone formation.

8 Subjects (3 Female, 5 Male) were enrolled at the UCSF Oral and Maxillofacial Surgery Clinic. IRB approved consent was obtained from each participant for CT imaging at 3 intervals: immediately post-operative (T0), 3- and 6- months follow-up (T1, T2 respectively). A standard imaging protocol based on height/weight was used for each patient in a 16 row multi-slice CT scanner (Lightspeed, GE, Milwaukee, Wisconsin). The CT scans were analyzed at PACS workstations (AGFA, Somerville, New Jersey). Using image analysis software, the CT images were analyzed and quantified for densitometric and volumetric data of the regenerated osseous tissue. Using known values of bone mineral density from the calibration phantom, the computed density was converted from Hounsfield Units to mg/mL hydroxy-apatite. The area of the outlined form was given in units of cm²; volume was calculated by multiplying the computed area in the region of interest by the thickness of the axial CT slice and represented in units of mm³.

To compare regenerative capacity as a function of age, the subjects were assigned to the adult (>16 years) or pediatric (≤ 16 years) group. The adult group: 3 subjects (2 Female, 1 Male); each subject demonstrated incomplete regeneration at T2. The average volume of regenerated bone was 2049.45 mm³, with an average density of 323.76 mg/ml hydroxy-apatite. The pediatric group: 5 subjects (1 Female, 4 Male) exhibited complete rib regeneration, typically by T1. The average final volume of the young group was 4511.45 mm³, and a density of 305.45 mg/ml hydroxy-apatite.

Despite evidence of bone regeneration in all of the subjects enrolled in the study, the pediatric group exhibited substantial and complete regeneration of osseous tissue compared to the adult group.

Tempo and Timing of Bone Mineral Accrual During the Pre, Peri and Post Adolescent Growth Periods. M. R. Forwood¹, A. D. G. Baxter-Jones^{*2}, R. A. Faulkner², R. L. Mirwald^{*2}, D. A. Bailey². ¹School of Biomedical Sciences, The University of Queensland, Brisbane, Australia, ²College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada.

Existing data on bone mineral acquisition during growth is limited because most studies have been cross-sectional in design or have failed to adequately control for maturational differences in growing children. Starting in 1991 we have been monitoring bone mineral accrual and bone strength in a sample of children who are now in their mid-twenties. From our original sample we present data on 52 boys and 52 girls who have been measured annually for seven consecutive years across the adolescent growth spurt years and again for up to three years as adults. Bone mineral content of the lumbar spine, femoral neck and total body was measured by DXA (Hologic 2000 QDR in the array mode). To control for maturational differences in children of the same chronological age a cubic spline curve was

applied to each subject's longitudinal height data and an age of peak linear growth (PHV) for each subject was determined. Pre-adolescence was then defined as the stage of growth up to 2 years before the age of PHV; Peri-adolescence from 2 years before the age of PHV until two years after PHV. Post adolescence was defined as the stage of growth from PHV +2 until adult status (PHV + 10 years). The purpose of the study was to describe bone mineral accrual at the three bone sites during these three developmental time periods; pre-adolescence, peri-adolescence and post-adolescence. The following graph shows the percent of adult accrual during the four year growth period surrounding PHV (Defined as Peri-adolescence = PHV ±2yr). At all sites, for both sexes, over 98% of bone mineral has been laid down by 4 years beyond the age of PHV.

A Model of Secondary Amenorrhea in the Adolescent Female Rat. R. Joshi¹, V. R. Yingling². ¹Kinesiology, Temple University, Philadelphia, PA, USA, ²Kinesiology & Anatomy and Cell Biology, Temple University, Philadelphia, PA, USA.

Optimizing peak bone mass during late adolescence may be effective in reducing the effects of osteoporosis. Osteopenia, osteoporosis, stress fracture as well as a failure to achieve peak bone strength are all observed in young women with secondary amenorrhea. Multiple factors contribute to bone deficits in secondary amenorrhea including increased bone resorption through suppressed estrogen levels and suppressed bone formation resulting from decreased insulin-like growth factor-1 (IGF-1) levels. Therefore it is important to develop an animal model to reproduce a milieu similar to that of secondary amenorrhea in humans to study the effects of this devastating condition on bone structure. The purpose of this study was to access the effects of secondary amenorrhea induced by gonadotropin releasing hormone antagonist (GnRH-a) injections on serum levels of estradiol and IGF-1. At 23 days of age, 40 female Sprague Dawley rats were randomly assigned into a baseline group (BL) (n=6) sacrificed on day 25, a baseline 65 group (BL65) (n=10) sacrificed on day 65, an aged-match control group (C) (n=15) sacrificed on day 90, and an experimental group (Ex) (n=9) that received daily injections (2.5 mg/kg/dose) intraperitoneally for a 25 day period from day 65 to day 90. The study was approved by the IACUC. Differences in body weights and serum levels of estradiol and IGF-1 were detected using a One-way ANOVA (p < 0.05). Body weights were similar on day 65 prior to the injection protocol however on day 90, Ex group weights were significantly greater than C. Estradiol levels were suppressed by 36% in Ex compared to C and 26% compared to BL65. IGF-1 levels were 19% higher compared to C and similar to BL65 levels, IGF-1 values typically decrease as animals mature. The decrease in estradiol levels following GnRH suppression resulted from decreased pulsatile secretion of GnRH from the hypothalamus which then resulted in decreased LH and FSH secretion from the pituitary. The increase in IGF-1 levels is not similar to the clinical condition of secondary amenorrhea which results in suppressed IGF-1 levels. These data suggest that secondary amenorrhea is not only a suppression of the reproductive axis (Hypothalamic-Pituitary-Gonadal) but also results from a suppressed somatic axis (GH-IGF-1). In conclusion, modeling secondary amenorrhea using a GnRH-a may model a subset of the clinical condition.

Estradiol and IGF-1 mean (SD) * p<0.05				
	BL	BL65	C	Ex
Estradiol (pg/ml)	13.44* (1.65)	20.83 (5.08)	24.08 (4.7)	15.49* (1.99)
IGF-1 (ng/ml)	827.6 (94.8)	1256.3* (212.1)	966.1 (217.5)	1195.1* (110.7)

Is Development of Ovulatory Cycles in Adolescence Important for Peak Bone Mass? S. Kalyan*, S. I. Barr*, R. Alamoudi*, J. C. Prior. Medicine, University of British Columbia, Vancouver, BC, Canada.

The purpose of this study was to investigate the potential importance of establishing ovulatory cycles following menarche in bone mineral accretion in peripubescent girls. Healthy premenarcheal Caucasian girls were recruited to this 3-year prospective study of bone development (SI Barr, JBM, 2001). The mean enrollment age of the 38 girls who completed the study was 10.6 ± 0.6 years. Body mass index (BMI, kg^2/m^2) and bone mineral density (BMD) by DXA of the total body (TB) and lumbar spine (LS) were measured every 12 months for 36 months. Participants reported when and if menarche occurred. 33 experienced menarche and 5 did not. Progesterone was measured in saliva 3-weeks after flow and weekly thereafter until the next flow by 13 of the menstruating girls; levels > 40 nmol indicated ovulation. Nine of the 13 girls had at least one ovulatory cycle. The earliest following menarche that ovulation occurred was 10 ± 5 months. The 4 girls who did not ovulate were only sampled in cycles occurring < 8 months post-menarche. BMI at baseline (18.31 ± 2.6) or 36 months (21.21 ± 3.5) did not relate to change in BMD ($r = 0.017$ and 0.163 , respectively). However, there was a significant positive correlation between the change in both LS and TB BMD and time since menarche ($r^2 = 0.14$, $p < 0.05$; $r^2 = 0.40$, $p < 0.0001$, respectively). Regression analysis (Figure 1) with the 95% confidence interval suggests that greater gains in BMD are noted at the time following menarche when cycles are more likely to become ovulatory. Although the effect of menarche on bone accrual is already appreciated, the influence of ovulatory cycles in peripubertal girls as a determinant of bone gain has not been investigated. Results of this study provide preliminary evidence to suggest that attaining ovulatory cycles contributes to optimal peak bone mass. This hypothesis is line with previous work showing that ovulatory disturbances accounted for 24% of the variance seen in changes of cancellous-bone density in regularly cycling premenopausal women (JC Prior, NEJM, 1990).

Figure 1: Regression analysis of the change in BMD over 3 years in relation to time since menarche.

5-Year Follow-up of Bone Mineral Distribution and Bending Strength Changes Across Puberty: Comparison Between Biological Age-Aligned Boys and Girls. S. Kontulainen¹, H. Macdonald², J. Johnston², H. McKay². ¹University of Saskatchewan, Saskatoon, SK, Canada, ²University of British Columbia, Vancouver, BC, Canada.

The greater incidence of fragility fractures in older women compared to men may be related to sex-specific patterns of bone strength development during growth [1]. Thus, the aim of this 5-year follow-up was to assess changes in bone bending strength to the smallest (Imin) and greatest (Imax) direction of rigidity, and polar distribution of bone mineral content (PDBMC) at the tibial diaphysis in boys and girls at the same maturational stage. Biological age was defined as years from age at peak height velocity for 98 participants (52 girls) in the Healthy Bones II Study. A single slice at the 50% site of the tibial diaphysis was acquired using the Norland/Stratec XCT 2000. Bonalyse 2.1 was used to assess cortical bone Imax and Imin, the polar distribution of bone mineral content (PDBMC) and muscle cross-sectional area (MCSA). K-mode with an outer threshold of $200 \text{ mg}/\text{cm}^2$ was used to define the periosteal bone surface and an inner threshold of $480 \text{ mg}/\text{cm}^2$ was used to separate cortical bone from trabecular bone. PDBMC defines the angular distribution of bone around the centre of mass. The distance from the centre represents the mass (in grams) in a 1 cm thick section. Data were analyzed using a hierarchical (random effects) modelling approach. During and after rapid skeletal growth boys distributed their bone mass further from the neutral axis, especially towards the anterior and posterior directions of the tibial diaphysis, when compared with girls at the same biological age (Fig 1). This resulted in a greater magnitude of the sex-difference in the direction of greatest bending rigidity (Imax). When biological age, tibial length and MCSA were controlled for, boys had a statistically significant greater increase in bending strength in both directions. These results are in accordance with evidence from anthropological samples suggesting that

lower limb bones of adult males are more adapted for anterior-posterior (A-P) bending and common loading direction compared with females [2]. However, this phenomenon may be site-specific and further research at other bone sites is warranted.

Age-Related Distribution of Bone and Skeletal Parameters in 1,322 Young Women. T. Kuroda¹, Y. Onoe¹, S. Orito¹, M. Ohara¹, M. Sakai¹, K. Ishitani¹, H. Okano¹, A. Uyama², M. Kume², H. Ohta¹. ¹Dept. of Obstetrics and Gynecology, Tokyo Women's Medical University, Tokyo, Japan, ²School of Nursing, Tokyo Women's Medical University, Tokyo, Japan.

Objective: The age-related distribution of bone and skeletal parameters was examined in young female subjects to establish methodologies for prophylaxis of osteoporosis through acquisition of high bone mineral density (BMD) in younger years as well as to identify interventional measures aimed at acquisition of high BMD in these women.

Subjects and Methods: All students attending School of Nursing at Tokyo Women's Medical University, and Toho Girls Junior and Senior High Schools during August 2004 and August 2006 were enrolled in the study with the exclusion of those who were receiving treatments that could affect bone. The subjects were inquired about their date of birth, birth weight, weeks at birth, and age at menarche using a questionnaire, and their body height and weight were also measured. As relevant bone-related parameters, BMD, bone mineral content (BMC), and bone area (BA) in the lumbar spine (L2-4) as well as in the total proximal femur (hip) were measured in these subjects using QDR-4500; (Hologic Inc., USA). In addition, blood samples were drawn from the subjects to measure their calcium (Ca), phosphorus (P), bone-specific alkaline phosphatase (BAP), and urinary N telopeptide of type I collagen (NTX) levels.

Results: 1,322 students comprised our study subjects who ranged in age from 12 to 30 years of age. Their mean birth weight was $3,101 \pm 431.3$ g, and their mean age at menarche was 12.0 ± 1.2 years old. Their body height peaked at the age of 14 years, and their body weight peaked at the age of 21 years of age. Their BMD peaked at the age of 18 years of age but their L2-4 BMD gradually increased thereafter. In contrast, their total hip BMD peaked at the age of 18 years but decreased thereafter. Their L2-4 BA showed a rapid increase until the age of 14 years, while their total hip BA continued to increase gradually beyond the age of 14 years. Their L2-4 BMC exhibited a rapid increase until the age of 18 years and continued to increase gradually with increasing weight, while their total hip BMC remained constant between the ages of 18 and 23 years old and then decreased thereafter. Additionally, their BAP and NTX values were shown to decrease by about 80% between the ages of 12 and 18 years. **Conclusions:** Of all constituents of BMD examined, BMC was associated with increases in body weight and changes in bone metabolic markers. In contrast, BA was associated with increases in body height until the age of 14 years, although it appeared to be influenced by body weight beyond that age. Study results pointed to a need for lifestyle intervention by the age of 18 and increasing body weight beyond that age to ensure acquisition of high BMD in young women.

Correcting DXA Pediatric Bone Mineral Density Measurements to Account for Fat Inhomogeneity. D. C. Lee, T. A. L. Wren, V. Gilsanz. Departments of Orthopaedic Surgery & Radiology, Childrens Hospital Los Angeles, Los Angeles, CA, USA.

Dual energy x-ray absorptiometry (DXA) assumes that the soft-tissue anterior/posterior (AP) to the vertebrae (bone region) has the same attenuation properties as soft tissue adjacent/lateral to the bone (soft tissue region). DXA areal bone mineral density (aBMD) measurements are therefore subject to error when there is an inhomogeneous distribution of soft-tissue. The purpose of this study was to use computed tomography (CT) to calculate the error in vertebral aBMD due to inhomogeneous fat distribution and to develop an equation to correct for this error using easily obtained clinical parameters.

CT (General Electric CT-T 9800) scans were performed on the lumbar vertebrae of 700

children (350 boys, 350 girls), age 5-24 yr. Based on CT axial slices through L3, fat percent was determined in the bone and soft tissue regions. The error in vertebral aBMD was then calculated and correlated with anthropometric parameters including age, height, weight, body mass index (BMI), and trunk width (laterally), thickness (AP), and circumference. A correction equation was generated using stepwise regression. This equation was tested on a separate validation group of 101 subjects (46 boys, 55 girls) to determine the extent to which the soft tissue error was reduced.

Fat percentage was higher in the bone region than in the soft tissue region in 599 out of 700 subjects (85.5%), with an average difference of $6.0 \pm 5.7\%$ ($p < 0.001$). This inhomogeneity resulted in an average error of $-7.2 \pm 7.4\%$ in aBMD measurements (range: -21.6% to 5.5%). Stepwise regression analysis indicated that weight and trunk width had the strongest influence on the measured error ($p < 0.001$). The correction equation derived from the stepwise regression was (Corrected aBMD [g/cm^2] = aBMD [g/cm^2] - $0.1144 + 0.0011 \times \text{Weight [kg]} + 0.0004 \times \text{Body Width [mm]}$). When this equation was applied to the validation group, the range of error decreased by 25.7% and the average was reduced from $-7.7 \pm 8.3\%$ to $-0.9 \pm 6.3\%$ (Figure).

Our findings show that soft-tissue AP to the vertebrae contains more fat than soft-tissue lateral to the vertebrae, resulting in erroneously low aBMD values. Using a correction equation based on weight and trunk width, this error can be reduced significantly. Further correction may be obtained by developing equations tailored for specific subgroups such as by age, gender, sexual or skeletal maturity, or measures of body composition.

Body Composition - Bone Relationship in Females Is Hormonal Stage Dependent: A Longitudinal Study. A. E. Lyytikäinen¹, F. Tylavsky², Q. Wang¹, H. Suominen¹, M. Alén¹, V. Ristimäki¹, E. Völgyi¹, S. M. Cheng¹, P. Rahkila¹, U. M. Kujala¹, E. Seeman³, S. Cheng¹. ¹Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, ²Department of Preventive Medicine, University of Tennessee, Memphis, TN, USA, ³Department of Medicine, University of Melbourne, Melbourne, Australia.

The relationships of bone mass to lean and fat mass are controversial. We hypothesized that 1) the associations of bone mass (BM) with lean tissue mass (LM) and fat mass (FM) will change during puberty and 2) the loss of BM in premenopausal and postmenopausal females is accompanied by the loss of LM. We followed the growth of 10-13-year (y) old girls ($n=258$) 84 months (mo). In addition 80 pre-menopause (PreM, mean age 43y) and 28 peri-menopause (PeriM, mean age 49y) mothers, and 72 post-menopause grandmothers (PostGM, mean age 67y) of these girls were measured twice at a 42 mo interval. Whole body BM, LM, and FM were assessed by DXA (Prodigy, GE Lunar). Hierarchical linear model was used to evaluate the changes in BM, LM, and FM relative to menarche for the girls and annual change in the mothers and grandmothers. The mean menarche age for the girls was 13.0 ± 0.9 y. The girls' BM accrual was accompanied by LM accrual until 3y after menarche. Thereafter, growth of LM ceased, but FM continued to increase (0.96 kg/y) and was the main contributor of body weight change (1.12 kg/y) near peak HT [164.5 cm (48mo), 164.8 cm (84mo)]. The annual changes of BM were associated with those of LM ($r^2=0.327$ for 0-24mo, $r^2=0.277$ for 24-36mo and $r^2=0.404$ for 36-84mo) and FM ($r^2=0.165$ for 0-24mo; $r^2=0.185$ for 24-36mo; and $r^2=0.313$ for 36-84mo). In PreM, no changes in BM and FM were observed, but LM decreased 0.4 kg , $0.94\%/y$. LM decreased both in PeriM (0.53 kg , $1.3\%/y$) and PostGM (0.63 kg , $1.5\%/y$). This decrease was the factor that accounted for the loss of BM (PeriM= 33 g , $1.3\%/y$, and PostGM= 20 g , $0.9\%/y$). In summary, the changes in BM and LM are synchronized during rapid growth period in early puberty. In late puberty LM ceases to increase, and the fat accumulation is associated with bone accrual. The small increase in LM has higher impact than that of fat during postpuberty to early adulthood. In premenopausal women, although LM decreases, its effect on BM is minor. However, in both peri- and postmenopausal females, the loss of LM is of great importance in the loss of BM. In conclusion, the influence of body composition on bone mass gain or loss is stage-dependent from prepuberty to late postmenopausal years.

Tibial Bone Mineral Density and Geometric Properties in Females of Three Generations. H. Q. Ma, E. Völgyi, H. Suominen, Q. Wang, P. Rahkila*, S. M. Cheng, A. Lyytikäinen, M. Alén*, S. Cheng. Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland.

The evolution of bone mineral density (BMD) and geometric properties throughout life is not well understood. In this study we investigated the volumetric BMD and geometric properties of the tibial shaft in female of three generations. Altogether 82 girls (G, mean age 17.9 ± 1.0 yrs), 76 mothers (M, 47 ± 4.8 yrs) and 47 grandmothers (GM, 71 ± 5.0 yrs) were measured using peripheral quantitative computed tomography. Total tibial cross-section area (tCSA), total bone mineral density (tBMD), cortical cross-section area (cCSA), cortical bone mineral density (cBMD), cortical thickness (cTh), bone marrow cross-section area (bmCSA), and muscle cross-section area (mCSA) were determined. Analysis of variance was used to compare the differences between generation groups. The girls had smaller tCSA than mothers and grandmothers showing the unaccomplished bone periosteal expansion. However, the tBMD of the GM group was 10% lower than either in the G or M groups due to the age related bone loss. The cCSA and cBMD were highest in the M group. The G group also had significantly higher cBMD than the GM group. The GM group had the thinnest cTh and largest bmCSA. Our results showed that the periosteal apposition may continue throughout life and endocortical resorption occurs in adult, but to a similar degree to the periosteal apposition in young adults keeping their cortical thickness unchanged. In older female, the periosteal apposition is less than the endocortical resorption thus cortex become thinner and bones become fragile.

Effect of the Dietary Habit of Skipping Breakfast on Bone Metabolism, Skeleton and Nutritional Status in Young Japanese Women. Y. Onoe¹, T. Kuroda¹, Y. Miyabara¹, M. Sakai¹, R. Yoshikata¹, M. Ohara¹, S. Orito¹, H. Okano¹, M. Kume², S. Sasaki³, H. Ohta¹. ¹Dpt. of Obstetrics and Gynecology, Tokyo Women's Medical University, Tokyo, Japan, ²Faculty of Nursing, Tokyo Women's Medical University, Tokyo, Japan, ³School of Public Health, the University of Tokyo, Tokyo, Japan.

The dietary habit of skipping meals not only affects systemic nutritional status but also influences intake of nutrients that are related to bone metabolism. However, it is unclear what effect such dietary habit may have on bone metabolism and skeleton. In our previous study, we have reported that ensuring appropriate physical activity, BMI, and serum 25(OH) D levels are crucial to acquisition of high bone volume during younger years. In this study, we examined the effect of skipping breakfast on nutritional status, intake of nutrients related to bone, and bone metabolism. Two hundred seventy-five healthy female volunteers aged 19 to 25 years old were enrolled in our study. All subjects were interviewed about their background information, and their height and body weight were measured. Their sera were tested for bone metabolic markers, such as BAP and NTX. Bone mineral density (BMD) was measured in these subjects using DXA (QDR 4500). The subjects were also asked about their current physical activity using a questionnaire as well as about their current diet using the self-administered Diet History Questionnaire (DHQ). The number of meals each subject skipped for breakfast, lunch and dinner during 1 week was obtained from the DHQ. Eighteen subjects (6.5%) had no breakfast during the week, while 131 subjects (45%) had breakfast every day of the week. The subjects were divided into two groups: those who had breakfast every day (group I) and those who skipped breakfast (group II). Significant differences were noted between groups in total energy intake and intake of three major nutrients (carbohydrate, protein and fat), with total energy intake and intake of the major nutrients becoming significantly lower with the increasing frequency of breakfast skipped. Oral intake of bone metabolism-related nutrients (Vit D, Vit K, Ca, P, Mg and K) was highest in group I with intake of each nutrient becoming significantly lower with the increasing number of meals skipped. Group I showed significantly higher BMD than group II in both the hip and L2-4. However, the habit of skipping breakfast had no significant effect on BMI. The habit of skipping meals had no significant effect on BAP, while it was significantly negatively correlated with NTX. Our data demonstrates that the habit of skipping breakfast leads to a decrease in systemic nutritional status, intake of nutrients, and bone metabolic and skeletal indices, thus suggesting that the habit of skipping breakfast hinders acquisition of high bone volume.

Correlation of Isokinetic Knee and Trunk Muscular Strength with Bone Mineral Content in Female Soccer Players. M. F. Saccol^{*1}, N. C. Oliveira^{*1}, A. S. Pinto^{*1}, R. M. Pereira¹, L. Takayama^{*1}, J. D. Greve^{*2}, F. R. Lima^{*1}.

¹Rheumatology Division (Bone Metabolism Laboratory), University of São Paulo, São Paulo, Brazil, ²Orthopedic Institute, University of São Paulo, São Paulo, Brazil.

The purpose of this study was to assess the correlation between knee and trunk muscle strength and bone mineral values in female junior soccer players. Twenty-two consecutive female soccer players with at least 15 h.wk⁻¹ of training during the previous year were compared with 20 females not engaged in regular exercise. Bone mineral density (BMD) and bone mineral content (BMC) were measured in lumbar spine (L1-L4), femoral neck and total femur of dominant hip, dominant leg and whole body by dual-energy X-ray absorptiometry (DXA). Fat mass and lean mass were also determined using whole body scan by DXA. Isokinetic muscle measurements were performed using the Biodex System 3 dynamometer with knee or trunk attachment on. Knee and trunk flexors and extensors strength were evaluated with 5 repetitions (concentric and eccentric modes) for the following variables: peak torque (PT), total work (TW) and set total work (STW). Statistical analysis was performed using Student t-test and Pearson's correlation. The two groups were alike regarding age, height, weight and calcium intake ($p>0.05$). Female soccer players had higher percentage of lean body mass (72.45 ± 3.52 vs. $66.75\pm5.45\%$, $p<0.001$) and lower percentage of body fat (23.7 ± 3.67 vs. $29.94\pm5.75\%$, $p<0.001$) compared to controls. For bone mineral values, the athletes demonstrated significant higher BMD and BMC compared to control group, in all sites evaluated ($p<0.05$). Dominant knee strength were also significantly higher for soccer group (concentric extension PT 150.46 ± 31.08 vs. 129.47 ± 21.72 Nm, $p=0.016$; eccentric extension PT 127.21 ± 27.15 vs. 104.85 ± 25.46 Nm, $p=0.009$). Related to trunk strength, only concentric mode had higher performance in the soccer group (concentric extension PT 214.23 ± 52.24 vs. 146.12 ± 49.72 Nm, $p<0.001$). All knee strength extension variables demonstrated positive correlation to BMC of leg, femoral neck and total femur of dominant hip ($0.46<r<0.70$). This correlation was also found for flexion knee strength, but only with PT variable ($0.42<r<0.64$). On trunk evaluation, only flexors strength performance were correlated with BMC of total trunk at variables TW ($r=0.525$) e STW ($r=0.513$). These findings of positive correlation between muscle strength and bone mineral values in a specific site reinforces that there is a direct role of muscle function on the accretion of the regional bone mineral mass.

Weight Bearing Bones Are More Sensitive to Physical Exercise in Boys than in Girls During Pre- and Early Puberty. S. Kriemler^{*1}, L. Zahner^{*1}, J. Puder^{*2}, C. Braun-Fahrlander^{*3}, C. Schindler^{*3}, M. Kraenzlin⁴, R. E. Rizzoli⁵.

¹Institute Sport & Health, Basel, Switzerland, ²Division Endocrinology, Diabetes & Clinical Nutrition, Basel, Switzerland, ³Institute Social & Preventive Medicine, Basel, Switzerland, ⁴Endocrinology, Diabetes and Clinical Nutrition, Basel, Switzerland, ⁵Rehabilitation & Geriatrics, University Hospital, Geneva, Switzerland.

Background: Physical activity (PA) positively influences bone mineral accrual. However, little is known whether there are gender differences in bone sensitivity to loading and to what extent spontaneous objectively recorded PA influences bone mineral mass independently from muscle mass. We investigated gender differences in the association between bone mineral density/content (BMD/BMC) and measures of PA, during pre- and early puberty.

Methods: We measured BMD/BMC and fat-free mass in 374 6-13-year-old children from randomly selected schools at the hip, lumbar spine and total body by DXA. PA was evaluated by accelerometers, and lower extremity strength by a jump&reach test.

Results: Boys had higher hip and total body BMD than girls at all ages. Boys had higher fat-free mass, greater lower extremity muscle strength and were more physically active than girls at all ages. Total hip BMD was positively associated with time spent in total and vigorous PA in boys ($r=0.33$ and 0.27 , respectively, $p<0.01$), but not in girls ($r=0.02$ and 0.04 , $p=ns$), even after adjusting for fat-free mass and lower extremity strength. While boys and girls in the lowest tertile of vigorous PA (22 min per day) had similar hip BMD (0.668 vs 0.679 g*cm⁻²), those boys in the highest tertile (72 min per day) had significantly higher values than the corresponding girls (0.730 vs. 0.692 g*cm⁻², $p<0.05$). In multiple logistic regression analyses, a low hip BMD in boys was best predicted by fat-free mass (OR 0.55 [95%CI 0.38, 0.78] per 1 kg) and total PA (OR 0.69 [95%CI 0.49, 0.98] per 106 counts), while in girls predictors included fat-free mass (OR 0.63 [95%CI 0.50, 0.79] per 1 kg) and jump&reach (OR 0.90 [95%CI 0.84, 0.98] per 1 cm). Similar data were obtained for femoral neck BMD/BMC. There was no influence of PA on lumbar spine BMD in either gender.

Conclusion: Though at low physical activity during pre- and early puberty, hip BMD is similar in both genders, it increases proportionally to PA, and differences in bone mineral mass between genders appears, likely related to a different sensitivity of bone to physical loading, independently from muscle mass.

Accrual of Lean Mass Has More Impact Than the Accrual of Fat Mass on BMC During Growth. F. A. Tylavsky¹, G. Somes^{*1}, M. Alen², A. Lyytikäinen³, V. Ristimäa^{*3}, S. M. Cheng³, H. Suominen³, U. M. Kujala^{*3}, S. Cheng³.

¹Preventive Medicine, University of Tennessee, Memphis, TN, USA,

²Health Sciences, University of Jyväskylä, Jyväskylä, Finland, ³University of Jyväskylä, Jyväskylä, Finland.

Many reports have focused on the role lean (LM) and fat mass (FM) plays in the accrual of bone mass. The objective of this study was to examine the relationship between FM and LM and bone mineral content (BMC), bone mineral density (BMD) as girls transition through puberty.

The study subjects consisted of 258 10-13-year old girls at the baseline. They were followed on average of 6.5 years and their results reflect the entire follow-up period ($n=217$). Whole body BMC, LM and FM were assessed by DXA (Prodigy, GE Lunar). Height, weight, Tanner stage and menarche status was obtained at baseline, 6, 12, 24, 36, and 84 months. 218 participants provided 1160 observations with a minimum of 2 and a maximum of 8 observations. 206 participants provided observations before menarche with a range of 1 to 6 observations from 51.6 months before menarche. 193 subjects provided observations after menarche with a range of 1 to 7 observations to 95.6 months after menarche.

	Mean \pm SD, kg			
	Weight	Fat Mass	Lean Mass	BMC
Before Menarche	43 \pm 8	11.4 \pm 6	30.0 \pm 4	1.6 \pm 0.3
After Menarche	54.1 \pm 9	15.4 \pm 7	36.3 \pm 4	2.1 \pm 0.3

Using random coefficients modeling in the MIXED procedure of SAS we found that subjects gained about 0.49 kg/month before menarche (BM) and 0.17 kg/month after menarche.

The weight gain was respectively portioned into 124 g/mo of fat and 355 g/mo of lean mass before menarche; and 108 g/mo of fat mass and 59 g/mo of lean mass after menarche. Regardless of menarche status, the effect of gains in lean and fat on BMC is that for every kg of fat mass there is a 16 g gain of BMC during puberty; for every kg of lean mass there is a gain of 47 grams of BMC; indicating the important effect of lean mass on the bone mass. We also found that the relative position within a cohort, LM, and BMC is already established by early puberty with fat mass being subject to environmental and pubertal changes. These findings provide evidence and implications for prevention of fat mass gain in those children who are at risk of overweight or obesity.

Determinants of Change in Bone Volumetric Density and Geometry Differ Between Boys and Girls in a Multiethnic Population. R. J. Wetzsteon, B. C. Kaufman^{*}, J. M. Hughes^{*}, S. Stovitz^{*}, M. A. Petit. Kinesiology, University of Minnesota, Minneapolis, MN, USA.

The purpose of this study was to explore determinants of change in bone volumetric density (vBMD, mg/mm³), bone area and estimated bone strength in a multi-ethnic population of boys and girls. A total of 116 (60 boys, 56 girls) children aged 10.9 ± 0.8 years at baseline participated. Ethnicity was based on CDC categories (17% Caucasian, 27% African American, 24% Hispanic, 10% Asian, 22% Other). Measurements of height, weight, and tibia length were taken by standard techniques; daily calcium intake and physical activity (PA score) were assessed by questionnaire; and dynamic power estimated by a vertical jump test. Peripheral quantitative computed tomography (pQCT) was used to assess the 50% site of the tibia for cortical volumetric density (CoD), area (CoA), polar strength-strain index (SSI_p), muscle cross-sectional area (MCSA), and total fat area (FatA). All measurements were taken at baseline and after 5-months. At baseline, boys and girls were similar in age, weight, calcium intake, PAscore, and vertical jump ($p < 0.10$ for all). Girls were significantly taller ($p = 0.04$). Baseline CoA and SSI_p did not differ between the boys and girls, but girls had greater CoD ($+2.2\%$, $p = .001$) which remained significant after adjusting for height. All bone values increased significantly over 5 months, but the magnitude of the change did not differ between boys and girls. Stepwise regression analyses were run to determine predictors of change with change in tibia length entered in the first step, and other predictors (change in MCSA, change in FatA, age, ethnicity, PAscore, average daily calcium, and change in vertical jump) entered in a stepwise manner if $p < 0.05$. Separate models were run for boys and girls. For both boys and girls, change in tibia length explained ~20% of the variance for change in SSI_p. For girls, change in MCSA explained an additional 31%, with daily calcium and change in vertical jump explaining and additional 10% of the variance. For boys, only change in MCSA entered the model explaining an additional 23% of the variance for change in SSI_p. These data are consistent with recently published data showing higher bone vBMD in girls. They also suggest that MCSA may be a reasonable surrogate of muscle force in boys, but for girls other factors (muscle power and calcium) may be important predictors of change in bone strength.

Deletion of the 25 Hydroxy Vitamin D 1 α Hydroxylase from Mice Expressing the Null Mutation for the Calcium Sensing Receptor Converts a Hypercalcemic to a Hypocalcemic Hyperparathyroid Phenotype. C. Richard^{*1}, D. Miao², R. Samadfar^{*1}, Y. Wang^{*1}, G. N. Hendy¹, D. Goltzman¹.¹Dept of Medicine, Calcium Laboratory, McGill University, Royal Victoria Hospital, Montreal, PQ, Canada; ²Department of Human Anatomy, Nanjing Medical University, Nanjing, China, China.

The calcium sensing receptor (CaSR) is functional mainly in the parathyroid gland and kidney, but likely as well in other tissues such as the gastrointestinal tract and the skeleton. These tissues are also target sites for the action of 1,25-dihydroxyvitamin D [1,25(OH)₂D]. Mice which are heterozygous or homozygous for the calcium sensing receptor null mutation (CaSR^{-/-} and CaSR^{-/-} respectively) develop hypercalcemia and hyperparathyroidism to a moderate or severe degree, respectively. Mice which are homozygous for targeted deletion of the 25 hydroxyvitamin-D 1 α -hydroxylase [1 α (OH)ase^{-/-}] which synthesizes 1,25(OH)₂D develop hypocalcemia, hyperparathyroidism and rickets but survive long term. To assess the interactions between the important calcium regulating molecules, CaSR and 1,25(OH)₂D, we created compound mutants of the CaSR and 1 α (OH)ase mutants and assessed their growth, biochemistry and skeletal morphology. CaSR ^{+/+};1 α (OH)ase^{+/+} mice grew normally and exhibited normal longevity. CaSR ^{+/+};1 α (OH)ase^{-/-} mice developed severe rickets and osteomalacia as assessed by faxitron x-ray analysis and von Kossa staining of the skeleton but survived at least 2 months. CaSR ^{-/-};1 α (OH)ase^{-/-} mice developed even more severe rickets, osteomalacia and growth retardation but also survived long term. BMD, assessed by PIXIMUS, was reduced by 68% in the lumbar spine and by 49% in the femur compared to wild type mice, but only by 58% and 38% in the lumbar spine and femur respectively of the CaSR ^{+/+};1 α (OH)ase^{-/-} mice. Although CaSR^{-/-};1 α (OH)ase^{+/+} mice develop severe hypercalcemia and most die before or shortly after weaning, deletion of the 1 α (OH)ase in CaSR^{-/-};1 α (OH)ase^{-/-} mice facilitated survival for at least 2 months although these animals exhibited the most severe growth retardation, rickets and osteomalacia of all mutants. All mutant animals showed evidence of hyperparathyroidism with CaSR^{+/+};1 α (OH)ase^{+/+} and CaSR^{-/-};1 α (OH)ase^{+/+} mice displaying hypercalcemia. In contrast, CaSR^{+/+};1 α (OH)ase^{-/-} mice and CaSR^{-/-};1 α (OH)ase^{-/-} mice were severely hypocalcemic (serum calcium 1.28 and 1.27mM respectively). The results indicate that the phenotypic manifestations of hyperparathyroidism may be markedly influenced by the vitamin D status of animals with CaSR mutations, confirm that elimination of hypercalcemia sustains longevity in mice homozygous for the CaSR null mutation, and suggest that mutations in the CaSR contribute to worsening of skeletal mineralization.

Targeted Inactivation of the Vitamin D Receptor by Caspase-3. P. J. Malloy^{*}, D. Feldman. Department of Medicine, Stanford University, Stanford, CA, USA.

Calcitriol inhibits the growth of many cells including breast, colon, ovarian, pancreatic, and prostate cancer cells by causing cell cycle arrest and in some cells by inducing apoptosis. In breast cancer cells, calcitriol induces apoptosis by a caspase independent mechanism. On the other hand, in prostate cancer cells, calcitriol induction of apoptosis involves activation of caspase activity. Calcitriol actions are mediated by the vitamin D receptor (VDR) a member of the steroid-thyroid-retinoid receptor superfamily of nuclear transcription factors. In LNCaP prostate cancer cells induction of apoptosis by staurosporine abolished [³H]1,25(OH)₂D₃ binding and VDR protein suggesting to us that the VDR might be targeted for inactivation by caspases, a family of cysteine proteases that are activated during apoptosis. We identified a potential caspase-3 cleavage site (DxxDS) in helix H2n (D₁₉₅MMDS₁₉₉) in the VDR ligand-binding domain. Mutations (D195A, D198A and S199A) were generated in the putative caspase-3 cleavage site and their effects on caspase cleavage of VDR examined. In reporter gene assays, all of the VDR mutants exhibited transactivation activity similar to the WT VDR. COS-7 cells transfected with WT and mutant VDR cDNA expression vectors were then treated with staurosporine and VDR examined by western blot. A 22 kDa cleavage fragment was detected on western blot from cleavage of the WT VDR and the S199A mutant VDR but not the D195A or D198A mutant VDRs. Addition of the caspase-3 specific inhibitor z-DEVD-FMK prevented cleavage of the WT VDR *in vivo*. Treatment of transfected COS-7 cells with calcitriol also resulted in cleavage of the WT VDR but not the D198A mutant VDR. Calcitriol-induced cleavage of the WT VDR was blocked with z-DEVD-FMK demonstrating that calcitriol activates caspase-3 in these cells. *In vitro* treatment with caspase-3 resulted in the cleavage of WT VDR and S199A but not D195A or D198A mutant VDRs. WT VDR was also cleaved by caspase-6, and -7 but not caspase-8 *in vitro*. In conclusion, our results demonstrate that the VDR is cleaved by caspase-3 *in vivo*. We further demonstrate that calcitriol induces caspase-3 activity that results in the cleavage of the VDR. Our results suggest that activation of caspase-3 by calcitriol, while contributing to apoptosis may also may limit the apoptotic effects of calcitriol in cells that express caspase-3. Since caspases also regulate the activity of many proteins under non-apoptotic conditions, the inactivation of VDR by caspases may be of general importance as a mechanism to limit calcitriol activity.

WG3

The Vitamin D Receptor, Hedgehog Signaling and Epidermal Carcinogenesis. A. E. Teichert^{*1}, J. J. Welsh^{*2}, D. D. Bikle¹. ¹Endocrine Unit, UCSF-NCIRE, San Francisco, CA, USA; ²Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, USA.

Over 1 million skin cancers occur annually in the United States, 80% of which are basal cell carcinomas (BCC) (16% squamous cell carcinomas, 4% melanomas), making it by far the most common cancer. Extensive epidemiologic data support the concept that the incidence of a number of epithelial malignancies (e.g. breast, prostate, colon) is reduced by increasing 25OHD levels. 1,25(OH)₂D₃, produced by the kidney from 25OHD or locally produced, reduces proliferation and enhances differentiation and thus has been investigated for a role in preventing or treating cancer. However, UVB exposure, which increases 1,25(OH)₂D₃ production in the keratinocyte, causes skin cancer. Conceivably, the 1,25(OH)₂D₃ produced by the skin provides at least partial protection from UVB induced skin cancer such that lack of 1,25(OH)₂D₃ or its receptor would make the skin even more sensitive to UVB induced malignancy.

We have chosen UVB epidermal carcinogenesis as a model to directly address the issue of the balance between the increased risk of UVB exposure as an inducer of carcinogenesis with the benefit of promoting vitamin D and thus 1,25(OH)₂D₃ production in the epidermis as a chemopreventive measure.

Mice deficient for the vitamin D receptor (VDR null mice), for which 1,25(OH)₂D₃ is a ligand, have a marked hyperproliferative response in the hair follicle and epidermis and decreased epidermal differentiation. These mice, when treated with 7,12 dimethylbenzanthracene (DMBA), unlike their wildtype littermates, develop skin tumors containing hair follicle elements and/or are of basal cell origin, tumors characteristic of overexpression of the hedgehog (HH) signaling pathway in keratinocytes. We found that the epidermis and hair follicles of the VDR null animals, as well as the DMBA induced tumors in VDR null mice, overexpress elements of the HH signaling pathway [Sonic Hedgehog (Shh), Patched 1 (Ptc1), Smoothened (Smoh), Gli 1, and Gli 2]. Moreover, keratinocytes in which the VDR has been knocked down with siRNA directed against the VDR show increased expression of Shh.

Interestingly, mice overexpressing Gli1, Gli2, or Shh in their basal keratinocytes or grafted with human keratinocytes overexpressing Shh develop BCC like lesions. Furthermore, BCC show overexpression of Ptc1, Smoh, Gli1 and Gli2, raising the question of a link between the vitamin D system, HH signaling and skin cancer predisposition.

These results suggest then that increased expression of Shh in the keratinocytes of the VDR null animal activates the HH signaling pathway, predisposing the skin to the development of BCC.

Childhood Hyperparathyroidism with Bilateral Slipped Femoral Epiphysis, Severe Bone Disease and Vitamin D Deficiency. R.N. Mehrotra¹, J. Pingle², U K Nayak³. ¹Department of Endocrinology, ²Orthopedics, and ³Head & Neck Surgery, Apollo Hospitals, Jubilee Hills, Hyderabad, India.

Primary Hyperparathyroidism (PHPT) in children is an uncommon disease. It constitutes less than 5% of all cases of PHPT. PHPT causing slipped epiphyses has been described, but is an uncommon manifestation. In contrast to asymptomatic disease seen in the west PHPT in Asians presents with more severe bone disease, large glands and are associated with low Vitamin D levels. This report is about a child with PHPT from India who presented with B/L slipped epiphyses and had associated severe bone disease. 12 year old girl had onset of pain in both the hip joints five years. She had associated symptoms of proximal weakness. As X-rays showed B/L slipped epiphyses she underwent fixation by screws. Repeat X-rays showed no healing. There has been gradually increasing valgus deformity at the knee. Her proximal weakness has increased. So much so that at presentation she was bed ridden because of severe deformity. During admission during transport she suffered a fracture of right fore arm. Initial calcium done previously was 8.2 mg/dl. At our hospital it was 11.9, with Phosphorus of 3 mg/dl. Alkaline phosphatase was 4050 u/l. Intact PTH levels was 2867 picogm/ml and 25 Hydroxy Vitamin D was 6.6 nanogm/ml. The X-rays showed subperiosteal re-absorption, Brown tumors, and severe deformities. U/S neck revealed parathyroid lesion of 2x3 cm. This was confirmed on Sestamibi scan. She underwent removal of parathyroid tumor. During surgery both neck sides were explored, but there was no evidence of second adenoma. Biopsy from second gland was normal. Immediate post op she had hypocalcaemia because of hungry bone disease. Histopathology showed parathyroid adenoma. She has been on Vitamin D and calcium supplements since then. At last follow up calcium was 9.0 mg/dl, PTH and alkaline phosphatase had declined. Repeat X-rays showed healing of Slipped epiphysis. Due to persistent deformities she underwent corrective osteotomies, and now she is able to walk.

Vitamin D deficiency and poor calcium intake modifies the disease presentation of PHPT in Indians. Slipped epiphysis seems to be due to changes in the metaphyseal spongiosa which leads to un locking of interdigitations due to increased PTH levels.

WG5

Tissue-specific Knockout of CaRs in Parathyroid Cells: A Model of Primary Hyperparathyroidism. W. Chang, C. Tu, T-H. Chen, D. Bikle, D. Shoback. Endocrine Research Unit, University of California, Department of Veterans Affairs Medical Center, San Francisco, CA, USA.

Serum ionized $[Ca^{2+}]$ is tightly maintained by the steep inverse relationship between $[Ca^{2+}]$ and the level of parathyroid hormone (PTH) secretion. Increases in the extracellular $[Ca^{2+}]$ ($[Ca^{2+}]_e$) activate signaling pathways that inhibit PTH secretion by ligating the extracellular Ca^{2+} receptor (CaR) expressed on parathyroid cells. Heterozygous and homozygous loss-of-function mutations in the CaR gene cause familial benign hypocalciuric hyperparathyroidism (FBHH) and neonatal severe hyperparathyroidism (NSHPT), respectively. Patients with these disorders demonstrate both hyperparathyroidism (HPT) and hypocalciuria depending on gene dosage effects. The deletion of both parathyroid and renal CaRs is thought to be necessary for the development of this phenotype. Mutations in the CaRs in FBHH and NSHPT cause reduced responsiveness and/or expression of the receptor in both parathyroid (PT) and kidney cells. To determine the contribution of parathyroid vs renal CaRs to the metabolic disturbances in NSHPT and FBHH and to discern the role of CaRs in tissues beyond the parathyroid and kidney, we generated a floxed CaR mouse ($CaR^{lox/lox}$) by inserting loxP sites flanking exon 7 of the CaR, which encodes the transmembrane and intracellular loops of the CaR. We bred parathyroid (PT)-specific CaR knockout ($^{PT}CaR^{-/-}$) mice using this $CaR^{lox/lox}$ mouse crossed to a transgenic PTH promoter Cre mouse line. The resulting heterozygous knockout ($^{PT}CaR^{-/-}$) mice were backcrossed to the $CaR^{lox/lox}$ mice to generate heterozygous and homozygous ($^{PT}CaR^{-/-}$) knockout mice and their wild-type (WT) littermates for analyses. $^{PT}CaR^{+/+}$ and $^{PT}CaR^{-/-}$ mice were born alive in normal Mendelian ratios. Serum total $[Ca^{2+}]$ were significantly elevated in the $^{PT}CaR^{-/-}$ (12.75 \pm 0.12 mg/dl) and $^{PT}CaR^{-/-}$ (15.60 \pm 0.19 mg/dl) mice, compared to WT controls (11.58 \pm 0.34 mg/dl), consistent with the phenotype of HPT and a gene-dosage effect. Urine $[Ca^{2+}]$ were also increased by \approx 60 and 80% in $^{PT}CaR^{+/+}$ and $^{PT}CaR^{-/-}$ mice, respectively, vs controls, supporting a compensatory hypercalciuria in $^{PT}CaR^{+/+}$ and $^{PT}CaR^{-/-}$ mice. While the $^{PT}CaR^{+/+}$ mice developed normally, the body weight of the $^{PT}CaR^{-/-}$ mice was \approx 25% of their WT and heterozygous littermates. The bones of $^{PT}CaR^{-/-}$ mice were significantly smaller and severely undermineralized as indicated by micro-computed tomography (μ CT) scans. This work confirms that decrements in parathyroid cell CaR expression are sufficient to induce HPT, growth retardation, and skeletal demineralization after birth. This floxed CaR mouse model will provide the opportunity to understand the role of CaRs in other tissues unhampered by the global metabolic disturbances of the generalized CaR knockout.

WG6

Bone Mass in Adults and Children with Hypoparathyroidism. MT Collins^{1,4}, JE McKie^{1,4}, JC Reynolds², KK Winer³. ¹Skeletal Clinical Studies Unit, CSDB, NIDCR; ²Nuclear Medicine Department; ³NICHD, NIH, Bethesda, MD, USA; ⁴Authors Contributed Equally.

Hypoparathyroidism is a rare condition that is associated with high bone mass. The mechanism of the development of high bone mass is unknown. Since adults and children differ in the cellular processes by which they maintain their bone mass, adults by remodeling and children primarily by modeling, differences between adults and children may shed light on the mechanism by which high bone mass is achieved in hypoparathyroidism. Seventy-five subjects were studied. There were 30 children (18/12 M/F, ages 4-19, median 11, length of disease 3mo.-15y, median 6.5y), and 45 adults (13/32 M/F, ages 20-75, median 45, length of disease 3mo.-35y, median 10y). Bone mineral density (BMD) was measured by Hologic DXA and Z-scores were calculated using the manufacturer's most recent reference database.

BMD at the PA spine (PASp) and femoral neck (FN) were increased in adults (mean Z-score = 1.8 \pm 2.0 and 0.98 \pm 1.1, respectively), but normal in children (0.36 \pm 1.3 and 0 \pm 1.4, respectively, for PASp adult to child comparison p=0.0008, and FN p=0.0017). To assess whether or not differences in BMD between adults and children were the result of length of hypoparathyroidism, adults and children were grouped and matched by length of disease (\leq 5 y, and 6-15 y). When there was \leq 5 y of hypoparathyroidism, there was no difference between adults and children in BMD Z-score at either the PASp or the FN (PASp: 0.95 \pm 0.89 vs 0.62 \pm 1.3, p=0.41, FN: 0.56 \pm 0.87 vs 0.37 \pm 1.6, p=0.69). However, when adults and children with 6-15 y of hypoparathyroidism were compared, adults had increased mean BMD Z-score at the PASp and FN (1.9 \pm 0.86 and 0.20 \pm 1.3, respectively, vs 1.0 \pm .93 and -0.25 \pm 1.3, respectively, for PASp adult to child comparison p=0.002, and FN p=0.016). When subjects with hypoparathyroidism due to autoimmune polyglandular syndrome (who often have malabsorption, gonadal failure, and/or are on glucocorticoid treatment for adrenal insufficiency) were excluded from the analysis, there was a significant positive correlation between length of disease and BMD in adults (PASp: R=0.41, p=0.0066, FN: R=0.35, p=0.03), but not in children (PASp R=-0.24, p=0.33, FN R=-0.25, p=0.30). Hypoparathyroidism did not have an effect on growth, as height was normal in children (height Z-score = -0.21 \pm 1.2).

From these data, it appears that normal skeletal modeling is not dependent on PTH, and the elevated BMD seen in hypoparathyroidism occurs only in the adult (remodeling) skeleton. These observations create novel perspectives from which to assess the role of PTH in the formation of the skeleton and the accrual of bone mass.

Genetic Mosaicism for *de novo* Mutations of the Calcium Sensing Receptor (CASR) Gene: Implications for Recurrence Risks in Autosomal Dominant Hypoparathyroidism. DEC Cole, BYL Wong, L Canaff, GN Hendy. Depts. of Laboratory Medicine & Pathobiology, Medicine, and Paediatrics (Genetics), University of Toronto, Toronto ON and Depts. of Medicine, Physiology and Human Genetics, McGill University, Montreal QC Canada.

In sporadic cases of autosomal dominant hypoparathyroidism (ADH) and familial hypocalciuric hypercalcemia (FHH), *de novo* mutations of the calcium sensing receptor gene (CASR) are not uncommon. Previously, we described somatic mosaicism in the healthy mother of two siblings with severe ADH due to an activating F788L mutation of CASR (JCEM 2003;88:3674). Here we report on the analysis of nine more parent/proband triads – five with *de novo* ADH and four with *de novo* FHH. Analysis of heterozygosity by denaturing high performance liquid chromatography (dHPLC) revealed that CASR exon 4 amplified from leukocyte DNA of the mother of one ADH proband (E228K mutation) had an abnormal melting profile suggestive of mosaicism. This was confirmed by allele-specific amplification for the 228K variant and inspection of the sequencing capillary electrophoretograms as well as sequence analysis of multiple subclones of the exon 4 amplicon. The degree of heterozygosity was estimated at \sim 10%, like the mother of the F788L proband, and is similar to that found in other *de novo* dominant disorders. In the eight remaining cases, dHPLC profiles were all normal, indicating that if somatic mosaicism was present, the proportion of the mutant allele in peripheral leukocytes was less than 1%. Our second mosaic family emphasizes that *de novo* mutations in offspring cannot be regarded as eliminating all risk for recurrence. Mosaicism should be factored into the *a priori* risk estimate and appropriate testing offered as part of the counseling process. Whether there is some significance to the fact that maternal activating mutations account for both instances of mosaicism remains to be seen. Similarly, the absence of any evidence for mosaicism in the other eight cases (ADH or FHH) may well be associated with reduced risk of recurrence, a supposition that can be addressed when a larger case cohort is evaluated.

WG8

Rett Syndrome: Bone Mass Determination in Girls and Mice. J. Shapiro, A. Boskey, G. Bibat, S. Doty, M. Blue, B. Metcalf, A. Khosravi, S. Naidu. Kennedy Krieger Institute, Baltimore, MD, Hospital for Special Surgery, NYC, NY, USA.

The purpose of this study was to evaluate osteoporosis in Rett (RTT) syndrome and the RTT murine model. RTT is an X-linked disorder caused by mutations in the Methyl-CpG-Binding Protein (MeCP2) located at Xq28. Some patients with severe seizures and RTT-like features have mutations in cyclin-dependent kinase-like 5 (CDKL5). Features of RTT include deceleration of head growth, early onset cognitive defects, and a movement disorder with stereotypic hand movements. Decreased bone mass on x-rays and an increase in fractures has been observed in RTT children unrelated to their ambulatory status.

Diagnosis was confirmed by mutational analysis in 25 RTT girls ages 1-14. Hologic DXA (n=19) scans were performed. Additionally, 6 MeCP2 deleted (heterozygote-/-) females and (knockout -/-) males were compared to 6 wks control C57BL/6 male and female mice by Faxitron and micro-computed analyses (GE-EVS), histology, and Fourier transform infrared imaging spectroscopy of mineral and matrix. For the girls, 8 of 17 subjects had lumbar spine Z-scores -2.0 or less; Z-scores were within reference range in 9 children. DXA values low for age occurred as early as 6 years. Four children were post pubertal. DXA hip scans could not be obtained because of anatomic variation and motion. Mean BMI ages 1-14 was 16.9 ± 2.1 , 15/24 used anticonvulsant drugs.

Micro CT Analysis of wild type (wt) and mutant mice (females (het) and male ko) are shown in the table as means with n=2/group.

	BMD(mg/cc)	Cortical			BMD	Trabecular		
		BVF	Imin*	Imax*		BVF	TbN	TbSp
M wt	1025.3	0.33	0.062	0.053	568.6	0.187	12.3	0.060
M ko	931.3	0.21	0.034	0.027	502.9	0.121	9.2	0.098
F wt	977.3	0.23	0.0313	0.026	477	0.126	8.52	0.105
F het	1024.	0.30	0.046	0.037	511	0.099	7.02	0.129

BVF Fractional bone volume; * Areal moment of inertia; TbN: trabecular number TbS: trabecular separation

Based on the 2 samples/group analyzed to date (-/-) bone has lower BMD and BVF, smaller moments of inertia, lower TbN and greater trabecular separation. The male (-/-) has decreased BMD, BVF, lower TbN and greater TbS. The (+/-) bone did not have altered BMD, but had greater BVF, but lower TbN and increased TbSp. The increased Imin and Imax suggests bone are stronger in the (+/-) females. Histochemical stains indicate a more intense procollagen presence in the (+/+) female compared to the (+/-) female. The intensity of stain was similar in (+/+) vs (-/-) males (n=4).

In conclusion, the low bone mass observed in 50 % of Rett children parallels the preliminary data that the MeCP2 murine models provide as models for RTT syndrome.

Bone Adaptation to Impact Loading - Significance of Loading Intensity. A. Vainionpää*¹, R. Korpelainen*², J. Leppäluoto*³, T. Jämsä*¹. ¹Department of Medical Technology, University of Oulu, Oulu, Finland, ²Department of Sports Medicine, Oulu Deaconess Institute, Oulu, Finland, ³Department of Physiology, University of Oulu, Oulu, Finland.

It is important to find efficient strategies for prevention of osteoporosis and fragility fractures as the prevention with medication is impossible at the population level. Exercise is one of the major prevention strategies even though the optimal loading patterns of bone have not yet been clearly defined in terms of bone loading forces in clinical settings. Our aim was to study the effects of impact loading on bone and assess the intensity and amount of efficient impact loading.

We conducted a 12 month population-based exercise intervention in 120 premenopausal women aged 35 to 40 years. The women were randomized equally to exercise (EG) and control groups (CG). The exercise regimen consisted of supervised, progressive high-impact exercises three times per week and an additional home program. Bone mineral density (BMD) in the proximal femur was measured by dual x-ray absorptiometry and bone geometry in the mid-femur was quantified by computed tomography (QCT). Also bone turnover was examined by using biochemical markers (TRACP-5b, PINP and Uncoupling Index). Daily impact loading was continuously recorded with a novel accelerometer-based measurement device and analyzed as the daily number of impacts within five acceleration ranges between 0.3 g to 9.2 g (g=acceleration of gravity, 9.81 m/s²).

Regular impact exercise increased the femoral neck BMD by 1.5 % (p=0.003) and led to geometric adaptations by increasing the mid-femur periosteal circumference by 0.2 % (p=0.03) when compared to controls. It also altered bone turnover balance in favour of bone formation. The women with the highest number of impacts at the intensity level above 4 g had the greatest increment in proximal femur BMD. The number of impacts needed exceeding this level was 60 impacts per day. Impacts exceeding 2.5 g were associated with increased periosteal circumference and enhanced bone turnover favouring bone formation.

According to our results, impact loading has significant dose- and intensity dependent effect on weight-bearing bones. The threshold for improving BMD in the hip is 60 impacts per day exceeding 4 g, while geometric adaptation and bone turnover activation can be achieved with lower intensity levels. Impacts required for osteogenic effects can be obtained during habitual exercise training. These thresholds for osteogenic exercise give tools to promote efficient exercise patterns to be included in everyday routines and personal activities, thus increasing the potential to affect in community level.

Timing of Peak Bone Mass and Bone Mineral Density Are Influenced by High-Level Physical Activity in Young Adults of Both Sexes. S. Breban*, C. Chappard, C. Jaffre*, C. Benhamou. Chr Orleans, INSERM Unit U658, Orleans, France.

Optimization of Peak Bone Mass may help to prevent osteoporosis and sport is known to be beneficial for bone tissue by increasing Bone Mineral Density (BMD). No study has reported effects of physical activity on Peak Bone Mass. Thus, the aim of this cross-sectional study was to analyse the influence of physical activity on timing and level of Peak Bone Mass.

70 girls and 90 boys aged 17-28 years participated in this study. The sample included 40 athlete-girls and 60 athlete-boys participating in weightlifting, ball collective sports or judo for more than 6 hours per week (9.6±3.5 hours per week for women and 10.4±3.7 for men). They were age and sex matched with control girls (n=30) and boys (n=30). Bone Mineral Content (BMC, g) and BMD (g/cm²) were measured by DXA (Delphi, Hologic®, Waltham, MA), at lumbar spine (LS) and non dominant femur (total and femoral neck (FN)). We also evaluated whole body (WB) BMC and BMD, with derived analysis of trunk, lower and upper limbs. Height, weight and body composition were derived from these DXA measurements. The timing of Peak Bone Mass was analysed by the inflexions of the age/BMD curves at all bone sites. Our variables were best fitted by second order polynomial regression equations. Thus, the model was expressed as $y=ax^2+bx+c$. The age of maximal bone mass was determined as the maximum of the curve, i.e. when $x = -b/2a$. Athletes had higher BMD measurements than controls in both sexes at all bone sites (p<0.05). Consequently all the Peak Bone Mass levels were significantly higher in athletes than controls. BMD peaks were achieved around 21.5 (FN), 22 years (LS), and 24-25 years (WB, upper and lower limbs) in athlete girls; BMD peaks were reached before 17 years for all bone sites except for LS (21.8 years) in control girls. In athlete boys, BMD peaks were reached before 17 years for upper and lower limbs, and ranged from 21.0 years (FN) to 25.5 and 26.0 years respectively for WB and LS. Finally, in control boys, BMD peaks were reached before 17 years at all bone sites. Timing of Peak Bone Mass was different according to bone sites, sex and athletic or non athletic status. Thus, those results confirm that weight-bearing physical activity lead to a better bone status compared to non athletes, in both sexes and even after puberty. Moreover, our data suggest that the Peak Bone Mass was not reached at all bone sites before 17 years: thus, it is yet possible to optimize BMD and Peak Bone Mass in young adults between 17 and 28 years. High level weight-bearing physical activity seemed to induce a delayed and higher Peak Bone Mass compared to controls.

Disclosures: S. Breban, None.

Exercise Prevents Falls and Maintains Bone Mineral Density in Elderly Postmenopausal Women. Preliminary data of the Erlangen Senior Fitness and Prevention (SEFIP) Study. W. Kemmler*, S. von Stengel*, W. A. Kalender*, K. Engelke. Institute of Medical Physics, University of Erlangen, Erlangen, Germany.

The aim of the study was to demonstrate that an intensive aerobic and strength training can maintain BMD at the spine and the hip and can prevent falls in elderly community-living women.

Via population registers we recruited 246 community-living women of 65 years and older. Exclusion criteria were medication or diseases related to bone metabolism, low aerobic capacity (<75 W on ergometry), and medication potentially increasing the likelihood of falls. There were no inclusion or exclusion conditions based on BMD or prevalent fractures. Subjects were randomly assigned to an exercise intervention group (EG: 2-3 sessions/week) or to a wellness control group (WCG: 1 session/week for three 10 week blocks). The exercise training consisted of 20 min of intense aerobic dancing (70-85% HF_{max}), 5 min of specific balance exercises and 35 min of isometric and dynamic (60-70% 1RM) strength training. No machines were used for the strength training part. All subjects were individually supplemented with calcium and cholecalciferol up to a maximum of 1500 mg/d and 500 IU/d. Bone mineral density at the lumbar spine and the hip was measured with DXA and QCT. Falls as defined by the PROFANE workgroup were counted using daily protocols conducted by all participants. Here we present initial 12 month DXA and fall results for 182 participants (EG: n=90; WCG: n=92).

After 12 months there were significant differences between exercise and wellness control group of BMD of the spine (EG: +1.4% vs. WCG: -0.3%) and of the hip (EG: -0.2% vs. WCG: -1.3%). The number of falls was significantly higher in the WCG (n=124) than in the EG (n=72). The same was true for injurious falls (EG: n=28 vs. WCG: n=42). In the exercise group 5 and in the wellness control group 8 fractures occurred but the power of the subset of patients included in this preliminary analysis was too low for the difference to be significant.

In conclusion preliminary results of our randomized exercise trial show that exercise training positively impact BMD at the hip and spine as well as fall frequency and may prevent fall related fractures in elderly subjects. The training scheme used in the study can easily be transferred into rehabilitation programs as no special equipment was used.

Disclosures: K. Engelke, Synarc 3.

Relationship Between Serum 25-hydroxyvitamin D₃ Concentration and Walking Ability, Leg Strength, or Balance in Community-Dwelling Japanese Frail Elderlies. J. Okuno*, S. Tomura*, H. Yanagi*, N. Yabushita*, T. Okura*, K. Tanaka*. Graduate school of Comprehensive Human Sciences, University of Tsukuba, Tsukuba City, Japan.

The aim of this study was to evaluate the relationship between serum 25-hydroxyvitamin D₃ (25OHD) concentration and walking ability, muscle strength, or balance in community-dwelling Japanese frail elderlies. The study was a longitudinal study conducted in a town near Tsukuba city (latitude 36°north) from June to September, in 2005 and 2006. Forty-five participants were community dwelling elderlies aged 65 years and over who required minimum support or nursing care to maintain their ADL. Their mean age was 76.5±5.9 years (mean±SD, range: 65-90). Of the participants, 32 attended a 3-month exercise program for nursing care prevention once per week (exercise group). The remaining 13 received only advice for nursing care prevention (control group). The Ethics Committee of University of Tsukuba approved the study. An interview was conducted based on a questionnaire including score of functional capacity of ADL (Tokyo Metropolitan Institute of Gerontology (TMIG) score), experiences of fall, stumbling and body sway during the past one year, walking ability, and the frequency of going outside of the home. The serum levels of 25OHD, intact parathyroid hormone (iPTH) and calcium were measured. The following physical tests were performed at baseline and 3 months: Timed Up & Go (TUG) and a 5-meter walk for walking ability, functional reach and foot balance with open eyes for balance, trunk flexion for flexibility, and ankle strength and grip strength for muscle strength. Among 45 patients who underwent the tests, 66.7% and 40% had difficulties in standing up and in walking, respectively. 54.3% experienced falls, 73.8% experienced stumbling and body sway more than once during the past one year. The mean level of 25OHD was 62.1±13.7 nmol/L (mean±SD, range: 27.5-87.5). At baseline, the rate of 25OHD levels less than 50 nmol/L that is the cut-off point of 25OHD resulting from the significant difference of intact PTH level was 18.0%. At baseline and 3 months there were no significant differences in physical tests between the control group and the exercise group. The subjects with 25OHD levels more than 50 nmol/L at baseline improved their walking ability and ankle strength for a period of three months in both groups. On the other hand, the subjects with 25OHD levels less than 50 nmol/L did not improve their physical performance even in the exercise group. It is suggested that serum 25OHD level is related to walking ability and muscle strength in Japanese frail elderlies, and that serum 25OHD level more than 50 nmol/L may be needed for maintaining their mobility or balance.

Sclerotic Bone Changes Found on Densitometry Testing in a Patient with a Remote History of Breast Cancer. L. Eck, R. Bhattacharya, B. Lukert. University of Kansas Medical Center, Kansas City, KS, USA.

Background: Sclerosing bone disorders presenting with increased skeletal mass are caused by many rare, often hereditary dysplastic conditions, as well as by dietary, metabolic, endocrine, hematologic, infectious, and neoplastic processes.

Case Report: A 53 year old white female with a remote history of breast cancer on aromatase inhibition therapy presented for routine osteoporosis evaluation. Her only subjective complaint was mild, intermittent left sided back discomfort of six months duration. Densitometry findings were significant for substantial increases in bone mineral density since testing two years prior. The lumbar spine density was 1.684g/cm² which was increased from 1.115g/cm², resulting in a 51% upward trend. The hip density was 1.241g/cm² which was increased from 0.980g/cm², resulting in a 28% upward trend. Concomitant laboratory testing was significant for normal renal function, recent onset normocytic anemia, serum calcium of 8.7mg/dL (8.5-10.4mg/dL), PTH of 92 pg/mL (10-65pg/mL), elevated phosphorous of 4.4mg/dL (2-4mg/dL), significantly elevated alkaline phosphatase of 361U/L (25-110U/L) and bone specific alkaline phosphatase of 129.0mcg/L (5-18.2mcg/L), elevated AST at 103U/L (7-40), normal 25-hydroxy vitamin D at 35ng/dL, and a normal TSH.

Due to substantially increased bone mass on densitometry, an evaluation for a pathologic etiology of osteosclerosis was undertaken. Hepatitis C serology was negative. Heavy metal screening was normal. Vitamin A intoxication was ruled out. Serum and urine protein electrophoresis were unremarkable. An ACE level was found to be within normal limits. Plain films of the hip and spine revealed diffuse osteosclerotic changes. A technetium bone scan revealed mild to moderately increased activity in bilateral humeral heads and calcanei. CT scans of the chest and abdomen showed trabecular sclerosis without evidence of lytic lesions. A bone marrow biopsy and aspirate was performed and was significant for carcinoma cells with positive histochemical staining for pan-cytokeratin consistent with metastatic breast cancer. An increased number of osteoblasts were seen on the bone marrow touch preps. A bone biopsy was performed. The specimen was suboptimal but did show evidence of increased bone turnover.

Discussion: This case highlights the finding of osteosclerotic breast cancer metastases in a patient greater than ten years out from her initial breast cancer diagnosis. Sclerosing bone disorders can be identified with routine bone densitometry. The differential diagnosis of non-hereditary sclerosing bone disorders includes fluorosis, heavy metal poisoning, hepatitis C, hypervitaminosis A and D, hyper-, hypo-, and pseudohypoparathyroidism, renal osteodystrophy, leukemia, lymphomas, mastocytosis, multiple myeloma, sarcoidosis, and skeletal metastases.

Bone metastases in breast cancer may be osteolytic, osteosclerotic, or a mixture of the two. Osteoblastic metastases are lesions having both increased bone formation and resorption. The metastatic lesion is radiodense/sclerotic in appearance when bone formation is greater than resorption. Osteoblastic metastases begin in the marrow cavity. Most prostate cancer metastases and few breast cancer metastases are osteoblastic. The tumor-related factors that induce new bone formation may include endothelin-1, prostate specific antigen, bone morphogenic proteins, urokinase, insulin-like growth factors, osteoprotegerin, or other substances.

It is imperative that we are cognizant of osteosclerotic findings on dual energy densitometry as well as unusual increases in density on serial testing in order to avoid missing underlying pathologic conditions.

WG14

Osteomalacia Following Gastric Bypass and Biliopancreatic Diversion Surgery. A.O. Al-Shoha, R. Lakhdar, D. S. Rao. Internal Medicine and Bone & Mineral Metabolism, Henry Ford Hospital, Detroit, MI, USA

Gastric bypass surgery (GBS) and Biliopancreatic diversion (BPD) are the two most common procedures for morbid obesity, a disorder that is increasing in epidemic proportions in the US and world wide. There have been reports of metabolic bone disease after GBS. However, to our knowledge, only two cases of post-GBS osteomalacia (OM) have been reported. The diagnosis of OM in both cases was based solely on biochemical findings. We report 4 patients with bone biopsy confirmed OM after GBS.

Four patients (3 women and 1 man; age range 29-53y) were seen for evaluation of metabolic bone disease not responding to "usual" therapy. Two of the 4 patients had BPD; one of those 2 had gastric stapling (GS) about 9y before BPD (Case 2). The other 2 patients had Roux en-Y GBS (GBS); one of those had GS at the time of GBS (Case 3) and the other had jejunoileal bypass 26y before GBS (Case 4). Clinical features included generalized bone pain and tenderness, muscle weakness, difficulty walking, and waddling gait, stooping posture, and fractures. Two patients (Cases 2 and 4) had history of kidney stones at presentation. Diagnoses prior to referral were varied including arthritis, gout, vitamin D deficiency and osteoporosis. Serum chemistry (Table) and radiological findings were suggestive of OM in all the 4 cases, and the diagnosis was confirmed by bone biopsies. Following high doses of Vitamin D and calcium therapy there was significant improvement in the symptoms and functional status and biochemical variables.

	Case 1	Case 2	Case 3	Case 4
Time to presentation (years)	5	2	5	5
25-hydroxyvitamin D (ng/mL)	9	6	5	7
Corrected Calcium (mg/dL)	9.5	8.8	8.9	7.3
Alkaline Phosphatase (IU/L)	249	227	1246	178
PTH (pg/mL)	297	324	504	498

Our experience suggests that GBS may predispose to severe Vitamin D depletion and OM in the absence of high dose vitamin D and calcium supplements. The current "usual" recommendations are grossly inadequate in this population and the presentation may be non-specific and misleading. Prospective long-term studies are needed to determine the appropriate vitamin D dose to prevent metabolic bone disease in this uniquely susceptible population.

WG15

Unusual Presentation of Severe Vitamin D Deficiency Osteomalacia in a Patient with Congenital Hypophosphatemia. M. Cardenas, M. Honasoge. Henry Ford Hospital, Detroit, MI, USA.

Introduction: Congenital hypophosphatemic osteomalacia (HPOM) is generally not associated with secondary hyperparathyroidism (SHPT) in the absence of phosphate therapy. We present a patient with HPOM diagnosed in adulthood with severe vitamin D deficiency and SHPT.

Case Report: Thirty year old man was referred for evaluation of multiple low trauma fractures and muscle weakness. He has a history of intractable seizure disorder and mental retardation since age 18 months. No gait abnormalities, pain or deformities were noted during childhood. Progressive weakness and severe kyphosis developed over the past 8 years to the point that he was unable to walk without assistance. He has been on multiple medications for seizure disorder including phenobarbital, phenytoin, carbamazepine and more recently levetiracetam, and topiramate. Hypophosphatemia was noted 5 years ago and calcitriol 0.25mcg/d and ergocalciferol 50,000 IU/monthly were started by a neurologist. No family history of hypophosphatemia or rickets. Mother and sister are short but their serum phosphate levels are normal.

He was short (height 154cm, length of the legs 79cm), with severe kyphosis and proximal muscle weakness. Serum phosphate was 1.9 mg/dl and calcium 8.4 mg/dl, 25-OHD was 9ng/ml, and alkaline phosphatase and PTH were high (538 IU/L & 267 pg/ml respectively). His renal function was normal, but with mild metabolic acidosis. BMD by QCT was high in the spine (T score +8.2 and Z score of +8.1) and normal in the hip (T score of -0.9 and Z score of -0.9). X-rays showed osteosclerosis in the axial and marked osteopenia in the appendicular skeleton. Multiple healing pseudofractures were seen in the forearms, femur and fibula along with enthesiopathy around the pelvic bones.

Calcitriol and ergocalciferol doses were increased to 0.5mcg bid and 50,000 IU twice a week respectively. Therapy with sodium phosphate 500mg tid and calcium carbonate 600mg tid was started and topiramate discontinued. Hypophosphatemia and metabolic acidosis improved but SHPT continues despite vitamin D and calcium repletion. Proximal muscle weakness has improved.

Discussion: The patient has rather unique clinical, radiological and biochemical features of congenital HPOM complicated by severe vitamin D depletion and SHPT. Diagnosis was delayed until fractures and muscle weakness related to vitamin D deficiency complicated the clinical picture. Numerous healing pseudofractures in the forearm, an unusual finding in vitamin D depletion, are most likely due to trauma related to wheelchair use. Prior use of phenobarbital, phenytoin and carbamazepine may have aggravated vitamin D deficiency.

Conclusion: Diagnosis of HPOM may be complicated by severe vitamin D depletion and SHPT especially in patients on anticonvulsant therapy. Topiramate may aggravate metabolic acidosis related to SHPT.

WG16

Use of Teriparatide in Hajdu-Cheney Syndrome. P.J. Tebben, R.D. Tiegs, B.L. Clarke. Endocrinology and Metabolism, Mayo Clinic, Rochester, MN, USA.

To describe the response of two patients with Hajdu-Cheney Syndrome (HCS) to therapy with teriparatide.

The clinical, biochemical, and radiographic data of two patients with HCS are provided.

Case 1: A 55 year-old female was referred for evaluation and management of osteoporosis and HCS. Clinical findings included progressive acro-osteolysis, short stature, delayed closure of several cranial sutures, enlarged sella turcica, premature loss of teeth, low bone density, and fractures. During a 2 year course of conjugated equine estrogen (0.625 mg/day) and alendronate (70 mg/week) her bone mineral density (BMD) at the spine (L2-L4) declined by 8.2% and at the left hip declined by 3.5%. Serum calcium, phosphorus, creatinine, PTH, and alkaline phosphatase were within the reference range.

Due to declining BMD and vertebral fractures, teriparatide 20 mcg daily for 2 years was substituted for the alendronate. A 12.4% and 4.2% improvement was seen in the spine and left hip, respectively, over the initial 6 months of treatment followed by subsequent decrements in BMD at both sites. She also sustained a left tibial fracture after one year of teriparatide. Acro-osteolysis in her hands progressed while on teriparatide, a process that continued after substituting intravenous zoledronic acid (ZA) for teriparatide. Her BMD continued to decline on ZA.

Case 2: A 50 year old male was referred for evaluation of progressive acro-osteolysis affecting his left hand that was first apparent as a teenager. Although the disease was quiescent for several years, he developed similar findings in his right hand at age 35 while working as an artist. Features consistent with HCS included progressive acro-osteolysis, low BMD, and fractures. Teriparatide therapy had been initiated prior to his referral and after three years of alendronate. Serum calcium and total alkaline phosphatase were mildly elevated presumably due to teriparatide. Serum phosphorus and creatinine were within the reference range.

BMD increased by 7.3% and 10.2% at the spine and left hip, respectively, while on alendronate. BMD increased by 5% at the spine, but declined by 6.2% at the hip while on teriparatide. It was also felt that the rate of progression of acro-osteolysis had increased while on teriparatide.

HCS is an autosomal dominant condition characterized by a slowly progressive skeletal dysplasia including acro-osteolysis. Low BMD, fractures, short stature, and typical facial features are frequently described. The molecular pathogenesis is unknown. Beneficial effects of bisphosphonates have been reported in patients with HCS. Our two cases suggest that teriparatide does not effectively improve bone density or slow acro-osteolysis and that bisphosphonate therapy may be superior.

WG17

Very Low or Undetectable Intact Parathyroid Hormone Levels in Patients with Surgically Verified Parathyroid Adenomas. S. Bhadada¹, M. Cardenas², A. Bhansali¹, BR Mittal², A. Behra³, G.V. Chanukya¹, U. Nahar⁴, D. Sudhaker Rao⁵. ¹Departments of Endocrinology, ²General Surgery, ³Nuclear Medicine, ⁴Pathology, Postgraduate Institute of Medical Education & Research, Chandigarh, India; ⁵Bone & Mineral Research Laboratory, Henry Ford Health System, Detroit, MI, USA.

Background: In patients with primary hyperparathyroidism (PHPT), serum PTH levels are either within the upper half of the reference range or clearly elevated in most patients. However, a few case reports have appeared with very low or undetectable PTH levels in patients with PHPT. We report 3 such patients and explore potential reasons for undetectable or low serum PTH levels in patients with surgically verified PHPT, review the relevant literature, offer suggestions for management of such patients occasionally encountered in clinical practice and for future research to help understand mechanisms underlying "undetectable" or inappropriately low PTH levels. Material & Methods: Serum intact PTH level was measured pre and postoperatively by immunochemiluminometric assay and the results were confirmed by at least two repeated measurements on different occasions. The 3 unusual patients with PHPT had typical biochemical and/or clinical features of the disease (pancreatitis and kidney stones). However, the serum PTH levels were either very low or undetectable in the context of hypercalcemia in two patients and normal serum calcium in the third. All patients had ^{99m}Tc sestamibi scan showing increased uptake in one of the parathyroid glands. The patients underwent surgery with the removal of a parathyroid adenoma.

Results: The mean serum Ca was 10.4 ± 1.3 mg/dl and 11.8 ± 0.29 mg/dl in the two patients with hypercalcemia and 8.6 ± 1.3 mg/dl in the third, but serum PTH levels were either very low or suppressed in all (2; 10 and 12.3 pg/ml respectively). Post-operatively, serum calcium levels normalized in the two hypercalcemic patients. In contrast, serum intact PTH levels, which were either suppressed or very low before surgery, rose and remained within the reference range in all the 3 patients.

Conclusions: In the context of a high degree of clinical suspicion, the diagnosis of PHPT should be pursued despite suppressed or low normal serum PTH levels after careful and thorough exclusion of other rare causes of hypercalcemia. However, secretion of PTHrP remains a possibility. Further research on various PTH molecular species secreted by parathyroid adenomas and potential post-translational changes in PTH molecule that might interfere with in vitro measurements should be pursued to understand the precise reason(s) for such anomalous findings.

Novel Algorithm Using ^{99m}Tc-MIBI Scintigraphy, Sequential Whole Body Magnetic Resonance Imaging and Venous Sampling for Fibroblast Growth Factor -23 for Tumor Localization in Tumor Induced Osteomalacia. Sushil Kumar Gupta¹, Srikanth Kongara^{1*}, Sanjay Gambhir², Amit Agarwal³, RV Phadke⁴, Sunil Jain⁴, Manoj Kathuria⁴, Rakesh Pandey⁵, V. Ramesh⁵, Amit Rawat⁵, Isha Tyagi⁶, Rajan Syal⁶, Raman Boddula¹, Gangadhar Taduri⁷, Madan M Godbole¹, Gunter Path⁸, Luitgard Kraus⁸, Jochen Seufert⁸. ¹Department of Endocrinology, ²Nuclear Medicine, ³Endocrine Surgery, ⁴Radiodiagnosis, ⁵Pathology and ⁶Neurosurgery (Neuro-otology unit). Sanjay Gandhi Post Graduate Institute of Medical Sciences, Raebareli Road, Lucknow, India; ⁷Department of Nephrology, Nizams Institute of Medical Sciences, Hyderabad, India; ⁸Division of Endocrinology and Diabetology, Department of Internal Medicine-2, University Hospital of Freiburg, Freiburg, Germany.

Background: Localization of mesenchymal tumors causing tumor induced osteomalacia (TIO) is often difficult, delaying surgical cure by several years. No standardized protocol exists for rapid tumor localization. We have evaluated the role of whole body ^{99m}Tc-MIBI scintigraphy, sequential whole body magnetic resonance imaging (MRI), and venous sampling for fibroblast growth factor-23 (FGF-23) in tumor localization in suspected cases of TIO.

Methods: Six patients of adult onset hypophosphatemic osteomalacia were subjected to ^{99m}Tc-MIBI scintigraphy. Focused MRI was done for MIBI positive regions in five patients. Sequential whole body MRI was performed in a systematic manner starting from areas of highest regional prevalence to lowest regional prevalence (pelvis and thighs, legs and foot, head and neck, upper limbs, thorax and abdomen) in MIBI negative case. Selective or systemic venous sampling for serum FGF-23 was performed in five patients. FGF-23 mRNA expression analysis of tumor tissue was done post operatively in all. Serial estimations for serum calcium, phosphorus, and FGF-23 were performed postoperatively.

Results: Whole body ^{99m}Tc-MIBI scintigraphy revealed enhancing lesions in five patients which were subsequently confirmed as tumors by focused MRI. In one MIBI negative patient, sequential whole body MRI localized the tumor. Baseline serum FGF23 levels were elevated in all patients (range: 91.5-3863 RU/ml, normal range: 11-30). Venous sampling identified higher FGF-23 concentration in the major draining vein of tumor as compared to contralateral/distant vein in four patients. Surgical cure was achieved in 4 patients while 2 patients had incomplete excision of tumor. Tumor tissue from all the patients abundantly expressed FGF-23 mRNA. Postoperatively, serum FGF-23 declined to normal or marginally above the normal range in surgically cured patients.

Conclusion: Whole body ^{99m}Tc-MIBI scintigraphy, sequential whole body MRI and venous sampling for FGF-23 facilitate early localization of phosphaturic tumors in suspected TIO patients. Serum FGF-23 monitoring improves postoperative management.

WG19

Risedronate Preserves Bone Turn Over as Measured by Biochemical Markers After 5 Years Treatment in Postmenopausal Greek Women. I.C. Koulouris, G. Skarantavos, Th. Kaplanoglou, P. Katsimbri, E. Metania, G. Antipas, E. Konstantellou, P.N. Soukakos. 1st University Orthopaedic Clinic, Attikon University Hospital, Athens, Greece, and Agios Panteleimon General Hospital, Pireaus, Greece.

Increased rates of bone turn over, as observe in many PO women, are associated with loss of bone mass, determination of trabecular architecture and a decrease in mineralization of bone tissue.

The aim of this study was to investigate the effect on uNTX, sCTX and PTHi following daily continuous administration of Risedronate for 60 months in early postmenopausal Greek women.

Material and Methods: Forty early postmenopausal women between 48-53 years old (mean 50 years), 6 months -1year after the menopause, with T score <2SD on lumbar spine DEXA and without any prior metabolic disorders or fractures were separated into 2 groups: Group A (n=30) received 5mg Risedronate, 1mcg Alfacalcidol and 1000 mg Calcium carbonate daily for 12 months and 0.5 mg Alfacalcidol and calcium for the rest of the study period, while group B(n=10) received the same doses of Alfacalcidol and calcium for the first 12 months and only 1000 mg calcium carbonate thereafter. From 36 months Risedronate was given as 35mg once weekly. Serum and urine bone turnover markers were measured at 0,6,12,24,36,48 and 60 month intervals by automated electrochemiluminescence assay. No premenopausal values were available for comparison. Two patients in group A discontinued treatment after 24 months was to investigate the effect of daily administration of Risedronate to early postmenopausal Greek women for 5years by measuring sCTX changes, uNTX, urine PTHrP, serum osteocalcin, PTHi and 25(OH) D. A questionnaire including VAS score and PPI score concerning quality of life indexes was completed and reevaluated by all patients at the above intervals. Results:: 1)Group A showed a statistically significant decrease in uNTX (16,15%,p<0.0005) as early as 6 months after treatment whilst there were no statistically significant changes after the 12month period. In group B uNTX was increased (10,9 %, p<0.0005) while the rest of the markers showed a statistically significant decrease for the same period. No values fell below the normal range Group 2)A showed a statistically significant decrease in sCTX(11,69%,p<0.0005) as early as 6 months after treatment whilst there were no statistically significant changes after the 12month period. In group B sCTX was increased (13.32%, p<0.0005) while the rest of the markers showed a statistically significant decrease for the same period. No values fell below the normal range.3) PTHi changes both of groups its not significant.A showed improved indexes in the quality of life scores.

Conclusion: Changes in the measured markers, especially sCTX, uNTX, demonstrate that Risedronate effectively decreases the turnover as early as 6 months after treatment and the effect is maintained without further changes from the end of the first year until the end of the 60 months period provided that vitD is sufficient. The fact that no values fell below normal, during the first year of treatment and bone markers continued to keep this values during the following years of treatment, excludes the untoward presence of frozen bone. Quality of life was also improved in the Risedronate group without any untoward effects from upper gastrointestinal tract and musculoskeletal system. No values fell below normal, during the first year of treatment and bone markers continued to keep this value during the following 5 years of treatment.

WG20

Old Before His Time: A 16 Y/O Male with Idiopathic Juvenile Osteoporosis. Vollbrecht, Jill E., and Rao, D. Sudhaker. Bone & Mineral Metabolism, Henry Ford Health System, Detroit, MI, USA.

Idiopathic juvenile osteoporosis (IJO) is a self-limited phenomenon causing reduced trabecular bone formation, which leads to vertebral and metaphyseal fractures during early puberty. While the disease course follows a typical clinical pattern, the diagnosis is often made well after it has resolved, leaving the clinician with many questions regarding the appropriate treatment. We present a case of a 16 y/o male with recurrent fractures and IJO.

This patient is a 16 and 5/12 months' y/o Caucasian male who was referred for evaluation of recurrent fractures. The patient had been diagnosed with skull and rib fractures at ages 3 and 6 years, respectively, after two traumatic accidents. He remained fracture-free until age 10, when he sustained distal radius, metacarpal, and fibula fractures while playing sports. At age 11, he fractured his right mid-femur after falling from standing height during a soccer game; its repair required retrograde intramedullary flexible nailing. Later that year, spine radiographs, obtained to evaluate complaints of back pain, showed symmetric, biconcave compression deformities of most thoracic and lumbar vertebrae. Shortly thereafter, he developed a transverse fracture of the left scapula while rollerblading.

The patient has no family history of recurrent fractures, and has had no other medical problems. His height has historically placed him between the 5th and 10th percentiles for gender and age, and his weight has remained at the 50th percentile. His physical exam at age 11 was notable for Tanner I virilization. His initial laboratory evaluation, performed in 2003, was unremarkable except for an abnormality in growth hormone: post-dexamethasone cortisol 1 ug/dL (0-5 ug/dL); 25(OH)-vitamin D 61 ng/mL (15-80 ng/mL); iPTH 31 pg/mL (10-75 pg/mL); calcium 10.2 mg/dL (8.2-10.2 mg/dL); P 5.3 mg/dL (2.5-4.5 mg/dL) BSAP 157.2 U/L (20-166 U/L for age); alkaline phosphatase 252 U/L (38-126 U/L for age); IGF-I 63 ng/mL (109-485 ng/mL for a Tanner I male).

He was treated with daily growth hormone injections for one year based on his low IGF-I, but demonstrated no significant change in height. A skin biopsy was obtained for evaluation of possible osteogenesis imperfecta, was normal. After his evaluation was complete, no diagnosis was made and no treatment offered. At age 15, he re-fractured his right mid-femur and again required intramedullary nailing; his orthopedic surgeon noted atypical "softening" and "widening" of the bone during the procedure.

One year after his second femur fracture, he presented for a second opinion on his fractures. His physical exam at age 16 demonstrated a visible limp and marked thoracic kyphosis, as well as Tanner III virilization. His IGF-I had normalized (IGF-I 166 ng/mL (94-765 ng/mL)), and all other labs were essentially unchanged. Total testosterone was slightly low: 203 ng/dL (241-827 ng/dL).

Given that the locations of his fractures were predominantly metaphyseal and vertebral, and that they occurred during early puberty, a presumptive diagnosis of IJO is made. IJO has been described in fewer than 200 cases in the medical literature, and is generally associated with a return to normal bone density by adulthood. The dilemma in managing these patients involves determining the appropriate treatment within the appropriate timeframe, which is often difficult to assess. It is unclear whether or not treatment with anabolic or antiresorptive therapy is beneficial once the patient's bone density begins to recover, as is likely the case in this patient.

Glucocorticoid Enhances the Expression of a Wnt Antagonist, Secreted Frizzled-Related Protein 3, in Cultured Human Osteoblasts. K. Ohnaka^{*1}, Y. Matsuzaki^{*1}, M. Tanabe^{*1}, M. Adachi^{*1}, H. Kawate^{*1}, R. Takayanagi².

¹Department of Geriatric Medicine, Kyushu University, Fukuoka, Japan;

²Department of Medicine and Bioregulatory Science, Kyushu University, Fukuoka, Japan.

Glucocorticoid-induced osteoporosis (GIO) is one of the most frequent and serious problems of long-term glucocorticoid therapy. Although the major cause of GIO is considered to be impairment of bone formation, detailed mechanism underlying GIO remains to be fully elucidated. Recently, the Wnt signal emerged as a novel key pathway for promoting bone formation. In this study, we investigated the effect of glucocorticoid on a Wnt antagonist, secreted frizzled-related protein (sFRP), in cultured human osteoblasts and an osteosarcoma-derived cell line, MG-63 cells. The expression of mRNA for secreted frizzled-related protein 3 (sFRP3) was markedly induced by dexamethasone among sFRP families. The expression of sFRP3 was also enhanced by hydrocortisone and prednisolone, but not by 17- β estradiol, dehydrotestosterone or 1, 25-dihydroxyvitamin D3. Similar effect of dexamethasone on sFRP3 expression was observed in MG-63 cells. To examine the effect of sFRP3 on osteoblast function, we then generated an expression vector containing entire coding region of human sFRP3 cDNA (pcDNA-sFRP3-HA). Transient transfection of pcDNA-sFRP3-HA suppressed the Wnt3a-induced the accumulation of cytosolic β -catenin in MG-63 cells. Transfection of sFRP3 also decreased the Tcf/Lef-dependent transcriptional activity in MG-63 cells. Furthermore, sFRP3 suppressed the proliferation of MG-63 cells. These data suggest that glucocorticoid may impair osteoblast function and bone formation by enhancement of sFRP3 in human osteoblastic cells, which may be involved in the pathogenesis of GIO.

Regulation of RANKL Expression by Glucocorticoid in Human Osteoblast-like Cells. F. Hirano, N. Maruyama^{*}, K. Komura^{*}, K. Okamoto^{*}, Y. Makino^{*}, M. Haneda^{*}. Medicine, Asahikawa Medical College, Asahikawa, Japan.

Glucocorticoid-induced osteoporosis remains the most common secondary form of metabolic bone diseases. The soluble and transmembrane cytokines, RANKL, are produced by the osteoblast under hormonal and cytokine control and are essential for osteoclastogenesis and bone resorption. In contrast, osteoprotegerin is known to bind to RANKL and to block the interaction between RANKL and its receptor RANK. Glucocorticoid has been reported to induce RANKL mRNA expression in osteoblasts, although circulating soluble RANKL is reduced by glucocorticoid. The reasons of this discrepancy are still unknown. The purpose of this study was to clarify the regulation of RANKL expression by glucocorticoid in human osteoblast-like cells. We used human osteoblast-like cell line MG-63 and examined effect of glucocorticoid on RANKL expression. Quantitative real-time RT-PCR and ELISA methods revealed that 100 nM dexamethasone (DEX) significantly increased RANKL mRNA expression (15-fold, $p < 0.05$) in MG-63 cells for a time-dependent manner and decreased soluble RANKL protein in supernatant, as expected. In addition, we found that DEX did not influence RANKL transcriptional activity by reporter gene assay using human RANKL promoter. Moreover, Treatment with actinomycin D and DEX markedly prolonged the half-life of RANKL mRNA in MG-63 cells, as compared to treatment with actinomycin D alone ($T_{1/2}$ = over 24h v.s. 10h), presumably indicating that DEX-induced RANKL mRNA expression is due to the stabilization of RANKL mRNA. Next, we investigated effect of glucocorticoid on the expression of TNF converting enzyme (TACE), a known RANKL sheddase. The activity of TACE was dose-dependently reduced by DEX. Moreover, 100 nM DEX significantly decreased both mRNA- and protein-expression of TACE by quantitative real-time RT-PCR and ELISA, respectively. Furthermore, 100 nM DEX clearly induced transmembrane RANKL protein in MG-63 cells by flow cytometry and Western blot analysis, suggesting that DEX-reduced soluble RANKL protein expression in supernatant is associated with the decreases of TACE activity and protein expression in MG-63 cells. In conclusion, we presented glucocorticoid up-regulated RANKL mRNA expression via the stabilization of RANKL mRNA and reduced soluble RANKL expression via the decrease of TACE expression, possibly indicating that glucocorticoid-induced transmembrane RANKL expression in osteoblasts mainly played a pivotal role in osteoclastogenesis.

Periarticular Bone Loss in Arthritis: Role of Synovial Glucocorticoid Generation. M. S. Cooper¹, R. Hardy^{*1}, E. H. Rabbitt^{*1}, N. J. Gittos¹, M. Hewison², C. D. Buckley^{*1}, K. Raza^{*1}, P. M. Stewart^{*1}. ¹University of Birmingham, Birmingham, United Kingdom; ²Cedars-Sinai Medical Centre, Los Angeles, CA, USA.

Periarticular osteoporosis is a common feature of inflammatory arthritis. This feature is related to disease activity and is associated with uncoupling of bone resorption from formation. We previously hypothesised that local glucocorticoid generation within osteoblasts in response to inflammation may underlie this bone loss. An alternative possibility is that excess glucocorticoids are generated from other joint tissues. Primary synovial fibroblasts express the 11 β -hydroxysteroid dehydrogenase type 1 (11 β -HSD1) enzyme that generates the active glucocorticoids cortisol and prednisolone from their inactive counterparts cortisone and prednisone suggesting that synovium might generate glucocorticoids. We have now explored this hypothesis by characterizing glucocorticoid metabolism in synovial tissue explants from patients with rheumatoid arthritis (RA) and osteoarthritis (OA). Glucocorticoid metabolism was examined in synovial tissue taken from subjects with OA (n=8) or RA (n=12) during orthopedic surgery using radiolabelled steroids and TLC. Immunohistochemistry was used to identify the cellular distribution of enzymes. The functional consequences of enzyme activity on IL-6 production were examined by ELISA. All synovial biopsies had substantial capacity to activate glucocorticoids (cortisone to cortisol and prednisone to prednisolone) which was blocked by a specific 11 β -HSD1 inhibitor confirming 11 β -HSD1 expression. No difference in steroid metabolism was seen between samples from RA and OA subjects. In patients with RA, synovial cortisol generation increased with the ESR of the tissue donor ($R^2=0.4$, $p < 0.05$). 11 β -HSD1 activity had functional consequences with cortisone able to decrease synovial IL-6 production in tissue from patients with RA or OA (31+15% for RA, 36+9% for OA, both $p < 0.05$). Steroid inactivation was also apparent in synovium and was not blocked by inhibition of 11 β -HSD1. Using immunohistochemistry 11 β -HSD2 expressing cells were identified in RA synovium and expression colocalized with the monocyte marker CD68. This pattern was distinct from 11 β -HSD1 which was expressed in fibroblasts. Synovial tissue metabolises glucocorticoids with the predominant effect being glucocorticoid activation and this increases with inflammation. Endogenous glucocorticoid production in the joint is likely to regulate tissue inflammation but in excess might detrimentally impact on periarticular bone integrity. Additionally, a subset of immune cells expressing 11 β -HSD2 within synovium will be resistant to cortisol/prednisolone through steroid inactivation and this could perpetuate synovial inflammation.

Associations of Osteoporotic Spinal Deformity with Back Strength Among Elderly Women in Japan and the United States. M. Hongo¹, M. Sinaki², N. Miyakoshi¹, Y. Shimada¹, E. Itoi³. ¹Dept. of Orthopedic Surgery, Akita University, Akita, Japan; ²Dept. of Physical Medicine and Rehabilitation, Mayo Clinic, Rochester, MN, USA; ³Dept. of Orthopedic Surgery, Tohoku University, Sendai, Japan.

Kyphosis is associated with diminished daily physical function, increased risk of falls, and increased mortality risk. Back extensor strength (BES) is an important factor in maintaining the sagittal alignment of spine and preventing vertebral fractures. When back exercises are prescribed, it is important to know the associations of the sagittal alignment with BES. However, there is a controversy in the literature regarding the influence of the thoracic and lumbar spinal curvatures on BES or quality of life. We hypothesized that the regional or ethnic factor may influence the relationship between thoracic and lumbar sagittal curve, BES and other factors. The purpose of this cross-sectional study was to assess the associations of osteoporotic spinal deformity with back strength in elderly women in Japan and the United States. Using the same inclusion criteria, 104 Asian women residing in Akita, Japan and 102 Caucasian women residing in Minnesota with postmenopausal osteoporosis were selected for this study. Kyphosis angle of the thoracic and lumbar spine were measured with lateral radiographs. Isometric BES was evaluated using a custom-made dynamometer. Correlations between the kyphosis angle, isometric BES, bone mineral density, physical activity score or quality of life score, the number of vertebral fractures, and grip strengths were analyzed. No significant difference was found in thoracic kyphosis between Akita and Minnesota (43.1° and 44.1°, respectively), whereas lumbar kyphosis angle in Akita was significantly larger than in Minnesota (-15.4° and -54.0° p<0.0001). In Akita, BES showed significant negative correlation with lumbar kyphosis angle (r=-0.492, p<0.0001), but no correlation with thoracic kyphosis angle (r=-0.004, p=0.97). In Minnesota, BES showed significant negative correlation with thoracic kyphosis angle (r=-0.372, p<0.0001), but no correlation was found with lumbar kyphosis angle (r=-0.087, p=0.362). In addition, quality of life score in Akita demonstrated significant correlation with lumbar kyphosis, but not with thoracic kyphosis. Physical activity score in Minnesota showed significant negative correlation with thoracic kyphosis, but not with lumbar kyphosis. In conclusion, there was a significant difference in lumbar kyphosis angle between the two countries. Lumbar kyphosis angle has more significant influences in maintaining BES and quality of life among women in Akita, Japan compared with those in Minnesota.

Significant Reduction of Vertebral Fractures: Comparison of Rehabilitation of Osteoporosis Program-Exercise (ROPE) versus No-ROPE, with or without Pharmacotherapy. Diana A. Kurmen, Mehrsheed Sinaki. Department of Physical Medicine and Rehabilitation, Mayo Clinic, Rochester, MN, USA

The objective of this study was to determine whether patients with osteoporosis who received the Rehabilitation of Osteoporosis Program-Exercise (ROPE) had reduced risk of vertebral fracture as compared with those who did not (No-ROPE). To avoid bias in choice of treatment, none of the subjects or evaluators had knowledge of group assignment.

We reviewed the medical records of 200 patients. One hundred and twelve patients with osteoporosis met the inclusion criteria, i.e. women older than age 40 with the diagnosis of osteoporosis, baseline and follow-up radiographs of spine. Patients with steroid-induced bone loss and active malignancy were excluded. Two groups were formed: 71 subjects in the ROPE group and 41 subjects in the No-ROPE group met the enrollment criteria. Follow up was the date of follow up x-rays or recurrence of fracture/back pain. The duration of follow up ranged from 3 months to 118 months with an average of 45.5 months.

The results showed that 56 of the 71 ROPE subjects (78.9%) and 20 of the 41 No-ROPE subjects (48.8%) had no new fracture at the time of final follow up. Interestingly, 56 subjects (78.9%) of the 71 ROPE subjects had received pharmacotherapy whereas all 41 (100%) of the No-ROPE subjects had received pharmacotherapy for bone loss.

The 79% of the ROPE population without new fracture were distributed as: 29.6% combination therapy, 26.8% bisphosphonates only, 9.9% calcium only, and 12.7 % no pharmacotherapy. The 49% of the No-ROPE population without new fracture were distributed as: 26.8% combination therapy, 17.1% bisphosphonates only, and 4.9% calcium only.

In the population taking some kind of pharmacotherapy, 21.1% had new fractures during the time to follow up in the ROPE group versus 51.2% in the No-ROPE group.

The No-ROPE group was four times more susceptible to fracture during the time to follow up (P = 0.001), Pearson Chi Sq test. The group with the lowest incidence of fractures was the ROPE group with combination pharmacotherapy.

To prevent vertebral osteoporosis fractures, we enthusiastically suggest that ROPE be mandatory for management of every woman with osteoporosis, regardless of choice of pharmacotherapy.

WG26

An Interdisciplinary Approach to Improve Pain and Mobility in Patients with Osteoporosis and Painful Vertebral Fractures by Kyphoplasty. C. Kasperk¹, M. Baier², G. Nöldge³. ¹University Clinic of Heidelberg, Dept. of Endocrinology and Metabolism, Heidelberg, Germany; ²University Clinic of Heidelberg, Dept. of Trauma Surgery, Heidelberg, Germany; ³University Clinic of Heidelberg, Dept. of Radiology, Heidelberg, Germany.

Osteoporosis and arteriosclerosis are associated diseases heavily impacting on the patients lifespan and quality of life (QoL) whereby the lifespan is shortened by an increased cardiovascular mortality of osteoporotic patients and the QoL is worsened by the occurrence of painful vertebral fractures, related disabilities and immobility. Immobility is a crucial risk factor for further bone loss and arteriosclerotic complications (e.g. stroke, hypertension). A prerequisite for an improved mobility of patients with osteoporosis/arteriosclerosis is a reduction of pain induced impairments of the musculoskeletal activity. Despite the accomplished pharmacological progress in the treatment of the osteoporotic disorder of bone metabolism painful vertebral fractures (VF) are still occurring during under any available antiresorptive or osteoanabolic treatment. Analgetic treatment of bone pain associated with 50 % of incident vertebral fractures does not improve the cause of the pain. Internal stabilization of painfully fractured vertebral bodies terminates the permanently ongoing microfracturing in VF and thus the irritation of pain fibres which are present in bone, even in the Haversian canals.

In this trial we sought to investigate how beneficial short term effects of KP on pain and mobility will affect long term outcome and fracture incidence. The selection of patients was done by an interdisciplinary team of endocrinologists, orthopaedic surgeons and radiologists on the basis of the precise knowledge of the complaints and X-rays, CT- and MRI scans of every patient to exclude other causes of pain than vertebral fracture associated pain.

KP was performed in 40 of 60 patients with primary osteoporosis and painful vertebral fractures, 40 patients received vertebral stabilization by balloon kyphoplasty, 20 served as non-KP controls (Con). All patients received pharmacological treatment (oral aminobisphosphonate, 1000 mg calcium + 1000 IE vitaminD3) and physiotherapy. Pain (VAS scale [100=most severe pain]), mobility (EVOS score [100=full mobility]) and radiomorphology were determined after 6, 12 and 36 months.

	PRE-KP KP Con	6 mo. KP Con	12 mo. KP Con	36 mo KP Con
Pain	74.5 66.4 40.1	53.1 64.4 55.7	53.7 65.7 54.5	52.7 64.0 53.6
297	39.8	43.8	44.3	43.6

Number of total new vertebral fractures after 3 years:

KP21 # (in 14 of 34 patients)

Con18 # (in 10 of 14 patients)p=0.0341

In a selected group of patients with painful vertebral fractures KP is superior to conservative treatment of painful osteoporotic vertebral fractures for at least 3 years after intervention. KP has long term beneficial effects on pain reduction, improved mobility and fracture incidence provided that an interdisciplinary team of endocrinologists, orthopaedic surgeons and radiologists select those patients whose pain truly originates from the fractured vertebral body and not from spondylitis, spondylarthrosis or destruction of the intervertebral disc.

WG27

Improving Trunk Strength and Endurance in Older Women with Vertebral Fractures. K. M. Shipp, D. T. Gold, C. F. Pieper*, K. W. Lyles. Duke University, Durham, NC, USA.

The trunk musculature is important for people with osteoporosis. First, strong, fatigue-resistant trunk muscles are necessary for erect postural alignment. Second, strong trunk extensors may prevent vertebral fractures. An observational study associated trunk extension strengthening over 2 years with decreased incidence of vertebral fractures in the next 8 years [1]. This presentation will review the evidence for the relationships between trunk alignment, strength, and endurance; functional status; and fracture risk. Time will be allotted for discussion, with the goal of identifying important, unanswered research questions regarding these parameters.

Our work at Duke University Medical Center with patients with vertebral fractures will be described. Particularly, results will be presented from a randomized clinical trial of a group exercise intervention (3X/week for 6 months) in older women (n=122, mean age 81 years) with vertebral fractures (mean # 2.3) [2]. Randomization was by site: 3 trunk exercise intervention sites (n=53) and 3 control sites (n=69). The trial was a modified cross-over design: the control sites received the exercise intervention after 6 months of health education sessions. The exercises included 1) stretches to increase trunk extension flexibility and 2) progressive resistive strengthening exercises for trunk extensors, abdominals, and posterior scapular groups.

Using mixed-model ANCOVA (intention-to-treat), we found a significant difference between groups for trunk extension strength at 6 months ($p=0.0001$; +6.6 ft-lbs. [up 24%] exercisers, -4.6 ft-lbs. controls). When the control subjects received the exercise intervention, there was a mean increase of 15.0 ft-lbs [up 45%].

The outcome of an ancillary study was the effect of the intervention on Timed Loaded Standing (TLS), a measure of combined trunk and arm endurance [3]. Using mixed-model ANCOVA (intention-to-treat), we found a trend for difference between groups for TLS time at 6 months ($p=0.0542$; +8.8 s exercisers, -8.9 s controls). Among compliers (those attending 2/3s of sessions), group was significant ($p=0.035$; +14.9 s exercisers, -10.3 s controls). Change in TLS time over 6 months was significantly correlated ($p<0.05$) with psychological symptoms and functional status.

These results showed that trunk extension strength and combined trunk and arm endurance could be increased, in older women with vertebral fractures, by 6 months of group, physical therapist-led, trunk-specific exercise classes.

Looking Beyond the Fracture: Women and Men with a Recent Clinical Fracture Have Bone and Fall Related Fracture Risks Far Beyond the Presence of Low Bone Mineral Density. Piet P. Geusens. University Hospital Maastricht, Department of Internal Medicine, Maastricht, The Netherlands.

Introduction: Fractures are associated with bone and fall related risk factors. Both have additive effects in predicting fractures. However, no data are available on the relative prevalence of these risk factors in patients with a recent clinical fracture.

We therefore systematically analysed these risk factors in subjects with a recent clinical fracture.

Methods: All women and men older than 50 years, admitted during a one-year period because of a recent fracture, were offered an evidence-based bone and fall related risk factor assessment and bone densitometry.

Results: Of the 941 consecutive patients, 798 (85%) were eligible for this study and 568 (60%) approved to participate. Fall-related risk factors (n= 425, 75% (95%CI: 71 % - 78 %)) and bone related risk factors (n=299, 53% (95%CI: 49% - 57%)) were more frequently present at the time of fracture than osteoporosis (DXA T score < -2.5 in spine and/or hip (n=201, 35% (95%CI: 31% - 39%)), and were irrespective of the fracture location, the age categories included, and gender. Overlap between bone and fall related risk factors were found in 50% of the patients. The 406 women in this study were compared with 492 postmenopausal women without a fracture history of another cohort study. Adjusted for age, weight, and height the patients with fractures had more osteoporosis (OR 2.9; 95%CI 2.0 - 4.1) and more had a history of falls (OR 4.0; 95%CI 2.7 - 5.9). Based on available osteoporosis guidelines many women with a fracture would not have been detected if screened for an increased fracture risk.

Conclusions: Women and men of 50 years and older with a recent clinical fracture have, at the time of fracture, bone and fall related risk factors far beyond the presence of osteoporosis. Together with the heterogeneity, multiple combinations and overlap of risk factors irrespective of age, fracture location and gender, this may implicate that an integrated bone and fall related risk factor assessment is to be preferred to trace subjects at risk for fracture. Integrated bone and fall related risk assessment and treatment studies are needed to document this.

WG29

Jump Starting Skeletal Health: Bone Increases from Jumping Exercise Persist Seven Years Post Intervention. K. B. Gunter*, A. Baxter-Jones*, R. Mirwald*, H. C. Almstedt*, S. Durski*, A. A. Fuller-Hayes*, C. M. Snow*.

¹Department of Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA; ²College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada; ³Department of Natural Science, Loyola Marymount University, Los Angeles, CA, USA.

Evidence suggests that bone mineral increases attributable to exercise training prior to puberty may confer a significant advantage into adulthood. However, there is a dearth of supportive prospective longitudinal data. We assessed the change in bone mineral content (BMC) at the left proximal femur over eight years in children who participated in a seven-month jumping intervention and who were pre-pubertal at study onset.

We hypothesized that jumpers would accrue and retain more BMC compared to controls and therefore be at a considerable advantage in optimizing peak bone mass accrual. Subjects were drawn from the BUGSY study (Building Growing Skeletons in Youth), an ongoing mixed longitudinal study of bone mineral accretion in growing children initiated in the fall of 1997. Participants were recruited from local elementary schools in Corvallis, Oregon and were randomly assigned within classrooms to either an intervention (jumping) or control (stretching) group. Subjects were assessed at baseline, at the end of the intervention (7 months) and at approximately 19 months. Participants were reassessed at 31, 43, 55, 67, 79 and 91 months from study entry for a total of nine measurement occasions over approximately 8 years. Bone mineral content was assessed by dual-energy X-ray absorptiometry. Multi-level random effects models were constructed and used to predict change from study entry in BMC at each measurement occasion. We were able to utilize data from a total of 421 DXA scans on 57 individuals who were measured on 3 or more occasions. At 7 months, the intervention group had 3.6% more total hip bone accrual than the non-intervention group ($p<0.05$), once the effects of change in age, height and weight were accounted for. The effects of the intervention, in terms of percentage contribution to total hip BMC, decreased at each measurement occasion thereafter. After an average of 7.6 years, the intervention group had 1.4% more total hip bone accrual than the non-intervention group, once the effects of change in age, height and weight were accounted for ($p<0.05$). This provides the first evidence that changes in BMC attributable to short-term exercise undertaken prior to puberty persist more than 7 years following exercise cessation in growing children. If the benefits are sustained into adulthood, effectively increasing peak bone mass, this could have substantial effects on fracture risk.

Weight Bearing Bones Are More Sensitive to Physical Exercise in Boys than in Girls During Pre- and Early Puberty. S. Kriemler*, L. Zahner*, J. Puder*, C. Braun-Fahrlander*, C. Schindler*, M. Kraenzlin*, R. E. Rizzoli*.

¹Institute Sport & Health, Basel, Switzerland; ²Division Endocrinology, Diabetes & Clinical Nutrition, Basel, Switzerland; ³Institute Social & Preventive Medicine, Basel, Switzerland; ⁴Endocrinology, Diabetes and Clinical Nutrition, Basel, Switzerland; ⁵Rehabilitation & Geriatrics, University Hospital, Geneva, Switzerland.

Background: Physical activity (PA) positively influences bone mineral accrual. However, little is known whether there are gender differences in bone sensitivity to loading and to what extent spontaneous objectively recorded PA influences bone mineral mass independently from muscle mass. We investigated gender differences in the association between bone mineral density/content (BMD/BMC) and measures of PA, during preand early puberty. Methods: We measured BMD/BMC and fat-free mass in 374 6-13-year-old children from randomly selected schools at the hip, lumbar spine and total body by DXA. PA was evaluated by accelerometers, and lower extremity strength by a jump&reach test.

Results: Boys had higher hip and total body BMD than girls at all ages. Boys had higher fat-free mass, greater lower extremity muscle strength and were more physically active than girls at all ages. Total hip BMD was positively associated with time spent in total and vigorous PA in boys ($r=0.33$ and 0.27 , respectively, $p<0.01$), but not in girls ($r=0.02$ and 0.04 , $p=ns$), even after adjusting for fat-free mass and lower extremity strength. While boys and girls in the lowest tertile of vigorous PA (22 min per day) had similar hip BMD (0.668 vs 0.679 g*cm⁻²), those boys in the highest tertile (72 min per day) had significantly higher values than the corresponding girls (0.730 vs 0.692 g*cm⁻², $p<0.05$). In multiple logistic regression analyses, a low hip BMD in boys was best predicted by fat-free mass (OR 0.55 [95%CI 0.38, 0.78] per 1 kg) and total PA (OR 0.69 [95%CI 0.49, 0.98] per 106 counts), while in girls predictors included fat-free mass (OR 0.63 [95%CI 0.50, 0.79] per 1 kg) and jump&reach (OR 0.90 [95%CI 0.84, 0.98] per 1 cm). Similar data were obtained for femoral neck BMD/BMC. There was no influence of PA on lumbar spine BMD in either gender.

Conclusion: Though at low physical activity during pre- and early puberty, hip BMD is similar in both genders, it increases proportionally to PA, and differences in bone mineral mass between genders appears, likely related to a different sensitivity of bone to physical loading, independently from muscle mass.

Disclosures: R.E. Rizzoli, None.

WG31

Effects of Daily Muscle Trainings on Falls and Vertebral Fractures in the Elderly Osteoporotic Women. T. Horiuchi¹, A. Kanemaru^{*2}, T. Katoh^{*2}, H. Tobimatsu^{*1}. ¹Endocrinology, Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan; ²Rehabilitation, Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan.

Objective: We conducted a randomized case control study for one year to examine the effects of the home daily exercises to prevent osteoporotic women from falling and suffering of fracture.

Subjects & Methods: Ninety-three osteoporotic elderly women were recruited to participate in this study and they were divided into two groups: one is the control whose physical strength we only estimate, whereas the other group were intervened by exercise. The exercise group were instructed to repeat daily muscle training at home. The exercise instruction include muscle training to increase the strength of abdominal, back, quadriceps, gastrocnemius, soleus and plantaris muscles. In order to evaluate muscle strength we measured grasp power (GP), knee flexion strength (KNS), maximal walk velocity (MAW) and 3m timed up and go test (TUGT), lumbar and femoral bone mineral density and bone metabolic markers before and after one-year training, checking the reproducibility and QOL with SF36 every six months. Falls frequencies and vertebral fractures incidences were also examined. Statistics were done using a two-way ANOVA and stepwise multiple regression analysis. The medications for osteoporotics have not been altered in all participants during this study.

Results: LBMD were significantly increased in both groups for one year ($p < 0.05$). In exercise group GP, MAW and KNS were significantly increased, and TUGT were significantly decreased ($p < 0.05$). There was a graph interaction between control and intervention group in left KNS, which means that a significant difference between two groups disappeared in one year ($p = 0.006$). Physical component score and mental component score in SF36 were not changed in both groups. Falls frequencies were decreased in two groups, showing a trend of steep reduction in a training group. There was no significant difference in vertebral fracture incidence between two groups. In multivariate regression analysis TUGT was significantly associated with Falls frequencies ($p < 0.0001$).

Conclusion: Exercise for the elderly women are effective to increase the strengths of muscles. Exercises might be effective to prevent elderly osteoporotics from falling. We should furthermore continue to perform exercise instruction as an intervention using TUGT.

Disclosures: T. Horiuchi, None.

Load-specific Differences in Femoral Neck Cortical Geometry: Preliminary data from 3-D MRI Study of Proximal Femur of Athletes. R. Nikander¹, H. Sievänen¹, P. Dastidar^{*2}, A. Heinonen³, P. Kannus^{*4}. ¹Bone Research, UKK Institute for Health Promotion Research, Tampere, Finland; ²Department of Radiology, University Hospital, Tampere, Finland; ³Department of Health Science, University of Jyväskylä, Jyväskylä, Finland; ⁴Department of Trauma, Musculoskeletal Surgery and Rehabilitation, University and University Hospital, Tampere, Finland.

During normal walking, femoral neck (FN) is subjected to a large number of consecutive, low magnitude impacts from typical directions. In contrast, during sport performance, power-lifters' femoral neck experiences very high magnitude, low rate loading from unusual direction, while swimmers' femoral neck is subjected to high rate muscle activity lacking virtually the weight-bearing component. We aimed to investigate the differences in the femoral neck cortical geometry among world-class power-lifters, national level swimmers and normal exercisers serving as referents. In this preliminary analysis of accumulating bone data from five power-lifters, five swimmers and five referents were compared. In all groups, the femoral neck cortical structure was assessed with DXA and 3-D MRI of the proximal femur. ANCOVA (age, weight and height as covariates) were used for statistical analysis. The femoral neck BMC and BMD were 35% and 31% higher in power-lifters, but 11% and 13% lower in swimmers compared with controls ($0.02 < p < 0.07$). Interestingly, the shape of power-lifters' femoral neck appeared to be round at the narrowest section, while swimmers' and controls' FN seemed to be oval being wider in the superior-inferior direction. Although the inter-group differences in the femoral neck cortical thickness did not reach statistical significance, a clear trend suggesting substantially thicker cortices in power-lifters in all anatomic directions (anterior 22%, posterior 52%, superior 12% and inferior 45%) was found, while the cortices between swimmers and referents were similar. The strong femoral neck structure (more mass, denser bone, round shape and thick cortices) seemed to be characteristic of power-lifting performance. High magnitude loading produced at low rate seemed to account for strong femoral neck, while non-weight bearing, low-magnitude loading, despite large number of repetitions at relatively high rate, seems not benefit to bone structure at all.

TENS (Transcutaneous Electrical Nerve Stimulation) in the Management of Osteoporosis-related Pain. S. Kalra^{*1}, A. Sharma^{*1}, B. Kalra^{*2}, N. Kumar^{*3}. ¹Endocrinology, Bharti Hospital, Karnal, India; ²Gynaecology, Bharti Hospital, Karnal, India; ³Physiotherapy, Bharti Hospital, Karnal, India.

Pain is a disabling symptom in persons with osteoporosis, and it often reduces the quality of life. This paper studies the effect of TENS in subjects with osteoporosis, complaining of pain.

30 adult osteoporosis patients with lower limb pain, receiving five sittings of TENS on daily or alternate day basis, were compared with 30 age-matched, disease-matched patients who were administered daily diclofenac and five sittings with sham electrodes.

Pain scores, measured by visual analog score, reduced significantly in both groups, but much more so in the TENS group (from 4.60 ± 0.54 to 1.60 ± 0.54) than the sham electrodes + diclofenac group (from 4.40 ± 0.54 to 3.60 ± 0.54). This difference was maintained after 3 weeks, even though the TENS sittings had stopped. Best improvement was obtained in patients with burning (3.28 ± 0.64) and lancinating (3.12 ± 0.64) pain.

Least benefit was in patients with deep pain (2.15 ± 0.35) and restless legs syndrome (2.16 ± 0.56).

The dose of TENS used varied from 5.5 to 9.0 Hz on the initial day to 3.5 to 5.5 Hz on the last sitting. The dose varied insignificantly for different symptoms.

Validated health-related questionnaires were used to assess the effect of physiotherapy sessions in the subjects. Physician communication score improved from 1.43 ± 1.19 to 3.93 ± 0.86 over one month of therapy in all subjects. Time spent by them in stretching/strengthening exercise increased from 0.0 ± 0.0 to 15.0 ± 0.0 minutes per week. The social/role activities limitation due to the disease reduced from 2.25 ± 0.63 to 1.08 ± 0.39 . Cognitive symptom management improved from 1.30 ± 0.63 to 2.00 ± 0.67 .

The health distress score fell from 3.20 ± 0.82 to 1.35 ± 0.47 while energy/fatigue scores raised from 2.25 ± 0.51 to 3.30 ± 0.50 in all subjects. No difference was noted in these scores between the two groups.

This paper demonstrates the beneficial effect of TENS on pain related to osteoporosis, and the advantageous effects of regular physiotherapy on various health-related parameters in persons with osteoporosis.

Patient and Physician Attitudes Toward Vitamin D in Osteoporosis Treatment. S. P. Chan^{*1}, J. A. West², L. E. Wehren², S. S. Sen^{*2}. ¹University of Malaya, Malaya, Malaysia, ²Merck, Rahway, NJ, USA.

BACKGROUND: Vitamin D is essential for calcium absorption and bone health, and most osteoporosis treatment guidelines recommend vitamin D supplementation. This study explored the knowledge and attitudes of physicians and patients towards supplement use in osteoporosis treatment.

METHODS: Randomly selected Physicians from Malaysia, Taiwan, Philippines, Korea, and Singapore and their postmenopausal women patients with osteoporosis were surveyed. Physicians rated the importance of vitamin D and calcium in osteoporosis management on a scale of 1(not important) to 10 (extremely important) and estimated supplement use by their patients. Patients reported their use of vitamin D and calcium and their perceptions regarding these supplements.

RESULTS: 237 physicians (37 from Malaysia, and 50 each from Taiwan, Philippines, Korea, and Singapore), and 1463 patients (251, 218, 194, 400, and 400 from Malaysia, Taiwan, Philippines, Korea, and Singapore respectively) completed the survey. 84% of patients in Malaysia, 46% in Taiwan, 16% in the Philippines, and 55% each in Singapore and Korea reported never having discussed Vitamin D supplementation with their Physician. Physicians and patients in all countries reported that calcium was discussed more frequently than Vitamin D. Physicians reported that their patients have little knowledge of the relationship between vitamin D and calcium, and this was confirmed by patient responses.

CONCLUSION: Most osteoporosis patients recognize the importance of calcium, but have less awareness of that of Vitamin D. Lack of understanding about the role of Vitamin D and numerous concomitant medications can reduce compliance with Vitamin D supplementation.

So How Was It? Patient Opinions on Osteoporosis Interventions in the Fracture Clinic Setting. D. E. Beaton, E. R. Bogoch, R. Sujic*, V. Elliot-Gibson*. Mobility Program, St. Michael's Hospital, Toronto, ON, Canada.

Our study aims to understand factors that influence fragility fracture patient's adherence with St. Michael's Hospital Osteoporosis Exemplary Care Program's recommendations for further osteoporosis testing and treatment. Our previous research indicates that coordinator-based interventions are an effective way of preventing future fractures. The results of this study will help identify key variables to consider when evaluating the Ontario Osteoporosis Strategy's Fracture Clinic Screening Program which is based on the coordinator model.

This is a qualitative study using focus-group methodology. Out of 45 patients who were eligible based on the study criteria, 24 patients participated in five focus groups. Transcripts of the five focus groups were transferred to N-Vivo for storing and sorting the data. Transcripts were coded for content and links between descriptive labels were made. By using qualitative method, we are hoping to explore the impact of the Osteoporosis Exemplary Care Program in a much more contextualized fashion.

Emerging results support Anderson's behavioural model of health care utilization. Perceived need and susceptibility were associated with osteoporosis prevention efforts and treatment adherence as reported by the patients involved in the focus groups. The most frequent barriers that patients identified in diagnosis and treatment of osteoporosis included the perceived lack of clear and reliable information regarding the nature of BMD testing and proper treatment as well as the lack of general practitioner's recommendations about osteoporosis care and prevention. Most often cited facilitators of osteoporosis testing and treatment included thorough follow up by an osteoporosis coordinator, accessibility and ease of BMD testing and general practitioners' recommendations for treatment and testing.

General practitioners were named as key influence over the initiation of prevention and treatment of osteoporosis.

Disclosures: D.E. Beaton, None.

Improvement of the Persistence with Teriparatide in Postmenopausal Osteoporosis: The French Experience of an Education Program. K. Briot¹, P. Ravaud^{*2}, S. Liu-Léage^{*3}, C. Roux¹. ¹Rheumatology, Cochin Hospital, Paris, France, ²Biostatistics and Epidemiology, Bichat Hospital, Paris, France, ³Lilly France, Suresnes, France.

Several anti-osteoporotic treatments have been proved effective in decreasing the risk of fractures but available data suggest low adherence and persistence rates in patients taking medications for osteoporosis. This can result in failure in treatment efficacy. Several strategies have been developed to improve adherence and persistence. Teriparatide, prescribed 20 µg/day injected subcutaneously, is an anabolic treatment licensed for established postmenopausal osteoporosis. Education program has been developed after its launch, to help elderly women to deal with the pen take and consequently better follow the

prescribed treatment. The objective is to assess the efficacy of an education program to improve the persistence with teriparatide in postmenopausal osteoporotic women. This education program has been created by the promotor of teriparatide since its launch of teriparatide in France in September 2004 and it is proposed to each woman who begins the teriparatide. The program includes injection technique learning, osteoporosis education, observance and persistence assessment. Women are interviewed by regular calling of a nurse, each month the first year and every 3 months the 6 following months. Data about persistence and side-effects are available for the period September 2004 to December 2006. Persistence is defined as the percentage of patients still on treatment at the end of the 18-month course. Since the launch of teriparatide in France in September 2004, 4518 postmenopausal women (mean age 73.6 ± 11.4 years) with osteoporosis (lumbar spine and/or femoral T score ≤ -2.5) and vertebral fractures (4 fractures on average) have participated to the program. At the end of the year 2006, 1951 women have been followed at least 18 months. Of these 1951 women, persistence at 18 months was 82.6%. Main reasons for discontinuation, as declared by the patients, were side-effects (43.8%), wish of the patient (23.8%), physicians' decisions (17%) and deaths (5.3%). Persistence has been compared to the data of the French universal health insurance system; and it has been estimated that persistence at 18 months was closed to 0% for women who have been prescribed teriparatide without any education program. This study shows that an education program can highly improve the persistence with teriparatide at 18 months. Persistence is greater than that of existing oral therapies for osteoporosis, and this high persistence should improve the effectiveness of this therapy.

Compliance with Osteoporosis Treatment and Incidence of Hip and Wrist Fracture after Forearm BMD Screening. M. W. J. Davie, T. Jones*, N. Dugard*. Charles Salt Research Centre, Robert Jones & Agnes Hunt Orthopaedic Hospital NHS Trust, Oswestry, United Kingdom.

Treatment compliance in osteoporosis may affect fracture outcome. To investigate compliance and fracture after a screening programme, we revisited 1299 women aged 50-97y screened by forearm scanning after a minimum of 3 years. Women were scanned at the request of their doctor (GP) and treatment advised if BMD values were <0.34g/cm² (osteoporosis (OP)). Treatment was decided by the woman's GP. No follow up was arranged. Women completed a detailed questionnaire at the scanning visit and again when revisited. Women lost to follow up were traced through health records and treatment details between scanning and revisit obtained from the women's own GP. 74% of women returned their questionnaires with no difference between those osteoporotic and those not. Fractures were validated with a 10% sample (and were correct within 5%).

All but 98.5% were traced of whom 14.4% had died. 254 women had osteoporosis at the first visit (aged 50-9, 2.4% had OP, 60-9 15.8%, and >69 54.3%). Of these 37.4% had never started any treatment (excluding Ca and Vit D only) - with no difference across ages. 1.3% had HRT and 98.7% Bisphosphonate (BP) of which 38% used Didronel, 43% Fosamax and 19% had had >1 BP. Compliance with BP dropped to 73.8% after 1yr (no difference across ages) with 22.9% only collecting 1 script. Fewer women with OP in institutions had ever had treatment (28%, p<0.01) and were also more likely to stop treatment (28.6% had only 1 script). Excluding women who were no longer available compliance at 2yr was 68.3%, 3yr 58.6%, 4yr 50% and 49.6% at 5yr. Hip fracture occurred in 1 woman with OP out of 38 (age 76.6±8.1y) who were never treated and in 7 of 55 women (73.2±7.3y (age p<0.05)) fully compliant for 5yr. The excess in women fully compliant occurred after >3y treatment (2 had used Didronel, 2 Fosamax, 3 both). Wrist fractures occurred in 3 women in each group.

Compliance declined early suggesting early follow up is indicated. Treatment in institutions may be overlooked. Compliance is not necessarily associated with hip fracture reduction. However the age of patients with hip fracture (75% were >80y) is consistent with BP efficacy being less in this age group. Moreover most of the hip fractures occurred >3y after treatment started when BP may be less effective at preventing hip fracture.

WG38

An Outreach Program Improved Osteoporosis Management after a Fracture. A. C. Feldstein¹, W. M. Vollmer^{*1}, D. H. Smith^{*1}, A. Petrick^{*1}, J. Schneider^{*1}, H. Glauber^{*2}, M. Herson^{*2}. ¹Center for Health Research, Kaiser Permanente Northwest, Portland, OR, USA, ²Northwest Permanente, Portland, OR, USA.

This longitudinal retrospective cohort study evaluated implementation of a 2-phase intervention to improve management of osteoporosis after a fracture. Stakeholder barriers and facilitators of osteoporosis management were also determined. The study setting was a nonprofit group model HMO in the U.S. Pacific Northwest with 15 clinics, 480,000 members, and comprehensive electronic medical record data. Study participants were women members aged 67 or older who sustained a qualifying clinical fracture(s) and who had not received a bone mineral density (BMD) measurement or osteoporosis treatment in the 12 months prior to the fracture (n=3588) and their 255 primary care providers (PCPs). Interviews/focus groups were conducted with 58 patients, health care managers, PCPs, and

orthopedic clinicians. Phase 1 included outreach to clinicians and patients; Phase 2 added clinician/staff incentives. The primary outcome was "osteoporosis management" receipt of a BMD measurement or osteoporosis medication in the 6 months after an index fracture. Prior to the intervention, 13.4% (95% confidence interval [CI] = 12.0%-14.8%) of fracture patients had received osteoporosis management; the pre-intervention time trend was not significant. After the intervention, the unadjusted probability of osteoporosis management increased on average by 3.1% (95% CI = 2.6%-3.5%) every 2 months throughout both study phases. There was no significant added improvement in Phase 2. Overall, the probability of osteoporosis management increased from the baseline level to 44.0% (95% CI = 40.0%-48.0%) by the end of the study period (20 months post intervention). Adjusted models revealed that osteoporosis management was less likely in older patients and in those with dementia and was more likely in those with fractures more highly associated with osteoporosis. Improvement varied by clinic and was less likely for patients with dementia. Patient knowledge gaps and fatalism were common, especially among older patients. Common clinician barriers were lack of time, difficulty interpreting all relevant results, patient management concerns in the transition from specialty to primary care, and frustration with the side effects of and poor patient adherence to osteoporosis medications. This study found that an outreach program to clinicians and patients improved the management of osteoporosis after a fracture. More-tailored interventions may be necessary for high-risk subgroups. There is also a need for more effective patient and clinician education and a stronger role for specialists.

Bringing Bone Health to Seniors' Communities: A Unique Approach to Help Manage Osteoporosis. M. Kloseck^{*1}, M. van Zandvoort^{*2}, R. Crilly³, M. Speechley^{*4}.

¹Faculty of Health Sciences, University of Western Ontario, London, ON, Canada, ²Department of Health and Rehabilitation Sciences, Faculty of Health Sciences, University of Western Ontario, London, ON, Canada, ³Department of Medicine, University of Western Ontario, London, ON, Canada, ⁴Department of Epidemiology and Biostatistics, University of Western Ontario, London, ON, Canada.

Osteoporosis is preventable and treatable, yet there is a significant care gap in Canada. We hypothesized that engaging seniors in raising awareness, identifying neighbours and others in their community at risk and a peer-led senior-friendly education program would increase diagnosis and treatment of osteoporosis, and that ongoing peer support would encourage compliance and persistence with medication and lifestyle change. This hypothesis is being tested in a randomized controlled trial (RCT). In Phase 1 (completed) community capacity building and participatory action research methodology was used to train seniors in a local community to act as peer educators and mentors within their community. Ten seniors (mean age=82 yrs. + 6.74 yrs. SD, range=71-90) participated in a 2-week training program containing 5 osteoporosis education modules and 1 session on public presentation skills delivered by local experts. Once trained, these seniors formed the Community Osteoporosis Advisory Committee which collaboratively developed a peer advisor training manual, designed a community information and recruiting program, and developed a senior-friendly education and support program which they practiced until all were comfortable. Pre- and post-knowledge surveys showed a statistically significant change ($p=.04$) in knowledge from project start to end of Phase 1. Confidence by seniors in their role as osteoporosis advisors increased significantly ($p=.02$), as did confidence in their ability to deliver information to their neighbours through community presentations ($p=.02$). Overall confidence in their role as peer educators and mentors increased significantly from project start to end of Phase 1 ($p=.01$). In Phase 2 (in progress) the senior-led education and support program is being tested in a RCT ($n=100$) in a local community of seniors ($n=2500$, mean age=79 + 9.53 SD). Outcomes include BMDs performed, treatments begun, appropriateness of treatment and persistence. Preliminary baseline knowledge surveys ($n=33$, mean age=81 + 7.18 yrs. SD, range 67-91 yrs., 97% female, 3% male) show a substantial gap in knowledge. On the 19-item osteoporosis questionnaire the mean correct minus incorrect score=6.15 + 4.79 SD. Scores ranged from -4 to 16 out of 19. Forty-one percent reported having fallen in the past year. This unique approach to diagnosing and treating osteoporosis may be a useful model for other communities of seniors.

WG40

Fracture Risk Assessment in Dialysis Patients. S. Jamal, University of Toronto, Canada.

After one year, over half of the men and women with stage 5 chronic kidney disease (CKD) will have a fracture. Dual energy x-ray absorptiometry (DXA) is inconsistently associated with fracture these patients. For example, we recently published a meta analysis of cross-sectional, observational studies which reported on the unadjusted association between BMD and fracture. While we found that BMD was lower in patients with stage 5 CKD who have fractures we also noted that there were important limitations of all the studies included in our meta analysis and our results should be interpreted with caution.

One reason for the lack of association between DXA and fracture may be due to underlying metabolic bone disease, one of the most common being osteitis fibrosa from secondary hyperparathyroidism. Hyperparathyroid bone disease has preferential effects on cortical components of bone and measures such as DXA, which do distinguish between trabecular and cortical components, may not detect cortical abnormalities in HD patients.

In contrast to DXA, peripheral quantitative computed tomography (pQCT) discriminates between trabecular and cortical components, allows assessment of volumetric density, and can be used to derive indices of bone strength. pQCT studies in HD patients consistently demonstrate a selective decrease in cortical measures due to elevated levels of PTH. However, the associations between pQCT measures and fractures are not known.

This session will review the relative contributions of pQCT (trabecular and cortical) and DXA measurements to fracture risk among hemodialysis (HD) patients. Specifically, we will report on the cross sectional associations between cortical and trabecular measures and fractures in 36 men and 16 women, 50 years and older, on HD for at least one year. Low trauma non-spine fractures since starting HD were identified by self report and confirmed by review of radiographs or radiology reports. Prevalent vertebral fractures were identified by morphometry of lateral spine X-rays. pQCT measurements of the non-dominant radius included trabecular density, cortical density, total area, cortical area, and cortical thickness. We also obtained DXA measurements of the hip and lumbar spine. We used logistic regression models, adjusted for age, weight, and gender to examine the association between fracture (vertebral and/or self-reported non-spine) and each pQCT measure.

The mean (SD) age was 65.8 (9.0) years, the mean weight was 72.3 (15.6) kg, most (32 of 52) subjects were Caucasian, and there were 32 fractures in 27 subjects (prevalent vertebral fracture or low trauma fracture) since starting dialysis. A decrease in cortical density was associated with fractures (OR = 16.7; 95% CI: 2.9 to 83.3), as was a decrease in cortical area (OR = 3.0; 95% CI: 1.3 to 7.3), and a decrease in cortical thickness (OR = 3.3; 95% CI: 1.4 to 7.9). Fractures were not associated with pQCT trabecular density (OR = 1.2; 95% CI: 0.6 to 2.3), total area (OR = 1.1; 95% CI: 0.59 to 1.7) or DXA measurements of the hip and spine.

Our findings suggest that cortical parameters of the radius were associated with fractures in HD patients. If confirmed in prospective studies, these findings may explain the lack of association between fracture and DXA measurements and raise the possibility that pQCT could be used to identify HD patients at high risk of fracture.

WG41

Bone-muscle Disconnect During Pubertal-driven Skeletal Growth in Type 1 Diabetes. (T1DM). MA Murray¹, H Slater², KK Clarke², JL Quick², and L Moyer-Mileur² ¹Division of Pediatric Endocrinology and ²Center for Pediatric Nutrition Research, Department of Pediatrics, University of Utah, Salt Lake City, Utah.

Purpose: To compare bone characteristics in adolescents with T1DM to healthy reference and examine associations between T1DM-related factors and bone-muscle characteristics during pubertal-driven skeletal growth. **Methods:** Measures of tibia bone characteristics by pQCT (XCT-2000, Stratec) and whole body, hip, and spine by DXA (4500A, Hologic) were performed in adolescents with T1DM ages 12-17 y (n=42; 26 girls) at baseline and 12 months later. Results were compared to a regional reference (n=199). Height, weight, diet and health histories, Tanner stage, disease duration, insulin regimen, and glucose control (average glycosylated hemoglobin (HbA1c) were recorded. Glucose control, bone biomarkers, and bone characteristics were compared in a separate cohort of T1DM adolescent girls (n=11) age 12-15y with good glucose control (HbA1c <8.0%) and matched controls (n=11). **Results:** T1DM adolescents had lower baseline and 12-month gains for tibia trabecular volumetric density (vBMD, mg/cm³) and cortical bone mineral content (BMC, mg) and whole body BMC relative to lean body mass (Figure 1, p<0.05). Disease duration (6.1 ± 3.8 y) was inversely related to tibia cortical bone cross-sectional area (CSA, mm²) and whole body BMC (R²=0.25-0.34, p<0.05) while average HbA1c (8.5 ± 1.0%) was a negative predictor of height-adjusted whole body BMC gains (R²=0.32, p<0.01). In the cohort study, height-adjusted whole body BMC/bone area (BA, cm²) and FN areal BMD (aBMD, gm/cm²) and bone apparent density (BMAD, gm/cm³) values were significantly lower in T1DM girls despite good to moderate glucose control when compared to healthy controls (p<0.05). The evaluation of tibia bone geometry and density revealed T1DM girls had significantly lower cortical BMC and cortical BMC/muscle CSA (Figure 2; p<0.05) with a trend toward thinner cortical bone thickness (p=0.07). Higher urine magnesium excretion was predictive of a greater height deficit, lighter bones, decreased FN BMAD, and lower tibia cortical bone area, thickness, and BMC (R=0.51 to 0.84, p<0.05) accounting for 26% to 60% of the variance. Higher fasting serum glucose was the single significant predictor of greater bone resorption (R=0.69, p<0.01) and urine magnesium excretion (R=0.77, p<0.001) accounting for 48% and 61% of the variability observed in urine deoxypyridinoline and magnesium levels, respectively. **Conclusions:** These findings provide further support for compromised bone mineral acquisition associated with poor glucose control leading to a bone-muscle disconnect during pubertal-driven skeletal growth in adolescents with T1DM.

Figure 1. Lower whole body BMC/Muscle in T1DM boys and girls vs. Reference (p<0.05)

Figure 2. Decreased Tibia BMC/Muscle in T1DM girls vs. Controls (p<0.05)

***(Asterisk) Denotes Non-ASBMR Membership**

Numeric

$\alpha 5$

Integrin association with Cx43 regulates the function of osteocyte hemichannels in response to shear stress, T504

$\alpha_9\beta_1$

ADAM8 binds to increase osteoclast formation and function by interacting with Pyk2 and activating paxillin, 1099

$\beta 2$

Adrenergic receptor deficiency enhances bone mass in by antagonizing against aging-induced bone loss and blunts anabolic effects of PTH on osteoblasts, M390, O390, S390
 Modify RANKL/OPG expression and cell proliferation in human osteoblasts and osteoblastic cells, T006

A

A disintegrin and metalloproteinase 8 (ADAM8)

Binds $\alpha_9\beta_1$ to increase osteoclast formation and function by interacting with Pyk2 and activating paxillin, 1099

A-raf

Dispensable for endochondral bone development, W095

Abbott Diagnostics

Development of an assay for 25OH(D) on the ARCHITECT Analyzer, W156

Ac45

Cytoplasmic terminus is required for proper interaction with V0 domain subunits and efficient osteoclastic bone resorption, M104

Actin

Binding activity in the B subunit is required for sorting V-ATPase in osteoclasts, M092
 HMGB1 regulates cytoskeleton organization and RANKL-induced osteoclastogenesis in a manner dependent on RAGE, M079
 Polymerization through activation of RhoA, mechanosensitivity of osteoblasts is regulated by, W010

Activating transcription factor 4 (ATF4)

ATF4 is required for the anabolic actions of PTH on bone in vivo, 1007
 Synergistically activates osteoblast-specific osteocalcin gene expression, M037

Activation domain 3 (AD3)

Supports synergistic Runx2-MINT activation of the osteocalcin FGF response element via a DMAT-sensitive kinase, T036

Activin

Novel nodal-binding protein G11 inhibits matrix mineralization in osteoblasts, M203

ADAM. See A disintegrin and metalloproteinase

ADAMTS-7/12

α_2 M is a novel substrate for, and inhibits degradation of COMP, M166

Adenomas. See adenomas by type

Adenosine receptors (AR)

Adenosine A_1 receptor blockade reverses bone loss in OVX mice and deletion of adenosine A_{2A} receptors leads to diminished bone density, 1124
 In the osteoclast, W078

Adipocyte differentiation

Combination of Vitamin D and BADGE potentiates their pharmacological inhibition of PPAR γ and increases osteogenic differentiation of adipocyte precursors, W155
 Inhibiting, GILZ enhances osteoblast differentiation of bone marrow mesenchymal stem cells by, T057
 From MSC, CLA regulates, T047
 And osteoblast differentiation, opposing effects of GH and alcohol reveal a critical role in the relationship between, M196

Adipocytes

Bone marrow, secretion of adipokines and hypertrophic changes in, M473
 RANKL is produced by and stimulates osteoclastogenesis, W079

Adipogenesis

Accelerated, misexpressions of SOX9 during skeletogenesis lead to, 1180
 Bone marrow, effect of estrogens on, M243
 Classical ER signaling is essential for estrogen mediated enhancement of osteogenesis but not for inhibition of, M250, S250
 Differentially modulated by PTH and the N- and C-terminal fragments of PTHrP, T050
 Estrogen suppression is mediated by TGF β , M024
 Factors produced in ovary inhibit musculoskeletal growth and promote adipogenesis during puberty, M246, S246
 Marrow, reflects global energy utilization through activation of PPARG and modulation by "clock" genes in a genotype-specific manner, M021, O021, S021

Adipokines

Secretion and hypertrophic changes in bone marrow adipocytes, M473

Adiponectin

Action influences osteoblast-related gene expression, W014
 Anabolic to bone in vitro but negative effects in vivo, T174
 Changes in adiponectin and leptin serum levels in osteoporotic postmenopausal women after treatment with raloxifene or ALN, T454

Adiponectin receptor 1 (ADIPOR1)

Association of ADIPOR1 and ADIPOR2 gene polymorphisms with BMD in postmenopausal Korean women, T220

Adipose-derived stem cells (ASC). See Stem cells, adipose-derived

Adipose tissue

Accuracy and precision of adipose tissue cross-sectional area measured using pQCT, T268
 MSC from, osteogenic differentiation and interaction with Ti6Al4V, T053
 Overexpression of Δ FosB decreases, in a non-cell autonomous manner by increasing energy expenditure independently of bone cells, 1248
 Pericytes derived from, characterization and evaluation of their osteogenic potential, 1215

Adolescence. See Puberty

Adolescent idiopathic scoliosis (AIS). See Scoliosis, adolescent idiopathic

Adrenomedullin (AM)

Development of small molecule AM antagonists for treatment of bone metastases, T260

Advanced glycation end products (AGE)

AGEs induce vascular calcification through the RAGE/p38 MAPK signaling pathway, W447
 Comprehensive analysis of bone-related gene expression induced by acute oxidative stress, W413

Aft4

Inhibiting the transactivation activity of, vimentin negatively regulates osteoblast differentiation by, T027

AG490

Regulates osteoclast survival via distinct signaling pathways, T100

Aggrecan

Tissue-specific expression is regulated through both regulatory enhancer and repressor elements, W102

Aging, premature

Homozygous missense mutation in *KLOTHO* causes severe tumoral calcinosis but not, 1113

AIDS. See HIV/AIDS

Akt

Contributes to maintenance of bone mass and turnover by inhibiting apoptosis of osteoblasts through FoxO3a/Bim axis, 1211
 Effects on β -catenin regulate osteoblasts' responses to mechanical strain and PTH, T067
 PC1 selective activation of *Runx2*-II isoform transcription is mediated through, 1142
 Signaling, Osx mediates the feedback regulation of BMP-2 via, T029
 Signaling pathways, regulation of chondrocyte proliferation, function, and differentiation by, M123, S123

Akt inhibitor

Ultrasound induces HIF-1 activation and iNOS expression through, T511

Albuminuria

Predicts bone loss in older adults, M495

Alcoholism

Effects of low-dose PTH on body composition, bone mass and turnover and ectopic osteoinduction in chronic alcohol abuse, M391
 Opposing effects of GH reveal a critical role in the reciprocal relationship between adipocyte and osteoblast differentiation, M196

Alendronate (ALN)

Change of bone markers after once-weekly low dose ALN in postmenopausal women with moderate bone loss, T379

Comparison of ALN and strontium ranelate in men with established primary osteoporosis, T374

Comparison of effects of ALN and raloxifene on the lumbar BMD, bone turnover, and lipid metabolism in elderly women with osteoporosis, T398

Effect of combined treatment of ALN and Vitamin K $_2$ on BMD and strength, W328

Efficacy of ALN for the treatment of osteoporosis in postmenopausal women with subclinical hyperthyroidism, W364

Efficacy of continued ALN for fractures in women without prevalent vertebral fracture, 1057

- Impairs angiogenesis and bone formation during the early stages of bone healing in an animal model for ONJ, 1265
- Improved tendency in esophageal-gastroduodenal mucosal effect of enterocoating ALN combined with calcitriol drug compared with ALN only in Korean postmenopausal women, T378
- Induced bone matrix changes on resorption and turnover, effects of, W330
- Lipid profile and BMD changes in postmenopausal Korean women treated with ALN, T400
- Low-energy femoral diaphyseal fractures associated with ALN use, M430, S430
- Mechanistic bases of BMD increase during ALN therapy, M435, O435, S435
- Mineralization status of bone matrix in postmenopausal women during a 10-year ALN treatment period, M437, S437
- Pretreatments abolish this process, GC suppresses the differentiation of osteoblasts by enhancing the expressions of BMP antagonists, M059
- Prevention of bone loss in acute spinal cord patients over one year with ALN, T392
- Prior ALN treatment does not inhibit the early stimulation of osteoblast activity in response to TPTD, M388, S388
- Randomized, active-controlled, 6-month study of once weekly 280 mg oral buffered ALN solution for treatment of PDB, M476
- Alfacalcidol (ALF)**
Differential effects of ALF in the distal tibial metaphyses, M417
Effect of ALF on volumetric BMD measured by pQCT in ALN-treated postmenopausal women with osteopenia or osteoporosis, M453
- Alkali therapy**
Biochemical and histological assessment of the effects of alkali therapy on bone during high animal protein intake, T365
- Allantoin**
Percutaneous injection of allantoin accelerates fracture repair, W258
- Alox5**
Alox5 null mice have reduced cortical bone density, altered bone turnover and low serum IGF-1, 1228
- Alpha-2**
Osteoblast response to titanium microtopography is dependent on, W002
- Alpha lipoic acid**
Alpha lipoic acid attenuates vascular smooth muscle calcification via the expressional regulation of genes related to apoptosis and oxidative stress, W436
- Alpha1**
Modify RANKL/OPG expression and cell proliferation in human osteoblasts and osteoblastic cells, T006
- Atherosclerosis**
Bone formation in atherosclerotic vessels, T473
Does low bone mass predict carotid atherosclerosis in postmenopausal women?, T352
- AluI**
Polymorphism in ESR2 is associated with reduced risk of osteoporotic fractures, T218
- Aluminum (Al)**
Distribution and localization of Al in bone tissues of aluminum osteopathy, W090
- Ameloblast**
Differentiation and proliferation, CAII regulates via intracellular pH-dependent mechanism, T121
- Amelogenesis**
Identification of calcein expression using ACP DDRT-PCR method, T129
- Amenorrhea.** See also *Menarche*
Bone formation is predicted by resting metabolic rate and leptin in exercising women with hypothalamic amenorrhea, T197
Fracture risk factors in breast cancer survivors with chemotherapy-induced amenorrhea, M299
Increased caloric intake is associated with reversal of amenorrhea and favorable changes in metabolic and bone markers, T200
Model of secondary amenorrhea in the adolescent female rat, W510
- Amino terminal domain (NTD)**
Identification of proteins that interact with the collagen type XI ($\alpha 1$), M149
- Aminobisphosphonate**
Giant osteoclast formation after long-term oral aminobisphosphonate therapy for postmenopausal osteoporosis, 1058
- Aminoimidazole-4-carboxamide ribonucleoside (AICAR)**
AMPK activator in vivo, osteoclast formation and osteolysis are promoted by, 1150
Induce the differentiation and mineralization of osteoblastic MC3T3-E1 cells via inhibiting the mevalonate pathway and enhancing BMP-2 expression, M056, S056
- AMP-activated protein kinase (AMPK)**
Activator AICAR in vivo, osteoclast formation and osteolysis are promoted by, 1150
- Amputees**
BMD and bone quality in unilateral lower limb amputees, W504
- Amyloid precursor protein (APP)**
Cleavage products of, regulate osteoblast function, T145
- ANA**
Responses of bone in ANA knock-out mice to ovariectomy, T030
- Anagen**
Induction, similar effects of proteasome inhibition on osteoblast differentiation and, W111
- Androgens**
Act directly via the AR in mineralizing osteoblasts to regulate bone turnover and maintain trabecular bone, 1217
Alpha/beta-T cells do not modulate androgen withdrawal-induced bone loss in aged rats, M466, S466
Attenuate p66^{shc} phosphorylation via an ERK and PKC β signaling cascade, T185
- Androgen receptors (AR)**
Androgenic effects on bone and body composition depend on concerted and additive activation of, M244, S244
Androgens act directly in mineralizing osteoblasts to regulate bone turnover and maintain trabecular bone, 1217
Gene, association of tri-nucleotide (CAG and GGC) repeat polymorphism in Taiwanese women with refractory or remission RA, W433
Role in the lineage commitment of BMSCs, T198
Signaling, dissection of, T203
- Anemia**
Hip geometric structure is weaker in anemic women, M381, S381
Lower hip BMD among ethnically diverse postmenopausal women with anemia, W255
- Angiogenesis**
Chondrostatin as a new inhibitor of, T259
Dramatic increase in bone marrow of rescued RANKL-deficient mice by expression of soluble RANKL transgene, M096, S096
Genetic and pharmacologic activation of the HIF-1 pathway promotes, 1065
- Angiopoietin 1 (Angpt1)**
Overexpression of osteoblast specific, increases bone mass, M016, S016
- Angiotensin converting enzyme (ACE)**
ACE-011 increases BMD and improves microarchitecture in cynomolgus monkeys, 1230
ACE inhibitor use is not associated with serum concentrations of bone related hormones in older men, T469
Single dose of ACE-011 is associated with increases in bone formation and decreases in bone resorption markers in healthy, postmenopausal women, 1132
- Angiotensin II (Ang II)**
Receptor in osteoclasts and its roles on differentiation and survival, expression of, W073
Suppresses bone mass via AT1 receptor in long bones of adult mice, M141
- Angiotensin II type 1 (AT1)**
Receptor in long bones of adult mice, Ang II suppresses bone mass via, M141
- ank.** See *Progressive ankylosis gene*
- Ankylosing spondylitis (AS)**
Bone metabolism in an animal model of, W441
Increased expression of RANKL in stimulated T-cells from patients with, W446
- Annealing controlled primers (ACP)**
Identification of calcein expression in rat amelogenesis using, T129
- Annexin V/VI/VIII**
Collagen interactions regulate growth plate chondrocyte mineralization, 1111
Critical bone matrix-dependent osteoclast gene transcriptionally regulated by RANKL and NFATc1, W068
Loss affects endochondral bone formation, T131
- Annulus fibrosis**
Effect of removal of nucleus pulposus cells on, M124
- Anoikis**
Small GTPase RhoA and its effector kinase ROCK mediate actin cytoskeleton reorganization leading to, M233, S233
- Anorexia nervosa**
BMD in Japanese adolescent girls with anorexia nervosa, T308
Thin healthy women have a similar low bone mass as women with anorexia nervosa, W405
- Anterior cruciate ligament (ACL)**
Tibial insertion after rupture, cell death and cell proliferation of cartilage layer in, W096
- Anti-epileptic drugs (AED).** See *Epilepsy*
- Anticoagulants**
Long-term use of oral anticoagulants and risk for osteoporosis, W300
- Antidepressants**
Fragility fracture increases antidepressant use among women 65 years of age and older, M429

- Is antidepressant use associated with bone loss or fractures in postmenopausal women?, 1272
- Antiresorptive agents**
Treatment with increases circulating FGF-23, decreases renal expression of 25OH(D) 1(OH)ase, and reduces circulating 1,25(OH)₂D, W127
- Anulus fibrosus cells**
IGF-1-treated, activation of Erk1/2 prevents the FasL-induced apoptosis in, T117
- AP-1**
M-CSF stimulates bone resorbing activity of mature human osteoclasts via increased activation of, T075
- Apatite-wollastonite (A-W)**
Bespoke bioceramic scaffolds support MSC growth and osteogenic differentiation, M050
- APC^{min}**
Evaluation of bone phenotype in mice carrying APC^{min} gene mutation, M175
- Apoptogenesis**
Smad4 has a direct apoptogenic role at the mitochondria, M205
- Apoptosis**
Captured under a microscope connected with time-lapse motion video picture, decisive moment of, M072
Cementoblast cultured on fibrin induces fibrinolysis and, T139
17β-Estradiol abrogates in skeletal muscle cells through extra-nuclear estrogen receptors, T196
Evaluation in GC-induced osteoporosis in rats treated with Ris, W318
FasL-induced, activation of Erk1/2 prevents in IGF-1-treated anulus fibrosus cells, T117
Hormonal regulation of hypertrophic chondrocyte, W094
Osteoblast, regulation by estrogens is preserved when the ER cannot directly interact with DNA, T184
Osteoclast, FADD-caspase-8 axis regulates, T102
Proteasome inhibition induces apoptosis in growth plate chondrocytes, M121, S121
Regulation of skeletal homeostasis by anti-apoptotic molecule Bcl-2, 1290
In young and old mice, comparative analysis of osteoclast bone resorption activity and, W081
- 2-Arachidonyl glyceryl (2-AG)**
Long-term effect of 2-AG ether on body weight and bone mass, W344
- ARCHITECT Analyzer**
Development of an assay for 25OH(D) on the, W156
- Arkadia**
Represses skeletal muscle differentiation through enhancement of Myostatin and TGFβ signaling, M206
- Aromatase**. See also *CYP19*
Characterization of regions upstream of exon II of, that mediate regulation by cAMP in murine osteoblasts, T032
Local overexpression in osteoblasts leads to clearly increased bone mass, 1218
- Arthritis**. See also *Osteoarthritis*
Adjuvant-induced, possible suppressive role of Galectin-3 in osteoclastic bone destruction accompanying, M108
Periarticular bone loss in arthritis, WG23
Periarticular bone loss in, role of synovial GC generation, M232
- Value of bone and cartilage markers in the conservatively treated community-based inception VERA cohort, M500
- Arthritis, autoimmune**
Immunoregulatory role of RANKL-stimulated dendritic cells on, T162
- Arthritis, collagen-induced (CIA)**
Anti-GGT antibody attenuates osteoclastic bone erosion, T090
Effects of HO-1 on, T130
Small molecule inducer of activated CD4⁺ T cell death inhibits disease progression in, M499
Therapeutic effect of KHB9 on cartilage degradation and inflammation in, M135
- Arthritis, inflammatory**
Osteoblast-mediated bone formation is suppressed at sites of focal bone erosion in inflammatory arthritis, W007
- Arthritis, juvenile chronic (JCA)**
Prevalence of osteopenia in children with early JCA, T515
- Arthritis, KRN**
Serum-induced, transgenic disruption of GC signaling in mature osteoblasts attenuates, T183
- Arthritis, psoriatic (PsA)**
BMD and prevalence of osteoporosis and fractures in PsA, M470
- Arthritis, rheumatoid (RA)**
Anti-TNF treatment in RA patients does not alter the one-year change in spine and hip BMD compared to control patients, M497
Effect of ETN on bone metabolism in patients with, W434
Evaluation of the BMD and body composition in early RA, W440
Importance of biochemical markers of bone and cartilage turnover as the predictors of radiographic progression in patients with early RA, W431
Joint destruction, treatment with anti-TNFα antibody recovers osteoclast maturation deviated from bone remodeling cycle, W439
Osteoporosis and RA, which nutritional factors are associated?, W442
Refractory or remission, association of tri-nucleotide (CAG and GGC) repeat polymorphism of AR gene in Taiwanese women with, W433
Rheumatoid synovial fibroblasts promote osteoclastogenic activity by activating RANKL via TLR-2 and TLR-4 activation, W435
TRACP isoform 5a as a marker of disease severity in RA, W432
- Arthritis, TNF-mediated**
VDR deficiency aggravates, W443
- Aryl hydrocarbon receptor (AhR)**
Crosstalk in BaP-mediated inhibition of osteoclastogenesis, NF-κB but not NFATc1 is involved in, T106
- ASARM-peptides**
Directly responsible for defective mineralization in HYP, 1155
SIBLING (minhibins), degradation of MEPE, DMP1 and release of, 1155
- Ataxia telangiectasia mutated (Atm)**
Genetic interaction between, p53 in bone development, M271
Regulates osteoblast differentiation through the BMP-Smad1/5/8 pathway, M017
- ATDC5**
Gene-trap mutagenesis revealed the involvement of vinculin in chondrogenic differentiation in, M137
Identification of a novel chondrogenic factor SNX19 using a real-time fluorescence monitoring cell line, 1185
- ATF4**
As a crucial partner of c/EBP in osteoblast differentiation, W029
Regulates chondrocyte proliferation and differentiation by direct targeting Ihh transcription, 1183
- Athletes**. See also *Exercise*
Effect of combined strength and speed training on cortical bone geometry and mass distribution in master athletes, W505
Relationship between serum 25OH(D) and bone markers in professional football players, W503
- Atomic layer deposition (ALD)**
Derived HA surface, attachment of osteoblast-like cell on, W009
- Atorvastatin**
Inhibits lipid induced aortic valve calcification and osteoporosis via the Lrp5/Wnt mediated pathways in vivo and in vitro, 1154
- ATP**
1,25(OH)₂ Vitamin D₃-induced release, molecular mechanisms in osteoblasts, 1030
Modulation of MAPKs and c-fos expression in osteoblastic and breast cancer cells, T064
PTH enhances induced ERK1/2 activation via a competitive mechanism involving GRK2 in osteoblastic cells, T060
Released from human osteoblasts by multiple mechanisms, M065
- Autocrine mechanism**
RANKL stimulates osteoclasts to release VEGF-C and enhances osteoclastic bone resorption through, 1100
- Autosomal recessive hypophosphatemic rickets (ARHR)**. See *Rickets*
- AZD0530**
Phase II pilot study of safety and effects on bone resorption of AZD0530 in prostate or breast cancer patients with bone metastases, W189
- B**
- B-raf**
Dispensable for endochondral bone development, W095
- B₁**
Induction of kinin receptor in osteoarthritis is performed by vasoactive peptide ET-1, M117
- BAG-1**
Role as an intracellular binding protein for 1,25-dihydroxyvitamin D₃, M252
- Basic multicellular unit (BMU)**
Activity, lacunocanalicular fluid flow and regulation of, M069
- Bax deficiency**
Bax-deficient mice exhibit marked increase in callus size and cartilage during endochondral repair of femur fractures, 1223
- Bazedoxifene**
Efficacy of bazedoxifene for prevention of postmenopausal osteoporosis, 1209
Efficacy of bazedoxifene in reducing new vertebral fracture risk in postmenopausal women with osteoporosis, 1206

- Safety and tolerability of bazedoxifene in postmenopausal women with osteoporosis, W385
- Bazedoxifene acetate (BZA)**
Effects of BZA on bone loss, M404
Safety and tolerability of BZA for the prevention of postmenopausal osteoporosis, W387
- bcl-x**
Osteoclast-specific deletion of gene, functional analysis of Bcl-xL in osteoclasts by, 1098
- Bcl-xL**
Functional analysis in osteoclasts by osteoclast-specific deletion of bcl-x gene in mice, 1098
Molecular interaction with Bnip3 determines the cell fate of hypertrophic chondrocytes, 1181
- Bcl2**
Anti-apoptotic molecule, regulation of skeletal homeostasis by, 1290
In osteoclastogenesis ex vivo, role of, W083
- Benzo[a]pyrene (BaP)**
Mediated inhibition of osteoclastogenesis, NF- κ B but not NFATc1 is involved in AhR-RANKL crosstalk in, T106
- Beta-adrenergic receptors**
Beta-adrenergic receptor agonist administration during hindlimb unloading attenuates losses in bone geometry, structure, and mechanical properties, M514, S514
- Beta blockade**
Mitigates bone loss during energy restriction partially via leptin, 1110
- BHH9**
Effects on expression of VEGF and their receptors during osteoblast differentiation, W042
- Biglycan (bgn)**
And fmod control bone mass by regulating osteoclast differentiation through BMSC, M157, O157, S157
- Bim**
Akt1 contributes to maintenance of bone mass and turnover by inhibiting apoptosis of osteoblasts through, 1211
- Bioceramics**
Scaffolds support MSC growth and osteogenic differentiation, M050
- Bioluminescence**
Application in stem cell-based bone formation, W046
- Biomechanics**
Biomechanical testing in experimental bone interventions, W457
And body size quantitative trait loci in HcB/8 and HcB/23 F2 mice, W466
Correlation between growth patterns and material composition leads to preferred sets of adult bone traits, 1242
Functional muscle-bone unit in young active women, W488
Technique for calculating area moment of inertia of long bones using CT data, W225
Topological analysis and spatial distribution of apparent trabecular bone in radiographs correlate to biomechanical bone properties, W229
- Bioreactors**
Design for osteochondral tissue, M151
- Birth weight**
Birth weight predicts lean body mass and thus BMC in healthy men at peak bone mass, M467
Impact of birth weight and age at menarche on skeletal growth in young women, W256
- Bisphenol-A-diglycidyl ether (BADGE)**
Combination with Vitamin D potentiates their pharmacological inhibition of PPAR γ and increases osteogenic differentiation of adipocyte precursors, W155
- Bisphosphonates**
Adherence and fracture risk, M440, S440
Affinity to hydroxyapatite and farnesyl pyrophosphate inhibitory potency, together, drive in vivo efficacy, W325
Analog that lacks anti-remodeling activity prevents osteocyte and osteoblast apoptosis in vivo, 1011
Are bone resorption markers during osteoporosis treatment with bisphosphonates within the lower half of the premenopausal range?, M314
Case of GI side effects or contraindications for oral bisphosphonates treatment with intravenous pamidronate is a good alternative, T388
Cause inflammatory response in vivo and in human peripheral blood mononuclear and polymorphonuclear cells in vitro, W361
Changes in bone resorption markers during osteoporosis treatment with oral bisphosphonates, M315
Convenience and preference perceptions after one year of oral bisphosphonate treatment in a group of Brazilian women, W383
Essential mechanistic studies of the esophagogastric transit of oral bisphosphonates, W327
FDPS, *GGPS1* and *FDFT1* gene polymorphisms as pharmacogenetic markers for the response to bisphosphonates, T213
How quickly do oral bisphosphonates work, and are there differences between them?, T380
Impact of GI medication usage with regard to discontinuation and restart behavior with oral bisphosphonates in three large U.S. Physician groups, M442
Long-term bisphosphonates therapy and increase fracture risks, W375
Longitudinal patterns of adherence with bisphosphonates, M444
Modeling the contribution of long-term persistence with weekly or yearly bisphosphonate treatment to fracture outcomes, M443, S443
Therapy and hip fractures within the Ris and ALN (REAL) Cohort Study, T384
Three-year effects of bisphosphonates on treatment of osteoporosis and on reducing the risk for vertebral fractures of RA patients, W358
Treatment during long-term disuse blunts the recovery response of bone to restored weight-bearing, M403, S403
Use increases in patients with osteopenia and prior fractures following a multifaceted osteoporosis educational intervention, T396
Use increases in patients with osteoporosis following an integrated osteoporosis educational intervention, M436
Women are more persistent with monthly bisphosphonate therapy compared to weekly bisphosphonates, W366
Year 3 effects on bone mass in women using bisphosphonates after PTH therapy, 1094
- BK channels**
In human osteoblast-like cells, properties and function, W045

Molecular interaction with Bcl-xL determines the cell fate of hypertrophic chondrocytes, 1181
- Body mass index (BMI)**
High cholesterol, smoking and coffee consumption but low BMI are risk factors for fractures, T343
High leisure time physical activity and high BMI protect against fractures, but heavy work and smoking increase risk, W288
- Bone accretion**
Skeletal muscle-specific overexpression PAPP-A increases, T080
- Bone adaptation**
Bone adaptation to impact loading, M525, S525
Functional, comparison of in vivo model to the calculated mechanical environment, W086
Inadequate, in bone cell specific Cx43 deficient mice, 1285
Site specific, modulation by signaling in osteocytic networks, W060
- Bone area**
Increased due to mechanical loading gradually decreased following cessation of loading, T151
- Bone cells** See also Bone marrow stromal cells; Fetal bone cells
Evidence for lineage dependent non-canonical Wnt signal transduction by, 1139
Induced proliferation and recruitment, effects of mechanical strain on osteocytes, W054
Mechanical loading of, collagen and osteopontin upregulation by, T154
PHD1 and PHD3 are expressed but are not essential for bone homeostasis, T132
Specific Cx43 deficient mice, inadequate bone adaptation in, 1285
- Bone density**
At age of peak bone mass in women is not associated with history of childhood fractures, M535, S535
And body composition values in healthy Japanese girls, T512
Clinical evaluation of jaw bone density with a newly developed "jaw bone density evaluation system," T280
EPO as a regulator of in elderly men, M177
Muscle cross section and muscular power in the lower limbs in healthy postmenopausal women, patients on corticosteroids and fracture patients, M367
Use of s-RANKL, s-FREE RANKL and OPG serum levels for prediction of bone density, W219
- Bone destruction**
Osteoclastic, possible suppressive role of Galectin-3 accompanying adjuvant-induced arthritis in rats, M108

Bone development

Embryonic, BMP signaling in osteoblasts negatively regulates canonical Wnt signaling to reduce bone mass during, M270, S270
 Endochondral, A-raf and B-raf are dispensable for, W095
 Genetic interaction between p53 and Atm in, M271
 Intramembranous, osteoblast-targeted disruption of GC signaling delays, T182

Bone erosion

NEMO (IKK) modulates, T098

Bone fillers

Development of novel mini-tetrapod bone fillers, T356

Bone formation

In 2D and 3D tissue engineered constructs, use of statins to enhance, T003
 Deletion of Cnb1 in osteoblast reveals novel role for calcineurin in, T283
 Ectopic, functional RNAi screening for Runx2-regulated genes corresponding to, M273
 Effects of CIB on, W006
 Effects of traumatic brain injury on, during fracture healing in a rat model, M008
 Endochondral, BMP canonical signaling through receptor Smad 1 and Smad 5 is required for, M171, S171
 Endochondral during embryonic development, CITED1 ablation impairs, M142, O142, S142
 Endochondral, loss of annexin VI affects, T131
 Endochondral, osteogenic stem cell homing to sites of, T071
 Endochondral, role of the transcription factor Lbh in, M122
 Haversian-type bone and blood vessels guided by the artificial ECM of vasculature-inducing geometry, M154
 Imatinib mesylate inhibits and decreases bone mass in vivo by inhibiting PDGFR-mediated osteoblast mitogenesis, T018
 Impaired in mice lacking Gs α in early osteoblasts leads to marked bone fragility, T020
 NELL-1 promotes in a spinal fusion model, M200
 New approach to assess rates and IHC/ISH in the same bone specimen, T115
 New, TGF β stimulates in neonatal calvariae via suppression of DKK1, M197
 OASIS is involved in, M029, S029
 OsM is an essential stimulus of osteoclastogenesis and, T068
 Osteal macrophages, novel regulators of, T186
 In osteoblastic cells, osteoclasts secrete an activity promoting, T005
 Osx as a regulator of, M010, S010
 Over-expression of Runx2 in mesenchymal cells enhanced, T066
 Point mutation of endofin at PP1c-binding domain (F872A) stimulates, T256
 Rate falls after puberty in Brlt OI mouse due to cellular uncoupling, W166
 In skeletal remodeling, TRIP-1 as an important co-regulator of, T252
 Stem cell-based, application of bioluminescence in, W046
 TGF β 1 induces migration of MSCs in coupling bone resorption and formation, T072
 In vitro and in vivo, Zfp521 is a novel inhibitor of Runx2 activity with opposite effects on, T250

In vivo ectopic induced by BMP-2, noggin siRNA gene transfer enhances, W121

In vivo, PGD₂ in, T001

In vivo tibial compression stimulates bone formation, M521

Bone fragility

Impaired bone formation in mice lacking Gs α in early osteoblasts leads to, T020
 Knockout of CatK in adult mice does not result in, W063
 May be caused by mechanostress inequality in transitional period from a steady-state bone metabolism to another state, W470

Bone geometry

Dok-1 and Dok-2 deficiency enhances bone resorption and modulates in vivo, M086, S086
 Heritability of the principal components of a statistical shape model describing midshaft femur geometry, W172
 Load-specific differences in femoral neck cortical geometry, WG32

Bone growth

Local CNP clearance system as a regulator of CNP-GC-B system for, T168
 Rapid site-specific bone growth by a combination of bone marrow ablation, PTH and bisphosphonate therapy, W143
 Reduced, deficiency of GPR30 leads to, T201
 Sexual dimorphism in radial and longitudinal bone growth differ by tempo and magnitude, T039

Bone healing

Implication of OPN and BSP in, M160, S160
 Intramembranous, local application of GH and IGF-1 have a similar effect on, M193
 Normal endochondral bone healing follows continuous bisphosphonate pre-treatment, T089

Bone health

Approach for screening natural plant ingredients for development of nutraceutical supplements to support bone health, W338
 Bringing bone health to seniors' communities, W376

Bone homeostasis

Dimorphic effects of Notch signaling in, T212
 PHD1 and PHD3 are expressed in bone cells but are not essential for, T132

Bone loss

Antiepileptic drugs affect bone loss via reproductive hormones, W415
 Beta blockade mitigates during energy restriction partially via leptin, T110
 Comparative analysis of expression profile in the anatomically separated parts of femurs prepared from unloading induced bone loss model, T153
 Comparison of a soluble ACTRIIA, PTH and ZOL for treatment of established bone loss, T233
 DEX-induced in vitro, silencing *Dkk1* expression rescues, M057
 Following small bowel transplantation, T497
 Of lactation, estrogen deficiency and PTHrP infusion do not fully reproduce, M220
 Ovariectomy-induced, purinergic P2X₂ receptor is responsible for, M248, S248
 Overexpression of low molecular weight isoform of FGF-2 partly prevents, T160
 Periarticular in arthritis, role of synovial GC generation, M232

Selective deletion of the membrane-bound CSF1 isoform in vivo does not affect estrogen-deficiency, T255

Tri-partite relationships between bone, cartilage and adipogenic changes contribute to bone loss, T277

Use of RAP-011 in combination with PTH or ZOL using a mouse model of established bone loss, M394, S394

In vivo, I κ B α -deficient mice display increased, T147

Bone markers

Relationship with serum 25OH(D) in professional football players, W503
 Responses to short-term training, W056

Bone marrow

Adipogenesis, effect of estrogens on, M243
 Adiposity, opposing effects of GH and alcohol reveal a critical role in the reciprocal relationship between adipocyte and osteoblast differentiation, M196
 Cell culture, differentiation during medullary bone formation period in Japanese quail, M091
 Dramatic increase in hematopoiesis and angiogenesis of rescued RANKL-deficient mice by expression of soluble RANKL transgene, M096, S096
 IGF-1 engineered MSCs improve the fracture healing process, M191, S191
 Long-term follow up of BMD, bone turnover markers and 25-hydroxyvitamin D in bone marrow transplant survivors, T499
 MSC from, osteogenic differentiation and interaction with Ti6Al4V, T053
 Secretion of adipokines and hypertrophic changes in adipocytes, M473

Bone marrow-derived mesenchymal stem cells (bmMSC). See Mesenchymal stem cells, bone marrow-derived**Bone marrow fat cells**

Temporal feature in the process of steroid-associated ON development, T178

Bone marrow stromal cells (BMSC)

Activation of LXR inhibits hedgehog signaling and osteogenic differentiation of, W023
 bgn and fmod control bone mass by regulating osteoclast differentiation through, M157, O157, S157
 Calcitriol inhibits differentiation into osteoblasts in a manner cooperative with but independent of TGF β , T069
 Differentiated cell line, PTHrP induces MKP-1 in, M001
 FGF2 and TGF β 1 have opposite effects on the mural cell phenotype of CD146⁺, M178
 Nondestructive evaluation of cell numbers in BMSCs, T043
 PTH/PTHrP receptor modulates the pool of, W138
 Rapamycin inhibits osteoblast proliferation and differentiation in, M007
 Role of AR in the lineage commitment of, T198
 Role of EphB/ephrin-B interactions in cell attachment and spreading of mesenchymal precursors derived from, W033

Bone mass

Ang II suppresses via AT1 receptor in long bones of adult mice, M141
 Body mass influences bone mass independent of leptin signaling, M148, S148

- Bone varies the spatial distribution of its mass, rather than its mass, to optimize strength and minimize bulk, M333
- Cancellous, opposing effects of GH and alcohol reveal a critical role in the reciprocal relationship between adipocyte and osteoblast differentiation, M196
- Determinants of bone mass and fracture in adolescent children, 1042
- Determinants of bone mass and size in term, near-term, and preterm boys, M532
- During embryonic bone development, BMP signaling in osteoblasts negatively regulates canonical Wnt signaling to reduce, M270, S270
- Expression of *OCZF* directed by the CatK promoter affects, M099, O099, S099
- Imatinib mesylate inhibits bone formation and decreases in vivo by inhibiting PDGFR-mediated osteoblast mitogenesis, T018
- Increased, transgenic expression of an engineered Gs-coupled receptor in osteoblasts produces, 1019
- Interaction between dietary fat and polymorphisms in a previously undetected, alternate 3 UTR of the PPARG gene influences bone mass, M285
- Local overexpression of aromatase in osteoblasts leads to clearly increased, 1218
- Low, transgenic mice overexpressing sFRP-4 have, but do not exhibit disturbed phosphate homeostasis, M209
- Low, with null mutation in TGIF, 1286
- Maintenance of by inhibiting apoptosis of osteoblasts through FoxO3a/Bim axis, Akt1 contributes to, 1211
- Osteoclast specific ablation of *dicer* increases, 1292
- Overexpression of osteoblast specific *Angpt1* increases, M016, S016
- Peak spine and hip bone mass in Korean women, W262
- Reference graphs of age-related changes in bone mass, volumetric density, design and strength and of muscle-bone interactions in normal men and women, W235

- TRIP-1, an important co-regulator of bone formation in, 1252
- TRPV4 affects by regulating Ca signaling required for osteoclast activity, 1101
- TSG-6 as a new regulator of, T092
- In various bony microenvironments, distinct roles of ITAM signaling in, 1291
- In vivo, PGD $_2$ in, T001
- Bone repair**
- Endochondral, SDF-1/CXCR4 is essential for in vivo, T163
- Interest of platelet-derived products for bone reparation, T498
- Osteoblasts in adult bone use *Slug* for, but not remodeling, 1213
- Bone resorption**
- Activity and apoptosis in young and old mice, comparative analysis of, W081
- Conditional inactivation of the CTSK gene in adult mice results in osteopetrosis without activation of compensatory mechanisms for, W064
- Defects in osteoclasts, disruption of WASP-associated signaling complex formation leads to, M113
- Development of cell-based assays for identifying antiresorptive compounds targeting RANK signaling through HTS, M102
- Diphyllin abrogates acidification of, T093
- Dok-1 and Dok-2 deficiency enhances and modulates the geometry of bone in vivo, M086, S086
- Effect of food intake on bone resorption in cynomolgus monkeys, W221
- Effects of ALN-induced bone matrix changes on, W330
- High cardiovascular risk in men with increased bone resorption or low bone mass, M468, S468
- Increased activity of large osteoclasts in inflammation, mechanisms leading to, T105
- Increased, transgenic overexpression of PTP-oc in cells of osteoclastic lineage led to, M112, O112, S112
- Inflammatory induced by LPS in vivo, TNFR1 and TNFR2 differentially regulate, M110, S110
- Inflammatory, TNF α /CCL3-5/CCR5 cascade mediates RANKL $^+$ cells migration in, M181
- M-CSF stimulates activity of mature human osteoclasts via increased activation of AP-1 and NFB, T075

- Modeling role of ER in transcellular Ca flux in, M105
- Murine model, use of nanogels as a drug delivery system for TNF α antagonist in, M101
- Osteoclast activity by regulating the V-ATPase and Rho activity, CK-B involves, M083
- Osteoclast activity, canonical NF- κ B pathway mediates, T094
- Osteoclast specific ablation of dicer suppresses, T292
- Osteoclastic, cytoplasmic terminus of a V-ATPase accessory subunit Ac45 is required for proper interaction with V0 domain subunits and, M104
- Osteoclastic, potential role of Rab3D-calmodulin interaction in, M103, S103
- Osteoclastic through an autocrine mechanism, RANKL stimulates osteoclasts to release VEGF-C and enhance, I100
- Osteoclastic, VGLUT1 knockout mice develop osteopenia due to an increase in, T085
- Osteoclasts secrete an activity promoting bone formation and canonical Wnt signaling in osteoblastic cells, T005
- Small GTPase cdc42 enhances, I146
- TGF β 1 induces migration of MSCs in coupling bone resorption and formation, I072
- in vitro, homogenous fluorescence-based Ca assay for the rapid determination of, T096
- Bone sialoprotein (BSP)**
- Implication in bone healing, M160, S160
- Mediated osteoblast differentiation and mineralization is principally dependent on the intrinsic characteristics of responding cells, T149
- Post-translationally modified, NFATc1 mediates the stimulatory effects on the resorptive activity of rabbit osteoclasts, T099
- Bone size**
- Coadaptation among trabecular and cortical traits contribute to genetic variation affecting bone size in recombinant inbred mouse vertebrae, T241
- ENU mutation mapped to a distal region of Chromosome 11 is major determinant of bone size independent of body growth, T211
- Genetic control of by regulating the differentiated function of periosteal cells, locus on Chr 4 exerts, W008
- IGFBP-3, 4 and 5 triple knock-out mice have larger bones, M189
- Targeted disruption of Efnb1 in osteoblasts reduces, I107
- Bone-specific alkaline phosphatase (BAP)**
- Development of an assay for the LIAISON[®] Analyzer, W217
- Bone strength**
- Assumptions and limitations in image-based strength assessment of bone, M509
- DXA and QCT geometric structural measurements of proximal femoral strength, T291
- Genetic and environmental effects on muscle cross-sectional area and structural strength of tibia in older female twins, T204
- Genetic loci for bone structure and strength identified in inbred COP and DA rats, W185
- Genome-wide scan of metacarpal bone geometric strength indices in the Framingham Study, W177
- Is bone strength a simple function of muscle, or does other mechanical loading play a role?, I037
- Lean and not fat mass is associated with male proximal femur strength, W471
- And toughness are reduced by loss of architecture, W240
- Trends in femur structural strength with aging in Canadian adults, W233
- Bone strength indices (BSI)**
- Longitudinal change in BSIs, T285
- Bone surface**
- Mast cell migration precedes and appears essential for PTH-induced peritrabecular fibrosis, M482, S482
- Sex-specific changes during adolescent growth, pQCT analysis of the mid-tibia, M527
- Bone texture**
- Laws' masks descriptors applied to bone texture analysis, T295
- Morphological texture analysis of radiographs of the proximal femur, W449
- Bone tissue**
- Effects of GC on BMP-2 and BMP-7 expressions in, M234
- Bone turnover**
- Age-related changes in bone turnover in men, W218
- Androgens act directly via the AR in mineralizing osteoblasts to regulate, I217
- Association of dietary Ca, BMD and biochemical markers of bone turnover among rural Thai women, T313
- Biochemical markers of bone turnover, hip bone loss and non-spine fracture in men, I074
- Cancellous, opposing effects of GH and alcohol reveal a critical role in the reciprocal relationship between adipocyte and osteoblast differentiation, M196
- Effect of energy restriction on bone turnover in physically active females, W001
- Effects of ALN-induced bone matrix changes on, W330
- Effects on bone turnover of the potent, once-daily, oral Src inhibitor AZD0530 in patients with advanced solid malignancies, W192
- Environmental influences on variability in levels of bone turnover markers, M313
- Establishing a reference range for bone turnover markers in 635 healthy, young, premenopausal women, I168
- Fluctuation of the normal values of the biochemical markers of bone turnover in Greek premenopausal women, W208
- GLP-1 action in normal and type 2 diabetic state, T207
- In late gestation and six months postpartum, T002
- Maintenance of by inhibiting apoptosis of osteoblasts through FoxO3a/Bim axis, Akt1 contributes to, I211
- Markers and prediction of fracture, I073
- Markers of bone turnover in peripubertal girls, M317
- Prevalence of severe suppression of bone turnover among patients with atypical osteoporotic fractures, W359
- Reproducibility of biochemical markers of bone turnover in clinical practice, W215
- Serum IGFBP-2 is a marker of, I253
- Bortezomib**
- Anti-myeloma response of bortezomib is associated with reduced osteoclastogenesis and increased osteoblastogenesis and bone mass in myelomatous bones, I173
- Brain injury, traumatic**
- Effects on bone formation/remodeling during fracture healing in a rat model, M008
- Breast cancer**
- Accelerated bone resorption, due to dietary Ca deficiency, promotes tumor growth in a murine model of breast cancer bone metastasis, I006
- Cell lines, activation of FXR by bone-derived lipid, M249
- Components of native bone environment involved in breast cancer metastasis, T252
- Conditional ablation of PTHrP in mammary epithelial cells inhibits progression, I295
- Fracture threshold in breast cancer patients treated with adjuvant aromatase inhibitors, M147
- Heparin-like polysaccharides markedly reduce osteolytic bone destruction and tumor growth in a mouse model of breast cancer bone metastasis, T241
- High extracellular Ca directly stimulates MDA-MB 231 breast cancer cell by a mechanism involving the CaR, T250
- Oral bisphosphonate treatment prevents the changes of BMD and bone biomarkers in postmenopausal Japanese women with early breast cancer treated with aromatase inhibitor, W186
- Runx2 regulates the Ihh-PTHrP pathway in breast cancer cells, M295, S295
- Sclerotic bone changes found on densitometry testing in a patient with a remote history of breast cancer, W13
- Serum TRACP 5b increases with advancement of osteolysis in a nude mouse model of breast cancer bone metastasis, T239
- Breast cancer cells**
- MAPKs and c-fos expression in, ATP modulation of, T064
- Btk**
- Lack of Btk results in osteoporosis, despite defects in osteoclast function, T097
- C**
- c/EBP α**
- Reciprocal regulation of Dkk1 gene transcription by, I140
- c/EBP β**
- As a crucial partner of ATF4 in osteoblast differentiation, W029
- c-fms**
- Antibody inhibits mechanical stress-induced root resorption, M107
- c-Fos**
- Activation, endogenous TNF in osteoclast precursor cells promotes osteoclastogenesis via, T077
- ATP modulation of, in osteoblastic and breast cancer cells, T064
- Expression in osteoclastogenesis, POZ-Zn transcriptional regulator OCZF/LRF is induced by RANKL and increases, W067
- C-reactive protein (CRP)**
- BMD and hip fracture risk in elderly men and women, T347

- In patients with osteoporotic non-traumatic fractures, W203
- c-Src**
Activation of MAPKs by 17 β -estradiol is mediated in skeletal muscle cells, T194
Interaction of galectin-9 with lipid rafts induces osteoblast proliferation through, W005
Mediated osteoblast differentiation, role of IL-6 signaling in, T170
- C-terminal**
Regulatory domain, growth inhibition of osteoblast progenitors by Runx2 depends on, M047, S047
- C2C12**
TNF α stimulated Msx2 expression in, M020
- C3H10T1/2**
Mineralization of murine mesenchymal cells in micromass culture, W088
- C57BL/6**
Aging, exhibit increased oxidative stress and defective replication, M052, S052
Effect of age on bone mass and bone material properties in C57BL/6 mice, T464
- C57BL/6J**
Seasonal changes in bone and body mass are gender and compartment specific, M269
- CaCl₂**
Hydrothermal treatment with, improving bone bonding ability of Ti, W011
- Calbindin-D_{9k}**
Studies using nullmutant mice reveal active intestinal Ca transport in the absence of calbindin-D_{9k} or TRPV6, 1026
- Calcaneal speed of sound (SOS)**
Improved standardization of calcaneal SOS measurements, T304
- Calcification**
Role of Fe³⁺ ion and ferritin on differentiation of chondrocytes at the stage of, M131
- Calcification, abdominal aortic (AAC)**
On VFA images predicts incident myocardial infarction and stroke independent of clinical cardiovascular disease risk factors, 1076
- Calcification, vascular**
And aortic gene expression are consistent with hyperphosphatemia in OPG-deficient mice, 1117
Associated with increased expression of receptor activator of NF- κ B ligand (RANKL), oxidative stress-induced, 1216
Establishment of model using high dose of Vitamin D, T431
- Calcilytics**
Block the suppressive effect of calcimimetics on PTH mRNA levels in parathyroid cells, M228
- Calcimimetics**
Calcilytics block the suppressive effect on PTH mRNA levels in parathyroid cells, M228
- Calcineurin (Cn)**
Deletion of Cnbl in osteoblast reveals novel role for, in bone formation, 1283
- Calcinosis**
Acro-osteolysis and calcinosis, M490
Homozygous missense mutation in *KLOTHO* causes, 1113
- Calcitonin (CT)**
Analgesic efficacy of CT for vertebral fracture pain, M446
Deletion of the CGRP gene causes a profound cortical resorption phenotype, 1120
And TPTD for vertebral fracture pain, M012
- Calcitonin-gene related peptides (CGRP)**
Deletion of the CT gene causes a profound cortical resorption phenotype, 1120
- Calcitriol (CaI)**
Combination of calcitriol shows more bone sparing effect by suppressing secondary increment of PTH in raloxifene therapy, T433
Inhibits BMSC differentiation into osteoblasts in a mannner cooperative with but independent of TGF β , T069
And its analog successfully elongate survival period and improve the skeletal growth via independent pathway of VDR, W157
Treatment of XLH increases FGF-23 concentration, W123
- Calcium (Ca)**
Absorption from commonly consumed vegetables in healthy Thai women, M396
Comparison of the effects of Ca as carbonate or citrate on bone resorption markers in early postmenopausal women, T417
Density of bone correlates with trabecular bone architecture, M505
Dietary protein and BMD in the presence of low versus high Ca in men and women of the Framingham Study, W266
Effect of Ca channel antagonists on bone metabolism in aged male and female brown Norway rats, M018
Effect of Ca plus Vitamin D supplement on hip geometric structures, 1207
Effect of low-Ca diet on bone properties, W136
Effect of nutritional Ca on the risk of postmenopausal fractures varies with age, M344, S344
Effect of plasma 1,25(OH)₂D concentration or intake on negative correlation between plasma 25OH(D) and PTH concentrations in Japanese adolescents, W159
Effects of Ca sources and soluble silicate on bone metabolism and the related gene expression, W409
Efficiency of dietary Ca use for skeletal growth and mineralization in young pigs fed diets with various phosphorus concentrations, M400
EPO as a regulator of in elderly men, M177
Higher dietary Ca intake along with higher Vitamin D status could suppress bone turnover and BMD decrease in Asian osteoporotic patients, W270
Homogenous fluorescence-based assay for the rapid determination of in vitro bone resorption, T096
Independent and 1,25-dihydroxyvitamin D₃-dependent regulation of the RAS in 25(OH)D 1 α -hydroxylase knockout mice, W150
Intact CaR and PTH genes are required to regulate extracellular concentrations independently, M230
Intake and the risk of osteoporosis and fractures in French women, M345
Intake of Ca and other minerals through water, T307
Low Ca intake and insufficient serum Vitamin D status in treated and non-treated postmenopausal osteoporotic women, T316
Nothing works without Vitamin D and, T393
PC1 selective activation of *Runx2*-II isoform transcription is mediated through, 1142
And phospholipase C γ 2 signaling regulates RANKL-induced osteoclastogenesis, 1104
- PTH upregulates placental transfer in response to fetal hypocalcemia while PTHrP does not, W137
- RANKL-induced expression of TRPV2 is involved in osteoclastogenesis via Ca signaling activation, T103
- Serum Ca values after 4 and 24 weeks of treatment with full-length PTH(1-84) of postmenopausal women with primary osteoporosis, M426
- Signaling required for osteoclast activity, TRPV4 affects bone remodeling by regulating, 1101
- Studies using nullmutant mice reveal active intestinal Ca transport in the absence of calbindin-D_{9k} or TRPV6, 1026
- Supplementation improves lipid profile but does not decrease the incidence of cardiovascular events in postmenopausal women, M449
- Transcellular flux, modeling role of ER in bone resorbing osteoclasts, M105
- Transgenic expression of the hVDR in the proximal small intestine of VDR-null mice improves the utilization of rescue diet in young mice, W154
- Uptake in intestinal epithelial cells, role of TRPV6 and β -glucuronidase in 1,25(OH)₂D₃- and PTH-stimulated, M258
- Urinary excretion of ⁴⁵Ca in mice, T236
- Validation of a simple isotope method for estimating true Ca fractional absorption in adolescent girls, T134
- And Vitamin D supplementation improves bone health in a population-based sample of postmenopausal women, T359
- Calcium (Ca²⁺)**
Presence of, non-adherent circulating progenitor cells with osteoblastic potential become adherent and are able to mineralize, T040
RANKL-evoked oscillations mediated by RGS10 in osteoclast differentiation, mechanism of, M093, S093
- Calcium/creatinine clearance ratio (CCCR)**
24h-urine, discriminative power for the separation between FHH and PHPT, M222
- Calcium excretion (CE)**
24h-urine, discriminative power for the separation between FHH and PHPT, M222
- Calcium phosphate (CaP)**
Effects of Pit-1 type III Na-dependent phosphate transporter overexpression on, W128
Layers, Co incorporation stimulates osteoclast differentiation and activation via HIF pathway, W075
Regulating hormone STC-2 is positively and negatively regulated by 1,25(OH)₂D₃ and PTH in renal proximal tubular cells, W130
- Calcium-sensitive receptors (CaR)**
Activation with cinacalcet increases serum gastrin levels in healthy older subjects, M221
Antagonism of CaR stimulates dose-related release of endogenous PTH in normal volunteers, M427, S427
Conditional ablation causes abnormalities in skeletal development and mineralization, M223, O223, S223
Critical role in bone development, conditional knockouts in early and mature osteoblasts reveal, 1284
Dampens the calcemic response to exogenous 1,25-(OH)₂ Vitamin D in vivo independent of PTH, M224

- Deletion of the 25OH(D) 1 α (OH)ase from mice expressing the null mutation converts a hypercalcemic to a hypocalcemic hyperparathyroid phenotype, M231
- Dose-dependent increases in endogenous PTH concentrations after administration of a CaR antagonist to normal volunteers, I131
- Expression in cartilage is essential for embryonic skeletal development in vivo, I176
- Genetic mosaicism for de novo mutations of the *CASR* gene, WG7
- Intact genes are required to regulate the extracellular Mg and Ca concentrations independently, M230
- Plays a significant role in protection against hypercalcemia, M227, S227
- Regulates PMCA2 activity in mammary epithelial cells, M219, S219
- Regulation by Gcm2 in hyperplastic parathyroid cells, M226
- Testin as a novel binding partner of, M225
- Upregulation of gene expression by the proinflammatory cytokine, IL-6, I187
- Calcyclin**
Expression, identification in rat amelogenesis using ACP DDRT-PCR method, T129
- Calmodulin (CaM)**
CaMK-CREB pathway regulates osteoclast differentiation and function, M114, S114
- Diverging pathways of regulation of osteoclastogenesis, W070
- Potential role in osteoclastic bone resorption, M103, S103
- Calmodulin-dependent kinases (CaMK)**
CREB pathway regulates osteoclast differentiation and function, M114, S114
- Calvariae**
Bone defects, induction of mineralized tissues by in vivo transplantation of cultured dental pulp cells in, T017
- Dynamic imaging reveals the motile properties of osteoblasts and osteocytes and suggests heterogeneity of osteoblasts in bone, I045
- Neonatal, TGF β stimulates new bone formation via suppression of DKK1, M197
- Osteoblast cultures, 1,25(OH) $_2$ D $_3$ inhibits bone nodule mineralization through the FGF-23-mediating ERK pathway in, M210, S210
- cAMP response element binding (CREB) protein.** See also *Cyclic adenosine 3,5-monophosphate*
CaMK-CREB pathway regulates osteoclast differentiation and function, M114, S114
- Endogenous signaling enhances Smad-mediated BMP signaling, W118
- Phosphorylation and DNA binding along with demethylation and deacetylation are required for ultimate activation of CYP27B1 promoter by PTH, W132
- cAMP response element (CRE).** See also *Cyclic adenosine 3,5-monophosphate*
Endogenous CREB signaling enhances Smad-mediated BMP signaling, W118
- Camurati-Engelmann Disease (CED)**
T β RI inhibitor rescues uncoupled bone resorption and formation caused by TGF- β 1 mutations in CED, I032
- Cancer.** See also cancer by type
Computed microtomography of bone specimens in the diagnosis of bone metastases, W201
- Examination of RXR α phosphorylation at serine 260 using specific antibodies in cancer cell lines and tumor tissues, M257
- New urine assay for sensitive detection and assessment of cancer-induced skeletal perturbations, W193
- Non-canonical hedgehog signaling regulates Gli2 and PTHrP expression in osteolytic cancer cells, M296
- capn4**
Knockout mice, characterization of osteoblast-specific, I024
- Carbonic anhydrase II (CAII)**
Regulates differentiation and proliferation of ameloblast via intracellular pH-dependent mechanism, T121
- Carcinogenesis**
Epidermal, VDR, HH signaling and, W158
- VDR, hedgehog signaling and epidermal carcinogenesis, WG3
- Carcinoma**
Gender differences on PTHR1 in non-small cell lung carcinoma, M240
- Non-small cell lung, sex effects on PTHR1 in, M240
- Carcinoma, squamous cell (SCC)**
Role of CXCL13 in associated osteolysis in athymic mice, T257
- Carcinoma, thyroid**
Change of BMD and biochemical markers of bone turnover in patients on suppressive L-thyroxine therapy for differentiated thyroid carcinoma, T339
- Carney Complex (CNC)**
Characterization of bone tumors in a mouse model for CNC, T045
- Carotenoid**
Lack of association of carotenoid intake with BMD in older adults, T317
- Cartilage**
Articular, differential accumulation of Pb and Zn in the tidemark of normal and osteoarthritic human, W271
- Calcified, alterations in collagen structure and mineral composition in a monkey model of OA, W089
- Cell death and cell proliferation in human ACL tibial insertion after rupture, W096
- Degeneration, intra-articular OCIF/OPG prevents in a murine model of osteoarthritis, W097
- Degradation and inflammation, therapeutic effect of KHB9 in CIA, M135
- Delayed remodeling during fracture healing in MMP-13 null mutant mice, M163, S163
- Development, p63 plays a central role by directly regulating key genes for chondrogenesis, I182
- Differentiation, targeted overexpression of PTH2R in chondrocytes impairs, W139
- Does increased local bone resorption result in increased cartilage degradation?, T135
- ECM homeostasis is regulated by RAR γ repression function, W103
- Epiphyseal, mice overexpressing nucleolar PTHrP driven by type II collagen promoter show disordered distribution of chondrocytes in, M116
- Expression of CaR is essential for embryonic skeletal development in vivo, I176
- Formation, inhibitory Smad6 and Smad7 differently regulate, M130, S130
- Formation, over-expression of Runx2 in mesenchymal cells enhanced bone formation but inhibited, I066
- Growth plate, Per1 modulates FGF and VEGF signaling and is essential for vascularization in the development of, I064
- Matrix proteins, effect of IL-6 and sIL-6R on the expression of, T146
- Novel TNF α responsive C/EBP site regulates *Cd-rap* expression, M132
- OPG inhibits degradation in a knee instability mouse model, M134
- Cartilage cells**
Role of Nkx3.2 in muscle/cartilage cell fate determination, W105
- Cartilage oligomeric matrix protein (COMP)**
 α_2 M is a novel substrate for ADAMTS-7 and ADAMTS-12 and inhibits their degradation of, M166
- Cas interacting zinc finger protein (CIZ).** See *Nuclear matrix protein 4/cas interacting zinc finger protein (Nmp4/CIZ)*
- Caspase-3**
Role in the anabolic actions of PTH in bone, I188
- Targeted inactivation of the VDR by, M265, S265
- Targeted inactivation of the VDR by caspase-3, WG2
- Caspase-8**
FADD axis regulates osteoclast apoptosis, T102
- β -Catenin**
AKT's effects regulate osteoblasts' responses to mechanical strain and PTH, T067
- Identification of a novel Wnt response element in the OPG gene promoter and its regulation with BMP-2 signaling, M031, S031
- Mechanical activation of is enhanced after caveolin-1 knock-down, T505
- Pathways, protective effects of mechanical strain on osteocyte viability is mediated by the effects of prostaglandin on, M237
- PTH activates signaling through LRP5/6, I297
- Signaling, FFSS and PE $_2$ activates in MLO-Y4 osteocytic and 2T3 osteoblastic cells, W053
- Signaling, greater sensitivity of osteocytes to shear stress as compared to osteoblasts, W052
- Signaling in osteoblasts, ER α is required for strain-related, M064, O064, S064
- Signaling is compromised in ER α -/- mouse tibia, mechanical loading induced, M036, S036
- Signaling, oxidative stress suppresses osteoblastogenesis by antagonizing, M174
- Cathepsin K (CatK)**
Bone effects of CatK inhibitor in OVX rhesus monkeys, M411, S411
- Conditional inactivation in adult mice results in osteopetrosis without activation of compensatory mechanisms for impaired bone resorption, W064
- Dual-action inhibitors, modulation of human osteoclast function, M389
- Dual-action inhibitors, regulation of human MSC lineage commitment, W315
- Generated type I collagen fragments, regulation of osteoclast activity by, W065
- Inhibition of osteolytic bone metastases in breast cancer with a CatK inhibitor, M291, S291
- Inhibitors for the treatment of osteoporosis, M408
- Inhibitors prevent matrix-derived growth factor degradation by human osteoclasts, W335
- Knockout in adult mice does not result in bone fragility, W063

- MK-0822 is a potent and selective CatK inhibitor that maintains its high selectivity in whole cell assays, W334
- Promoter affects bone mass and osteoclast formation in transgenic mice, expression of *OCZF* directed by, M099, O099, S099
- Randomized, double-blind, placebo-controlled study of a CatK inhibitor in the treatment of postmenopausal women with low BMD, 1128
- CaV1.3**
In bone mechanotransduction, role of, W494
- Caveolin-1**
Knock-down, mechanical activation of β -catenin is enhanced after, T505
Phosphorylation in response to fluid shear in osteoblasts is mediated by P2X7 activation, T061
- CCAAT/enhancer binding protein (C/EBP)**
Novel TNF α responsive site regulates cartilage *Cd-rap* expression, M132
- CCL3/4/5**
Cascade of gene expression indicates essential for osteoclast formation, T073
TNF α /CCR5 cascade mediates RANKL⁺ cells migration in inflammatory bone resorption, M181
- CCN2**. See *Connective tissue growth factor*
- CCR1/5**
Deficient mice have a high turnover osteoporosis that is greater in females than in males, 1254
TNF α /CCL3-5 cascade mediates RANKL⁺ cells migration in inflammatory bone resorption, M181
- CD-1**
Mice, demonstration of an anabolic effect of PGE₂ on bone in, M180
- Cd-rap**
Expression, novel TNF α responsive C/EBP site regulates cartilage, M132
- CD34⁺ cells**
Contributes to fracture healing, local transplantation of G-CSF mobilized, W048
- CD40L**
Mediated cross-talk between T cells and stromal cells is required for estrogen deficiency and PTH to induce bone loss, 1136
- CD146⁺**
BMSCs, FGF2 and TGF β 1 have opposite effects on the mural cell phenotype of, M178
- CD155**
Expression and possible role in osteoclastogenesis, M077
- CDC42**
Small GTPase enhances osteoclastogenesis and bone resorption, 1146
- Cell adhesion**
Rho GTPase signaling pathways in osteoclasts, Wrch1/RhoU role in, M073, S073
- Cell attachment**
Role of EphB/ephrin-B interactions in, W033
- Cell death**
And cell proliferation of cartilage layer in human ACL tibial insertion after rupture, W096
Role in injury-induced calcification from TNF α receptor p55/- p75/- mice, W091
Small molecule inducer of activated CD4⁺ T cell death inhibits disease progression in CIA models, M499
- Cell differentiation**
Microarray expression analyses to examine the effects of DEX on, T048
- Cell proliferation**
And cell death of cartilage layer in human ACL tibial insertion after rupture, W096
Mediation of musculoskeletal tumor cells by an IFI16 protein, T265
Osr2 functions in, M003
- Cementoblasts**
Cell lines, PTHrP induces MKP-1 in, M001
NOX expression in NOS knock-out mice, T173
- Cementum**
Cementoblast cultured on fibrin induces fibrinolysis and its apoptosis, T139
- Cerebral palsy (CP)**
Evaluation of the muscle-bone relationship in the midhigh of children with CP, T516
- cEts1**
Identification as potential primary target in the secondary gene regulation of the FGF-23 gene by 1,25-dihydroxyvitamin D3, W161
- Chemotaxis**
Molecular mechanisms of LPA-stimulated osteoblastic cell, M058, S058
- Chloride channel 7 (CIC-7)**
Deficient mice, characterization of the bone phenotype in, M272, O272
- Chloride channel 7 (CLCN7)**
Association study of *CLCN7* polymorphisms and areal BMD in white or black women or white men, T215
Deficient mice, characterization of the bone phenotype in, S272
- Chlorobenzenes (CIB)**
Effects on bone formation, W006
- Cholecalciferol**
Age modifies the impact of Vitamin D3 supplementation on the 25OH(D)/PTH ratio, M414
Comparison of three high-dose oral Vitamin D₃ supplementation regimens, M415, S415
Effect of a single large oral dose of cholecalciferol on serum 25-hydroxyvitamin D levels, 1210
Effect of four weeks of Vitamin D3 supplementation during late winter on markers of the Vitamin D endocrine system and bone turnover, W272
Effect of Vitamin-D3 and Ca on fracture risk in 65-71 year old women in a 3-year randomized clinical trial, 1270
Modulation of RANKL gene expression by Runx2 and Vitamin D3, 1219
Supplementation, age modifies the impact on the 25OH(D)/PTH ratio, M414
- Cholestatic liver**. See *Liver*
- Chondroclasts**
Formation and recruitment, OPG negatively regulates in endochondral ossification, M136, S136
- Chondrocytes**
Analysis of the role of Runx1 in chondrocyte differentiation using chondrocyte-specific Runx1 deficient mice, M133, S133
Articular in vitro, epigenetic mechanisms are involved in the cytokine-induced de novo expression of IL-1 β in, M184
Articular, regulation of MMP expression by EPAS1 in, T122
Articular specific gene, identification of Hs.43125 as, T120
Atf4 regulates proliferation and differentiation by direct targeting *Ihh* transcription, 1183
Chondrocytic phenotype, epigenetic modulatory agents suppress, W099
- Collagen/annexin V interactions regulate growth plate chondrocyte mineralization, 1111
- Differentiation, *Msx2* promotes late stages by up-regulating *Ihh* expression, W092
- Differentiation, role of Fe³⁺ ion and ferritin at the stage of calcification, M131
- Differentiation, *Twist1* stage-specifically regulates downstream of TGF β and Wnt signaling, M129
- Differentiation, *Zfp521* regulates downstream of PTHrP, 1069
- Disordered distribution in the epiphyseal cartilage, mice overexpressing nucleolar PTHrP driven by type II collagen promoter show, M116
- Endplate, IGF-1 regulation of collagen II and MMP-13 gene expression via distinct signaling pathways in, T116
- Growth plate, hydrostatic loading in vitro, M119
- Growth plate, proteasome inhibition induces permanent growth retardation and apoptosis in, M121, S121
- Growth plate, thyroid hormone-induced terminal differentiation involves IGF-1 modulation of canonical Wnt signaling, M118, S118
- HIF2A induces COL10A1 and promotes hypertrophic differentiation of, 1175
- IL-1 β -treated articular, regulation of MMP-9 expression by MMP-12 in, M139
- Rat growth plate, LPA promotes maturation and survival in, M187
- Regulation of proliferation, function, and differentiation by Akt signaling pathways, M123, S123
- Targeted overexpression of PTH2R impairs cartilage differentiation and trabecular bone growth, W139
- Chondrocytes, hypertrophic**
Establishment of a rat culture system for studying the morphological diversity of, M120
Hormonal regulation of apoptosis, W094
Identification of novel transcription factors necessary for, M164
Localization of the *Cis*-enhancer element for mouse *Col10a1* expression in vivo, W106
Molecular interaction between Bcl-xL and Bnip3 determines the cell fate of, 1181
Molecular network underlying chondrocyte hypertrophy causing osteoarthritis, M127, S127
Non-covalent interaction of MMP-13 and LTBP1 in a unique TGF β large latent complex produced by, M128
PTHrP suppresses ERK activation in, W095
Regulation by MATN3 through modulating BMP signaling pathways, 1063
Trps1 transcription factor regulates chondrocyte hypertrophy and perichondrial mineralization through repression of Runx2, 1184
- Chondrocytic cells**
ENC1 is expressed in, T056
- Chondrogenesis**
ECM1 is a novel potent mediator of, 1062
Epigenetic status monitored by DNA methylation in the 5-flanking regions of CpG-rich promoters are stable during, T126
Gene-trap mutagenesis revealed the involvement of vinculin in chondrogenic differentiation in ATDC5 cells, M137
Of mesenchymal cells, identification and characterization of miRNAs expressed during, T123

- p63 plays a central role in cartilage development by directly regulating key genes for, T182
Transcriptional induction of SOX9 by NF- κ B subunit p65 during, W101
- Chondrogenic differentiation**
Runx1 regulates, T112
- Chondrostatin**
New inhibitor of angiogenesis, tumor invasion and osteoclast activity, T259
- Chr 4**
Locus on exerts genetic control of bone size by regulating the differentiated function of periosteal cells, W008
- Chromatin immunoprecipitation (ChIP)**
On-chip analysis reveals novel GC response genes adjacent to genomic binding sites for SHREs in osteoblastic cells, M061
- Chromatin remodeling**
Complex, positive and negative regulation of osteoblast differentiation by the SWI/SNF, M030
- Chromosomes**
Single substitutions alter functional interactions among femoral morphological traits and mineral density in inbred mice, W173
- Cinacalcet**
Activation of the CaR increases serum gastrin levels in healthy older subjects, M221
- Cis-enhancer**
Localization for mouse *Col10a1* expression in hypertrophic chondrocytes in vivo, W106
- CITED1**
Ablation impairs endochondral bone formation during embryonic development, M142, O142, S142
- Ciz**
Interacts with ECM proteins, W012
- Clodronate**
Efficacy of clodronate on fracture risk in women selected by 10-year fracture probability, T060
- Cloning.** See *Molecular cloning*
- Clostridium histolyticum***
Class I collagenase, collagen binding characteristics of CBD from, M204
- Cnb1**
Deletion reveals novel role for calcineurin in bone formation, T283
- CNP**
Local clearance system as a regulator of CNP-GC-B system for bone growth, T168
- Co-culture system**
Spacio-temporal analysis of osteoclastogenesis using, M078
- Cobalt (Co)**
Incorporation into CaP layers stimulates osteoclast differentiation and activation via HIF pathway, W075
- Col3.6-HSD2**
GC loss-of-function model spanning early and late osteoblast differentiation, M235, S235
- COL10A1.** See *Collagen, type X*
- Collagen**
Alterations in structure and mineral composition in calcified cartilage and subchondral bone in a monkey model of OA, W089
Annexin V interactions regulate growth plate chondrocyte mineralization, T111
Binding characteristics of CBD from *Clostridium histolyticum* class I collagenase, M204
Effect of collagen degradation on the stiffness of bone, W474
New surface modified DBM by rhBMP-2 hybrid coating, T133
Quality and quantity in MC3T3-E1 cell culture system, LOX regulates, M011
Upregulation by mechanical loading of bone cells, T154
- Collagen, type I**
Abnormal production by human osteoarthritic osteoblasts, T143
Conditional knockout of BMP-2 using the 3.6 Col1a1-Cre model, T106
Regulation of osteoclast activity by CatK-generated fragments, W065
- Collagen, type II**
IGF-1 regulation of gene expression in endplate chondrocytes via distinct signaling pathways, T116
Promoter, mice overexpressing nucleolar PTHrP show disordered distribution of chondrocytes in the epiphyseal cartilage, M116
- Collagen, type X (COL10)**
Expression, localization of the *Cis*-enhancer element in hypertrophic chondrocytes in vivo, W106
HIF2A induces and promotes hypertrophic differentiation of chondrocytes, T175
Transcriptional regulation by Runx2, M127, S127
- Collagen, type XI**
Analysis of the function of the CTCF-binding site between *Rxb* and, T119
Identification of proteins that interact with the NTD, M149
- Collagen, type XII.** See also *Fibril-associated collagen*
Expression of splice variants of collagen XII in human osteoblast-like cells, M144
- Collagen binding domain (CBD)**
Collagen binding characteristics from *Clostridium histolyticum* class I collagenase, M204
- Collagen-induced arthritis (CIA).** See *Arthritis, collagen-induced*
- Collagenase**
Collagen binding characteristics of CBD from *Clostridium histolyticum* class I, M204
Limited digestion increases solubility and induction potential of human DBM in vitro, T156
- Colon cancer**
Chemoprevention, novel nutritionally-derived ligand of the VDR with implications for bone health and, M255, S255
- Colony stimulating factor 1 (CSF-1)**
BMP-2-inducible *Osx* increases osteoblastic ratio to induce osteoclast maturation, M100
Osteoblasts express CSF-1R and are a target for, T039
Selective deletion of the membrane-bound isoform in vivo does not affect estrogen-deficiency bone loss in mice, T255
Tumor cells metastatic to bone express CSF-1 and support osteoclast survival, T086
- Colony stimulating factor 1 receptor (CSF-1R)**
Osteoblasts express and are a target for CSF-1, T039
- Computed posturography**
Fracture and sway analyzed by computed posturography, W290
- Computed tomography, high-resolution peripheral quantitative (HR-pQCT)**
Assessment of cortical bone, W228
Bone microarchitecture as assessed by HRpQCT in chronic kidney disease, T490
- Bone microarchitecture as assessed by HRpQCT in HIV⁺ postmenopausal women, W444
Correlations between HR-pQCT and high-field MR in vivo bone imaging, T286
Densitometric derived structural indices in HR-pQCT are independent of cortical geometry, T107
High-resolution CT images yield accurate microstructural information if processed by 3-D extensions of standard histomorphometric analysis or fuzzy segmentation approaches, T287
HRpQCT of the radius reflects iliac crest biopsy measures of microstructure and mechanical competence, T164
In vivo assessment of 3-D bone microarchitecture with HR-pQCT in patients with and without fractures, M330, S330
- Computed tomography, micro (μ CT)**
Comparison of bone architecture via micro-CT after long-term treatment with Ris and ALN, T386
Evaluation of polychromatic μ CT mineralization measurement by comparison to synchrotron radiation CT, T110
- Computed tomography, multi-detector (MDCT)**
Trabecular bone structural analysis using 64 MDCT, M326
- Computed tomography, peripheral quantitative (pQCT)**
Comparison of pQCT-based measures of radial bone geometry and apparent trabecular structure acquired using different algorithms, T284
Model effects in the OVX rhesus monkey as measured with pQCT, T290
Sex-specific bone surface changes during adolescent growth, analysis of the mid-tibia, M527
Using pQCT to assess regional bone changes resulting from short-term exercise interventions, W496
- Computed tomography, quantitative (QCT)**
BMD in hip and spine by quantitative CT and previous history as predictors of incidental low trauma fractures in elderly men and women, T278
Of the forearm using clinical CT scanners, M325
And high-resolution CT are better surrogate measures of bone strength than DXA for patients on TPTD treatment, T165
- Conductive heart failure (CHF)**
Spironolactone use and risk of fraction in men with CHF, M352
- Conjugated linoleic acid (CLA)**
Regulates osteoblast and adipocyte differentiation from MSC, T047
- Connective tissue growth factor (CTGF)**
Causes osteopenia in vivo, T178
Crosstalk with TGF β 1 in MSC condensation, M158
Induces NFAT and osteoblastogenesis in vitro, T172
Inhibits BMP-2-induced osteoblast differentiation by interacting with BMP and Notch signaling pathways, T070
Novel transcription factor-like function of MMP-3/stromelysin-1 that regulates gene transcription, T125
Over-expressing in cells of the osteoblast lineage, skeletal phenotype in transgenic mice, T287

Connexin43 (Cx43)

- Amplifies FGF2-responsiveness in a Runx2/PKC δ -dependent manner, W027
- Channels in osteocytes, FFSS promotes intracellular assembly and formation of, M520
- Deficiency, alteration of ET1 effects on calvarial osteoblastic cells, M054
- Deficiency, attenuated response to skeletal load in, M518, S518
- Deficiency, inadequate bone adaptation in bone cell specific, 1285
- $\alpha 5$ integrin association regulates the function of osteocyte hemichannels in response to shear stress, T504
- Involvement in IL-1 β -induced osteoarthritis-associated changes in synovial fibroblasts, T169

Contraceptives

- Does oral contraceptive use adversely impact bone density in young women?, T351

Copenhagen 2331 (COP) rats

- Identification of sex-specific QTL for femoral neck density and strength in inbred, W171

Cortical bone

- Deletion of the CT/CGRP gene causes a profound cortical resorption phenotype, 1120
- Differences in regional femoral neck cortical thickness with aging, T460
- Dimensions, serum PTH is associated with, W135
- Evolution of the crack-growth resistance and toughening mechanisms of human cortical bone via in-situ electron microscopy, W455
- High-dose estradiol treatment causes destruction and is associated with an increased death rate in old WT and ERKO male mice, T193
- Iliac cortical bone structure in osteoporotic women, T296
- Load-specific differences in femoral neck cortical geometry, W497
- Long-distance runners have greater cortical thickness of distal tibia but not of distal radius, T466
- Novel MRI-based technique for quantifying cortical bone water and porosity in-vivo, M329
- Osteoblast-specific knockout of *Igf1r* alters mechanical properties of, W464
- Positively associated with serum IGF-1 and testosterone and negatively with fibrinogen, M194
- Quality and strength in both OVX and sham-operated rats are lowered by limiting physical activity, W479
- Quality and strength of cortical bone are lowered by limiting physical activity, 1160
- Regional thinning of cortical bone in the femoral neck with age, T294
- Size, UGT2B7 H²⁶⁸Y polymorphism is associated with in young adult men, T199

Corticosteroids

- Modulation of P2X₇R in osteoblasts by estrogen and, M055

CpG

- Rich promoters, epigenetic status monitored by DNA methylation in the 5-flanking regions are stable during chondrogenesis, T126

Cranial sutures

- Hypoplastic, spontaneous mutation in the mouse *Lmna* gene results in, M146, S146

Craniofacial bones

- Development, temporal regulation of histogenesis by mesenchyme during, W040

Craniofacial defects

- Analysis of cranial defect healing in CXCR2^{-/-} mice, M276
- Craniofacial reconstruction with BMP-2, M170
- Nell-1 partially rescues in *Runx2* haploinsufficient mice, 1105

Cranio metaphyseal dysplasia (CMD)

- Phe377del Mutation in the Ank gene causes CMD-like phenotype, M268, S268

cre

- Conditional knockout of BMP-2 using the 3.6 Col1a1-Cre model, 1106
- Mediated Dlx3 inactivation in mice, study of inducible, M027, S027

Creatine kinase brain type (CK-B)

- Involves the bone resorptive activity of osteoclast activity by regulating the V-ATPase and Rho activity, M083

Creatinine clearance (CrCl)

- Significant lower balance and muscle power performance and higher risk for falls in elderly people with a decreasing CrCl, M278
- Significantly higher risk for fall-associated fractures with a CrCl below 65, M256

CTCF

- Binding site, analysis of the function between the *Kxrb* and the *Col11a2* genes, T119

 α CTX

- Comparison of α CTX levels in healthy prepubertal children, adolescent, pre- and postmenopausal women, W223

Curcumin (CM)

- Novel nutritionally-derived ligand of the VDR with implications for colon cancer chemoprevention and bone health, M255, S255

CUSUM

- New CUSUM method for simultaneous quality control of BMD, BMC, and area for DXA scanners, T270

CXC chemokine ligand 13 (CXCL13)

- Role in SCC associated osteolysis in athymic mice, T257

CXCR4

- SDF-1 is essential for in vivo endochondral bone repair, T163

CXR

- Prevalence of vertebral fractures on CXR in elderly African-American and Caucasian women, M340

Cyclic adenosine 3,5-monophosphate (cAMP).

- See also *cAMP response element*
- Endogenous CREB signaling enhances Smad-mediated BMP signaling, W118
- Pathways, protective effects of mechanical strain on osteocyte viability is mediated by the effects of prostaglandin on, M237
- Regulation by, characterization of regions upstream of exon II of the human CYP19 gene that mediate in murine osteoblasts, T032

Cyclodextrins

- Osteotropic cyclodextrins as novel bone anabolic agents, W324

Cyclooxygenase 2 (COX-2)

- Acid-induced stimulation of, in osteoblasts mediated by IP₃, M063
- BMP-2 induces sustained expression in MC3T3-E1 osteoblasts, M168
- Deficiency impairs periosteal progenitor cell activation and differentiation, rescued by Ep4 agonist, 1251
- Expression, evaluation in GC-induced osteoporosis in rats treated with Ris, W318

- Transcription by GILZ, novel mechanism of GC action-inhibition of, T180

CYP19. See also Aromatase

- Aromatase deficiency in an adult Chinese male caused by heterozygote for two new point mutations in the CYP19 gene, W168
- Characterization of regions upstream of exon II of, that mediate regulation by cAMP in murine osteoblasts, T032

CYP21B1

- Promoter, CREB phosphorylation and DNA binding along with demethylation and deacetylation are required for ultimate activation by PTH, W132

CYP27B1

- Derepression of gene expression mediates DNA-demethylation, M260

Cystic fibrosis (CF)

- ALN once weekly for the prevention and treatment of osteoporosis in Canadian adult cystic fibrosis patients, W360

Cytokines

- Induced de novo expression of IL-1 β in human articular chondrocytes in vitro, epigenetic mechanisms are involved in, M184
 - Interactions between PTH and the gp130 pathway in differentiating osteoblasts, W025
 - Intracellular profile of RANKL expressing lymphocytes, T164
 - Pro-inflammatory, effects on SOCS-2 expression in the growth plate, W093
 - Regulation of human osteoclast precursor generation by, T079
 - Serum, relationship to BMD and BMC in postmenopausal women, M183
 - Upregulation of CASR gene expression by the proinflammatory cytokine, IL-6, 1187
- Cytoskeleton organization/reorganization**
- HMBG1 regulates actin and RANKL-induced osteoclastogenesis in a manner dependent on RAGE, M079
 - Small GTPase RhoA and its effector kinase ROCK mediate, leading to osteocyte anoikis by GC, M233, S233

D**Dan**

- Enhancing the expressions of BMP antagonists, GC suppresses the differentiation of osteoblasts by, M059

DANCE Study

- Direct Assessment of Non-vertebral Fracture in Community Experience (DANCE) Study, W303

DDOC

- CD11c⁺ dendritic cells-derived osteoclasts, precursor analyses of, M080

Dehydroepiandrosterone (DHEA)

- Serum DHEA is independent of estradiol and testosterone related to incident fractures in elderly men, 1200

Deminerized bone matrix (DBM)

- Allogeneic osteoinductivity, xenogeneic BMP complex enhances, M173
- Limited collagenase digestion increases solubility and induction potential in vitro, T156
- New surface modified by rhBMP-2-collagen hybrid coating, T133
- Osteogenesis of the human LF by, T008

Dendritic cell-specific transmembrane protein (DC-STAMP)

Transgenic mice, cell-cell fusion of osteoclasts is stimulated in, 1102

Dendritic cells

CD11c⁺-derived osteoclasts, precursor analyses of, M080

In myeloma, up-regulation of TACE in monocytes ameliorates their deflected differentiation into, M302

RANKL-stimulated, immunoregulatory role on autoimmune arthritis in MRL/*lpr* mice, T162

Denosumab (DMab)

Comparison of DMab and ALN in combination with PTH in OVX knockin mice expressing humanized RANKL, 1126

Decreased bone turnover and porosity are associated with improved bone strength in OVX cynomolgus monkeys treated with DMab, M409, O409, S409

Effect of DMab on BMD and bone turnover markers, 1205

Improves cortical and cancellous bone mass and bone strength in OVX cynomolgus monkeys, 1082

Increases BMD in patients with RA, 1208

RANKL inhibition by DMab prevents cortical bone loss in a murine model of GIO, 1009

Densitometers

Reliability of two consecutive prodigy densitometers, T278

Dental enamel

Changes in dental enamel crystals by bleaching, W480

Dental pulp cells

In vivo transplantation in calvarial bone defects, induction of mineralized tissues by, T017

Dental pulp stem cells (DPSC). See Stem cells, dental pulp**Dentin**

Enamel phenotype and sexual dimorphism in dentin of *dssp*-null mouse molars, T148

Dentin matrix protein 1 (DMP1)

57 kDa C-terminal fragment of DMP1 retains all biological activity, 1296

Degradation of, and release of SIBLING ASARM-peptides (minhibins), 1155

Identification of novel DMP1 mutations in two unrelated kindreds with ARHP, W165

Mutants causing ARHR, molecular analyses of, 1116

Osteocyte specific expression after mechanical stimulation in the mouse ulnae loading model, W050

Dentine

Organic matrix down-regulate osteoclastic activity in root resorption, T095

Deoxyribonucleic acid (DNA)

Binding and CREB phosphorylation along with demethylation and deacetylation are required for ultimate activation of CYP27B1 promoter by PTH, W132

Demethylation, derepression of CYP27B1 gene expression mediates, M260

Methylation, epigenetic status monitored in the 5-flanking regions of CpG-rich promoters are stable during chondrogenesis, T126

Dexamethasone (DEX)

Effect of, on the osteoblastic differentiation of human ASC, T051

Induced bone loss in vitro, silencing *Dkk1* expression rescues, M057

Microarray expression analyses to examine the effects on cell differentiation, T048

Dhe (dominant hair and ears)

Spontaneous mutation in the mouse *Lmna* gene results in hypoplastic cranial sutures and under-mineralization of the skeleton, M146, S146

Diabetes mellitus

Correlation between cortical bone structure and biomechanics and metabolic indicators in spontaneously diabetic, eSS rats, T472

And fracture risk in older men, 1161

GLP-1 action on bone turnover in, T207

Vitamin D status and infection frequency in diabetic patients, W153

Diabetes mellitus, type 1

Bone-muscle disconnect during pubertal-driven skeletal growth in type 1 diabetes, WG41

Multifactorial etiology of weak bones in type 1 diabetes, M457

Poor long-term glycemic control is not associated with decreased BMD in type 1 diabetes, W414

Diabetes mellitus, type 2

BMD changes in male veterans with type 2 diabetes, T355

GLP-1 action on bone turnover in, T207

Low vitamin D level and high bone turnover in aged type 2 diabetic patient, M456

OPG as cardiovascular risk marker in patients with, T167

Serum pentosidine level is positively associated with the presence of vertebral fractures in postmenopausal women with type 2 diabetes, M316, S316

Type 2 diabetic patients with charcot arthropathy display reduced calcaneal stiffness despite normal foot BMD, W448

Dicer

Osteoclast specific ablation suppresses bone resorption and increases bone mass, 1292

Dickkopf-1 (DKK1)

TGF β stimulates new bone formation in neonatal calvariae via suppression of, M197

Differential display PCR screening (DDRT-PCR)

Identification of calcein expression in rat amelogenesis using, T129

Dihydrotestosterone (DHT)

Treatment reverses gonadectomy-induced changes in fat and lean mass in male but not female mice, T202

1,25-Dihydroxyvitamin D (1,25(OH)₂D)

Automated measurement on the LIAISON[®] Analyzer, W211

Effect of plasma concentration or Ca intake on negative correlation between plasma 25OH(D) and PTH concentrations in Japanese adolescents, W159

Intracrine synthesis and action of rescues TLR suppression of innate immunity, 1028

Treatment with antiresorptive agents reduces circulating 1,25(OH)₂D, W127

1,25-Dihydroxyvitamin D₃ (1,25(OH)₂D₃). See also Vitamin D

CaP regulating hormone STC-2 is positively and negatively regulated by, in renal proximal tubular cells, W130

Co-stimulation with BMP-2 enhances the expression of VDR and RANKL mRNA in osteoblasts, W162

Dependent and Ca-independent regulation of the RAS in 25(OH)D 1 α -hydroxylase knockout mice, W150

Effect of, on the osteoblastic differentiation of human ASC, T051

Identification of cEts1 and STAT1 as potential primary targets in the secondary gene regulation of the FGF-23 gene by, W161

Inhibits bone nodule mineralization through the FGF-23-mediating ERK pathway in calvaria osteoblast cultures, M210, S210

PTH(7-84) inhibits PTH(1-34)-induced production in primary cultured murine renal tubules, T482

Role for BAG-1 as an intracellular binding protein for, M252

Role of TRPV 6 and β -glucuronidase in stimulated Ca uptake in intestinal epithelial cells, M258

1,25-Dihydroxyvitamin D₃ (1,25(OH)₂D₃)

Hypersensitivity in MVNP expressing cells, changes in VDR coregulator recruitment result in, W152

Induced ATP release, molecular mechanisms in osteoblasts, 1030

2-Dimethylamino-4,5,6,7-tetrabromo-1H-benzimidazole (DMAT)

Sensitive kinase, Runx2 transcriptional AD3 supports synergistic Runx2-MINT activation of the osteocalcin FGF response element via, T036

Diphyllin

Abrogates acidification of the osteoclastic resorption lacunae and bone resorption, T093

Distraction osteogenesis. See Osteogenesis, distraction**Dkk1**

Reciprocal regulation of gene transcription by Mx2 and c/EBP α , 1140

Silencing expression rescues DEX-induced bone loss in vitro, M057

DLAM

DLAMs antagonize bone resorption via suppressing RANKL expression in osteoblasts, M262, O262, S262

Dlx3/5

Gene family, gene networks in osteoblasts that are regulated by, W017

Inactivation in mice, study of inducible cre mediated, M027, S027

Overexpression promotes early odontoblast maturation, M028

Dok-1/2

Deficiency enhances bone resorption and modulates the geometry of bone in vivo, M086, S086

Doxorubicin (DOX)

Effectively inhibits osteoclast differentiation and function, M106

Effects of DOX on BMC and density, W299

Duodenum

Rapidly senses and modulates renal phosphate reabsorption via novel PTH- and phosphatonin-independent pathways, M207

Dup(3q) syndrome

Microdeletion involving TNIK alters the phenotype of Dup(3q) syndrome, T470

Dwarfism

A comparative analysis of BMD, M274
Body composition and BMD analysis, T209
Effect of treatment with depot GH on bone remodeling and heel ultrasonometry in dwarfism due to mutation in the GHRH-R gene, T428

Dynein/dynactin complex

Rab3D recruits to secretory vesicles in osteoclasts through direct interaction with Tctex-1, 1293

E

e-NOS. See *Nitric oxygen synthetase*

E-Selectin ligand-1 (ESL-1)

Negatively regulates TGF β in the Golgi during skeletogenesis, M202, S202

E2F1

Repression of gene expression, TIEG suppresses osteoblast cell proliferation through, M035

E4bp4

Induced by GCs and represses promoter activity in osteoblasts, T179

E11

Targeted deletion in osteocytes results in increased skeletal size and BMD, 1043

Ecto-nucleotide pyrophosphatase phosphodiesterase 1 (ENPP1)

ENPP1 as a candidate gene for femoral bone geometry, T219

Ectoderm neural cortex 1 (ENC1)

Expressed in chondrocytic and osteoblastic cells, T056

Ectopic bone

Osteoclasts generated in are derived from pOCs, W071

Efnb1. See *Ephrin B1*

Egr2

Novel pro-survival functions in promotion of M-CSF-mediated osteoclast survival downstream of the MEK/ERK pathway, M111

Elasticity

New method to determine variation of the elasticity of single trabeculae, W459
Osteoblasts and osteocytes, W061

Elcatonin

Injections after drill-hole injury inhibits osteoclast differentiation and prevents the decrease of BMD in non-injured bones with promotion of repair in the cortical bone defect, W336

Electrophoresis, two-dimensional (2-DE)

Skeletal development analysis by 2-DE in white bream (*Diplodus sargus*), T210

Embryogenesis

Using RCAN to deliver short hairpin siRNA to silence gene expression of Wdr5 in chicken limb bud during, T141

Embryonic development

CITED1 ablation impairs endochondral bone formation during, M142, O142, S142

End-stage renal disease (ESRD)

Tartrate-resistant acid phosphatase isoforms in ESRD, M494

Endochondral fracture union

Osteopetrotic *ia/ia* rat exhibits reduced osteoclast activity, resulting in normal endochondral fracture union but delayed hard callus remodeling, T088

Endochondral ossification. See *Ossification, endochondral*

Endofin

Point mutation at PP1c-binding domain (F872A) stimulates bone formation, 1256

Endoplasmic reticulum (ER)

Modeling role in transcellular Ca flux in bone resorbing osteoclasts, M105

Endothelial cells. See *Human bone marrow endothelial cells*

Endothelial PAS domain protein 1 (EPAS1)

Regulation of MMP expression in articular chondrocytes, T122

Endothelial progenitor cells (EPC)

Healing of critical-sized bone defects by EPC, T009
Osteogenic differentiation of circulating, M042

Endothelin-1 (ET-1)

Effects on calvarial osteoblastic cells from Cx43-deficient mice, alteration of, M054
Induction of kinin B₁ receptor in osteoarthritis is performed by vasoactive peptide ET-1, M117

Enhancer binding protein. See also *CCAAT/enhancer binding protein*

EP2

Receptors to upregulate RGS2 expression in osteoblasts, PGE₂ acts through, T063

EP4

COX-2 deficiency impairs periosteal progenitor cell activation and differentiation, rescued by, 1251

Receptors to upregulate RGS2 expression in osteoblasts, PGE₂ acts through, T063

EphB

Role in cell attachment and spreading of mesenchymal precursors derived from human BMSC and DPSC, W033

Ephrin-B1/2

Anabolic action of PTH in osteoblasts, potential involvement of, T012

Role in cell attachment and spreading of mesenchymal precursors derived from human BMSC and DPSC, W033

Targeted disruption in osteoblasts reduces bone size, 1107

Ephrins

PTH-regulated gene expression in the mouse skeleton suggest a role for ephrins in PTH anabolism versus catabolism, 1121

Epidermal growth factor (EGF)

Like ligands stimulate osteoclastogenesis by regulating expression of osteoclast regulatory factors by osteoblasts, T175

Epigenome

Epigenetic mechanisms are involved in the cytokine-induced de novo expression of IL-1 β in human articular chondrocytes in vitro, M184

Epigenetic modulatory agents suppress the chondrocytic phenotype, W099

Epigenetic status monitored by DNA methylation in the 5-flanking regions of CpG-rich promoters are stable during chondrogenesis, T126

Epilepsy

AED affect bone loss via reproductive hormones, W415

Effect of AED on BMD, T349

Epithelial cells

Intestinal, role of TRPV 6 and β -glucuronidase in 1,25(OH)₂D₃- and PTH-stimulated Ca uptake in, M258

Mammary, CaR regulates PMCA2 activity in, M219, S219

Mammary, conditional ablation of PTHrP inhibits breast cancer progression, 1295

Equol

Possible role of equol status in the effects of isoflavone on bone and fat mass in postmenopausal Japanese women, W389

Producers after soy challenge is related to high bone turnover in premenopausal women, M247

Ergocalciferol

Daily versus monthly oral Vitamin D2 and D3, M451

Measurement by the LIAISON[®] 25 OH Vitamin D TOTAL assay, W216

Vitamin D₂ supplementation suppresses endogenous levels of 25-hydroxyvitamin D₃, M264

ERK

Activation in hypertrophic chondrocytes, PTHrP suppresses, W095

Estrogens or androgens attenuate p66^{shc} phosphorylation via a signaling cascade, T185

FGF-23-mediating pathway, 1,25(OH)₂D₃ inhibits bone nodule mineralization through, M210, S210

Interaction of galectin-9 with lipid rafts induces osteoblast proliferation through, W005

Pathway, novel pro-survival functions of Egr2 in promotion of M-CSF-mediated osteoclast survival downstream of, M111

ERK1/2

Activation prevents the FasL-induced apoptosis in IGF-1-treated anulus fibrosus cells, T117

ATP induced activation, PTH enhances via a competitive mechanism involving GRK2 in osteoblastic cells, T060

Essential for osteoblast differentiation, 1141

Extracellular inorganic Pi induces phosphorylation and up-regulates a target gene of FGF-23 in renal proximal tubule cells via NaPi-IIa, W131

ERKO mice

High-dose estradiol treatment causes destruction of cortical bone and is associated with an increased death rate in, T193

Erythropoietin (EPO)

As a regulator of bone density and serum Ca in elderly men, M177

Escherichia coli

Molecular analysis of two novel mutations in the VDR corepressor *hr* and expression of rHr in, M259, S259

ESR2

AluI polymorphism is associated with reduced risk of osteoporotic fractures, T218

Estradiol

Directed gene transactivation, control by an IEBP and an ERE-BP, 1221

Genetic determinants of serum levels of free estradiol and free testosterone in young adult Swedish men, M245

Mediates rescue of the dominant-negative effects of ERE-BP in vivo, 1222

17 β -Estradiol

Abrogates apoptosis in skeletal muscle cells through extra-nuclear estrogen receptors, T196

Activation of MAPKs is mediated by PKC and c-Src in skeletal muscle cells, T194

Additive and synergistic effects of 17 β -estradiol and DHA on bone post-ovariectomy, T362

Estrogen

Attenuate IL-6 and TNF α production in osteoblastic cells by decreasing oxidative stress and its effects on NF- κ B activation, T186

Attenuate p66^{shc} phosphorylation via an ERK and PKC β signaling cascade, T185

Comparison of early-stage immobilization and estrogen-deficiency induced bone loss assessed by in vivo micro-CT, T462

- Deficiency and PTHrP infusion do not fully reproduce the bone loss of lactation, M220
- Deletion of TIF-2 results in skeletal resistance to estrogen but a high bone mass phenotype due to concomitant resistance to PPAR γ , 1235
- Down-regulation of klotho protein expression by, T192
- Effect of estrogen deficiency on gene expression pattern in the bone tissue of postmenopausal versus premenopausal healthy women, T124
- Effect on bone marrow adipogenesis, M243
- Effects of estrogen on circulating dlk1/pref-1/FA1 levels in postmenopausal women and correlations with bone turnover and volumetric BMD, W418
- High-dose estradiol treatment causes destruction of cortical bone and is associated with an increased death rate in old WT and ERKO male mice, T193
- Identification of primary target cells for the classical genomic effects of raloxifene and, T188
- Low-dose estrogen oral contraceptive use and BMD in adolescents and young adult women, W292
- Mediated enhancement, classical signaling is essential for osteogenesis but not for inhibition of adipogenesis, M250, S250
- Metabolite-mediated inhibitions, regulation of protein synthesis factors in osteosarcoma cells, T254
- Modulation of P2X₇R in osteoblasts by corticosteroids and, M055
- Periosteal and endosteal modeling process is affected differently in response to fatigue loading than during development, M463
- Preferentially suppresses osteogenic gene expression in mice lacking classical ERE signaling, T195
- Regulation of oxidative stress and osteoblast apoptosis is preserved when the ER cannot directly interact with DNA, T184
- Some but not all estrogen-like molecules have both bone and cartilage protective effects, W205
- Suppression of adipogenesis is mediated by TGF β , M024
- Estrogen deficiency**
Bone loss, selective deletion of the membrane-bound CSF1 isoform in vivo does not affect, 1255
- Estrogen receptors (ER)**
In AIS, T189
Cannot directly interact with DNA, regulation of oxidative stress and osteoblast apoptosis by estrogens is preserved, T184
Extra-nuclear, 17 β -estradiol abrogates apoptosis in skeletal muscle cells through, T196
Liganded versus unliganded ER, T044
- Estrogen receptor (ER)**
Androgenic effects on bone and body composition depend on concerted and additive activation of, M244, S244
Classical signaling is essential for estrogen mediated enhancement of osteogenesis but not for inhibition of adipogenesis, M250, S250
Mouse tibia, mechanical loading induced Wnt/ β -catenin signaling is compromised in, M036, S036
Required for strain-related β -catenin signaling in osteoblasts, M064, O064, S064
- Unliganded potentiates BMP-induced transcription and osteoblastogenesis, T190
- Estrogen receptor β (ER β)**
Role for ER β in trabecular bone mechanotransduction, 1084
Unliganded potentiates BMP-induced transcription and osteoblastogenesis, T190
- Estrogen receptor-related receptor gamma (ERR γ)**
Negatively regulates osteoblast differentiation and mineralization through Runx2- and Smad-dependent pathway, W015
- Estrogen response element binding protein (ERE-BP)**
Control of estradiol-directed gene transactivation by, 1221
Estradiol mediates rescue of the dominant-negative effects of, 1222
- Estrogen response element (ERE)**
Classical signaling, estrogen preferentially suppresses osteogenic gene expression in mice lacking, T195
- Etanercept (ETN)**
Effect of ETN on bone metabolism in patients with RA, W434
- Etidronate**
Inhibits progression of vascular calcification and decrease in BMD in chronic dialysis patients, T491
- Exercise.** See also *Athletes*
Association of body weight and daily walking steps with QUS parameters and urinary DPD in elderly Japanese women, W493
Bone biomarker responses to short-term training, W056
Bone increases from jumping exercise persist seven years post intervention, WG29, M530, S530
Bone turnover response of men and women to a strenuous gender-integrated recruit training regimen, W487
Characterization of muscle disuse atrophy and recovery in mice using an in vivo casting model, W489
Comparison of Rehabilitation of Osteoporosis Program-Exercise (ROPE) versus No-ROPE, with or without pharmacotherapy, W393
Effect of resistance exercise on in vivo-derived tomography measures and mechanical properties of rodent bone, W498
Effect of vibration resistance exercise during 56 days of bed rest on different muscle properties, W484
Effects of 3 months of aerobic exercise on bone turnover in premenopausal non-obese women, W062
Effects of daily muscle trainings on falls and vertebral fractures in the elderly osteoporotic women, WG31, T340
Effects of endurance running training on bone quality in growing rats, W491
Effects of vibration plus resistance training on bone metabolism in postmenopausal women, W501
Eight months of twice-weekly ten-minute jumping activity for PE warm up improves bone in adolescent boys and girls, M524
Electrically stimulated eccentric muscle contraction benefits bone in the tibia of hindlimb unloaded rats at both the mid-diaphysis and proximal metaphysis, W490
Flexible multibody simulation approach in the analysis of tibial strains during walking, W502
- Gold standard measurement of physical activity energy expenditure and BMD in older adults, T346
- Independent contribution of physical activity to bone mass during growth, M531
- Induced changes in the macro-architectural parameters of cortical bone as boys progress through puberty, W485
- Influence of exercise and low dose oral contraceptives on vertebral and femoral bone mass in young adult women, T450
- Is golf a good sport for bone health in the elderly?, M522
- Long-term macro-architectural benefits of high impact exercise during growth, W483
- Measures of fitness and body composition in childhood are associated with calcaneal quantitative ultrasound in adulthood, W265
- Physical activity in young adulthood is an independent predictor of BMD in elderly Swedish men, T310
- Positive association of physical exercise and coffee consumption with BMD in postmenopausal women, T336
- Prevents falls and maintains BMD in elderly postmenopausal women, WG11, T415
- Quality and strength of cortical bone are lowered by limiting physical activity, W381
- Quality and strength of cortical bone in both OVX and sham-operated rats are lowered by limiting physical activity, W479
- Regular physical activity has only a temporary effect on bone gain in pubertal girls, M533, S533
- Role of dynamic muscle contractions on inhibition of bone loss and muscle atrophy in a functional disuse mouse model, W482
- School-based physical activity intervention positively affects change in I_{max} in pre- and early pubertal boys, 1040
- Timing of peak bone mass and BMD are influenced by high-level physical activity in young adults of both sex, WG10
- Timing of peak bone mass and BMD are influenced by high-level physical activity in young adults of both sexes, M534
- Weight bearing bones are more sensitive to physical exercise in boys than in girls during pre- and early puberty, WG30
- exon II**
Regions upstream of, characterization of the human CYP19 gene that mediate regulation by cAMP in murine osteoblasts, T032
- External apical root resorption (EARR)**
in vitro, hypoxia contributes to the formation of, T010
- Extracellular matrix (ECM)**
Artificial vasculature-inducing geometry, formation of haversian-type bone and blood vessels guided by, M154
Cartilage homeostasis is regulated by RAR γ repression function, W103
Conditional deletion of FN in osteoblasts reveals distinct roles in orchestrating assembly of proteins and in osteoblast differentiation, 1177
Proteins affect both osteoclast formation and resorptive activity, M087
Proteins, Ciz interacts with, W012
Provision of, correction of increased oxidative stress and defective replication in MSC from aging C57BL/6, M052, S052

Extracellular matrix protein 1 (ECM1)

Novel potent mediator of chondrogenesis, 1062

Extracorporeal shockwave therapy (ESWT)

Stimulates bone remodeling in the rat, evaluated with in vivo micro-SPECT scanning, W347
Unfocused ESW therapy diminishes bone loss in OVX rats, W346

F**F872A**

Point mutation of endofin at PP1c-binding domain stimulates bone formation, 1256

Factor inhibiting ATF4-mediated transcription (FIAT)

Expression of a hypomorphic allele improves long bone mechanical properties, M033, S033

Familial hypocalciuric hypercalcemia (FHH).

See *Hypercalcemia, familial hypocalciuric*

Farnesoid X receptor (FXR)

Activation in breast cancer cell lines by bone-derived lipid, M249

Farnesyl pyrophosphate synthase (FPPS)

Mode of binding of N-containing bisphosphonates in FPPS, W320

FAS-associating death domain-containing protein (FADD)

Caspase-8 axis regulates osteoclast apoptosis, T102

FasL

Activation of Erk1/2 prevents the induced apoptosis in IGF-1-treated anulus fibrosus cells, T117

Fat-1 transgene

Endogenously produced n-3 fatty acids (Fat-1 transgene) protects bone after ovariectomy in mice, M397, S397

Fatty acids

Interrelation between dietary fatty acids and fibers in modulating bone quantity and quality during skeletal growth, W467

Fc gamma receptor II B (FcR)

Osteoclast precursor cells, characterization of OIP-1/hSca binding to, 1103

Femoral bones

Determinants of femoral neck bone loss in the HORIZON-PFT study, T387

Ferritin

Role on differentiation of chondrocytes at the stage of calcification, M131

Fetal bone cells. See also *Bone cells*

For tissue engineering, T041

Fibril-associated collagen (FACIT)

Expression of splice variants of collagen XII in human osteoblast-like cells, M144

Fibrin

Cementoblast cultured on, induces fibrinolysis and its apoptosis, T139

Fibrinogen

Cortical bone is positively associated with serum IGF-1 and testosterone and negatively with, M194

Fibrinolysis

Cementoblast cultured on fibrin induces, T139

Fibroblasts

Continuous local infusion of basic growth factor enhances consolidation of the bone segment lengthened by distraction osteogenesis, T155
Rheumatoid synovial, promote osteoclastogenic activity by activating RANKL via TLR-2 and TLR-4 activation, W435
Synovial, involvement of Cx43 in IL-1 β -induced osteoarthritis-associated changes in, T169

Fibroblast growth factors (FGF)

Runx2 transcriptional AD3 supports synergistic Runx2-MINT activation of the osteocalcin response element via a DMAT-sensitive kinase, T036

Signaling, Perl modulates and is essential for vascularization in the development of the cartilage growth plate, 1064

Spatial and temporal localization of components of signaling pathways in the postnatal LVGP, M125

Fibroblast growth factor 2 (FGF-2)

Overexpression of low molecular weight isoform partly prevents bone loss, T160

Responsiveness, Cx43 amplifies in a Runx2/PKC δ -dependent manner, W027

And TGF β 1 have opposite effects on the mural cell phenotype of CD146⁺ BMSCs, M178

Fibroblast growth factor 4 (FGF-4)

Downstream signal transactivation by transgene partially imitates changes of BMP-2 induced osteogenic transcription factors in NIH3T3 cells, W016

Fibroblast growth factor 7 (FGF-7)

As a potent in vivo phosphaturic agent, M212, S212

Fibroblast growth factor 23 (FGF-23)

Age-dependent regulation of FGF-23 production in murine bone, T159

Association of serum FGF-23 and urinary GGT with BMD, M318

Concentration, treatment of XLH with calcitriol and phosphate increases, W123

Controls NaPi-IIa trafficking via crosstalk between the PI-3 kinase and MAPK pathways, T158

Evaluation of FGF-23 (c-terminal and intact)

ELISA kits in end-stage renal disease patients, M211

Extracellular inorganic Pi induces ERK1/2 phosphorylation and up-regulates a target gene in renal proximal tubule cells via NaPi-IIa, W131

Gene, identification of cEts1 and STAT1 as potential primary targets in the secondary gene regulation of, W161

As an independent predictor of BMD in a population-based cohort of elderly men, W125

Is an independent predictor of BMD in a population-based cohort of elderly men, W125

Klotho ablation completely reverses the biochemical and skeletal alterations in R176Q transgenic mice, M208, S208

Mediating ERK pathway, 1,25(OH) $_2$ D $_3$ inhibits bone nodule mineralization through, M210, S210

Osteocytic regulation of Pi homeostasis through, 1296

Phosphate-independent effects on skeletogenesis, 1114

Possible direct regulatory role of active Vitamin D increased by ultraviolet B on, W126

Protein, analysis and importance of glycosylation status in, W129

PTH expression is negatively regulated in primary parathyroid cells, 1191

Regulatory mechanism of production and circulatory level of, W124

Rise in FGF-23 precedes 1-84PTH and linear decline in calcitriol precedes rise in FGF-23 in non-diabetic predialysis patients, M215

Treatment with antiresorptive agents increases circulating, W127

Venous sampling as a tool for pre-operative localization of tumors giving rise to TIO, M213

Fibroblast growth factor receptors (FGFR)

Continued enhanced function delayed fracture healing, T157

FGFR 3 and FGFR 4 are not physiologically relevant FGF-23 targets in the kidney, 1227

In silico identification of selective FGFR modulators, M393

Fibrodysplasia ossificans progressiva (FOP)

Activation of BMP signaling by the FOP

ACVR1 R206H mutation, 1151

ALK2 induces heterotopic bone formation in patients with FOP, 1034

Diagnosis of FOP prior to the onset of heterotopic ossification, T478

Fibromodulin (fmod)

And bgn control bone mass by regulating osteoclast differentiation through BMSC, M157, O157, S157

Fibronectin (FN)

Conditional deletion in osteoblasts reveals distinct roles in orchestrating assembly of bone ECM proteins and in osteoblast differentiation, 1177

Isoform of FN is responsible for decreased bone formation in patients with primary biliary cirrhosis and this effect is not exclusively mediated by beta1 integrins, T007

Matrix, PAI-1 increases femoral mineralization independent of estrogen status through modulation of, T137

Selective deletion in osteoblasts affects bone density and osteoblast function, 1179

Filamin B (FLNB)

Variation in the *FLNB* gene regulates bone density in two populations of Caucasian women, 1203

Finite element analysis/modeling (FEA/FEM)

Based on in vivo HR-pQCT images of the radius tend to improve wrist fracture prediction, 1280

Combined axial compression and flexion loading mode to evaluate strength of vertebral bodies using a voxel-based FEM, W476

Correlation between the mechanical properties of trabecular bone assessed by FEA and experimental test, W451

Fracture strength of the distal radius can be estimated by nonlinear FEA using 3D HR-pQCT, W460

Methodology for bone strength prediction using parametric statistical shape and density FEM, W452

More accurately predict structural behavior of human cancellous bone when using specimen-specific tissue properties, M502

Novel patient-specific FEM to predict damage accumulation in vertebral bodies under axial compression, W475

Flavanones, citrus

Effect of citrus flavanones on bone metabolism, W407

Fluid flow shear stress (FFSS). See also *Shear stress*

Activates β -catenin signaling in MLO-Y4 osteocytic and 2T3 osteoblastic cells, W053

And mechanical strain induce a similar osteogenic gene response via divergent signaling pathways, M517

- Promotes intracellular assembly and formation of Cx43-forming channels in osteocytes, M520
- Fluorescence resonance energy transfer (FRET)**
Analysis reveals selective binding of long- and short-acting PTH(1-28) analogs to distinct PTH receptor conformations, W144
- Fluoride**
Phenotypic variations of fluoride responses between inbred strains of mice, W350
- 5-Fluorouracil (5-FU)**
Insensitive osteoclast precursors in vivo, osteoclast niche is composed of, M082, S082
- Follicle-stimulating hormone (FSH)**
Association between FSH and bone mass in postmenopausal women, T467
Elevated FSH predicts increased hip fracture risk, T468
- Follistatin**
Enhancing the expressions of BMP antagonists, GC suppresses the differentiation of osteoblasts by, M059
- ΔFosB**
Overexpression of decreases adipose mass in a non-cell autonomous manner by increasing energy expenditure independently of bone cells, 1248
- Δ2FosB**
Zfp521 regulates chondrocyte differentiation downstream of PTHrP, 1069
- FoxO3a**
Akt1 contributes to maintenance of bone mass and turnover by inhibiting apoptosis of osteoblasts through, 1211
- Fracture healing**
Absence of sFRP1 accelerates, 1258
Analysis of differing approaches for the assessment of large scale transcriptional profiling of, T111
Continued enhanced Fgfr2 function delayed, T157
Effects of traumatic brain injury on bone formation/remodeling during, M008
IGF-1 engineered bone marrow MSCs improve, M191, S191
Local transplantation of G-CSF mobilized CD34+ cells contributes to, W048
Local transplantation of hMADS cells improve, W003
Novel model of impaired, M153
rhPDGF-BB and βTCP accelerate fracture healing, W316
Shh in osteoclast formation and, T082
Temporal pattern of gene expression and histology of stress fracture healing in the rat ulna-loading model, 1246
- Fracture risk**
Age increases the risk of subsequent fractures following an initial fracture among women in managed care population, W296
Assessment in dialysis patients, WG40
Asymmetry in leg power increases non-spine and hip fracture risk in older men, 1158
Clinical and nonvertebral fracture risk is reduced with the use of IBN in women with postmenopausal osteoporosis, W355
Clinical low-trauma fractures cluster in time in postmenopausal women, 1276
Clinical risk factors for fracture are additive in postmenopausal women who are at risk for fracture in a primary care setting, W294
Clinical validation of a simplified absolute fracture risk algorithm in Canadian women, 1080

Chondrocytes, thyroid hormone-induced terminal differentiation involves IGF-1 modulation of canonical Wnt signaling, M118, S118
Effects of pro-inflammatory cytokines on SOCS-2 expression in, W093
Postnatal development, IGF-1 signaling is required for, 1109
- Growth retardation**
GC-induced, identification and functional involvement of lipocalin 2 in, T177
- Grx5**
Regulates osteoblast cell functions by protecting against oxidative stress, M005
- Gs**
Signaling in osteoblasts, Designer GPCRs suggest opposing roles for, 1021
- Gsa**
Ability of XLs to mimic in mediating PTH signaling in vivo, M218
Mice lacking in early osteoblasts leads to marked bone fragility, impaired bone formation in, 1020
- GSK-3 β**
Inhibits osteoblastic bone formation through suppression of Runx2 transcriptional activity by the phosphorylation at a specific site, 1247
- GTPase.** See also *Rho GTPase*
RhoA and its effector kinase ROCK mediate actin cytoskeleton reorganization leading to osteocyte anoikis by GC, M233, S233
Small cdc42 enhances osteoclastogenesis and bone resorption, 1146
- Guanylyl cyclase B (GC-B)**
Local CNP clearance system as a regulator of CNP-GC-B system for bone growth, T168
- GW bodies**
Alterations are associated with osteoclastogenesis, M094
- ## H
- H3 lysine 9 methyltransferase**
Histone is a transcriptional coactivator for VDR, 1027
- Hairless (hr)**
Molecular analysis of two novel mutations in the VDR corepressor and expression of rHr in *E. coli*, M259, S259
- Hairy enhancer of split 1 (HES-1)**
An anti-adipogenic mediator of osteogenic oxysterols and hedgehog signaling, W043
- Hajdu-Cheney Syndrome (HCS)**
TPD therapy in HCS, T479
Use of TPD in HCS, WG16
- Haploinsufficiency**
Modeling BMP and bisphosphonate combination therapy in wild type and Nf1 haploinsufficient mice, W164
Nell-1 partially rescues craniofacial defects in *Runx2* haploinsufficient mice, 1105
- Haplotype association mapping (HAM)**
Genome-wide HAM leads to an identification of a genetic variant in CER1 associated with BMD in premenopausal women, T214
- HcB/8/23**
Biomechanics and body size quantitative trait loci in mice, W466
- Hedgehog homolog (HH).** See also *Indian hedgehog homolog*; *Sonic hedgehog homolog*
Activation of LXR inhibits hedgehog signaling and osteogenic differentiation of BMSC, W023
HES-1 is an anti-adipogenic mediator of osteogenic oxysterols and hedgehog signaling, W043
Pathway, molecular mechanisms for BMP-2 transcription by, 1257
Signaling, VDR and epidermal carcinogenesis, W158
- Height loss**
And decreased physical function in Japanese women, M346
Is associated with impaired quality of life in the elderly, M365
Predicts fractures in middle aged and older men and women, 1281
- Hematopoiesis**
Dramatic increase in bone marrow of rescued RANKL-deficient mice by expression of soluble RANKL transgene, M096, S096
- Hematopoietic cells**
PGE₂ increases a specific subset of primitive hematopoietic cells in vivo, M039, S039

- Hematopoietic stem cells (HSC).** See *Stem cells, hematopoietic*
- Heme oxygenase-1 (HO-1)**
Effects on CIA model, T130
- Hemodialysis**
Non-invasive study of bone and cardiovascular disease in chronic hemodialysis subjects, T488
Prospective controlled study assessing the clinical benefit of evening administration of Vitamin D in hemodialysis patients, T494
- Heparan sulfate proteoglycans (HSPG)**
Sulfation during in vitro osteogenesis, W036
- Hepatic osteodystrophy.** See *Osteodystrophy, hepatic*
- Hesr**
Endogenous, redundantly support osteoblast differentiation, W019
- Heterotopic ossification (HO).** See *Ossification, heterotopic*
- Hey**
Endogenous, redundantly support osteoblast differentiation, W019
- High-mobility group box 1 (HMGB1)**
Regulates actin cytoskeleton organization and RANKL-induced osteoclastogenesis in a manner dependent on RAGE, M079
- High-mobility group proteins (HMGs)**
Coupled with TNF α production are essential for osteoclastogenesis, T071
- High throughput screening (HTS)**
Development of cell-based assays for identifying antiresorptive compounds targeting RANK signaling through, M102
- Highly active anti-retroviral therapy (HAART)**
Aberrations in Wnt/ β -catenin signaling driving HAART-induced bone loss in vitro, M469
- Hip axis length (HAL)**
Association between peak HAL and polymorphisms of the VDR and ER1 genes in healthy Chinese men, T230
- Hip fractures**
BMD and hip fracture, 1079
Competing risk of subsequent fracture and death after hip fracture in nursing home residents, M362, S362
Compliance with osteoporosis treatment and incidence of hip and wrist fracture after forearm BMD screening, WG37
Decline in age adjusted hip fracture incidence but a drastic increase in hip fractures among the very oldest, 1051
An epidemiological study of hip fractures in Korean women, W282
Hip muscle cross-sectional area and attenuation, 1282
Hip structural geometry and incidence of osteoporotic fractures in the WHI-BMD cohort, T288
Impact of incident hip fracture on quality of life in older men, M355
Increased mortality in patients with a hip fracture, 1049
Leg lean mass and risk of hip fracture, M347, S347
Loss of follow up after fragility hip fractures in some regions in Czech Republic, W245
Novel, integrated approach to the management of patients following hip fracture, T328
Relationships between leptin, PTH, Vitamin D and bone metabolism markers in patients with hip fracture, M460
Serum 25(OH)D and the risk of hip fractures, 1202
- Using a case-manager to improve osteoporosis treatment after hip fracture, T329
What are the characteristics of postmenopausal women with the T-score of the total hip that is lower than that of the lumbar spine?, W248
- Hip strength**
Comparison of the effects of TPTD and ALN on parameters of total hip strength as assessed by FEA, 1089
- Hip structure analysis (HSA)**
Age effects on hip structure, 1054
Changes in hip geometric structures with aging, M373, O373, S373
Heterogeneity in structure is not captured using the hip structural analysis, M334
In vivo comparison of CT and DXA methods of proximal femur cross-sectional geometry measurement using HSA, W226
- Histogenesis**
Temporal regulation of, by mesenchyme during craniofacial bone development, W040
- Histomorphometry**
Image processing for 3-D dynamic histomorphometry, W481
- HIV/AIDS**
Osteopenia and lipodistrophy in HIV-infected patients, M496
TREM2 pathway is involved in osteoclastogenesis induced by NRTIs in AIDS, W074
- Homeobox protein**
Identification of as a regulator of Osx expression and mediator of TNF action, 1143
- Homocysteine**
Levels and risk of hip fracture in postmenopausal women with poor renal function, M471, S471
- Hormones**
Bone relationship in females is hormonal stage dependent, W515
Concerted growth of bone length and width, influence of sex hormones, IGF-1 and muscle size, 1083
Hormonal regulation of hypertrophic chondrocyte apoptosis, W094
- Hormone therapy**
Methods of transition from hormone therapy to raloxifene or other regimens administered to postmenopausal women for the prevention or treatment of osteoporosis, W388
- HRT**
Postmenopausal osteoporosis HRT and weight gain, M401
- Hs.43125**
Identification as an articular chondrocyte-specific gene, T120
- hSca.** See *Osteoclast inhibitory peptide-1*

- Human bone marrow endothelial (HBME) cells**
PTHrP-induced MCP-1 production promotes osteoclast differentiation in vitro, T247
- Human mesenchymal stem cells (hMSC).** See *Mesenchymal stem cells, human*
- Human multipotent adipose-derived stem (hMADS) cells**
Local transplantation of, improve fracture healing, W003
- Human osteoprogenitor (HOP) cells**
Cell cooperation between, and HUVEC in tissue engineering, M041, S041
- Human osteosarcoma cells (U2OS)**
PDTC inhibits SOD1 gene and cell growth by activating JNK pathway in, W018
- Human type 1a2 procollagen promoter (hCol1a2)**
Nuclear targeting sequence together with human Runx2 enhancer elements drives robust expression in transgenic mouse osteoblasts, 1288
- Human umbilical vein endothelial cells (HUVEC)**
Cell cooperation between HOP and, in tissue engineering, M041, S041
- Human Vitamin D receptor (hVDR).** See *Vitamin D receptor*
- Hyaluronic acid (HA)**
Biological trials of HA acid on osteoclast differentiation induced by IL-1, M161
- Hybridization, in situ (ISH)**
New approach to assess bone formation rates and, T115
- Hydrostatic loading**
Of growth plate chondrocytes in vitro, M119
- Hydroxyapatite (Hap)**
Attachment of cell on ALD-derived surface, W009
Increase of the mechanical strength of novel unidirectional porous ceramics in vivo, T128
- Hydroxyfasudil**
Induce the differentiation and mineralization of osteoblastic MC3T3-E1 cells via inhibiting the mevalonate pathway and enhancing BMP-2 expression, M056, S056
- 1 α -Hydroxylase (1(OH)ase)**
Deletion of the 25OH(D) from mice expressing the null mutation for the CaSR converts a hypercalcemic to a hypocalcemic hyperparathyroid phenotype, M231
Gene knockout mice by transplantation of wild-type NA-BM-MSC, partial rescue of the Vitamin D deficient phenotype of, T058
Knockout mice, Ca-independent and 1,25-dihydroxyvitamin D3-dependent regulation of the RAS in, W150
Treatment with antiresorptive agents decreases renal expression of 25OH(D), W127
- 25-Hydroxyvitamin D (25OH(D))**
Age modifies the impact of Vitamin D3 supplementation on the PTH ratio, M414
Deletion of the 1 α (OH)ase from mice expressing the null mutation for the CaSR converts a hypercalcemic to a hypocalcemic hyperparathyroid phenotype, M231
Development of an assay on the Abbott ARCHITECT Analyzer, W156
Effect of plasma 1,25(OH) $_2$ D concentration or Ca intake on negative correlation with PTH concentrations in Japanese adolescents, W159
Reduction in serum 25(OH)D during PTH treatment, T373
Serum, relationship with bone markers in professional football players, W503
Treatment with antiresorptive agents decreases renal expression of 1 α (OH)ase, W127
- 25-Hydroxyvitamin D $_3$ (25OH(D) $_3$).** See also *Vitamin D*
Relationship between serum 25-hydroxyvitamin D $_3$ concentration and walking ability, leg strength, or balance in community-dwelling Japanese frail elderlies, W394
Relationship between serum 25(OH)D $_3$ concentration and walking ability, leg strength, or balance in community-dwelling Japanese frail elderlies, WG12

- Vitamin D₂ supplementation suppresses endogenous levels of 25-hydroxyvitamin D₃, M264
- Hydroxyapatite ceramics**
Surgical treatment for benign bone tumors with fully interconnected porous hydroxyapatite ceramics, T264
- HYP**
ASARM-peptides are directly responsible for defective mineralization in, I155
- Hypercalcemia**
CaR plays a significant role in protection against, M227, S227
Deletion of the 25OH(D) 1(OH)ase from mice expressing the null mutation for the CaSR converts a hypercalcemic to a hypocalcemic hyperparathyroid phenotype, WG1, M231
Orally-active nonsecosteroidal Vitamin D agonists increased bone mass without causing hypercalcemia, M416
Role of Npt2c, involved in HHRH, I115
Tissue-selective, non-secosteroidal VDRM with improved therapeutic window of bone efficacy over hypercalcemia, I012
- Hypercalcemia, familial hypocalciuric (FHH)**
Discriminative power of the 24h-urine CCCR, the 24h-urine CR and the 24h-urine CE for the separation between PHPT and, M222
- Hypercalciuria**
Effect of hypercalciuria on bone density and strength in genetic hypercalciuria stone-forming rats, M267
How should hypercalciuria be defined?, M383, S383
- Hypercholesterolemia**
LRP5 mutations are associated with osteoporosis, impaired glucose tolerance and hypercholesterolemia, M281, S281
- Hypergravity**
Prevents bone loss in rats following ovariectomy, W492
- Hyperkyphosis**
And physical function in older community dwelling women, M363
To what extent do vertebral fractures, disc height loss, low bone density, and poor muscle strength contribute to hyperkyphosis in older women?, W280
- Hyperparathyroidism**
Comparison of rapid iPTH to IRMA in patients with, M216
Deletion of the 25OH(D) 1(OH)ase from mice expressing the null mutation for the CaSR converts a hypercalcemic to a hypocalcemic hyperparathyroid phenotype, M231
Secondary, role in relation to osteoporosis, M195
- Hyperparathyroidism, childhood**
Childhood hyperparathyroidism with bilateral slipped femoral epiphysis, severe bone disease and Vitamin D deficiency, WG4
- Hyperparathyroidism, normocalcaemic primary (NPHPT)**
Asymptomatic, screening in the United States, T481
Effect of bisphosphonates on BMD in subjects with NPHPT, T403
- Hyperparathyroidism, primary (PHPT, I-HPT)**
Bone quality in mild PHPT, T486
Cardiovascular manifestations of PHPT, M481
Discriminative power of the 24h-urine CCCR, the 24h-urine CR and the 24h-urine CE for the separation between FHH and, M222
- Long-term morbidity and mortality in untreated mild PHPT, T484
Marked improvement of cortical bone geometry after parathyroidectomy in postmenopausal women with primary hyperparathyroidism, M484, S484
Neurocognitive changes in mild, W146
Phosphate stimulates greater PTH release and parathyroid cell proliferation in organ cultures of parathyroid tissue from patients with II-HPT than with I-HPT, W141
- Hyperparathyroidism, secondary (II-HPT)**
Impact of cinacalcet HCL on bone remodeling and minimodeling in patients with secondary hyperparathyroidism, T495
Minimodeling reduces the rate of cortical bone loss in patients with secondary hyperparathyroidism, T496
Phosphate stimulates greater PTH release and parathyroid cell proliferation in organ cultures of parathyroid tissue from patients with II-HPT than with I-HPT, W141
And postpartum Vitamin D insufficiency in healthy Danish women, W151
Protein-PTH mRNA interactions that determine PTH mRNA stability in, M217, S217
- Hyperphosphatemia**
Mediates oxidative stress in bovine aortic endothelial cells, T493
Vascular calcification and aortic gene expression are consistent with, in OPG-deficient mice, I117
- Hypertension**
Activation of renin-angiotensin system induces osteoporosis independently of hypertension, I238
Vitamin D status is inversely associated with blood pressure, M483
- Hypertrophic chondrocytes.** See *Chondrocytes, hypertrophic*
- Hypervitaminosis D**
Fetal, results in neonatal lethality, M266
- Hypocalcemia**
Deletion of the 25OH(D) 1α(OH)ase from mice expressing the null mutation for the CaSR converts a hypercalcemic to a hypocalcemic hyperparathyroid phenotype, M231
Fetal, PTH upregulates placental Ca transfer in response to, W137
Related phenotype of VDR knockout mice, overexpression of human VDR in the intestine rescues, I025
- Hypogonadism**
Prevention and treatment of hypogonadism-associated bone loss and bone metastases by OPG-Fc in a model of mixed osteolytic/osteoblastic metastases, M311, S311
- Hyponatremia**
Induces bone loss and prevents fat accumulation in aged F344 Brown Norway rats, T448
- Hypoparathyroidism**
Bone mass in adults and children with hypoparathyroidism, WG6
Dominant-negative GCMB mutations cause hypoparathyroidism, I031
Protein-PTH mRNA interactions that determine PTH mRNA stability in, M217, S217
Use of PTH in hypoparathyroidism, T485
- Hypophosphatasia (HPP)**
Enzyme replacement therapy for murine HPP, I259
- Possible hypophosphatasia in a man with hypophosphatasemia, spinal ankylosis, and recurrent fractures, T474
- Hypophosphatemic rickets.** See *Rickets, hypophosphatemic*
- Hypovitaminosis D**
Prevalence of hypovitaminosis D and its correlation with different PTH values in a sample of postmenopausal women in Buenos Aires, W149
Prevalence of hypovitaminosis D and male hypogonadism in prednisone-treated rheumatic disease patients, T436
Severe hypovitaminosis D, associated with hyperparathyroidism and osteopenia/osteoporosis in a cohort of long-term kidney transplant recipients with excellent kidney function, T500
- Hypoxia**
Accelerates the transformation of osteoblasts to osteocytes, W013
Contributes to the formation of the EARR in vitro, T010
Role of hypoxia in cancers that metastasize to bone, I003
- Hypoxia-inducible factor (HIF)**
Pathway, Co incorporation into CaP layers stimulates osteoclast differentiation and activation via, W075
- Hypoxia-inducible factor 1 (HIF-1)**
Activation through integrin/ILK/Akt pathway in cultured osteoblasts, ultrasound induces, T511
- Hypoxia-inducible factor 1α (HIF-1)α**
Disruption of HIF-1α in osteoblasts exacerbates ovariectomy induced bone loss in mice, I013
Genetic and pharmacologic activation promotes angiogenesis and accelerates bone regeneration, I065
- Hypoxia-inducible factor 2α (HIF2A)**
Induces COL10A1 and promotes hypertrophic differentiation of chondrocytes, I175

I-HPT. See *Hyperparathyroidism*
i-NOS. See *Nitric oxygen synthetase*
Ibandronate (IBN)

- Benefits of oral IBN on non-vertebral fracture risk in postmenopausal osteoporosis, T389
Ca enhances anti-tumor effects of IBN in breast cancer cells, T240
Comparable adherence and improvement in GI tolerability with monthly oral and quarterly intravenous IBN in patients who discontinued previous bisphosphonates because of GI intolerance, W362
Daily and monthly IBN restores bone loss in androgen-deficient male rats, W319
Daily or intermittent oral IBN preserves trabecular microarchitecture, W368
Effect of oral IBN following weekly PTH, M418
Efficacy and safety of intravenous IBN for Chinese primary osteoporotic women, W323
Monthly IBN is associated with reduced risk of serious GI events compared with weekly bisphosphonates, W353
Monthly oral IBN is well tolerated and efficacious in Japanese osteoporotic subjects, T405
Oral monthly IBN is associated with rapid suppression of serum CTX within three days of treatment initiation, W367

- Quarterly intravenous IBN injections provide continuing benefits in women with postmenopausal osteoporosis, W363
- Relationship between increasing annual cumulative exposure to IBN, increases in BMD and reductions in clinical fractures, W365
- Significant reduction in non-vertebral fractures with high- versus low-dose IBN, M428
- Tolerability of once-monthly IBN across different age groups of women switched from once-weekly bisphosphonates, W352
- Icariin**
Icariin exerts bone protective effects in vivo and in vitro, W337
- ICSBP**. See *IRF-8*
- IGF**. See *Insulin-like growth factor*
- IHH**
Spatial and temporal localization of components of signaling pathways in the postnatal LVGP, M125
- II-HPT**. See *Hyperparathyroidism*
- IKB kinase β (IKK β)**
Mice with a myeloid lineage-specific deletion demonstrate both in vivo and in vitro defects in osteoclastogenesis, 1294
- IKB kinase γ (IKK γ)**
Modulates osteoclastogenesis and bone erosion, T098
- IKB α**
Deficient mice display increased osteoclast formation and activity and bone loss in vivo, 1147
- Ikaros**
Transcription factors, *Osr1* gene expression is regulated by, W030
- Ile-Pro-Pro (IPP)**
Enhance osteoblast function in vitro, W038
- Imatinib mesylate**
Inhibits bone formation and decreases bone mass in vivo by inhibiting PDGFR-mediated osteoblast mitogenesis, T018
Suppresses bone metastases by inhibiting osteoclasts through blockade of M-CSF signals, 1170
- Immunohistochemistry (IHC)**
New approach to assess bone formation rates and, T115
- Immunoradiometric PTH assay (IRMA)**
Comparison of rapid iPTH in patients with hyperparathyroidism, M216
- Immunoreceptor tyrosine-based activation motif (ITAM)**
Signaling in bone remodeling in various bony microenvironments, distinct roles of, 1291
- Immunosuppressants**
Effects of immunosuppressants on bone metabolism, T503
- Incisor absent (*ia/ia*) rats**
Osteopetrotic rat exhibits reduced osteoclast activity, resulting in normal endochondral fracture union but delayed hard callus remodeling, T088
- Indian hedgehog homolog (Ihh)**. See also *Hedgehog homolog*
Essential for postnatal bone, T011
Expression, *Msx2* promotes late stages of chondrocyte differentiation by up-regulating, W092
Promoted osteoblast differentiation through Gli2 ubiquitination, *Trep1* ubiquitin complex regulates, T055
- Transcription, *Atf4* regulates chondrocyte proliferation and differentiation by direct targeting, 1183
- Inducible nitric oxide synthase (iNOS)**
Expression through integrin/ILK/Akt pathway in cultured osteoblasts, ultrasound induces, T511
- Inflammation**
Mechanisms leading to increased resorptive activity of large osteoclasts in, T105
- Inflammatory bowel disease (IBD)**
Barrier site metabolism of Vitamin D, 1029
- Inorganic phosphate**. See *Phosphate, inorganic*
- Insoluble collagenous bone matrix (ICBM)**
Acid swelling overcomes osteogenesis inhibition of xenogeneic collagenous matrix delivery system used for naturally-derived BMP complex, M172
- Insulin**
Promotes osteoblast differentiation independent from IGF-1 signaling and its receptor is required for normal postnatal bone acquisition, 1070
- Insulin-like growth factor (IGF)**
LMP-1 accelerates MC3T3-E1 osteoblast differentiation in part through modulation of, T037
- Insulin-like growth factor 1 (IGF-1)**
Ablation of signaling disrupts the communication between osteoblasts and osteoclasts, M241, S241
Carrier components determine skeletal integrity via direct and indirect mechanisms, 1138
Continuous infusion into the epiphysis of the tibia, M188
Cortical bone is positively associated with, and negatively with fibrinogen, M194
Engineered bone marrow MSCs improve the fracture healing process, M191, S191
Expression of and biomechanical studies in experimental model of cholestatic liver, W416
Local application has a similar effect on intramembranous bone healing, M193
Low serum IGF-1 levels results in cortical osteopenia but increased life span in elderly mice, W314
Modulation of canonical Wnt signaling, thyroid hormone-induced terminal differentiation of growth plate chondrocytes involves, M118, S118
Overexpression of osteoblast IGF-1 blunts the deleterious effects of low protein intake on bone strength, W401
Regulation of collagen II and MMP-13 gene expression in endplate chondrocytes via distinct signaling pathways, T116
Role of status and secondary hyperparathyroidism in relation to osteoporosis, M195
Signaling, insulin promotes osteoblast differentiation independent from, 1070
Signaling is required for postnatal growth plate development, T109
Systemic, shows concerted anabolic actions on bone and muscle, M192
Treated anulus fibrosus cells, activation of *Erk1/2* prevents the FasL-induced apoptosis in, T117
In vivo models to study receptor dynamics of bone stem cells, M190
- Insulin-like growth factor binding protein 1/2/3/4/5 (IGFBP-1/2/3/4/5)**
Regulation of and osteocalcin expression in mouse osteoblasts, role of NFI-X transcription factor in, T034
Role of status and secondary hyperparathyroidism in relation to osteoporosis, M195
Serum, a marker of bone turnover, 1253
Triple knock-out mice have larger bones, M189
- Insulin-like growth factor receptor gene (*Igf1r*)**
Osteoblast-specific knockout alters mechanical properties of cortical bone, W464
- Intact parathyroid hormone**. See *Parathyroid hormone, intact*
- Integrin**
Association with Cx43 regulates the function of osteocyte hemichannels in response to shear stress, T504
Bone metastases select for integrin $\alpha 2\beta 1$ negative cells in prostate cancer cell line DU145, M301
Osteoblast response to titanium microtopography is dependent on $\alpha 2$, W002
Regulation of expression by NFATc1 and PU.1 in osteoclasts, M071
Ultrasound induces HIF-1 activation and iNOS expression through, T511
- Integrin-linked kinase (ILK) inhibitor**
Ultrasound induces HIF-1 activation and iNOS expression through, T511
- Interferon-inducible protein 16 (IFI16)**
Mediation of cell proliferation and tumorigenicity of musculoskeletal tumor cells by, T265
- Interleukin-1 (IL-1)**
Induced osteoclastogenesis, *IVVY*⁵³⁵⁻⁵³⁸ plays an essential role in, M084, S084
- Interleukin-1 β (IL-1 β)**
Epigenetic mechanisms are involved in the cytokine-induced de novo expression in human articular chondrocytes in vitro, M184
Induced osteoarthritis-associated changes in synovial fibroblasts, involvement of Cx43 in, T169
Treated articular chondrocytes, regulation of MMP-9 expression by MMP-12 in, M139
- Interleukin-6 (IL-6)**
Effect on the expression of cartilage matrix proteins, T146
Estrogens attenuate production in osteoblastic cells by decreasing oxidative stress and its effects on NF- κ B activation, T186
Signalling, role in c-Src-mediated osteoblast differentiation, T170
Upregulation of CASR gene expression by IL-6, 1187
- Interleukin-8 (IL-8)**
Human breast stem cell transformation and invasiveness is mediated upregulation by *TWIST* interactions with NF- κ B, T242
- Interleukin-12 (IL-12)**
Related cytokines on osteoclast formation and T cell properties, effects of, T076
- Interleukin-15 (IL-15)**
Association study of IL-15 polymorphisms with BMD and fracture risk in postmenopausal Korean women, W257
- Interleukin-23 (IL-23)**
Effects on osteoclast formation and T cell properties, T076
Enhanced osteoclastogenesis is mediated by STAT3 and NF- κ B via upregulation of RANKL from CD4⁺T cells, T078

Interleukin-27 (IL-27)

- Effects on osteoclast formation and T cell properties, T076
- Suppressive effect in osteoclastogenesis, T072

Interleukin-33 (IL-33)

- Inhibits osteoclast formation indirectly through osteoblastic cells, T081

Intervertebral disc (IVD)

- Degeneration in OVX rats, M251
- Effect of removal of nucleus pulposus cells on the annulus fibrosis of, M124
- Lumbar, histological and molecular analysis of the growth and differentiation of, M126

Intracellular assembly

- FFSS promotes, and formation of Cx43-forming channels in osteocytes, M520

Intracellular estradiol binding protein (IEBP)

- Control of estradiol-directed gene transactivation by, 1221

Intracellular scaffold

- Osteoclasts, Tm-2/3 regulate, M074

Intracrine

- Synthesis and action of 1,25-dihydroxyvitamin D rescues TLR suppression of innate immunity, 1028

IP₃

- Acid-induced stimulation of COX2 and RANKL in osteoblasts is mediated by, M063

IRF-8

- As negative regulator of osteoclast differentiation in vitro and in vivo, 1145

Iron (Fe)

- Uptake through the Tfr1 promotes osteoclast differentiation and function, M097

Iron (Fe³⁺)

- Role on differentiation of chondrocytes at the stage of calcification, M131

Isoflavone

- Isoflavone and soya foods intakes in Brazilian population, W275

IVVY⁵³⁵⁻⁵³⁸

- RANK cytoplasmic motif plays an essential role in TNF- and IL-1-induced osteoclastogenesis, M084, S084

J**Jagged1**

- Signaling promotes osteoclast differentiation in vitro, M085

Jak2 specific inhibitor. See *AG490***JNK**

- Activating pathway in U2OS, PDTC inhibits SOD1 gene and cell growth by, W018

K**KCI**

- Cotransport expression in canine osteosarcoma cell lines, investigation of, T031

Keratinocytes

- Skin, PTHrP regulates antimicrobial peptide production by, M238

KHBJ9

- Therapeutic effect on cartilage degradation and inflammation in CIA, M135

Kidneys

- Effects of GC on BMP-2 and BMP-7 expressions in, M234
- FGFR 3 and FGFR 4 are not physiologically relevant FGF-23 targets in, 1227

Kidney disease, chronic (CKD)

- Mechanism of skeletal involvement in cardiovascular mortality in CKD, T489
- Stages classified by serum cystatin-C and incidence of hip fracture in the WHI-OS, T325

Kidney stones

- Reduced formation and altered renal phosphate-homeostasis in mice overexpressing murine-MEPE, 1118

Klotho

- Ablation completely reverses the biochemical and skeletal alterations in FGF-23 (R176Q) transgenic mice, M208, S208
- Homozygous missense mutation causes severe tumoral calcinosis but not premature aging, 1113
- Protein, down-regulation of expression by estrogen, T192

KR62980

- Enhances bone formation through promoting osteoblastogenesis and inhibiting osteoclastogenesis, M387

KRN arthritis. See *Arthritis, KRN***Krox20**

- Analysis of gene regulation reveals Srf function in bone and cooperation with NFAT1, M025, S025
- Opposing effects of GCs and Wnt signaling on, T026

Kyphoplasty

- Adjacent fractures in the thoracic and lumbar spine after the treatment with balloon kyphoplasty, W397
- Balloon kyphoplasty in the treatment of osteolytic lesions in the thoracic and lumbar spine due to cancer, T258
- Importance of balloon kyphoplasty in the management of vertebral fractures, W392
- Interdisciplinary approach to improve pain and mobility in patients with osteoporosis and painful vertebral fractures by kyphoplasty, W26
- Three-year outcome after kyphoplasty in a prospective controlled trial role of initial bone edema and selection of cement type, T416
- Treatment of osteoporotic vertebral body fractures by means of percutaneous balloon kyphoplasty, W395

Kyphosis

- Computer-based measure of kyphosis predicts fractures in the thoracic spine of postmenopausal women, M356, S356
- X-ray ordering improves in patients with height loss or kyphosis following an osteoporosis educational intervention, T332

L**Lactase phlorizin hydrolase**

- Decreased activity of lactase phlorizin hydrolase and BMD in postmenopausal women, M284

Lactation

- Estrogen deficiency and PTHrP infusion do not fully reproduce the bone loss of, M220

Lactose

- Transgenic expression of the hVDR in the proximal small intestine of VDR-null mice improves the utilization of rescue diet in young mice, W154

Lacunae

- Estimation of osteocyte density from total lacunar population, W058

- Histochemical assessments on the distribution of OLCS, W059

- Osteoclastic resorption and bone resorption, diphyllin abrogates acidification of, T093
- Prednisolone induces osteocyte's death and erosion of osteocytic lacunae walls, W458

Lacunocanalicular fluid flow

- And regulation of BMU activity, M069

Lamin A/C

- Inhibits osteogenic differentiation of human MSC, siRNA specific knockdown of, M038

Lasofloxifene

- Lasofloxifene preserves lumbar vertebral strength by preventing bone loss and the deterioration of bone architecture and geometry, T435

Latent TGFβ binding protein (LTBP1)

- Non-covalent interaction with MMP-13 in a unique TGFβ large latent complex produced by hypertrophic chondrocytes, M128

Lbh (limb, bud and heart)

- Role in endochondral bone formation, M122

Lead (Pb)

- Differential accumulation in the tidemark of normal and osteoarthritic human articular cartilage and subchondral bone, W271

Lead (Pb²⁺)

- Bovine ion-bound osteocalcin and implications for toxicity, three-dimensional ¹H NMR structure of, M159

Left

- Nuclear interactions are ligand independent, W148

Leptin

- Beta blockade mitigates bone loss during energy restriction partially via, 1110
- Central control of bone remodelling by NMU, mediator of the leptin-dependent regulation of bone formation, 1061
- Deficient (ob/ob) mice exhibit increased bone mechanosensitivity and corresponding osteoblasts show increased anabolic shear stress responses in vitro, 1081
- Sexual dimorphism in the relationship between serum leptin and skeletal health in healthy adolescents, W507

Leu-Lys-Pro (LKP)

- Enhance osteoblast function in vitro, W038

Leukemia, lymphoblastic (ALL)

- BMD, body composition, BMI and height in children treated for ALL, T513
- Bone morbidity at diagnosis among children with ALL, M489, S489

Leupaxin (LPXN)

- Characterization of LPXN as a focal adhesion-associated protein in prostate cancer cells, W191

LIAISON® Analyzer

- Automated measurement of 1,25(OH)₂D on the, W211
- Development of a BAP assay for, W217
- Measurement of 25OH Vitamin D₂ by, W216

Ligamentum flavum (LF)

- Effect of pore size and surface modification of the circular PEG polymer scaffold on adhesion of cultured, M075
- Osteogenesis of, by demineralized bone matrix, T008

LIM mineralization protein 1 (LMP-1)

- Accelerates MC3T3-E1 osteoblast differentiation in part through modulation of the IGF system, T037

Limb development

Over-expression of Runx2 in mesenchymal cells enhanced bone formation but inhibited cartilage formation and, 1066
SOST overexpression impairs, M179, O179, S179

LIMD1

Modulates osteoblast differentiation and function, W047

Lipids

Bone-derived, activation of FXR in breast cancer cell lines by, M249

Lipocalin 2

Identification and functional involvement in GC-induced growth retardation, T177

Lipopolysaccharide (LPS)

Stimulates the formation of osteoclast-like cells by increasing M-CSF and PGE₂ production by osteoclasts, T084
Synergistically induces osteoclast differentiation, W084
TNFR1 and TNFR2 differentially regulate inflammatory bone resorption induced by, M110, S110

Lipoprotein lipase (LPL)

Association of LPL Hind III polymorphism with lumbar BMD in Korean premenopausal women, T224

Lipoproteins

Metabolism of postprandial, bone plays an important role in mice, T015

Liver

Cholestatic, expression of IGF-1 and GHR and biomechanical studies in experimental model of, W416

Liver X receptors (LXR)

Activation of inhibits hedgehog signaling and osteogenic differentiation of BMSC, W023

Lmna

Spontaneous mutation results in hypoplastic cranial sutures and under-mineralization of the skeleton, M146, S146

Long bones

Ang II suppresses bone mass via AT1 receptor in, M141
Growth plates, analysis of matrix vesicle proteins from, W085
Mechanical properties, expression of a hypomorphic allele of FIAT improves, S033

Lovastatin

Local delivery of lovastatin by a biodegradable polymer increases callus strength in rats, W341

LRF

Induced by RANKL and increases c-Fos expression in osteoclastogenesis, W067

LRP5

Compromised fracture healing in Lrp5 null mice, W456
Gain of function mutation is associated with an increased osteogenic response to loading in trabecular bone, M523, S523
Gene expression and bone turnover with disuse, M511
Haplotype-based analysis of the LRP5 gene in relation to osteoporosis phenotypes, M289
Influence of A1330V LRP5 gene polymorphism on volumetric BMD and structural parameters of bone in men and women, W230
Large-scale analysis of association between polymorphisms in the LRP-5 and LRP-6 genes and BMD and fracture, T199
Mineral and matrix characteristics in mice with LRP5 G171V mutation, M155

PTH activates β -catenin signaling through, 1297
Signals in U2OS osteoblast-like cells, mutations in LRP5 β -propeller 1 block SOST-mediated inhibition of, 1048

LRP5 β -propeller 1

Mutations in block SOST-mediated inhibition of the LRP5-Wnt-TCF signals in U2OS osteoblast-like cells, 1048

LRP5 G171V

Mutation and age-related bone fragility, M279, S279

Mutation protects against disuse-related trabecular bone fragility, M512, S512

Lumbar fusion

After posterolateral, bone metabolism using OP-1, W119

Lumbar vertebral growth plate (LVGP)

Postnatal, spatial and temporal localization of components of the TGF, BMP, IHH and FGF signaling pathways in, M125

Luminex xMAP

Development of multiplex immunoassay panels for simultaneous quantification of bone metabolism markers using Luminex xMAP technology, W206

Lung cancer

RANKL inhibition blocks lung cancer-induced osteolytic lesions and reduces skeletal tumor burden in both RANK-expressing and RANK-negative lung cancers, M307, S307

Lupus

BMD in Hispanic lupus patients, W254

Lupus erythematosus, systemic (SLE)

Low bone mass is common in premenopausal black women with SLE on prednisone, W247

Luteinizing hormone receptor (LHR)

Association of LHR polymorphism with BMD in young men, M286

Lymphatic growth factor

RANKL stimulates osteoclasts to release VEGF-C and enhances osteoclastic bone resorption through an autocrine mechanism, T100

Lymphocytes

RANKL expressing, intracellular cytokine profile of, T164

Lymphoid enhancer binding factor (Lef) 1

Isoform regulates osteoblast maturation, T023

Lymphoma, non-Hodgkin's (NHL)

Chemotherapy is associated with increased risk of fracture in elderly patients with NHL, T345
Elderly patients with NHL who receive chemotherapy at higher risk for osteopenia and osteoporosis, M374

Lysine-specific gingipain (Kgp)

Synergistically induces osteoclast differentiation, W084

Lysophosphatidic acid (LPA)

Induces osteocyte dendrite outgrowth, M182, S182
Production of, P2X7 receptors couple to, M062, S062
Promotes maturation and survival in rat growth plate chondrocytes, M187
Stimulated osteoblastic cell chemotaxis, molecular mechanisms of, M058, S058

Lysyl oxidase (LOX)

Regulates collagen quality and quantity in MC3T3-E1 cell culture system, M011

M **α_2 -Macroglobulin (α_2 M)**

Novel substrate for ADAMTS-7 and ADAMTS-12 and inhibits their degradation of COMP, M166

Macrophages

Identification of TNF α shedding enzyme in, M186

Osteal, novel regulators of bone formation, T186
That enhance osteoblast mineralization, primary murine osteoblast cultures contain, M015

Macrophage colony-stimulating factor (M-CSF)

Independent mechanisms for osteoclastogenesis, W072

Mediated osteoclast survival downstream of the MEK/ERK pathway, novel pro-survival functions of Egr2 in promotion of, M111
Production by osteoclasts, nicotine and LPS stimulate the formation of osteoclast-like cells by increasing, T084

Stimulates bone resorbing activity of mature human osteoclasts via increased activation of AP-1 and NF κ B, T075

Magnesium (Mg)

Intact CaR and PTH genes are required to regulate extracellular concentrations independently, M230

Mammalian P bodies. See GW bodies**Mammalian target of rapamycin (mTOR)**

Signaling, a novel molecular mechanism underlying Wnt's anabolic effects on osteogenesis, T108

Mandibular bones

Histological and biochemical characterization of mandibular bones in senile osteoporotic mice, T147

MAP kinase phosphatase-1 (MKP-1)

PTHrP induces in differentiated BMSC, osteoblast and cementoblast cell lines, M001

MAPK. See Mitogen-activated protein kinases**Marrow**

Marrow fat and peak bone mass, T449

Mast cells

Migration to bone surfaces precedes and appears essential for PTH-induced peritrabecular fibrosis, M482, S482

Matrilin-3 (MATN3)

Regulation of chondrocyte hypertrophy and BMD by, T063

Matrix metalloproteinase (MMP)

Expression of is pleiotropic on alkaline phosphatase expression in osteogenic differentiation, T019
MT3-MMP is a major mesenchymal collagenase essential for skeletal development, M167
Novel transcription factor-like function of stromelysin-1 that regulates CTGF/CCN2 gene transcription, T125
Regulation of expression by EPAS1 in articular chondrocytes, T122
Regulation of expression by MMP-12 in IL-1 β -treated articular chondrocytes, M139
Regulation of MMP-9 expression in IL-1 β -treated articular chondrocytes, M139
Rescue of MT1-MMP expression in cartilage increases survival, chondrocyte proliferation and bone formation, M165, O165, S165

Matrix metalloproteinase 13 (MMP-13)

IGF-1 regulation of gene expression in endplate chondrocytes via distinct signaling pathways, T116

- Induction in osteoblasts, Nmp4/CIZ contributes to fluid shear stress induced, T506
- Non-covalent interaction with LTBP1 in a unique TGF β large latent complex produced by hypertrophic chondrocytes, M128
- Null mutant mice, delayed cartilage and bone remodeling during fracture healing in, M163, S163
- Promoter activation, identification and characterization of Runx2 phosphorylation sites involved in, W026
- Matrix vesicles**
Poteins from long bone growth plates, analysis of, W085
- MC3T3-E1 cells**
BMP-2 induces sustained expression of COX-2 in, M168
- Differentiation and mineralization of osteoblastic via inhibiting the mevalonate pathway and enhancing BMP-2 expression, M056, S056
- LMP-1 accelerates osteoblast differentiation in part through modulation of the IGF system, T037
- LOX regulates collagen quality and quantity in culture system, M011
- Podn affects cell proliferation and in vitro mineralization possibly by inducing cellular senescence in, T142
- Rapamycin inhibits osteoblast proliferation and differentiation in, M007
- McCune-Albright syndrome (MAS)**
Severe hypertension, a possible complication of MAS, M488
- MCP-1**
Cascade of gene expression indicates CCL2 is essential for osteoclast formation, T073
- PTHrP-induced production by HBME cells and osteoblasts promotes osteoclast differentiation in vitro, T247
- Mean carotid plaque thickness (MCPT)**
PTH levels are associated with, W145
- Measles virus nucleocapsid protein (MVNP)**
Enhances NFATc1 activation during osteoclastogenesis in PD, M479
- Expressing cells, changes in VDR coregulator recruitment result in $1\alpha,25(\text{OH})_2\text{D}_3$ hypersensitivity in, W152
- Mechanical loading**
Bone adaptation to impact loading, WG9
- Bone traits are determined early in life but adapt during growth to accommodate local loading circumstances, I197
- Do periosteal and intracortical responses to ulnar fatigue loading differ between old and young rats?, M461
- Effect of hindlimb unloading on bone in two strains of mature mice, M513
- Effects of mechanical loading and estrogen are structurally distinct, I087
- Effects on matrix production by osteoblastic cells cultured in polyurethane scaffolds, T508
- Identification of genes that may modulate the musculoskeletal system's early response to unloading, T510
- Increased vBMD and bone area due to mechanical loading gradually decreased following cessation of loading, T151
- Knee loading stimulates wound healing in mouse femora, M526
- Males have an enhanced osteogenic responsiveness to loading versus females, W500
- Mechanical properties**
Of cortical bone, osteoblast-specific knockout of *Igf1r* alters, W464
- Heritability of lumbar trabecular bone mechanical properties in baboons, W176
- Improved analysis of bone nano-mechanical properties using a novel nanoindentation technique, W463
- Mechanical enhancement of bone quality is paralleled by suppression of fat production, W495
- Testing of mechanical properties of hip protectors using high-tech materials, T418
- Mechanical strength**
Increase of novel unidirectional porous HAp ceramics in vivo, T128
- Mechanical stress/strain**
AKT's effects on β -catenin regulate osteoblasts' responses to, T067
- Effects on osteocytes, induced bone cell proliferation and recruitment, W054
- And fluid shear stress induce a similar osteogenic gene response via divergent signaling pathways, M517
- Induced root resorption, M-CSF receptor c-fms antibody inhibits, M107
- Protective effects on osteocyte viability is mediated by the effects of prostaglandin on the cAMP/PKA and the β -catenin pathways, M237
- Medullary bone**
Formation, osteoclast differentiation in Japanese quail bone marrow cell culture, M091
- MEK**
Pathway, novel pro-survival functions of Egr2 in promotion of M-CSF-mediated osteoclast survival downstream of, M111
- Melanoma**
Melanoma bone metastasis, W188
- TGF β receptor I kinase inhibitor reduces the development and progression of melanoma bone metastases, M305, S305
- Melatonin (Mel)**
Hormonal and pharmacological modulation of MT2 receptor inhibits osteoclast maturation and activity, T087
- Melatonin receptor isoform 1 (MT1)**
Benign and malignant bone tumors express the MT1, T262
- MEN1**
In MEN1 the estimated ratio of mutated p27 versus mutated MEN1 genes is below 1:100, T483
- Menadione (K_3)**
Biosynthesis of MK-4 from PK and, T136
- Menaquinone-4 (MK-4)**
Biosynthesis from PK and K_3 in bone, T136
- Effect of Vitamin K2 in addition to Ris on the patients with postmenopausal osteoporosis, T424
- Synthesis and biological evaluation of Vitamin K_2 metabolites, T261
- Menarche.** See also *Amenorrhea*
Influence of menarcheal age on microstructural constituents of distal tibia in 20-year-old women and their middle-aged mothers, T463
- Menopause**
Impact of herbal remedies for menopause on BMD, M339, S339
- Postmenopausal osteoporosis and weight gain, W386
- Relationship of bone turnover markers, ovarian hormones and cytokines during menopause, M458
- Relationship of serum cytokines and monocyte gene expression to BMD and BMC in postmenopausal women, M183
- MEPE**
Abnormal bone-mineralization, osteoclastogenesis and bone-turnover in transgenic-mice overexpressing MEPE, I226
- Degradation of, and release of SIBLING ASARM-peptides (minhibins), I155
- Murine, reduced kidney-stone formation and altered renal phosphate-homeostasis in mice overexpressing, I118
- Osteocyte specific expression after mechanical stimulation in the mouse ulnae loading model, W050
- Mesenchymal cells**
Differentiation and mineralization, temporal expression of PHOSPHO1 during chick limb bud, W087
- Identification and characterization of miRNAs expressed during chondrogenesis of, T123
- Murine, mineralization of C3H10T1/2 cells in micromass culture, W088
- Over-expression of Runx2 enhanced bone formation but inhibited cartilage formation and limb development, I066
- Mesenchymal stem cells (MSC)**
Adipocyte differentiation of, osteoblast differentiation by inhibiting, T057
- Age-related intrinsic changes in human bone marrow-derived MSC and their differentiation to osteoblasts, W031
- BMP-Mediated adult bone marrow-derived MSC, active fragment of Spp24 enhances differentiation to osteoblasts, T144
- CLA regulates osteoblast and adipocyte differentiation from, T047
- Concentration and bone repair, M046
- Condensation, crosstalk between CTGF and TGF1 in, M158
- Cytoplasmic interaction of p21 with Runx2 during osteogenic differentiation of, T049
- Differentiation to osteoblasts, Snail inhibits, T033
- Enhanced properties in dynamic three-dimensional cultures, M051
- Fom aging C57BL/6 exhibit increased oxidative stress and defective replication, M052, S052
- Growth and osteogenic differentiation, bespoke bioceramic scaffolds support, M050
- From human adipose tissue and bone marrow, osteogenic differentiation and interaction with Ti6Al4V, T053
- IGF-1 engineered bone marrow improve the fracture healing process, M191, S191
- Precursors derived from human BMSC and DPSC, role of EphB/ephrin-B interactions in cell attachment and spreading of, W033
- siRNA specific knockdown of lamin A/C inhibits osteogenic differentiation of, M038
- TGF β 1 induces migration in coupling bone resorption and formation, I072
- Mesenchymal stem cells, bone marrow-derived (bmMSC)**
Progenitor cells in tmMPC have characteristic similarities to, W039
- Mesenchymal stem cells, human (hMSC)**
Derived osteoblasts, effects of PDE7 and PDE8A inhibition on the differentiation of, T046

- Osteogenesis, activation of the non-canonical Wnt pathway during, T048
- Regulation of lineage commitment, dual-action CTSK inhibitors, W315
- Mesenchymal stem cells, non-adherent bone marrow-derived (NA-BM-MSD)**
- Wild-type, partial rescue of the Vitamin D deficient phenotype of 1 α -hydroxylase gene knockout mice by transplantation of, T058
- Mesenchyme**
- During craniofacial bone development, temporal regulation of histogenesis by, W040
- Messenger RNA (mRNA).** See *Ribonucleic acid*
- Metabolic bone diseases**

Transcription factor in regulation of IGFBP-5 and osteocalcin expression in mouse osteoblasts, role of, T034
- Nuclear factor κB (NF-κB)**
But not NFATc1 is involved in AhR-RANKL crosstalk in BaP-mediated inhibition of osteoclastogenesis, T106
Canonical pathway mediates osteoclast bone resorption activity, T094
Constitutive activity of the NF-κB p65/p50 transcriptional complex is critical for bone metastasis in breast cancer, T249

Estrogens attenuate IL-6 and TNF α production in osteoblastic cells by decreasing oxidative stress and its effects on, T186

Human breast stem cell transformation and invasiveness is mediated upregulation of IL-8 by *TWIST* interactions with, T242

IL-23-enhanced osteoclastogenesis is mediated by via upregulation of RANKL from CD4⁺T cells, T078

M-CSF stimulates bone resorbing activity of mature human osteoclasts via increased activation of, T075

Matrix PRELP inhibits osteoclastogenesis inactivating, W080

Oxidative stress-induced vascular calcification is associated with increased expression of receptor activator of, 1216

Regulated gene expression and kinase phosphorylation oscillate rapidly over time, M198

Transcriptional induction of SOX9 by subunit p65 during chondrogenesis, W101

Nuclear factor κ B2 (NF- κ B2)
Limits TNF-induced osteoclastogenesis through precursor cell cycle regulation, 1148

Nuclear factor of activated T cells (NFAT)
Activation during osteoclastogenesis in PD, MVNP enhances, M479

Activation, endogenous TNF in osteoclast precursor cells promotes osteoclastogenesis via, T077

Analysis of Krox20 gene regulation reveals Srf function in bone and cooperation with, M025, S025

AnxA8 is a critical bone matrix-dependent osteoclast gene transcriptionally regulated by, W068

In bone mechanotransduction, a novel role for, M519

CTGF induces in vitro, T172

Down-regulation of, PIAS3 modulates osteoclastogenesis by, W066

Mediates the stimulatory effects of post-translationally modified BSP on the resorptive activity of rabbit osteoclasts, T099

NF- κ B but not NFATc1 is involved in AhR-RANKL crosstalk in BaP-mediated inhibition of osteoclastogenesis, T106

In osteoclasts, regulation of integrin expression by, M071

Nuclear matrix protein 4/cas interacting zinc finger protein (Nmp4/CIZ)
Contributes to fluid shear stress induced *MMP-13* gene induction in osteoblasts, T506

Nucleocytoplasmic shuttling
Ciz, a nucleocytoplasmic shuttling protein, interacts with ECM proteins, W012

Nucleoside reverse transcriptase inhibitors (NRTI)
TREM2 pathway is involved in osteoclastogenesis induced by, W074

Nucleus pulposus (NP) cells
Effect of removal on the annulus fibrosis of the IVD, M124

Nutrition
Diet effects on bone mechanical and molecular markers, T360

Effect of a high-protein diet on bone and body composition, W410

Effect of home parenteral nutrition on BMD, W249

Effect of the dietary habit of skipping breakfast on bone metabolism, skeleton and nutritional status in young Japanese women, W517

High protein intake enhances the positive influence of physical activity on BMC in pre-pubertal boys, 1041

More alkaline diet may enhance the favorable impact of dietary protein on lean tissue mass in older adults, W403

Negative effect of dietary protein intake on bone mass accretion in Chinese pubertal girls with low Ca intake, 1038

Negative impact of caloric restriction on the BMD, T457

Nutrition survey about the status of fat-soluble vitamins in Japanese women, T311

Propensity to accumulate bone microdamages is increased in adult female rats fed an isocaloric low protein diet, W404

Restricting dietary protein may improve skeletal integrity in exercising female rats, T361

O

Obesity

A stronger marker than body weight for BMD in Caucasian women but not in men, M335

Bone growth, adipocytokines and physical training in obese children, T477

Effect of diet and exercise-induced weight loss on regional and total body BMD of obese subjects, M320

Effects of weight reduction on bone mass and structure in obese women, T319

Increased markers of bone formation seen following bariatric surgery in morbidly obese patients, T444

Influence of moderate energy restriction and seafood consumption on bone turnover in overweight young adults, W408

Influence of overweight/obesity on BMD of various skeletal sites in early-postmenopausal women, W274

Relative efficacy of Vitamin D2 or D3 treatment for D-insufficiency in morbidly obese subjects, T445

OCT-1547

OCT-1547 inhibits osteoclast differentiation through inhibition of PLC γ 2 activation and NFATc1 induction, M410

OCZF

Expression directed by the CatK promoter affects bone mass and osteoclast formation in transgenic mice, M099, O099, S099

Odd-skipped related 1/2 (Osr1/2)

Functions in cell proliferation, M003

Gene expression is regulated by Runx2 and Ikaros transcription factors, W030

Odontoblasts

Maturation, Dlx5 overexpression promotes early, M028

NOX expression in NOS knock-out mice, T173

Old astrocyte specifically induced substance (OASIS)

Involved in normal bone formation, M029, S029

Olpadronate

Novel effects of high doses of olpadronate on cortical bone and mechanism of fracture in young rat femurs, W321

Oncogenic osteomalacia. See *Osteomalacia, oncogenic*

Oncostatin M (OsM)

An essential stimulus of bone formation and osteoclastogenesis, 1068

Osseointegration

Ti implantation in rat maxillae, bone remodeling after, T127

Ossification, endochondral

Mechanisms of Osx control of, W098

OPG negatively regulates chondroclast formation and recruitment in, M136, S136

Phenotypical heterogeneity between osteoclasts involved in, T083

Pit-1 controls endochondral ossification through regulating chondrocyte apoptosis, 1224

Ossification, heterotopic (HO)

Characterization of a new traumatic mouse model of, T171

Progenitor cells in tmMPC have characteristic similarities to bmMSCs, W039

Ossification of the posterior longitudinal ligament (OPLL)

Functional RNAi screening for Runx2-regulated genes corresponding to ectopic bone formation in human spinal ligaments, M273

Runx2 haploinsufficiency ameliorates the ectopic calcification in a mouse model OPLL, W100

Ostabolin-CTM

Increases lumbar spine and hip BMD after one year of therapy, 1130

Pulmonary delivery of the PTH analogue Ostabolin-CTM stimulates markers of bone formation in postmenopausal women, M421, S421

Osteoactivin (OA).

Bone cell autonomous effects of, in vivo, 1023

Osteoarthritis (OA).

See also *Arthritis*

Abnormal collagen type 1 production by human osteoarthritic osteoblasts, T143

Alterations in collagen structure and mineral composition in calcified cartilage and subchondral bone in a monkey model of, W089

Associated changes in synovial fibroblasts, involvement of Cx43 in IL-1 β -induced, T169

Back-scattered electron imaging of bone mineralization in osteoarthritis, T113

Differential accumulation of Pb and Zn in the tidemark of normal and osteoarthritic human articular cartilage and subchondral bone, W271

Increased bone resorption in knee osteoarthritis with severe joint surface wear, W207

Induction of kinin B₁ receptor is performed by vasoactive peptide ET-1, M117

Intra-articular OCIF/OPG prevents cartilage degeneration in a murine model of, W097

Of knee decreases regional and total BMD in Japanese women, T456

Molecular network underlying chondrocyte hypertrophy causing, M127, S127

OPG inhibits cartilage degradation in a knee instability mouse model, M134

Prevalence of radiographic osteoarthritis of knee and lumbar spine and its association with pain, W438

Regulation of the transcription factor Pitx1 and its role in OA pathogenesis, 1035

Osteoblasts

From 5-HTT knockout mice display reduced growth and mineralization capacity, M013

Ablation of IGF-1 signaling disrupts the communication between osteoblasts and, M241, S241

- Abnormal collagen type 1 production by human osteoarthritic, T143
- Acid-induced stimulation of COX2 and RANKL in, mediated by IP₃, M063
- Active fragment of Spp24 enhances but is not indispensable for BMP-mediated adult bone marrow-derived MSC differentiation to, T144
- In adult bone use *Slug* for regeneration and repair but not remodeling, 1213
- Alpha1 and beta2 adrenergic agents modify RANKL/OPG expression and cell proliferation in, T006
- ATP is released from, by multiple mechanisms, M065
- Calcitriol inhibits BMSC differentiation into, in a manner cooperative with but independent of TGFβ, T069
- Calvaria cultures, 1,25(OH)₂D₃ inhibits bone nodule mineralization through the FGF-23-mediating ERK pathway in, M210, S210
- Cell lines, PTHrP induces MKP-1 in, M001
- Characterization of regions upstream of exon II of the human CYP19 gene that mediate regulation by cAMP in murine, T032
- Cleavage products of APP regulate function of, T145
- Co-stimulation of 1,25-(OH)₂D₃ and BMP-2 enhances the expression of VDR and RANKL mRNA in, W162
- Conditional ablation of the CaR causes abnormalities in skeletal development and mineralization, M223, O223, S223
- Conditional deletion of FN reveals distinct roles in orchestrating assembly of bone ECM proteins and in osteoblast differentiation, 1177
- Conditional knockouts in early and mature, reveal a critical role for CaRs in bone development, 1284
- Cultured, GC enhances the expression of sFRP3 in, T176
- Cultures, opposing effects of GCs and Wnt signaling on Krox20 and mineral deposition in, T026
- Deletion of Cnb1 reveals novel role for calcineurin in bone formation, 1283
- Designer GPCRs suggest opposing roles for Gs and Gi signaling in, 1021
- Dynamic imaging in living calvaria reveals the motile properties and suggests heterogeneity in bone, 1045
- Dynamic imaging of fluorescently tagged populations integrates mineralization dynamics with osteoblast to osteocyte transition, 1044
- Early, impaired bone formation in mice lacking Gs leads to marked bone fragility, 1020
- EGF-like ligands stimulate osteoclastogenesis by regulating expression of osteoclast regulatory factors by, T175
- Elastic modulus of, W061
- ERα is required for strain-related β-catenin signaling in, M064, O064, S064
- Express CSF-1R and are a target for CSF-1, T039
- Expression of osteoblast-specific transcription factors in aged mice, W024
- Function, bone plays an important role in the metabolism of postprandial lipoproteins in mice, T015
- Function in vitro, bioactive tripeptides enhance, W038
- Function, TWEAK is a regulator of, M009
- Gene networks that are regulated by the *Dlx* gene family, W017
- GGPP promotes survival and is involved in anti-apoptotic effects of PTH, 1192
- Greater sensitivity of osteocytes to shear stress as compared to, PGE₂ production and Wnt/β-catenin signaling, W052
- Gremlin induces MAPK signaling in, W122
- Growth inhibition by Runx2 depends on its C-terminal regulatory domain and is accompanied by changes in G-protein coupled signaling pathways, M047, S047
- GSK-3 inhibits osteoblastic bone formation through suppression of Runx2 transcriptional activity by the phosphorylation at a specific site, 1247
- hCol1a2 nuclear targeting sequence together with human Runx2 enhancer elements drives robust expression in, 1288
- Identification of specific co-regulator complex for VDR, W022
- Identification of TCTP as a nuclear matrix protein in, M143
- Increasing number is not sufficient to enhance the function of the HSC niche, M053
- Inhibiting apoptosis of through FoxO3a/Bim axis, Akt1 contributes to maintenance of bone mass and turnover by, 1211
- Inhibiting proliferation and differentiation in MC3T3-E1 cells and primary mouse BMSCs, rapamycin, M007
- Isolation and immunohistochemical analysis of OMD expressed in, T016
- Local overexpression of aromatase leads to clearly increased bone mass, 1218
- Maturation, Lef 1 isoform regulates, T023
- Mature, GC stimulate Wnt expression in, T062
- Mature, transgenic disruption of GC signaling attenuates KRN serum-induced arthritis in vivo, T183
- MC3T3-E1, BMP-2 induces sustained expression of COX-2 in, M168
- Mineralization, primary murine cultures contain macrophages that enhance, M015
- Mineralizing, androgens act directly via the AR to regulate bone turnover and maintain trabecular bone, 1217
- Modulation of P2X₇R by estrogen and corticosteroids, M055
- Molecular mechanisms of 1α,25(OH)₂ Vitamin D₃-induced ATP release in, 1030
- Nmp4/CIZ contributes to fluid shear stress induced *MMP-13* gene induction, T506
- Novel activin/nodal-binding protein G11 inhibits matrix mineralization in, M203
- P2X₇ receptors couple to production of LPA, a novel signaling axis promoting osteogenesis, M062, S062
- PDGFR-mediated mitogenesis, imatinib mesylate inhibits bone formation and decreases bone mass in vivo by inhibiting, T018
- PGE₂ acts through EP2/EP4 receptors to upregulate RGS2 expression in, T063
- Phosphorylation of caveolin-1 in response to fluid shear is mediated by P2X₇ activation, T061
- Pitx2 inhibits osteoblastic conversion of myoblasts through interfering the promoter activity of *Osx* gene, T021
- Potential involvement of Ephrin B2 in the anabolic action of PTH in, T012
- Proliferation through the c-Src/ERK signaling pathway, interaction of galectin-9 with lipid rafts induces, W005
- PTHrP-induced MCP-1 production promotes osteoclast differentiation in vitro, T247
- Regulation of oxidative stress and osteoblast apoptosis by estrogens is preserved when the ER cannot directly interact with DNA, T184
- Related gene expression, adiponectin action influences, W014
- Response to titanium microtopography is dependent on integrin alpha-2, W002
- Responses to mechanical strain and PTH, AKT's effects on β-catenin regulate, T067
- Role of NF1-X transcription factor in regulation of IGFBP-5 and osteocalcin expression in, T034
- Role of Wnt3A signaling in maturation of, T166
- ROS expression of NOS1, 2 and 3 in knockout mice, M006
- Selective deletion of FN affects bone density and osteoblast function, 1179
- Skeletal phenotype in transgenic mice over-expressing CTGF in cells of the lineage, 1287
- Snail inhibits the differentiation of MSC to, T033
- Specific knockout of *Igf1r* alters mechanical properties of cortical bone, W464
- Targeted disruption of *Efnb1* reduces bone size, 1107
- Targeted disruption of GC signaling delays intramembranous bone development in vivo, T182
- TGFβ suppresses POEM expression in, M201
- TIEG as a novel mediator of Runx2 expression and activity in, 1144
- TIEG directly binds to and represses the OPG promoter, resulting in decreased support of osteoclast differentiation, W028
- Transcription factor E4bp4 is induced by GCs and represses promoter activity in, T179
- Transformation to osteocytes, hypoxia accelerates, W013
- Transgenic expression of an engineered Gs-coupled receptor in, produces increased bone mass, 1019
- Ultrasound induces HIF-1 activation and iNOS expression, T511
- In vitro and in vivo, *Zfp521* is a novel inhibitor of Runx2 activity with opposite effects on, 1250
- Osteoblast differentiation**
- And adipocyte differentiation, opposing effects of GH and alcohol reveal a critical role in the reciprocal relationship between, M196

- Maturation and activity, hormonal and pharmacological modulation of MT2 Mel receptor inhibits, T087
- Maturation, BMP-2-inducible *Osx* increases osteoblastic CSF-1 and RANKL/OPG ratio to induce, M100
- Maturation deviated from bone remodeling cycle in RA joint destruction, treatment with anti-TNF- α antibody recovers, W439
- Motility, myoIIA regulates precursor cell fusion and, W069
- In myeloma, up-regulation of TACE in monocytes ameliorates their deflected differentiation into, M302
- NFATc1 mediates the stimulatory effects of post-translationally modified BSP on the resorptive activity of rabbit, T099
- Niche is composed of 5-FU-insensitive osteoclast precursors in vivo, M082, S082
- Novel pro-survival functions of *Egr2* in promotion of M-CSF-mediated osteoclast survival downstream of the MEK/ERK pathway, M111
- Osteopetrotic *ia/ia* rat exhibits reduced activity, resulting in normal endochondral fracture union but delayed hard callus remodeling, T088
- P2X7 nucleotide receptors couple to isoform-specific activation of PKC in, M109
- Phenotypical heterogeneity involved in the endochondral ossification and bone remodeling, T083
- Possible suppressive role of Galectin-3 in osteoclastic bone destruction accompanying adjuvant-induced arthritis in rats, M108
- Rab3D recruits the dynein complex to secretory vesicles through direct interaction with Tctex-1, I293
- RANKL signaling in, effect of p62 mutations, M474
- RANKL stimulates, to release VEGF-C and enhance bone resorption through an autocrine mechanism, I100
- Regulation of activity by CatK-generated type I collagen fragments, W065
- Regulation of integrin expression by NFATc1 and PU.1 in, M071
- Regulatory factors, EGF-like ligands stimulate osteoclastogenesis by regulating expression of, T175
- Rho GTPase signaling pathways, *Wrch1/RhoU* role in cell adhesion and osteolysis, M073, S073
- Ruffled border membrane, electroneutral sodium/bicarbonate cotransporter NBCn1 is expressed in, T091
- Secrete an activity promoting bone formation and canonical Wnt signaling in osteoblastic cells, T005
- Sex steroids hormone receptors mediate osteoprotective effects by regulating its life cycle, I220
- Specific ablation of *dicer* suppresses bone resorption and increases bone mass, I292
- Survival via distinct signaling pathways, AG490 regulates, T100
- Tm-2/3 regulate the intracellular scaffold of, M074
- Transgenic overexpression of PTP-oc in cells of osteoclastic lineage led to increased bone resorption and marked reduction in trabecular bone mass and density in adult mice, M112, O112, S112
- Osteoclast-associated receptor (OSCAR)**
Down-regulation of, PIAS3 modulates osteoclastogenesis by, W066
- Osteoclast-derived zinc finger (OCZF)**
Induced by RANKL and increases c-Fos expression in osteoclastogenesis, W067
- Osteoclast differentiation**
And activation via HIF pathway, Co incorporation into CaP layers stimulates, W075
- bgn and *fnod* control bone mass by regulation through BMSC, M157, O157, S157
- Effects of modeled microgravity on, T052
- And function, CaMK-CREB pathway regulates, M114, S114
- And function, G-CSF enhances, T074
- And function, iron uptake through the TfR1 promotes, M097
- And function, tetracyclines Dox and Mino effectively inhibit, M106
- Kgp and LPS synergistically induce, W084
- Mechanism of RANKL-evoked $[\text{Ca}^{2+}]_i$ oscillations mediated by RGS10 in, M093, S093
- During medullary bone formation period in Japanese quail bone marrow cell culture, M091
- Role of P-Rex1 in, M098
- And survival, expression of Ang II receptor and its roles on, W073
- Tec tyrosine kinases are essential for, I289
- TIEG directly binds to and represses the OPG promoter in osteoblasts resulting in decreased support of, W028
- In vitro and in vivo, transcription factor IRF-8 is a negative regulator of, I145
- In vitro, Jagged1-Notch2 signaling promotes, M085
- In vitro, PTHrP-induced MCP-1 production by HBME cells and osteoblasts promotes, T247
- Osteoclast inhibitory peptide-1 (OIP-1)**
Characterization of binding to FcR γ on osteoclast precursor cells, I103
- Osteoclast-like cells**
Formation, nicotine and LPS stimulate by increasing M-CSF and PGE₂ production, T084
- Osteoclast precursor cells (pOC)**
Characterization of OIP-1/hSca binding to FcR γ on, I103
- Endogenous TNF α promotes osteoclastogenesis via c-Fos and NFATc1 activation, T077
- Generation, regulation by type II cytokines and STATs, T079
- Osteoclastic protein-tyrosine phosphatase (PTP-oc)**
Transgenic overexpression in cells of osteoclastic lineage led to increased bone resorption and marked reduction in trabecular bone mass and density in adult mice, M112, O112, S112
- Osteoclastogenesis**
Alterations in MicroRNAs and GW bodies are associated with, M094
- Diverging pathways of CaM regulation of osteoclastogenesis, W070
- EGF-like ligands stimulate by regulating expression of osteoclast regulatory factors by osteoblasts, T175
- Ex vivo, role of *Bcl2* in, W083
- Expression and possible role of PVR/CD155/Necl-5 in, M077
- Expression and transcriptional activity of Mitf isoforms during, T101
- Fat-1* gene prevents ovariectomy induced bone loss by modulating osteoclastogenesis, I135
- HMGs coupled with TNF α production are essential for, T071
- IL-23-enhanced is mediated by STAT3 and NF- κ B via upregulation of RANKL from CD4⁺T cells, T078
- Induced by NRTIs in AIDS, TREM2 pathway is involved in, W074
- Inhibition by prosthetic wear debris involves suppression of RANK expression, W076
- M-CSF independent mechanisms for, W072
- Matrix PRELP inhibits, inactivating the NF- κ B signal, W080
- Mice with a myeloid lineage-specific deletion of IKK β demonstrate both in vivo and in vitro defects in, I294
- MVNP enhances NFATc1 activation during, M479

- NEMO (IKK γ) modulates, T098
 NF- κ B but not NFATc1 is involved in AhR-RANKL crosstalk in BaP-mediated inhibition of, T106
 OsM is an essential stimulus of bone formation and, 1068
 PIAS3 modulates by down-regulation of NFATc1 and OSCAR, W066
 POZ-Zn transcriptional regulator OCZF/LRF is induced by RANKL and increases c-Fos expression, W067
 RANKL-induced, Ca and phospholipase C γ 2 signaling regulates, 1104
 RANKL-induced, high D(+)glucose concentration inhibits, W082
 RANKL-induced, HMGB1 regulates actin cytoskeleton organization in a manner dependent on RAGE, M079
 RANKL-induced, PIAS3 negatively regulates, M089
 RANKL-induced, Wnt5a enhances, 1149
 RANKL is produced by adipocytes and stimulates, W079
 Rheumatoid synovial fibroblasts promote osteoclastogenic activity by activating RANKL via TLR-2 and TLR-4 activation, W435
 RNAi machinery is essential for, M090, S090
 Small GTPase cdc42 enhances, 1146
 Spacio-temporal analysis using co-culture system, M078
 Suboptimal 25(OH)D $_3$ levels causes increased osteoclastogenesis and bone loss, W402
 Suppression by DMS, a SPHK inhibition-independent action, M088
 Suppressive effect of IL-27 in, T072
 TNF-induced, NF- κ B2 limits through precursor cell cycle regulation, 1148
 TNF α - and IL-1-induced, IVVY⁵³⁵⁻⁵³⁸ plays an essential role in, M084, S084
 Via c-Fos and NFATc1 activation, endogenous TNF in osteoclast precursor cells promotes, T077
 Via Ca signaling activation, RANKL-induced expression of TRPV2 is involved in, T103
 In vivo activation of TLR9 modulates, M081
- Osteoclastogenesis inhibitory factor (OCIF)**
 Intra-articular, prevents cartilage degeneration in a murine model of osteoarthritis, W097
- Osteocyte-lacunar canalicular system (OLCS)**
 Histochemical assessments on the distribution of, W059
- Osteocytes**
 Density, estimation from total lacunar population, W058
 DMP1 and MEPE expression after mechanical stimulation in the mouse ulnae loading model, W050
 Dynamic imaging in living calvaria reveals the motile properties and suggests heterogeneity of osteoblasts in bone, 1045
 Dynamic imaging of fluorescently tagged populations integrates mineralization dynamics with osteoblast to osteocyte transition, 1044
 Effects of mechanical strain on, induced bone cell proliferation and recruitment, W054
 Elastic modulus of, W061
 FFSS promotes intracellular assembly and formation of Cx43-forming channels in, M520
 Greater sensitivity to shear stress as compared to osteoblasts, PGE $_2$ production and Wnt/ β -catenin signaling, W052
 Hemichannels, α 5 integrin association with Cx43 regulates in response to shear stress, T504
 Hypoxia accelerates the transformation of osteoblasts to, W013
 LPA induces dendrite outgrowth, M182, S182
 Microstructural variation in the bone matrix and cell attachments modify strain amplification on, M066
 Osteocytic regulation of Pi homeostasis through FGF-23, 1296
 Prednisolone induces death and erosion of osteocytic lacunae walls, W458
 Presence of p120-catenin in, T507
 Primary, effects of PTH(1-34) on, M068, S068
 Protective effects of mechanical strain on viability is mediated by the effects of prostaglandin on the cAMP/PKA and the β -catenin pathways, M237
 Small GTPase RhoA and its effector kinase ROCK mediate actin cytoskeleton reorganization leading to anoikis by GC, M233, S233
 Target ablation of PTH/PTHrP receptor in, 1047
 Targeted deletion of E11/gp38 results in increased skeletal size and BMD, 1043
 Viability, ex vivo model in trabecular bone, W055
- Osteocytic cells**
 FFSS and PE $_2$ activates -catenin signaling in MLO-Y4, W053
 Nanoprobe osteocytic subcellular compartments by SERS, W057
- Osteocytic networks**
 Modulation of site specific bone adaptation by signaling in, W060
- Osteodystrophy, hepatic**
 Expression of IGF-1 and GHR and biomechanical studies in experimental model of cholestatic liver, W416
- Osteodystrophy, renal (ROD)**
 Structural implications of low-magnitude mechanical stimulation in a pilot study of patients with ROD, M493, S493
- Osteoformin**
 Enhances gap junction communication of human preosteoblastic cells in culture, M040
- Osteogenesis**
 Acceleration of fracture healing via enhanced, through SCF/cKit pathway, T013
 Acid swelling overcomes inhibition of xenogeneic collagenous matrix delivery system used for naturally-derived BMP complex, M172
 BMP-2-induced, diverse effects of noggin on, W107
 Circulating osteogenic precursor cells of hematopoietic origin, 1156
 Classical ER α signaling is essential for estrogen mediated enhancement of, M250, S250
 Combination of Vitamin D and BADGE potentiates their pharmacological inhibition of PPAR and increases osteogenic differentiation of adipocyte precursors, W155
 Differentially modulated by PTH and the N- and C-terminal fragments of PTHrP, T050
 Downstream signal transactivation by FGF-4/Osx transgene partially imitates changes of BMP-2 induced transcription factors in NIH3T3 cells, W016
 Estrogen preferentially suppresses osteogenic gene expression in mice lacking classical ERE signaling, T195
 Gene response via divergent signaling pathways, fluid shear stress and mechanical strain induce a similar, M517
 HES-1 is an anti-adipogenic mediator of osteogenic oxysterols and hedgehog signaling, W043
 Of the human LF by demineralized bone matrix, T008
 Induced, tension stress/stain in canine leg lengthening procedures, T059
 mTOR signaling, a novel molecular mechanism underlying Wnt's anabolic effects on, 1108
 P2X7 receptors on osteoblasts couple to production of LPA, a novel signaling axis promoting, M062, S062
 Pericytes derived from adipose tissue, characterization and evaluation of their osteogenic potential, 1215
 Proinflammatory control of BMP-Smad-driven transcription and, W044
 Role in injury-induced calcification from TNF α receptor p55/- p75/- mice, W091
 In vitro assay to assess secreted osteogenic factors from genetically engineered cells, T038
 In vitro, HSPG sulfation during, W036
 In vitro, miRNA expression profiling and function during, 1214
- Osteogenesis, distraction**
 Continuous local infusion of basic fibroblast growth factor enhances consolidation of the bone segment lengthened by, T155
 Increased expression of BMP antagonists during, W112
- Osteogenesis imperfecta (OI)**
 Carrier frequency of recurring mutation causing severe/lethal recessive type VIII OI in African-Americans, T471
 Influence of the gene polymorphisms of collagenase-1 in OI, T216
 Mutations in CRTAP or P3H1 cause dysregulation of Prolyl-3-hydroxylation and recessive OI, 1261
 Phenotypic analysis of the Crtap $^{-/-}$ mice, first animal model for recessive OI, M150, S150
 Sequencing of Col1 in three patients with multiple fractures of unknown aetiology reveals novel mutations causing OI with normal to high BMD, 1196
 Treatment of OI in adults with TPTD, 1260
 Vitamin D deficiency in OI, T437
- Osteogenic differentiation**
 Bespoke bioceramic scaffolds support MSC growth and, M050
 Of BMSC, activation of LXR inhibits hedgehog signaling and, W023
 Of circulating EPC, M042
 Expression of MMP-14 is pleiotropic on alkaline phosphatase expression in, T019
 Of human MSC, siRNA specific knockdown of lamin A/C inhibits, M038
 And interaction with Ti6Al4V, MSC from human adipose tissue and bone marrow, T053
 Of MSC, cytoplasmic interaction of p21 with Runx2 during, T049
 Zfp64 is a downstream target of Runx2 and regulates as a coactivator of Notch1, T035
- Osteogenic index (OI)**
 Bone biomarker responses to short-term training, W056

Osteogenic protein-1 (OP-1)

Bone metabolism after posterolateral lumbar fusion using, W119

Osteogenic stem cells. See *Stem cells, osteogenic Osteoinductivity*

Allogeneic DBM, xenogeneic BMP complex enhances, M173

Osteolysis

Collapse of the vascular bone remodeling compartment is a key process in the development of myeloma-induced osteolysis, 1005

Comparative study of anti-resorptive and anti-cancer treatments in the geometrical and biomechanical properties of rat femurs with tumor-induced osteolysis, W199

Osteoclast formation and, promoted by the AMPK activator AICAR in vivo, 1150

Rho GTPase signaling pathways in osteoclasts, Wrch1/RhoU role in, M073, S073

Role of CXCL13 in SCC associated osteolysis in, T257

Osteomalacia

Following gastric bypass and biliopancreatic diversion surgery, WG14, W420

Unusual presentation of severe Vitamin D deficiency osteomalacia in a patient with congenital hypophosphatemia, WG15

Osteomalacia, oncogenic (OOM)

Minimally invasive treatment by radiofrequency ablation, W422

Osteomalacia, tumor-induced (TIO)

Lack of efficacy of octreotide in the treatment of TIO, W424

Novel algorithm using ^{99m}Tc-MIBI scintigraphy, sequential whole body MRI and venous sampling for FGF-23 for tumor localization in, WG18

Venous sampling for FGF-23 as a tool for pre-operative localization of tumors giving rise to, M213

Osteomodulin (OMD)

Expressed in osteoblast, isolation and immunohistochemical analysis of, T016

Osteonecrosis (ON)

Experimental rabbit model of lunette-like osteonecrosis, T502

Steroid-associated development, temporal feature of bone marrow fat cells in the process of, T178

Osteonecrosis of femoral head (ONFH)

Association study of catalase gene polymorphisms with an ONFH in Korean population, T223

Osteonecrosis of the jaw (ONJ)

ONJ under bisphosphonate therapy, M298, S298
Progression of ONJ in breast cancer patients even with discontinuation of intravenous BP therapy, T233

ZOL delayed the wound healing of tooth extraction socket but failed to cause ONJ in mice, T243

Osteons

Within osteons infrared parameters linked to specific bone properties vary as a function of tissue and animal age, T109

Osteopenia

Comparison of estrogen, raloxifene and bisphosphonate administration for prevention of bone loss in climacteric women complicated with osteopenia, M431

Effect of onion on ovariectomy-induced osteopenia, T364

Female, but not male, TIEG-null mice display severe osteopenia and abnormal cancellous bone microarchitecture, M152, S152

Longitudinal changes in bone density and management in men with osteopenia, T266

One-week evaluation of pharmaceuticals in sRANKL-injected osteopenia model mice, W332

Severe, in PERK-knockout mice is due to impaired osteoblast differentiation associated with reduction of type II RUNX2 expression, 1022

VGLUT1 knockout mice develop, due to an increase in osteoclastic bone resorption, T085

In vivo, CTGF causes, 1178

Osteopenia, diabetic

TRX-1 overexpression attenuates streptozotocin-induced diabetic osteopenia, M498, O498, S498

Osteopetrosis

Conditional inactivation of the CTSK gene in adult mice results in, without activation of compensatory mechanisms for impaired bone resorption, W064

Osteopontin (OPN)

β-Adrenergic signaling requires bone matrix protein OPN to suppress bone formation and to activate bone resorption, 1015

Implication in bone healing, M160, S160

Upregulation by mechanical loading of bone cells, T154

Osteoporosis

AluI polymorphism in ESR2 is associated with reduced risk of osteoporotic fractures, T218

Antifracture efficacy of combined treatment with ALN and ALF for osteoporosis in early-phase treatment, T438

Associations of osteoporotic spinal deformity with back strength among elderly women, M472

Back extensor strength, lumbar spine mobility and spinal inclination as related factors for falls in osteoporotic patients, T341

Basis for osteoporosis in the aldehyde reductase knockout mouse, 1016

Bringing bone health to seniors' communities, WG39

Care pathways for hospital patients with fragility fractures, T407

Clinical factors associated with osteoporotic fractures in a representative population of French women, T344

Community-based program to minimize osteoporosis and fractures risks, W400

Comparative efficacy of osteoporosis treatment in postmenopausal women, T397

Compliance with osteoporosis treatment and incidence of hip and wrist fracture after forearm BMD screening, W377

Compromised bone marrow perfusion in osteoporosis, 1133

Dental status, low bone mass, and other osteoporosis-related conditions as predictors of adverse outcomes in an elderly population, W302

To determine serum fluoride levels in patients with osteoporosis is quite useful for the judgment of effectiveness of osteoporosis treatment, W419

Enhancement of prognosis of osteoporotic fractures by genetic marker, 1201

Evaluation of vertebrae fragility by osteoporosis, W462

Factors associated with lack of osteoporosis care at the time of fragility fracture, W295

Factors influencing the diagnosis and the treatment of osteoporosis following a fragility fracture, M364, S364

Factors influencing women persistence with osteoporosis treatment after 6 months of treatment, M372

Factors predicting osteoporosis treatment initiation in a regionally-based clinical cohort, M321, S321

Fosamax® (ALN sodium) and cholecalciferol (Vitamin D₃) in the treatment of men and postmenopausal women with osteoporosis, T432

GC-induced in rats treated with Ris, evaluation of cell apoptosis and COX-2 expression in, W318

Group-based patient-education program increases knowledge of osteoporosis and adherence to pharmacological treatment, W382

High turnover, incidence in CCR1-deficient mice is greater in females than in males, 1254

Identification of the CACNA2D2 gene on chromosome 3p21 as a novel susceptibility gene for osteoporosis, M282

Identifying the treatment care gap in postmenopausal women at the Southlake Regional Health Centre, W372

Integrated model for evaluation and simulation of therapeutic responses to bone-related therapies, W417

Is osteoporosis related to future incidence of osteoarthritis over 10 years, or vice-versa?, W307

Knowledge of osteoporosis among tertiary students in Vietnam, W340

Long-term retention of knowledge from an osteoporosis education program, T337

Material properties of osteoporotic ewes, M501

Mouse model for diabetes-mediated

osteoporosis, T206

Osteoporotic fragility fractures in older adults admitted in a French primary care department, W287

Outreach program improved osteoporosis management after a fracture, W378

Patient opinions on osteoporosis interventions in the fracture clinic setting, WG35, M439

Post-fracture screening program, T323

Postmenopausal, and weight gain, W386

Prevalence of osteoporosis and Vitamin D deficiency/insufficiency among elderly people with falls in Denmark, T446

Prevalence of secondary causes of osteoporosis among breast cancer patients with osteoporosis and osteopenia, M312

Qualitative method and the method based on the concept of 10 years probability of bone fracture in qualifying patients for pharmacological treatment of osteoporosis, T275

Randomized controlled assessment for effectiveness of an evidence-based guideline for osteoporosis and osteoporotic fracture prevention, T334

- Relationship between the knowledge on osteoporosis in females and BMD at hip, spine and forearm, T274
- Risk factors for osteoporosis and BMD in late postpartum women, T342
- Risk factors for osteoporosis and fragility fractures in postmenopausal women and men older than 50 attended in a primary care center of Spain, T348
- Role of Fas/Fas ligand system in estrogen deficiency-induced osteoporosis, M004, S004

- Small organic molecule compound protects against inflammatory bone loss in periodontitis, M412
- Periosteal cells**
Locus on Chr 4 exerts genetic control of bone size by regulating the differentiated function of, W008
- Periostin-like factor (PLF)**
Role in remodeling of bone following injury, T020
- Peripheral artery disease (PAD)**
And osteoporosis in older adults, W304
- Peritrabecular fibrosis**
PTH-induced, mast cell migration to bone surfaces precedes and appears essential for, M482, S482
- PERK**
Severe osteopenia in, due to impaired osteoblast differentiation associated with reduction of type II RUNX2 expression, 1022
- Perlecan**
Modulates FGF and VEGF signaling and is essential for vascularization in the development of the cartilage growth plate, 1064
- Peroxisome proliferator activator γ 2 (PPAR γ 2)**
Combination of Vitamin D and BADGE potentiates the pharmacological inhibition and increases osteogenic differentiation of adipocyte precursors, W155
- PHD1/3**
PHD1/3 are expressed in bone cells but are not essential for bone homeostasis, T132
- PHEX**
Dominant XLH, a new mutation of PHEX gene, T118
- Phosphatases**
Dual-specificity, modulation of WNT3A-induced signaling through, T042
- Phosphate**
Disturbed homeostasis, transgenic mice overexpressing sFRP-4 have low bone mass but do not exhibit, M209
- FGF-7 is a potent in vivo phosphaturic agent, M212, S212
- Independent effects of FGF-23 on skeletogenesis, 1114
- Reduced kidney-stone formation and altered renal homeostasis in mice overexpressing murine-MEPE, 1118
- Regulates chondrocyte differentiation in a model of embryonic endochondral bone formation, W104
- Renal, duodenum rapidly senses and modulates reabsorption via novel PTH- and phosphatonin-independent pathways, M207
- Stimulates greater PTH release and parathyroid cell proliferation in organ cultures of parathyroid tissue from patients with II-HPT than with I-HPT, W141
- Treatment of XLH increases FGF-23 concentration, W123
- Phosphate, inorganic (Pi)**
Effect of PGD₂ on Na-dependent phosphate transport activity in osteoblast-like cells, T066
- Extracellular, induces ERK1/2 phosphorylation and up-regulates a target gene of FGF-23 in renal proximal tubule cells via NaPi-IIa, W131
- Osteocytic regulation of homeostasis through FGF-23, 1296
- Renal reabsorptive process of Npt2a, role of Npt2c in, M214, S214
- Role of type III NaPi transporters in osteoblastic differentiation, W035
- Phosphate, Pit-1 type III**
Na-dependent, effects of transporter overexpression on Ca phosphate and bone metabolism, W128
- Phosphatidylinositol 3 kinase (PI3K)**
FGF-23 controls NaPi-IIa trafficking via crosstalk with the MAPK pathway, T158
- PC1 selective activation of *Runx2*-II isoform transcription is mediated through, 1142
- Signaling, Osx mediates the feedback regulation of BMP-2 via, T029
- Phosphatonin**
Independent pathways, duodenum rapidly senses and modulates renal phosphate reabsorption via, M207
- PHOSPHOI**
Temporal expression during chick limb bud mesenchymal cell differentiation and mineralization, W087
- Phospholipase C (PLC)**
Signaling via the PTH/PTHrP receptor is essential for normal full response to PTH in both bone and kidney, 1119

Phospholipase C γ 2

Signaling regulates RANKL-induced osteoclastogenesis, I104

Phosphoprotein-24 (Spp24), secreted

Active fragment enhances BMP-mediated adult bone marrow-derived MSC differentiation to osteoblasts, T144

Converted from an inhibitor to a functional enhancer during BMP-directed osteoblastogenesis, M156

Phosphorous (P)

Addition of P to Cd exacerbate the compromised BMD gain in OVX rats, T451

Phosphorylation

Of caveolin-1 in response to fluid shear in osteoblasts is mediated by P2X7 activation, T061

CREB and DNA binding along with demethylation and deacetylation are required for ultimate activation of CYP27B1 promoter by PTH, W132

ERK1/2, extracellular inorganic Pi induces and up-regulates a target gene of FGF-23 in renal proximal tubule cells via NaPi-IIa, W131

Oscillate rapidly over time, NF- κ B-regulated gene expression and, M198

RXR α , examination at serine 260 using specific antibodies in cancer cell lines and tumor tissues, M257

Sites involved in matrix MMP-13 promoter activation, identification and characterization of Runx2, W026

PHPT. See Hyperparathyroidism, primary**Phylloquinone (PK)**

Biosynthesis of MK-4 from K $_2$ and, T136

Physical activity. See Exercise**Pitx2**

Inhibits osteoblastic conversion of myoblasts through interfering the promoter activity of Osx gene, T021

PKA. See Protein kinase A**PKC μ . See Protein kinase D****Placental growth factor (PIGF)**

Specific inhibition of the VEGF homologue PIGF is protective against osteolytic bone metastasis, I169

Plasma membrane calcium ATPase, isoform 2 (PMCA2)

CaR regulates activity in mammary epithelial cells, M219, S219

Plasminogen activator inhibitors (PAI)

Increases femoral mineralization independent of estrogen status through modulation of FN matrix, T137

PAI-1 deficiency enhances fracture callus size but reduces cartilage remodeling during fracture repair, W163

Platelet-derived growth factor receptor (PDGFR)

Mediated osteoblast mitogenesis, imatinib mesylate inhibits bone formation and decreases bone mass in vivo by inhibiting, T018

Pleiotropy

Genome-wide measure of pleiotropy among osteoporosis-related traits in the Framingham Study, M277, S277

Plums

Dried plum polyphenols stimulate osteoblast activity and attenuate detrimental effects of TNF on Runx2, Osx and IGF-1 in MC3T3-E1 cells, T363

Year-long study to demonstrate the bone reversal efficacy of dried plums in postmenopausal women, M445

Podocalyxin (PODXL)

Increased expression in TIEG knockout osteoclast precursors delays osteoclast formation and reduces osteoclast size, M070

Podocan (Podn)

Affects cell proliferation and in vitro mineralization by inducing cellular senescence in MC3T3-E1 cell, T142

Podosomes

myo10 regulates osteoclast adhesion through linkage of microtubules and, M076

Poliovirus receptor (PVR)

Expression and possible role in osteoclastogenesis, M077

Poly(3-hydroxybutyrate-co-3-hydroxyvalerate) (PHBV)

Biomaterial implanted in a murine tibial defect, analysis of in vivo responses to hydrogen peroxide purified, T140

Polycystin-1 (PC1)

Selective activation of Runx2-II isoform transcription is mediated through the Ca-PI3K-Akt pathway, I142

Polyethylene glycol (PEG)

Effect of pore size and surface modification of the circular polymer scaffold on adhesion of cultured human LF cells, M075

Polymorphism

Alu polymorphism in ESR2 is associated with reduced risk of osteoporotic fractures, T218

Association of tri-nucleotide (CAG and GGC) repeat polymorphism of AR gene in Taiwanese women with refractory or remission RA, W433

H²⁶⁸Y, UGT2B7 is associated with serum sex steroid levels and cortical bone size in young adult men, T199

Polyunsaturated fatty acids

Oxidized metabolites of polyunsaturated fatty acids stimulate osteoblast apoptosis via both PPAR γ -dependent and independent mechanisms, M002, S002

Polyurethane

Scaffolds, effects of compressive loading on matrix production by osteoblastic cells cultured in, T508

Postmitotic osteoclast precursors (pOCP)

Osteoclast niche is composed of 5-FU-insensitive osteoclast precursors in vivo, M082, S082

Osteoclasts generated in ectopic bone are derived from, W071

Postnatal bone

Biology, role of BMP-2 in, I106

Ihh is essential for, T011

Normal acquisition, insulin promotes osteoblast differentiation independent from IGF-1 signaling and its receptor is required for, I070

Potassium (K)

Association between urinary K and hip bone mass in a prospective cohort study of elderly postmenopausal women, T321

Poverty

As a risk factor for osteoporotic fractures, T335

POZ-Zn

Transcriptional regulator OCZF/LRF is induced by RANKL and increases c-Fos expression in osteoclastogenesis, W067

PPARG

Marrow adipogenesis and osteoblastogenesis reflect global energy utilization through activation of, M021, O021, S021

Pravastatin

Administration of pravastatin inhibits suppressed osteoblast dysfunction and bone turnover in uremic rats, M492

Prednisolone

Induces osteocyte's death and erosion of osteocytic lacunae walls, W458

Pregnancy-associated plasma protein-A (PAPP-A)

Skeletal muscle-specific overexpression increases bone accretion, T080

Premature aging. See Aging, premature**Preosteoblast epidermal growth factor-like repeat protein with MAM domain (POEM)**

TGF β suppresses expression in osteoblasts, M201

Primary hyperparathyroidism (PHPT). See Hyperparathyroidism, primary**Procollagen aminoterminal propeptide (PINP)**

Development of a highly sensitive high-throughput mass spectrometry-based assay for PINP, W202

Non-radioactive immunoassay for PINP, W214

Serum PINP is a useful marker of bone formation, W210

Progenitor cells

Activation and differentiation, COX-2 deficiency impairs periosteal, I251

Non-adherent circulating, with osteoblastic potential become adherent in the presence of Ca²⁺ and are able to mineralize, T040

In tmMPC have characteristic similarities to bmMSCs, W039

Progressive ankylosis gene (ank)

Regulates osteoblast differentiation, M043, S043

Proline/arginine-rich end leucine-rich repeat protein (PRELP)

Matrix inhibits osteoclastogenesis inactivating the NF- κ B signal, W080

Propranolol

Long-term propranolol improves BMC and lean body mass in pediatric burn patients, M487, S487

Prostaglandins

Role of prostaglandins in strontium ranelate effects on osteoblastic differentiation and growth factor production, W333

Prostaglandin D₂ (PGD₂)

In bone formation and remodeling in vivo, T001

Effect of, on Na-dependent phosphate transport activity in osteoblast-like cells, T066

Prostaglandin E₂ (PGE₂)

Activates β -catenin signaling in MLO-Y4 osteocytic and 2T3 osteoblastic cells, W053

Acts through EP2/EP4 receptors to upregulate RGS2 expression in osteoblasts, T063

Demonstration of an anabolic effect on bone in CD-1 mice, M180

Effects of long-term treatment with a PGE₂

receptor subtype 4 agonist and PTH at skeletal sites with moderate osteopenia, M385

Effects on the cAMP/PKA and the β -catenin pathways, protective effects of mechanical strain on osteocyte viability is mediated by, M237

Increases a specific subset of primitive

hematopoietic cells in vivo, M039, S039

Production and Wnt/ β -catenin signaling, greater sensitivity of osteocytes to shear stress as compared to osteoblasts, W052

Production by osteoclasts, nicotine and LPS stimulate the formation of osteoclast-like cells by increasing, T084

Receptor EP4 antagonist attenuates osteolysis due to cancer metastasis, W196

Prostate cancer

Activation of MCP-1/CCR2 axis promotes prostate cancer invasion and the tumor-induced osteoclast activity in vitro, T248

Fracture risk is increased in Danish men with prostate cancer, T256

MTA1 was highly expressed and localized in nucleus in prostate cancer bone metastasis, T253

Non-isomerized C-telopeptides of Type I collagen (ALPHA CTX) for early detection and treatment monitoring of bone metastases secondary to prostate cancer, T245

Osteoblast-prostate cancer cell signaling, T244

PTHrP-induced MCP-1 production by HBME cells and osteoblasts promotes osteoclast differentiation in vitro, T247

PTHrP regulation of AKR1C1-3 and growth in prostate cancer cells, T234

TGF β increases osteolytic prostate cancer bone metastases and expression of pro-metastatic genes, T238

WISP-1/CCN-4, a novel target for inhibiting prostate cancer growth in bone, I174

Wnts increase osteoblast activity in prostate cancer through BMP, T235

Prostate cancer, hormone-refractory (HRPC)

$\alpha_v\beta_3$ integrin inhibitor MK-0429 is generally safe and decreases bone turnover in men with HRPC and MBD, T246

Prosthetic wear

Inhibition of osteoclastogenesis involves suppression of RANK expression, W076

Proteasome

Inhibition induces permanent growth retardation and apoptosis in growth plate chondrocytes, M121, S121

Inhibition on osteoblast differentiation and anagen induction, similar effects of, W111

Protein inhibitor of activated STAT3 (PIAS3)

Modulates osteoclastogenesis by down-regulation of NFATc1 and OSCAR, W066

Negatively regulates RANKL-induced osteoclastogenesis, M089

Protein kinases

Stress activated, TNF α dependent redox signals upregulate Mx2 gene transcription via, T165

Protein kinase A (PKA)

Pathways, protective effects of mechanical strain on osteocyte viability is mediated by the effects of prostaglandin on, M237

Protein kinase C β (PKC β)

Estrogens or androgens attenuate p66^{shc} phosphorylation via a signaling cascade, T185

Protein kinase C delta (PKC δ)

Cx43 amplifies FGF2-responsiveness in a dependent manner, W027

Protein kinase C (PKC)

Activation of MAPKs by 17 β -estradiol is mediated in skeletal muscle cells, T194

Isoform-specific activation in osteoclasts, P2X7 nucleotide receptors couple to, M109

Translocation revealed by live-cell imaging, spatio-temporal patterning of, M109

Protein kinase D

As an essential mediator during osteoblast differentiation, M019

Protein phosphatase 1 (PP1c)

Binding domain (F872A), point mutation of endofin stimulates bone formation, I256

Protein related to DAN and cerberus (PRDC)

Expressed in skeletogenesis and prevents osteoblastic differentiation, W115

Protein synthesis

Regulation in estrogen metabolite-mediated inhibitions of osteosarcoma cells, T254

Protein tyrosine kinase 2 (Pyk2)

ADAM8 binds $\alpha_v\beta_1$ to increase osteoclast formation and function by interacting with, I099

Proton pump inhibitors (PPI)

Chronic PPI use is not associated with an increased risk of osteoporotic fra, M351, S351

Prx1. See also *Homeobox protein; MHox*

Identification of as a regulator of Osx expression and mediator of TNF action, I143

Pseudoarthritis. See also *Arthritis*

Prognostic factor on MRI findings inducing prolonged intractable pain due to pseudoarthrosis following osteoporotic vertebral fracture, W286

Pseudohypoparathyroidism. See also *Hypoparathyroidism*

Hyperparathyroid bone disease in two sisters with pseudohypoparathyroidism 1b, W429

Psychiatric illness

Association between psychiatric illness and falls, T354

PTEN

And osteoblastogenesis, W034

PTH. See *Parathyroid hormone*

PTH/PTHrP receptor (PTHR)

Analysis of interaction mechanisms using a new, long-acting PTH(1-28) analog reveals selective binding to distinct PTH receptor conformations and biological consequences in vivo, I190

PU.1

In osteoclasts, regulation of integrin expression by, M071

Puberty

Decreases in cortical thickness are associated with the pubertal increase in forearm fractures in girls, I193

Effect of plasma 1,25(OH) $_2$ D concentration or Ca intake on negative correlation between plasma 25OH(D) and PTH concentrations in Japanese adolescents, W159

Fat mass is inversely related to subsequent change in bone size and mass in young prepubertal children, M536

Five-year follow-up of bone mineral distribution and bending strength changes across puberty, W512

Is development of ovulatory cycles in adolescence important for peak bone mass?, W511

Optimising bone health in pre-pubertal children, W486

Sex-specific bone surface changes during, pQCT analysis of the mid-tibia, M527

Tempo and timing of bone mineral accrual during the pre-, peri- and post-adolescent growth periods, W509

Weight bearing bones are more sensitive to physical exercise in boys than in girls during pre- and early puberty, W519

Pulmonary disease, chronic obstructive (COPD)

BMD and serum Vitamin D levels in patients with COPD without GC use, M454

Epidemiology of COPD and osteoporosis, W298

Prevalence and risk factors of osteoporosis and vertebral fractures in COPD males, M376

Vertebral fractures in patients with COPD patients, T330

Pulposus cells

Effect of vertebroplasty filler materials on viability and gene expression of mouse and human, M138

Pulse wave velocity (PWV)

Association of PWV and BMD, W293

PYK2

Deletion of PYK2 led to high bone mass through a positive balance between bone formation and resorption, I014

Pyrrolidine dithiocarbamate (PDTC)

Inhibits SOD1 gene and cell growth by activating JNK pathway in U2OS, W018

Q

Quantitative trait loci (QTL)

Candidate genes of every known QTL of BMD in whole mouse genome, M280

On Chr 11 regulates bone shape in SAMP6 mice, W181

Evidence for QTL underlying normal variation in calcaneal QUS measures, W179

For femoral BMD identified in two separate chicken intercrosses are syntenic to loci controlling human BMD, W182

Genome-wide scan for QTL influencing BMD, W174

In HcB/8 and HcB/23 F2 mice, W466

Identification of sex-specific for femoral neck density and strength in inbred COP and DA rats, W171

Identification of sex-specific QTL for femoral neck density and strength in inbred Dark Agouti (DA) rats, W171

Identifying mechanical loading QTL by gene expression changes for alkaline phosphatase and bone sialoprotein, T152

Mapping to Chromosome 2p influences variation in bending resistance of bone, W180

Positional cloning identified ESR2, ESRRB, BMP4 and LTBP2 as the candidate genes for the QTL in Chromosome 14 for BMD variation, W175

Serum alkaline phosphatase QTLs provide evidence that genes on Chromosome 5 and 11 regulate bone formation and affect bone size and strength, T212

R

R176Q. See *Fibroblast growth factor 23*

R325Q

Single nucleotide polymorphism R325Q in the Vitamin K-dependent GGCC gene has effects on the correlation between dietary Vitamin K intake and gamma-carboxylation of serum osteocalcin, T318

Rab3D

Potential role in osteoclastic bone resorption, M103, S103

Recruits the dynein complex to secretory vesicles in osteoclasts through direct interaction with Tctex-1, I293

Rac2

Knockout mice have an augmented anabolic response to PTH, I008

Radiation

- Acute 7 gray dose of gamma-radiation induces a profound and rapid loss of trabecular bone, M464
- Bone microarchitecture of irradiated and bone marrow transplanted mice, M067
- Low-level radiation can enhance trabecular bone quantity and architecture, W276
- Murine bone loss following local irradiation, M145

Radiation, electromagnetic

- Bone density changes with pulsing EM field treatment of the forearm after disuse, T430

Radiation, ionizing

- Increased active osteoclasts are associated with acute cancellous bone loss in adult mice exposed to ionizing radiation and musculoskeletal disuse, M462

Radiation, ultraviolet

- Effects of UV-B light on serum Vitamin D levels, M450
- Personal exposure and Vitamin D synthesis, M261
- Possible direct regulatory role of active Vitamin D increased by ultraviolet B on FGF-23, W126

Radiofrequency ablation

- Minimally invasive treatment of OOM by, W422

Radiographic texture analysis (RTA)

- Clinical utility of RTA performed on densitometric calcaneal images, M331

Radiography

- Texture analysis and geometry measurements on plain radiographic femurs, W231

Raloxifene

- Adherence to raloxifene therapy, W379
- Comparison of serum TRACP type 5b assays and other bone resorption markers for monitoring raloxifene therapy, W209
- Identification of primary target cells for the classical genomic effects of estrogen and, T188

Raman spectroscopy

- Measurement protocols for the noninvasive assessment of bone constituent properties by Raman spectroscopy, T108

RAP-011

- Increases BMD in combination with prior antiresorptive therapy, W312

Rapamycin

- Differentially alters the skeletal response to PTH and mechanical loading, 1245
- Inhibits osteoblast proliferation and differentiation in MC3T3-E1 cells and primary mouse BMSCs, M007

RAR γ

- Repression function, cartilage ECM homeostasis is regulated by, W103

Reactive oxygen species (ROS)

- Estrogens attenuate IL-6 and TNF α production in osteoblastic cells by decreasing oxidative stress and its effects on NF- κ B activation, T186
- Expression in osteoblasts of NOS1, 2 and 3 in knockout mice, M006
- Grx5 regulates osteoblast cell functions by protecting against oxidative stress, M005
- Oxidative stress suppresses osteoblastogenesis by antagonizing Wnt/ β -catenin and BMP signaling, M174
- Regulation of RANKL-induced MAPK activation by, M115

Receptor activator of NF- κ B (RANK)

- Characterization of gene promoter region, molecular cloning and, M095
- Expression, inhibition of osteoclastogenesis by prosthetic wear debris involves suppression of, W076
- IVVY⁵³⁵⁻⁵³⁸ plays an essential role in TNF α - and IL-1-induced osteoclastogenesis, M084, S084
- Signaling in human osteoclasts, effect of p62 mutations, M474
- Signaling through HTS, development of cell-based assays for identifying antiresorptive compounds targeting, M102

Receptor activator of NF- κ B ligand (RANKL).

- See also *Nuclear factor B*
- Acid-induced stimulation of, in osteoblasts mediated by IP₃, M063
- Activating via TLR-2 and TLR-4 activation, rheumatoid synovial fibroblasts promote osteoclastogenic activity by, W435

- Expressing lymphocytes, intracellular cytokine profile of, T164
- Expression and cell proliferation in human osteoblasts and osteoblastic cells, alpha 1 and beta2 adrenergic agents modify, T006
- Gene, targeted deletion of a distant transcriptional enhancer reduces bone remodeling and increases bone mass, 1067
- High D(+)glucose concentration inhibits RANKL-induced osteoclastogenesis, W082
- Increased expression in stimulated T-cells from patients with AS, W446
- Induced expression of TRPV2 is involved in osteoclastogenesis via Ca signaling activation, T103
- Induced MAPK activation by ROS, regulation of, M115
- Induced osteoclastogenesis, Ca and phospholipase C γ 2 signaling regulates, 1104
- Induced osteoclastogenesis, HMGB1 regulates actin cytoskeleton organization in a manner dependent on RAGE, M079
- Induced osteoclastogenesis, PIAS3 negatively regulates, M089
- Induced osteoclastogenesis, Wnt5a enhances, 1149
- Modulation of RANKL gene expression by Runx2 and Vitamin D3, 1219
- mRNA, co-stimulation of 1,25-(OH)₂D₃ and BMP-2 enhances the expression in osteoblasts, W162
- Oxidative stress-induced vascular calcification is associated with increased expression of receptor activator of, 1216

- POZ-Zn transcriptional regulator OCZF/LRF is induced by, W067

- Produced by adipocytes and stimulates osteoclastogenesis, W079

- Regulation of expression by GC in osteoblast-like cells, T068

- Regulation of RANKL expression by GC in human osteoblast-like cells, WG22

- Stimulated dendritic cells on autoimmune arthritis in MRL/*lpr* mice, immunoregulatory role of, T162

- Stimulates osteoclasts to release VEGF-C and enhance osteoclastic bone resorption through an autocrine mechanism, 1100

- Upregulation from CD4⁺T cells, IL-23-enhanced osteoclastogenesis is mediated by STAT3 and NF-B via, T078

Receptor for advanced glycation endproducts (RAGE)

- HMGB1 regulates actin cytoskeleton organization and RANKL-induced osteoclastogenesis in a manner dependent on, M079

Regulator of G-protein signaling 10 (RGS10)

- Osteoclast differentiation, mechanism of RANKL-evoked [Ca²⁺]_i oscillations mediated by, M093, S093

Renin-angiotension system (RAS)

- Ca-independent and 1,25-dihydroxyvitamin D₃-dependent regulation in 25(OH)D 1 α -hydroxylase knockout mice, W150

Replication

- Defective, MSC from aging C57BL/6 exhibit increased oxidative stress and, M052, S052

Replication competent avian virus system (RCAN)

- Using to deliver short hairpin siRNA to silence gene expression of Wdr5 in chicken limb bud during embryogenesis, T141

Retinoblastoma

- Related pocket protein Rbl2 is a candidate gene for a QTL affecting peak bone mass and strength, 1237

Retinoblastoma binding protein 1 (RBP-1)

- A novel factor critical for Runx2 expression and transcriptional activation, W021

Retinoic acid (RA)

- Effect of, on the osteoblastic differentiation of human ASC, T051

Retinoid X receptor α (RXR α)

- Examination of phosphorylation at serine 260 using specific antibodies in cancer cell lines and tumor tissues, M257

Rett's syndrome

- Bone mass determination in girls and mice, WG8
- Bone ultrasonography in the longitudinal monitoring of bone status in patient with Rett's syndrome, T514

RGS2

- Expression in, PGE₂ acts through EP2/EP4 receptors to upregulate, T063

rhBMP-2

- New surface modified DBM by collagen hybrid coating, T133

Rheumatoid arthritis (RA). See Arthritis, rheumatoid**Rhizoma drynaria (RD)**

- Total flavonoid fraction of RD and its active ingredient, naringin, exert bone protective effect in vivo and in vitro, W342

Protein-PTH interactions that determine PTH stability in secondary hyperparathyroidism and hypoparathyroidism, M217, S217
PTH, calcilytics block the suppressive effect of calcimimetics on levels in parathyroid cells, M228
RANKL, co-stimulation of 1,25-(OH)₂D₃ and BMP-2 enhances the expression in osteoblasts, W162
- Ribonucleic acid, short hairpin (shRNA)**
Using RCAN to deliver short hairpin siRNA to silence gene expression of *Wdr5* in chicken limb bud during embryogenesis, T141
- Ribonucleic acid, small interfering (siRNA)**
Noggin gene transfer enhances the in vivo ectopic bone formation induced by BMP-2, W121
Specific knockdown of lamin A/C inhibits osteogenic differentiation of human MSC, M038
Using RCAN to deliver short hairpin siRNA to silence gene expression of *Wdr5* in chicken limb bud during embryogenesis, T141
- Rickets**
Is associated with failure of epiphyseal/metaphyseal bone tether formation, W421
- Rickets, autosomal recessive hypophosphatemic (ARHR)**
Molecular analyses of DMP1 mutants causing, I116
- Rickets, hereditary hypophosphatemic with hypercalciuria, (HHRH)**
Role of *Npt2c*, involved in, I115
- Rickets, X-linked hypophosphatemic (XLH)**
7B2 protein regulates FGF-23 degradation and production in XLH, I225
Dominant XLH, a new mutation of *PHEX* gene, T118
Growth and response to active Vitamin D and P treatment is highly associated with haplotype of the VD promoter in XLR, I195
Three novel mutations of the *Phex* in three Chinese families with XLH, W170
Treatment with calcitriol and phosphate increases FGF-23 concentration, W123
- Risedronate (Ris)**
Cost-effectiveness of Ris versus IBN, W322
Early and sustained non-vertebral fracture efficacy with Ris, M438
Effect of Ris on bone loss associated with liver transplantation, T501
- Effect of Ris on risk of clinical fracture among patients with prior hip fracture, M432, S432
Effects of Ris and raloxifene on serum lipid levels in postmenopausal women, W370
Effects of Ris on bone change at children with OI, T520
Efficacy and tolerability of a once-a-month dosing regimen of Ris for the treatment of postmenopausal osteoporosis, T382
Efficacy for non-vertebral fractures is consistent across age groups, W351
Evaluation of cell apoptosis and COX-2 expression in GC-induced osteoporosis in rats treated with, W318
Patients previously treated with Ris demonstrate greater responsiveness to TPTD than those previously treated with ALN, I091
Patient's satisfaction and compliance for Ris, once-weekly versus once-daily, T401
Patients treated with Ris have a fracture risk similar to patients 20 years younger in age, W317
Persistence with Ris therapy is already high and further improved by a patient educational program, T394
Preserves bone turnover as measured by biochemical markers after 5 years treatment in postmenopausal Greek women, WG19, T402
Prevents bone loss in breast cancer survivors, I017
Reduces osteonal cortical porosity in osteoporotic women, M508, S508
Therapeutic effects of Ris for two years on bone metabolic markers, especially on TRACP-5b, W357
Treatment in type 2 diabetic men with primary osteoporosis, M433
Two-consecutive days-a-month Ris reduces vertebral fracture risk at one year, W373
Vertebral fracture efficacy with Ris is apparent early and is sustained, W374
- RNA interference (RNAi)**
Functional screening for *Runx2*-regulated genes corresponding to ectopic bone formation in human spinal ligaments, M273

Osteoclast, electroneutral sodium/bicarbonate cotransporter *NBCn1* is expressed in, T091
- Runx1**
Analysis of the role in chondrocyte differentiation using chondrocyte-specific *Runx1* deficient mice, M133, S133
Regulates chondrogenic differentiation, I112
- Runx2**
Activity, *Zfp521* is a novel inhibitor of with opposite effects on osteoblasts and bone formation in vitro and in vivo, I250
During BMP2-regulated osteoblastogenesis, *Osx* functions as downstream of, W020
Cx43 amplifies FGF2-responsiveness in a dependent manner, W027
Cytoplasmic interaction of p21 with, during osteogenic differentiation of MSC, T049
- Enhancer elements drives robust expression in transgenic mouse osteoblasts, *hCol1a2* nuclear targeting sequence together with, I288
ERRγ negatively regulates osteoblast differentiation and mineralization through, W015
Expression and activity in osteoblasts, TIEG as a novel mediator of, I144
Expression and transcriptional activation, *RBP1* as a novel factor critical for, W021
Growth inhibition of osteoblast progenitors depends on its C-terminal regulatory domain and is accompanied by changes in G-protein coupled signaling pathways, M047, S047
Haploinsufficient mice, *Nell-1* partially rescues craniofacial defects in, I105
Modulation of RANKL gene expression by *Runx2* and Vitamin D3, I219
Nell-1 partially rescues craniofacial defects in *Runx2* haploinsufficient mice, I105
Novel R131G *RUNX2* mutation causing cleidocranial dysplasia disrupts heterodimerization with core binding factor-β, M022
Over-expression in mesenchymal cells enhanced bone formation but inhibited cartilage formation and limb development, I066
Phosphorylation sites involved in matrix MMP-13 promoter activation, identification and characterization of, W026
Regulated genes corresponding to ectopic bone formation in human spinal ligaments, functional RNAi screening for, M273
Regulation of activity, orphan nuclear receptor *SHP* promotes osteoblast differentiation by, T024
Regulation of at the nuclear lamina, M032
Synergistically activates osteoblast-specific osteocalcin gene expression, M037
Transcription factors, *Osr1* gene expression is regulated by, W030
Transcriptional activity by the phosphorylation at a specific site, *GSK-3β* inhibits osteoblastic bone formation through suppression of, I247
Transcriptional AD3 supports synergistic MINT activation of the osteocalcin FGF response element via a *DMAT*-sensitive kinase, T036
Transcriptional regulation of *COL10* by, M127, S127
Translation, regulation by 5- and 3-UTR binding proteins, M026
Trinucleotide repeat mutations are associated with decreased bone density and altered protein function, I033
Trps1 transcription factor regulates chondrocyte hypertrophy and perichondrial mineralization through repression of, I184
Zfp64 is a downstream target of, and regulates myogenic and osteogenic differentiation as a coactivator of *Notch1*, T035
- RUNX2-II**
Isoform transcription is mediated through the *Ca-PI3K-Akt* pathway, *PC1* selective activation of, I142
Reduction of expression, severe osteopenia in *PERK*-knockout mice is due to impaired osteoblast differentiation associated with, I022
- Rxrb**
Analysis of the function of the CTCF-binding site between *Col11a2* and, T119

S**SABRE Study**

Study of Anastrozole with the Bisphosphonate Ris (SABRE Study), M300, S300

Saos-2

Ubc9 promotes stability of Smad4 and regulates BMP signaling pathway in, T065

Sarcoidosis

Progression of vertebral deformities but no change in BMD in patients with sarcoidosis, W279

Sarcopenia

In ageing men with osteopenia, osteoporosis and normal BMD, W264

SB-423557

Oral treatment with SB-423557 causes PTH release in multiple species and positive bone forming effects in the rat, M386, O386, S386

Sclerosis

Of the principal medial compressive trabeculae in the osteoporotic femur may mask the bone mineral loss of the femoral cortex, T293

Sclerostin (SOST)

Anti-sclerostin antibody increases markers of bone formation in healthy postmenopausal women, I129

Bone enhancer, control of by PTH via MEF2 transcription factors, I046

Inhibition leads to increased periosteal and endocortical bone formation as well as decreased cortical porosity, I232

Mediated inhibition of the LRP5-Wnt-TCF signals in U2OS osteoblast-like cells, mutations in LRP5 β -propeller 1 block, I048

Overexpression impairs limb patterning, M179, O179, S179

Treatment with an anti-sclerostin antibody directly stimulates bone formation in a dose-dependent manner, I231

Treatment with an anti-sclerostin antibody increased bone mass by stimulating bone formation without increasing bone resorption, I122

Scoliosis, adolescent idiopathic (AIS)

Estrogen receptors in, T189

SDF-1

CXCR4 is essential for in vivo endochondral bone repair, T163

Sealing ring

Defects in formation in osteoclasts, disruption of WASP-associated signaling complex formation leads to, M113

Secondary hyperparathyroidism (II-HPT). See Hyperparathyroidism, secondary**Secreted frizzled related proteins (SFRP)**

Differential effects on osteoblastic differentiation of mouse pluripotent mesenchymal cell line, M044

Secreted frizzled related protein 1 (sFRP1)

Absence of accelerates fracture healing, I258
Small molecule inhibitor of the Wnt antagonist SFRP-1 stimulates bone formation, I010

Secreted frizzled related protein 3/4 (sFRP3/4)

GC enhances the expression in cultured osteoblasts, T176
GC enhances the expression of a Wnt antagonist, sFRP3, in cultured human osteoblasts, WG21
Transgenic mice overexpressing have low bone mass but do not exhibit disturbed phosphate homeostasis, M209

In vitro and in vivo effects of sFRP3 overexpressed by Phi 31 integrase strategy, W049

Secretory vesicles

Rab3D recruits the dynein complex through direct interaction with Tctex-1, I293

Selective androgen receptor modulator (SARM)

Bone specific SARMS Increased BMD in a different manner from anti-resorptive agent raloxifene with minimum effects on the uterus, M402

Combination treatment with a bisphosphonate has additive effects in osteopenic female rats, M405, S405

Selective serotonin reuptake inhibitors (SSRI)

SSRI use is associated with increased risk of fracture among older men, I159

Senescence

Cellular, Podn affects cell proliferation and in vitro mineralization by inducing in MC3T3-E1 cell, T142

Serine 260

Examination of RXR phosphorylation using specific antibodies in cancer cell lines and tumor tissues, M257

Serotonin transporter (5-HTT)

Osteoblasts from knockout mice display reduced growth and mineralization capacity, M013

Serum response factor (Srf)

Function in bone and cooperation with NFAT1, analysis of Krox20 gene regulation reveals, M025, S025

Sham-operated rats

Quality and strength of cortical bone are lowered by limiting physical activity, W479

Shear stress. See also Fluid flow shear stress

$\alpha 5$ integrin association with Cx43 regulates the function of osteocyte hemichannels in response to, T504

Greater sensitivity of osteocytes as compared to osteoblasts, PGE₂ production and Wnt/ β -catenin signaling, W052

Short hairpin RNA (shRNA). See Ribonucleic acid, short hairpin**SIBLING**

Degradation of MEPE, DMP1 and release of ASARM-peptides (minhibins), I155

Side population (SP) cells

Co-expressing Stro-1, identification of, T054

Silent information regulator T-1 (SIRT-1)

Aging-associated gene regulates osteoclast formation and bone mass in vivo, I097

Single nucleotide polymorphisms (SNP)

Association of bone mass with SNPs of frizzled genes in Wnt system and circulating OPG, T222

Identification of SNPs contributing to BMD and fractures, M275, S275

Multiplex SNP genotyping and data analysis on 360 Hungarian postmenopausal women, T226

Sirtuins

Effect of caloric restriction on bone is exerted through the stimulation of sirtuins, M048

Skeletal development

Conditional ablation of the osteoblast CaR causes abnormalities in, M223, O223, S223

In vivo, expression of CaR in cartilage is essential for embryonic, I176

Skeletal growth

CAL and its analog successfully elongate survival period and improve via independent pathway of VDR, W157

Genetic variation in post-natal skeletal growth defines functional interactions among adult bone traits and fragility, T204

Skeletal health

Racial differences in skeletal health, W261
Between two different groups of Hispanic American women, T283

Skeletal homeostasis

Regulation by anti-apoptotic molecule Bcl-2, I290

Skeletal load

Attenuated response in Cx43 deficient mice, M518, S518

Skeletal muscle

Activation of MAPKs by 17 β -estradiol is mediated by PKC and c-Src in, T194

Arkadia represses differentiation through enhancement of Myostatin and TGF β signaling, M206

Comparison between gene expression in skeletal muscle and bone of postmenopausal osteoporotic females and their controls, W213
17 β -Estradiol abrogates apoptosis through extra-nuclear estrogen receptors, T196

Specific overexpression PAPP-A increases bone accretion, T080

Skeletal parameters

Age-related distribution of bone and skeletal parameters in 1322 young women, W513

Skeletal phenotype

In transgenic mice over-expressing CTGF in cells of the osteoblast lineage, I287

Skeletal remodeling. See Bone remodeling**Skeletal size**

And fracture risk in a large clinical cohort, I163
Increased, targeted deletion of E11/gp38 results in, I043

Skeletogenesis

ESL-1 negatively regulates TGF β in the Golgi during, M202, S202

Misexpressions of SOX9 lead to accelerated adipogenesis in transgenic mice, I180

Phosphate-independent effects of FGF-23 on, I114

PRDC is expressed in, and prevents osteoblastic differentiation, W115

Skeleton

Under-mineralization, spontaneous mutation in the mouse *Lmna* gene results in, M146, S146

Skin color

Seasonal variations and the impact on Vitamin D status, M263

Slug

Osteoblasts in adult bone use, for regeneration and repair but not remodeling, I213

Smad

ERR γ negatively regulates osteoblast differentiation and mineralization through, W015

Mediated BMP signaling, endogenous CREB signaling enhances, W118

Modulation of the signaling pathway, TIEG suppresses osteoblast cell proliferation through, M035

Proinflammatory control of BMP-driven transcription and osteogenesis, W044

Signaling, new insights into the determination of, by TGF β superfamily, M199

Smad1

Atm regulates osteoblast differentiation through, M017

Differentially regulate osteoblast differentiation and myogenesis in myoblasts, W117

- Protein, miR-26a targets of hADSCs, T028
Required for endochondral bone formation, BMP canonical signaling through, M171, S171
- Smad4**
Differentially regulate osteoblast differentiation and myogenesis in myoblasts, W117
Has a direct apoptogenic role at the mitochondria, M205
Ubc9 promotes stability of, and regulates BMP signaling pathway in osteoblastic Saos-2 cells, T065
- Smad5/6/7/8**
Atm regulates osteoblast differentiation through, M017
Inhibitory Smad6 and Smad7 differently regulate cartilage formation, M130, S130
Required for endochondral bone formation, BMP canonical signaling through, M171, S171
- Small heterodimer partner (SHP)**
Promotes osteoblast differentiation by regulation of Runx2 activity, T024
- Small interfering RNA (siRNA).** See *Ribonucleic acid, small interfering*
- Small leucine-rich proteoglycan (SLRP)**
bgn and fnod control bone mass by regulating osteoclast differentiation through BMSC, M157, O157, S157
- Snail**
Inhibits the differentiation of MSC to osteoblasts, T033
- SNF**
Chromatin remodeling complex, positive and negative regulation of osteoblast differentiation by, M030

Activated, small molecule inducer of cell death inhibits disease progression in CIA models, M499
 IL-23-enhanced osteoclastogenesis is mediated by STAT3 and NF- κ B via upregulation of RANKL from, T078
 Properties, effects of IL-12 related cytokines on osteoclast formation and, T076
 Stimulated from patients with AS, increased expression of RANKL in, W446

T-lymphocytes

Amplify the anabolic action of intermittent PTH treatment by regulating osteoclast formation, 1298

2T3

Osteoblastic cells, FFSS and PE₂ activates β -catenin signaling in, W053

Tartrate-resistant acid phosphatase (TRAP)

Negative regulator of osteoblast differentiation, T004

TCF

Signals in U2OS osteoblast-like cells, mutations in LRP5 β -propeller 1 block SOST-mediated inhibition of, 1048

Tctex-1

Rab3D recruits the dynein complex to secretory vesicles in osteoclasts through direct interaction with, 1293

Tea, green polyphenols (GTP)

Protective role of GTP in bone microarchitecture, W313

Tea, instant

Skeletal fluorosis from instant tea, W425

Tec

Tec tyrosine kinases are essential for osteoclast differentiation, 1289

Teriparatide (TPTD)

Adherence and persistence with TPTD therapy in commercial insurance plans and managed medicare, W380
 Administration following antiresorptive therapy (BBB-Study), M419, S419
 BMD response to TPTD in treatment naïve patients versus patients previously treated with a bisphosphonate, T367
 Bone apposition in patients on TPTD treatment is preferably directed to skeletal regions of local structural weakness, 1267
 Bone turnover markers demonstrate greater earlier responsiveness to TPTD following treatment with Ris compared with ALN, 1092

Changes in 25-hydroxy- and 1,25-dihydroxyvitamin D during treatment with TPTD, M424

In clinical practice, T427

Early adjuvant therapy with TPTD after major orthopaedic surgery of complicated fractures of long bones in postmenopausal women, M422

Effects of 2 year TPTD treatment on 3-D femoral neck bone distribution, geometry and bone strength, 1269

Effects of two years of TPTD treatment on bone strength assessed by HRCT based finite element analysis of human vertebrae in vivo, T368

Efficacy of adding TPTD versus switching to TPTD in postmenopausal women with osteoporosis previously treated with RLX or ALN, M423, O423, S423

Improvement of the persistence with TPTD in postmenopausal osteoporosis, WG36, M441

Improves bone microarchitecture in postmenopausal women previously treated with ALN, 1095

Monitoring BMD during the course of TPTD therapy in a community setting, T375

Persistence with TPTD therapy among participants in the DANCE trial, W384

Rapid and robust biochemical response to TPTD therapy for osteoporosis, T366

Reduces bone microdamage accumulation in postmenopausal women previously treated with ALN, 1093

Skeletal effects of TPTD in GC-treated mice, W311

Speeds fracture healing and initiates healing of non-unions in humans, M242

Treatment following bisphosphonate-resistant osteoporosis, T372

Treatment in osteoporotic patients treated with GC for chronic inflammatory/autoimmune rheumatic diseases, T370

Unusual osteoclast morphology in TPTD, 1096

Testin

As a novel binding partner of the CaR, M225

Testosterone

Cortical bone is positively associated with, and negatively with fibrinogen, M194

Low total and bioavailable testosterone does not play a role in renal bone disease in men on hemodialysis, M491

Presence of symptoms in men with low testosterone levels improves prediction of low BMD, M337

Serum testosterone in elderly men measured by liquid chromatography-tandem mass spectrometry and RIA, T191

Therapy increases vertebral and hip strength via complex changes in bone mass and structure, T476

Tet

Inducible expression systems for bone tissue engineering, in vitro characterization of bidirectional, W108

Tetracyclines

Dox and Mino effectively inhibit osteoclast differentiation and function, M106

TFIIA

Synergistically activates osteoblast-specific osteocalcin gene expression, M037

TG interacting factor (TGIF)

Null mutation in, low bone mass with, 1286

TGF. See *Transforming growth factor*

TGF β inducible early gene-1 (TIEG)

As a novel mediator of Runx2 expression and activity in osteoblasts, 1144

Directly binds to and represses the OPG promoter in osteoblasts, resulting in decreased support of osteoclast differentiation, W028

Increased expression of anti-adhesive PODXL delays osteoclast formation and reduces osteoclast size, M070

Suppresses osteoblast cell proliferation through modulation of the TGF β /Smad signaling pathway and repression of E2F1 gene expression, M035

TGF β receptor interacting protein (TRIP-1)

An important co-regulator of bone formation in skeletal remodeling, 1252

Thalassemia

Evaluation of bone microarchitecture with HR-pQCT in patients with thalassemia, W238

Thiazide

Comparison of the effects of thiazide diuretics and ACE inhibitors on fracture risk, M366, S366

6-Thioguanine

Acts on Gli2 to decrease PTHrP expression and osteolysis, M294

Threonine 137

Is an important determinant of sodium-phosphate co-transport in human NaPi-IIc, 1264

Thyroid hormone

Induced terminal differentiation of growth plate chondrocytes involves IGF-1 modulation of canonical Wnt signaling, M118, S118

Thyroid stimulating hormone (TSH)

Associations of TSH receptor gene polymorphisms with BMD in postmenopausal women, T225

Is both anti-resorptive and anabolic in vivo, 1153

Ti6Al4V alloy

MSC from human adipose tissue and bone marrow, osteogenic differentiation and interaction with, T053

Tibia

Continuous infusion of IGF-1 into the epiphysis of, M188

Sex-specific bone surface changes during adolescent growth, pQCT analysis of, M527

Tibial insertion

After rupture, cell death and cell proliferation of cartilage layer in human ACL, W096

Tissue engineering

Cell cooperation between HOP cells and HUVEC in, M041, S041

Human fetal bone cells for, T041

Use of statins to enhance bone mineralization and formation in 2D and 3D constructs, T003

In vitro characterization of bidirectional Tet-inducible expression systems for, W108

Tissue inhibitor of metalloproteinase 1 (TIMP-1)

Inhibitor of metalloproteinases TIMP-1 rescues the strong bone loss induced by Runx2 overexpression, M162

Titanium (Ti)

Implantation in rat maxillae, bone remodeling after achievement of osseointegration by, T127

Improving bone bonding ability of, by hydrothermal treatment with CaCl₂, W011

Osteoblast response to microtopography is dependent on integrin α -2, W002

TNF. See *Tumor necrosis factor*

TNF-like weak inducer of apoptosis (TWEAK)

As regulator of osteoblast function, M009

TNF-mediated arthritis. See *Arthritis, TNF-mediated***TNF-stimulated gene-6 (TSG-6)**

As a new regulator of bone remodeling, T092

TNF α converting enzyme (TACE)

Up-regulation in monocytes ameliorates their deflected differentiation into osteoclasts and dendritic cells in myeloma, M302

Toll-like receptor (TLR)

Activation, rheumatoid synovial fibroblasts promote osteoclastogenic activity by activating RANKL via, W435

Suppression of innate immunity, intracrine synthesis and action of 1,25-dihydroxyvitamin D rescues, 1028

In vivo activation modulates osteoclastogenesis, M081

Tooth development

Role of TROY in, M176, S176

Tooth roots

Resorption, dentine organic matrix down-regulate osteoclastic activity in, T095

Resorption, mechanical stress-induced, M-CSF receptor c-fms antibody inhibits, M107

Toremifene

Preserves bone architecture and strength in aged ORX rat, M406

Trabecular bone

Age-related changes in vertebral trabecular architecture in female macaques, T459

Androgens act directly via the AR in mineralizing osteoblasts to maintain, 1217

Ex vivo model of stress shielding and osteocyte viability in, W055

Growth, targeted overexpression of PTH2R in chondrocytes impairs cartilage differentiation and, W139

Increased age and a rod-like trabecular architecture are independently associated with accumulation of microdamage in human vertebral trabecular bone, T461

Marked reduction in mass and density, transgenic overexpression of PTP-oc in cells of osteoclastic lineage led to, M112, O112, S112

Mass evaluation as related to cortical mass in the human leg, W237

Microarchitecture assessed by micro-MRI in postmenopausal women with osteoporosis on therapy, W239

Microstructure assessments of the distal radius using a compact MRI, W241

Radiographic analysis of trabecular bone structure and bone geometry in the prediction of hip fracture load, W454

Regional variations in three-dimensional microstructural properties of proximal femoral trabeculae with aging, M503

Structure in men of African heritage, T353

Three-dimensional in vivo trabecular microstructure analysis of spine, calcaneus, and femoral head/neck/trochanter in Japanese postmenopausal women, T465

TRACP5b

New specific immunoassay for intact serum TRACP5b demonstrates increased sensitivity in osteoporosis, M319

Transcription factors

Necessary for chondrocyte hypertrophy, identification of novel, M164

Transcutaneous electrical nerve stimulation (TENS)

In the management of osteoporosis-related pain, WG33, T421

Transferrin receptor 1 (TfR1)

Iron uptake promotes osteoclast differentiation and function, M097

Transforming growth factor β (TGF β)

Calcitriol inhibits BMSC differentiation into osteoblasts in a manner cooperative with but independent of, T069

Drives expression of osteogenic molecules in bone metastatic breast cancer cells, M297

ESL-1 negatively regulates in the Golgi during skeletogenesis, M202, S202

Estrogen suppression of adipogenesis is mediated by, M024

Identification of a novel TGF β dependent-prometastatic signature mediating bone colonization, 1001

Inhibition suppresses myeloma cell growth via enhancement of osteoblast differentiation, T263

Large latent complex produced by hypertrophic chondrocytes, non-covalent interaction of MMP-13 and LTBP1 in, M128

Modulation of the signaling pathway, TIEG suppresses osteoblast cell proliferation through, M035

Signaling, Arkadia represses skeletal muscle differentiation through enhancement of, M206

Signaling, Twist1 stage-specifically regulates chondrocyte differentiation downstream of, M129

Spatial and temporal localization of components of signaling pathways in the postnatal LVGP, M125

Stimulates new bone formation in neonatal calvariae via suppression of DKK1, M197

Superfamily, new insights into the determination of Smads signaling by, M199

Suppresses POEM expression in osteoblasts, M201

Type III receptor regulates BMP signaling in differentiating osteoblasts in vitro and in vivo, W114

Transforming growth factor β 1 (TGF β 1)

Crosstalk with CTGF in MSC condensation, M158

And FGF2 have opposite effects on the mural cell phenotype of CD146⁺ BMSCs, M178

Induces migration of MSCs in coupling bone resorption and formation, 1072

Transgenic mice

DC-STAMP, cell-cell fusion of osteoclasts is stimulated in, 1102

Expression of *OCZF* directed by the CatK promoter affects bone mass and osteoclast formation in, M099, O099, S099

hCol1a2 nuclear targeting sequence together with human Runx2 enhancer elements drives robust expression in, 1288

Transient receptor potential (TRP)

Affects bone remodeling by regulating Ca signaling required for osteoclast activity, 1101

Channels are both present and functional in human osteoblast-like cells, T022

RANKL-induced expression is involved in osteoclastogenesis via Ca signaling activation, T103

Translationally controlled tumor protein (TCTP)

As a nuclear matrix protein in osteoblasts, identification of, M143

TRAP5b

Profiles in children with chronic kidney disease, T492

Traumatized muscle (tmMPC)

Progenitor cells have characteristic similarities to bmMSCs, W039

 β Trep1

Ubiquitin complex regulates Ihh-promoted osteoblast differentiation through Gli2 ubiquitination, T055

Triggering receptor expressed on myeloid cells 2 (TREM2)

Pathway is involved in osteoclastogenesis induced by NRTIs in AIDS, W074

Tripeptides, bioactive. See also *Ile-Pro-Pro; Leu-Lys-Pro; Val-Pro-Pro*

Enhance osteoblast function in vitro, W038

Tropomyosin-2/3 (Tm-2/3)

Regulate the intracellular scaffold of osteoclasts, M074

TROY

Role in tooth development, M176, S176

Trps1

Transcription factor regulates chondrocyte hypertrophy and perichondrial mineralization through repression of Runx2, 1184

TRPV4/6

Osmosensing receptor TRPV4 mediates cancer-induced bone pain, 1002

Role in 1,25(OH)₂D₃- and PTH-stimulated Ca uptake in intestinal epithelial cells, M258

Studies using nullmutant mice reveal active intestinal Ca transport in the absence of calbindin-D_{9k} or TRPV6, 1026

Tumor-induced hypophosphatemic osteomalacia (TIO). See *Osteomalacia, tumor-induced***Tumor invasion**

Chondrostatin as a new inhibitor of, T259

Tumor necrosis factor (TNF)

Identification of Prx1, MHOx, as a regulator of Osx expression and mediator of, 1143

Tumor necrosis factor α (TNF α)

Antagonist in murine bone resorption model, use of nanogels as a drug delivery system for, M101

Anti-TNF α antibody, treatment with recovers osteoclast maturation deviated from bone remodeling cycle in RA joint destruction, W439

CCL3-5/CCR5 cascade mediates RANKL⁺ cells migration in inflammatory bone resorption, M181

Dependent redox signals upregulate Mx2 gene transcription via stress activated protein kinases in arterial myofibroblasts, T165

Endogenous in osteoclast precursor cells promotes osteoclastogenesis via c-Fos and NFATc1 activation, T077

Estrogens attenuate production in osteoblastic cells by decreasing oxidative stress and its effects on NF- κ B activation, T186

Induced osteoclastogenesis, IVVY⁵³⁵⁻⁵³⁸ plays an essential role in, M084, S084

Induced osteoclastogenesis through precursor cell cycle regulation, NF- κ B2 limits, 1148

Novel responsive C/EBP site regulates cartilage *Cd-rap* expression, M132

Production coupled with HMGs are essential for osteoclastogenesis, T071

Role of cell death and osteogenic activity in injury-induced calcification from, W091
 Shedding enzyme, identification in macrophages, M186
 Stimulated *Msx2* expression in C2C12 cells, M020
 Upregulates aortic BMP2-*Msx2*-Wnt signaling in diabetic LDLR-/- mice, M185, O185, S185

Tumor necrosis factor receptor 1/2 (TNFR1/2)

Differentially regulate inflammatory bone resorption induced by LPS in vivo, M110, S110

Tumoral calcinosis. See *Calcinosis, tumoral*

Tumorigenesis

Mediation of musculoskeletal tumor cells by an IFI16 protein, T265

Turmeric

Extracts for postmenopausal osteoporosis treatment, W349

TWIST

Interactions with NF- κ B, human breast stem cell transformation and invasiveness is mediated upregulation of IL-8 by, T242

Twist1

Stage-specifically regulates chondrocyte differentiation downstream of TGF β and Wnt signaling, M129

Txnip

Deficient HcB/19 mice have decreased BMD and femoral strength, W465

Tyrosine kinases. See also *Protein tyrosine kinase*

Tec, essential for osteoclast differentiation, 1289

U

U2OS. See also Human osteosarcoma cells

Mutations in LRP5 β -propeller 1 block SOST-mediated inhibition of the LRP5-Wnt-TCF signals in, 1048

Ubc9

Promotes stability of Smad4 and regulates BMP signaling pathway in osteoblastic Saos-2 cells, T065

Ubiquitin

β Trcp1 complex regulates *Ihh*-promoted osteoblast differentiation through Gli2 ubiquitination, T055

UDP glucuronosyltransferase (UGT) 2B7

H²⁶⁸Y polymorphism is associated with serum sex steroid levels and cortical bone size in young adult men, T199

Ultrasound

Bone age measurements by ultrasound are equivalent to radiological assessments, T518
 Induces HIF-1 activation and iNOS expression through integrin/ILK/Akt pathway, T511
 New through-transmission approach for ultrasonic assessment of the radius, T301
 Respiratory function is associated with bone ultrasound measures and hip fracture, M360, O360, S360

Ultrasound, broadband attenuation (BUA)

Calcaneal BUA and risk factors for osteoporotic fractures in postmenopausal South Asian and Caucasian women, T302
 Improved accuracy of BUA measurement using phase insensitive detection, T305

Ultrasound, quantitative (QUS)

Canadian normative data for sunlight omniscense QUS, T303
 Newly developed QUS scanner for the proximal femur, T297

Precision study of QUS and DXA in Korean women, T306

Predicts incident vertebral and hip fractures at least as strongly as DXA, 1075

Ultraviolet radiation. See *Radiation, ultraviolet*

Uremic bone disease

Novel central mechanism in uremic bone disease, 1263

3/5-UTR

Binding proteins, regulation of RUNX2 translation by, M026

V

Vacuolar H⁺-ATPase (V-ATPase)

Actin binding activity in the B subunit is required for sorting, M092

CK-B involves the bone resorptive activity of osteoclast activity by regulating, M083

Cytoplasmic terminus of accessory subunit Ac45 is required for proper interaction with V0 domain subunits and efficient osteoclastic bone resorption, M104

Diphyllin abrogates acidification of the osteoclastic resorption lacunae and bone resorption, T093

Domain subunits and efficient osteoclastic bone resorption, cCytoplasmic terminus of a V-ATPase accessory subunit Ac45 is required for proper interaction with, M104

Val.Pro-Pro (VPP)

Enhance osteoblast function in vitro, W038

Vascular calcification. See *Calcification, vascular*

Vascular endothelial growth factor (VEGF)

Effects of BHH9 on expression and their receptors during osteoblast differentiation, W042

Vascularization

Perl modulates FGF and VEGF signaling and is essential in the development of the cartilage growth plate, 1064

Vasculogenesis

Acceleration of fracture healing via enhanced, through SCF/cKit pathway, T013

Veganism

Bone health of vegans, T300

VEGF

RANKL stimulates osteoclasts to release and enhance osteoclastic bone resorption through an autocrine mechanism, 1100

Signaling, Perl modulates and is essential for vascularization in the development of the cartilage growth plate, 1064

Vertebral fractures

Assessment of vertebral fracture threshold and ALN therapeutic effects by a QCT-based nonlinear FEM in postmenopausal women, W453

Clinical risk factors for incident vertebral fractures, 1077

Detection of prevalent vertebral fractures using a combination of physical examination maneuvers, W285

Health-related quality of life 7 years after hip or vertebral fractures, W391

Identifying clinical vertebral fractures using administrative claims data, M354

Impact of incident vertebral fractures on health-related quality of life in postmenopausal women, M359

Improving trunk strength and endurance in older women with vertebral fractures, WG27, W398

Long-term risk factors for incident vertebral fractures in healthy older women after 15 years of follow-up, 1271

Low levels of 25-hydroxyvitamin D associated with moderate/severe vertebral fractures, T326

Morphometric vertebral fracture status and WHO predictors of fracture risk, M371, S371

No ethnic differences in vertebral fractures were found between Caucasians, Mestizos and other ethnic background in the Latin-American Vertebral Osteoporosis Study (LAVOS), M380

Physical impact of morphometric vertebral fractures in me, W289

Prevalence of asymptomatic vertebral fractures in postmenopausal women with osteoporosis in Buenos Aires, T327

Proportion of clinical vertebral and nonvertebral fractures among women in a managed care population, T408

Significant reduction of vertebral fractures, ROPE versus No-ROPE, with or without pharmacotherapy, WG25

Vertebral compression fractures in patients with poor bone quality, T419

Vertebral fracture lines are not smooth, but mixtures of multiple Schmorl's nodes and endplate perforations, M353, S353

Vertebral shape

Automated assessment of vertebral shape by statistical shape modelling on lateral radiographs, W227

MRI-based measurement of vertebral shape in Japanese women, T292

Vertebral stenosis

Life quality in patients with surgically treated vertebral stenosis and the relation with bone quality, W396

Vertebroplasty

Effect of filler materials on viability and gene expression of mouse and human nucleus pulposus cells, M138

Vesicular glutamate transporter (VGLUT)

Knockout mice develop osteopenia due to an increase in osteoclastic bone resorption, T085

Vimentin

Negatively regulates osteoblast differentiation by inhibiting the transactivation activity of Atf4, T027

Vinculin

Involvement in chondrogenic differentiation in ATDC5 cells, gene-trap mutagenesis revealed, M137

Vitamin A

Deficiency delays healing process after cortical bone and bone marrow injury, W004
 Physical closure from chronic Vitamin A intoxication, W430

Vitamin D

Absence of toxicity despite high dietary Vitamin D and Ca intake in non-human primates, T358
 Active, possible direct regulatory role increased by ultraviolet B on FGF-23, W126

Association of Vitamin D status with BMD considering seasonal changes of Vitamin D, M322

Automated measurement of 1,25(OH)₂D on the LIAISON[®] Analyzer, W211

Barrier site metabolism of, 1029

CaSR dampens the calcemic response to exogenous 1,25-(OH)₂ Vitamin D in vivo independent of PTH, M224

Combination with BADGE potentiates their pharmacological inhibition of PPAR γ and increases osteogenic differentiation of adipocyte precursors, W155

Deficiency, a common occurrence in both high and low energy fractures, W468

Deficiency in a central Italian town normal population (MIMOSA-G project), M236

Deficiency in oncologic patients, W197

Deficiency, low BMD, and acculturation in Hispanic men, M338

Deficient phenotype of 1 α -hydroxylase gene knockout mice by transplantation of wild-type NA-BM-MSC, partial rescue of, T058

Effects of UV-B light on serum levels, M450

Establishment of vascular calcification model using high dose of, T431

Evidence for plain Vitamin D and active D-hormone analogs for prevention of falls and fractures, T442

Global Vitamin D levels in relation to age, gender, ethnicity, and latitude, W160

Heritability of serum 25-hydroxyvitamin D suggests genetic factors contribute to endogenous Vitamin D production, W184

Inadequacy, bone mineralization and, 1300

Incidence of osteoporotic fractures and Vitamin D status in hip-fracture patients, T350

Insufficiency in the adult, low-energy fracture population, T443

Insufficiency is associated with lower bone density in African-American men, M370

Measurement of 25OH Vitamin D₂ by the LIAISON[®] 25 OH Vitamin D TOTAL assay, W216

Nothing works without Ca and, T393

Patient and physician attitudes toward Vitamin D in osteoporosis treatment, WG34, T447

Postnatal Vitamin D supplementation normalized neonatal bone and lean mass following maternal dietary Vitamin D deficiency, W428

Postpartum insufficiency and secondary hyperparathyroidism in healthy Danish women, W151

Prevalence of Vitamin D and Ca supplementation following low impact hip fracture, T440

Prevalence of Vitamin D deficiency in women age 45 and older in a small Michigan community and the effect of Vitamin D supplementation on myalgia, T441

Prevalence of Vitamin D insufficiency in patients with breast cancer, M292

Severe depletion in Arab-American women living in Dearborn, MI, USA, W423

Skeletal and Vitamin D status in two indigenous North American populations, W246

Status and bone health in adolescents, W269

Status and infection frequency in diabetic patients, W153

Status, bone mass, and bone metabolism in postmenopausal Japanese women, T439

Status in postmenopausal Japanese-American women living in Hawaii, T315

Status/insufficiency may predict physical performance in a group of osteopenic/osteoporotic women, T271

Status of apparently healthy schoolgirls from two different socioeconomic strata in Delhi, T521

Status, seasonal skin color variations and the impact on, M263

Supplementation and 25OHD levels in long-term care residents, M413

Synthesis, personal ultraviolet exposure and, M261

Vitamin D binding protein (DBP)
Internalization by monocytes, M253, S253

Vitamin D receptor (VDR)
CAL and its analog successfully elongate survival period and improve the skeletal growth via independent pathway of, W157

Changes in coregulator recruitment result in 1,25(OH)₂D₃ hypersensitivity in MVNP expressing cells, W152

Co-stimulation of 1,25-(OH)₂D₃ and BMP-2 enhances the expression in osteoblasts, W162

Deficiency aggravates TNF-mediated arthritis, W443

Expression in multiple tissues in adult and developing *Danio rerio* (zebrafish), M254

Gene polymorphisms modulate the musculo-skeletal response to Vitamin D supplementation in healthy girls, 1194

HH signaling and epidermal carcinogenesis, W158

Histone H3 lysine 9 methyltransferase is a transcriptional coactivator for, 1027

Identification of osteoblast-specific co-regulator complex for, W022

Lack of major survival benefit of VDR gene polymorphisms, M283

Molecular analysis of two novel mutations in the corepressor *hr* and expression of rHr in *E. coli*, M259, S259

Novel nutritionally-derived ligand with implications for colon cancer chemoprevention and bone health, M255, S255

Nuclear interactions are ligand independent, W148

Overexpression of human VDR in the intestine rescues the hypocalcaemia-related phenotype of VDR knockout mice, 1025

Targeted inactivation by caspase-3, M265, S265

Transgenic expression in the proximal small intestine of VDR-null mice improves the utilization of Ca- and lactose-rich (rescue) diet in young mice, W154

Vitamin D₂. See *Ergocalciferol*

Vitamin D₃. See *Cholecalciferol*

Vitamin E

High dose Vitamin E prevents the formation atherosclerotic lesions but does not reverse loss of bone due to orchidectomy, T410

Vitamin K

Supplementation in postmenopausal women with osteopenia, M399, S399

Vitamin K₁. See *Phylloquinone*

Vitamin K₂. See *Menaquinone-4*

Vitamin K₃. See *Menadione*

W

Walcott-Rallison Syndrome. See *PERK*

Wdr5

In chicken limb bud during embryogenesis, using RCAN to deliver short hairpin siRNA to silence gene expression of, T141

Essential for osteoblast differentiation, W032

Weight gain/loss

Influence of prior and current weight change on forearm bone loss in menopausal women, T338

Postmenopausal osteoporosis and, W386

Wiscott-Aldrich Syndrome protein (WASP)

Disruption of signaling complex formation leads to defects in sealing ring formation and bone resorption in osteoclasts, M113

Wnt

Absence of sFRP1 accelerates fracture healing, 1258

Activation of the non-canonical pathway during hMSC osteogenesis, T048

BMP signaling in osteoblasts negatively regulates canonical signaling to reduce bone mass during embryonic bone development, M270, S270

Canonical signaling, thyroid hormone-induced terminal differentiation of growth plate chondrocytes involves IGF-1 modulation of, M118, S118

ENC1 is expressed in chondrocytic and osteoblastic cells, T056

GC enhances the expression of sFRP3 in cultured osteoblasts, T176

GC stimulate expression in mature osteoblasts, T062

Identification of a novel β -catenin response element in the OPG gene promoter and its regulation with BMP-2 signaling, M031, S031

Inhibition of signaling by Osx, 1249

Lineage dependent non-canonical signal transduction by bone cells, evidence for, 1139

mTOR signaling, a novel molecular mechanism underlying anabolic effects on osteogenesis, 1108

Signaling, greater sensitivity of osteocytes to shear stress as compared to osteoblasts, W052

Signaling in osteoblastic cells, osteoclasts secrete an activity promoting bone formation and canonical, T005

Signaling is compromised in ER-/- mouse tibia, mechanical loading induced, M036, S036

Signaling on Krox20 and mineral deposition in osteoblast cultures, opposing effects of, T026

Signaling, oxidative stress suppresses osteoblastogenesis by antagonizing, M174

Signaling, Twist1 stage-specifically regulates chondrocyte differentiation downstream of, M129

Signals in U2OS osteoblast-like cells, mutations in LRP5 β -propeller 1 block SOST-mediated inhibition of, 1048

Wnt inhibitory factor 1 (WIF-1)

Differential effects on osteoblastic differentiation of mouse pluripotent mesenchymal cell line, M044

Wnt3A

Induced signaling through dual-specificity phosphatases, modulation of, T042

Signaling, role in maturation of osteoblasts, T166

Wnt5A

Enhances RANKL-induced osteoclastogenesis, 1149

Signals through Ror2 to promote osteoblastogenesis, M045, S045

Women's Health Initiative (WHI)

Associations between body composition and hip geometry in postmenopausal women in the WHI, M377, S377

Comparisons of load normalized section modulus among women with and without fracture history in the WHI, M348

Ethnic variations in hip geometry among women at baseline from the WHI, 1052

Wrch1

Role in cell adhesion and osteolysis, Rho GTPase signaling pathways in osteoclasts, M073, S073

Wrist fracture

Functional decline after incident wrist fracture, 1273

X

X-linked hypophosphatemic rickets (XLH). See *Rickets*

X-ray absorptiometry, dual (DXA)

Association between DXA-assessed muscle-bone proportionality and fractures in pre- and postmenopausal women, W234

Body composition measurements with lunar iDXA, T281

Comparison of femur structure measurements derived from DXA and QCT, W232

Comparison of iDXA measurements of mid-body fat mass and tape-measured circumferences in overweight women, W273

Correcting DXA pediatric BMD measurements to account for fat inhomogeneity, W514

Poor bone growth in children with CP is underestimated by dual-energy x-ray absorptiometry, T517

Ultrasound and dual-energy x-ray absorptiometry comparisons at the distal radius, T299

Use of DXA-based structural engineering models of the proximal femur to predict hip fracture, M332, S332

Utility of lumbar spine DXA scanning in women undergoing asymptomatic osteoporosis screening, M323, S323

In vivo and in vitro comparison of DXA scanners, T272

X-ray absorptiometry, volumetric dual (VXA)

Hip geometry and density parameters derived from VXA correlate strongly with 3D QCT, W224

XLs

Ability to mimic Gsln mediating PTH signaling in vivo, M218

XXY mice

Have an osteoporotic phenotype, 1018

Y**Young's modulus**

Variation of the Young's modulus of single trabeculae in a sheep femur, W469

Z**ZETOS system**

Calibration of the ZETOS bone loading system, T509

Zfp521

Novel inhibitor of Runx2 activity with opposite effects on osteoblasts and bone formation in vitro and in vivo, 1250

Zinc finger protein 64 (Zfp64)

As a downstream target of Runx2 and regulates myogenic and osteogenic differentiation as a coactivator of Notch1, T035

Zinc finger protein 521 (Zfp521)

Regulates chondrocyte differentiation downstream of PTHrP, 1069

Zinc (Zn)

Differential accumulation in the tidemark of normal and osteoarthritic human articular cartilage and subchondral bone, W271

Zoledronate

Effects of intravenous zoledronate on bone turnover and BMD persist for at least 24 months, T376

Zoledronic acid (ZOL)

Effects of ZOL once-yearly on bone remodeling and structure in osteoporotic women are consistent across age, M434, S434

Efficacy and safety of ZOL in preventing fractures in men and women with prevalent hip fracture, 1055

Reduction of bone turnover markers with annual infusion of ZOL in postmenopausal osteoporosis, T385

Risk factors for serious adverse events of atrial fibrillation in the HORIZON-PFT trial of ZOL, 1056

In vitro effects of ZOL alone or in combination with radiation therapy on cells of the metastatic bone environment, M304
