can activate the β -catenin signaling pathway in addition to the classical cAMP/PKA pathway, LiCl (10 mM) was tested and found to protect against Dex induced cell death equivalent to FFSS and PGE₂. FFSS, PGE₂, and LiCl increased phosphorylation of both GSK-3 α and β . Wortmannin (1 μ M), a PI3K inhibitor, but not H89, reduced the phosphorylation of GSK-3. FFSS, PGE₂, and LiCl induced nuclear translocation of β -catenin. These studies provide evidence that osteocyte production of PGE₂ in response to mechanical shear stress is protective against GC induced osteocyte cell death, not only through the classical cAMP/PKA pathway, but also the PI3K/GSK-3/ β -catenin pathway. It will be important to determine if increased mechanical loading alone or in combination with therapeutics will reduce or prevent the detrimental effects of GC on osteocyte viability and bone integrity.

PTHrP Regulates Antimicrobial Peptide Production by Skin Keratinocytes. L. J. Defetos¹, D. W. Burton¹, J. Schaubert^{*2}, S. Tu^{*1}, R. A. Dorschner^{*2}, R. L. Gallo^{*2}. ¹Medicine, Veterans Administration San Diego Healthcare System and University of California, San Diego, CA, USA, ²Dermatology, Veterans Administration San Diego Healthcare System and University of California, San Diego, CA, USA.

PTHrP is expressed in normal skin keratinocytes at relatively high levels, but its function in this tissue is not well studied. Reports have demonstrated that PTHrP expression is increased in skin inflammation and that PTHrP contributes to the progression of other inflammatory diseases, such as rheumatoid and osteoarthritis. In this study, we investigated the interaction of PTHrP with antimicrobial peptides made by keratinocytes. We altered the amount of PTHrP that was expressed by an immortalized keratinocyte cell line (HaCaT) using transfection to increase expression and siRNA techniques to inhibit it. Real-time PCR was used to measure the levels of cellular antimicrobial peptides, including cathelicidin and α - and β -defensins. PTHrP 1-139, 1-141, and 1-173 transfection into HaCaT cells stimulated cathelicidin mRNA expression. While all three isoforms had a stimulatory effect, it was greatest for PTHrP 1-173 (150%), least for PTHrP 1-139 (50%), and intermediate for PTHrP 1-141 (80%), compared to vector control cells. Deletion of the 1-32 domain in the PTHrP expression plasmids prevented the increase in cathelicidin. No PTHrP effects were observed on α - or β -defensin mRNA expression. Inhibition studies using siRNA duplexes targeted to PTHrP 16-22, included in all three isoforms, demonstrated an 89% and 65% decrease in PTHrP and cathelicidin expression, respectively, compared to control (non-silencing) siRNA duplex targeted to a non-mammalian protein from *Thermotoga maritima*. Our results demonstrate that PTHrP regulates the expression of cathelicidin in keratinocytes and that both the 1-32 and 140-173 amino acids of PTHrP are required for the maximal stimulatory effect on cathelicidin expression. These data illustrate the contribution of keratinocyte-derived PTHrP to the immune defense of skin. The known interactions of vitamin D with PTHrP posit a novel regulatory network also involving toll receptors for the innate immune pathway in skin and perhaps other tissues.

Sex Effects on PTHR1 in Non-Small Cell Lung Carcinoma. R. H. Hastings^{*}, A. Ko^{*}, R. Quintana^{*}, Y. Rascon^{*}. VA San Diego Healthcare System, San Diego, CA, USA.

Parathyroid hormone-related protein (PTHrP) is associated with increased survival in women with non-small cell lung carcinoma but not in men (Hastings et al. Clin Cancer Res 2006; 12:499-506). The sex dependence could arise from hormonal mechanisms, since lung carcinomas express receptors for gonadal steroids and estrogen is known to upregulate the type 1 PTH receptor (PTHrP1). This project tested the effects of estrogen on PTHR1 expression in orthotopic A549 lung adenocarcinomas model in female athymic mice. A549 cells express PTHrP, PTHR1 and estrogen receptor beta. Experimental animals received a subcutaneous estradiol pellet (0.72 mg/60 d to increase serum estradiol levels from control levels of <40 pmol/L, a known anomaly in athymic mice, to over 300 pmol. Immunoblots demonstrated significantly increased PTHR1 protein levels in estradiol-treated lung (Figure 1, $P < 0.01$) at 4 wks after tumor implantation. Estrogen also increased levels in lung carcinomas compared to controls, but the differences were not significant. At this point, our working hypothesis points to pulmonary endothelial cells as the site of estradiol action in lung. PTHrP 1-34 is known to stimulate endothelial cell apoptosis and to decrease tumor angiogenesis (Bakre, Nature Med 2002; 8:995-1003). Thus, the model in Figure 2 could explain the sex-selective association between lung carcinoma PTHrP expression and prolonged survival in female patients. Tumor-derived PTHrP would act on endothelial cells to inhibit angiogenesis, as a result slowing tumor growth and leading to longer survival. The effect would manifest predominantly in females because of estrogen-dependent increases in endothelial PTHR1. Studies are underway to test these hypotheses.

Teriparatide [rhPTH(1-34)] Speeds Fracture Healing and Initiates Healing of Non-unions in Humans. E. N. Schwartz, D. M. Steinberg^{*}. Northern California Institute for Bone Health, Inc., Oakland, CA, USA.

Teriparatide (TPTD) stimulates osteoblast function. Osteoblast function is a key to fracture healing. Numerous studies have shown increased fracture healing with TPTD in a variety of experimental models. In these studies, intermittent low dose TPTD increased callus formation, increased production of bone matrix proteins and increased other potential mechanisms of fracture healing.

There is anecdotal information that TPTD may enhance fracture healing in humans. Accordingly, a variety of acute traumatic fractures (n = 20) of multiple body sites including a stress fracture of the femoral shaft, a fracture of a metacarpal, a fracture of the ankle and a fracture of the thumb all healed within a window of 3-5 weeks when healing of each fracture was estimated to take 6-8 weeks. Fracture healing was assessed by x-ray and CT scanning.

Additionally, these same mechanisms of enhanced fracture healing might also be useful in cases of fracture non-union. Accordingly, a variety of patients with different sites and lengths of time of non-union (n = 10) were treated by intermittent low dose TPTD. These included sites such as navicular bone in the ankle (2 fractures), the ischium, the distal tibial shaft, and other sites. About 50% of the non-unions had been previously operated on (ORIF). About 50% of the treated TPTD non-unions went on to partial or complete fracture healing based on x-ray, CT scanning or operative findings.

The risk factors for healing and non-healing of non-unions are not completely understood at this time.

The cases discussed indicate a possible role for TPTD in acute and stress fracture healing and a possible role in healing of certain fracture non-unions in humans.

The Effect of Estrogens on Bone Marrow Adipogenesis: A New Role for Sirtuins in Age-Related Bone Loss. A. Elbaz¹, D. Rivas¹, G. Duque². ¹Lady Davis Institute for Medical Research, Montreal, PQ, Canada, ²Medicine/Geriatrics, McGill University, Montreal, PQ, Canada.

Estrogens (E₂) are known to increase bone mass through the regulation of osteoclastic activity. In the case of age-related bone loss, the role of E₂ remains unclear since the predominant feature of this type of bone loss is not a higher level of osteoclastic activity but the infiltration of bone marrow by fat. In this study, we investigated whether E₂ have an effect on bone marrow adipogenesis and if this potential effect is exerted through the regulation of Sirt1 a recently reported suppressor of PPAR γ 2 in visceral and subcutaneous fat. We hypothesize that E₂ have an inhibitory effect on bone marrow adipogenesis through the induction of Sirt1 expression. To examine this hypothesis, young (5 month) and aged (24 month) female C57Bl/6J mice (n=10 per group) were either gonadally-intact, ovariectomized (OVX) or OVX and E₂ (estradiol-3,17- β -diol Steroids Inc., Witten, NH, USA) treated (OVX/E₂) to produce mean circulating levels of E₂ of 12 to 18 ng/ml. After three weeks of treatment, mice were sacrificed and both side tibia and femur dissected and fixed. Hematoxylin/Eosin (H/E), Toluidine Blue and oil red-O stainings were performed. Additionally, expression of Sirt1 was determined by immunofluorescence. Post-mortem uterus weight was taken as an index of the effect of estrogen deprivation (OVX) or supplementation (E₂ treatment) and was significantly reduced ($P < 0.05$) in OVX group (44 ± 1 mg, mean \pm s.e.m) compared to intact (76 ± 2 mg) or OVX/E₂ mice (64 ± 3 mg). We found significant differences in fat volume between old OVX and old OVX/E₂ with a significant reduction seen in the treated mice ($p < 0.001$). In contrast, no differences were found between the young groups. Additionally, we found that the reduction in bone marrow fat volume in OVX/E₂ mice correlated with high levels of Sirt1 expression and with reduced levels of PPAR γ 2 ($p < 0.01$) within the bone marrow. In summary, we have assessed the effect of estrogen on bone marrow adipogenesis in a model of young and old OVX mice. We have found that estrogens only inhibited bone marrow fat infiltration in old mice and that this effect is associated with higher levels of Sirt1 expression. This is an initial step in the understanding of the effect of estrogens on bone marrow adipogenesis through the activation of Sirtuins.

Genetic Determinants of Serum Levels of Free Estradiol and Free Testosterone in Young Adult Swedish Men - The GOOD Study. A. Eriksson¹, M. Lorentzon¹, S. Nilsson², L. Vandenput¹, F. Labrie³, C. Ohlsson¹. ¹Center for Bone Research at the Sahlgrenska Academy, Göteborg University, Göteborg, Sweden, ²Division of Mathematical Statistics, Chalmers University of Technology, Göteborg, Sweden, ³Laboratory of Molecular Endocrinology and Oncology, Laval University, Quebec, PQ, Canada.

Sex hormones are important for skeletal growth and maintenance. Genetic factors are important regulators of serum sex hormone levels. However, the magnitude of contribution to this regulation from individual genes is not well known. The aim of this study was to investigate which sex hormone-related genes are the most important ones for regulation of calculated free serum estradiol (E2) and testosterone (T) levels, as a result of genetic variations, in young adult men. We used the Gothenburg Osteoporosis and Obesity Determinants (GOOD) study, a population-based study consisting of 1068 young men, age 18.9 ± 0.6 yrs (mean \pm SD). E2 and T in serum were analyzed using gas chromatography/mass spectrometry (GC-MS). Serum SHBG levels were measured using IRMA. Free E2 (FE2) and free T (FT) were calculated using a method described by Vermeulen et al (1), taking the concentrations of T, E2 and SHBG into account, and assuming an albumin concentration of 43 g/l. Genomic DNA was extracted from whole blood. We selected 51 candidate genes coding for hypothalamic and pituitary hormones regulating sex steroid secretion, enzymes involved in synthesis, metabolism or conversion of sex steroids, sex steroid receptors and carrier proteins. Single nucleotide polymorphisms (SNPs) with a minor allele frequency $\geq 5\%$ were selected from HapMapData Rel 21a/phaseII using a pairwise correlation method ($r^2 \geq 0.80$) including 10 kb upstream and 5 kb downstream of each gene. Genotyping was performed on the Illumina Bead Station Platform and was successful in $\geq 95\%$ of the study subjects in 626 of 765 selected SNPs ($\sim 81.8\%$). For FE2 the most strongly correlated SNP was found in CYP19. For FT the corresponding SNP was found in the FSHR (follicle stimulating hormone receptor) gene. An SNP in LHCG (luteinizing hormone/choriogonadotropin receptor) was the second most strongly correlated SNP for both FE2 and FT2. For each of these genes linear regression with all genotyped SNPs included were performed. Backward elimination was used to build the best models. For FE2 the best models of SNPs in CYP19 and LHCG explained 2.7 % and 2.9 % respectively of variation in serum levels ($p < 0.001$). For FT SNPs in FSHR and LHCG explained 4.0 % and 2.7 % respectively ($p < 0.001$). In conclusion, genetic variations in CYP19 and FSHR are important determinants of FE2 and FT respectively, in young Swedish men. Genetic variations in LHCG are important determinants of both FE2 and FT.

Equol Producers After Soy Challenge Is Related to High Bone Turnover in Premenopausal Women. H. Kwak^{*1}, M. Kim^{*2}, C. Hwang^{*1}, S. Lee^{*1}, M. Jung^{*1}, Y. Kang^{*1}, C. Yim^{*1}, S. Park^{*1}, H. Yoon¹, K. Han^{*1}. ¹Laboratory of Endocrinology, Cheil Hospital and Women's Healthcare Center, Kwandong University College of Medicine, Seoul, Republic of Korea, ²Department of Internal Medicine, Marynoll General Hospital, Inje University School of Medicine, Busan, Republic of Korea.

Soybean isoflavones, the main phyto-estrogen, have been known to be able to modulate the action of endogenous estrogens and metabolism of phyto-estrogens might be affected by the menstrual cycles in premenopausal women. There have been few studies about metabolism of soy isoflavones and metabolites activity on bone in premenopausal women, therefore, we investigated the effect of isoflavones on bone turnover markers after challenge of soy isoflavones in premenopausal women. Premenopausal women were randomly assigned to receive either a 120mg soy extract-containing capsule (isoflavone group) or a lactose-containing capsule as placebo once a day for 3 menstrual cycles. Food records, blood samples, and 24hr urine collections were obtained from each subject at the beginning and end of the study. The isoflavone group showed increased concentrations of urinary isoflavone metabolites (equol, diadzein, genistein and dihydrodaidzein) after administration of soy extract-containing capsules compared to the placebo group. A bone formation marker, serum osteocalcin (OC) was increased after treatment in the isoflavone group compared to the placebo group, but the change of a bone resorption marker, urine deoxypyridinoline (DPD) after treatment was not different between two groups. As urinary isoflavone metabolites showed large inter-individual variation, we performed subgroup analyses according to previous studies. Equol is one of the isoflavone metabolites known to have high activity as diadzein or genistein, so that we divided the isoflavone group into the non-equol producer group (< 1000 nmol/l of urinary equol) and the equol producer group (> 1000 nmol/l of urinary equol). Serum OC was significantly increased after treatment in the equol producer group compared to the placebo and non-equol producer groups. And levels of urine DPD didn't change after soy challenge in the equol producer group, however, decreased in the placebo and non-equol producer groups. In conclusion, these data suggested that some premenopausal women who have ability to produce high amount of equol from soy isoflavones would result in relatively enhanced bone turnover rate after soy isoflavone intake and high-dose equol might have anti-estrogenic effects on bone metabolism in premenopausal women.

Activation of Farnesoid X Receptor in Breast Cancer Cell Lines by Bone-Derived Lipid. F. Journe¹, C. Chaboteaux^{*1}, V. Durbecq^{*1}, D. Larsimon^{*1}, G. Laurent^{*2}, J. J. Body¹. ¹Institut Bordet, Brussels, Belgium, ²Université de Mons-Hainaut, Mons, Belgium.

The skeleton is the most common site for metastasis of breast cancer. Cancer cells enhance the destruction of the bone matrix and increase the release of many growth factors and cytokines that stimulate metastatic cells proliferation. This vicious cycle is the key mechanism underlying the development of bone metastases. Recent data indicate that bone tissue also contains bile acids (BAs), which are accumulated from serum and which could stimulate the migration of breast tumor cells towards bone (Silva, J Lipid Res 2006). BAs are physiological ligands for farnesoid X receptor (FXR). FXR is a nuclear receptor involved in the regulation of BA metabolism in liver and intestine. In this context, it has been shown to heterodimerize with the retinoid X receptor (RXR). We have recently demonstrated the presence of FXR in human breast cancer specimens. In postmenopausal breast cancer patients, we found a correlation between FXR expression and that of estrogen receptor (ER) and proliferation markers. In the present study, we determined the effects of FXR activation by chenodeoxycholic acid (CDCA) in breast cancer cells, and examined its expression in bone metastasis specimens. We found that 50 μ M CDCA stimulated the proliferation of ER(+) MCF-7 cells cultured in steroid-free medium (EC50=15 μ M), while it had no effect on ER(-) MDA-MB-231 cells. Antiestrogens completely suppressed the mitogenic effect of CDCA in MCF-7 cells. Moreover, CDCA downregulated ER by 40% and stimulated the transactivation of progesterone receptor (PgR) by 316% in MCF-7 cells. Antiestrogens completely abolished PgR induction, and FXR gene silencing (siRNA) inhibited CDCA-stimulated cell proliferation as well as PgR induction. CDCA did not compete with [3H]-17 β -estradiol for binding to human recombinant ER immobilized on hydroxylapatite gel. In addition, FXR immunoprecipitation and subsequent ER demonstration by Western blotting revealed physical interaction between both receptors within 30 min. Finally, bone metastases from 32 breast cancer patients were examined for FXR expression by immunohistochemistry. FXR was expressed in 58% of bone metastasis specimens. In conclusion, our data reveal a positive crosstalk between FXR and ER, which accounts for FXR-mediated ER activation and subsequent mitogenic effects of FXR agonists in MCF-7 cells. Therefore, because of significant FXR and ER expressions in bone metastases of breast cancer, bone-derived lipids might contribute to the vicious cycle of tumor-induced osteolysis, especially in postmenopausal or estrogen-depleted cancer patients.

Degeneration of Intervertebral Disc in Ovariectomized Rats. M. Kato¹, N. Fujita^{*1}, N. Hosogane^{*1}, H. Takaishi^{*1}, J. Takito^{*1}, T. Kikuchi^{*2}, M. Matsumoto^{*3}, K. Chiba^{*1}, Y. Toyama^{*1}. ¹Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan, ²National Hospital Organization Murayama Medical Center, Tokyo, Japan, ³Department of Musculoskeletal Reconstruction and Regeneration Surgery, Keio University School of Medicine, Tokyo, Japan.

The intervertebral discs, which consists of water-rich nucleus pulposus and lamellar annulus fibrosus, degenerate with age and become source of low back pain. Estrogen deficiency in postmenopausal state closely associates with osteoporosis and may induce vertebral fractures. The purpose of this study is to investigate whether and how estrogen is involved in the degenerative process of the intervertebral discs. Eight-week-old female Wistar rats were sham operated (Sham) or ovariectomized (OVX). We collected the nucleus pulposus (NP) and the annulus fibrosus (AF) from the intervertebral discs at 1 week, 2 weeks, 3 months, 7 months, and 1 year after the operation. Histological observations at 7 months after the surgery indicated that the cell number of the NP and AF decreased significantly in OVX rats than that in Sham rats. Lamellar structure of the AF was disorganized in OVX rats. T2 weighted MRI images at 1 year after the surgery exhibited lower signal intensity of the NP of OVX rats than that of Sham rats. RT-PCR detected the expression of estrogen receptors (ER) α and ER β , in both the NP and AF. Immunofluorescence using confocal microscope revealed the nuclear localization of ER α and ER β in AF cells. In AF cells, nuclear localization of exogenously transfected DsRed-tagged ER α tended to aggregate under estradiol treatment and disperse under estrogen antagonist, ICI182780, administration. Real-time RT-PCR indicated that the expression level of type II collagen of the AF and NP in OVX rats was approximately 0.4 points lower ($P<0.05$) than that in Sham rats at 2 weeks and 7 months after the surgery. Decreased type II collagen mRNA expression and histological evidence of degeneration in the intervertebral discs of OVX rats suggests that menopause is one of the factors inducing disc degeneration and that estrogen may be involved in intervertebral disc homeostasis.

Co-Chaperone Potentiation of Vitamin D Receptor-Mediated Transactivation: A Role for Bag-1 as an Intracellular Binding Protein for 1,25-Dihydroxyvitamin D₃. R. F. Chun, M. Gacad^{*}, L. Nguyen^{*}, M. Hewison, J. S. Adams. Endocrinology, Diabetes and Metabolism, Cedars-Sinai Medical Center, Los Angeles, CA, USA.

In recent studies we have proposed that mitochondrial metabolism and nuclear signaling of vitamin D metabolites are not simply dependent on intercompartmental concentration gradients of free hormone in the target cell, but instead involve protein chaperones that interact with and traffic vitamin D metabolites to specific intracellular destinations. For example, the constitutively-expressed member of the heat shock protein-70 family (hsc70) is able to bind both 25-hydroxyvitamin D₃ (25D₃) and 1,25-dihydroxyvitamin D₃ (1,25D₃), potentiating 25D₃ metabolism and 1,25D₃-mediated gene transactivation. Hsc70 also recruits and interacts with the co-chaperone protein BAG-1. Competitive ligand binding assays showed that, like hsc70, recombinant BAG-1 is able to bind 25D₃ (K_d=0.57 nM) and 1,25D₃ (K_d=0.19 nM) with high affinity. To investigate the functional significance of this, we transiently overexpressed the naturally-occurring short (S), medium (M) and long (L) variants of BAG-1 in human, 1 α -hydroxylase (CYP27b1)-expressing kidney HKC-8 cells stably transfected with a 1,25D₃-responsive 24-hydroxylase (CYP24) promoter-reporter construct. Physiologically relevant concentrations of 25D₃ (200 nM) and 1,25D₃ (5 nM) were able to induce CYP24 promoter activity in these cells. CYP24 reporter activity was amplified 1.5-2.0-fold following over-expression of BAG-1S, L or M. By contrast, BAG-1 isoforms had no effect on metabolism of 25D₃ to either 1,25D₃ or 24,25D₃ by HKC-8 cells, indicating that the induction of CYP24 promoter activity by 25D₃ and potentiation of this effect by BAG-1 involves intracrine conversion to 1,25D₃. Further studies showed that transfection of HKC-8 cells with cDNA for BAG-1S in which the hsc70-binding domain was mutated resulted in decreased binding of 1,25D₃ leading to a concomitant loss of potentiation of CYP24 promoter transactivation. Similar loss or promoter-reporter activity in the presence of mutant BAG-1S was not observed for 25D₃ which retained binding to this form of BAG-1S. These data 1] highlight a novel role for BAG-1 as an intracellular binding protein for 1,25D₃ and 2] suggest that BAG-1 is able to potentiate vitamin D receptor (VDR)-mediated transactivation by acting as a nuclear chaperone for exogenous or endogenously synthesized 1,25D₃. We postulate that hsc70 and BAG-1 interact to provide a chaperone complex for 1,25D₃, but not 25D₃, thereby providing a novel mechanism for fine tuning the intracellular actions of the hormone.

Expression of the 1,25-Dihydroxyvitamin D₃ Receptor in Multiple Tissues in Adult and Developing Danio rerio (Zebrafish). T. Craig^{*}, R. Kumar. Nephrology Research, Mayo Clinic Rochester, Rochester, MN, USA.

The receptor for 1,25-dihydroxyvitamin D₃ (VDR) mediates many of the functions of 1,25-dihydroxyvitamin D₃ in cellular growth and development and mineral homeostasis. In order to better understand the functions of VDR, we utilized zebrafish (*Danio rerio*) as a model organism in which investigations of both adults and developing embryos are facile compared to larger vertebrates. Immunohistochemistry was carried out in decalcified male and female zebrafish adults (5 months age) and in developing fertilized embryos at 72 hours using antibodies against VDR. Mounted sections from formalin-fixed paraffin-embedded tissue blocks were treated with a polyclonal antibody raised in rabbits against the VDR or pre-immune rabbit control serum. Anti-rabbit HRP secondary antibody/diaminobenzidine (DAB) staining, with hematoxylin, as a counter-stain was used to visualize the primary antibody bound to the receptor. We observed intense staining for the VDR in epithelial cells of the intestine, oropharynx, cells covering gill lamellae, osteoblasts, osteocytes, pharyngeal teeth, kidney tubules (but not glomeruli), rods and cones of the retina, spinal cord, and epithelia of the olfactory organ. Less intense staining was observed in the ovaries and testes, with large areas of testes without immunostaining for the receptor.

We conclude that the VDR is expressed in calcium and phosphate transporting epithelia of the intestine, gills, and kidney and in osteoblasts, teeth, and neural cells. The use of zebrafish as a model may allow performance of experiments specific to the VDR that are difficult to carry out in other vertebrates.

A Significant Higher Risk for Fall-Associated Fractures with a Creatinine Clearance Below 65. L. C. Dukas^{*1}, E. Schacht², M. Runge^{*3}. ¹Acute Geriatric University Clinic, Kantonsspital Basel, Basel, Switzerland, ²Zurich Osteoporosis Research Group ZORG, Zurich, Switzerland, ³Center for Muscle and Bone Research, Aerpah Klinikum, Esslingen, Germany.

A Creatinine clearance of <65ml/min. is associated with decreasing balance and muscle power and an increased risk for falls. In this study we investigated if a Creatinine clearance of <65ml/min. is also associated with a higher fracture incidence. In a cross-sectional study in 1781 German men and women treated for osteoporosis, we assessed the association between the Creatinine clearance and the risk for fractures within the last 12 months. The Creatinine clearance was calculated using the established Cockcroft-Gault formula. Results are from spearman correlation analyses and logistic regression analyses. The p-values are two-sided. 1410 women and 371 men aged 60 years and older with a mean BMI of 26kg/m² and a mean Creatinine clearance of 60.2ml/min. participated in this study. A Creatinine clearance of <65ml/min. was significantly associated with a 44% higher fall associated fracture incidence compared to a Creatinine clearance of >65ml/min. Participants with a Creatinine clearance of <65ml/min. had significantly more vertebral fractures ($P=0.008$), hip fractures ($p=.002$) and fractures of the radius ($p=.002$) but not significantly more fractures in other localization ($p=0.08$), compared to participants with a Creatinine clearance of >65ml/min. We found no association between the Creatinine clearance and non-fall associated fractures ($p=.49$). We are the first to describe, that patients with a low Creatinine clearance of <65ml/min have a significant higher increased risk for falls and a higher increased risk for fall associated fractures, compared to patients with a Creatinine clearance of >65ml/min. Since the higher risk for falls, associated with a Creatinine clearance of <65ml/min., is due to decreasing calcitriol serum levels, we hypothesize that also the higher fall-associated fracture incidence observed with a Creatinine Clearance of <65ml/min., is due to decreasing calcitriol serum levels.

Examination of Human Retinoid X Receptor alpha Phosphorylation at Serine 260 Using Specific Antibodies in Cancer Cell Lines and Tumor Tissues. D. C. Huang, X. F. Yang*, L. Nguyen-Yamamoto, R. Kremer. Department of Medicine, Royal Victoria Hospital and McGill University, Montreal, PQ, Canada.

The retinoid X receptor alpha (RXR α) is a member of the nuclear receptor superfamily which regulates transcription of target genes through its heterodimerization with several partners including the vitamin D receptor. In previous studies, we have shown that phosphorylation of serine 260 of the human RXR α disrupts signaling and induces resistance to ligand activation of several partners of RXR α . Here we report the development of novel polyclonal antibodies which specifically react with phosphoserine residue 260 of human RXR α (PS260). Antiserum raised against PS260 or non-phosphorylated human RXR α S260 were purified with PS260 or S260 affinity columns. Specificity of antibodies against PS260 was examined by ELISA and demonstrated selective reactivity with PS260 peptide (Figure). We next examined hRXR α phosphorylation at serine 260 in several cell lines in which MAPKinase/Erk is activated prior to and following treatment with the MAPKinase inhibitor U0126 and showed a strong decrease in hRXR α serine 260 phosphorylation. We next examined human tissues from breast, colon and lung cancers by Western blot analysis using PS260, S260 and ERK antibodies. A strong correlation was observed between ERK expression and hRXR α phosphorylation at serine 260. Furthermore, a positive correlation was observed between tumor staging and hRXR α phosphorylation. Overall, our data indicate that antibodies specifically raised against phosphorylated hRXR α at serine 260 may be useful indicators of tumor progression of several types of cancers.

Role of TRPV 6 and β -Glucuronidase in 1,25(OH) $_2$ D $_3$ - and PTH-Stimulated Calcium Uptake in Intestinal Epithelial Cells. R. C. Khanal*, N. M. Smith*, T. M. Sterling*, S. Tunsophon*, I. Nemere. Nutrition and Food Sciences, Utah State University, Logan, UT, USA.

We have found that 1,25(OH) $_2$ D $_3$ -stimulated 45 Ca uptake can be demonstrated in isolated intestinal cells of adult chickens, and that the response is mediated by the 1,25D $_3$ -MARRS receptor, but not the VDR, as judged by preincubation with the appropriate antibodies. Such cells retain hormone-stimulated PKA, believed to mediate 45 Ca uptake, but lack steroid-stimulated PKC, believed to mediate efflux. PKC mediated efflux is supported by the observation that in freshly isolated cells from young chicks, 1,25(OH) $_2$ D $_3$ -stimulated 45 Ca uptake can only be demonstrated in cells pretreated with calphostin C, since without the PKC inhibitor, steroid-stimulated uptake is matched by efflux. Moreover, treatment of such cells with phorbol ester rapidly stimulated 45 Ca efflux. We have also discovered that cultured intestinal cells exhibited hormone stimulated PKC activity after 50 h, but it was diminished by 64 h, and lost by 72 h. Using the 72 h cultured cell model system, we have verified that 300 pM 1,25(OH) $_2$ D $_3$ stimulated 45 Ca uptake, and that this response is inhibited by pretreatment with Ab099 against the receptor. To further study the mechanism of calcium uptake, we found that 1,25(OH) $_2$ D $_3$ also stimulated the release of β -glucuronidase, a lysosomal marker enzyme and activator of TRPV calcium transporters. Moreover, treatment of isolated enterocytes with β -glucuronidase stimulated 45 Ca uptake in the absence of hormone. To determine whether the PKA signal transduction pathway is responsible for exocytosis of β -glucuronidase, we treated cells with PTH-known to activate PKA but not PKC in the chick model system-forskolin, or phorbol ester. PTH and forskolin-both of which stimulate 45 Ca uptake-were each found to stimulate β -

glucuronidase release, while phorbol ester had no effect. Finally, using siRNA to either TRPV 6 or β -glucuronidase abolished 1,25(OH) $_2$ D $_3$ -stimulated 45 Ca uptake, relative to controls transfected with scrambled siRNA.

Derepression of CYP27B1 Gene Expression Mediates DNA-Demethylation. M. Kim*, I. Takada*, K. Takeyama*, S. Kato. Institute of Molecular and Cellular Biosciences, Tokyo, Japan.

25(OH)D $_3$ 1 α -hydroxylase (CYP27B1) gene is a key enzyme in vitaminD synthesis, hydroxylating 25(OH) $_2$ D $_3$ to the active form of vitaminD, 1 α ,25(OH) $_2$ D $_3$. 1 α ,25(OH) $_2$ D $_3$ negatively regulates gene expression through Vitamin D receptor(VDR) binding to promoter, while PKA signaling activated by parathyroid hormone induced gene expression. The transactivation function by VDRE, a bHLH transcriptional factor recognizing negative VDRE in CYP27B1 promoter(1 α nVDRE), was found to be suppressed by liganded VDR/HDAC co-repressor complex(EMBO J. 23, 1598, 2004). We further reported that Dnmts interacts with VDRE /VDR/HDAC co-repressor complex, 1 α ,25(OH) $_2$ D $_3$ -dependent transrepression of CYP27B1 gene links repressive histone modification with epigenetic DNA methylation.

Now we reports that DNA methylation and demethylation have a critical role of CYP27B1 gene regulation. ChIP assay showed that Dnmt and HDAC sequentially interacts with 1 α nVDRE, and then sequential changes in DNA methylation pattern were occurred. However, DNA methylation status couldn't induced of heterochromatin formation of CYP27B1 gene, instead that, DNA demethylation occurred on CYP27B1 promoter by depleting of 1 α ,25(OH) $_2$ D $_3$. Furthermore, demethylation was increased when activates PKA signaling under cAMP pathway. Demethylation was observed later for one hour since 1 α ,25(OH) $_2$ D $_3$ is depleted. These changes occurred in the absence of cell growth or cell division. Furthermore, demethylation was inhibited by a treatment with actinomycin, a transcription inhibitor. These results suggest that this demethylation links to transcriptional mechanism. Thus, we propose the presence of demethylase enzyme that removes 1 α ,25(OH) $_2$ D $_3$ -induced DNA methylation.

Personal Ultraviolet Exposure and Vitamin D Synthesis. M. G. Kimlin, A. Brodie, C. A. Lang. Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia.

The association between exposure to ultraviolet radiation and the synthesis of Vitamin D [25(OH)D] is an area that is under increasing scrutiny. It is currently assumed that incidental UV exposure, particularly in a sunny climate should provide adequate vitamin D status for the population.

This research was undertaken to test this assumption among healthy free-living adults aged 19 to 82 years, in southeast Queensland, Australia (27°S), during late February/early March 2007 (Australian summer). 42 adults (17 males, median age 43 years) participated in this project, by having a blood sample taken to assess baseline serum 25(OH)D status and answering a self-reported questionnaire which sought demographic data and information about sun exposure. Participants were distributed with UV dosimeters to assess personal sun exposure. A second blood sample at 48-hour post-baseline blood, was collected along with the used UV dosimeters. This research was approved by Queensland University of Technology Human Research Ethics Committee and conducted under the guidelines of the Declaration of Helsinki.

The mean blood serum 25(OH)D at baseline was 75nm/L (min., 16, max., 160 nm/L) and 48 hours post baseline was 79nm/L (min., 21, max., 183 nm/L). The median personal UV exposure in the first 24 hours (as measured with the UV dosimeters) was 1.05 MED (minimal erythemal dose) with a range of 0 MED to 15.8 MED and in the final 24 hours the median personal UV exposure was 1.92 MED with a range of 0.2 MED to 7.4 MED. No significant correlation was found between personal UV exposure over the 48 hour period and change in 25(OH)D status between baseline and final collection. Additionally, self reported time in the sun (during this 48 hour period) was not related to change in 25(OH)D status. No relationships were also found between sunscreen use, age or gender. These results suggest that short term sun exposure does not impact on the 25(OH)D status, even though high exposures were of such intensity to promote the production of 25(OH)D.

Seasonal Skin Colour Variations and the Impact on Vitamin D Status. C. A. Lang¹, A. Brodie¹, S. Harrison^{*2}, M. G. Kimlin¹. ¹Institute of Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia, ²Skin Cancer Research Group, James Cook University, Townsville, Australia.

The influence of sunlight exposure on Vitamin D [25(OH)D] status is an intriguing and complex question. The current theory is that incidental UV exposure, particularly in a sunny climate should provide adequate 25(OH)D, however, an individual's characteristics, such as skin colour also contributes to an individual's potential to synthesize 25(OH)D. The aim of this research was to investigate the relationship between skin colour and 25(OH)D status of healthy adults in the 2007 summer and the 2006 winter in Queensland, Australia (27°S). A sample of blood was collected to assess 25(OH)D status at each time point. Skin colour was determined using a Minolta 2500D spectrophotometer recording spectral skin reflectance on the dorsum of the hand, forehead and upper inner arm. Melanin Density (MD) was calculated using the formula described by Dwyer et al. This research was approved by Queensland University of Technology Human Research Ethics Committee and conducted under the guidelines of the Declaration of Helsinki. Sixty participants (18m / 42f) with a median age 53 years (18 to 87 years) completed both summer and winter cross-sectional surveys. 53% described themselves as having a fair complexion, 25% medium and 18% an olive/dark complexion. There were 60% of the sample with an adequate (>50nm/l) 25(OH)D level in winter compared with 86.7% in summer (p=0.005). Vitamin D levels in winter (median 53.5 nm/l, interquartile range (IQR) 40.3nm/l) were significantly lower (z = -4.28, p<0.001) than summer (median 72.0 nm/l, IQR 38.8 nm/l). There was a median seasonal difference in 25(OH)D of 16.0 nm/l, with a wide range (-43.0 to 69 nm/l) that was not associated with age, gender, occupation or self reported skin colour. Median MD levels of a high UV exposure site (forehead) were significantly lower (z = -3.59, p<0.001) in winter (median 2.55 (IQR 1.74) than summer (median 3.02, IQR 1.61). There was a significant inverse correlation between the winter levels of forehead MD and 25(OH)D status (r=-0.353, p=0.006) and no correlation between the summer forehead MD and 25(OH)D (r = 0.012, p=0.927). These results indicate that seasonal variations in skin colour, due to seasonal exposure, cannot be used as a crude indicator for 25(OH)D status. Why the forehead MD was correlated in winter but not summer remains unanswered. Further research is required into the interactions between the solar UV environment and Vitamin D synthesis, particular with respect to seasonal variability of skin colour.

Vitamin D₂ Supplementation Suppresses Endogenous Levels of 25-Hydroxyvitamin D₃; Clinical Application of A New, Direct Immunoassay for the Specific Detection of 25-Hydroxyvitamin D₃. B. Li^{*1}, I. Byrjalsen¹, C. Christiansen¹, P. Glendenning^{*2}, D. Henriksen^{*3}, S. Vasikaran^{*2}, P. Qvist¹. ¹Nordic Bioscience A/S, Herlev, Denmark, ²Department of Core Clinical Pathology & Biochemistry, Royal Perth Hospital, Perth, Australia, ³Sanos Bioscience A/S, Roedovre, Denmark.

The nutritional vitamin D status is assessed on the basis of 25-hydroxyvitamin D (25(OH)D) levels in circulation, however there is no consensus on the relative potency of the two main vitamin D forms, D₃ and D₂. Therefore it is important to have available specific data for the endogenous form 25(OH)D₃ as well as for the corresponding D₂ forms. The present study was performed to determine the circulating levels of 25(OH)D₃ during vitamin D₂ and D₃ supplementation, respectively, using a new, direct immunoassay specific for 25-hydroxyvitamin D₃.

Serum samples were obtained at baseline and three months after supplementation with vitamin D₃ (39 participants, 400-800 IU/day) and vitamin D₂ (45 participants, 1000 IU/day), respectively. 25(OH)D₃ levels were determined by a new direct, vitamin D₃ specific ELISA based on polyclonal antibodies with <1% cross-reactivity to 25(OH)D₂ (Nordic Bioscience Diagnostics A/S, Herlev, Denmark). The direct 25(OH)D₃ ELISA demonstrated excellent correlation (r=0.95) to 25(OH)D₃ levels determined by HPLC through the Vitamin D External Quality Assessment Scheme (DEQAS, UK).

In the vitamin D₂ treated group, the relative levels of 25(OH)D₃ increase 21% (post vs pre treatment in individuals) after 3 months treatment (P<0.01). In contrast, vitamin D₂ supplementation induced 15% reduction (post vs pre treatment in individuals) compared to pre-treatment (P<0.01). The data suggest, that the decrease of 25(OH)D₃ level in vitamin D₂ group could be caused by the vitamin D₂ supplementation, which could give rise to competition between vitamin D₂ and vitamin D₃ for the substrate of vitamin D 25-hydroxylase.

Further studies are needed to confirm the suppression of endogenous vitamin D₃ levels during vitamin D₂ supplementation and its clinical relevance.

Fetal Hypervitaminosis D Results in Neonatal Lethality. L. Lieben^{*}, R. Van Looveren^{*}, R. Bouillon, G. Carmeliet. Laboratory of Experimental Medicine & Endocrinology, K.U.Leuven, Leuven, Belgium.

1,25(OH)₂vitaminD₃ [1,25(OH)₂D₃] is the major regulator of calcium homeostasis but is dispensable for fetal bone development. Hypervitaminosis D is deleterious during adult life but its effect on embryonic development is still enigmatic. To this end, vitamin D receptor deficient (VDR^{-/-}) females, showing highly elevated serum 1,25(OH)₂D₃ levels (p<0.001 vs. VDR^{+/+} mothers) were mated with VDR^{+/+} males generating offspring that either can (VDR^{+/+}) or cannot respond (VDR^{-/-}) to possible high 1,25(OH)₂D₃ levels.

VDR^{-/-} mice conceived less frequently, but both genotypes were born in the anticipated Mendelian ratio (47% VDR^{+/+} and 53% VDR^{-/-} pups). Although genotypes were indistinguishable in appearance and weight at birth, 97% of VDR^{+/+} pups died immediately thereafter. Further analyses were therefore performed at embryonic day 18.

No manifest difference in serum calcium levels was observed between genotypes. Surprisingly, bone mass was decreased in VDR^{+/+} embryos, whereas it was normal in VDR^{-/-} embryos. More specifically, femoral calcium content was decreased by 30% in VDR^{+/+} fetuses as compared to VDR^{-/-} littermates and to VDR^{+/+} embryos of VDR^{+/+} mother (p<0.001). This is primarily due to reduced cortical bone volume as shown by histomorphometry (-50% vs. VDR^{+/+} fetuses of VDR^{+/+} mother; p<0.001). Transplacental calcium transport was significantly decreased in VDR^{+/+} fetuses (-20%; p<0.05), although no difference was found in the placental TRPV6 and calbindin-D_{9k} mRNA level between genotypes. In addition, amniotic fluid calcium levels were increased in VDR^{+/+} embryos (1.2x; p<0.001) despite increased TRPV5 mRNA expression (5x; p<0.001) compared to VDR^{-/-} littermates. These data indicate that bone mineralization is impaired in VDR^{+/+} fetuses of VDR^{-/-} mothers, associated with normocalcemia and increased calcium excretion.

A likely explanation are the increased 1,25(OH)₂D₃ levels detected both in VDR^{-/-} (14x) and VDR^{+/+} fetuses (9x) of VDR^{-/-} mothers compared to VDR^{+/+} embryos of VDR^{+/+} mothers (p<0.001), suggesting diffusion of 1,25(OH)₂D₃ through the maternal-fetal barrier. VDR^{+/+} fetuses responded to this elevated 1,25(OH)₂D₃ level with increased mRNA level of fibroblast growth factor 23 in the femur (5x; p<0.001) and 24-hydroxylase in the kidney (1.7x; p<0.05) and decreased renal expression of 1α-hydroxylase (-80%) as compared to VDR^{+/+} embryos of VDR^{+/+} mothers.

In conclusion, our data indicate that 1,25(OH)₂D₃ diffuses through the maternal-fetal barrier and that fetuses control their serum 1,25(OH)₂D₃ levels by activating feedback loops. Moreover, excessive 1,25(OH)₂D₃ is toxic for the fetus resulting in decreased bone mineralization and neonatal lethality.

Effect of Hypercalciuria on Bone Density and Strength in Genetic Hypercalciuria Stone-Forming Rats. M. D. Grynaps¹, A. Ng^{*1}, S. D. Waldman^{*2}, D. A. Bushinsky³. ¹Pathology, Mount Sinai Hospital Research Institute, Toronto, ON, Canada, ²Chemical Engineering, Queens University, Kingston, ON, Canada, ³Nephrology/Medicine, University of Rochester, Rochester, NY, USA.

Hypercalciuria is the most common metabolic abnormality in patients with calcium (Ca) containing kidney stones. Patients with hypercalciuria often excrete more Ca than they absorb, indicating a net loss of total body Ca, almost certainly derived from bone. A number of studies have shown a decrease in bone mineral density (BMD) and an increase in fracture rate in hypercalciuric stone formers compared to controls. However, in human stone formers it is difficult to determine if the reduction in BMD is due to a primary bone disorder or to any number of dietary factors that may be altered in stone formers over their lifetime. To study the independent effect of hypercalciuria on bone, we utilized the genetic hypercalciuric stone-forming (GHS) rats which were established by successively inbreeding the most hypercalciuric progeny of hypercalciuric Sprague-Dawley rats. Sixteen 46th generation female GHS and control (Ctl) rats were placed in metabolic cages and fed a 1.2 % Ca diet for 6 weeks, and then their femurs, tibiae, humeri and lumbar spines were studied for BMD, histomorphometry, image analysis and mechanical tests. All comparisons are to Ctl rats. Urine Ca excretion was significantly greater in the GHS rats. BMD in both the femur and vertebrae (L1-L5) was significantly lower in the GHS rats. In the femur, trabecular bone volume and thickness were significantly lower in the GHS rats; however, trabecular number was not altered. Neither osteoid volume nor osteoid surface was altered in GHS rats. In the femur, the number of end points, multiple points, the length of node-to-free struts and the length of the node-to-node struts were each significantly higher in the GHS rats. In the humeri, failure stress was not different; however, failure strain and toughness were lower and modulus of elasticity higher in the GHS rats. Cortical and trabecular hardness was lower in the GHS compared to Ctl. Backscattered imaging (BSE) revealed that the GHS rat cortical bone is more mineralized than that of Ctl. Thus, the GHS rats, fed an ample Ca diet, have reduced bone mineral density with reduced trabecular volume, mineralized volume and thickness and their bones are more brittle and fracture prone, indicating that hypercalciuric stone-forming rats have an intrinsic bone disorder that is not secondary to diet.

Seasonal Changes in Bone and Body Mass in C57BL/6J Inbred Mice Are Gender and Compartment Specific. K. M. Delahunty^{*1}, L. G. Horton¹, H. F. Coombs^{*1}, W. G. Beamer¹, M. L. Bouxsein², C. J. Rosen¹. ¹The Jackson Laboratory, Bar Harbor, ME, USA, ²Beth Israel Deconess Medical Center, Boston, MA, USA.

Seasonal bone loss in humans has been thought due to changes in vitamin D. We previously reported that C57BL/6J (B6) mice at The Jackson Laboratory had lower areal (a)BMD, measured by DXA, in Winter versus Summer despite no changes in 25OH vitamin D. However, these data were obtained retrospectively. To test the hypothesis that seasonal bone loss occurs in B6 and to characterize physiological changes, we performed a cross sectional study in July 2006 (Summer), and February 2007 (Winter) using 16 week B6 virgin female (n=20-24) and male (n=18-21) mice from the same colony and animal room. We measured morphometric phenotypes by DXA, total femoral volumetric (v)BMD by pQCT, trabecular bone by Micro CT40, and serum IGF-I by RIA. The mice were fed the defined NIH31 diet, 16% fat by kcal, and unrefined for nutrient sources.

Female body weight, percent body fat and femur length did not show seasonal changes, but serum IGF-I was 25% lower in Winter than in Summer (p<0.006). In Winter, males had higher body weight (p<0.013), but no increase in percent body fat or femoral length, while serum IGF-I was reduced (~25%, p<0.001). Total femoral vBMD was also lower in Winter than Summer for both females (p=0.017) and males (p<0.01). But in the mid shaft of the femur, during Winter males had markedly reduced percent bone area (p<0.003) accompanied by expansion of periosteal (p=0.005) and endosteal (p<0.002) circumferences. Females in Winter had no changes at the mid shaft, but a decrease in total femoral mineral (p=0.042). By contrast for the distal femur, females had significantly lower BV/TV in Winter than in Summer (p=0.02), with fewer trabeculae (p=0.02), more spacing (p=0.03), and lower connectivity density (p<0.05); males had no seasonal changes in trabecular bone. Summary: Seasonal changes in bone, body mass and IGF-I occur in B6 mice despite controlled conditions that include: a) constant diet, b) 14:10hr light:dark cycle, c) minimal changes in humidity, and d) constant room temperatures. Seasonal changes in males resulted in compensation for Winter bone loss by expansion of periosteum and preservation of trabecular bone. In females, both BMC and trabecular bone were decreased in the Winter. Mechanistically, the cues - environmental or endogenous - driving these skeletal changes are unknown. Further studies that control for factors such as nutrient composition, are necessary to gauge the true magnitude of seasonal change, the mechanisms involved, and the relevance for future mouse and human studies.

Genetic Interaction Between p53 and Atm in Bone Development. Y. Hu^{*}, W. Leong^{*}, B. Au^{*}, B. Li. Institute of Molecular and Cell Biology, Singapore, Singapore.

p53 and Atm play critical roles in DNA damage response with p53 being a target of the Atm kinase. Recent studies show that p53 is a negative regulator of osteoblast differentiation, osteoblast-dependent osteoclastogenesis and bone remodeling (Wang et al. J Cell Biol 172:115, 2006; Zambetti et al. J Cell Biol 172:795, 2006; Lengner et al. J Cell Biol 172:909, 2006). p53(-/-) mice display a high bone mass phenotype; p53(-/-) osteoblasts show accelerated differentiation and increased expression of osteoblast-specific transcription factor, osterix. On the other hand, Atm plays a positive role in regulating expression of osterix. Atm(-/-) mice show reduced bone mass, decreased bone formation rate and defective differentiation of osteoblasts (Rasheed et al. Hum. Mol. Genet. 15:1938, 2006; Hishiyama et al. Bone 37:497, 2005). To study the relationship of these two genes in bone development, we generate p53 and Atm double knockout mice. By using calcein double labeling method we found P53(-/-)Atm(-/-) mice have a high bone mass, increased bone formation rate. The p53(-/-) Atm(-/-) osteoblasts show accelerated differentiation justified by ALP and Von Kossa staining. The cells also show increased expression of osterix but not Runx2. Overall, these results indicate that p53 may function downstream of Atm in regulating bone development.

A Functional RNAi Screening for Runx2-regulated Genes Corresponding to Ectopic Bone Formation in Human Spinal Ligaments. M. Kishiya^{*1}, K. Furukawa^{*1}, K. Kanemaru^{*1}, H. Kudo^{*2}, T. Numasawa^{*2}, T. Yokoyama^{*2}, S. Toh^{*2}, S. Motomura^{*1}. ¹Pharmacology, Hirosaki University School of Medicine, Hirosaki, Japan, ²Orthopaedic Surgery, Hirosaki University School of Medicine, Hirosaki, Japan.

Ossification of the posterior longitudinal ligament of the spine (OPLL) is characterized by ectopic bone formation in the spinal ligaments which enlarges with time and compresses spinal cord, resulting a serious neurological symptoms. We have previously reported that osteoblast differentiation keyfactor (Runx2) were enhanced in OPLL cells. To clarify a role of Runx2 in the ectopic ossification, effects of osteogenic medium (OS:48h) and RNA interference (using siRNAs targeted to Runx2) on gene expressions were analyzed by genome-wide linkage analysis (microarray) and the results were confirmed by real-time PCR in the ligament cells derived from tissues of OPLL and non-OPLL (CSM; Cervical spondylotic myelopathy) patients obtained during surgery to decompress the spinal cord for myelopathy.

Microarray demonstrated 22 candidate genes regulated by Runx2 in OPLL cells. In addition to osteogenic markers, any chondrogenic markers and angiogenic markers were influenced by OS induction and RNAi for Runx2. Particularly, Aggrecan-1 and angiopoietin-1 were significantly increased by OS induction in OPLL cells but not in non-OPLL cells and decreased by siRNAs for Runx2, but Runx2 were not decreased by siRNAs for angiopoietin-1. Furthermore, VEGF-A down-regulated by OS induction was up-regulated by siRNA for Runx2 or angiopoietin-1.

In our study, we suggested that OPLL development result in forming the metaplasia of spinal ligament cells and was derived through a mechanism of endochondral ossification. Furthermore, angiopoietin-1 and VEGF-A is downstream of Runx2 both in OPLL cells and osteoblasts. In our present study, we investigated any circulation factors in OPLL patients. OPLL patients was bleeding tendency in the perioperative period. Particularly, blood loss after surgery was significantly increased than non-OPLL patients. Other factors (function of platelets, coagulation abnormality, Hypertension, operation time...et al) was not significant between OPLL patients and non-OPLL patients. These data supported that OPLL patients find abnormality of microangiogenic function.

At least we can say that there is some remarkable relation in OPLL development. Signaling pathway between skeletogenesis and vasculogenesis or angiogenesis could have been on contact with Runx2, events that may regulate angiogenesis, and OPLL growth. These data may become a key to elucidate the disease state of OPLL between ectopic bone formation and angiogenesis. Angiopoietin-1 may play an important role in the disease state of OPLL.

Disclosures: M. Kishiya, None.

Dwarfism: A Comparative Analysis of Bone Mineral Density. D. C. Andrade^{*1}, M. G. Pippa^{*2}, S. R. Eis³, C. A. Brandao⁴, C. A. Zerbin². ¹Clinical Research, Centro Paulista de Investigação Clínica, Sao Paulo, Brazil, ²Rheumatology, Hospital Heliopolis, Sao Paulo, Brazil, ³Clinical Research, Centro de Diagnóstico e Pesquisa da Osteoporose do Espírito Santo, Vitoria, Brazil, ⁴Bone Densitometry, Fleury Medicina e Saúde, Sao Paulo, Brazil.

Dwarfism is a medical condition which result in short stature. It refers to an adult height of 4 feet 10 inches or under and can be caused by a wide variety of conditions, most of which are genetic. The most common type, accounting for 70% of all cases of short stature, is called achondroplasia. This one results from a spontaneous mutation in one gene or a child can inherit the gene from a parent who has achondroplasia. Characteristically, the arms are shorter than the forearms and the thighs are shorter than the legs, although trunk growth is nearly normal. Little is known about bone mass adjusted for body size and body composition compartments in children with dwarfism. Our objective was to evaluate the influence of short high in bone mineral density (BMD). We compared BMD results of dwarfs with a normal population. Twenty females and males dwarfs and were studied. All of them were submitted to dual-energy X-ray absorptiometry (DXA) in order to analyze BMD of lumbar spine. Control group was formed by normal females and males, that were matched by sex and age. Areal BMD was measured and reported in g/cm². Adjusted BMD was calculated by the relation between bone mineral content (BMC)/ height and results were given in g/m². Apparent BMD (App BMD) was calculated according to Bachrach. Variables were evaluated as descriptive patterns. The adherence to normal curve was evaluated by Kolmogorov Smirnov test. To compare the difference of quantitative variables between dwarfs and control group the Student t test was used. The effective P value to be considered significant was < 0.05. Data were analysed using the statistical computer program Minitab version 15.0%. Dwarf population showed lower means for all anthropometric values, but BMI [(weight = 52.8 Kg); (height = 1.23 m); (BMI = 34.4 Kg / m²)] when compared to control group [(weight = 65.3 Kg); (height = 1.62 m); (BMI = 34.4 Kg / m²)]. Analysing bone mass we observed that there were no significant differences between Dwarfs and control group concerning to areal L1-L4 BMD (1.035 g/cm²; 1.122 g/cm²) p = 0.158, L1-L4 Z-score (-0.71 SD; -0.44 SD) p = 0.532, and L1-L4 App BMD (0.308 g/cm²; 0.313 g/cm²) p = 0.735. Dwarfs presented lower values of L1-L4 BMC (48.40g) and L1-L4, area BMD (45.65) when compared to control group L1-L4 BMC (58.50g) p = 0.040; L1-L4 area BMD (51.67g) p = 0.026. Interestingly Adjusted L1-L4 was higher in Dwarfs when compared to controls (0.837 g/cm² / 0.697 g/cm² respectively), p = 0.001. Our results suggest BMD in Dwarfs should be based on analysis of adjusted L1-L4 BMD instead of App BMD.

Analysis of Cranial Defect Healing in CXCR2 Receptor2 Knock-out (CXCR2^{-/-}) Mice. D. S. Bischoff^{*1}, T. Sakamoto^{*1}, N. S. Makhijani^{*1}, H. E. Gruber², D. T. Yamaguchi¹. ¹Research Service, VA Greater Los Angeles Healthcare System, Los Angeles, CA, USA, ²Orthopaedic Surgery, Carolinas Medical Center, Charlotte, NC, USA.

The potential role of CXC chemokines bearing the glu-leu-arg (ELR⁺) motif in bone repair was studied using a mouse cranial defect (CD) model in CXCR2^{-/-} mice. Inflammation is the initial step in bone repair. ELR⁺ CXC chemokines are released by inflammatory cells and serve as angiogenic factors. Previously we have shown that osteogenic differentiation of hMSCs increases expression of the ELR⁺ CXC chemokine, IL-8 (CXCL8). CXCL8 signals through the CXCR2 receptor in mice. We created 1.8 mm CDs in 6 week old male CXCR2^{-/-} and wild-type (WT) mice and allowed the CDs to repair over a 12-week period. CXCR2^{-/-} mice were significantly reduced in size and weight compared to their WT littermates. Weight, length, and DEXA measurements were taken (total, femur, tibia, radius, humerus, and vertebrae) before surgery and 6 and 12 weeks after surgery. CXCR2^{-/-} mice were significantly smaller in weight (54% of WT at 6 weeks, 75% at 12 and 18 weeks, p<0.0001) and length from base of tail to nose tip (82% at 6 weeks, 90% at 12 and 18 weeks, p<0.0004). DEXA analysis indicated that bone mineral density (BMD) and bone mineral content (BMC) were significantly decreased in CXCR2^{-/-} mice in all bones, and total area (TA), bone area (BA), total tissue mass (TTM), and lean body mass (LBM) significantly decreased in all with the exception of the vertebrae. There was no difference in % fat between CXCR2^{-/-} and WT mice. Normalizing for the size differences with weight or LBM, BMD is significantly decreased in CXCR2^{-/-} mice only at 6 weeks whereas BMC is slightly increased in the CXCR2^{-/-} mice at 18 weeks of age. CDs were analyzed using the BIOQUANT system. Although the CDs were not completely healed even after 12 weeks, preliminary analysis indicates that there was significant bone in-growth in both the CXCR2^{-/-} and WT CDs. Old and new bone were identified using polarized light and quantitated for numbers of osteocytes (OCy) and blood vessels (BV) around the original CD. New bone in CXCR2^{-/-} mice had more OCy than WT (2618 vs 2049 OCy/ μm^2). CXCR2^{-/-} old bone had about half as many OCy as new bone but still more than WT old bone (1282 vs 1043 OCy/ μm^2). In new bone, the number of BV in WT was ~2X more than seen in CXCR2^{-/-} (43 vs 20 BV/ μm^2). The number of BV in the old bone was more closely matched (9 vs 11 BV/ μm^2 for WT and CXCR2^{-/-} respectively). Conclusion: CXCR2^{-/-} mice have 1) reduced weight and size; 2) reduced BMD at 6 weeks of age but not at later time points; 3) increased BMC at 18 weeks of age; 4) increased number of OCy in new bone; and 5) decreased number of BV in new bone.

Significant Lower Balance and Muscle Power Performance and Higher Risk for Falls in Elderly People with a Decreasing Creatinine Clearance. L. C. Dukas^{*1}, E. Schacht², M. Runge^{*3}. ¹Acute Geriatric University Clinic, Kantonsspital Basel, Basel, Switzerland, ²Zurich Osteoporosis Research Group ZORG, Zurich, Switzerland, ³Center for Muscle and Bone Research, Aerpah Klinikum, Esslingen, Germany.

A Creatinine clearance (CrCl) of <65ml/min. is associated with a significant increased risk for falls. In a German study a decreasing creatinine clearance was associated with significantly decreasing muscle power and balance. We assessed this association in a multinational study. For this cross-sectional study data were collected from 7 European countries including Russia. 1190 women and 127 men aged 60 years and older with a mean BMI of 27.2kg/m² and a mean CrCl of 58.6ml/min., freshly diagnosed and therefore untreated for osteoporosis, participated in this study. The CrCl was calculated using the established Cockcroft-Gault formula. Results are from spearman correlation analyses and from logistic regression analyses. The p-values are two-sided.

A decreasing CrCl was multivariate controlled significantly associated with lower performance in the Timed-up-and-go test (TUG) (corr-0.1341, p<.0001) and in the Chair Rising test (corr-0.1266, p<.0001). Performance in the Tandem Stand was not associated with the CrCl. A CrCl of <65ml/min. was multivariate controlled a significant risk factor for falls.

We found a significant correlation between decreasing CrCl and lower performance in balance and muscle power tests. However, contrary to the findings in another study the performance in the Tandem Stand test was not significantly associated with a decreasing CrCl. Furthermore we found that a CrCl<65ml/min is, independent from the performance in muscle and balance tests, a significant risk factor for falls. Our results together with the results from already published studies allows us to suggest a low CrCl of <65ml/min. to be a diagnostic tool to identify elderly frail patients.

Candidate Genes of Every Known QTL of BMD in Whole Mouse Genome. Q. Xiong^{*}, Y. Jiao, W. Gu. Departments of Orthopaedic Surgery - Campbell Clinic, University of Tennessee Health Science Center, Memphis, TN, USA.

One difficulty in the identification of candidate genes for QTL is that the genomic region of a QTL is generally considered as too large to search the candidate genes. In this study, we systematically examined all the genes in each of QTL of BMD identified from mouse study.

Methods: To identify every QTL, literature search was conducted with key words "Bone" and "QTL" in PubMed for every publication up to January 2007. Genes within a QTL region are obtained from Ensembl database (<http://www.ensembl.org/index.html>). For every known gene in QTL, their potential connection with BMD was evaluated by searching information from Online Mendelian Inheritance in Man (OMIM) at <http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=OMIM> and PubMed at <http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed>. Searching terms are the combination of the symbol of the gene with any of those eight key words: bone mineral density, BMD, bone strength, bone size, osteoporosis, osteoblast, osteoclast, and fracture.

Results: We obtained candidate genes for every known BMD QTL. A total of 74 BMD QTL cover 1,210,895,314 bp genomic sequence which is roughly 46% of the total mouse genome sequences. Every autosomal chromosome except chromosome 8, contains at least one BMD QTL. Within the 1,210,895,314 genomic sequences of total of 74 BMD QTL, a total of 15,075 genes have been located. Among all those genes, 290 have been nominated as candidate genes according our bioinformatics search. For any potential candidate, at least the abstract of one reference was read to confirm the link between the gene and BMD. For a gene with more than one reference that indicates its candidacy, at least two references were read and cited in this study. Many BMD QTL have been located on the gene rich regions of the genome. The average gene density through whole mouse genome is about one gene per 95,977 bp. Within the total of 1,210,895,314 BMD QTL genome sequences, there is about one gene per 80,324 bp, while in the genome region outside of BMD QTL regions, there is about one gene per 114,894 bp.

Discussion and Conclusion: Our search reveals that a very large number of candidate genes exists within QTL regions. For most of them, we do not aware any report on the investigation or even being listed as candidates. The other important finding is that the association between polymorphism of many candidate genes and BMD has been reported in human studies. As the rapid development of technologies and genome projects such as knockout of genes in whole mouse genome, information of gene function accumulates in an unexpected speed. Those information should be useful for our gene identification of QTL. A comprehensive search of candidate genes for known QTL may provide unexpected benefit for QTL studies.

Identification of the CACNA2D2 Gene on Chromosome 3p21 as a Novel Susceptibility Gene for Osteoporosis. Q. Huang^{*1}, C. Cheung^{*1}, P. Fong^{*2}, M. Ng^{*1}, W. Mak^{*2}, V. Chan^{*1}, P. Sham^{*2}, A. Kung¹. ¹Medicine, The University of Hong Kong, Hong Kong, China, ²Genome Research Center, The University of Hong Kong, Hong Kong, China.

Evidence of linkage of chromosome 3p to bone mineral density (BMD) has been previously reported in individual as well as meta-analysis of genome wide linkage scans. To identify the quantitative trait loci gene underlying BMD variation at chromosome 3p, we performed a region-wide association study with 200 single-nucleotide polymorphisms (SNPs) across 6Mb of chromosome 3p21 in 1,243 case-control Chinese subjects. The cases were subjects with low BMD (Z-scores ≤ -1.28 , equivalent to the lowest 10 percent of the population) at either the L1-4 lumbar spine or femoral neck. Control subjects had high BMD (Z-score $\geq +1.0$) at the corresponding sites. Two hundred tag SNPs were selected and genotyped using the high-throughput Sequenom genotyping platform. One hundred thirty-five SNPs met quality control criteria (genotyping call rate >0.9, minor allele frequency > 0.01, duplicate error rate <0.02 and Hardy-Weinberg equilibrium p values >0.01) and were analyzed for the high-throughput Sequenom genotyping platform. Binary logistic regression analyses were performed to test for associations between each SNP genotype and BMD. Haplotype association analyses were performed by WHAP. Five SNPs (rs11918619, rs1471217, rs2336664, rs7626551, and rs2257216) were associated with spine BMD and two SNPs (rs2236953, rs2624839) with femoral neck BMD (p<0.01) in single marker associations. The region that contained 6 SNPs, located within the CACNA2D2 gene, showed the strongest association with femoral neck BMD in the haplotype analyses (permutation p<0.002). In addition, we consistently detected significant associations for the haplotype CCGATGCCAC of the CACNA2D2 gene with BMD at the spine, trochanter and total hip region. Our results suggest that CACNA2D2, which encodes a voltage-dependent calcium channel subunit, is a novel susceptibility gene for BMD variation in Chinese and is likely to be involved in the pathogenesis of osteoporosis. Replication study is currently being conducted in Japanese population.

Lack of Major Survival Benefit of Vitamin D Receptor Gene Polymorphisms. A. Arabi¹, L. Zahed^{2*}, Z. Mahfoud^{3*}, J. Maalouf¹, M. Choucair^{4*}, M. Nabulsi^{4*}, G. El-Hajj Fuleihan¹. ¹Calcium Metabolism and Osteoporosis Program, American University of Beirut, Beirut, Lebanon, ²Pathology and Laboratory Medicine, American University of Beirut, Beirut, Lebanon, ³Epidemiology and Population Health, American University of Beirut, Beirut, Lebanon, ⁴Pediatrics, American University of Beirut, Beirut, Lebanon.

Vitamin D has recently emerged as an important risk factor for several health problems associated with increased mortality. Vitamin D receptor (VDR) is widely expressed in most immune cell types and other tissues, and prostate, breast and colon cancer cells exhibit increased levels of VDR protein when compared to their normal counterparts. This raises the possibility that some VDR genotypes may be associated with higher mortality rate and therefore their frequency distribution may decrease in the surviving elderly. The aim of this study was to look for a survival benefit of VDR gene polymorphisms by comparing the genotype frequencies in children to those in the elderly in a population of the same ethnic background.

Data from 203 elderly subjects aged 65-85 years who participated in a population-based study assessing the prevalence of osteoporosis, and data from 336 children aged 10-17 years who participated in a vitamin D trial were used. In both groups, polymorphisms in the VDR gene were assessed with the restriction enzymes BsmI, TaqI and ApaI.

The frequency distributions of VDR genotypes were similar to those reported in white populations. The heterozygote genotype for all enzymes was the most frequent in both age groups (Table 1). The frequencies of genotypes in both age groups were in Hardy-Weinberg equilibrium. There was no difference in the frequency distribution of VDR genotypes between the young and the elderly, both by gender and in the overall group.

The lack of difference in the frequency distribution of VDR genotypes between the children and the elderly within the same population renders the role of VDR as a major modulator of the relationship between vitamin D and conditions associated with high mortality unlikely.

Table 1. Frequency distribution of VDR genotypes according to the restriction enzyme in children and in the elderly*

		Children	Elderly
Bsm	bb	110 (33%)	62 (31%)
	Bb	169 (50%)	96 (48%)
	BB	56 (17%)	43 (21%)
Apa	aa	53 (16%)	23 (12%)
	Aa	161 (48%)	102 (50%)
	AA	122 (36%)	78 (38%)
Taq	tt	47 (14%)	39 (20%)
	Tt	170 (51%)	99 (48%)
	TT	119 (35%)	66 (32%)

* No significant difference between the children and the elderly within gender or in the overall group.

The Decreased Activity of Lactase Phlorizin Hydrolase and Bone Mineral Density in Postmenopausal Women. K. Bácsi*, J. P. Kósa*, B. Balla*, Á. Lazáry, Z. Nagy, I. Takács, G. Speer*, P. Lakatos. First Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

The CC genotype of the -13910 T/C dimorphism (LCT) related to lactose intolerance and decreased calcium absorption from gut is accompanied with reduced activity of lactase phlorizin hydrolase. We hypothesized that the altered calcium absorption throughout life has an impact on bone mineral density (BMD) of postmenopausal women. We studied 200 osteoporotic, 235 osteopenic and 160 healthy women. Genotyping, osteodensitometry at the lumbar spine, total hip, femur head, Ward's triangle and radius as well as serum calcium measurements were carried out in all subjects. The -13910 T/C polymorphism was significantly associated with the BMD at the Ward's triangle (Z-score (TT) = 0.082±0.787, Z-score (TC) = -0.179±0.829, Z-score (CC) = -0.334±0.871; p=0.028) and in a recessive model at the radius (Z-score (TT+TC) = 0.406±1.322, Z-score (CC) = 0.105±1.415; p=0.038) in the whole study population. Similar relationship was seen at the femoral head (Z-score (TT+TC) = 0.595±1.02, Z-score (CC) = 0.148±1.063; p=0.013) but only in the unified groups of osteoporotic and healthy women. Also, we found significant association between genotypes and both the total hip density (Z-score (TT) = -0.717±0.841, Z-score (TC) = -1.106±0.877, Z-score (CC) = -1.003±0.826; p=0.043) and the Ward's triangle density (Z-score (TT) = -0.375±0.606, Z-score (TC) = -0.819±0.485, Z-score (CC) = -0.88±0.541; p=0.015) in osteoporotic and osteopenic patients together. All results remained significant after adjustment for menopausal age and body mass index. We could not detect any associations between genotypes and BMD at the lumbar spine in the study groups. Our data suggest that the -13910 T/C dimorphism might have an influence on bone mass at cortical but not trabecular bone.

An Interaction Between Dietary Fat and Polymorphisms in a Previously Undetected, Alternate 3' UTR of the PPARG Gene Influences Bone Mass in Both Mice and Humans. C. L. Ackert-Bicknell¹, J. Graber^{1*}, K. Cho², S. Demissie^{2*}, J. Ordoñez^{3*}, W. G. Beamer¹, D. P. Kiel⁴, C. J. Rosen¹. ¹The Jackson Laboratory, Bar Harbor, ME, USA, ²Boston University School of Public Health, Boston, MA, USA, ³Tufts University, Boston, MA, USA, ⁴Hebrew SeniorLife, Boston, MA, USA.

We previously identified a Quantitative Trait Locus (QTL) for volumetric BMD on mouse Chromosome (Chr) 6 and now name Peroxisome Proliferator-Activated Receptor-gamma (Pparg) as a likely candidate gene. The B6.C3H-6T (6T) congenic mouse was created for the purpose of understanding the biology underlying this QTL and was generated by introgressing a 30 cM region of Chr 6 from C3H/HeJ (C3H) onto C57BL/6J (B6). Female 6T mice have low BMD and increased adipocyte infiltration in bone marrow. PPARG is a nuclear receptor known to be key for maturation of adipocytes. Existing annotation of PPARG indicated a 3' Untranslated Region (3' UTR) with an approximate length of 210 nucleotides (nt). Examination of the pattern of evolutionary conservation downstream of this site led us to predict a previously undetected alternative 3' processing site that would result in a longer (~3450 nt) 3' UTR. We have sequenced the genomic region between the two 3' processing sites and found 25 polymorphisms in C3H, when compared to B6. Dietary fat is able to activate PPARG and female 6T mice fed a high fat diet (60% fat) have lower aBMD than low fat (11% fat) fed 6T mice. There is no difference in aBMD in B6 mice fed the two diets. Using Real Time RT-PCR, we examined expression of Pparg transcripts containing this alternate 3' UTR in bone. There was no difference between B6 mice fed the low and high fat diets, (fold = 1.52±0.4, p = 0.318) and between B6 and 6T mice fed a low fat diet (fold = 1.8±0.6, p = 0.18). 6T mice fed high fat had a 4.3±1.4 fold increase compared to B6 mice fed low fat (p = 0.036) and a 2.25±0.6 fold increase compared to 6T mice fed low fat (p=0.016). We examined 13 SNPs in the PPARG gene in the Framingham Offspring Cohort. For three of these SNPs, rs1152004, rs1175381 and rs1186464, we found a significant interaction with dietary fat intake for the phenotype of DXA BMD of the trochanter region in women. SNPs rs1152004 and rs1175381 are located in a region of high evolutionary conservation very near to the alternative 3'-processing site in PPARG. The usage of alternative 3' UTR can affect transcript stability and translation efficiency. These findings suggest that dietary fat has a significant influence on BMD but is dependent on alleles in the rare, extended 3' UTR of PPARG.

Association of Luteinizing Hormone Receptor Polymorphism with Bone Mineral Density in Young Men - Results from Odense Androgen Study. C. L. Brasen^{1*}, T. L. Nielsen^{2*}, B. Abrahamson³, L. Christiansen^{4*}, C. Hagen^{2*}, M. Andersen^{2*}, K. Brixen², L. Bathum^{1*}. ¹Dept. of Biochemistry, Pharmacology and Genetics, Odense Universitetshospital, Odense C, Denmark, ²Department of Endocrinology, Odense Universitetshospital, Odense C, Denmark, ³Department of Medicine & Endocrinology, Copenhagen University Hospital Gentofte, Hellerup, Denmark, ⁴Department of Epidemiology, Institute of Public Health, University of Southern Denmark, Odense C, Denmark.

The N312S polymorphism in the luteinizing hormone receptor (LHR) has previously been shown to be associated with genital undermasculinization. We investigated the hypothesis, that the N312S polymorphism in LHR is associated with bone mineral density (BMD).

We genotyped 783 healthy men aged 20-29 years from the population-based Odense Androgen Study for the N312S polymorphism in LHR and investigated association with BMD in the spine, hip, truncus and extremities as well as whole body BMD. 406 of the participants underwent MRI scans to determine visceral and subcutaneous adipose tissue (VAT and SAT), muscle tissue and femoral compacta area. We furthermore tested for association with testicular volume, height, lean body mass, carboxy-terminal telopeptide of type I collagen (ICTP), bone-specific alkaline phosphatase (bone ALP), luteinizing hormone, testosterone, oestrogen, dihydrotestosterone (dht) and androstenedione.

Genotype distribution (AA, 0.20; AG, 0.48; GG, 0.32) was consistent with the Hardy-Weinberg equilibrium. Using the entire study group, we found significant association between LHR alleles and testicular-volume (p=0.03) as well as with BMD in spine (p=0.04) and trend association between LHR alleles and BMD in truncus and whole body BMD.

Stratifying participants into "sedentary" and "non-sedentary", we found that in the sedentary participants (n=615), LHR N312S was significantly associated with testicular volume, BMD in spine, truncus, and whole body. The results also indicated a trend association with BMD in hip and extremities, as well as the level of ICTP.

Additional stratification by smoking showed that in the group of sedentary ever-smokers (n=199) LHR alleles were significantly associated with BMD in spine, truncus, extremities and whole body, (p<0.01 for all), ICTP (p=0.04) and bone ALP (p=0.002). The difference in mean BMD in the spine equals 5.9%. Furthermore there was a trend association with BMD in hip and lean body mass. Finally we found a trend association with VAT, SAT and femoral compacta area.

These findings strengthen the hypothesis that the LHR N312S polymorphism is associated to genital undermasculinization and hereby low BMD. More studies are needed to verify these results. Interaction with other polymorphisms will be discussed.

Disclosures: C.L. Brasen, None.

Study of 7 Polymorphisms Genes (LCT, MTHFR, COLIA-1 and Promoters of RANKL, OPG, IL-6 and TCIRG1) Previously Described as Linked to Osteoporotic Fractures: Lack of Association in French Women.

V. Breuil¹, D. Quincey², J. Testa³, C. Albert¹, C. H. Roux¹, Z. Mroueh², H. Cham¹, O. Brocq¹, C. Grisot¹, L. Euler-Ziegler¹, G. Carle². ¹Rheumatology, CHU de Nice - Medical School, Nice, France, ²CNRS - Faculté de Médecine, GEPITOS-Université de Nice Sophia Antipolis, Nice, France, ³Informatique Médicale, CHU de Nice - Medical School, Nice, France.

Osteoporosis (OP) is have a strong genetic determination and numerous polymorphisms are reported to be associated with it. However, these associations depend on the population studied. Thus, we tested in a French population 7 genes polymorphisms [Lactase Transferase (LCT), RANKL promoter, Collagen 1 α (COLIA-1), OPG promoter, IL-6 promoter, methylenetetrahydrofolate reductase (MTHFR), and TCIRG1 promoter] previously reported to be associated with OP fractures.

Two groups of postmenopausal women were selected, 50 to 80 years old: one control group free of OP fracture and with normal BMD (T-score >-1 SD at hip and spine) in without any anti-OP treatment, and one group of OP women with at least one fracture and a low BMD (T-score <-2.5 SD at hip and/or spine); secondary OP were excluded. For each patient, genomic DNA was isolated from peripheral blood and polymorphisms genotyped by PCR and restriction analysis. The univariate statistical analysis used Chi² or Fisher test (qualitative variables) and Kruskal-Wallis (quantitative variables); the multivariate analysis used logistic regression.

159 women (89 OP and 70 controls) were enrolled. The 2 groups were similar regarding age of menopause, statine, betablockers, neuroleptics or antidepressants use. In the OP group, there was significant higher rate of family history of OP, higher age, age of puberty and loss of height, as well as significant lower weight, height, body mass index, high blood pressure. In the OP group, 47 vertebral fractures and 62 non vertebral fractures were recorded. The analysis of each polymorphism didn't show any significant differences between the 2 groups. To take in account the polygenic pattern of the disease, we tested whether the OP group presented significantly more polymorphisms on the 7 genes than the control group and failed to detect any difference. However, we found a significant association between the polymorphism of IL-6 or TCIRG1 promoter and family history of OP ($p=0.01$), as well as other polymorphisms associated with hyperlipidaemia, height, loss of height, BMI, and diabetes.

In our French population, we did not found the polymorphisms associations with OP fractures previously described. This could be related to the sample size, even if some of the previous studies enrolled a similar number of subjects, or, as previously described for numerous polymorphisms, to a geographical factor.

A Haplotype-Based Analysis of the LRP5 Gene in Relation to Osteoporosis Phenotypes. L. Agueda¹, X. Nogues², M. Bustamante¹, S. Jurado², N. Garcia-Giral², J. Garces², L. Mellibovsky², S. Balcells¹, A. Diez-Perez², D. Grinberg¹. ¹Genetics, University of Barcelona, CIBERER, IBUB, Barcelona, Spain, ²URFOA, IMIM, Hospital del Mar, Autonomous University of Barcelona, Barcelona, Spain.

LRP5 encodes the low-density lipoprotein receptor-related protein 5, a transmembrane protein involved in Wnt signaling. In bone, LRP5 is an important regulator of osteoblast growth and differentiation, affecting peak bone mass in vertebrates. Rare mutations in LRP5 result in severe phenotypes associated with bone. Whether common variants in LRP5 are associated with normal BMD variation or osteoporosis phenotypes remains controversial. In this study, we employed a haplotype-based approach to comprehensively examine the contribution of common variation at the LRP5 genomic region to osteoporosis susceptibility.

A total of 24 SNPs were selected to cover a 150 kb genomic region including the LRP5 gene and flanking regions, about 7 kb at each side. Most of these SNPs were tag-SNPs selected based on HapMap-CEU data. The remaining were either missense changes or SNPs previously studied by others. Genotyping was performed using SNPlex or TaqMan methodologies. Association, both at single SNP or block-haplotype level, was tested against LS-BMD, FN-BMD and osteoporotic fracture in a cohort of 964 Spanish postmenopausal women (BARCOS cohort). Statistical methods included ANCOVA and logistic regression.

At the single SNP level, a significant association with LS BMD was found for SNP#1, located in the promoter region ($p=0.011$, recessive model). The SNP#6 (intron 1) was associated with both LS BMD ($p=0.025$, additive model) and FN BMD ($p=0.031$, recessive model). Three SNPs, SNP#11 (intron 1; $p=0.007$, additive model), SNP#13 (intron 5; $p=0.041$, recessive model) and SNP#15 (intron 5; $p=0.019$, recessive model) were significantly associated with the risk of osteoporotic fracture, with ORs of 1.70, 1.66 and 1.79, respectively. In general, haplotype analyses did not provide additional information to that obtained from SNP analyses. The only exception was one block-haplotype (tagged by SNPs 10, 11 and 12), which showed a significant association with LS BMD ($p=0.043$), while none of the tag-SNPs gave a significant result on their own.

In conclusion, we found that genetic variation in the first half of the LRP5 genomic region was associated with osteoporotic phenotypes in the BARCOS cohort.

An $\alpha_v\beta_3$ Integrin Antagonist (MK-0429) Inhibits Osteolytic Lesions in Breast Cancer and Melanoma Lung Metastases. M. Pickarski, G. Wesolowski, G. Neusch*, T. Prueksaritanont*, L. T. Duong. Merck Res. Labs., West Point, PA, USA.

There is significant evidence to support multiple roles of $\alpha_v\beta_3$ integrin in mediating osteoclastic bone resorption, tumor progression and metastasis. Increased expression of $\alpha_v\beta_3$ in several tumors, including breast cancer and melanoma, is correlated with a greater metastatic potential and the development of bone metastases. Previously, we demonstrated the efficacy of MK-0429 as a safe, well tolerated, orally active antiresorptive in reversing estrogen-deficiency induced bone loss in preclinical animal models and in postmenopausal women. Here, we evaluated the efficacy of MK-0429 in inhibiting the proliferation of breast cancer (BrCa), prostate cancer (PCa) and melanoma cells.

Cell Lines	BrCa		PCa		Melanoma	
	MDA-MB-231	22RV1	PC3-M	DU145	B16-F10	
IC ₅₀ nM	639 \pm 370	488 \pm 360	863 \pm 475	736 \pm 196	96 \pm 61	

MK-0429 also inhibited MDA-MB-231 breast cancer (IC₅₀ = 2.1 nM) and PC3-M prostate cancer (IC₅₀ = 4.1 nM) cell migration to vitronectin; and blocked MDA-231 matrigel invasion (IC₅₀ = 7.0 nM), comparable to its potency to inhibition of osteoclastic bone resorption in vitro (IC₅₀ = 12 nM). In this study, MK-0429 was evaluated in the prevention of bone metastasis growth using the intra-tibial engraftment model of MDA-MB-231 breast carcinoma in nude rats. Bone loss and skeletal tumor growth were determined by μ CT and histology over a 6-week period. Compared to vehicle, treatment with oral MK-0429 at 100, and 300 mg/kg, bid, significantly prevented osteolytic lesions by 22 and 42%, respectively, compared to 45% with zoledronic acid (ZOL, 7.5 μ g/kg, sc, wky). Compared to vehicle, MK-0429 also reduced tumor volume by 40 and 66%, vs. a 56% reduction with ZOL. MK-0429 significantly inhibited cortical disruption, tumor necrosis, tumor infiltration between the trabecular bone plates, and invasion of the bone marrow. While having no effect on melanoma growth in an s.c. xenograft model, MK-0429 reduced the incidence of B16-F10 pulmonary metastases by 60% vs. vehicle. Taken together, these data show that MK-0429 had both anti-resorptive and anti-metastatic activities in preclinical models of breast cancer bone metastasis, as well as extraskelatal activity in blocking melanoma lung metastasis. Compared to the i.v. bisphosphonates, MK-0429 may represent a novel oral therapy for the treatment of patients with bone metastasis.

Prevalence of Vitamin D Insufficiency in Patients with Breast Cancer. N. Napoli, C. Ma, S. Vattikuti*, M. R. Azadfar*, A. Rastelli, M. Ellis*, R. C. Armamento-Villareal. Medicine, Washington University School of Medicine, St. Louis, MO, USA.

Previous studies have shown that aromatase inhibitor therapy in patients with ER+/PR+ breast cancer is associated with bone loss and increased incidence of fractures. As these studies were not designed to investigate skeletal outcomes as the primary endpoint, the vitamin D status of these patients remains undetermined. The objective of our study is to determine the incidence of vitamin D deficiency in patients with newly-diagnosed breast cancer who are about to initiate aromatase inhibitor therapy. We have recruited 80 postmenopausal patients (69 Caucasians, 11 African-Americans) between 40 to 80 years old from March 2006 to March 2007, with newly-diagnosed Stage 1 to 11a, ER+/PR+ breast cancer who will be initiated on aromatase inhibitors by their oncologists. Table 1 shows the clinical data of the whole study population. Baseline vitamin D levels were available in 70 patients. Analysis of serum vitamin D levels showed that 60 out of 70 patients (85.7%) of which 51 were Caucasians and 9 were African-Americans, have insufficient levels, i.e. <30 ng/ml (31 patients between 20-30 ng/ml, 25 between 10-19 ng/ml and 4 have <10 ng/ml). The vitamin D levels were significantly lower in African-Americans compared to Caucasians (16.3 ± 10.8 ng/ml vs 22.3 ± 8.3 ng/ml, $p=0.04$). Analysis according to the time of presentation showed no seasonal variation in vitamin D levels (April to September = 23.2 ± 9.1 vs October to March = 20.5 ± 8.8 ng/ml, $p=0.24$). In summary, insufficient vitamin D levels is common among patients with breast cancer perhaps from a combination of poor sunlight exposure (from lack of physical activity) and poor intake (from lack of appetite). The prevalence of vitamin D insufficiency appears to be higher in our cohort than what has been reported in the literature for otherwise healthy postmenopausal women without breast cancer (Holick MF, et al. J Clin Endocrinol Metab. 2005 Jun;90(6):3215-24. Epub 2005 Mar 29). Low vitamin D levels may aggravate bone loss from aromatase inhibitors, thus, routine vitamin D determination followed by appropriate supplementation may be necessary in breast cancer patients, most especially in those who will be starting aromatase inhibitor therapy.

Clinical data of the whole study population (N=80)	
Age (years)	62.6 \pm 9.6
Years since menopause	16.8 \pm 15.5
Menopausal age (years)	47.6 \pm 7.4
Body mass index (kg/m ²)	30.7 \pm 6.1
Waist To Hip ratio	0.86 \pm 0.06
Calcium (mg/dl)	9.7 \pm 0.5
Alkaline Phosphatase(IU/l)	91 \pm 33.5
Vitamin D(ng/ml)	21.4 \pm 8.9

6-Thioguanine Acts on Gli2 to Decrease PTHrP Expression and Osteolysis. M. P. Nguyen¹, J. A. Sterling², A. J. Roberts^{3*}, G. R. Mundy². ¹Department of Medicine, Vanderbilt University, Nashville, TN, USA, ²Center for Bone Biology, Department of Clinical Pharmacology, Vanderbilt University, Nashville, TN, USA.

Breast and lung tumor cells frequently metastasize to bone, where they cause osteolytic bone destruction. Parathyroid hormone-related peptide (PTHrP) has been identified as one of the major mediators of osteolysis and hypercalcemia in tumors that metastasize to bone. Thus, compounds that inhibit tumor cell production of PTHrP can potentially be clinical treatments for osteolytic metastases. Our laboratory has previously demonstrated that guanosine nucleotides, represented by 6-thioguanine (6-TG), reduces PTHrP production, tumor-induced osteolysis, and tumor burden in bone. 6-TG was identified from screening a diverse library of small molecular weight chemicals that inhibit PTHrP promoter activity, using a cell-based screen with PTHrP promoter as the molecular target (Gallwitz et al, JCI 2002). This observation raises the possibility that 6-TG or a related compound may be effective in reducing PTHrP production by cancer cells and thus provides a useful therapeutic approach to hypercalcemia and osteolysis caused by PTHrP excess. In this study, we have attempted to determine the molecular mechanism by which 6-TG inhibits the PTHrP promoter. Recently, we have found that PTHrP production in cancer cells is regulated by activation of the developmental Hedgehog (Hh) pathway, specifically by the Hh pathway transcriptional activator, Gli2. We hypothesized that 6-TG inhibits PTHrP through regulating Gli2 expression. To test this hypothesis we utilized the osteolytic and PTHrP producing tumor cells, RWG2, a human squamous cell carcinoma, and MDA-231, breast carcinoma cells. We treated these cells with either 6-TG or purine as a negative control. We found that 6-TG treatment of RWG2 and MDA-231 human cancer cells decreases Gli2 expression by Western blot and real-time PCR by approximately 10-fold. These effects correlated with decreases in PTHrP expression by real-time PCR and PTHrP promoter-luciferase activity. Since 6-TG can decrease Gli2 mRNA expression, it is also possible that 6-TG directly affects Gli2 promoter activity. We have therefore cloned the Gli2 promoter to determine if 6-TG can repress Gli2 promoter activity in osteolytic tumor cells. Currently, our data demonstrates that 6-TG inhibits PTHrP through regulating Gli2, suggesting that specific inhibitors of Gli2 expression may be a potential approach for treating osteolytic metastases.

Non-Canonical Hedgehog Signaling Regulates Gli2 and PTHrP Expression in Osteolytic Cancer Cells. J. A. Sterling¹, S. S. Padalecki², B. G. Grubbs², M. P. Nguyen¹, A. J. Roberts^{3*}, B. O. Oyajobi², G. R. Mundy¹. ¹Center for Bone Biology, Vanderbilt University, Nashville, TN, USA, ²University of Texas Health Science Center, San Antonio, TX, USA.

Cancer cells cause osteolysis and hypercalcemia by over-production of PTHrP. We have shown previously that PTHrP expression and osteolysis by cancer cells are regulated by Gli2, a Hedgehog (Hh) signaling molecule. Gli2 is a developmental protein mis-expressed in some tumors. Understanding whether Gli2 expression in cancer cells is regulated through Hh receptor signaling or other mechanisms is important for target-based drug approaches for inhibiting Hh signaling and PTHrP in osteolytic breast cancer. To clarify this, we have used several approaches. We examined cancer cells associated with increased PTHrP expression for expression of Hh signaling receptors and determined the effects of specific receptor antagonists. The absence of these receptors would indicate the Hh pathway is stimulated independently of Hh ligand. We also determined the effects of antagonists specific for Gli2. Hh molecules utilize two receptors Smoothened (Smo), the signaling receptor, and Patched (Ptc). We found that osteolytic MDA-231 human breast cancer cells express Ptc but do not express Smo. Without the presence of the signaling receptor, the observed increase in Gli2 is unlikely due to canonical signaling. To verify that Gli2 is not regulated by canonical Hh signaling, we utilized the Hh antagonist cyclopamine. Cyclopamine had no effect on growth of MDA-231 cells in vitro and did not decrease Gli2 or PTHrP expression by real-time PCR. When athymic nude mice were inoculated with MDA-MB-231 cells via the intracardiac route, and treated with 10mg/kg/day of cyclopamine, there was no inhibitory effect on tumor-induced osteolysis. However, overexpression of intracellular molecules that modulate Hh signaling by down-regulating Gli2 protein in MDA-231 cells decreased PTHrP expression. Specifically, Suppressor of Fused (SuFu), a protein that binds to Gli2 and prevents it from translocating to the nucleus, blocked Gli2 stimulation of PTHrP, while a dominant-negative SuFu increased PTHrP promoter activity. Furthermore, overexpression of a dominant-negative β -TrCP, the E3 ligase which targets Gli2 for ubiquitination and proteasomal degradation, increased PTHrP promoter activity by inhibiting the degradation of Gli2. Together, our data confirm that Gli2 mediates PTHrP expression, and that Gli2 expression is not driven by signals initiated by Hh in breast cancer. Although these data suggest Hh antagonists such as cyclopamine will not be effective treatments for osteolytic bone metastases, they do indicate the potential utility of targeting Gli2 degradation.

TGF β Drives Expression of Osteogenic Molecules in Bone Metastatic Breast Cancer Cells: A Potential Mechanism for Breast Cancer Osteomimicry. M. Ni^{1*}, J. A. Sterling², A. Roberts^{3*}, L. Lin^{3*}, G. R. Mundy², R. L. Caldwell⁴. ¹Department of Pharmacology, Vanderbilt University School of Medicine, Nashville, TN, USA, ²Department of Medicine/Clinical Pharmacology, Vanderbilt University School of Medicine, Nashville, TN, USA, ³Department of Pharmacology, Vanderbilt University School of Medicine, Nashville, TN, USA, ⁴Orthopaedics and Rehabilitation, Vanderbilt University School of Medicine, Nashville, TN, USA.

As tumor cells leave the primary environment, expression of molecules important for homing to the targeted organ ensues. For bone metastatic cancer cells, these molecules are similar to those expressed by bone cells, a process called osteomimicry. They include Runx2 and other molecules in the Wnt/B-catenin pathway which are important in osteoblast differentiation. Several groups have reported similar findings, yet the significance of these molecules is unclear. We have previously demonstrated that osteolytic breast cancer cells express the Hedgehog (Hh) signaling molecule Gli2, which drives BMP2 expression and the Wnt/B-catenin pathway in osteoblasts. We hypothesized that expression of BMP2 and Wnt/B-catenin pathway components are dependent on activation of the Hh pathway in breast cancer cells. We found that wild type (WT) MDA-MB-231 human breast cancer cells express Gli2 and BMP2. Since breast cancer cells in bone are exposed to high concentrations of TGF- β , we examined these cells for Gli2 and BMP2 regulation by TGF- β . We also examined MDA-MB-231 cells deficient in TGF- β signaling (DN-TGF- β RII). In WT MDA-MB-231 cells, we found high levels of BMP2 expression that were increased after TGF- β treatment. BMP2 expression was absent in DN-TGF- β RII cells. We found TGF- β treatment increases BMP receptor type II (BMPRII) expression in WT cells, suggesting that bone metastatic breast cancer cells are able to respond to the observed increase in BMP2. To determine if TGF- β could increase BMP2 signaling, we tested the effect of TGF- β on a SMAD6 promoter-reporter construct, revealing that TGF- β increases activity from the SMAD6 promoter. Contrary to other tumor cell types that exhibit decreased proliferation after BMP2 treatment, cell proliferation assays did not indicate a BMP2-mediated growth inhibition in WT breast cancer cells. We then examined an MDA-MB-231 clone over-expressing a dominant-negative, kinase-deficient BMPRII and found decreased tumor cell proliferation compared to WT cancer cells. Our data suggest that the Hh pathway, and specifically Gli2, may drive expression of downstream molecules implicated in osteomimicry, and that the process is enhanced by TGF- β expression in the bone metastatic microenvironment.

Fracture Risk Factors in Breast Cancer Survivors with Chemotherapy-induced Amenorrhea. K. M. Winters-Stone^{*1}, L. Nail^{*1}, A. Schwartz^{*2}, K. Witzke^{*3}. ¹School of Nursing, Oregon Health & Science University, Portland, OR, USA, ²School of Nursing, Arizona State University, Tempe, AZ, USA, ³Kinesiology, California State Univ., San Marcos, CA, USA.

Premenopausal breast cancer survivors (BCS) who experience chemotherapy-induced amenorrhea may have elevated fracture risk due to both chemotherapy and hypoestrogenism. Low estrogen is associated with bone loss and possible neuromuscular declines, whereas chemotherapy for breast cancer is also associated with bone loss, and with weight gain and neurological symptoms. Our pilot study aimed to describe the baseline and one-year change in fractures, falls and bone health in breast cancer survivors with premature menopause within one year following treatment completion. We collected baseline and one year follow-up data to describe changes in fractures and risk factors over time in premenopausal women with early stage breast cancer who experienced chemotherapy-related loss of menstrual cycles (N=47; mean age: 46 yrs; 12.2±4.5 mos. post-chemotherapy). Data on premenopausal, cancer-free controls (N=30; mean age: 41 yrs) were used as a reference group. Bone health was assessed by measuring bone mineral density (BMD) of the proximal femur (hip) and lumbar spine via DXA (Hologic Discovery Wi) and by measuring bone turnover via levels of serum osteocalcin (OC) and urinary deoxypyridinoline cross-links (Dpd). DXA data were also described as T-scores derived from spine and hip BMD values categorized as either normal (≥1) or low (<1). Baseline fall and fracture history were assessed retrospectively by questionnaire and prospectively over 12-months by monthly postcards. Comparisons between groups were determined by ANCOVA on baseline and 12 month values, adjusting for group differences in age and by chi-square for frequency data. There were no significant differences between groups for spine or hip BMD at either time point. However, more BCS were classified as having low spine BMD compared to controls both at baseline 39% vs. 17% for BCS and controls, respectively, p=.06 and at follow-up (44% vs. 20% for BCS and controls, respectively, p<.05). Levels of both OC and Dpd were significantly greater in BCS versus controls both at baseline and at 12-mos. follow-up (p<.01). In BCS, 11% had a history of fracture at baseline compared with 3% of controls (n.s.) and fracture rates over 1 yr were similar between groups. At baseline 42% of BCS had fallen in the last year compared to 50% of controls (n.s.), but over 1 year 70% of BCS experienced 1+ falls compared to 43% of controls (p=.05). Prematurely menopausal breast cancer survivors should be screened for bone health and fall history and if positive should be considered for therapeutic intervention to decrease fracture risk, such as exercise and/or medication.

Bone Metastases Select for Integrin $\alpha 2 \beta 1$ Negative Cells in Prostate Cancer Cell Line DU145. J. Yin, K. Tracy*, Y. Ward*, K. Kelly*. National Cancer Institute, Bethesda, MD, USA.

The metastatic process involves making and breaking contacts with different extracellular matrix (ECM) components in the primary tumor and metastatic sites. ECM binding is mediated by cell surface integrins. The integrin expression patterns in prostate cancer bone metastasis have not been well studied. To determine whether changes in integrin expression affect prostate cancer metastasis to bone, we studied the integrin expression profile of bone tropic cells in a xenograft model of prostate cancer metastasis. DU145 cells expressing the Ras effector mutant, Ras^{V12G37}, gain the ability to colonize bone, in part as a result of activating the Ral Pathway. Ras signaling through growth factor receptors is commonly activated in prostate cancer progression, and Ral is an important downstream pathway of Ras. All clones isolated from bone metastasis had increased bone metastatic activity compared with the parental DU145/Ras^{V12G37} cells as evidenced by development of more and larger bone metastases at earlier times. The DU145 cell line expresses low levels of integrin $\alpha 1$, and high level of integrin $\alpha 2$, αv , $\beta 1$, and $\beta 3$. Although over-expression of Ras^{V12G37} in a polyclonal population of DU145 cells did not significantly alter the expression of integrins $\alpha 1$, αv , $\beta 1$ and $\beta 3$, about 10% of cells demonstrated loss of integrin $\alpha 2$ expression. Interestingly, integrin $\alpha 2$ expression was lost in 4 out of 5 cell lines isolated from bone metastases, indicating selection within the population for rare $\alpha 2 \beta 1$ negative cells. In addition, loss of integrin $\alpha 2$ expression was correlated with high Ras expression and high RalA activity. We then performed cell adhesion assays on several ECM components including collagens I and IV, laminin and fibronectin. All isolated bone metastatic cell lines with low integrin $\alpha 2$ expression lost adhesiveness to collagen I and IV, while adhesion to laminin or fibronectin remained unchanged. These results suggest that cells with higher RalA activity and loss of integrin $\alpha 2$ are selected in the development of bone metastasis. Downregulation of integrin $\alpha 2$ has been observed in prostate cancer patients, and v-Ras has been shown to down-regulate integrin $\alpha 2$ expression. Our results indicate that high Ras activity and/or loss of integrin $\alpha 2$ may be a marker of prostate cancer bone metastasis.

Up-regulation of TACE in Monocytes Ameliorates their Deflected Differentiation into Osteoclasts and Dendritic Cells in Myeloma. M. Abe¹, M. Hiasa^{*2}, S. Kido¹, K. Takeuchi^{*1}, K. Kitazoe^{*1}, A. Oda^{*1}, H. Amou^{*1}, K. Kagawa^{*1}, T. Hashimoto^{*1}, S. Ozaki^{*1}, T. Matsumoto¹. ¹Department of Medicine and Bioregulatory Sciences, University of Tokushima Graduate School of Medicine, Tokushima, Japan, ²Orthodontics and Dentofacial Orthopedics, University of Tokushima Graduate School of Medicine, Tokushima, Japan.

Monocytes are a common precursor for both osteoclasts (OC) and dendritic cells (DC). M-CSF and RANK ligand induce osteoclastogenesis from monocytes, while GM-CSF and IL-4 in combination trigger the differentiation of DC. We demonstrated that GM-CSF and IL-4 up-regulate TNF-alpha converting enzyme (TACE) expression and activity in monocytes, which cleaves membrane-bound M-CSFR to disrupt M-CSF signaling and inhibit induction of osteoclastogenesis. Multiple myeloma (MM) cells affect the reciprocal regulation of monocytic differentiation into OC and DC lineages towards OC lineage to cause devastating bone destruction and immune suppression in MM. In the present study, we therefore explored a role of up-regulation of TACE in monocytes in the skewed induction of OC and DC differentiation by MM cells. GM-CSF and IL-4 up-regulated the levels of soluble M-CSFR in the co-cultures of monocytes with U266 MM cells. Addition of TAPI-0, a TACE inhibitor, substantially reduced the soluble M-CSFR levels enhanced by GM-CSF and IL-4, suggesting that up-regulation of TACE by GM-CSF and IL-4 mediates cleavage of cell-surface M-CSFR on monocytes in the presence of MM cells. Importantly, the GM-CSF and IL-4 treatment also disrupted osteoclastogenesis in rabbit bone cell cultures enhanced by U266 MM cells as well as by M-CSF and RANK ligand. Addition of TAPI-0 restored the MM cell-mediated osteoclastogenesis suppressed by GM-CSF and IL-4. In contrast, TAPI-0 potently suppressed CD1a+ DC differentiation induced by GM-CSF and IL-4 in the presence of MM cells. These results suggest that up-regulation of TACE by GM-CSF and IL-4 is able to disrupt osteoclastogenesis enhanced by MM cells, while inducing DC formation. Therefore, GM-CSF and IL-4 in combination or other alternatives to up-regulate endogenous TACE activity in monocytes may have a potential as a novel therapeutic maneuver to drive into DC lineage the monocytic differentiation deflected to OC lineage in MM.

In Vitro Effects of Zoledronic Acid Alone or in Combination with Radiation Therapy on Cells of the Metastatic Bone Environment. S. A. Arrington, B. S. Margulies*, E. R. Fisher*, M. J. Allen. Orthopedic Surgery, SUNY Upstate Medical University, Syracuse, NY, USA.

The specific aim of this current study was to determine the effect of zoledronic acid (ZA) on individual cell types involved in the metastatic bone environment. In addition we wanted to analyze whether ZA increased breast cancer cell sensitivity to radiation therapy. Mouse marrow stromal cells (ST2), mouse osteoblast-like cells (MC3T3), and human breast cancer cells (F10) were cultured with up to 100µM of ZA for two and seven days. Additionally, F10 cells were treated 24 hours after seeding with radiation (0 Gy to 20 Gy) alone or in combination with 5 µM ZA. Cells were assayed 7 days post-treatment. Cell viability was measured using an MTT assay. Treatment affects on cell cycle were analyzed using flow cytometry. ZA caused a dose-dependent decrease in cell viability with IC₅₀ ranging from 55 µM (F10 cells) to 7 µM (ST2 cells) and 5 µM (MC3T3 cells) 7 days post-treatment. This indicates that F10 breast cancer cells are less sensitive to ZA. F10 cells treated with 5 Gy radiation in combination with ZA showed significant decreases in cell viability compared to cells treated with 5 Gy alone (p=0.0406). Cell cycle analysis revealed G2/M arrest in ST2 cells treated with 5 µM ZA, whereas F10 cells displayed an increase in G0/G1. F10 cells treated with radiation showed a dose dependent increase in G2/M arrest, which was further increased by the addition of 5 µM ZA (Figure 1). These results indicate that when F10 cells are exposed to ZA, they may be blocked from entering S-phase. There was a dramatic increase of cells in G2/M after treatment with 10 Gy and 5 µM ZA, compared to treatment with 10 Gy alone. Taken together these results indicate that even though breast cancer cells are less sensitive to the effects of ZA, compared to marrow stromal cells and osteoblasts, ZA is still effective in causing disruptions to the cell cycle and decreasing cell viability. These effects are further enhanced when ZA is combined with radiation therapy. These findings correlate well with previous work in our mouse model, which also demonstrated decreased tumor damage in tumor-burdened bones treated with radiation and ZA compared to radiation alone.

Anti-tumor Actions of 2-Methoxyestradiol Is Accompanied by an Increase in Osteoprotegerin Expression in Osteosarcoma Cells. M. Benedikt*, J. P. Szatkowski*, K. L. Shogren*, G. Sarkar*, M. J. Yaszemski, A. Maran. Orthopedic Research, Mayo Clinic, Rochester, MN, USA.

Osteosarcoma is the most common bone malignancy that primarily affects children and young adults. About 30% of patients diagnosed with osteosarcoma will develop metastatic disease. Although a combination of surgery and adjunctive chemotherapy has resulted in improved survival rates, the mortality rate remains very high. 2-Methoxyestradiol (2-ME), a naturally occurring metabolite of 17 β -estradiol has been implicated in the inhibition of tumor cell proliferation. Previous results show that 2-ME did not affect the growth of normal osteoblasts in vivo and in vitro, but inhibited the proliferation and induced apoptosis in osteosarcoma cells. Several recent studies have demonstrated that the expression of bone remodeling proteins osteoprotegerin (OPG) and receptor activator of nuclear factor kappa B ligand (RANKL) are altered in different human cancers. To investigate whether the OPG/RANKL system is involved in the anti-tumor actions of 2-ME, we studied the expression of OPG protein in 2-ME-treated human osteosarcoma cells. Western blot analysis showed that OPG protein levels increased by 2-fold in 2-ME (10 μ M)-treated MG63 osteosarcoma cells. Furthermore a tumorigenic estrogen metabolite, 16 α -hydroxyestradiol which does not induce cell death, had no effect on OPG protein levels. Our results also show that 2-ME treatment increased OPG protein levels in TE85, KHOS, 143B, ROS, SAOS, LM8 human osteosarcoma cells. Thus, these findings suggest that there may be a close association between OPG regulation and 2-ME-mediated cell death in osteosarcoma cells.

C-terminal PTHrP(109-119) in Human Serum and Urine Is a Useful Biomarker for Malignancies. D. Burton*¹, C. Chalberg*¹, K. C. Smith*¹, R. L. Fitzgerald², D. A. Herold², L. J. Deftos¹. ¹Medicine, Veterans Administration San Diego Healthcare System and University of California, San Diego, CA, USA, ²Pathology, Veterans Administration San Diego Healthcare System and University of California, San Diego, CA, USA.

Since PTHrP is the most common oncoprotein secreted by human cancers it is a logical biomarker for many malignancies. However, most serum immunoassays for PTHrP can only detect this oncoprotein when it is markedly elevated, usually late in the course of the cancer. This lack of sensitivity limits the clinical value of contemporary PTHrP assays, both research and commercial. In order to address this limitation, we applied newly-developed PTHrP immunoassays to the measurement of PTHrP in the serum and urine of human subjects. We utilized PTHrP immunoassays with differing immunochemical formats to evaluate the PTHrP signature in the serum and urine of patients with calcium and skeletal disorders. In the present study, we collected serum or urine samples from over 200 patients that were either normo- or hypercalcemic (Ca²⁺ > 10.6 mg/dL). We employed three human PTHrP epitope-specific immunoassays directed against human PTHrP amino acids 1-34, 38-64 and 109-119 with assay limits of detection of 2.0, 0.6 and 0.8 fmol/tube, respectively. The PTHrP(1-34) (N-PTHrP) species was undetectable in all urine specimens tested, while the PTHrP(38-64) form averaged 0.025 pmol/L. The PTHrP(109-119) (C-PTHrP) fragment was the most readily detectable form of PTHrP present in urine, averaging 0.52 pmol/L in our patient survey. Similar PTHrP fragment ratios were observed in the sera. Serum C-PTHrP levels ranged from undetectable to 3.1 nmol/L. Cancer patients had higher serum C-PTHrP levels than normal, non-tumor bearing subjects (p < 0.05). There was not a significant correlation between serum Ca²⁺ and serum C-PTHrP, which likely indicates inactivation by proteolysis of the hypercalcemia inducing N-PTHrP fragment. We next analyzed the serum and urine PTHrP from cancer patients using size-exclusion chromatography (Sephacryl S100 beads). Immunoreactive C-PTHrP peaks were observed in both fluids, but the N-PTHrP assay did not detect any PTHrP in the fractions. These results demonstrate the stability of the C-PTHrP species in biological fluids and the processing of the N-PTHrP species. Extension of our studies should lead to the development of testing procedures that may be useful in the early diagnosis and clinical management of patients with PTHrP-expressing cancers.

The Ubiquitin-Proteasome Pathway Is Dysregulated in Myeloma Cells in the Bone Microenvironment In Vivo. C. M. Edwards, J. A. Fowler, R. L. Caldwell, A. L. Bates*, J. R. Edwards, J. Zhang*, D. E. Foehr*, R. Parker*, A. Roberts*, G. R. Mundy. Vanderbilt Center for Bone Biology, Vanderbilt University, Nashville, TN, USA.

There is abundant evidence that myeloma cells are dependent on host cells for their aggressive behavior in vivo. Recent basic and clinical data shows that myeloma cells are exquisitely sensitive to proteasome inhibition, suggesting that the ubiquitin-proteasome pathway, which is present in all cells, is critical for myeloma cell growth and survival. We hypothesized that activity of the ubiquitin-proteasome pathway in myeloma cells may be increased by and dependent on host cells. We have examined this new concept using the well-characterized 5TGM1 murine model of myeloma. 5TGM1-GFP cells were inoculated into C57Bl/KaLwRij mice, resulting in tumor growth within the bone marrow and development of the characteristic osteolytic bone disease of myeloma. 5TGM1-GFP cells were then isolated from the bone marrow of myeloma-bearing mice by FACS and compared with pre-inoculation cells. A significant increase in chymotrypsin-like proteasome activity was found in 5TGM1 myeloma cells following in vivo growth in bone, as compared to the pre-inoculation cells. Protein profiling by MALDI mass spectrometry revealed a number of regulated proteins, including a reduction in free ubiquitin in myeloma cells following in vivo growth in bone. This decrease in free ubiquitin expression was confirmed by western blotting. Real time PCR demonstrated no significant difference in expression of ubiquitin mRNA in myeloma cells following in vivo growth in bone, suggesting post-translational regulation of ubiquitin in the bone microenvironment. Consistent with an increase in proteasome activity, a decrease in expression of β -catenin, which is degraded by the proteasome, was also demonstrated in myeloma cells isolated from bone when compared to the pre-inoculation cells. Treatment of pre-inoculation 5TGM1 myeloma cells with conditioned media from 14M1 stromal cells, which were isolated from myeloma-bearing mice, demonstrated a significant increase in proteasome activity suggesting the involvement of a soluble factor released from the host microenvironment in mediating the increase in proteasome activity. Our data demonstrate that the ubiquitin-proteasome pathway is dysregulated in myeloma cells within the bone microenvironment in vivo, associated with a reduction in free ubiquitin and an increase in proteasome activity. This suggests that the ubiquitin-proteasome pathway in myeloma cells may be controlled by host factors, and that these host-tumor interactions may contribute to the survival of myeloma cells within the bone microenvironment in vivo.

Prevalence of Secondary Causes of Osteoporosis Among Breast Cancer Patients with Osteoporosis and Osteopenia. P. M. Camacho¹, A. Dayal^{*1}, J. Diaz^{*1}, E. Nabhan^{*1}, M. Agarwal^{*2}, J. Norton^{*3}, P. Robinson^{*4}, K. S. Albain^{*4}. ¹Endocrinology and Metabolism, Loyola University Chicago, Maywood, IL, USA, ²Medicine, Christ Hospital, Oak Lawn, IL, USA, ³Cancer Center, Loyola University Chicago, Maywood, IL, USA, ⁴Hematology/Oncology, Loyola University Chicago, Maywood, IL, USA.

Purpose: The main objective of this study was to determine the prevalence of secondary causes of osteoporosis among breast cancer patients being evaluated for osteopenia (low bone mass) and osteoporosis.

Methods: We conducted a retrospective chart review of 238 postmenopausal women consecutively referred to Loyola University Medical Center Endocrinology clinics from 2000-2005, for the management of osteoporosis or osteopenia. Patients were divided into two groups: those without a history of breast cancer or NBC group (N=174), and those with breast cancer or BC group (N=64). The BC group was comprised of patients with early stage breast cancer in the midst of or considering adjuvant hormonal therapy with aromatase inhibitors. Histories and biochemical data from their initial consultation were analyzed. Statistical analysis of each patient population was performed to elucidate the prevalence of secondary causes of osteoporosis in patients with breast cancer relative to the group of patients without breast cancer.

Results: The demographics of the two groups differed in age (64.2 \pm 14.2 in NBC versus 59.5 \pm 10.6 in BC group, p=0.015), mean weight (63.5 \pm 13.7 in NBC versus 73.62 \pm 20.95 kg in BC, p < 0.001), 25 OH Vitamin D levels (28.7 \pm 13.1 in NBC versus 34.03 \pm 15.1 ng/ml in BC, p = 0.019) and degree of bone loss (spine T score of -1.966 \pm 1.34 in NBC versus -0.918 \pm 1.41 in BC, p < 0.001). The presence of at least one secondary cause of osteoporosis was seen in 78.1% of the breast cancer patient group (excluding cancer-related therapies), and in 77% of the non-breast cancer group. Newly diagnosed metabolic bone disorders were seen in 57.8% of the breast cancer population. The most common secondary cause in both groups was vitamin D deficiency, which was seen in 37.5% of the breast cancer group and 51% of the non-breast cancer group. In the BC group, this was followed by idiopathic hypercalciuria (15.6% versus 8% in NBC, trend towards higher prevalence in BC than the NBC group p=0.085), normocalcemic hyperparathyroidism (3.1%) and primary hyperparathyroidism (1.6%).

Conclusion: We found a high prevalence of secondary causes of osteoporosis among breast cancer patients undergoing or considering adjuvant hormonal therapy with aromatase inhibitors. Previously published reports of bone loss and fractures seen in patients on such

agents may have been partly due to the presence of these disorders. It is prudent to obtain a baseline DXA and to screen patients with breast cancer for secondary causes of bone loss.

Environmental Influences on Variability in Levels of Bone Turnover Markers. O. S. Donescu¹, M. C. Battie^{*2}, T. Videman^{*3}. ¹Research, Toronto Rehabilitation Institute at University of Toronto, Toronto, ON, Canada, ²Physical Therapy, University of Alberta, Edmonton, AB, Canada, ³Rehabilitation Science, University of Alberta, Edmonton, AB, Canada.

Biochemical markers may capture the imbalance between bone formation and resorption and may also allow quantitative evaluation of rates of bone loss. Therefore, determinants of marker levels may also provide insights into factors influencing bone turnover and osteoporosis. The aim of the study was to estimate the influence of environmental factors (e.g. lifetime physical activities at work and leisure time, calcium intake, smoking, alcohol and coffee consumption) in determining procollagen type I amino-terminal propeptide (PINP), type I collagen carboxy-terminal telopeptide (ICTP) and urinary amino-terminal type I collagen telopeptide (NTx) marker levels in 147 monozygotic (MZ) and 153 dizygotic (DZ) male twin pairs.

Biochemical markers of bone turnover originating from type I procollagen synthesis or type I collagen breakdown were examined in men using a classic twin study design based on MZ and DZ twins. An extensive, structured interview was conducted to obtain data on exposure to suspected environmental and behavioral risk factors, such as recent and lifetime experiences of smoking, alcohol, coffee consumption, dietary calcium intake, lifetime leisure time activities and sport participation, sitting at work, job heaviness, as well as medical history and medication use. Clinical examinations of each subject were also conducted, including dual magnetic resonance imaging (MRI) of the lumbar spine, serum and urine samples (obtained over a one and a half-day period) and lifting tests. After excluding subjects with medical conditions or taking medications thought to influence biological variation of markers, 98 MZ and 108 DZ male twin pairs were left. Subjects age ranged from 40-56 years (48 +/- 7.9) for MZ and 42-56 (49 +/- 6.7) for DZ twins.

The effect of dietary calcium, smoking, coffee and alcohol, as well as lifetime physical activity (e.g. leisure time activities, sport participation, occupational loading) were not significant determinants of biochemical marker levels in this group of adult men. The genetic and environmental variance in bone markers PINP, NTx and ICTP was largely independent from the environmental or behavioral factors studied, suggesting that these factors have a minor influence in bone formation and degradation in men. In conclusion, possible interventions focusing on these behavioral factors in adulthood might be of limited value in targeting bone resorption or formation.

Monitoring Therapy: Are Bone Resorption Markers (BRM) During Osteoporosis Treatment with Bisphosphonates Within the Lower Half of the Premenopausal Range? D. A. Eekman^{*1}, H. J. G. M. Derikx^{*2}, I. E. M. Bultink^{*1}, A. P. van Zanten^{*3}, W. F. Lems¹. ¹Rheumatology, VU University Medical Center, Amsterdam, The Netherlands, ²Rheumatology, Slotervaart Hospital, Amsterdam, The Netherlands, ³Clinical Chemistry, Slotervaart Hospital, Amsterdam, The Netherlands.

Background and objectives: Although oral bisphosphonates (OB) are efficacious, adherence to anti-osteoporotic treatment is generally poor. It has been suggested that adequate monitoring of the effects of therapy with BRM has a positive effect on adherence (1). We observed in which proportion of patients, diagnosed with osteoporosis and treated with an OB, the urinary excretion of the total fraction of deoxypyridinoline (DPD) is in the lower half of the premenopausal range. (2)

Patients and methods: all consecutive patients visiting the osteoporosis outpatient clinic of the Slotervaart hospital using an OB for at least three months were enrolled. Urine samples were collected by asking the patients to collect their fasting second morning-void. Total DPD was determined by high performance liquid chromatography using commercial reagents (Chromsystems, München, Germany). Day to day variation of this technique is lower than 8 %. The mean (SD) urinary excretion of DPD is 9.3 (2.2) µmol/mmol creatinine, based on fasting second morning-void samples of 35 healthy premenopausal women at 3 consecutive moments. Results: 38 patients were enrolled, 31 women and 7 men, mean age (SD) 69 (11) years. The mean BMD (SD) of the spine and hip was 0.800 (0.147) g/cm² and 0.704 (0.086) g/cm², respectively. All patients were treated with bisphosphonates: alendronate (22), risedronate (11), ibandronate (5).

The mean (SD) urinary excretion of DPD was 8.86 (6.44) µmol/mmol creatinine. In 71% of the patients the DPD excretion was below the premenopausal mean (<9.3 µmol/mmol creatinine).

Conclusion: In our ongoing study in patients with osteoporosis chronically treated with bisphosphonates, bone resorption was within the premenopausal range in more than 70% of the patients: the (biological) target of therapy.

Our data illustrate that measuring BRM is feasible in a non-academic outpatient clinic, and suggest that measurement of urinary excretion of DPD might be a valuable tool to improve adherence to therapy.

Changes in Bone Resorption Markers During Osteoporosis Treatment with Oral Bisphosphonates. D. A. Eekman^{*1}, H. J. G. M. Derikx^{*2}, I. E. M. Bultink^{*1}, A. P. van Zanten^{*3}, W. F. Lems¹. ¹Rheumatology, VU University Medical Center, Amsterdam, The Netherlands, ²Rheumatology, Slotervaart Hospital, Amsterdam, The Netherlands, ³Clinical Chemistry, Slotervaart Hospital, Amsterdam, The Netherlands.

Background: Adherence to anti-osteoporotic treatment is generally poor; it has been suggested that monitoring therapy with measurement of bone resorption markers (BRM) might improve it. (1) In large observational studies it has been shown that already after 3 months of therapy, BRM can be decreased by more than 30%. (1) Several BRM are available; we investigated the changes in the total fraction of deoxypyridinoline (DPD) during treatment with bisphosphonates.

Objectives: to observe in daily practice in which proportion of patients, diagnosed with osteoporosis and subsequently treated with bisphosphonates, the urinary excretion of DPD has decreased by 30% or more, at least 3 months after starting with therapy.

Patients and methods: in this ongoing project, all consecutive patients who come to the osteoporosis outpatient clinic of the Slotervaart Hospital and start with bisphosphonates are enrolled. Urine samples are collected by asking the patients to collect their second fasting urine. DPD is determined by high performance liquid chromatography using commercial reagents (Chromsystems, München, Germany). Day to day variation of this technique is lower than 8 %. Reference values were determined in a group of 35 healthy premenopausal women as 6.6 - 15.4 µmol DPD / mmol creatinine.

Results: so far 19 patients are enrolled, 18 women and 1 man, mean (SD) age 67 (15) years. The mean BMD of the spine was 0.806 g/cm² and of the hip 0.699 g/cm². All patients started with bisphosphonates: alendronate (7), risedronate (5), ibandronate (6) and pamidronate (1). Seventy-nine percent of the patients were treated with calcium/vitamin D.

During anti-osteoporotic treatment the mean (SD) decrease in urinary excretion of DPD was 36% (18). In 12 of the 19 patients (63%), the urinary excretion decreased by more than 30%.

In 6 of the 7 patients we found an explanation for the non-occurrence of a decrease in bone resorption: secondary osteoporosis in 3 and in 3 patients it appeared that they had not taken their medication adequately.

Conclusion: In 63 % of the patients we found a favourable bone marker response. In the others we found either a cause for secondary osteoporosis, or a failure in adherence to therapy.

We think that this ongoing project (so far in a limited number of patients) emphasizes that it might be useful to use the markers of bone resorption during osteoporosis treatment with bisphosphonates in daily practice.

Markers of Bone Turnover in Peripubertal Girls. K. M. Fagerlund^{*1}, M. Lehtonen-Veromaa^{*2}, T. Möttönen^{*3}, A. Leino^{*4}, J. Viikari^{*3}, H. K. Väänänen^{*1}, J. M. Halleen⁵. ¹Institute of Biomedicine, Department of Anatomy, University of Turku, Turku, Finland, ²Paavo Nurmi Center, Sport and Exercise Medicine Unit, Department of Physiology, University of Turku, Turku, Finland, ³Department of Medicine, Turku University Central Hospital, Turku, Finland, ⁴Central Laboratory, Turku University Central Hospital, Turku, Finland, ⁵Pharmatest Services Ltd, Turku, Finland.

Puberty is a time of large increase in bone mass and it is associated with high values of bone turnover markers. During puberty, bone turnover is affected by bone remodeling, bone modeling and growth. Little research has been conducted on serum levels of bone turnover markers of children at different ages. We studied changes in bone turnover markers and their association with changes in bone mineral density (BMD) in peripubertal girls. A total of 170 healthy peripubertal Caucasian girls aged 10-19 years were included in the study. The following serum markers of bone turnover were measured: TRACP 5b, a marker of osteoclast number; C-terminal cross-linked telopeptides of type I collagen (CTX), a marker of osteoclast activity; bone-specific alkaline phosphatase (BAP), a marker of osteoblast number; and procollagen I N-terminal propeptide (PINP), a marker of osteoblast activity. The mean activity of a single osteoclast was determined at each age group using the resorption index CTX/TRACP 5b, and the mean activity of a single osteoblast using the formation index PINP/BAP. Turnover index was calculated as the ratio of CTX/PINP. BMD was measured from lumbar spine (LBMD) and femoral neck (FBMD) at baseline, 2 and 6 years. All bone turnover markers correlated significantly with each other and with LBMD and FBMD. Highest levels of all bone turnover markers were observed at the age of menarche (10-12 years). The values decreased during aging until they reached the normal adult levels at the age of 17. BAP and TRACP 5b decreased at a similar rate, while PINP decreased at a higher rate and CTX at a lower rate. As a result, the resorption index and turnover index increased and the formation index decreased up to the age of 17. These results demonstrate that bone turnover markers decrease and correlate significantly with BMD in growing children. The number of osteoclasts and the number of osteoblasts is decreased at a similar rate. However, osteoblast activity is decreased at a higher rate than osteoclast activity, and the mean activity of a single osteoblast is decreased, while the mean activity of a single osteoclast is increased up to the age of 17.

Association of Serum FGF-23 and Urinary γ -glutamyltransferase (GGT) with Bone Mineral Density: Hiroshima Cohort Study. S. Fujiwara¹, W. Ohishi^{*1}, N. Masunari^{*1}, K. Ikeda². ¹Clinical Studies, Radiation Effects Research Foundation, Hiroshima, Japan, ²Bone and Joint Disease, National Center for Geriatrics and Gerontology (NCGG), Obu, Japan.

Recently, γ -glutamyltransferase (GGT) was identified as a novel bone-resorbing factor (J Biol Chem 2004, Endocrinology 2007), and its urinary excretion correlated with bone resorption activity in the body (Bone 2006). Fibroblast growth factor (FGF)-23 has emerged as an endocrine regulator of phosphate and vitamin D metabolism, and is a product of osteocytes. The objective of this study was to determine if serum FGF-23 and urinary GGT are related to bone mineral density (BMD) in a population-based cohort. The study population consisted of 1,380 subjects (478 men and 902 women) aged 59 to 101 years old (average age 72.3), followed up by biennial health examinations. Serum FGF-23, and urinary CTX and NTX were measured by ELISA kits. GGT activity in the urine was determined by autoanalyzer and corrected for creatinine concentration. BMD was measured in the spine and the hip by dual X-ray absorptiometry (QDR-4500, Hologic). Multiple linear regression was used for analysis. The study protocol was approved by the ethics committee of the Radiation Effects Research Foundation, and written informed consent was obtained from all participants. Serum FGF-23 concentration was found to increase with age, but no sex difference was observed. Serum FGF-23 concentration correlated positively with body weight and serum creatinine concentration, and negatively with height. After adjusting for age, sex, and body weight, serum FGF-23 concentration was associated positively with spinal BMD ($p=0.01$). Urinary GGT excretion was higher in men than in women, and increased with age with marginal significance ($p=0.08$). Positive correlation was observed between urinary GGT and urinary CTX ($p<.0001$) and NTX ($p<.0001$). After adjusting for age, sex, and body weight, urinary GGT was associated negatively with spinal ($p=0.05$) and hip BMD ($p=0.02$). It is thus concluded that serum FGF-23 and urinary GGT are potential makers for bone metabolism.

A New Specific Immunoassay for Intact Serum TRACP5b Demonstrates Increased Sensitivity in Osteoporosis. Y. Lhoste^{*}, P. Vergnaud^{*}, P. Garnero. Synarc, Lyon, France.

Tartrate resistant acid phosphatase 5b (TRACP5b) is secreted by osteoclastic cells and is closely related to TRACP isoenzyme 5a which is mainly derived from macrophages. Current immunoassays for circulating TRACP 5b use antibodies that recognize both intact and fragmented TRACP5a and 5b, selectivity for TRACP5b being partly achieved by performing the measurements at optimal pH for TRACP5b. Recently a new immunoassay (Metra® TRACP5b, Quidel Corporation) has been developed. It uses two monoclonal antibodies raised against purified bone TRACP5b that shows limited crossreactivity for purified TRACP5a. One antibody captures active intact TRACP5b and the other eliminates interference of inactive fragments. The activity of TRACP5b is assessed using the substrate 2-chloro-4-nitrophenyl phosphate (CNPP) which is more specific for TRACP 5b than pNPP used in existing assay. The aim of this study was to evaluate the analytical and clinical performance of this new specific TRACP5b ELISA (M-TRACP5b) in postmenopausal osteoporosis.

The M-TRACP5b assay exhibited a cross-reactivity of only 8.5% for circulating heparin-chromatography purified TRACP 5a. The intra and inter assay coefficients of variation were below 6%. Analytical dilution of serum samples and recovery of spiked human bone purified TRACP5b ranged from 84 to 101% and 95 to 106%, respectively. The sensitivity of the test has been determined at 0.08 U/L. Intra-patient coefficient of variation assessed on 14 untreated postmenopausal women sampled 3 times over 2 months was 12%. In 103 healthy untreated pre and postmenopausal women, serum M-TRACP5b correlated significantly ($r=0.84$, $p<0.0001$) with the existing SBA-TRACP5b (SBA-Sciences). Serum M-TRACP5b increased by an average of 174% (3.32 ± 1.07 vs 1.21 ± 0.47 U/L, $p<0.001$) in 48 untreated postmenopausal women compared to 55 healthy premenopausal women aged from 35 to 45 years. When expressed as SDs from the mean of premenopausal levels (T-score), postmenopausal levels were significantly higher for M-TRACP5b than SBA-TRACP5b (mean T-score: +4.5 vs +2.9, $p<0.001$). After 3 months of treatment of 42 osteoporotic women with alendronate (oral 10 mg/day), the decrease of serum M-TRACP5b was significantly larger than that of SBA-TRACP5b [median (25, 75 pct): -44% (-62, -29%) vs -28% (-37%, -9%), $p<0.001$]. In conclusion, the new ELISA for intact TRACP5b has a low cross-reactivity with circulating TRACP5a, demonstrates good analytical performances and is highly sensitive to detect changes of osteoclastic number/activity following menopause or bisphosphonate therapy.

Effect of Diet and Exercise-induced Weight Loss on Regional and Total Body BMD of Obese Subjects. H. S. Barden¹, M. K. Oates^{*2}, R. Huizenga^{*3}. ¹GE Healthcare, Madison, WI, USA, ²Mary K Oates MD, Santa Maria, CA, USA, ³Cedars Sinai Medical Center, Los Angeles, CA, USA.

The effect of weight loss on bone densitometry measurements is a topic of interest for subjects and clinicians participating in weight loss programs. Some researchers have suggested that dual-energy x-ray absorptiometry (DXA) measurement of bone mineral

content (BMC) or bone area in obese subjects might be compromised by potentially negative effects of increased soft tissue thickness and increased x-ray attenuation on bone edge detection. The Lunar iDXA (GE Healthcare) uses a high-definition detector to provide improved image quality, precision and accuracy, especially in obese subjects. Recently, obese subjects participating in a weight-loss reality television show were measured with iDXA at the beginning and end of the 8-month program.

We measured 25 female and 22 male subjects at total body, lumbar spine (L1-L4) and proximal femur before and after the weight loss and aggressive exercise program. Average (SD) weights at baseline were 110 kg (9.7 kg) and 152 kg (20.0 kg) for females and males, respectively. Average (SD) weight losses were 27.5 kg (12.1 kg) and 49.3 kg (20.0 kg) for females and males, respectively. Percent weight losses for females and males were ~25% and 32%, respectively.

BMD change with weight loss was minimal (-1% or less) for total body and total femur. Lumbar spine BMD increased 1.5% and 6% for females and males, respectively. Average changes in bone areas were negligible (<0.4%) for all regions, indicating consistent edge detection with changing body weight and no magnification errors due to changes in distance of the bone above tabletop. Regressions of BMD and Area change with weight loss were non-significant for total body and total femur. There was a significant increase in BMD with weight loss in men at the spine. It is unclear if the larger increase in spine BMD seen in men vs women, despite losing a greater percent of their total weight, is related to observed greater weight-bearing aerobic and weight-lifting exercise, greater initial percentage lean mass or hormonal differences.

We conclude that bone results with the iDXA appeared relatively unaffected by rapid, large changes in weight in these very obese subjects. BMD changes were minimal for all regions with the exception of L1-L4 in men, and bone area changes for all regions were negligible. Table 1. Bone Densitometry Changes with Weight Changes in Obese Subjects

		Females	Males
		% Change (SD)	% Change (SD)
Total Body	BMD	-0.4% (1.5%)	-0.8% (2.6%)
	BMC	-0.7% (1.8%)	-1.0% (2.3%)
	Area	-0.3% (1.9%)	-0.1% (1.9%)
Spine L1-L4	BMD	1.5% (3.0%)	6.4% (4.2%)
	BMC	1.2% (4.1%)	6.3% (5.2%)
	Area	-0.3% (1.6%)	-0.2% (2.6%)
Total Femur	BMD	-1.1% (2.4%)	-0.4% (3.3%)

Association Of Vitamin D Status With Bone Mineral Density Considering Seasonal Changes of Vitamin D. S. Choi^{*}, B. Kim^{*}. Family Practices and Community Health, Ajou University Hospital, Suwon, Republic of Korea.

Vitamin D deficiency that causes secondary hyperparathyroidism has been considered as major contributor for osteoporosis. Serum 25-hydroxyvitamin D level has seasonal changes. We assessed whether low random serum 25-hydroxyvitamin D level can indicate vitamin D deficiency that leads low bone mineral density considering seasonal variation. Subjects for this study were 2,878 women who had periodic health examination in Ajou university hospital. We measured serum 25-hydroxyvitamin D level by radioimmunoassay and bone mineral density by DEXA.

Serum 25-hydroxyvitamin D levels were high in summer and autumn, low in winter and spring. However, serum 25-hydroxyvitamin D levels did not reflect bone mineral density at any season.

Serum 25-hydroxyvitamin D levels on a spot represent the transient vitamin D status, not vitamin D status affecting long term bone mineral density. When 25-hydroxyvitamin D levels are used to detect the vitamin D deficiency, the cautious interpretation should be necessary.

Serum 25-OHVD levels in groups by BMD			
BMD in L2-L4 spines	n (%)	mean \pm SD	P-value
Normal	1740 (60.5)	15.630 \pm 7.8720	0.618
Osteopenia	861 (29.9)	15.949 \pm 8.7178	
osteoporosis	277 (9.6)	15.898 \pm 8.9077	

Serum 25-OHVD levels in groups by BMD-Summer			
BMD in L2-L4 spines	n (%)	mean \pm SD	P-value

Longitudinal Patterns in Bone Mass Measurement Among U.S. Medicare Beneficiaries.

J. R. Curtis¹, L. Carbone², H. Cheng¹, B. Hayes³, A. Laster⁴, R. Matthews⁵, K. G. Saag¹, R. Sepanski⁵, B. Tanner⁶, C. Womack³, E. Delzell¹. ¹University of Alabama at Birmingham, Birmingham, AL, USA, ²Veterans Affairs Medical Center, Memphis, TN, USA, ³University of Tennessee, Memphis, TN, USA, ⁴Arthritis & Osteoporosis Consultants of the Carolinas, Charlotte, NC, USA, ⁵University of Tennessee, Nashville, TN, USA, ⁶Vanderbilt University, Nashville, TN, USA.

Background: The rising burden of osteoporosis has increased the importance of bone mass measurement (BMM). We examined longitudinal changes in BMM among older U.S. Medicare beneficiaries.

Methods: Using Medicare data (1999-2004), we studied beneficiaries age \geq 65 with part A+B, not HMO (A+B-HMO) and in the 5% sample. We identified central DXA claims performed in a physician office (non-facility) or hospital (facility); peripheral DXA; or other BMM. The number of persons with \geq 1 test/yr was divided by the number of beneficiaries to derive the % of eligible persons tested. The number of tests was multiplied by 20 to derive annual national estimates. For persons eligible in 2004, we added data from earlier years to obtain a cumulative prevalence of DXA utilization.

Results: The number of BMM tests are shown (Table); use of central DXA approximately doubled over 5 years, and ~2/3 were performed in physician offices. The proportion of beneficiaries receiving any BMM each year increased from 5.4% (1999) to 8.5% (2004); utilization among women from 8.5% to 13.2%; among men from 0.9% to 2.0%; among blacks from 2.3% to 5.2%; and among whites from 5.7% to 8.8%.

In 2004, there were an estimated 2.24 million central DXA scans; utilization among persons age 65-69, 70-79, and \geq 80 was 9.1%, 9.6%, and 6.8%. Across regions, DXA utilization in 2004 was highest in the South (8.9%) and lowest in the Midwest (7.9%). Among persons eligible in 2004, adding 1-5 prior years increased the cumulative prevalence of DXA utilization from 7.7% to 15.5% (1 extra year), 19.8%, 23.9%, 28.8%, and 29.6% (5 extra years).

Conclusions: The proportion of eligible U.S. Medicare beneficiaries age \geq 65 with A+B-HMO receiving BMM each year increased more than 50% from 1999-2004. A majority of scans were performed in physician offices. Data from only one year substantially underestimated BMM utilization; after aggregating up to 6 years of data, approximately 30% of beneficiaries received any BMM. Ongoing work will examine how these longitudinal patterns are affected by changes in DXA reimbursement.

	1999	2000	2001	2002	2003	2004
Central DXAs, non-facility	815,520	947,840	1,090,060	1,267,960	1,376,160	1,464,360

Quantitative Computed Tomography (QCT) of the Forearm Using Clinical CT Scanners.

K. Engelke¹, W. Timm¹, B. Stampa¹, E. Paris¹, T. Fuerst², C. Libanati³, H. K. Genant². ¹Synarc, Hamburg, Germany, ²Synarc, San Francisco, CA, USA, ³Amgen, Thousand Oaks, CA, USA.

This study aimed to demonstrate that clinical CT scanners can be used to determine BMD and geometrical parameters at the distal forearm. Dedicated pQCT scanners are typically used to assess BMD at the distal forearm from

single or limited peripheral skeleton slices. pQCT scanners use low power x-ray tubes, thus an evaluation of a larger volume requires long (several minutes) scanning time, increasing the likelihood of motion artifacts. In contrast, clinical whole body spiral CT scanners allow scanning of a 10 - 20 cm forearm section in seconds improving patient comfort and data acquisition quality.

We used a 120 kV, 1 mm slice thickness, pitch 1 scan protocol to image 10 cm of the forearm starting 0.5 cm distally of the radial styloid. BMD, cortical thickness and some geometrical parameters from single CT slices were measured using the Geanie software (Commit Inc. Finland). Custom software allowed extracting an arbitrary number of slices perpendicular to the radial axis at preconfigurable distances from the styloid process. A dedicated phantom developed in cooperation with QRM GmbH, Germany, was used for simultaneous calibration of the CT values to BMD. BMD accuracy as assessed from 110 scans of a European Forearm Phantom (EFP) was $3.0 \pm 3.6\%$.

We report cross sectional data from 252 postmenopausal women with QCT and DXA forearm scans. QCT analysis included 3 ultra distal slices (udQCT) located 10 mm proximal to the ulna styloid (distal end of the udDXA region), 1 distal slice (dQCT) located 20 mm proximal to the ulna styloid (proximal end of the udDXA region) and 1 mid slice (midQCT) located 40 mm proximal to the ulna styloid within the distal third of the midDXA region.

Along the radial axis, total radial BMD significantly changed for QCT from udQCT to dQCT by +105% and from dQCT to midQCT by +63%. The corresponding BMD change for DXA from udDXA to midDXA was +48%. Correlations (r^2) between QCT and DXA were: udQCT - udDXA: 0.46, average (udQCT and dQCT) - udDXA: 0.5, midQCT - midDXA: 0.48. A separate analysis of the cortex was performed for the distal and mid QCT slices. At the ultra distal location the cortex is too thin to be reliably analyzed. Cortical thickness significantly increased from distal to mid by +55%, trabecular BMD changed (n.s.) by -10%.

In conclusion forearm QCT, using clinical CT scanners, allows for an accurate and differential analysis of BMD along the axis of the radius. In addition QCT allows separate cortical and trabecular measurements, as well as the provision of radial geometrical parameters. Forearm QCT presents valuable information beyond that provided from simple projectional forearm DXA measurements.

Trabecular Bone Structural Analysis Using 64 Multi-Detector CT Scanner.

P. K. Saha¹, O. I. Saba², M. Hudson¹, A. Pick¹, G. El-Khoury¹, E. A. Hoffman¹. ¹University of Iowa, Iowa City, IA, USA, ²Siemens Medical Center Solutions USA, Inc., Iowa City, IA, USA.

Several studies have demonstrated association of skeletal diseases including osteoporosis and osteoarthritis with trabecular bone (TB) architectural changes. Multi-detector CT scanner (MDCT) is clinically widely available, less expensive, easy to use and fast to perform and has a low effective dose of about 0.05 mSv. The present study evaluates the role of MDCT for computing TB structural parameters. We imaged distal tibia in a cadaveric left leg of a 102 Y female using a Siemens Sensation 64 MDCT scanner at 120 kVp & 140 mAs to adequately visualize the bony structures. After scanning in a helical mode with a slice thickness of 0.6 mm and collimation of 12 x 0.6 mm, data was reconstructed at 0.3 mm slice thicknesses with a normal cone beam method utilizing a very sharp algorithm of U75u to achieve high image resolution. Three scans with pixel size of 0.15, 0.21 and 0.21 mm were acquired after repositioning the specimen each time. Imtek Micro-cat II was used for mCT imaging (28.8 μ m isotropic voxel) after removing soft tissue and dislocating tibia from the ankle joint. Three MDCT scans were used for reproducibility while the first scan was used for comparison with mCT data. Images were subjected to 3 sequential steps: 1) Bone volume fraction (BVf) computation using local thresholding, 2) resampling at 0.15 mm isotropic voxel using shape-based interpolation and 3) 3D rigid body registration. MDCT TB images have shown high visual agreement with TB architecture in mCT images (Figures 1a and b) and 3D continuity of TB structures is visible in longitudinal slices (Figure 1c). Ten cylindrical regions (ROI) each of 3.75 mm radius and length were chosen over TB region at 8 mm above distal cortical endplate. Four parameters, namely, bone volume/tissue volume (BV/TV), skeletal density (SkD), surface-curve ratio (SCR) and erosion index (EI) were computed for each ROI. Intra class correlations of three MDCT scans are 0.95, 0.97, 0.93 and 0.93 for BV/TV, SkD, SCR and EI while the r^2 values of linear correlation between MDCT and mCT data are 0.84, 0.87, 0.87, 0.98. Preliminary results of this study show high potential of MDCT as a modality for analyzing TB architecture.

Abnormal Trabecular Microarchitecture and Mechanical Competence in Premenopausal Women with Idiopathic Osteoporosis (IOP) Can Be Detected by High Resolution Peripheral Quantitative Computed Tomography (HRpQCT). A. Cohen¹, R. R. Recker², X. E. Guo³, X. H. Zhang^{*3}, J. Lappe^{*2}, H. F. Eisenberg^{*1}, D. J. McMahon¹, E. Shane¹. ¹Medicine, Columbia University, New York, NY, USA, ²Medicine, Creighton University, Omaha, NE, USA, ³Biomedical Engineering, Columbia University, New York, NY, USA.

IOP is an uncommon disorder in which young otherwise healthy individuals sustain low trauma fractures. In a retrospective biopsy study of premenopausal (PrM) women with IOP, we found reduced bone formation, increased resorption and, disrupted trabecular (Tb) architecture. We are now conducting a prospective study of the pathogenesis of decreased bone quality and mechanical competence in PrM IOP.

HRpQCT (XtremeCT, Scanco Medical AG) is a new imaging technology (resolution<100µm) that distinguishes cortical from Tb bone and yields in vivo measurements of Tb microstructure previously obtained only by bone biopsy. HRpQCT images can be subjected to finite element analyses (FEA) to determine elastic moduli (stiffness; E) in 3 directions. These E correlate well with mechanical strength.

To date, we have performed HRpQCT scans of radius and tibia in 8 IOP subjects (IOPs) and 9 healthy controls (C) (Table). IOPs and C had normal serum and urine calcium, PTH and 25-OHD; 2 causes of IOP were excluded by clinical/laboratory evaluation.

HRpQCT: At the radius, cortical density and thickness (Th) were similar in IOPs and C. In contrast, Tb number was 19% lower and separation 33% higher in IOPs, while Tb Th did not differ. The Tb network was also more heterogeneous (SD 1/TbN). Tibial cortical Th and Tb number were 20% and 26% lower respectively; Tb separation was 47% higher while Tb Th did not differ. At both sites, Tb density tended to be lower.

FEA: E's were lower in IOPs, but only significantly at the tibia. Variability of these measures was high.

In summary, our preliminary HRpQCT data show that PrM women with IOP have fewer, more widely separated trabeculae of similar thickness. This suggests that loss of entire Tb elements may underlie the more heterogeneous Tb network, decreased stiffness and increased fracture risk. It is not clear why decreased stiffness was found only at the tibia, as weightbearing would be expected to mitigate some of these differences. Future studies will focus on the pathogenesis of differences in Tb structure and mechanical competence. HRpQCT is a sensitive tool for investigation of bone microstructure and strength.

Peripheral Quantitative Computed Tomography (pQCT) Reproducibility of Volumetric Bone Density Measurements at the Radius and Tibia in Healthy Women. K. A. Szabo-Davenport¹, J. D. Adachi², D. Inglis^{*3}, L. Giangregorio^{*4}, C. Webber^{*5}, R. Tozer^{*6}, C. Gordon^{*7}, A. Papaioannou¹. ¹Department of Medical Sciences, McMaster University, Hamilton, ON, Canada, ²Department of Medicine, St. Joseph's Healthcare, McMaster University, Hamilton, ON, Canada, ³Department of Civil Engineering, McMaster University, Hamilton, ON, Canada, ⁴Department of Kinesiology, University of Waterloo, Waterloo, ON, Canada, ⁵Department of Nuclear Medicine, McMaster University, Hamilton, ON, Canada, ⁶Department of Pathology and Molecular Medicine, McMaster University, Hamilton, ON, Canada, ⁷Department of Radiology, McMaster University, Hamilton, ON, Canada.

Peripheral quantitative computed tomography (pQCT) allows the assessment of volumetric bone mineral density (vBMD) and the ability to separately evaluate cortical and trabecular bone compartments at peripheral sites. The objective of this cross-sectional study was to determine the in vivo reproducibility of vBMD measurements of the upper and lower extremity bones in healthy pre- and post-menopausal women via pQCT. Thirty women were recruited to participate in this study; 15 had scans taken of their non-dominant tibia and 15 had scans taken of their non-dominant radius. To better understand differences in bone density, distal (4% site) and diaphyseal sites of the radius (20% site) and tibia (38% site) were examined for trabecular and cortical bone. Trabecular vBMD (TRAB_DEN in mg/cm³), total vBMD (TOT_DEN in mg/cm³) and cortical vBMD (CRT_DEN in mg/cm³) were evaluated at all four sites. For each outcome, the root mean squared coefficient of variation (RMSCV) was calculated. In this population, the distal tibia gave the most favorable RMSCV for TOT_DEN and TRAB_DEN, while the

diaphyseal tibia gave the most favorable RMSCV for CRT_DEN. The data presented here suggest that pQCT scans at the tibia provide more reproducible measurements of total, cortical and trabecular bone.

	Root Mean Squared Coefficient of Variation (%)		
	TRAB_DEN	CRT_DEN	TOT_DEN
Radius 4%	2.0	2.2	5.1
Radius 20%	3.8	0.5	3.3
Tibia 4%	1.6	0.9	1.5
Tibia 38%	5.1	0.3	3.7

Novel MRI-Based Technique for Quantifying Cortical Bone Water and Porosity In-Vivo. A. Techawiboonwong^{*1}, H. K. Song^{*1}, B. S. Zemel^{*2}, F. W. Wehrli¹. ¹University of Pennsylvania, Philadelphia, PA, USA, ²The Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Cortical bone porosity is known to increase with age and to correlate inversely with mechanical strength. Measurement of porosity requires invasive techniques -- typically histology from sections or synchrotron µCT -- since typical pore sizes range from tens of micrometers (Haversian canals and osteocyte lacunae) to sub-micrometer (canaliculi). However, all pore spaces are occupied by water, which can be measured with suitable magnetic resonance imaging (MRI) techniques. However, surface interactions and diamagnetism of the mineral relative to water cause extremely short signal lifetime of the signal ($T_2 < 500\mu s$). Here we demonstrate the potential of a new MRI technique to quantify bone water (BW) as a new parameter of bone quality. In contrast to the signal void shown with conventional MRI for the tibial mid-shaft (Fig. 1a), ultrashort-TE radial images in conjunction with an external reference (containing 10% volume of H₂O in D₂O) allow BW quantification (Fig. 1b). MR images were obtained from women ages 20-40 years and 60-80 years (N=5 each) on a 3T scanner at a voxel size of 0.3x0.3x8mm³ in 9 minutes scan time. BW concentration was computed as $(I_{bone}/I_{ref})C_{ref}$ where C_{ref} is the H₂O concentration of the reference and I_{bone} and I_{ref} are the signal intensities corrected for losses during the excitation and spin relaxation. BW (vol %) was 27% larger in the older group (24.04±1.1 vs 17.44±2.2, p=0.0003). In contrast, BMD measured by pQCT at the same location was 1.122±0.033 versus 1.191±0.018 g/cm³, a difference of only 6% (p=0.003). The method was validated in situ in cortical bone of adult sheep where the H₂O fraction was controlled by graded exchange through immersion of the bone in H₂O/D₂O mixtures of varying volume fraction. Total BW was found to be ~19%. The linearity and goodness of fit ($r^2 > 0.99$) suggest the method to be highly accurate and precise (Fig. 2). It is concluded that our technique can quantify BW in vivo as a new index of bone quality.

Figure 1. Axial MR images of tibial mid-shaft acquired with (a) conventional gradient-echo; (b) ultrashort-TE radial MRI technique showing for cortical bone; circular structure on top of Fig. b is the reference sample.

Figure 2. Bone-water concentration quantified from MR images of sheep tibia specimens after graded isotopic exchange with D₂O.

Clinical Utility of Radiographic Texture Analysis (RTA) Performed on Densitometric Calcaneal Images. T. J. Vokes¹, M. Giger^{*2}. ¹Medicine/Endocrinology, University of Chicago, Chicago, IL, USA, ²Radiology, University of Chicago, Chicago, IL, USA.

RTA is an image-based non-invasive method of evaluating bone structure through computerized analysis of trabecular pattern of bone radiographs. We have applied RTA to calcaneal images obtained using a portable densitometer. RTA yields the following features: Fourier based measurements including RMS (root mean square variation, a measure of the variability in the radiographic texture pattern, the relative difference in the contrast between light and dark areas), and its directional measure, sdRMS (standard deviation of RMS) which is a measure of anisotropy of the trabecular pattern, and FMP (first moment of the power spectrum, a measure of the trabecular pattern's spatial frequency); and Minkowski fractal (MINK), a measure of roughness-smoothness of the trabecular pattern. 1) In 812 patients (739 female) referred for BMD at the University of Chicago we examined which biologic factors influence RTA. 2) In a subset of 331 postmenopausal women who had no secondary causes of and were not receiving treatment for osteoporosis, we determined how well RTA differentiated 48 women with from 283 women without vertebral fracture detected on VFA (Vertebral Fracture Assessment - densitometric spine image).

1) Relationship between RTA and biologic factors: In a multivariate regression analysis all RTA features were associated with age and weight ($p < 0.0001$ for all except $p = 0.02$ for MINK and age) while only MINK and RMS were associated ($p < 0.0001$) with heel BMD. 2) Utility of RTA in assessing fragility. In a univariate logistic regression analysis with presence of prevalent vertebral fractures as a binary outcome the separation between women with and without vertebral fractures using RTA and using BMD measurement were similar ($p = 0.002$ and $p < 0.001$ for sdRMS and MINK, respectively; $p = 0.01$, $p = 0.003$ and $p < 0.001$ for spine, heel and hip BMD, respectively). In a multivariate logistic regression, there was a significant association of vertebral fractures with RTA, BMD, and age with odds ratio (OR) of having a vertebral fracture of 2.0 for each decade increase in age ($p < 0.001$), OR=1.8 for 1 unit decrease in hip BMD T-score ($p = 0.003$), and OR=1.7 for 1 standard deviation decrease in sdRMS ($p = 0.003$) or MINK ($p = 0.008$).

These results suggest that RTA of heel images obtained using a portable densitometer characterizes bone properties not measured by BMD and that RTA provides assessment of fragility that is not captured by the currently used measurements such as BMD and clinical risk factors (age). Addition of RTA to BMD and clinical risk factors may improve the stratification of fracture risk.

Bone Varies the Spatial Distribution of its Mass, Rather Than its Mass, to Optimise Strength and Minimize Bulk. R. Zebaze¹, A. Jones^{*2}, A. Bohte^{*1}, Q. Wang^{*1}, M. Knackstedt^{*2}, E. Seeman¹. ¹Austin Health, Melbourne, Australia, ²ANU, Canberra, Australia.

Modelling and remodelling allow bones to adapt to the loading environment by modifying the spatial distribution of their mass rather than the mass itself. We hypothesized (i.) spatial distribution of cortical bone along the femoral neck (FN) as quantified by the variability in cortical thickness (CTh) around the cross sectional (CS) perimeter and along FN length is a better predictor of the cortical bone area (an indicator of axial compressive strength) than the average CTh, the commonly used estimator of cortical area, apparent density and strength indices. (ii.) The amount of material needed to optimise strength is minimized by varying the distribution of bone as compared to having a constant CTh around the CS perimeter.

The spatial distribution of cortical bone was quantified every 300 μ m along the FN (~200 slices/per specimen) using high-resolution micro-QCT in specimens from 13 Caucasian females (mean age 69 years). For each slice, CTh was measured at every degree around the CS perimeter and along the FN. The average FN CTh, the SD of CTh distribution (CTh SD), cortical area and total cross sectional area (TCSA) were computed for each specimen. Also, the CS perimeter was directly measured at 3 points: the neck-shaft junction, mid-FN and neck-head junction and FN CS perimeter was computed as the average of the 3 measurements. The estimated FN cortical area in the hypothetical situation where the cortical bone was uniformly distributed was calculated as FN average cortical thickness * FN CS perimeter.

In a model multivariate including CTh SD, average CTh and TCSA, CTh SD was the best predictor of cortical area $r = 0.76$ ($p < 0.01$); average CTh was not an independent predictor of cortical area. The estimated cortical area derived using the average CTh uniformly distributed around the perimeter (as done in all studies) was $46 \pm 6\%$ ($p < 0.05$) larger than the true (measured) cortical area. The greater the CTh SD, the greater the minimization achieved (i.e., the difference estimated - true cortical area correlated with CTh SD $r = 0.6$, $p < 0.05$).

Point specific modelling and remodelling on the endosteal and periosteal surfaces produce the variability in CTh needed to adapt bone to its loading conditions and so determines cortical area. Varying the spatial distribution of bone mass in this way minimizes the amount of material

needed to optimise strength while avoiding the energy cost and loss of mobility incurred by bulk. Rather than using means, the use of CTh SD may provide more information concerning the heterogeneity in structure so fundamental to its strength. Recognition of the importance of the spatial distribution of bone is essential for understanding the pathogenesis of bone fragility.

The Femoral Neck Is No Drinking Straw: Heterogeneity in Structure Is Not Captured Using the Hip Structural Analysis. R. Zebaze¹, A. Jones^{*2}, A. Bohte^{*1}, A. Ghasem-Zadeh^{*1}, M. Knackstedt^{*2}, E. Seeman¹. ¹Austin Health, Melbourne, Australia, ²ANU, Canberra, Australia.

Indirect estimates of femoral neck (FN) structure using hip structure analysis (HSA) are used to predict fracture, estimate age related changes in indices of bone strength, and responses to therapy. These estimates must accurately reflect FN structure and its diversity as this diversity accounts for differences in FN fragility in individuals differing by age, height, weight, race and sex. To determine whether single indices of FN structure and strength derived using HSA reflect the diversity of FN structure and strength, we measured cortical thickness (C.Th) at every degree around the perimeter of each of the ~200 cross sections (CS) along the FN, their total cross sectional area (CSA), shape, cortical area, and section modulus (Z) directly from tomographic images from a high-resolution micro-QCT obtained in postmortem specimens from 13 Caucasian females (mean age 69 years). The structure of the narrow neck (NN) and mid-FN was examined.

A single C.Th failed to capture the structural diversity within a CS. The coefficient of variation of C.Th around the CS averaged 80% (range 54 - 130%) depending on the cross section and varied within and between specimens. Along the FN, from slice to slice, there were varying large and small differences in external and internal architecture within or between specimens not captured by a single depth, width, total CSA or shape, cortical area (or cortical fraction), C.Th or Z. The structure of one CS resembled an adjacent one modestly. For example, two CS around the mid-FN separated by 1mm differed in Z by 12 to 30%. In a region of ± 1 mm to the mid-FN, in ~90% of cases, there was a difference in the average C.Th between at least two CS.

The NN used in HSA varied between specimens, was more distal in individuals with larger NSA ($r = 0.53$, $p < 0.05$) and corresponded to the mid-FN in 2 of 13 specimens; in most cases, NN and mid-FN were not comparable. The average C.Th at the NN and mid-FN differed by 5-23% depending on the specimen. Even greater differences in indices of strength were noted between these two cross sections. In ~65% of the specimens, the NN or mid-FN average C.Th differed from the average whole FN C.Th.

Interpretation of FN structure using HSA inadequately reflects the structural diversity and strength of the FN. The NN is not a constant referent predictive of the diverse structure of the FN and use of the HSA should be viewed with scepticism. Methods to quantify FN structural diversity may help to define the structural basis of bone strength and better predict fracture and treatments effects.

Resting Energy Expenditure: A Stronger Marker than Body Weight for BMD in Caucasian Women but Not in Men--The Rancho Bernardo Study. A. Afghani^{*1}, E. Barrett-Connor². ¹College of Health Sciences, Touro University International, Cypress, CA, USA, ²Department of Family and Preventive Medicine, School of Medicine, University of California, San Diego, La Jolla, CA, USA.

The association between resting energy expenditure (REE) and bone mineral density (BMD) has been reported in African-American women, who tend to have lower REEs compared with Caucasian women. The relation between REE and BMD has not been reported in Caucasian adults. 996 postmenopausal Caucasian women and 686 men aged 36-97 years participated in this community-based study. BMD of the lumbar spine (L1-L4), total hip, and total body was measured using dual energy x-ray absorptiometry. REE was calculated using the Harris-Benedict equation; waist and hip girth were measured by standard protocol; grip strength was measured by isometric dynamometry. REE was significantly lower in women than in men (1220 versus 1566 kcal/day, $p < 0.0001$). After adjusting for lean mass, however, REE was significantly higher in women than in men (1407 versus 1296 kcal/day, $p < 0.0001$). In stepwise multiple linear regressions adjusted for estrogen therapy, waist girth, hip girth, and grip strength, REE's contribution to the BMD variances were as follows:

	Spine BMD	Hip BMD	Total Body BMD
Women	13%	31%	30%
Men	0.05%	22%	21%

In women, when body weight replaced REE in the models, weight became the strongest covariate of BMD, but weight explained 9% less of the variance in hip BMD and 6% less of the variance in total body BMD than did REE. The contribution of weight to the variance of spine BMD was the same as the contribution of REE. In men, when body weight replaced REE in the models, there was no change in the variance of hip BMD, but weight explained 9.5% more of the variance in spine BMD and 3% more of the variance in total body BMD than did REE. In this Caucasian cohort, more of the variance in BMD is explained by REE than by weight in women, but in men, weight explains more of the variances in spine and in total body BMD than does REE.

Presence of Symptoms in Men with Low Testosterone Levels Improves Prediction of Low BMD. A. B. Araujo¹, T. G. Travison¹, B. Z. Leder², G. R. Esche^{*1}, J. B. McKinlay^{*1}. ¹New England Research Institutes, Watertown, MA, USA, ²Endocrine Unit, Massachusetts General Hospital, Boston, MA, USA.

While recent data show that measurement of bone mineral density (BMD) may be indicated in men with low testosterone (T), T is seldom measured in the absence of symptoms suggestive of androgen deficiency (AD). We examined associations between T, free T, symptoms suggestive of AD, and proximal femur BMD in a racially diverse sample of 1,219 randomly-selected men aged 30-79 y. BMD was measured by dual X-ray absorptiometry. Low BMD was defined as femoral neck or total hip BMD T-score < -1. T and sex hormone-binding globulin (SHBG) were measured by immunoassay, and free T was calculated from T and SHBG concentrations using the mass action equations. Subjects were considered symptomatic if they reported low libido, erectile dysfunction, or two or more of the following non-specific symptoms: sleep disturbance, depressed mood, lethargy, or diminished physical performance. We defined symptomatic AD as the combination of symptoms and serum total T < 300 ng/dL and serum free T < 5 ng/dL. We examined the proportions of men with low BMD in these risk groups, and calculated measures of sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). Mean age among the 991 men with complete sex steroid data was 47 ± 12 y (790 men had complete symptom data). Twenty-five percent of men had low total T, 10% had low free T, 8% had low total and free T, 20% were symptomatic, and 4% had symptomatic AD. Prevalence of low BMD was 34%, which varied considerably by risk group: low total T (30.6%), low free T (44.3%), low total and free T (43.7%), and symptomatic AD (59.7%). The screening characteristics of these measures are shown in the Figure. All measures had low sensitivity (<25%). Specificity was generally high at ≥ 74%. NPV ranged between 54%-69%. Finally, PPV was highest among men with symptomatic AD. In summary, the low prevalence, poor sensitivity, and relatively low PPV of biochemical hypogonadism in our diverse population appears to limit its utility as a screening test for low BMD. Conversely, men who are both biochemically hypogonadal and who report symptoms suggestive of AD have a higher prevalence of low BMD, yielding a higher PPV than for men with low total or free T (alone or in combination). Bone mineral density measurements may thus be indicated in these patients

Vitamin D Deficiency, Low Bone Mineral Density, and Acculturation in Hispanic Men. A. B. Araujo¹, T. G. Travison¹, G. R. Esche^{*1}, M. F. Holick², T. C. Chen², J. B. McKinlay^{*1}. ¹New England Research Institutes, Watertown, MA, USA, ²Boston Univ Medical School, Boston, MA, USA.

Health disparities occurring within ethnic groups are generally ignored, but in evolving populations such differences may have major public health implications. We examined serum 25-hydroxyvitamin D (25(OH)D) and bone mineral density (BMD) in 360 Puerto Rican, Dominican, Central American, and South American men ages 30-79 y. We examined variation in the proportion of men with 25(OH)D deficiency (<20 ng/mL) and low proximal femur BMD (femoral neck or total hip BMD T-score < -1) by ethnicity, acculturation (language preference and immigration status), and other risk factors. 25(OH)D deficiency was most common among men of Puerto Rican (26%) descent, compared with Dominican (21%), Central American (11%), and South American (9%) men. Percentages with low BMD were: South American (44%), Puerto Rican (34%), Dominican (29%), and Central American (23%). In spite of differences in prevalence of low BMD among the groups, mean differences in BMD were smaller -- with only South American men having significantly lower BMD -- driven mainly by subtle differences in the shape of their BMD distributions. Acculturation displayed a complex but consistent association with 25(OH)D and BMD. While men born in the US or who immigrated as a child did not differ with respect to low 25(OH)D or BMD according to language preference, there were large differences in low 25(OH)D ($p < 0.01$) and BMD ($p = 0.01$) according to language preference among men who immigrated later (see Figure). Multiple

regression models showed that low 25(OH)D and BMD were strongly related to acculturation, and clear differences among the groups with respect to acculturation. However, the explanatory power of acculturation in these differences was largely accounted for by differences in obesity, smoking, physical activity, and other risk factors. There is considerable variation in the skeletal status of male Hispanic ethnic subgroups, which is partly explained by acculturation but more so by differences in lifestyle and health behaviors. When considered in light of US demographic trends, evidence of a rising hip fracture incidence in Hispanics, and the wide range of diseases associated with suboptimal vitamin D status, these data have important implications for fractures, osteoporosis, and the sequelae of vitamin D deficiency.

Prevalence of Vertebral Fractures on Chest Radiographs (CXR) in Elderly African-American and Caucasian Women. B. Bennet^{*1}, O. Ahmed^{*2}, S. Thiel^{*3}, L. Dixon^{*3}, T. Vokes¹. ¹Department of Medicine, University of Chicago, Chicago, IL, USA, ²University of Illinois College of Medicine at Chicago, Chicago, IL, USA, ³Department of Radiology, University of Chicago, Chicago, IL, USA.

Introduction: Hospital discharge claims and population studies report that African-American (AA) women have lower rates of clinical vertebral fractures (Vfx) than Caucasian (CA) women. However, because only 1/3 of radiographically detected Vfx are clinically recognized, and radiographic Vfx have not been examined in AA, the true prevalence of Vfx in AA is not known. Therefore, we compared the prevalence of Vfx detected on routine CXRs in an unselected group of AA and CA female hospital patients.

Methods: Five hundred consecutive lateral CXRs obtained in women ages 60 and over at the University of Chicago were independently evaluated by 3 trained interpreters. Each vertebra was graded using Genant's semiquantitative scale (0=no fracture, 1=mild, 2=moderate and 3=severe compression fracture). Individual vertebra's grades were then added to generate a Spinal Deformity Index (SDI) for each subject. The presence of Vfx was defined by a SDI ≥ 2 from at least 2 of the 3 interpreters. The subjects were labeled with a clinical diagnosis of osteoporosis if the word "osteoporosis" was mentioned in their electronic medical record and with a BMD diagnosis of osteoporosis if they had BMD testing and had T-score ≤ -2.5 at hip or spine. Analysis was restricted to the 418 AA and CA subjects.

Results: Of the 418, 57 (13.6%) had Vfx: 11.9% of 38 AA and 19.4% of 98 CA ($p=0.06$). Only 9 of 57 Vfx (15.8%) detected by our study were mentioned in the official report, with the higher ($p<0.001$) percentage of Vfx reported in CA (4/19 or 21.1%) than in AA (5/38 or 13.2%). Clinical diagnosis of osteoporosis was recorded in 8.9% of study subjects, including 13.3% of CA and 7.5% of AA ($p=0.079$), and in 8/57 (14.0%) of subjects with Vfx. Of 418 subjects, 155 (37.1%) had BMD testing; 31.6% of CA and 38.8% of AA were tested ($p=0.202$). Prevalence of BMD diagnosis of osteoporosis did not differ between the two races: 36/124 (29.0%) in AA and 11/31 (35.5%) in CA ($p=0.49$). Among 57 subjects with Vfx, 19 had BMD testing. BMD diagnosis of osteoporosis was present in 5/6 (83.3%) of CA who had Vfx, but in only 5/13 (38.5%) of AA with Vfx ($p=0.069$).

Conclusion: Although the prevalence of vertebral fractures was lower (but not statistically significant) in AA, they were more likely to have vertebral fractures that were not recognized. Furthermore, they were less likely to have the diagnosis of osteoporosis even if they did have vertebral fractures.

Examination of the Effect of Dietary Habits on Bone Mineral Density in Healthy Men Aged 15-49 Years Living in the City of Debrecen, Hungary. H. P. Bhattoa^{*1}, A. Balogh². ¹Regional Osteoporosis Center and Department of Clinical Biochemistry and Molecular Pathology, University of Debrecen, Debrecen, Hungary, ²Regional Osteoporosis Center, Department of Obstetrics and Gynecology, University of Debrecen, Debrecen, Hungary.

Diet is known to be one of the most important predictors of bone mineral density, the aim of the present study is to characterize the dietary habits and examine its effects on BMD in a healthy male population aged 15-49 years.

The study protocol expressed a target of enrolling 200 subjects, who were stratified by age into seven 5-year age-bands (15-19, 20-24, 25-29, 30-34, 35-39, 40-44, 45-49 years). The local population based register was used to select a population based random sample. Subjects with a longer than 3 month history of chronic disease affecting bone metabolism were excluded. Other exclusion criteria included previous non-traumatic fracture and prolonged immobilization (>1 month). The subjects were interviewed for approximately one hour according to a modified version of the WHO osteoporosis questionnaire. Information sought included age, socio-demographic status, fracture history (both in the subject and their family), tobacco consumption, physical activity, and dietary calcium, carbohydrate, fat and protein intake. Bone mineral density (BMD) was measured using the DPX-L dual energy X-ray absorptiometry densitometer (Madison, Wisconsin, USA). Bone mineral density was measured at the L2-L4 lumbar spine (LS) and the femur neck (FN). Statistical analysis was performed using SPSS (version 9) for windows.

A total of 177 subjects were enrolled into the study (mean age 39.9 ± 8.7 years). Across the study population, highly significant differences in BMD were observed between the age-band at both skeletal sites ($p < 0.05$). It was not possible to estimate peak bone mass due to the marked fluctuations in mean BMD across the age-bands. The mean LS BMD was lowest in the oldest age-band. The mean FN BMD was highest between 25-29 years and gradually decreased with age, the lowest values being seen in the 35-39 year age-band.

There was a significant correlation between LS BMD and weight, age, daily dietary calcium intake and daily protein intake; FN BMD and weight, age, BMI, dietary calcium, protein, fat and energy intake.

Our findings suggest that among the dietary components examined, daily dietary calcium, protein, fat and energy intake correlated significantly with FN BMD and only the daily dietary calcium and protein intake correlated with LS BMD. The knowledge of the dietary components best responsible for a healthy bone mass may help formulate adequate diet oriented preventive strategies in those between 15-49 years of age as such reduce the burden of osteoporosis later in life.

Dietary Calcium, Phosphorous, Protein and Bone Metabolism in Korean Postmenopausal Women. H. Chung¹, E. Kim², I. Jeong^{*1}, K. Ahn^{*1}, D. Kim¹, M. Kwon^{*1}, S. Rhee^{*1}, S. Chon^{*1}, S. Oh^{*1}, J. Woo^{*1}, S. Kim^{*1}, J. Kim^{*1}, Y. Kim^{*1}. ¹Kyung Hee University, Seoul, Republic of Korea, ²Fatima Hospital, Daegu, Republic of Korea.

There is a consensus that adequate calcium intake helps to prevent bone resorption and osteoporosis especially in person with low calcium diets. Even though people are concerned about bone health and are encouraged to take calcium supplementation, we believe that most people do not have enough calcium in their diets. The purpose of this study was to determine the nutritional status, urine calcium, bone markers and their relationship in Korean postmenopausal women. The subjects were 80 healthy female with postmenopausal osteopenia and osteoporosis (mean age, 57.8 y). Dietary calcium, phosphorus and protein were measured by 24 hrs recall method and urine calcium, bone markers were measured in fasting. The mean (SD) daily dietary intakes of Ca, P, protein were 603 (204.2) mg, 993 (246.3) mg, 63.9 (16.1) g respectively. Only 5% of the participants had a calcium intake of more than 1000 mg. 51% of the subjects showed 25-OH D of less than 30 ng/mL. The subjects showing hypercalciuria (>300mg/d) was 14.7%. Multiple regression analysis showed that urinary calcium excretion was associated with serum P, CTX, 25-OH D but not dietary Ca. Serum Mg was negatively correlated with osteocalcin ($r = -0.286$, $p = 0.013$), CTX ($r = -0.289$, $p = 0.01$). Nutritional support including calcium supplementation should be required for the most postmenopausal women and should be encouraged in persons who are interested in improving bone health.

Calcium Intake and the Risk of Osteoporosis and Fractures in French Women. P. Fardellone¹, C. Roux², E. Lespessailles³, F. Cotte^{*4}, A. Gaudin^{*5}. ¹Rheumatology, CHU Hopital Nord, Amiens, 80054, France, ²Rheumatology, Université René Descartes, Hôpital Cochin, Paris, France, ³Rheumatology, CHR Orléans, Orléans, France, ⁴Health Outcomes Studies, GlaxoSmithKline, Marly le Roi, France, ⁵Health Outcomes Studies, GlaxoSmithKline, France, Marly le Roi, France.

Background: The influence of calcium intake from dietary sources on the risk of osteoporosis and fracture prevention is hotly discussed and somewhat confusing.

Objectives: The aim of the study was to assess in French women aged 45 or more years the calcium intake and its relation to osteoporosis and fracture prevalence.

Methods: This study is a cross-sectional observational epidemiological survey carried out in a representative sample of the population of women aged 45 or more years constituted according to the quota method, a stratified random sampling method. Calcium intake from dietary sources was assessed by a validated auto-questionnaire. The investigation on the prevalence of osteoporosis and fractures were conducted by face-to-face home interviews which took place between September and December 2006.

Results: Among the 2,613 interviewed women aged 45 or more years (mean age, 65.8 ± 11.2 years) the prevalence of osteoporosis diagnosed by densitometry was 9.7%. Fractures were reported by 101 subjects (3.9% of the total population and 39.9% of the BMD-diagnosed osteoporotic women). 68.4% of osteoporotic women took supplements of calcium and vitamin D, with no differences between osteoporotic women with fracture or no-fracture history (68.1% vs. 68.6%).

2,135 women returned their questionnaire on calcium intake. The mean calcium intake was $754.1 (+/- 364.2)$ mg/d in the total population, with only 20.1% ingesting more than 1 000 mg/d and 37.2% ingesting less than 600 mg/d. The major single nutrient was milk representing an average daily calcium intake of 137 mg/d ($+/- 230.9$). The mean calcium intake was 795.1 mg/d ($+/- 417.8$) in osteoporotic women ($n=218$), milk representing the most important single nutrient (154.9 mg of calcium/d). These values are not significantly different in comparison with those of the general population.

Conclusion: Calcium intake by French women aged 45 or more years is somewhat low, but is not different between women with or without osteoporosis. The frequency of calcium and vitamin D supplementation is similar in women with fractures and the ones without. These results suggest that in women older than 45 years the diagnosis of osteoporosis or the presence of fractures does not influence the intake of calcium or vitamin D.

Height Loss and Decreased Physical Function in Japanese Women: The Hizen-Oshima Study. K. Aoyagi, Y. Abe. Public Health, Nagasaki University, Nagasaki, Japan.

Vertebral fractures lead to subsequent height loss, and previous studies reported that vertebral fractures are associated with decreased physical functioning. However, longitudinal changes of height to physical functioning remain uncertain. We examined the associations of height loss with changes of physical functioning among 373 Japanese women aged 42-91 years. Heights and data on physical functioning were obtained at baseline and at a follow-up examination an average of 3.4 years later. A self-administered questionnaire was used to survey participants about 14 items' difficulty in performing selected basic and instrumental activities of daily living (ADL). Height loss was defined the decrease of 2cm and over between examinations. Decreased physical function was defined as increased difficulty performing 3 or more ADLs. Frequency of height loss increased significantly with age. Height loss was associated with an existence of vertebral deformity at baseline (odds ratio [OR]; 2.28, 95% confidence interval [CI]; 0.96-5.41, $p=0.06$). In age and height at baseline adjusted logistic regression model, height loss was associated with increased difficulty in bending over or picking up a lightweight object (OR; 2.76, 95% CI; 0.91-8.36, $p=0.07$), lifting a 5 kg object from the floor (OR; 2.50, 95% CI; 0.99-6.23, $p=0.05$), reaching an object above her head (OR; 3.85, 95% CI; 1.61-9.20, $p=0.002$), and feeding or dressing herself (OR; 9.28, 95% CI; 1.55-55.34, $p=0.01$). Height loss increased the odds of decreased physical function by 2.4 times (95% CI; 0.9-6.6, $p=0.09$). In conclusion, height loss, possibly due to vertebral fractures, contributes to decreased physical function, as measured by ADLs, independent of age and height at baseline.

Towards a Weak Bone Phenotype: Comparisons of Load Normalized Section Modulus Among Women With and Without Fracture History in the Women's Health Initiative. T. J. Beck¹, Z. Chen², S. B. Going².

¹Radiology, Johns Hopkins University, Baltimore, MD, USA, ²Epidemiology and Statistics, University of Arizona College of Public Health, Tucson, AZ, USA.

Genetic differences in bone mechanical strength may contribute to fracture susceptibility in life but a clear phenotype of reduced strength is elusive. Low BMD is heritable and associated with increased fracture rates but BMD is a problematic phenotype due to age, gender, site, and body size dependence and an ambiguous relationship to mechanical properties. If a weak bone phenotype does exist, it is probably geometric since most individual differences and effects of age are geometric in nature, that is due to variance in the amount and distribution of bone tissue within bones. Size-corrected section moduli (SM), indices of bending resistance, are continually adapted to prevalent loads throughout life and changes across the lifespan are mainly in response to changing skeletal load. SM appear to maintain an equilibrium with prevalent loads thus a measurable deficiency in that equilibrium may serve as a weak bone phenotype. In this preliminary analysis we used height-adjusted femur section moduli normalized to total body lean mass as a relative strength-load index (cm³/kg). We hypothesized that this index might be diminished among women who suffer bone fractures. Using the Hip Structure Analysis software on DXA scans of the hip, SM were measured at the narrow-neck, intertrochanteric and proximal shaft regions on 6032 multi-ethnic postmenopausal women in the observational cohort of the Women's Health Initiative. Total body lean mass was measured from total body DXA scans. Based on self-reported fracture of any bone prior to enrollment and adjudicated fracture of any bone after enrollment, subjects were divided into four groups: fracture free (Hx-- N=3231), prior fracture only (Hx+- N=1992), new fracture only (Hx+ N=383) and both fractures (Hx++ N=426). Height adjusted indexes in fracture groups were compared to Hx-- (Figure) only the shaft index in Hx++ was non-significant. The results suggest that women who suffer fractures may have a deficit in load response and that this deficit may be greater among women with a history of fracture prior to enrollment and who also suffered new fractures during the observation period. It remains to be seen whether index differences are of genetic origin but the index may prove useful in future genetic studies of fracture susceptibility.

Validation of a Clinical Definition for Fragility Fracture. J. P. Brown¹, L. Bessette¹, S. Jean², K. S. Davison¹, M. Beaulieu³, M. Baranci⁴, J. Bessant⁵, L. Ste-Marie⁶. ¹Laval University, Quebec, PQ, Canada, ²INSPQ, Quebec, PQ, Canada, ³Merck Frosst Canada, Montreal, PQ, Canada, ⁴sanofi-aventis, Montreal, PQ, Canada, ⁵P&G Pharmaceuticals, Montreal, PQ, Canada, ⁶U. of Montreal, Montreal, PQ, Canada.

Despite numerous studies examining the epidemiology of osteoporotic or fragility fracture, there is still no clinical definition available in the literature. Fractures are classically considered to be osteoporotic where the fracture type is associated with decreased bone mineral density (BMD) and its incidence rises with age. This leads to the assumption that all fractures at a particular included site are due to osteoporosis, while fractures at a particular excluded site are unlikely to be osteoporosis-related. An alternative approach is to consider fragility fractures as being osteoporotic based on the mechanism of falling regardless of the site and respective BMD, particularly considering that the majority of fractures occurring in postmenopausal women occur in those with osteopenia or normal BMD.

The aim of this study was to validate a clinical definition for fragility fractures: a fracture occurring spontaneously or following a minor trauma, such as a fall from standing height, a

fall from the sitting position or a fall from laying down on a bed or a reclining deck chair from less than a meter high, a fall after having missed 1 to 3 steps in a staircase, after a movement outside of the typical plane of motion, or coughing. ROCQ (Recognizing Osteoporosis and Its Consequences in Québec) is an ongoing patient health management program aiming to improve the rate of diagnosis and treatment of osteoporosis for women 50+y that have suffered a fragility fracture. To date, 3288 women, mean age (SD) of 65.2 (10.3)y have been recruited 0 to 16 weeks following a fracture either at cast/outpatient clinic in 17 participating hospitals or by mail using the Health Administrative Database of the Province of Quebec (RAMQ) and together have experienced 3485 fracture events. Patients were contacted by phone to answer a short questionnaire to classify them as having either experienced a fragility or traumatic fracture. The proportion of fragility fractures increased progressively with age [73.8% (50-59y), 80.6% (60-69y), 85.5% (70-79y) and 92.8% (80+y)] and was similar between the various types of fracture[wrist (83.0%), humeral (76.1%), ankle (82.6%)], except for a higher proportion at the hip (93.0%), presumably because of its occurrence in older individuals. In conclusion, the proposed clinical definition of fragility fracture based on the mechanism of falling fulfills the criteria for the classical definition without the requirement of a low BMD and should be preferred in epidemiologic and clinical studies of osteoporotic fractures.

Spirolactone Use and Risk of Fracture in Men With Congestive Heart Failure. L. D. Carbone¹, J. Cross¹, S. Raza¹, R. Sepanski², S. Dhawan¹, B. Khan¹, M. Gupta¹, K. Ahmad¹, R. Khouzam¹, D. Dishmon¹, J. Nesheiwat¹, W. Christy¹, A. Hajjar¹, W. Nasser¹, M. Khan¹, C. Womack¹, T. Cho¹, A. Haskin¹, K. T. Weber². ¹Veterans Affairs Medical Center (VAMC), Memphis, TN, USA, ²University of Tennessee Health Science Center, Memphis, TN, USA.

Congestive heart failure (CHF), which is mediated in part by activation of the renin-angiotensin-aldosterone system, is a systemic, pro-inflammatory condition that has deleterious effects on multiple tissues, including the skeleton. Observational studies suggest that there is an interrelationship between CHF and osteoporosis. In experimental studies in rats receiving aldosterone/salt treatment, which stimulates the aldosteronism of CHF, we have identified reduced BMD and bone strength. Administration of spironolactone (Spiro) an aldosterone antagonist, attenuated bone loss, and decreased skeletal fragility in these rats. Persons living with CHF are a population at growing risk for osteoporosis, and use of Spiro for treatment of CHF is becoming increasingly common. The purpose of this translational study was to determine the association of Spiro use with incident atraumatic fractures in CHF.

The medical records of all male patients with an ICD-9 diagnosis consistent with CHF from 1999-2005 (n=4735) treated at VAMC, Memphis, TN, were reviewed. Cases were defined as men with CHF who had an incident atraumatic fracture between 1999-2005; controls were men with CHF without incident atraumatic fractures between these years. CHF controls were randomly selected and age and race matched to CHF cases. Information on clinical characteristics and medication use was recorded. Hazard ratios (HRs) with 95% confidence intervals for incident fractures were estimated from Cox proportional hazard models.

We identified 189 CHF cases with an incident fracture and matched these by age and race to 844 CHF controls with no incident fractures. After adjustment for BMI, smoking status, prevalent fractures and use of medications for osteoporosis and CHF, use of Spiro was associated with a significantly lower risk of all fractures (HR 0.481; 95% CI=0.307-.754). Use of Spiro was associated with a significantly decreased risk for nonvertebral (HR 0.393; 95% CI 0.233-0.661), but not vertebral fractures (HR 0.657; 95% CI 0.310-1.395). Both short term (less than or equal to six months) and long term (greater than six months) use of Spiro was associated with a reduced risk for all fractures (p<0.019 for both). Spiro use was associated with a reduced risk of fractures in both systolic and diastolic heart failure.

Short and long-term use of Spiro was associated with a reduced risk of osteoporotic-related fractures in men with CHF. Further longitudinal studies of the effects of Spiro use on osteoporosis in patients with CHF are warranted.

Identifying Clinical Vertebral Fractures Using Administrative Claims Data: A Validation Study. J. R. Curtis¹, A. Mudano¹, D. H. Solomon², Y. Kim¹, K. G. Saag¹. ¹University of Alabama at Birmingham, Birmingham, AL, USA, ²Brigham and Women's, Boston, MA, USA.

Background: Administrative claims data is often used to identify fracture endpoints in research that examines the effectiveness of osteoporosis therapies. However, the absence of validated claims-based algorithms to identify clinical vertebral compression fractures (VCF) lead to the potential for fracture misclassification.

Methods: Using the claims databases of a multi-state managed care organization from 1/03 - 6/04, we identified patients with ≥ 1 claim for a vertebral compression fracture (ICD9: 805.2, 805.4, 805.8, or 733.13) and excluded patients with claims for malignancies (ICD9: 140.xx to 208.xx, 170.2, 198.5, 203.00, 203.01, 228.09, 238.0, 238.6, 239.2). A random sample of these individuals was selected, and diagnostic radiology reports commonly used to identify VCFs (e.g. x-rays, MRI) prior to or following the initial VCF were requested. Records were reviewed by two independent abstractors to confirm a prevalent VCF. Uncertainties were resolved by consensus among a 3 person review panel. The sensitivity, specificity, and positive predictive value of claims-based criteria were validated against a gold-standard of a radiographically confirmed VCF.

Results: We identified and requested records for 267 patients with ≥ 1 claim for a VCF and received records for 187 persons. Among these individuals, 84% had a confirmed VCF (95% CI 79 - 89%). The diagnostic properties of 3 additional criteria sets compared to the initial screening approach are shown (Table).

Conclusions: The majority of single VCF claims represent confirmed VCF events based on radiographic confirmation. Requiring >1 VCF code or that the VCF code appears after and proximate to radiology claims for specific diagnostic imaging procedures improves the positive predictive value of confirmed VCF events.

	Sensitivity	Specificity	Positive Predictive Value
≥ 1 VCF codes appearing same day or after radiology claim, %	82	50	90
≥ 1 VCF codes appearing same day or within 90 days after radiology claim, %	71	70	93
≥ 2 VCF codes on different days, %	64	80	95

Impact of Incident Hip Fracture on Quality of Life in Older Men: the Osteoporotic Fractures in Men (MrOS) Study. H. A. Fink¹, N. Parimi², B. C. Taylor³, J. T. Schousboe⁴, A. N. A. Tosteson⁵, M. L. Stefanick⁶, K. E. Ensrud³. ¹GRECC, VA Medical Center, Minneapolis, MN, USA, ²California Pacific Medical Center, San Francisco, CA, USA, ³CCDOR, VA Medical Center, Minneapolis, MN, USA, ⁴Park Nicollet Clinic, Minneapolis, MN, USA, ⁵Dartmouth Medical School, Lebanon, NH, USA, ⁶Stanford University Medical Center, Stanford, CA, USA.

Older men with incident hip fractures (fx) often have poor pre-existing health and would be likely to experience health decline unrelated to hip fx. We aimed to estimate the excess decline in self-reported quality of life (QOL) in older men attributable to incident hip fx.

We utilized data from MrOS, a prospective osteoporosis study in men aged ≥ 65 years. Total hip and lumbar spine BMD were measured with DXA. QOL was measured with SF-12 (physical component scale [PCS-12] and mental component scale [MCS-12]) at baseline and visit two (mean interval 4.6 years). Self-reported incident hip fx were centrally confirmed by radiology reports. Linear regression was used to compare change in SF-12 measures between men with incident hip fx and men with no fx. Men with 2+ fx or a nonhip fx were excluded from analyses. Of 5992 men with baseline SF-12 data, 5513 had no incident fx and 48 had an incident hip fx and no other fx. Of men with hip fx, 17 (35%) died before visit two, with 25 of 31 (81%) hip fx survivors completing SF-12 follow-up. At baseline, those with hip fx were older, lighter, less physically active, had more comorbid conditions, lower PCS-12 scores, lower hip BMD, and more often had past fx. Among men with hip fx, those not completing follow-up SF-12 measures appeared less healthy than those with follow-up by all these measures. Among men with baseline and follow-up SF-12 measures, those with incident hip fx experienced a significantly greater mean decline in PCS-12 (-9.1 vs. -2.6, $p=0.02$) but no difference in mean change in MCS-12 (+0.8 vs. -0.5, $p=0.38$). PCS-12 decline appeared greater in men whose hip fx occurred <1 year vs. ≥ 1 year prior to visit two (-15.0 vs. -5.2, $p=0.06$). After adjustment for age, weight, and fall history, PCS-12 decline in men with hip fx overall remained significantly greater than for men without fx.

Among survivors, QOL decline in men with incident hip fx exceeded that in men without fx after accounting for other factors associated with QOL decline. The smaller decline in those with longer fx-to-follow-up intervals suggested that results derived solely from survivors to visit two likely underestimated QOL decline in men after hip fx. Future studies should characterize and distinguish QOL change preceding hip fx and short and long-term post-hip fx QOL change independently attributable to the hip fx.

Magnification Correction of Vertebral Body Heights During Quantitative Morphometry. A. Mukkananchery*, T. Fuerst, N. Bouzegaou*, G. von Ingersleben, Y. Chen*, C. Wu*, S. Pourfathi*, H. K. Genant. Synarc, Inc., San Francisco, CA, USA.

Vertebral quantitative morphometry (QM) is a common method used to detect incident vertebral fractures in adult women and men. One advantage of QM is the ability to define objective criteria for fracture based on vertebral height changes. However successful QM requires a standardized protocol for point placement and careful training of QM readers. Even with these efforts QM measurements are susceptible to technical errors affecting magnification of the radiographic image. In this study we documented the prevalence of such errors and investigated a technique for magnification correction in QM.

Standardized lateral radiographs of the thoracolumbar spine were acquired at baseline, one year and two years in 4,838 osteoporotic women participating in multi-center clinical trials. Radiographic acquisition was standardized. The films were digitized with a pixel size of 200 microns and QM was performed by trained readers on a proprietary reading workstation. Magnification factors (MF) between images from serial visits were determined by the mean of the ratio of posterior heights at follow-up compared to baseline. When MF was greater than 1 an increase in image size was observed. The MF was then used to adjust vertebral body heights of follow-up images to remove magnification differences and incident fracture was determined using standard criteria (20% change in height from baseline). The identification of an incident fracture by QM methods with and without MF correction was compared to vertebral fractures identified by semiquantitative (SQ) reading by a trained radiologist.

Magnification differences between visits resulted from geometric magnification changes as well as optical magnification changes due to digital x-rays printed at a scale not equal to 100%. Differences between visits exceeded 5% in 30% of subjects in Year 1 while magnification differences greater than 10% occurred in 7% of subjects. Variation increased at Year 2 with 43% and 13% of subjects exceeding these thresholds. Magnification adjustment improved the agreement of QM with SQ by decreasing the number of QM false negative cases by 14 and the number of false positive cases by 75.

Variation in magnification between visits during long term follow-up can be relatively common in spine radiography even with efforts to standardize image acquisition. However, the magnitude of magnification differences and low fracture incidence limits the impact on fracture assessment. SQ reading has greater immunity to magnification differences and is a necessary complement to QM fracture assessment.

Impact of Incident Vertebral Fractures on Health-Related Quality of Life in Postmenopausal Women: The OPUS Study. M. G. Glüer¹, T. Blenk², C. Graeff¹, D. Felsenberg², C. Roux³, D. M. Reid⁴, R. Eastell⁵, C. C. Glüer¹.
¹Medical Physics, Diagnostic Radiology, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany, ²Charité Universitätsmedizin, Berlin, Germany, ³René Descartes University, Paris, France, ⁴University of Aberdeen, Aberdeen, United Kingdom, ⁵University of Sheffield, Sheffield, United Kingdom.

Health Related Quality of Life (HRQoL) is impaired in patients with vertebral fractures. However, there are no population-based studies with repeated assessment of vertebral fracture and HRQoL at the same time points. We studied the impact of prevalent and/or incident vertebral fractures on HRQoL and compared it with HRQoL changes associated with aging.

In the OPUS study 2409 women were recruited from population-based registers at the 5 participating centers in Aberdeen, Berlin, Kiel, Paris, and Sheffield. At baseline and approximately 6 years later spinal x-rays were obtained and fracture status was assessed by central reading in Berlin (criteria: >20% height reductions and radiological signs of osteoporotic fracture). HRQoL was assessed with the following validated instruments: SF-12 incl. the physical score (PCS-12), EuroHealth, EuroQoL, QUALEFFO-41 (QE) including domain scores, and the symptoms domain of the OQLQ. For all instruments except for QE a lower score implies worse HRQoL.

In a subset of 1285 women (mean age 65.3 at baseline, range 55-80) complete data on vertebral fractures and HRQoL were evaluated. Groups were defined as having no fractures or any fracture, the latter with subgroups of: 'only baseline prevalent fractures', 'only incident fractures', and 'prevalent and incident fractures'.

The table lists those instruments for which at least a trend ($p < 0.2$) for associations was observed. Column 3 represents age-related changes in HRQoL ($^{\circ}$: $p < .05$, ** : $p < .01$, *** : $p < .001$). Columns 4-7 represent HRQoL changes associated with aging and fractures ($^{\circ}$: $p < .2$, * : $p < .05$, ** : $p < .01$ compared to age-related changes of column 3; significance indicates association with fracture and not just aging).

All instruments except for the OQLQ symptoms score revealed some significant reductions in HRQoL. These were similar for incident and prevalent fracture and generally larger if both fractures occurred. HRQoL losses in women with vertebral fractures were independent of the highly significant losses associated with aging.

Score	Mean HRQoL at 0yr, no fx group	HRQoL change 6yr - 0yr				
		No fracture n=1096	Any fracture n=189	Only prev fx n=156	Only inc fx n=33	Prev & inc fx n=22

Epidemiology of Children's Fractures: A Population-based Study. E. M. Hedström*, P. Michno*, U. Bergström*, O. Svensson. Department of Orthopaedics, Umeå University Hospital, Umeå, Sweden.

Fractures are most common in youth and senescence, when the skeleton is porous with weak points at the physes and metaphyses, respectively. However, there is little published on the general epidemiology of children's fractures. We present the fracture pattern within a population ≤19 years of age, seen at Umeå University Hospital (UUH).

All children sustaining fractures in the Umeå area are seen at UUH which serves as the regional hospital. During the period 1993-2005, when data was collected, the average annual population aged 0-19 in the region was 34,337.

All accidents resulting in injury seen at the hospital were recorded in a database including variables such as age, sex, date of injury, type of injury, mechanism of injury and treatment. From the database we extrapolated 8,768 cases among individuals aged 0-19 where injury resulted in at least one fracture. We then analysed these cases noting incidence rates, fracture type and mechanism of injury, including sex and age related differences.

The yearly incidence rate varied between 141-236 / 10,000 individuals. The minimum incidence rate occurred '94, and the maximum '04. The incidence rate for the whole period was 196 / 10,000 individuals and year. The most common fracture site was the distal

forearm (33%). The most common type of mechanism was falls (58%). The peak incidence occurred at 11-12 years of age in girls and at 13-14 years of age in boys. There was a predominance of boys in the material. The male to female incidence ratio for all fractures and ages was 1.49, a difference which became pronounced in teenage years, being most obvious in the 15 year olds where the male to female incidence ratio was 3.17.

Like in old age, children's fractures are due to both intrinsic and extrinsic factors, but we also have factors due to growth and changes in motor skills and activities. A better description of the epidemiology and possible age, sex and gender specific differences is necessary for optimal targeting of injury preventive measures in the future.

Hyperkyphosis and Physical Function in Older Community Dwelling Women: The Study of Osteoporotic Fractures (SOF). M. Huang¹, L. Palermo², K. Stone³, S. R. Cummings³, D. M. Kado¹. ¹Division of Geriatrics, Department of Medicine, UCLA, Los Angeles, CA, USA, ²Univ. of San Francisco, San Francisco, CA, USA, ³Research Institute, California Pacific Medical Center, San Francisco, CA, USA.

Maintaining physical functional ability is an important prerequisite for preserving independence in later life. Hyperkyphosis, or an increased thoracic curvature, is commonly observed in older persons and may be an important determinant of poor physical function. While the Cobb angle method is currently the standard kyphosis measure, data from studies demonstrating an association between hyperkyphosis and physical function have relied on gross clinical observations of stooped posture, and have not taken into consideration possible confounders such as underlying vertebral fractures. Therefore, we sought to determine the cross-sectional association between hyperkyphosis and self-reported and objectively measured physical function in a cohort of 1196 older women aged 65 or older who had radiographs available to measure Cobb angle kyphosis. The digitized Cobb angle (T4-T12) derived from supine lateral thoracic spine plain films was used to

calculate the degree of kyphosis. Participants were an average of 68.8 years old (SD= 3.3) and had a mean kyphosis angle of 44.6 degrees (SD = 12.1). Regression models were used to evaluate association between kyphosis and 1) self-reported being on feet \leq 4 hours/day (yes/no); 2) self-reported functional status (any difficulty in performing six tasks: walking 2-3 blocks, climbing or descending 10 steps, preparing meals, heavy housework, and shopping); 3) measured walking speed; and 4) grip strength. No significant findings between hyperkyphosis and being on feet \leq 4 hours/day or walking speed were detected. However, with each 10 degree increase of kyphosis, women were 1.13-fold more likely to report functional difficulty (95% CI: 1.00 - 1.28, $p = 0.05$) after adjustment for age, clinic, weight, height, physical activity, alcohol, health status, diabetes, and arthritis. Furthermore, with each 10 degree increase in kyphosis, there was 0.2 kg decline in grip strength ($p=0.01$) after adjustment for age, clinic, body mass index, weight, physical activity, health status, diabetes, and arthritis. Similarly, in multivariable adjusted models, women in the worst Cobb angle quartile were 1.6-fold more likely to be in the worst quartile of grip strength (95% CI: 1.2-2.2, $p = 0.001$). Longitudinal studies will be better able to determine whether hyperkyphosis predicts subsequent decline in physical function.

Height Loss Is Associated with Impaired Quality of Life in the Elderly. K. Tanaka¹, M. Himeno^{*1}, M. Kishimoto^{*1}, A. Kuwabara^{*1}, Y. Ogawa^{*1}, S. Manabe^{*1}, A. Miseki^{*1}, K. Muto^{*1}, M. Fujii^{*2}, N. Kawai^{*2}, J. Ohta^{*3}, S. Kido^{*1}, K. Yoh^{*4}. ¹Kyoto Women's University, Kyoto, Japan, ²Kayu Shirakawa, Kyoto, Japan, ³Shohakuen, Neyagawa, Japan, ⁴Hyogo Medical University, Hyogo, Japan.

Standing height is one of the essential parameters in the anthropometric assessment of the elderly. For example, it is a prerequisite for the estimation of energy expenditure and body composition. Its measurement is, however, too often difficult in the elderly. Although several equations have been published to estimate the height from other surrogate parameters, currently there is no consensus on the way, or more fundamentally, the validity of estimation. In this paper, we have studied these problems, and additionally the impact of height loss on the quality of life (QOL) of the elderly. Initial study including university students revealed that practically all the parameters well correlated with the standing height. In the following study including 187 subjects (52 males, 135 females, 83.2 \pm 9.5 years old), knee height, forearm length could be measured with accuracy in more than 90% of the subjects. In contrast, standing height, arm span, or demispan could be measured in the limited number of patients. In 52 female subjects, standing height could be measured. From the data from these subjects various equations were prepared, of which, the following one best predicted the standing height; standing height=1.82*knee height+1.39*forearm length-0.32*age+60.14 ($R^2=0.63$, $p<0.01$). Previously published equations exhibited marked discrepancies, especially on the way to incorporate the age-related height loss. Theoretically, there are two classes of height; maximum height and current height. The above-mentioned discrepancy probably reflects that these two heights were not clearly distinguished in the previous studies. Knee height is likely to be a good predictor of maximum height, thus could be a good parameter to be used in calculating the energy expenditure or body composition. Finally, the association of QOL with height was studied. The physical component summary (PCS) of SF-8 was significantly correlated with the current height ($r=0.48$, $p<0.05$), but not with knee height, which suggests that height loss is associated with decreased QOL. In summary, nutritional evaluation of the subjects with height loss are to be done using knee height or forearm length, which well reflects the maximum length.

Bone Density, Muscle Cross Section and Muscular Power in the Lower Limbs in Healthy Postmenopausal Women, Patients on Corticosteroids and Fracture Patients. P. Schneider, H. Haenschel*, E. Maiweg*, C. Reiners*. Clinic for Nuclear Medicine, University of Wuerzburg, Wuerzburg, Germany.

Purpose: We measured bone density parameters at various sites and muscular performance of the lower limbs to investigate the degree of association of bone and muscle status.

Methods: In 3 groups of females (45-89y.), 126 normal postmenopausal women (PW), 36 corticosteroid patients (CS), and, 24 osteoporotic fx patients (OFX), areal bone density (aBMD) was measured at hip and spine using DXA. Distal radius and femur volumetric bone density (vBMD), bone strength index at the tibia midshaft (BSI), largest calf muscle cross section(CMC) area were measured with pQCT. Maximum muscle force and power of the legs were measured with a ground force reaction device (Soehnle Professional GmbH,

Murrhardt Germany) during maximum force knee-bends over 10 seconds. The ratio of force and power to body weight was also considered. Correlations between parameters were calculated over the entire sample. Between-group differences were tested (Tukey's HSD Test). Significance level was set at $p<0.01$.

Results: In the whole sample aBMD and vBMD parameters correlated significantly ($r=0.50$ to 0.67), highest between lumbar spine and femur neck. Distal radius trabecular vBMD and femur neck aBMD were at $r=0.60$. Muscle force, power and cross section correlated with vBMD's and aBMD's in a range of $r=0.32$ to 0.56 ($p<0.001$). CMC and force or power in the tests ranged from $r=0.43$ to 0.56 . The muscle parameters per body weight did not significantly correlate with bone parameters. Between groups comparison showed aBMD's at femur neck and lumbar spine, tibial trabecular vBMD and tibial BSI to be significantly lower in the OFX as compared to the PW and CS group. No differences were found between PW and CS patients. All muscle parameters except power to weight ratio did not show any significant difference between groups. Power to weight ratio was lower in OFX patients. However, in CS, variance of muscle performance parameters was much larger than in PW. Age was negatively correlated with vBMD's and aBMD's ($r=-0.2$ to -0.36) and with muscle power or force ($r=-0.25$ to -0.5). CMC and BSI did not significantly correlate with age.

Conclusion: Prediction of BMD's was slightly better within DXA assessed sites (hip and lumbar spine) as compared to pQCT, or, between the 2 densitometric methods. The sign. difference of power per body weight ratio in OFX as compared to the PW and CS patients could indicate its importance in prevention of falls leading to fracture. In turn, it could also reflect degradation of muscular fitness following the fracture event, which could increase prospective fracture probability. Prospective fracture probability assessment should therefore also focus on accurate muscular performance assessment.

Vitamin D Insufficiency Is Associated with Lower Bone Density in African American Men. N. Akhter^{*1}, B. Sinnott^{*1}, D. Rao², K. Mahmood^{*1}, S. Kukreja³, E. Barengolts¹. ¹University of Illinois at Chicago, Chicago, IL, USA, ²Henry Ford Hospital, Detroit, MI, USA, ³Jesse Brown VA Medical Center, Chicago, IL, USA.

Prevalence and effects of Vitamin D insufficiency are well studied in women but not in African American (AA) males. In previous studies, a negative correlation between serum 25-hydroxy vitamin D (25-OHD) and bone mineral density (BMD) has been shown in Caucasians and Asians. In AA population despite lower serum 25-OHD and secondary hyperparathyroidism, BMD levels are higher. Thus it is not known whether low serum vitamin D has any deleterious effects on the skeleton in the AA population. In AA women, supplementation with vitamin D over 3 years did not increase BMD (Aloia et al. Arch Intern Med. 2005; 165:1618). There are no previous studies that have examined the effects of low serum 25-OHD on BMD in AA men. In the present study, we report data for 112 male veterans enrolled in an osteoporosis study. We examined prevalence of Vitamin D insufficiency and its correlation with age, serum calcium, body mass index (BMI) and BMD. Serum 25-OHD was measured by chemiluminescence assay (DiaSorin Inc., Stillwater, MN, normal range 15-80 ng/ml). BMD was measured by Lunar Prodigy Densitometer. Serum 25 OHD was sufficient in 48% (Group 1, 25OHD >15 ng/ml) and insufficient in 52% (Group 2, 25OHD ≤ 15 ng/ml) of the subjects. The data are presented in the table:

There was no difference between the two groups for age, BMI, calcium, and BMD. However, within Group 2, 25-OHD level correlated positively with BMD of Spine ($r=0.25$, $P=0.05$), Total Hip ($r=0.23$, $P<0.05$), Ward's triangle ($r=0.25$, $P=0.05$) and Trochanter ($r=0.3$, $P=0.02$). Our study suggests that in African American men, the deleterious effects of vitamin insufficiency on bone may be observed only at very low levels of 25-OHD. Further studies with vitamin D supplementation are needed to elucidate risks and consequences of various degrees of vitamin D deficiency in African American men.

Table 1

Characteristics	Group 1, n = 54 Mean \pm SD	Group 2, n = 58 Mean \pm SD	P value
Age, years	66.5 \pm 15.9	61.5 \pm 11.9	0.06

Factors Influencing Women Persistence with Osteoporosis Treatment After 6 Months of Treatment. V. Breuil¹, P. Fardellone², M. Rossignol³, B. Cortet⁴, F. Liard⁵, F. A. Allaert⁶, F. E. Cotté⁶, A. F. Gaudin⁷. ¹CHRU l'Archet, Nice, France, ²CHU, Amiens, France, ³RRSSS, Montréal, PQ, Canada, ⁴CHRU Roger Salengro, Lille, France, ⁵General Practitioner, Saint-Epain, France, ⁶DIM CHRU, Dijon, France, ⁷GSK, Marly le Roy, France.

A retrospective study carried out by 2029 GPs whose representativeness has been controlled.

The purpose was to describe the persistence of women treated for postmenopausal osteoporosis (PMO) for at least 6 months and factors influencing it. Each of them was requested to describe the first 2 successive postmenopausal osteoporotic women who have been persisting with osteoporosis treatment for at least 6 months during the last year, and to ask them to complete a self administered questionnaire.

3598 women 69.5±8.8 years old were included. Regarding risk factors of osteoporosis, 37.5% had maternal history of osteoporotic fracture, 21.5% an early menopause (<45y old), 19.6% were smoking more than 20 cig/day, 13.8% had a long duration of steroid use (≥ 6 months), 11.7% had a BMI < 19 kg/m² and 10.0% were immobilized more than 3 months. 71.3% of them had at least one osteoporotic fracture and the average number of fractures was 1.1 ± 1.0. They were located in vertebra (50.0%), wrist (48.9%) and hip (10.1%). 83.5% of women received the same treatment since the diagnostic of osteoporosis and were defined as persistent. Persistence was higher with weekly bisphosphonates (WBP) (89.8%) and SERM (84.6%) compare to daily bisphosphonates (DBP) (41.4%). The main reasons for non-persistence were "Treatment intolerance" for women treated with WBP and SERM (respectively 36.0% and 34.6%) and "Treatment strictness" with DBP (55.5%). Univariate analysis showed that "Consideration of PMO as a serious disease" and "Knowledge of PMO risk factors" were significantly higher in persistent patient comparing to non-persistent one (<0.01). Persistent patients had significantly more medical consultations (p<0.001). Women under 70 years were more persistent than the older (<0.05). With both daily or weekly regimens, logistic regression shows that persistence with bisphosphonates increases with the number of previous fracture (3 vs 0): OR=1.9, IC_{95%}=[1.1;3.3] and OR=1.7, IC_{95%}=[1.0;2.8], respectively.

Strictness of dosing regimen and intolerance on therapy appeared to be the main reasons for discontinuing PMO treatments. Otherwise, improving information of women and acknowledgement of PMO severity and consequences could be the major way for enhancing their persistence on therapy.

Elderly Patients with Non-Hodgkin's Lymphoma Who Receive Chemotherapy at Higher Risk for Osteopenia and Osteoporosis. M. E. Cabanillas¹, H. Lu¹, S. Fang², X. L. Du². ¹General Internal Medicine, MD Anderson Cancer Center, Houston, TX, USA, ²Division of Epidemiology, The School of Public Health, The University of Texas Health Science Center at Houston, Houston, TX, USA.

In order to determine the risk of osteopenia and osteoporosis associated with chemotherapy among elderly patients with Non-Hodgkin's Lymphoma (NHL), we studied a cohort of 13,570 patients aged ≥65 years with incident NHL in 1992-1999, identified from the SEER-Medicare linked data. We searched for any diagnosis of osteoporosis or osteopenia 1 year prior to and thereafter the diagnosis of NHL, during the 11 years of follow-up. Of 13,570 patients, 60% received chemotherapy. One year prior to the diagnosis of NHL, there were 335 (4.1%) patients who had claims for osteoporosis in the chemotherapy group versus 272 (5%) subjects in the no chemotherapy group (p=0.012). After diagnosis, patients who received chemotherapy had a statistically significant increase in rates of osteoporosis (10.1%) and osteopenia (8.1%) in the chemotherapy group compared to the no chemotherapy group (8.3% and 4.0%, respectively) (p<0.001). After controlling for ethnicity, age, gender, follow-up time, tumor stage, and geographic location, patients who received chemotherapy had a significantly increased odds ratio of 1.27 (95% CI: 1.12-1.45) for osteoporosis and 1.95 (95% CI: 1.66-2.30) for osteopenia compared to those who did not. In conclusion, this population-based retrospective cohort study demonstrated that chemotherapy was associated with an increased risk of developing osteopenia and osteoporosis in community dwelling elderly patients with NHL.

Osteoporosis and Osteopenia between NHL patients who received chemotherapy versus those who did not

	Received chemotherapy n=8152, n, (%)	Did not receive chemotherapy n=5418, n, (%)	p-value
Osteoporosis (1 year before diagnosis)	335 (4.1)	272 (5.0)	0.012
Osteoporosis (on/after diagnosis, or chemotherapy for those receiving chemotherapy)	822 (10.1)	449 (8.3)	<0.001
Osteopenia (1 year before diagnosis)	196 (2.4)	122 (2.3)	0.565
Osteopenia (on/after diagnosis, or chemotherapy for those receiving chemotherapy)	661 (8.1)	216 (4.0)	<0.001

Prevalence and Risk Factors of Osteoporosis and Vertebral Fractures in COPD Males. E. Casado¹, M. Gallego², M. Larrosa¹, C. Orellana¹, R. Valls³, E. Berlanga⁴, C. Domingo², J. Gratacós¹. ¹Rheumatology, Hospital Sabadell, Sabadell, Spain, ²Pneumology, Hospital Sabadell, Sabadell, Spain, ³Radiology, UDIAT, Sabadell, Spain, ⁴Laboratory, UDIAT, Sabadell, Spain.

The objective of our study was to determine the prevalence of densitometric osteoporosis (OP) and osteoporotic vertebral fractures in COPD patients. To identify the risk factors for the presence of OP and vertebral fractures in COPD patients.

Inclusion criteria: Male sex, older than 50, COPD defined according to ATS/ERS classification. Patients gave their informed consent to participate in the study. Exclusion criteria: Patients with COPD presenting any other concomitant pulmonary disease. Patients with COPD presenting rheumatologic and/or vertebral disease that may hinder the interpretation of the densitometry. Bone mass measurement was determined by dual-energy x-ray absorptiometry (DXA) at lumbar and femoral sites. OP was defined using the WHO score. X-ray of lumbar and dorsal spine was performed in order to evaluate the presence of vertebral fractures. Analytical parameters that influence the phospho-calcium metabolism were determined: calcemia, phosphoremia, 25-OH-vitamin D, PTH, alkaline phosphatase and testosterone. For each patient, age, weight, height, body mass index (BMI), comorbidities, toxins (cigarettes, alcohol), medications, degree of exposure to sun and daily calcium intake were recorded. Corticosteroids treatments in the previous five years and number of hospitalizations were also recorded.

211 patients were evaluated. Mean age was 66.78 years (50-84). 73 patients had a FEV1 between 50-80% and 138 had a FEV1 <50%. Prevalence of OP and fractures were respectively 41.6% and 33%. Dose of prednisone greater than 675 mg, BMI below 21, low blood levels of 25-OH-vitamin D, and FEV1<30% were associated significantly with OP (p <0.05). When logistic regression was performed only BMI (OR=0.9; 95% CI, 0.84-0.96) and FEV1<30% (OR=3.32; 95% CI, 1.36-8.06) remained in the model. Age, use of corticosteroid and FEV1<30% were associated significantly with vertebral fractures. When logistic regression analysis was performed, age (OR=1.06; 95% CI, 1.01-1.1) and FEV1<30% (OR=4.39; 95% CI, 1.66-11.59) remained in the model. In conclusion, the prevalence of OP and vertebral fractures are higher than expected in general population. COPD severity is an important riskfactor for OP and vertebral fracture.

Prevalence and Patterns of Presumed Osteoporosis (OP) Among Older Americans Based on Medicare Data. H. Cheng, L. C. Gary*, J. R. Curtis, M. L. Kilgore*, K. G. Saag*, H. Yun*, R. Matthews*, S. Swaminathan*, M. A. Morrisey*, E. Delzell*. Univ. of AL at Birmingham, B'ham, AL, USA.

Background OP prevalence is rising nationally, with recent prevalence estimates for older white women, based on femoral neck bone mineral density testing, of 13.6% for ages 60-69, 26.0% for ages 70-79 and 47.9% for ages 80+. Medicare data afford opportunities and challenges for studying the epidemiology of OP at a population level.

Methods We used Medicare claims data to estimate the prevalence of presumed OP in 2004 and to determine the contributions to estimated OP prevalence of claims for OP and related fractures. The Medicare Chronic Condition Data Warehouse provided data for an enhanced 5% national sample of beneficiaries. We studied 1,600,877 beneficiaries who were ≥ 65 years of age in 2004, had 12 months of Medicare Parts A and B coverage and were not enrolled in an HMO. We assessed claims for 1999-2004 to identify cases with three definitions (D) of presumed OP: D1, ≥ 1 physician service claim with a diagnosis code for OP or for fracture sites strongly associated with OP (i.e., hip, spine or wrist) in any year; D2, ≥ 1 claim for OP or for fractures strongly or usually associated with OP (e.g. pelvis, humerus, radius/ulna, femur, tibia/fibula or clavicle); D3, ≥ 1 claim for OP or for fractures

strongly, usually or sometimes associated with OP (e.g. ribs, scapula, patella or ankle). Results OP prevalence was 19.1% (D1) to 22.9% (D3) overall and varied by gender, race, age and number of years of data (table). For white women, D1-OP prevalence estimates (by age) were 15.7% (65-69), 26.9% (70-79) and 33.4% (80+). Of all D1 cases, 68% had ≥ 2 physician service claims, 71.4% had claims with diagnosis codes for OP only, 14.4% had claims for both OP and fracture, and 14.2% had claims for fracture but not OP. Among people with fracture claims, only 50% had a diagnosis code for OP. Conclusions Estimates of OP prevalence based on Medicare claims were similar to recent prevalence estimates obtained using bone mineral density testing for white women ages 65-79 years and were 20% (D3)-30% (D1) lower for white women ages 80+. Variation in claims-based prevalence by age, gender and race was similar to that found using other methodological approaches. OP-related fractures accounted for a substantial proportion of presumed OP cases. The low proportion of fracture patients with an OP diagnosis code may reflect low rates of OP testing among post-fracture patients.

Prevalence of presumed osteoporosis in 2004 (definition 1)			
Characteristic	Prevalence (%)	Characteristic	Prevalence (%)
Total	19.1	White women	27.5
Race/ethnicity		White women age	
Black	9.7	65-69	15.7
White	19.8	70-79	26.9
Other	21.9	80+	33.4
Gender, Women	26.5	Years of data	
Men	6.3	6	22.8
Age, 65-69	9.5	4-5	15.0
70-79	18.0	2-3	10.8

No Ethnic Differences in Vertebral Fractures Were Found Between Caucasians, Mestizos and Other Ethnic Background in the Latin-American Vertebral Osteoporosis Study (LAVOS). P. Clark¹, J. Talavera^{*1}, S. R. Cummings², D. Margarita³, F. Cons-Molina⁴, J. Zanchetta⁵, D. Messina⁶, L. Haddock⁷, S. Ragi⁸, J. Jaller⁹, a. The LAVOS Group¹. ¹Clinical Epidemiology Unit, IMSS, Mexico City, Mexico, ²Coordinating Center, UCSF, San Francisco, CA, USA, ³Clinica de Osteoporosis, Puebla, Mexico, Mexico, ⁴Unidad de Diagnostico de Osteoporosis, Mexicali, Mexico, Mexico, ⁵Instituto de Investigaciones Metabólicas, Buenos Aires, Argentina, ⁶Clinica de Osteoporosis, Buenos Aires, Argentina, ⁷Universidad de Puerto Rico, San José, Puerto Rico, ⁸CEDOES, Brazil, Brazil, ⁹Clinical Epidemiology Unit, Colombia, Barranquilla, Colombia.

Different rates of OP and fractures have been reported between groups with different ethnicity. Our aim was to determine if different ethnic backgrounds were associated with the risk of vertebral fractures in Latin American women.

A population based sampling frames were obtained from 5 countries within the Latin-American Region in women 50 years and older: Argentina, Brazil, Colombia, Mexico and Puerto Rico. A questionnaire to get demographic information, conventional risk factors, ethnic background and some life style characteristics was applied. BMD in two regions and lateral dorsal/lumbar x-rays were obtained in all cases accordingly with international protocols. Digital morphometry was used to determine vertebral deformities by modified Eastell criteria; all readings were concentrated in one center. A total of 1922 women from the five countries were included from which, 969 (50.4%) self-reported to be Mestizo, 748 (38.9%) Caucasians, and (10.7%) others (Black, Amerindians, Asians or native Indians). Prevalence of Vertebral fractures was 15.3% (148) in Mestizos, 15 % (112) in Caucasians and 10.7% (22) in other ethnic backgrounds. Ethnicity did not impact the fracture risk. The observed odds ratio between Mestizo and Caucasian was 0.98 (95% CI 0.74-1.29) and 0.67 (95% CI 0.40-1.10) between Mestizo and others. Conclusions: Ethnicity does not appear to have any impact in the risk of vertebral fractures in community dwelling Latin-American women.

Stage-of-Change Model Applied to Osteoporosis Medication Use at the Time of Fragility Fracture. B. G. Escott*, V. Elliot-Gibson*, E. R. Bogoch, D. E. Beaton. Mobility Program Clinical Research Unit, Department of Surgery, Keenan Research Center, Li Ka Shing Knowledge Institute, St. Michael's Hospital, University of Toronto, Toronto, ON, Canada.

The purpose of this study was to explore the readiness of patients who have sustained a fragility fracture to take osteoporosis (OP) medication and to identify differences in patient-related factors associated with the various stages of change.

This was a cross-sectional study of baseline data from a prospective cohort of women ≥ 40 years and men ≥ 50 years presenting to a fracture clinic with a low-trauma fragility fracture. Data collected at baseline via a self-reported survey included demographics, OP risk factors, prior OP investigation, diagnosis, treatment and adherence, OP awareness and health beliefs, and a single-item stage of change question adopted from Mauck (2002). We performed multivariable logistic regression to determine associations between baseline patient-related factors and different stages of change.

629 patients completed survey information and met our criteria. Preliminary analysis of willingness to take OP medication revealed a bimodal distribution at the extremes of Prochaska's stages of change with the majority of patients falling in the pre-contemplation or maintenance stages, the two groups analyzed in this study. 539 of 629 (85.7%) patients were either in the pre-contemplation (n=372 or 69%) or maintenance (n=165 or 31%) stages. Mean age (+/- SD) was 73 years (12) and 81% of subjects were female.

Multivariable analysis (adjusted OR; 95% CI) revealed that age >60 (2.5; 1.1-5.8), female gender (3.5; 1.5-7.5), self-reported history of previous fracture (3.3; 2.0-5.3) and self-described poor bone quality (19.9; 8.4-47.3) were significantly ($p<0.05$) associated with being in the maintenance stage compared to pre-contemplation stage. Previous BMD and OP diagnosis were very strongly associated with maintenance stage of change so were not included in the model. Fracture site and highest level of education were not significantly associated.

Higher stage of change was strongly associated with OP awareness. Patients already aware and caring for their OP were more likely to be >60 , female, have sustained a previous fracture and have greater self-awareness of bone quality. Mauck (2002) found few subjects in the intermediate or later stages of change in women suffering a hip fracture. In our study, the intermediate stages of change were not populated suggesting a need to target two main groups for intervention: maintainers for reinforcement and pre-contemplators to raise awareness. This health behavior could be explained using a simpler dichotomous model of motivation for health behavior change. Ref: Mauck et al. (2002) Osteoporos Int 13: 560-564.

Southern California Hispanic Women Osteoporosis Education and Screening Project. A. E. Focil*. President, California Hispanic Osteoporosis Foundation (CHOF), Oxnard, CA, USA.

This study identified Hispanic women at risk for osteoporosis to determine 1) if providing a fracture risk assessment in addition to osteoporosis education would motivate them to seek medical help and 2) if acculturation of Hispanic women had an impact on health seeking behavior. 318 postmenopausal Hispanic women of low economic/education status were recruited at osteoporosis screening events in Ventura County, CA. Osteoporosis education and written materials were provided in Spanish. After obtaining written informed consent, all participants received 1) a risk factor questionnaire; 2) an acculturation questionnaire; and 3) a heel peripheral bone density report. The latter half of women screened also received an absolute fracture risk report (AFR). A survey 6 months later (via telephone and in-home interviews) assessed osteoporosis awareness, if medical intervention was sought and if osteoporosis therapy was initiated.

At screening, 14% of Hispanic women in this study were taking estrogen (n = 45), 43% calcium (n = 137), and 21% vitamin D (n = 67). Overall, 38% of the Hispanic women in the study had low bone mass (LBM)/osteopenia (n = 121), 13% were osteoporotic (n = 43), and 31% of women ≥ 65 years old were osteoporotic. Follow-up surveys were completed in 201 out of 318 screened women (63%), 143 in the T-score only group (70%) and 58 from the T-score plus an AFR group (50%). There was no difference detected in the response with "seeking medical help" between women classified with LBM/osteopenia (40%) or osteoporosis (41%). The number of risk factors and/or a T-score with AFR did not have an impact on this parameter. Age, risk factors and a T-score plus AFR did not appear to influence physician ordering an axial DXA and/or prescribing an osteoporosis treatment or the likelihood of patients filling their prescriptions. There was a non-significant trend in the osteoporosis patients to seek medical help, receive an axial DXA, receive a prescription for osteoporosis therapy (30%), and fill the prescription (19%). The acculturation questionnaire showed that 310 out of 318 (97%) participants did not consider themselves as Americanized (75% viewed themselves as being "very Mexican"), reflecting a fairly homogeneous group of Hispanic women. It was therefore not possible to determine if acculturation of Hispanic women had an impact on health seeking behavior.

Providing an AFR did not appear to influence patient or physician behavior. Future studies need to identify factors that will change Hispanic women's and their physicians' behavior related to osteoporosis.

Effects of Long-Term Treatment with a Prostaglandin E₂ Receptor Subtype 4 Agonist and PTH at Skeletal Sites with Moderate Osteopenia in Aged Ovariectomized Rats. J. I. Aguirre, M. K. Altman*, S. M. Vanegas*, M. F. Rivera*, T. J. Wronski. Physiological Sciences, University of Florida, Gainesville, FL, USA.

Prostaglandin E₂ (PGE₂) is a strong stimulator of bone formation with the ability to restore lost cancellous bone mass in osteopenic ovariectomized (OVX) rats. We and others have shown that a PGE₂ receptor subtype 4 agonist (EP4A) stimulates cancellous bone formation at skeletal sites with severe and moderate osteopenia in aged OVX rats. We also observed that, despite the potent anabolic effect, this agonist was unable to restore cancellous bone mass in aged OVX rats at skeletal sites with severe osteopenia even after long-term treatment (11 weeks). The purposes of this study were to determine the effects of long-term treatment with EP4A at skeletal sites with moderate cancellous osteopenia, and to compare its bone-restorative efficacy with that of PTH treatment. Groups of OVX and sham-operated rats were maintained untreated for 1 year postovariectomy (15 months of age) to develop cancellous osteopenia. OVX rats were then treated SC with vehicle, the EP4A CP-734432 (3 mg/kg) daily, or PTH (80 µg/kg) 5 days/week for a period of 11 weeks. Cancellous bone histomorphometry was performed in the lumbar vertebra (LV) and proximal femur (PF). We found that after 11 weeks of vehicle treatment, OVX rats were moderately osteopenic at both the LV and PF with cancellous bone volumes of 23% and 30%, which corresponded to 60% and 65% decreases compared with the sham-operated controls, respectively. As expected, PTH treatment restored cancellous bone mass to near the level of sham-operated control rats at both skeletal sites. In contrast, EP4A treatment failed to increase cancellous bone mass in aged OVX rats at the LV and PF. Interestingly, osteoblast, osteoid, mineralizing, and osteoclast surfaces were significantly increased in rats treated with EP4A at both skeletal sites, but were unchanged or increased to a much lesser extent in OVX rats treated with PTH. Moreover, whereas EP4A induced significant increases in bone formation rate at both the LV and PF (14- and 4.3-fold, respectively), PTH did not induce significant changes in this variable after 11 weeks of treatment. These findings indicate that although EP4A stimulated cancellous bone formation and bone turnover to a greater extent than PTH, the agonist failed to translate this anabolic response into a restorative effect on cancellous bone at moderately osteopenic sites in aged OVX rats. These findings also suggest that the increase in bone resorption induced by EP4A is in balance with the increase in bone formation so that a net increase in cancellous bone mass failed to occur.

KR62980, a Novel Compound, Enhances Bone Formation Through Promoting Osteoblastogenesis and Inhibiting Osteoclastogenesis. M. Bae, H. Cheon*, J. Lee*, J. Heo*, H. Kim*. Medicinal Science Division, KRICT, Daejeon, Republic of Korea.

The renewal of bone is responsible for bone strength throughout our life as a result of the coordinated actions of two cells, the osteoclast and the osteoblasts. Metabolic bone diseases are considered to be conditions in which this bone resorption-formation balance is lost in favor of increased bone resorption by osteoclasts. Herein, we investigated whether KR62980 exhibits any effects on osteoblast and osteoclast differentiation. KR62980 induced alkaline phosphatase (ALP) activity and increased extracellular matrix calcification in primary osteoblast. Real time RT-PCR analysis revealed that KR62980 also increased the mRNA transcripts of specific genes involved in osteoblastic differentiation, including BSP, OC, ALP and Runx-2. Furthermore, the presence of KR62980 inhibited dose-dependently the osteoclast differentiation by reducing RANKL-induced expression of TRAP and actin ring formation with NFκB inactivation. To reveal sensitivity of KR62980 to changes in anti-osteoporotic activity, 4 week female ddy mice were subjected to ovariectomy (OVX), OVX with daily KR62980 or sham. Mice were imaged on week 8 via Micro-CT. OVX induced a decrease of bone mineral density (BMD) in distal femur over sham (p<0.05), a decrease of BMD which was blocked by daily KR62980 (p<0.01). Taken together, these results suggest that KR62980 deserve attention as potential drugs for treating bone disease.

Dual-Action Cathepsin K Inhibitors: Modulation of Human Osteoclast Function. A. J. Westover*, D. Chagnovich, M. W. Long. Velcura Therapeutics, Inc., Ann Arbor, MI, USA.

Cathepsin K (CTSK), a cysteine protease secreted by osteoclasts (OC), is an attractive target for therapies aimed at osteoporosis and other bone diseases. Moreover, the recent demonstration of CTSK's expression in osteoblast (OB) suggests that other functions exist for this enzyme.

VEL-0230 is a dual-action, orally-available CTSK inhibitor that has an anabolic effect on osteoblasts (stimulation of ex vivo and in vivo bone formation) while also acting to disrupt bone resorptive processes. The effects of VEL-0230 on the differentiation and function of human OC were studied by seeding them onto bovine bone slices in the presence or absence of VEL-0230. Evaluation of VEL-0230's actions on OC differentiation indicated that its continuous presence (10 days exposure) failed to affect M-CSF/Rank Ligand-induced OC differentiation and viability over a range of 10nM to 10µM. The actions of VEL-0230 on OC bone resorption were evaluated via collagen telopeptide CTX1 release into the bone-slice supernatant, coupled with the qualitative assessment of OC motility and pit-formation using Toluidine Blue. Levels of the CTX1 and bone pit depth were strongly inhibited by VEL-0230 in a concentration-dependent manner. Likewise, human OCs treated with VEL-0230 failed to migrate across bone surface, etching a shallow singular pit rather than forming the distinctive trail pattern indicative of OC resorption and migration. VEL-0230's mechanism of action (MOA) was investigated by examining its actions on the intracellular processing of CTSK. Cathepsin K is an autocatalytic enzyme that first cleaves its 38 kDa proenzyme to a 27 kDa active enzyme; a subsequent cleavage of this generates a 25 kDa molecule. Western analysis of VEL-0230 (a cell-permeable compound) treated OC shows a concentration-dependent increase in the relative abundance of the 27kDa and a concomitant reduction in the 25 kDa molecule, with little or no apparent change in the relative abundance of the 38 kDa proenzyme. While the relative abundance of the 27kDa form is high, CTSK enzymatic activity is essentially ablated (70% reduction at 1 µM; 100% at 10 µM). We conclude that VEL-0230 inhibits OC function, reducing pit formation, OC migration and collagen degradation without affecting OC differentiation. Mechanistically, this CTSK inhibitor seems to act after its first autocatalytic cleavage exposes the enzyme's active site, preventing further processing and inactivating the mature enzyme. Coupled with its anabolic actions, VEL-0230 represents a novel, dual-action (anabolic & anti-catabolic) therapeutic candidate for diseases such as osteoporosis. Further, this compound may also have therapeutic indications where cell mobility is a factor.

Effects of Low Dose Parathyroid Hormone on Body Composition, Bone Mass and Turnover and Ectopic Osteoinduction in a Rat Model for Chronic Alcohol Abuse. U. T. Iwaniec¹, C. H. Trevisiol^{1,2}, G. Maddalozzo¹, R. T. Turner¹. ¹Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA, ²Chemical Engineering, Oregon State University, Corvallis, OR, USA.

Parathyroid hormone (PTH) is used clinically to increase bone mass by enhancing bone formation. PTH is also under investigation as a therapy to accelerate fracture repair. We have recently shown that disuse greatly diminishes the bone anabolic response to low-dose (similar to a human therapeutic dose) PTH, suggesting that "life-style" factors may modulate the skeletal response to bone anabolic therapy. The prevalent use of alcohol may represent one of these factors. Chronic alcohol abuse is associated with osteoporosis and impaired fracture healing. Alcohol consumption also inhibits osteoinduction by demineralized allogeneic bone matrix (DABM); DABM is used clinically to facilitate bone fracture repair. Therefore, the present study investigated the effects of alcohol on the bone anabolic response to low-dose PTH: 1) during normal bone turnover, and 2) in a model of DABM-induced bone formation. Three-month-old male Sprague Dawley rats (4 groups; n=10-11 rats/group) were fed control or Lieber-DeCarli liquid diet with 35% of the calories derived from ethanol. The control rats were pair-fed an alcohol-free isocaloric diet. Following a 1 week adaptation to the diets, the rats were implanted subcutaneously with DABM cylinders prepared from femurs and tibiae of rats fed normal rat chow. The rats were then treated with PTH (1 µg/kg/d, 5 d/wk; +/- alcohol) or vehicle (+/- alcohol) for 6 weeks. Body composition was determined on day of necropsy using DXA. Tibiae were processed for histomorphometry. Bone architecture in DABM implants was evaluated by µCT. PTH treatment increased whole body bone mineral content (BMC) and bone mineral density (BMD). The hormone also increased bone formation and bone area/tissue area in the proximal tibial metaphysis. In contrast, PTH had minimal effects on osteoinduction by DABM. Alcohol consumption decreased whole body BMC, fat mass and % body fat. Alcohol also decreased bone formation and bone area/total area in tibia and impaired DABM-mediated osteoinduction. There was no interaction between PTH treatment and alcohol consumption for any of the endpoints measured. Our results suggest that PTH, at a dose rate that increases bone mass in a normal weight bearing bone, is ineffective in enhancing osteoinduction under non weight bearing conditions. In contrast, alcohol inhibited osteoinduction, and reduced bone formation in the presence or absence of therapeutic PTH. These results provide additional evidence that alcohol impairs bone healing and may reduce the efficacy of drugs intended to reverse bone loss.

In Silico Identification of Selective Fibroblast Growth Factor-Receptor Modulators. M. E. Leal¹, L. S. Holliday², D. A. Ostrov³, J. I. Aguirre¹, T. J. Wronski¹. ¹Physiological Sciences, University of Florida, Gainesville, FL, USA, ²Orthodontics, University of Florida, Gainesville, FL, USA, ³Pathology, Immunology and Laboratory Medicine, University of Florida, Gainesville, FL, USA.

Basic fibroblast growth factor (bFGF) has promise as a therapeutic agent for the treatment of osteoporosis, but induces side effects including anemia in a rat model. We are seeking small molecules that selectively modulate the fibroblast growth factor receptors (FGFRs) that are present in bone cells. The long-term goal is to identify a selective ligand for an FGFR that induces a stimulatory effect on bone formation with minimal adverse side effects in non-skeletal tissues. Our initial approach involves use of an in silico method to identify FGFR-selective small molecule ligands. We then screened these ligands for effects on growth of BaF3 cells that were stably-transfected with FGFR1c, FGFR2b, and FGFR3c, using a metabolic colorimetric assay. Small molecules identified as interacting with specific receptors were then screened for effects on osteoclast formation in mouse marrow cultures. We initially identified 36 small molecules predicted to interact selectively with FGFR1c and FGFR3c. None were agonists, but several inhibited the growth of BaF3 cells by 50-80% in the presence of bFGF and acidic FGF. From these, we identified one small molecule against FGFR1c (LWOH031c) and one against FGFR3c (LWOH193c) that were selective. LWOH031c reduced osteoclast formation by 80% in mouse marrow cultures in the presence of bFGF and other stimulators, but also reduced bFGF-stimulated proliferation of adherent cells. LWOH193c inhibited osteoclast formation by 80-90%, but did not reduce adherent cell proliferation. We are currently testing the effects of these molecules on bFGF-induced proliferation of calvarial osteoblasts and primary chondrocytes. In conclusion, we have identified small molecules that selectively interact with FGFR1c and FGFR3c to block stimulation by bFGF. Interestingly, both reduced osteoclast formation in mouse marrow cultures in response to bFGF and other stimulators of osteoclastogenesis. The inhibitor of FGFR3c had no detectable effect on proliferation of adherent cells. These molecules may be useful pharmacologically as FGFR-selective inhibitors, or may be derivatized to enable them to serve as selective agonists.

Effects of Intermittent Administration of Parathyroid Hormone (1-34 hPTH) on Distraction Osteogenesis in Rabbits. H. Maruno¹, S. Ichimura², T. Oohata², C. Uchikura², K. Satomi². ¹Orthopaedic, Kyorin Univ, Tokyo, Japan, ²Orthopaedic, Kyorin Univ., Tokyo, Japan.

<Objective> Our study examined the effects of intermittent administration of parathyroid hormone (1-34 hPTH) on distraction osteogenesis. <Materials and Methods> An external fixator was applied to 15 immature white Japanese rabbits and an osteotomy was performed on the right tibia. After a delay of 1-week, the distraction was started at a rate of 0.375 mm twice a day for 2 weeks. Beginning on distraction, hPTH was subcutaneously administered once a day, four days a week for a total of 4 weeks at a dose of 10 µg/kg (group P10) or 30 µg/kg (group P30) to five rabbits per group. Five rabbits received only the vehicle (group C) in the same manner. Seven weeks after osteotomy, the external fixator was removed, and rabbits were sacrificed 1-week later. We analysed the distracted callus by X-ray, DXA, pQCT, and µCT, to evaluate the bone union, BMD, cross section area and the morphology of callus. Three-point bending test was performed to assess biomechanical parameters. <Results> Bone union was found in all rabbits. The average BMD of the distracted callus (mg/mm³) was 321.0, 330.8 and 354.4 for group C, group P10 and group P30, respectively. The total cross section area (mm²) was 63.5, 53.6 and 81.7 and the value of group P30 was significantly larger than those of the other two groups. The cortical cross section area (mm²) of group P30 was largest and was significantly larger than that of group P10. µCT of group C showed the immature trabecular bone in the medullary cavity of the callus and the undefined lamellar formation of cortical bone. On the other hand, in PTH-administered groups, there was less immature trabecular bone in the medullary cavity, and the formation of lamellar structure in cortical bone was accelerated. Three-point bending analysis showed that fracture energy (N•mm) was 168.9, 240.1 and 583.0, respectively, and group P30 demonstrated a significantly larger value than the other two groups. <Discussion> PTH have a remodeling acceleration effect in bone fracture experiments. In relation to distraction osteogenesis, Seebach found an increase in bone mineral content and a stronger callus using rat femur models. The results in this study did not find any significant difference in bone density, but the cross section area and mechanical strength of the distracted callus of group P30 was significantly larger and higher. The morphology of the distracted callus in groups P10 and P30 also suggested a remodeling acceleration effect. We concluded that intermittent administration of PTH could be beneficial to shorten the consolidation period of callus formation in distraction osteogenesis.

Calcium Absorption from Commonly Consumed Vegetables in Healthy Thai Women. S. Charoenkiatkul¹, W. Kriengsinos¹, U. Suthutvoravut², C. M. Weaver³. ¹Institute of Nutrition, Mahidol University, Nakhonpathom, Thailand, ²Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand, ³Foods and Nutrition, Purdue University, West Lafayette, IN, USA.

The absorbability of calcium from ivy gourd, green leafy vegetable (*Coccinia grandis* Voigt.) and winged bean young pods (*Psophocarpus tetragonolobus*, (L) DC) were measured in 19 healthy adult women aged 20-45 y, in a three-way, randomized-order, crossover design with an average calcium load of 100 mg and milk as the referent. The test meals were extrinsically labeled with ⁴⁴Ca and given with rice as breakfast after an overnight fast. Absorption of calcium was determined on a blood sample drawn 5 h after ingestion of the test meal. Fractional calcium absorption (X ± SD) was 0.391 ± 0.128, from winged beans, 0.476 ± 0.109 from ivy gourd, and 0.552 ± 0.119, from milk. The difference in fractional calcium absorption for these two vegetables was significant (P<0.05) and the fractional calcium absorption from these two vegetables were both significantly lower than from milk. The difference was partly accounted for by the phytate, oxalate and dietary fiber content of the vegetables. However, the bioavailability of these two vegetables, commonly consumed among Thais, was relatively good compared to milk (71-86% of milk) and could be generally recommended to the public as calcium sources other than milk and Brassica vegetables.

Natural Plant Extracts, Gs-Ac and -H, Induce Osteoblast Differentiation and Reduce Osteoclast Differentiation. Y. Chung¹, H. Yoon¹, S. Yun¹, S. Yi¹, Y. Won², Y. Shin³, S. Lee⁴, S. Lee⁵, N. Song⁶, J. Ryu⁶.

¹Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, Republic of Korea, ²Orthopedic Surgery, Ajou University School of Medicine, Suwon, Republic of Korea, ³Endocrinology and Metabolism, Wonju College of Medicine, Wonju, Republic of Korea, ⁴Biochemistry, Eulji University College of Medicine, Daejeon, Republic of Korea, ⁵ISAM Internal Medicine Clinic, Busan, Republic of Korea, ⁶HL Genomics, Yongin, Republic of Korea.

Background: Bone is a dynamic organ that is continuously remodeled by combinational roles of osteoblasts and osteoclasts. Osteoporosis is a disease of imbalance in bone formation (osteoblast) and resorption (osteoclast), which leads to bone loss. We investigated that effects of natural plant extracts GS-Ac and -H on osteoblast and osteoclast differentiation.

Methods: Osteoblastic differentiation was evaluated with alkaline phosphatase (ALP) and mineralization assays. Osteoclastic differentiation was determined with osteoprotegerin (OPG) and tartrate resistant acid phosphatase (TRAP) staining.

Results: GS-Ac and -H (0.1, 0.05 mg/ml) increased ALP activity as 5-7-fold of control in osteoblast. Dexamethasone decreased ALP activity as 1.5-fold of control and GS-Ac, and -H increased as 2.3-10-fold of Dexamethasone. GS-Ac (0.1, 0.05 mg/ml) and GS-H (0.05 mg/ml) increased mineral nodule formation in osteoblast. OPG concentration was increased as 2.5-fold of control. TRAP-positive cells were decreased in GS-Ac treated osteoclast.

Conclusion: GS-Ac and -H promoted osteoblast differentiation and suppressed osteoclast differentiation.

Efficiency of Dietary Calcium Use for Skeletal Growth and Mineralization in Young Pigs Fed Diets with Various Phosphorus Concentrations. H. Singh*, D. K. Schneider*, T. D. Crenshaw. Animal Sciences, University of Wisconsin -Madison, Madison, WI, USA.

Efficiency of nutrient use (nutrient retained/consumed) is typically higher in animals fed diets with marginal deficiencies compared with animals allowed adequate intake of the nutrient. However, Ca efficiency was lower in pigs fed diets with a marginal Ca deficiency compared with Ca efficiency of pigs fed diets with excess Ca. The previous study (J Bone Miner Res 20:S193) was designed to assess recovery of skeletal growth in young pigs following a period of deficit growth induced by a Ca deficiency. Dietary P concentrations may have limited the efficiency of Ca use. The current study was designed to assess the impact of dietary P concentrations (either 70, 90, or 120% of requirements) on efficiency of Ca use in young pigs. Diets provided Ca at either 75 or 150% of requirements for each P level. Ca efficiency was estimated from Ca retention predicted with DXA scans (GE Prodigy, using scan modes previously shown accurate for pigs, J Bone Miner Res 20:S332) and dietary Ca consumption over a 27 day trial. In pigs fed diets with 90% of P requirements, Ca efficiency was greater if Ca was limited (75%) than if excess (150%). However, if pigs were fed diets with excess P (120%) no differences in Ca efficiency were detected between Ca levels. Pigs fed diets with only 70% of P requirements failed to gain bone mass over the 27 d trial regardless of the Ca level. Improvements in efficiency of P use were not detected in animals fed diets limited in P regardless of Ca levels. In conclusion, efficiency of Ca use in young pigs is altered by dietary P levels.

Diet Ca, % of required	75			150			
Diet P, % of required	70	90	120	70	90	120	SEM
BMC gain, g/d ^{bc}	-1.36	6.47	9.27	-1.75	4.37	13.11	0.40

Postmenopausal Osteoporosis HRT and Weight Gain. A. Bazarra-Fernandez*. ObGyn, Juan Canalejo University Hospital Trust, Amparo Lopez Jean 13 4^a A, La Coruña, Spain.

Background: Recent studies have found weight gained during menopause increase the risk of high blood pressure, the diabetes, heart disease, and has been strongly linked to increased incidence of breast and other hormone-related postmenopausal malignancies. These healthcare concerns have led to the conception of specific products that target menopausal weight gain.

Aim: Looking over weight gain and osteoporosis treatment in climacteric. Material and methods: 20 women who were 44 to 58 years old have been recruited. BMI was increased to age. Those with an intact uterus have moderate to severe vasomotor symptoms associated with the menopause, moderate to severe symptoms of vulvar and vaginal atrophy and risk of postmenopausal osteoporosis. They were ascribed to equal two 10 women groups. One group was assigned to 2 mg drospirenone /1 mg 17 beta- estradiol hemihydrate. The other group treated with. 40 mg soy bean.

Results: in the women on 2 mg drospirenone /1 mg 17 beta- estradiol hemihydrate medication decreased, moderate to severe symptoms of vulvar and vaginal atrophy vasomotor symptoms associated with the menopause in regard to the other group treated with 40 mg soy bean. They had weight main loss of 3 kg in one year, (P < 0.05).

Conclusions: Human HRT is in relation to decrease osteoporosis. Nobody noted 17 beta-estradiol is in relation to breast cancer. Estradiol is the same oestrogen produced by the ovaries before menopause. Drospirenone has the unique property of reducing water retention often associated with the use of oestrogen and other synthetic progestin hormones. The impact of obesity on hormone replacement therapy is due to many women associate hormones with weight gain. This late medication formula can be beneficial in minimizing uncomfortable symptoms, such as weight gain, hot flashes, night sweats, and mood swings, associated with the natural progression of a woman's life cycle. So, it is due to conduct one great try to make clear and more comprehensible these points.

Bone Specific SARMs (Selective Androgen Receptor Modulators) Increased Bone Mineral Density in a Different Manner from Anti-resorptive Agent, Raloxifene with Minimum Effects on the Uterus. K. Furuya¹, N. Yamamoto^{*1}, Y. Ohyabu^{*1}, T. Morikyu^{*1}, A. Iwata^{*1}, H. Ishige^{*2}, K. Kuzutani^{*3}, Y. Taquahashi^{*3}. ¹Drug Discovery Research Lab., Kaken Pharmaceutical, Co., Ltd., Kyoto, Japan, ²Chemistry Lab., Kaken Pharmaceutical, Co., Ltd., Kyoto, Japan, ³Safty Research Lab., Kaken Pharmaceutical, Co., Ltd., Fueda, Japan.

Estrogens and androgens are opposite sex steroid hormones and both affect bone metabolism and uterine homeostasis. Raloxifene is a selective estrogen receptor modulator (SERM) which has estrogenic effects on the bone with reduced side effects on the sexual organs. We have been demonstrated a concept of Selective Androgen Receptor Modulators (SARMs) as useful drugs for a treatment of osteoporosis through proving that anabolic effects on the bone can be separated from virilizing effects. This study compared our new SARM Compound R2 with Raloxifene in the effects on the bone and uterus. Female 12-week old Sprague-Dawley rats were ovariectomized (OVX) and were feed with a low calcium diet for 4 weeks to expedite reduction of the bone mineral density (BMD). Oral administration of Compound R2 (1, 10 mg/kg) or Raloxifene (1 mg/kg) were followed once a day for 8 weeks. Compound R2 significantly increased the BMD at the part between the diaphysis and proximal metaphysis of the femurs at 1 mg/kg, whereas Raloxifene slightly increased the BMD at the distal and proximal metaphysis which are cancellous bone rich parts. Concerning to the effects on the uterus, dihydrotestosterone had a major impact on the uterine muscle and also increased the endometrium. Compound R2 did not show any effects on the uterus at 1mg/kg and displayed minimum effects on the uterine muscle at 10mg/kg. On the other hand, Raloxifene displayed slightly thickening of the endometrium. These results demonstrate that Compound R2 is superior to Raloxifene in bone formation and specificity to the bone, suggesting that SARM is promising for the treatment of severe osteoporosis patients without anabolic effects on the uterus.

Effects of Bazedoxifene Acetate on Bone Loss: A 12-Month Study in Ovariectomized Rats. B. S. Komm¹, P. V. N. Bodine¹, D. R. Minck^{*2}. ¹WHMSB, Wyeth Research, Collegeville, PA, USA, ²Drug Safety, Wyeth Research, Chazy, NY, USA.

Bazedoxifene acetate (BZA) is a novel, stringently screened selective estrogen receptor modulator (SERM) currently in development for the prevention and treatment of postmenopausal osteoporosis and in combination with conjugated estrogens for the treatment of menopausal symptoms and prevention of postmenopausal osteoporosis. We examined the effects of BZA on bone mass/composition, biomechanics, and histomorphology in ovariectomized (OVX), 6-month-old female rats.

In the active treatment groups, 3 doses of BZA (0.15, 0.3, and 1.5 mg/kg/day) were administered to OVX animals by oral gavage for 12 months. Control groups included an untreated baseline group, untreated sham-operated animals, untreated OVX animals, and an estrogen-treated (17 α -ethinylestradiol [EST], 0.03 mg/kg/day) OVX group. Animals assigned to the baseline group received no treatments or procedures and were euthanized within 2 weeks of study initiation for testing. Untreated sham-operated and untreated OVX animals were administered only test vehicle, once daily. Dual energy x-ray absorptiometry (DXA) scans, peripheral quantitative computerized tomography (pQCT), and biomechanical and histomorphometric studies were conducted to assess bone mineral density (BMD), bone mineral content (BMC), and bone architecture and strength. Based on BMD and BMC analyses, BZA protected the skeleton from estrogen-dependent bone loss at several sites, with optimal protection observed with the 0.3 mg/kg/day dose. In vivo DXA data revealed a dose-related response to treatment with BZA for 11 of 12 parameters examined. Treatment with BZA 0.3- and 1.5-mg/kg/day reduced the loss of trabecular BMD at metaphysis (MTrabMDp) observed in OVX controls by 39%-41% and 34%-37%, respectively (P \leq 0.01), as confirmed by pQCT analysis at the tibia and femur; these doses of BZA resulted in more marked reductions in MTrabMDp loss than EST. A significant difference was observed between the BZA 0.3- and 1.5-mg/kg/day treatment groups and the OVX control group in maximal stress on the lumbar vertebra 4 on biomechanical testing (P \leq 0.01); BZA also increased maximum load reached in the neck of the femur, but this effect did not reach statistical significance. Histomorphometric analyses showed differential beneficial effects of treatment with BZA in protecting against the deleterious effects of ovariectomy on the skeleton.

We conclude that BZA, a novel SERM, exhibits a promising therapeutic profile based on demonstration of generally dose-related protective effects on several skeletal parameters in this animal model of accelerated bone loss.

Small Organic Molecule Compound Protects Against Inflammatory Bone Loss in a Rat Model of Periodontitis. R. Jin^{*1}, Y. Zhang^{*1}, Y. Liang^{*1}, X. Li^{*1}, R. Bhatt^{*1}, D. Wu^{*2}, J. Zheng^{*3}, L. Xu^{*4}, L. Golub^{*4}, D. Liu¹. ¹Enzo Therapeutics, Inc, Farmingdale, NY, USA, ²Yale University, New Haven, CT, USA, ³St Jude Hospital, Memphis, TN, USA, ⁴School of Dental Medicine, Stony Brook, NY, USA.

The canonical Wnt signaling pathway is initiated by the binding of Wnt proteins to receptor complexes consisting of LDL receptor-related protein (LRP) 5/6 and frizzled protein. An antagonist of the Wnt pathway, Dkk1 protein (Dkk), binds to the third YWTD repeat domain of LRP5 and Kremen, resulting in the removal of this co-receptor with inactivation of the Wnt pathway. Both human and mouse genetic studies provide supporting evidence that LRP5 has an important role in the regulation of bone remodeling. Hypomorphic or null alleles lead to early onset of osteoporosis; whereas, other LRP5 mutation alleles are associated with high bone mass. Our innovative approach combines structural biology, computational screening, and biological assays to identify small molecule compounds that are capable of disrupting LRP5-Dkk interactions and reversing the inhibitory effect of Dkk on Wnt signaling. We have employed a periodontitis model of bone loss to evaluate the effect that our small molecule compound has on protecting against bone resorption. In this model, lipopolysaccharide (LPS) was used to initiate inflammatory-induced alveolar bone loss. Prior to administering LPS between the first and second molar of the maxillae of Sprague Dawley rats, animals were pretreated with a small molecule test compound (SMTC) or vehicle by oral gavage. Animals were then exposed to LPS every other day and treatment with the SMTC was continued daily. Jaws were removed after 10 days, defleshed and stained with Loeffler's methylene blue in order to identify the cemento-enamel junction (CEJ) as a reference point to measure bone height. Histological analysis clearly showed significant bone resorption and root furcation in the LPS-treated animals, and little bone resorption in the LPS plus SMTC-treated animals. Linear measurements from the CEJs to the alveolar bone crest showed a mean bone loss of 0.94 ± 0.08 mm in LPS-treated animals; 0.59 ± 0.04 mm in LPS plus SMTC-treated animals; and 0.54 ± 0.04 in control animals. There were statistically significant differences between the LPS group and the LPS plus SMTC group ($p = 0.00006$) and between the control group and LPS group ($p = 0.00003$). As an indicator of protection, there was no significant difference between the control group and the LPS plus SMTC group ($p = 0.18$). These data clearly show that SMTC protects against bone resorption in an animal model of endotoxin-induced bone loss. This SMTC may represent an attractive potential new class of therapeutic agents for clinical use, and continued investigation is warranted.

Vitamin D Supplementation and 25OHD Levels in Long Term Care Residents. R. Crilly^{*1}, M. Mason^{*2}, M. Kloseck^{*3}. ¹Department of Medicine, University of Western Ontario, London, ON, Canada, ²Department of Health and Rehabilitation Sciences, Faculty of Health Science, University of Western Ontario, London, ON, Canada, ³Faculty of Health Sciences, University of Western Ontario, London, ON, Canada.

Osteoporosis is common in long term care patients who contribute about 30% of all hip fractures. Vitamin D supplementation has been shown to reduce hip fractures in these patients. Recent information in the community dwelling elderly has suggested that the doses of vitamin D used need to be higher to achieve the blood levels required to reduce the PTH levels. In LTC patients, where sunshine is a rarity, we hypothesized that the supplementation dose would need to be even higher. To date, 41 patients of 4 nursing homes have consented to participate. Patients were either on no supplementation, 400 IU per day or 1000 IU per day. Patients were on various doses of calcium supplementation (range 0-1500). No change in dose of D or calcium had been made for at least 3 months. Blood was drawn for 25 OHD and PTH levels. Patients with renal impairment shown by a creatinine over 130 nmol/L were excluded. 14 patients were on no vitamin D supplementation, 13 were on 400 IU and 14 on 1000IU. Patients were aged 84.4 ± 6.7 yrs SD (range 71-98 yrs.), with no age difference between the groups, had been in the institution for 35.2 months ± 30 SD (range 9-151) and, where applicable, on the current vitamin D dose for 11.3 ± 1.77 months SD. Mean levels of 25OHD in the three groups were 48.29 ± 19.07 ; 83.46 ± 21.75 ; and 87.4 ± 15.7 nmol/l for the three groups, no supplement; 400IU; and 1000IU respectively. The level for each treatment dose differed from the no-treatment group ($p < .001$) but not from each other. Parathyroid hormone levels on the other hand were similar in all groups (4.41 ± 2.0 ; 6.02 ± 4.16 ; 4.81 ± 2.87 for the zero, 400 and 1000 dose groups respectively), and there was no correlation between 25OHD levels and PTH levels overall. Mean levels of calcium supplementation was lower for those on zero and 400IU of vitamin D (405 ± 356 vs. 320 ± 473 mg/day) compared to those on 1000IU (769 ± 525 mg/day, $p = .044$ and $.031$ respectively). The lower PTH levels in those on no, or lower, vitamin D doses could not be explained by calcium supplementation levels, which was lower in those groups. We conclude on the basis of these unexpected preliminary results that the level of 25OHD levels achieved in LTC

residents is adequate on 400IU of vitamin D, that the PTH levels are lower than expected in those on no vitamin D, and calcium supplementation does not account for this finding.

Age Modifies the Impact of Vitamin D3 Supplementation on the 25-OH Vitamin D/ Parathyroid Hormone Ratio. H. J. Florez^{*}, E. P. Cherniack^{*}, O. Gómez-Marín^{*}, B. A. Roos^{*}, S. Levis, B. R. Troen. Miami VAMC, University of Miami Miller School of Medicine, Miami, FL, USA.

Both 25-hydroxyvitamin D (25OH-D) and parathyroid hormone (PTH) are associated with functional outcomes in the elderly. Recent evidence suggests that the 25OH-D/PTH ratio predicts functional recovery after hip fracture in older patients [1]. In a pilot study we evaluated supplementation with 2,000 IU/day of cholecalciferol (D3) for 6 months in elderly men at the Miami VA Medical Center. Participants were randomized to either placebo [$n = 17$, age (mean \pm SD: 79 ± 4 years)] or D3-treatment [$n = 17$, age: 80 ± 4 years]. No significant baseline differences were observed between participants aged 80 years and older compared to those age 70 to 79 years in 25OH-D (28.7 ± 9.1 vs. 29.7 ± 7.3 ng/ml, $p = 0.7$), PTH (48.6 ± 22.1 vs. 42.1 ± 19.6 pg/ml, $p = 0.4$), or the 25OH-D/PTH ratio (730 ± 409 vs. 893 ± 571 , $p = 0.3$). After 6 months of treatment, 25OH-D was higher in both D3-treated age subgroups compared to the placebo subgroups (Table), while no significant differences in PTH values were observed between age and treatment groups. D3 treatment increased the 25OH-D/PTH ratio compared to placebo participants, and the changes in this ratio were significantly higher only among those aged 80 years and older (619 ± 126 in D3-treated vs. -64.5 ± 133.6 in placebo participants, $p < 0.001$). These results suggest that D3 treatment improves 25OH-D levels in all elderly participants. However, the differences in the 25OH-D/ PTH ratio suggest that D3 treatment may provide additional functional benefits in those aged 80 and older. Further studies to characterize the response to D3 therapy in this elderly group are warranted.

Orally-active Nonsecosteroidal Vitamin D Agonists Increased Bone Mass in Ovariectomized Rats without Causing Hypercalcemia. S. Harada^{*1}, S. Takeda^{*1}, A. Sugita^{*1}, M. Ishigai^{*2}, H. Kashiwagi^{*3}, T. Takahashi^{*3}, T. Tamura^{*1}, K. Morikawa^{*3}, E. Ogata^{*4}, E. Ichikawa^{*1}. ¹Pharmaceutical Research Dept. 1, Fuji Gotemba Research Labs. Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, ²Pre-clinical Research Dept, Fuji Gotemba Research Labs. Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, ³Chemistry Research Dept. 1, Fuji Gotemba Research Labs. Chugai Pharmaceutical Co., Ltd., Gotemba, Japan, ⁴Cancer Institute Hospital, Tokyo, Japan.

Secosteroidal vitamin D receptor (VDR) agonists have been used for treatment of psoriasis, secondary hyperparathyroidism and osteoporosis. However, their efficacy is limited due to the development of hypercalcemia. Recently, several nonsecosteroidal compounds were demonstrated to be active as VDR agonists. To identify VDR agonists with less calcemic effects than those of secosteroidal structures, we designed and synthesized about seven hundred nonsecosteroidal VDR agonists using co-crystal structure of VDR and its agonists. In VDR agonists, there were good correlations between epithelial calcium channel 2 (ECaC2) induction in colon cancer cell line (Caco-2) in vitro and urinary calcium excretion in vivo, and also between osteocalcin (OC) secretion in MG63 osteoblast cell line in vitro and response of bone mineral density (BMD) in vivo. Therefore, nonsecosteroidal VDR analogs were first tested for their abilities to induce ECaC2 mRNA in Caco-2 and to induce the secretion of osteocalcin from MG63. Forty compounds which showed strong OC induction with less ECaC2 induction were selected for in vivo evaluations. Six compounds (e.g. CH5013072) significantly increased BMD of spine and femur without inducing hypercalcemia in ovariectomized rats after daily oral administration. Moreover, they decreased bone resorption parameters but had little effect on bone formation parameters. Thus, these nonsecosteroidal VDR agonists will be promising candidates as orally-active and less calcemic drugs for osteoporosis.

Differential Effects of Alfacalcidol in the Distal Tibial Metaphyses of Orchidectomized and Aged Male Rats. X. Y. Tian¹, X. Q. Liu¹, H. Y. Chen¹, R. B. Setterberg^{*1}, M. Li², W. S. S. Jee¹. ¹Division of Radiobiology, University of Utah School of Medicine, Salt Lake City, UT, USA, ²Department of Cardiovascular and Metabolic Disease, Pfizer Global Research and Development, Groton, CT, USA.

The purpose of the study was to compare the effects of alfacalcidol (ALF), a vitamin D analog, on the cancellous bone of distal tibial metaphysis in aged male and orchidectomized (ORX) rats. The distal tibia fuses its epiphyses at 3 months and is primarily a fatty marrow site with a cancellous bone histomorphometric profile similar to that in human iliac crest sites. Seventy male Sprague-Dawley rats were sham or ORX at 18 months of age and then orally treated with vehicle or ALF at 0.1 or 0.2 µg/kg/d, 5 days per week for 12 weeks. Double fluorescent-labeled undecalcified distal tibiae were processed for bone histomorphometry. An age-related increase in bone turnover without bone loss was seen in aged rats. Despite further increased bone turnover, ORX did not cause bone loss in aged rats. Treatment of aged rats with ALF at 0.1 and 0.2 µg/kg/d decreased %eroded perimeter (Er.Pm), mineralizing surface (MS/BS), surface referent bone formation rate (BFR/BS), and bone volume referent bone formation rate (BFR/BV), resulting in non-significant increases in ratio of mineralizing surface/eroded surface (MS/Er.Pm) and trabecular area (Tb.Ar). These data indicate that 12 weeks of treatment with ALF had a positive but moderate effect on the balance between bone formation and resorption in the aged male rats. Treatment of ORX rats with ALF at 0.1 µg/kg/d caused similar changes in the Er.Pm, MS/BS, BFR/BS, and BFR/BV but significantly increased MS/Er.Pm and Tb.Ar. Although treatment of ORX rats with ALF at 0.2 µg/kg/d decreased Er.Pm (-67%), it did not alter MS/BS, BFR/BS, and BFR/BV, resulting in significant increases in MS/Er.Pm (+220%) and Tb.Ar (+47%) compared with aged rats treated with vehicle. When compared with vehicle-treated ORX rats, ALF significantly decreased Er.Pm (-73%), MS/BS (-46%), and BFR/BV (-58%) whereas increased MS/Er.Pm (+173%) and Tb.Ar (+51%). These data revealed that ALF treatment suppressed bone resorption below normal level while maintaining bone formation at normal level, leading to a positive balance between bone formation and resorption and consequently increased bone mass in ORX rats. Thus, the positive effect of ALF is more pronounced in the distal tibia of ORX rats with a higher bone turnover than sham controls. The differential effects of ALF on bone in sham and ORX rats suggest that vitamin D analog such as alfacalcidol is more efficacious at a predominantly fatty marrow skeletal site with high bone turnover.

Disclosures: X.Y. Tian, None.

The Effect of Oral Ibandronate Following Weekly PTH: PTH Once Weekly Research Follow-up (POWR II). D. M. Black¹, L. Palermo¹, T. F. Hue¹, S. Majumdar¹, M. L. Bouxsein², C. J. Rosen³. ¹University of California, San Francisco, San Francisco, CA, USA, ²Beth Israel Deaconess Medical Center, Boston, MA, USA, ³MECOR, St. Joseph Hospital, Bangor, ME, USA.

Use of alendronate for one year following one year of daily PTH in the PaTH study led to large increases in BMD during the second year, in postmenopausal women. We recently reported the results from the PTH Once Weekly Research (POWR) study, which demonstrated that PTH 1-84 used once weekly (100 µg) led to an increase of about 2% in DXA spine BMD versus placebo. POWR II is a follow-up study, in which all POWR participants were offered open-label monthly ibandronate (150mg) for 12 months. In the POWR study, 50 women were randomized (1:1) to either one year of PTH 1-84 injections (100 µg weekly, after a 1 month daily loading period) or to placebo. At the end of the year, 48 adherent women were offered 1 year of ibandronate (150 mg/monthly). 43 women chose to take the ibandronate and are included in this analysis. The main endpoint

was changed in DXA spine BMD; secondary endpoints (not reported here) included hip BMD, QCT (hip and spine) and MRI (wrist) assessed trabecular BMD. We hypothesized that those who had been on weekly PTH would experience larger rises in BMD than those on placebo.

During the one year on ibandronate, the group formerly taking weekly PTH had a 1.1% increase in spine BMD compared to 3.1% increase in those who were on placebo injections (p=0.07). Cumulatively over two years (months 0-24), the group given weekly PTH followed by ibandronate increased 2.8% compared to 3.2% for those who had been given placebo then ibandronate (see Figure). Results for other endpoints were similar; showing no significant difference in the change in BMD during the second year regardless of earlier treatment with weekly PTH.

Over 24 months, mean BMD change in women on weekly PTH followed by ibandronate was the same as those on placebo followed by ibandronate. The weak anabolic effect of once weekly PTH achieved after 12 months, was insufficient to yield the subsequent BMD gain at 24 months, as seen with bisphosphonate use after daily PTH therapy in PaTH.

Characteristics of Postmenopausal Women Treated with PTH(1-84) in the TOP Study: Relationship of Baseline Serum and Urine Ca Values to Hypercalcemia and Hypercalciuria. H. A. Bone¹, S. Greenspan², S. Morris³, J. Bilezikian⁴. ¹Michigan Bone and Mineral Clinic, Detroit, MI, USA, ²Osteoporosis Prevention and Treatment Center, Pittsburgh, PA, USA, ³NPS Pharmaceuticals, Parsippany, NJ, USA, ⁴Columbia University College of Physicians and Surgeons, New York, NY, USA.

The TOP study, an 18-month, multinational, randomized, double blind, placebo-controlled trial, assessed the ability of recombinant human PTH(1-84) to reduce vertebral fracture incidence in postmenopausal osteoporotic women. 2679 subjects received daily Ca (700 mg) and vitamin D (400 IU) supplements in addition to either PTH(1-84) 100 µg SC daily or placebo. Inclusion criteria included a serum Ca ≤10.7 mg/dL and a urinary Ca to creatinine ratio of ≤1.0 mmol/mmol at screening, values that generally exceed the upper limits of normal for adults. These limits contrast with criteria for other studies of PTH-like peptides, e.g., teriparatide fracture study [PTH(1-34)] and the PaTH study [PTH(1-84)] in which subjects were excluded if baseline serum and urine Ca values were above normal to any degree (e.g. subjects must have serum calcium <10.2 mg/dL and urinary calcium <300 mg/24 hr). Of the 1286 subjects treated with PTH, 16% had serum Ca >10.2mg/dL and 10% had urine Ca >300 mg/24 hr at baseline, values that would have excluded them from participation in the other trials alluded to. Moreover, 3.1% of subjects had both hypercalcemia and hypercalciuria. Subjects treated with PTH(1-84) with a baseline urine Ca >300 mg/24 hr had an incidence of hypercalciuria at least 2-fold higher than in those with baseline urinary calcium ≤300 mg (>70%). Similarly, individuals treated with PTH(1-84) with baseline serum Ca >10.2 mg/dL had ~2-fold higher likelihood of hypercalcemia (47%). These results help to explain the substantially higher risk for either hypercalcemia and/or hypercalciuria in TOP as compared to the other trials. Although subjects who experienced hypercalcemia or hypercalciuria benefited from PTH by increases in BMD at multiple skeletal sites and a reduced incidence of vertebral fractures, these data emphasize the critical role that inclusion and exclusion criteria play in the interpretation of PTH safety profiles.

Early Adjuvant Therapy with Teriparatide after Major Orthopaedic Surgery of Complicated Fractures of Long Bones in Postmenopausal Women: Preliminary Clinical Results. C. F. Corradini^{*1}, F. M. Olivieri^{*2}, C. A. Verdoia^{*1}. ¹Orthopaedic and Traumatologic Clinic, Studies University of Milan, Milan, Italy, ²Nuclear Medicine, Policlinico Mangiagalli IRCSS Foundation, Milan, Italy.

INTRODUCTION: In the last years the postmenopausal population is increasingly afflicted by complicated fractures of long bones. These are represented by two main clinical situations: the sixties woman without any apparent bone metabolic problem that after a comminuted fracture of long bones suffers a series of complication as late consolidation or non union; the second is an eighties with a new on precedent fracture or periprosthetic fracture. In both the untreated metabolic impairment of bones creates always a trouble to the orthopaedic surgeon because of altered mechanical resistance. So the exigency to improve the bone quality has suggested the use of an anabolic agent with a direct action on osteoblasts.

The aim of the study was to evaluate if the adjuvant therapy with teriparatide may improve the clinical outcome of complex fractures in postmenopausal osteoporotic women.

CASES REPORT: we studied a consecutive series of 7 female patients between 63 and 94 years-old presenting a complex fracture of long bones. Biochemical determinations of bone turnover and calcium homeostasis were obtained on admission and 4, 12 and 24 weeks later. Rx of affected segment was repeated at least 2, 4, 6 months. BMD was measured by DXA during hospitalization and at 6 month.

They received daily subcutaneous teriparatide (25 microg) per day, 1000 mg calcium and 400-1200 IU of vitamin D daily as oral supplementation for 6 months from 15 days by operation.

FINDINGS: Four periprosthetic of the femur, one late consolidation of neck treated with intramedullary nail, one non union of the radio-ulna treated with plaques and screws, one re-fracture of the tibia. At 6 month all patients were cured in a range of 12-20 weeks in average 14. The vitamin D was at lower levels but the supplementation was sufficient to normalize. The other biochemical variables of bone formation and resorption peaked within the consolidation process and at 6 months were indistinguishable from baseline. Subjects increased bone mass by 11.4+/-2.4% in the spine, 3.4+/-2.0% in the total hip.

CONCLUSIONS: These data show that an early adjuvant therapy with teriparatide of complicated fractures in postmenopausal women permits an bone consolidation and functional recovery. Nevertheless further studies in humans will be required to define optimal efficacy, it is intriguing the possibility to obtain the fracture healing with a bone anabolic agent.

Changes in 25-hydroxy- and 1,25-dihydroxyvitamin D During Treatment with Teriparatide. F. Cosman¹, B. Dawson-Hughes², P. Chen³, J. H. Kregg³.

¹Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA, ²Jean Mayer US Department of Agriculture, Human Nutrition Research Center on Aging, Tufts University, Boston, MA, USA, ³Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN, USA.

Teriparatide (TPTD) treatment improves bone density, architecture, and strength. The objective of this study was to evaluate changes in 25-hydroxyvitamin D (25(OH)D) and 1,25-dihydroxyvitamin D (1,25(OH)₂D) in placebo-controlled TPTD trials in postmenopausal women (1)(n=1637) and men (2)(n=437) with osteoporosis. Subjects were supplemented with 400-1200 IU of vitamin D daily at least 1 month before baseline samples were obtained and then randomized to daily teriparatide 20 (TPTD20) or 40 (TPTD40) mcg or placebo. 25OHD was measured at baseline and 12 months and 1,25(OH)₂D was measured at baseline, 1, 3, 6, and 12 months in a subset of subjects. Lumbar spine BMD was measured at baseline and 18 months. At 12 months, 25OHD concentrations significantly declined (p<0.05 vs placebo) with TPTD20 treatment in women and men (Table). Concentrations of 1,25(OH)₂D increased significantly in both women and men (Table). Peak 1,25(OH)₂D increments occurred after 1 month with smaller increments persisting throughout 12 months of TPTD20 treatment. Results for subjects treated with TPTD40 were similar to those with TPTD20 (data not shown). Serum phosphorous did not change significantly in any group. The decline in 25OHD at 12 months and the increment in 1,25(OH)₂D at 1 month explained only 4% and 7%, respectively, of the variance in BMD response to TPTD. The mechanism for the changes in vitamin D levels may relate to TPTD-induced stimulation of 1-hydroxylase resulting in conversion of 25OHD to 1,25(OH)₂D. We conclude that treatment with TPTD decreases 25OHD and increases 1,25(OH)₂D.

Table. Changes from baseline in levels of 25OHD (ng/mL) and 1,25(OH)₂D (pmol/L) in women and men treated with teriparatide

Study	Treatment	Baseline	1 mo	3 mo	6 mo	12 mo

Serum Calcium Values After 4 and 24 Weeks of Treatment with Full-Length Parathyroid Hormone PTH(1-84) of Postmenopausal Women with Primary Osteoporosis: The First 125 Patients. M. Diaz-Curiel^{*}. Servicio de Medicina Interna. Fundacion Jimenez Diaz Madrid. Cátedra de Enfermedades Metabólicas, Unidad de Enfermedades Metabólicas Óseas, Madrid, Spain.

Background: The human recombinant parathyroid hormones (PTHs) represent a class of potent anabolic agents for the treatment of primary osteoporosis in postmenopausal women. All forms of PTH administration in this treatment increase serum calcium. However, prior clinical trials with PTH(1-84) resulted in markedly different incidences of hypercalcemia, with the incidence much higher in TOP than in PaTH. The PEAK (Preotact after a bREAK) trial employed inclusion/exclusion criteria aligned with those of the PaTH trial, therefore permitting an assessment of their impact on the incidence of hypercalcemia. **Method:** The PEAK study is an open label, international, multi centre, parallel group, phase III b, randomised trial, investigating lumbar spine BMD changes in postmenopausal women with primary osteoporosis the first year of which all patients are treated with PTH(1-84). The trial will enrol 390 postmenopausal women aged more than 50 years with primary osteoporosis with a lumbar spine T score ≤ -3.0 SD. Consistent with PaTH (but not TOP), woman with documented baseline hypercalcaemia or hypercalciuria, hyperparathyroidism or severe vitamin D deficiency will be excluded from participation in the study.

Results: 125 patients had reached 4 weeks of treatment with PTH(1-84). The majority (81%) of patients had a serum calcium below the upper limit of normal. 14% had mild elevations in serum calcium. 5% was above 2.67 mmol/l and only one of these had marked elevations of serum calcium (>=3.00 mmol/l).

Fourteen patients had reached 24 weeks of treatment with PTH(1-84). The majority of those patients had a serum calcium below the upper limit of normal.

Serum Calcium Values After 4 of Treatment With PTH(1-84)			
Total serum-calcium (mmol/l)	<2.55	2.55-2.67	>2.67
Number	101	18	6
Percentage	81	14	5

Conclusion: The majority of postmenopausal women with primary osteoporosis treated with PTH(1-84) for 4 weeks had a normal total serum calcium.

A Meta-Analysis of Individual Patient Data: Significant Reduction in Non-Vertebral Fractures With High- Versus Low-Dose Ibandronate. J. D. Adachi¹, G. Wells^{*2}, S. E. Papapoulos³, A. Cranney, for the SCIENCE Meta-analysis Group^{*2}. ¹McMaster University, Hamilton, ON, Canada, ²Ottawa Health Research Institute, Ottawa, ON, Canada, ³Leiden University Medical Center, Leiden, The Netherlands.

Ibandronate (IBN) 2.5mg daily, providing an annual cumulative exposure (ACE) of 5.5mg (0.6% oral bioavailability), significantly reduces vertebral fracture risk by 62% (p=0.0001) in postmenopausal osteoporosis and non-vertebral fracture risk by 69%

($p=0.013$) in high-risk patients (baseline femoral neck BMD T-score <-3).¹ Non-vertebral fracture efficacy was not shown in the overall study population who were relatively low risk.¹ Analyses of biochemical marker and BMD data obtained with high IBN ACE ($\geq 10.8\text{mg}$) predict that the licensed doses (monthly oral 150mg, quarterly i.v. 3mg [100% bioavailability]) would have significant antifracture efficacy.² To test this, individual patient data meta-analyses were used to assess the effect of different doses of IBN on non-vertebral fractures.

The analyses included all randomized, controlled trials of IBN; variable doses of IBN based on ACE were explored: 12mg, $\geq 10.8\text{mg}$, $\leq 7.2\text{mg}$ (ACE for daily oral 2.5mg). Here we present a time-to-event analysis conducted using Kaplan-Meier methodology comparing high ACEs ($\geq 10.8\text{mg}$) with lower ACEs with data taken from MOBILE and DIVA; hazard ratios (HRs) were derived from a Cox model with adjustments for clinical fracture, age, bone mineral density and study, first with the full model and then stepwise.

A significantly reduced rate of non-vertebral fractures was seen when combined high doses (ACE 12mg and $\geq 10.8\text{mg}$) were compared with ACE 5.5mg (table). In addition, there was a dose-response effect with increasing ACE (7.2-12mg) compared with ACE 5.5mg. Similar results were seen when ACE $\geq 10.8\text{mg}$ was compared with ACE $\leq 7.2\text{mg}$ (HR: 0.634; 95% CI: 0.427, 0.943; $p=0.0243$). Adjustment for covariates had minimal effect.

Overall, treatment effects on non-vertebral fractures were dose dependent. A significant effect on non-vertebral fracture risk reduction was seen when IBN doses providing ACE $\geq 10.8\text{mg}$ were compared with ACEs 5.5mg and $\leq 7.2\text{mg}$. These data indicate improved fracture efficacy for the licensed oral and i.v. doses versus oral daily dosing.

Fragility Fracture Increases Antidepressant Use among Women 65 Years of Age and Older. J. D. Adachi¹, N. N. Borisov², C. R. Purple², D. T. Gold³.

¹McMaster University, Hamilton, ON, Canada, ²Procter & Gamble Pharmaceuticals, Mason, OH, USA, ³Duke University Medical Ctr., Durham, NC, USA.

A fragility fracture is often the initiating event in a spiral of life-style altering comorbidities; these may include depression. The objective of this study was to assess antidepressant use among women ages 65 and over before and after fragility fracture in 2 integrated administrative medical claims databases (Ingenix Lab/RxTM and Medstat MarketScan[®]).

A retrospective cohort study was conducted among women with a new non-traumatic closed fracture verified with a diagnostic code between July 1, 2000 and December 31, 2003. The study included fractures at 9 anatomical sites: hip, femur, tibia/fibula, humerus, clavicle, pelvis, forearm, wrist, and spine. The cohort was observed 6 months prior and 6 months after the fracture to identify women who had antidepressant prescriptions.

A total of 19,554 women with a new fragility fracture were identified in the databases during the study period. The mean age was 79 years (SD=8). Nonvertebral fractures represented 77% of all index fragility fractures in this population. Overall, 3.7% more women were using antidepressant drugs 6 months after fragility fracture compared to 6 months before the fracture ($p<0.0001$). Women with a fragility fracture used 108 (SD=60) more prescriptions for antidepressants per 1,000 women after their fracture than before ($p<0.0001$). Specifically, women with fractures of the hip, tibia, pelvis, or spine had the highest significant increases in antidepressant use than women with other fractures (figure).

In this study, fragility fractures had a significant effect on antidepressant use. Women with a fragility fracture were more likely to use antidepressants after their fracture than before with significantly more prescriptions. The increased use of antidepressants might indicate a decreased quality of life associated with a fracture. A treatment for osteoporosis that reduces fracture incidence should reduce the cost associated with prescriptions for antidepressants as well. Therefore, this cost reduction should be considered in the cost-effectiveness analysis of treatments for osteoporosis.

Figure. Antidepressant prescriptions difference (per 1,000 fractured women): 6 months after fragility fracture compared to 6 months before the fracture

Comparison of Estrogen, Raloxifene and Bisphosphonate Administration for Prevention of Bone Loss in Climacteric Women Complicated with Osteopenia. K. Aisaka, K. Nagasaka*, S. Arita*, K. Itabashi*, Y. Takane*, Y. Ikezuki*, R. Matsuoka*, K. Kohda*. Obstetrics & Gynecology, Odaira Memorial Tokyo Hitachi Hospital, Tokyo, Japan.

Objective: Bisphosphonate (BIS) and SERM (Selective Estrogen Receptor Modulator, raloxifene) have been widely used for the prevention of bone loss in Japan. On the other hand, the hormone replacement therapy (HRT, using estrogens and progestogens) also performed to improve the QOL of the climacteric women even after the WHI report. The present study was performed to compare these medications for the treatment of bone loss and climacteric symptoms.

Subjects & Methods: The ethics committee of our hospital consulted on the protocol and was approved before beginning of the study. 198 patients of the climacteric women complicated with osteopenia were subjected (53.6 \pm 3.9 years old). Then, the subjected patients were divided three groups at random with the enough informed consents. Group A: Administrated BIS (risedronate 2.5mg/day), 76 cases, group B: Administrated SERM (raloxifene 60mg/day), 64 cases, and group C: HRT (conjugated equine estrogen 0.625mg + medroxyprogesterone acetate 2.5mg/day), 58 cases. The changes of BMD values (DXA method), urinary NTx and plasma BAP levels were compared among them.

Results: The percent changes of BMI in the group A, B, C were 1.19 \pm 0.64, 1.06 \pm 0.36, 1.02 \pm 0.54 % (6 months after), and 1.33 \pm 0.53, 1.17 \pm 0.46, 1.15 \pm 0.60 % (12 months after), respectively, and there was a significant increase in the group A ($p<0.025$). The urinary levels of NTx in the group A decreased significantly by the treatment compared to another groups (0, 1, 6 months after treatment): A: 48.6 \pm 15.8 \rightarrow 33.1 \pm 18.7 \rightarrow 24.3 \pm 13.7, B: 50.9 \pm 21.4 \rightarrow 42.9 \pm 29.6 \rightarrow 34.5 \pm 18.5, C: 47.3 \pm 20.2 \rightarrow 44.5 \pm 23.8 \rightarrow 35.7 \pm 20.1 nmolBCE/nmol.cre., $p<0.025$ -0.001). No significant changes were observed in plasma BAP levels among these three groups. The symptom of hot flush was suppressed in the group C, while increased in the group B. Conclusion: It was concluded that the inhibition effect toward bone resorption was the strongest in BIS administrated group. The improvement of the QOL in climacteric women was much better in the HRT group. From these results, BIS should be used for the patients of severe osteopenia, and the HRT should be considerable to precede the QOL of the climacteric women if they had no risks of the breast cancer.

Risedronate Treatment in Type 2 Diabetic Men with Primary Osteoporosis: A Three-Year Longitudinal Study. L. J. L. Ascanio*. Endocrinology, Endocrinological Foundations, Caracas, Venezuela.

Bisphosphonates have been widely used in the treatment of osteoporosis in women, whereas until now there have been few data on their use in men. The aim of this study was to evaluate the effect of a 3-year risedronate treatment on bone mineral density (BMD) and quantitative ultrasound (QUS) in type 2 diabetic men with primary osteoporosis. We studied 77 osteoporotic men (aged 57.1 ± 10.8 yrs) who completed a 3-year treatment with risedronate (35 mg/once a week) plus calcium (1000 mg/day) ($n = 39$), or calcium alone ($n = 38$). At baseline and at a 12-month interval, we measured BMD at the lumbar spine and femur (femoral neck and total hip) by DXA (Hologic) and speed of sound (SOS), broadband ultrasound attenuation (BUA) and Stiffness (S) at the os calcis by Achilles plus (Lunar). Risedronate treatment had significantly increased lumbar spine BMD by 4.2% at year 1, by 6.3% at year 2, and 8.8% at year 3. BMD at the femoral neck and total hip had increased by 2.1% and 1.6% at year 1, by 3.2% and 2.9% at year 2, and by 4.2% and 3.9% at year 3, respectively. BUA and Stiffness showed a significant increase in the risedronate-treated group at year 2 (3.2% and 4.9%, respectively) and at year 3 (3.8% and 6%, respectively). BMD at the lumbar spine showed the best longitudinal sensitivity whereas longitudinal sensitivity of both QUS at the heel and femur BMD were similar. In conclusion, this study confirms that Risedronate represents an important therapeutic advance in the management of male osteoporosis. BMD at the lumbar spine appears to be the best method for monitoring the effect of risedronate on bone mass in osteoporotic men with type 2 diabetic. Key words: Male osteoporosis _ Risedronate _ Bone mineral density _ Quantitative ultrasound

Mechanistic Bases of Bone Mineral Density Increase During Alendronate Therapy. D. Vashishth¹, P. Chavassieux², G. Boivin², P. D. Delmas². ¹INSERM Unite 831 Université de Lyon France & Rensselaer Polytechnic Institute, Troy, NY, USA, ²INSERM Unite 831 Université de Lyon, Lyon, France.

An increase in the mean degree of tissue mineralization (DMB) occurring through secondary mineralization has been proposed to increase bone mineral density (BMD) during bisphosphonate (BP) therapy [1]. In this study we conducted additional analyses on human iliac crest biopsies obtained as part of alendronate (ALN) clinical trials [2] to identify the mechanistic bases of BMD increase.

Out of a group of 16 patients on a three-year ALN-therapy [1], we identified two groups of 5 patients each showing lower (8.5 %) and higher (13.3%) bounds of BMD increase but no difference in baseline BMD. For all 10 patients, previously prepared microradiographs were reanalyzed to measure the mean degree of tissue mineralization (DMB) at the osteonal and interstitial compartments in both cortical and cancellous bone tissues. Based on a moving average analysis, six fields each of cortical and cancellous bone tissues were randomly selected for measurement from each biopsy. The average values for patients in each group within osteonal and interstitial compartments were compared between and across cortical and cancellous bone tissues. All DMB measurements were also tested for correlation with standard histomorphometric measures of bone structure (BV/TV, Tb.Th, Tb. Separation, Tb.N), osteoclast activity (EV/BV, E-Depth, Oc#/BS), osteoid (OS/BS, OV/BV, OTh), and bone formation (MAR, BFR/BS, FP) reported previously [2].

The low-BMD-gain group demonstrated no difference between the osteonal and interstitial bone compartments within cortical or cancellous bone tissues but demonstrated a higher DMB in cancellous than in cortical tissue ($p < 0.05$). In contrast, the high-BMD-gain group showed higher DMB in interstitial than in osteonal compartment for both cortical and cancellous tissues as well as a higher DMB in cancellous than in cortical tissue ($p < 0.05$). Out of all the DMB measures in cortical and cancellous tissues, only cortical bone interstitial level DMB correlated to bone formation rate (BFR/BS) ($r = -0.86$; $p = 0.006$) and formation period (FP) ($r = -0.75$; $p = 0.04$).

In conclusion, this study demonstrates that the effects of ALN-therapy are more evident in cancellous than in cortical bone. Moreover since the interstitial level DMB is at least partially dependent on the duration of secondary mineralization, and negatively correlated to formation parameters, slow bone formation rate and longer bone formation period produce conditions conducive to complete secondary mineralization and consequently larger BMD gain.

Bisphosphonate Use Increases in Patients with Osteoporosis Following an Integrated Osteoporosis Educational Intervention: Canadian Quality Circle (CQC) National Project. B. Kvern¹, G. Ioannidis², A. Papaioannou³, L. Thabane^{*2}, A. Gafni², A. Hodsman³, D. Johnstone⁴, L. Salach^{*5}, F. Jiwa^{*6}, J. D. Adachi². ¹University of Manitoba, Winnipeg, MB, Canada, ²McMaster University, Hamilton, ON, Canada, ³University of Western Ontario, London, ON, Canada, ⁴P&G Pharmaceuticals, Toronto, ON, Canada, ⁵Ontario College of Family Physicians, Toronto, ON, Canada, ⁶Osteoporosis Canada, Toronto, ON, Canada.

Quality Circles (QCs) methodology was used to improve primary care physicians' (PCPs) management of osteoporosis in accordance with the Osteoporosis Canada 2002 Guidelines. The QCs project involves a small group of people from comparable work environments who identify and analyze work related problems and recommend solutions. The study consists of five phases: wave I data collection, 1st educational intervention, wave II data collection, 2nd educational intervention, and wave III data collection. During the educational intervention, QC's met to discuss how they managed osteoporosis and to participate in an osteoporosis workshop. This interim analysis (wave I & II) evaluated the change in treatment in patients with osteoporosis (defined as a BMD t-score < -2.5). According to the guidelines, therapy should be initiated if a patient has a BMD t-score in the osteoporotic range. A total of 340 (wave I) and 301 (wave II) PCPs formed 34 QCs. For each wave, PCPs gathered data from different patients via chart reviews and a standardized collection form. A total of 8376 (wave I) and 7354 (wave II) patient records were selected at random and analyzed. All patients were women 55 years and older. The generalized estimating equations (GEE) approach was used to evaluate differences in bisphosphonate use in patients with osteoporosis pre and post educational intervention. The cluster variable for the GEE model was physician and the analysis was adjusted for patient's age, fracture status, family history of fracture, early menopausal status and other major and minor risk factors for fracture. An exchangeable correlation matrix was used for the analysis. Odds ratios (OR) and 95% confidence intervals (CI) were calculated. A total of 1774 and 1272 patients had osteoporosis during wave I and wave II, respectively. Of these, 1545 (87.1%) during wave I and 1148 (90.3%) during wave II were treated with a bisphosphonate. The adjusted likelihood of bisphosphonate use increased following the educational intervention for patients with osteoporosis (OR 1.30; 95% CI: 1.06, 1.61). In conclusion, a majority of patients with osteoporosis are being treated with bisphosphonate therapy. However, bisphosphonate use increased in patients with osteoporosis following the educational workshop. The use of bisphosphonates may reduce the future fracture risk of these high risk patients.

Early and Sustained Non-Vertebral Fracture Efficacy with Risedronate. R. Lindsay¹, C. Roux^{*2}, J. D. Adachi^{*3}, X. Zhou^{*4}, A. Grauer⁴, N. B. Watts⁵. ¹Helen Hayes Hospital, West Haverstraw, NY, USA, ²Cochin Hospital, Rene Descartes University, Paris, France, ³McMaster University, Hamilton, ON, Canada, ⁴Procter & Gamble Pharmaceuticals, Mason, OH, USA, ⁵University of Cincinnati, Cincinnati, OH, USA.

Previous analyses have shown non-vertebral fractures account for 77% of the osteoporosis-related fractures and over 90% of costs. Predicting an osteoporosis-related fracture is not possible. Therefore, treating with an agent that provides both early and sustained fracture protection will provide maximum benefit to patients. The objective of this analysis is to examine whether the non-vertebral fracture efficacy of risedronate meets these criteria.

Analysis population included 1169 postmenopausal women from VERT and ROE & RON trials with low BMD (LS T-score < -2.5 SD), who were treated with at least one dose of either placebo or risedronate 5mg daily. The mean age of the population was 67 years and 58% of the patients had at least one prevalent vertebral fracture at baseline. The fracture endpoint was radiographically confirmed osteoporosis related non-vertebral fracture. Risk difference of osteoporosis-related non-vertebral fracture between the placebo and risedronate 5mg groups was estimated using the difference of the Kaplan Meier (KM) estimators from month 3 through 36. The standard error of the risk difference was approximated by the square root of the sum of the variance of the KM estimators of the placebo and risedronate 5mg groups. The upper and lower bound of the 95% confidence intervals were calculated as the mean plus and minus 1.96 times the standard error of the estimated risk difference.

The findings are consistent with the rapid onset of fracture risk reduction with risedronate treatment. Relative to placebo, risedronate significantly reduced the risk for non-vertebral fracture starting from Month 6 with an absolute risk reduction of 1.8% (95% CI: 0.4%, 3.3%). The magnitude of the difference in the risk for non-vertebral fracture between the placebo and risedronate 5mg groups increased during the first 2 years and remained constant during the 3rd year of the trial with an absolute risk reduction of approximately 4%.

In summary, the results confirmed the risedronate rapid protection benefit against non-vertebral fracture as early as Month 6. Further, the risedronate anti-fracture efficacy was sustained through out the remaining study period.

So How Was It? Patient Opinions on Osteoporosis Interventions in the Fracture Clinic Setting. D. E. Beaton, E. R. Bogoch, R. Sujic*, V. Elliot-Gibson*. Mobility Program, St. Michael's Hospital, Toronto, ON, Canada.

Our study aims to understand factors that influence fragility fracture patient's adherence with St. Michael's Hospital Osteoporosis Exemplary Care Program's recommendations for further osteoporosis testing and treatment. Our previous research indicates that coordinator-based interventions are an effective way of preventing future fractures. The results of this study will help identify key variables to consider when evaluating the Ontario Osteoporosis Strategy's Fracture Clinic Screening Program which is based on the coordinator model.

This is a qualitative study using focus-group methodology. Out of 45 patients who were eligible based on the study criteria, 24 patients participated in five focus groups. Transcripts of the five focus groups were transferred to N-Vivo for storing and sorting the data. Transcripts were coded for content and links between descriptive labels were made. By using qualitative method, we are hoping to explore the impact of the Osteoporosis Exemplary Care Program in a much more contextualized fashion.

Emerging results support Anderson's behavioural model of health care utilization. Perceived need and susceptibility were associated with osteoporosis prevention efforts and treatment adherence as reported by the patients involved in the focus groups. The most frequent barriers that patients identified in diagnosis and treatment of osteoporosis included the perceived lack of clear and reliable information regarding the nature of BMD testing and proper treatment as well as the lack of general practitioner's recommendations about osteoporosis care and prevention. Most often cited facilitators of osteoporosis testing and treatment included thorough follow up by an osteoporosis coordinator, accessibility and ease of BMD testing and general practitioners' recommendations for treatment and testing.

General practitioners were named as key influence over the initiation of prevention and treatment of osteoporosis.

Improvement of the Persistence with Teriparatide in Postmenopausal Osteoporosis: The French Experience of an Education Program. K. Briot¹, P. Ravaud², S. Liu-Léage³, C. Roux¹. ¹Rheumatology, Cochin Hospital, Paris, France, ²Biostatistics and Epidemiology, Bichat Hospital, Paris, France, ³Lilly France, Suresnes, France.

Several anti-osteoporotic treatments have been proved effective in decreasing the risk of fractures but available data suggest low adherence and persistence rates in patients taking medications for osteoporosis. This can result in failure in treatment efficacy. Several strategies have been developed to improve adherence and persistence. Teriparatide, prescribed 20 µg/day injected subcutaneously, is an anabolic treatment licensed for established postmenopausal osteoporosis. Education program has been developed after its launch, to help elderly women to deal with the pen take and consequently better follow the prescribed treatment. The objective is to assess the efficacy of an education program to improve the persistence with teriparatide in postmenopausal osteoporotic women. This education program has been created by the promotor of teriparatide since its launch of teriparatide in France in September 2004 and it is proposed to each woman who begins the

teriparatide. The program includes injection technique learning, osteoporosis education, observance and persistence assessment. Women are interviewed by regular calling of a nurse, each month the first year and every 3 months the 6 following months. Data about persistence and side-effects are available for the period September 2004 to December 2006. Persistence is defined as the percentage of patients still on treatment at the end of the 18-month course. Since the launch of teriparatide in France in September 2004, 4518 postmenopausal women (mean age 73.6 ± 11.4 years) with osteoporosis (lumbar spine and/or femoral T score ≤ -2.5) and vertebral fractures (4 fractures on average) have participated to the program. At the end of the year 2006, 1951 women have been followed at least 18 months. Of these 1951 women, persistence at 18 months was 82.6%. Main reasons for discontinuation, as declared by the patients, were side-effects (43.8%), wish of the patient (23.8%), physicians' decisions (17%) and deaths (5.3%). Persistence has been compared to the data of the French universal health insurance system; and it has been estimated that persistence at 18 months was closed to 0% for women who have been prescribed teriparatide without any education program. This study shows that an education program can highly improve the persistence with teriparatide at 18 months. Persistence is greater than that of existing oral therapies for osteoporosis, and this high persistence should improve the effectiveness of this therapy.

The Impact of GI Medication Usage with Regard to Discontinuation and Restart Behavior with Oral Bisphosphonates in Three Large US Physician Groups. M. B. Nichol¹, W. W. Chan², T. Dow³, K. H. Kahler², S. Bamford³, L. D. Marks⁴, C. Parise⁴, G. Darah⁵. ¹JMRG Consulting, Encino, CA, USA, ²Novartis Pharmaceuticals Corp., East Hanover, NJ, USA, ³Physician Associates, Pasadena, CA, USA, ⁴Sutter Medical Group, Sacramento, CA, USA, ⁵ProMedica, Toledo, OH, USA.

Purpose: Clinical studies have demonstrated that women at risk of osteoporotic fracture reduce the risk of new osteoporotic fracture with bisphosphonate treatment. However, observational studies have also shown high discontinuation rates with these oral medications. This study investigated the impact of GI medication usage with regard to discontinuation and treatment re-initiation.

Methods: The study was based on a retrospective claims review of data from three large US physician groups. The groups represent a diverse patient base in terms of geographic and organizational considerations. Specifically, the groups are based in Northern and Southern California and Ohio; one is a network of independent physicians in private practice, and two are not-for-profit integrated health care networks. We evaluated the integrated administrative dataset for health plan eligibility as well as drug utilization information.

Results: 5,737 patients were selected for analysis. 4,074 patients (71.0%) initiated therapy on alendronate, and 1,663 patients (29.0%) initiated therapy on risendronate. One-third of women were aged 45 to less than 60, 40% were aged 60 to less than 75, with the remainder 75 and older, with no statistically significant differences by index medication. Approximately 20% of women used GI medications during the one year study period. Duration of GI therapy averaged 176 days (SD 126), with statistically significant differences seen by drug when the medical groups were combined (p = 0.017). Specifically, risendronate initiators averaged 194 days of GI therapy (SD 125) and alendronate initiators averaged 174 days (SD 127). Women typically added GI treatment after approximately three months (mean 93, SD 100) for both medications. Logistic regression analysis showed concurrent GI use was associated with a 74% greater likelihood of discontinuation with bisphosphonate treatment (95% CI: 1.36, 2.22) and a decreased likelihood of re-initiation of bisphosphonate treatment (Odds Ratio 0.76, 95% CI: 0.51, 1.14).

Conclusion: These data revealed that approximately 20% of bisphosphonate users were on GI therapy during the study period. However, rather than acting as a mitigating agent that was associated with better compliance, it appears that GI usage reflected side effect problems that jeopardize persistence. This area deserves further study to determine the direction of cause and effect.

Longitudinal Patterns of Adherence with Bisphosphonates. J. R. Curtis¹, A. Westfall^{*1}, H. Cheng¹, E. Delzell^{*1}, K. Lyles², K. G. Saag¹. ¹University of Alabama at Birmingham, Birmingham, AL, USA, ²Duke University, Durham, NC, USA.

Background: Poor adherence to bisphosphonates (BPs) appears associated with a greater rate of fracture (Fx). Misclassification of adherence and the impact of acute Fx on adherence may compromise interpretation of findings. We examined longitudinal patterns of BP adherence using less restrictive definitions than in some past studies that included an arbitrary definition of discontinuation. We also determined the impact of adherence associated with hip Fx.

Methods: Using claims data of a large consolidated health plan database, we identified persons initiating BPs and calculated adherence as a Medication Possession Ratio (MPR), allowing for BP switching. We compared adherence among individuals initiating weekly vs. daily BPs. MPR was examined at 1, 2, and 3 yrs and was compared among those with no fracture or with hip Fx. We also examined MPR in the 3 and 6 months immediately prior to a hip Fx compared to the 3 and 6 months following this Fx to determine how measured adherence changed following a Fx.

Results: We identified 87,099 new BP users with ≥ 1 year of follow-up. Mean \pm SD age was 60.1 ± 7.8 years. The proportion with MPR $\geq 80\%$ was 44% (Figure), 39%, and 36% at 1, 2, and 3 yrs, respectively. Among persons with MPR $\geq 80\%$ at yr 1, 80% of these had MPR $\geq 80\%$ at yr 2. Those who were initially prescribed weekly BPs had higher 1 yr MPR than those initially prescribed daily BPs (mean = 45% vs. 38%, $p < 0.001$).

Among those with a hip Fx, MPR at years 1, 2, and 3 was 9%, 12%, and 10% lower compared to those without Fx ($p < 0.001$ for each), and MPR in the 3 and 6 months following the hip Fx was -9% and -6% compared to before the hip Fx ($p < 0.0001$ and < 0.0001).

Conclusions: Using a definition of adherence that allowed for switching to different dosages or formulations of BPs, adherence was somewhat better than in past studies but remained suboptimal. Adherence at year 1 was a strong predictor of adherence in subsequent years. Adherence in the 3 and 6 months following a hip Fx was significant lower than immediately prior to the fracture, which may be real or an artifact of a lack of pharmacy data capture during periods that patients are hospitalized or in rehabilitation settings. Analyses that fail to consider adherence in a time-dependent fashion, before Fx occur, may magnify the apparent differences in Fx risk between adherent and non-adherent persons.

A Year-long Study to Demonstrate the Bone Reversal Efficacy of Dried Plums in Postmenopausal Women. B. H. Arjmandi¹, S. Hooshmand¹, S. C. Chai¹, R. L. Saadat^{*1}, L. Devareddy^{*1}, K. Brummel-Smith^{*2}. ¹Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA, ²Department of Geriatric, Florida State University, Tallahassee, FL, USA.

Our findings in rat models of osteoporosis as well as a short-term human study suggest that dried plums are highly effective in preventing and reversing ovarian hormone-deficiency-associated bone loss. Dried plums are rich in polyphenolic compounds and other nutrients that contain high antioxidant properties. Antioxidative properties of dried plum, in part, may be responsible for prevention of bone loss that is in part due to the rise in oxygen-derived free radical formation. It is necessary to confirm the findings of animal studies as well as positive effects of dried plum on biomarkers of bone formation in a relatively long-term clinical study. For this purpose, we are conducting a completely randomized comparative-controlled study to test the hypothesis that daily consumption of

dried plum increases bone mineral density (BMD) of osteopenic women 1 to 10 years postmenopausal. So far, we have recruited 85 (n=144) subjects who are not on hormone replacement therapy and have been randomly assigned to one of two treatment groups: dried plum (100 g/d) or dried apple (comparative control). All study participants are receiving 500 mg elemental calcium plus 250 IU vitamin D daily. BMD and bone mineral content (BMC) of lumbar spine, forearm, hip and whole body are being assessed at baseline and at the end of the study using dual-energy x-ray absorptiometry. Blood and 24-hr urine samples (baseline, 3-, 6-, and 12-month) are also assessed. Physical activity and dietary confounders will be examined as potential covariates. This study will provide critical data about an acceptable and efficacious food alternative to reverse bone loss in menopausal women. Based on our preliminary data, we anticipate subjects that are consuming dried plum will have an average gain of 3% BMD at all sites after one year. The urinary and blood interim analyses will be presented at the time of poster presentation.

Analgesic Efficacy of Calcitonin for Vertebral Fracture Pain. A. Bazarra-Fernandez^{*}, ObGyn, Juan Canalejo University Hospital Trust, Amparo Lopez Jean 13 4º A La Coruña, Spain.

Background: Fractures, especially vertebral fractures, are a common complication of osteoporosis, leading to significant pain.

Aim: To compare the pain release induced by osteoporotic vertebral fracture, through teriparatide and teriparatide plus calcitonine.

Methods: We performed a study to compare the analgesic effect of 20 mcg teriparatide versus 20 mcg teriparatide plus metered dose intranasal spray 200IU/activation calcitonin in two groups between postmenopausal women undergoing osteoporosis with vertebral fracture. A 10-point visual analog pain scale (1 = least to 10 = most painful) and a four-point pain grade (grade 1 = least to grade 4 = most painful) were used to measure the pain perception.

Results: The mean pain scores for the teriparatide and teriparatide plus calcitonin were 2.3 ± 1.1 and 8.5 ± 1.1 , respectively ($P < 0.05$), while the pain grades for teriparatide and teriparatide plus calcitonin were 1.5 ± 0.3 and 3.5 ± 0.4 , respectively ($P < 0.05$). In teriparatide group, analgesics were requested, but in teriparatide plus calcitonin group no analgesics were requested ($P < 0.001$).

Conclusion: Using teriparatide is more expensive than other osteoporosis treatment. Studies show that taking a bisphosphonate with hormone replacement therapy (HRT), results in increased bone mass when compared to taking either a bisphosphonate or estrogen alone. Besides, calcitonin is better for osteoporotic vertebral fracture pain release than HRT. However, a larger investigation will be needed to achieve more significant case number.

The Correction of BMD Measurements for Bone Strontium Content. G. M. Blake. Nuclear Medicine Department, King's College London School of Medicine, London, United Kingdom.

Strontium ranelate is a new oral treatment for osteoporosis associated with large increases in bone mineral density (BMD) compared with alternative therapies such as bisphosphonates. Much of the BMD increase during strontium ranelate treatment is a physical effect caused by the increased attenuation of X-rays due to the accumulation of strontium in bone tissue. The aim of this study was to assess the contribution made by bone strontium content (BSC) to the overall BMD increase by evaluating the percentage F of the BMD change explained by the physical presence of strontium in bone. A value of F less than 100% would provide evidence of the anabolic effect of strontium ranelate as an additional factor contributing to the overall BMD increase. Studies of mixtures of strontium hydroxyapatite (SrHA) and calcium hydroxyapatite (CaHA) scanned on a variety of dual-energy X-ray absorptiometry (DXA) systems show that a 1% molar ratio of SrHA/(CaHA+SrHA) causes a 10% overestimation of BMD. The correction of spine BMD measurements for the physical effects of strontium depends on knowledge of two further factors: (1) bone biopsy measurements of iliac crest BSC; (2) the ratio R of BSC at the DXA site to BSC at the iliac crest measured in animal studies. We used clinical trial data and values of R_{spine} measured in studies of monkeys and beagle dogs to determine values of F_{spine} for 1, 2 and 3 years treatment with strontium ranelate. Based on the average value of $R_{spine} = 0.7$ for male and female monkeys we found values for $F_{spine} = 75\% - 80\%$ for 1, 2 and 3 years of treatment. Using the value of $R_{spine} = 1.0$ from the beagle study gave values of $F_{spine} = 100\%$. Although values of F_{spine} as low as 40% are possible, we conclude that the most likely figure is 75% or greater. However, it is apparent that there are large uncertainties in the correction of BMD results for the effect of bone strontium and that the most important of these is the inference of BSC values at DXA sites from measurements of bone biopsy specimens.

Calcium Supplementation Improves Lipid Profile But Does Not Decrease the Incidence of Cardiovascular Events in Postmenopausal Women. M. J. Bolland*, B. Mason*, A. Horne*, R. Ames*, A. Grey, G. Gamble*, R. Doughty*, A. Barber*, I. R. Reid. Department of Medicine, University of Auckland, Auckland, New Zealand.

Previously we have shown that calcium supplementation produces beneficial changes in lipids that might impact upon the incidence of cardiovascular disease. We set out to determine the effect of calcium supplementation on myocardial infarction (MI), stroke, sudden death, and lipids in post-menopausal women.

We carried out a 5 year randomized, placebo-controlled trial of 1g daily calcium citrate supplementation in 1471 post-menopausal women (mean age 74y). MI, stroke, and sudden death events were recorded during the study. Hospital admissions for cardiovascular events were also obtained from a national database. All events were adjudicated by a physician and a cardiologist or neurologist. Serum lipids were measured annually in a substudy of 223 women.

There were increases in the number of women in the calcium group who during the study reported MI (32 vs 14, $P=0.007$), stroke (42 vs 38, $P=0.19$), and the composite endpoint of MI, stroke or sudden death (70 vs 45, $P=0.015$). After adjudication of events and identification of additional unreported events from the national database, the increases in number of women in the calcium group with MI (31 vs 21, $P=0.16$), stroke (34 vs 25, $P=0.23$), and the composite of MI, stroke or sudden death (60 vs 50, $P=0.32$) persisted but were not statistically significant. The relative risk of MI was 1.2 (1.0-1.5), stroke 1.2 (0.9-1.6), and the composite of MI, stroke or sudden death 1.1 (0.9-1.3). There were trends toward an increased rate of MI in the calcium group (11.1 vs 6.6 /1000 patient-years, $P=0.06$), stroke (11.4 vs 7.8 /1000, $P=0.18$), and the composite of MI, stroke, or sudden death (23.2 vs 16.3 /1000, $P=0.05$).

There were trends toward a greater decrease in LDL from baseline in the calcium group over 5 years (9.5% vs 6.2%, $P=0.05$) and a greater increase in HDL (10.4% vs 9.8%, $P=0.11$). There was a greater increase in the HDL:LDL ratio over 5 years in the calcium group ($P=0.015$).

In summary, 5 years of calcium supplementation, 1g daily, in postmenopausal women improved lipid profile but did not reduce the number of cardiovascular events. In fact, there were trends towards an increase in the rate of cardiovascular events in women receiving calcium.

The Effects of UV-B Light on Serum Vitamin D Levels in Humans. L. A. G. Armas¹, R. P. Heaney¹, M. J. Barger-Lux^{*1}, C. Huerter^{*2}, R. Lund^{*3}.

¹Osteoporosis Research Center, Creighton University, Omaha, NE, USA,

²Dermatology Department, Creighton University, Omaha, NE, USA,

³Nephrology Department, Creighton University, Omaha, NE, USA.

We report results of vitamin D levels after 4 weeks of exposure to graded doses of UV-B light delivered by a light booth. The subjects ($n=69$, age 19-49 yr, females = 41, males = 28) were healthy indoor workers with limited non-solar sources of Vitamin D.

Data were gathered from September through June for 2 consecutive years (71% completed the study from January through May). We determined BMI, 25(OH)D, vitamin D, Ca^{2+} and PTH at baseline. The subjects had 90% of their body exposed to broad-band UV-B light from a UV light booth 3 times a week for 4 weeks (12 treatments) in doses ranging from 20mJ to 80mJ per treatment. Serum Vitamin D was drawn at baseline, after 4 weeks of UV-B treatment, and again 4 weeks after completion of UV-B treatment.

At baseline, 80% percent of the subjects had undetectable vitamin D levels. The subjects' median serum vitamin D level was 0 nmol/L (0, 0 interquartile range). At 4 weeks, after 12 treatments with UV-B light, the median vitamin D level was 31.0 nmol/L (19.0, 42.5 interquartile range). Four subjects' vitamin D levels remained at 0 after UV-B treatment despite a median rise in their 25(OH)D levels of 26.6 nmol/L.

At week 8, the median vitamin D level decreased to 0 nmol/L (0, 5.9 interquartile range) with 57% of subjects' levels reaching 0 nmol/L.

The vitamin D response to UV-B light correlated positively with dose of UV-B light and the 25(OH)D level at week 4 and inversely correlated with age, body surface area, and body mass index.

In conclusion, serum vitamin D levels increase in response to UV-B light, but the body needs constant vitamin D input to maintain vitamin D levels. The serum vitamin D levels are quickly depleted by either storage by the body or conversion by the liver to 25(OH)D.

Disclosures: L.A.G. Armas, None.

This study received funding from: Dialysis Clinics, Inc., Endocrine Fellows Foundation.

Daily Versus Monthly Oral Vitamin D2 and D3: Effect on Serum 25OHD Concentration. N. Binkley, D. Gemar, R. Ramamurthy, D. Krueger, M. K. Drezner. University of Wisconsin Osteoporosis Research Program, University of Wisconsin-Madison, Madison, WI, USA.

It is widely assumed that ergocalciferol (D2) is less effective than cholecalciferol (D3) in maintaining normal serum 25 hydroxyvitamin D [25(OH)D] levels. However, data supporting this belief remains limited. The common suboptimal adherence to daily

supplements confounds this problem further since clinicians may elect to utilize high-dose vitamin D supplementation monthly. As only ergocalciferol is available as a high-dose prescription preparation in the US, evaluation of intermittent high-dose D2 supplementation on 25(OH)D status is required. Moreover, the logical hypothesis that appropriate timing of 25(OH)D measurement is required, such that a trough 25(OH)D value is obtained when dosing monthly, has not been tested. With these related considerations in mind, the purpose of this year long randomized, double-blind, placebo-controlled prospective clinical trial is to evaluate the effect of daily dosing of 1,600 IU D2 or D3 versus monthly dosing of 50,000 IU D2 and D3 on serum 25(OH)D concentration and concurrently to investigate the potential importance of obtaining trough 25(OH)D levels in adults over age 65 years. Study inclusion criteria include community dwelling men and women age ≥ 65 years with a serum 25(OH)D concentration between 10-60 ng/ml who were willing to use sunscreen when exposed to the sun. Those with hypercalcemia, hypercalciuria, renal failure, use of drugs interfering with vitamin D metabolism or a history of nephrolithiasis were excluded. Serum 25(OH)D was measured by reverse phase HPLC. At this time, 20 participants, age 74.3 ± 1.8 years (mean/SEM) have been randomized. At baseline, their serum 25(OH)D concentration was 31.1 ± 2.2 ng/ml. After one week of study, serum 25(OH)D concentration increased ($p < 0.001$) by 8.6 ± 0.6 ng/ml and 6.7 ± 1.4 ng/ml at three and seven days following receipt of 50,000 D3, but was not different from baseline in those receiving daily therapy with D2 or D3 or monthly D2. Our preliminary observations support the possibility that therapy with D3 may be more effective. However, as this study is ongoing, additional data, including the effect of intermittent monthly dosing, and the impact of specimen acquisition time relative to monthly dosing of D2 and D3, on serum 25(OH)D concentration will be reported.

Effect of Alfacalcidol on Volumetric Bone Mineral Density Measured by pQCT in Alendronate-Treated Postmenopausal Women with Osteopenia or Osteoporosis: 1 Year Interim Analysis of the ALFA Study. O. Bock¹, H. Boerst^{*1}, M. Runge^{*2}, G. Beller^{*1}, F. Touby^{*1}, J. Tuerk^{*2}, P. Martus^{*3}, E. Schacht^{*4}, J. Hashimoto^{*5}, D. Felsenberg¹. ¹Centre for Muscle and Bone Research, Charité - Campus Benjamin Franklin, Berlin, Germany, ²Centre for Muscle and Bone Research, Aerpah Kliniken Esslingen-Kennenburg, Esslingen, Germany, ³Institute of Biostatistics and Clinical Epidemiology, Charité - Campus Benjamin Franklin, Berlin, Germany, ⁴ZORG - Zurich Osteoporosis Research Group, Zurich, Switzerland, ⁵Bone Disease Area Department, Chugai Pharmaceutical Co.Ltd., Tokyo, Japan.

The purpose of the ALFA (Alfacalcidol & Falls) study (three-year prospective, randomized, double-blind, placebo-controlled trial) is to evaluate the effect of alfacalcidol 1 µg daily on the number of falls in postmenopausal, alendronate-treated, osteopenic or osteoporotic women. A pre-planned one year interim analysis was performed to examine the effect of alfacalcidol on bone mineral density (BMD) by DXA and pQCT.

A total of 278 postmenopausal women (mean age 73.7 years, SD 4.8) received either alfacalcidol 1 µg or placebo daily, in addition to alendronate 70 mg weekly and calcium 500 mg daily. Volumetric BMD (vBMD) at standardized sites of radius and tibia were measured by pQCT (Stratec XCT-2000) at baseline and after 3, 6, 9 and 12 months of treatment.

Baseline characteristics of patients, including age, BMI, bone markers, BMD at lumbar spine (mean T-Score -2.33 vs. -2.40 SD) and hip (mean T-Score -1.40 vs. -1.45 SD) were not significantly different between the two groups.

BMD	Volumetric BMD change from baseline after 1 year (per protocol analysis)		
	alfacalcidol + alendronate	placebo + alendronate	p value (T-test)
radius, trabecular	- 0.83 %	- 0.66 %	0.874
radius, cortical (mid shaft)	+ 0.26 %	- 0.19 %	0.032
tibia, trabecular	+ 0.04 %	- 0.50 %	0.042
tibia, cortical 14%	+ 0.20 %	- 0.25 %	< 0.001
tibia, cortical 38%	+ 0.16 %	- 0.13 %	0.002
tibia, cortical 66%	+ 0.17 %	+ 0.07 %	0.216

A slight, but significant increase of cortical vBMD at the mid shaft radius and the 14% and 38% measurement sites of the tibia was detectable after one year of additional alfacalcidol medication versus placebo in alendronate treated patients. Similar results were found for the trabecular vBMD at the tibia. Results were not significantly different for trabecular vBMD at the radius and cortical vBMD at the 66% measurement site of the tibia.

For the first time, our data showed an additional, potentially beneficial, effect of alfacalcidol 1 µg daily in alendronate-treated postmenopausal women not only on lumbar spine BMD measured by DXA (as reported earlier), but also on several volumetric BMD parameters at the appendicular skeleton. Their long-term change and possible impact on bone strength of the peripheral skeleton will be monitored in the actually ongoing study for three years.

Disclosures: O. Bock, None.

This study received funding from: Chugai Pharmaceutical Co., Ltd (Japan), GRY-Pharma GmbH (Germany) and Teva Pharmaceutical Industries (Israel).

M454

Bone Mineral Density (BMD) and Serum Vitamin D Levels in Patients with Chronic Obstructive Pulmonary Disease (COPD) Without Glucocorticoid Use. C. Franco^{*1}, C. A. M. Kulak¹, P. Gomes^{*1}, S. C. Radominski², V. Z. C. Borba¹, C. L. Boguzewski^{*1}. ¹Endocrinology, UFPR, Curitiba, Brazil, ²Reumatology, UFPR, Curitiba, Brazil.

The evaluation of BMD in patients with COPD is restricted to those in glucocorticoid use or with risk factors. It is not known if COPD per se affects bone mass and increases the risk of fracture. The purpose of this study was to evaluate the BMD, vitamin D levels and spirometric parameters in a group of COPD patients without systemic glucocorticoid (GC) use. We examined 28 women and 21 men (65.4 ± 9.2 years old) with COPD without chronic systemic GC use. Age below 25 years old and patients with any other cause for osteoporosis were excluded. Patients answered to a questionnaire and were submitted to DXA (Hologic QDRW1000) of lumbar spine and femur. The diagnosis of COPD was done by spirometry and blood was collected for laboratory exams. Past history of fractures were present in 22, 4%. The lumbar spine BMD (g/cm²) was 0.794 ± 0.169, femoral neck 0.704 ± 0.143, total femur 0.78 ± 0.15. Low bone mass was presented in 79.6% and 51% presented osteoporosis. There was a correlation between spirometry and BMD: lumbar (R=0, 38 p <0, 01), femoral neck (R=0, 40 p=0, 01), total femur (R=0, 36 p <0, 01). The mean levels of 25 OH vitaminD (25-OHD) was 20.8 ± 1.0 ng/dl, (28, 6% were 25-OHD insufficient; 6% were 25-OHD deficient and 67% had secondary hyperparathyroidism). Patients with oxygen saturation <88% presented lower 25-OHD levels, and who stopped smoking > 49 months had better BMD. In regression analysis, weight, current smoking, sex and time without smoking were related to the worsening of BMD (R² = 0,7) These data suggest that COPD patients present low bone mass, vitamin D insufficiency and increased fracture risk, independent of the GC use.

Remodelling of Bone Microarchitecture in Aging Mice Is Associated with Changes in Ephrins Gene Expression. E. N. Bianchi^{*}, R. Rizzoli, S. L. Ferrari. Div. of Bone Diseases, Geneva University Hospital, Geneva, Switzerland.

Continuous bone remodelling leads to prominent losses of trabecular microarchitecture in aging C57BL/6J mice, which mimics the deterioration of bone structure observed in post-menopausal women. The molecular mechanisms involved in this process however remain poorly understood. Binding of ephrin (Efn) B2 to the ephrin receptor (Eph) B4 was recently reported to induce stimulation of osteoblast differentiation and inhibition of osteoclastogenesis. We hypothesized that a decline in ephrins expression could be implicated in the changes of bone microarchitecture observed in aging mice. For this purpose, female C57BL/6J mice were sacrificed at 4 and 12 months of age, and trabecular (Tb) and cortical (Ct) bone microarchitecture analyzed by microCT (Scanco40) at distal and midshaft femur, respectively. RNA was extracted from the same regions of interest, i.e. the diaphysis (Dia) after flushing of the bone marrow and the metaphysis-epiphysis (Met) of femur. Expression levels of Efn B1 and B2 and Eph A3, A4, B2, B3 and B4 genes were determined by quantitative RT-PCR (TaqMan MGB probes).

Tb BV/TV decreased by 60% between 4 and 12 months of age (p=0.0001) associated with a decline in Tb number and connectivity, and an increase in Tb separation (all p<0.001). Meanwhile, Ct volume increased by 20-30%. Overall, Efn and Eph expression levels were higher in Met than Dia and in young compared to older mice. More precisely, expression of EfnB2 decreased by 65% (p<0.0001) in Met and 40% (p<0.02) in Dia with aging, whereas its receptors Eph B2, B3 and A4 decreased by 40% to 70% (p<0.05) in both compartments. In contrast, significant down-regulation (-35% to -50%, p<0.02) of EfnB1 and EphB4 occurred specifically in Met, but not in Dia. We then investigated expression of additional genes associated with osteoclast (OPG, RANKL and TRAP) and osteoblast/osteocyte activity (IGF-1 and SOST). OPG, RANKL and TRAP were more prominently expressed in Met than Dia (p<0.005), and both the RANKL/OPG ratio and TRAP gene expression were significantly down-regulated with age. In contrast, IGF-1 and SOST mRNA levels were twice as high in Dia than Met, and decreased only marginally with age in Dia.

In summary, reciprocal changes in bone geometry and trabecular content and distribution occur in the femur of aging mice. Neither the changes of OPG, RANKL and TRAP, nor those of IGF-1 and SOST can explain the age-related decline of trabecular microarchitecture. However, the decline of ephrins and ephrin receptors gene expression, particularly of EfnB1 and EphB4 in the Tb compartment, might favor uncoupling of bone formation from resorption and remodelling of skeletal microarchitecture.

Low Vitamin D Level and High Bone Turnover in Aged Type 2 Diabetic Patient. D. Chung, J. Chung^{*}, D. Myung^{*}, D. Cho^{*}, M. Chung^{*}. Internal Medicine, Chonnam National University Medical School, Gwangju City, Republic of Korea.

Bone mineral density in type 2 diabetic patient is known to be variable; such as increased, decreased, or not different from normal subject. Levels of bone turnover markers are also conflicting while several histomorphometric data shows low bone turnover status in diabetic bone. However, recent epidemiologic data showed that osteoporotic fracture rate is increased in type 2 diabetes even in patients with normal or high BMD possibly due to poor bone quality. Bone metabolism in diabetes is thought to be

affected by many factors including glycemic control status, presence of late chronic complications, disorder of calcium and vitamin D metabolism. In this study, we investigated the vitamin D status and bone turnover rate in 53 type 2 diabetic postmenopausal women (69.9±8.1 years, HbA1c was 8.2±2.3%) and 34 non-diabetic postmenopausal women (66.8±8.4 years). 25OHD, serum CTX and other laboratory data were acquired after overnight fasting. BMD was measured at the lumbar spine and femur using dual energy X-ray absorptiometry (Lunar Prodigy Advance). Body mass index and years since menopause were not different between two groups. The 25OHD level was significantly lower (p=0.001) in diabetic women (23.1±11.4 ng/ml) compared to normal subject (32.6±12.3 ng/ml). The serum CTX was significantly higher (p=0.013) in diabetic women (0.61±0.42 ng/ml) compared to non-diabetic women (0.39±0.29 ng/ml). However, the BMD at the spine and femur were not significantly different between two groups. These results suggest low serum vitamin D level and high bone turnover in aged type 2 diabetic patient may contribute to increased probability of osteoporotic fracture.

Multifactorial Etiology of Weak Bones in Type 1 Diabetes (T1DM). K. K. Danielson^{*1}, M. E. Elliott², M. Palta^{*3}. ¹Section of Pediatric Endocrinology, University of Chicago, Chicago, IL, USA, ²Pharmacy Practice Division, University of Wisconsin, Madison, WI, USA, ³Population Health Sciences and Biostatistics & Medical Informatics, University of Wisconsin, Madison, WI, USA.

Our research has demonstrated bone mineral density (BMD) and bone formation to be lower in women with T1DM than in matched controls. We also found that the earliest etiologic effects of T1DM on bone appear at the level of bone turnover. We therefore attempted to delineate the potential pathophysiologic mechanisms altering bone turnover in T1DM. The study included premenopausal women with T1DM enrolled in the Wisconsin Diabetes Registry (n=89). Each participant completed questionnaires, a physical exam, and blood draw to measure HbA1c, parathyroid hormone (PTH), insulin-like growth factor 1 (IGF-1), vitamin D, estradiol, osteocalcin and NTx. An Uncoupling Index (UI) was calculated as the difference between osteocalcin and NTx z-scores. Urinary albumin excretion (UAE; n=61) was collected as a measure of kidney function during the three years prior to the study (mean=1.7 years). The study was approved by the University of Wisconsin institutional review board. Mean age was 28 years (18-45 years) and 98% were Caucasian. Mean disease duration was 16 years and current mean HbA1c was 8.1%. Only 9.8% demonstrated early kidney impairment with elevated UAE (≥20 µg/min). A negative UI was exhibited by 66.3% of the sample, indicating bone resorption was outpacing formation. The final multivariable regression model for bone formation demonstrated several potential etiologic factors to be independently associated with osteocalcin (ng/ml): HbA1c (%; β=-0.3), PTH (10 pg/ml; β=0.4), IGF-1 (10 ng/ml; β=0.1), and logUAE (µg/min; β=0.3). The HbA1c coefficient did not attenuate when PTH, IGF-1, or UAE was added to the final model indicating they did not mediate the association between glycemic control and bone formation. The final model for bone resorption (NTx [nmol BCE/L]) also demonstrated a positive association with logUAE (β=1.6). Lastly, the UI (z-score) was independently associated with PTH (β=0.2) and IGF-1 (β=-0.1). In conclusion, uncoupled bone turnover in T1DM, encompassing low formation and net resorption, appears to be related to the poor glycemic control and low IGF-1 and PTH levels associated with T1DM. The progression of kidney disease, even the early stages as detected in our sample by slightly elevated UAE, may then accelerate this uncoupled bone turnover. These factors may eventually culminate in the low BMD and increased fracture risk seen in T1DM. Fortunately, this multifactorial process provides several potential targets for intervention.

Relationship of Bone Turnover Markers, Ovarian Hormones and Cytokines During Menopause. M. P. Desai^{*1}, V. R. Taskar^{*2}, M. Khatkhatay^{*1}. ¹Molecular Immunodiagnostics, National Institute for Research in Reproductive Health, Mumbai, India, ²Clinical, Streehit Karini, Mumbai, India.

Estrogen influences bone remodeling, by modulating the secretion of cytokines. Its deficiency at menopause causes accelerated bone loss and subsequently osteoporosis. The aim of the study was therefore to characterize the changes in cytokines and ovarian hormonal profiles and correlate with bone turnover markers and bone density. This would aid in identification of women at risk for osteoporosis and preventive therapy could be initiated. We studied a cross-sectional age stratified population sample of 124 premenopausal women (age: 21-40yrs), 68 perimenopausal women (age: 36-44 yrs) and 188 postmenopausal women (age: 41-75 yrs) not using any oral contraceptives or on hormone replacement therapy. Serum calcium, phosphorus and PTH were estimated to assess the bone homeostasis while bone mineral density (BMD) of lumbar spine and femoral neck was measured by DEXA. The women in the groups were classified into normal, osteopenic and osteoporotic based on BMD measurements and their ovarian hormonal status. Urinary estrone glucuronide (E₁G) and follicle stimulating hormone (FSH) were estimated by in-house assays, whereas serum interleukins (IL1, IL6 and TNFα) by optimized EIA assays. The bone markers such as Osteocalcin (OC), bone specific alkaline phosphatase (BSAP), urinary type I collagen telopeptide (CTX) and pyridinium crosslink de-oxypridinoline (Dpd) by ELISA kits. The perimenopausal women showed 30% higher CTx excretion (528 ± 126 µg/mol Cr, p<0.01), 28% higher

Dpd levels (5.02 ± 1.20 nMol / mol Cr, $p < .01$), increased levels of urinary FSH (38.6 ± 3.84 m IU / mg Cr, $p < 0.0001$) and IL6 (11.68 ± 2.61 ng/ml, $p < 0.05$) with osteopenic changes on BMD whereas E_1G bone formation markers and BMD though low did not show any significant change. In the osteopenic menopausal women all the bone markers were significantly elevated indicating increased rate of bone remodeling. Of the three cytokines, IL6 increased significantly (15.85 ± 3.5 ng/ml, $p < 0.0001$) correlating well with increased bone turnover (CTx 1126 ± 362 μ g / mol Cr and Dpd 8.49 ± 2.65 nM / mol Cr) while there was marginal increase in TNF α levels (6.5 pg/ml; $p < 0.0056$) only in the osteoporotic women. A significant drop in E_1G (8.99 ng/mgCr; $p < 0.0001$) and BMD measurements with rise in IL 6 was also observed in these women. The data suggests that elevated cytokines (IL 6 and TNF α) and bone resorption markers (CTx and Dpd) are associated with rapid of fall of estrogens in the first decade of menopause leading to postmenopausal osteoporosis. Combination of hormonal profiles, bone resorption markers and cytokines will thus aid in identifying women at risk for osteoporosis.

Relationships Between Leptin, PTH, Vitamin D and Bone Metabolism Markers in Patients with Hip Fracture. A. A. Fisher^{*1}, E. K. Southcott^{*1}, S. L. Goh^{*2}, W. Sriksalanukul^{*1}, M. W. Davis^{*1}, P. N. Smith^{*2}. ¹Department of Geriatric Medicine, The Canberra Hospital, Australian National University, The Canberra Hospital, Woden, ACT, Australia, ²Department of Orthopaedic Surgery, The Canberra Hospital, Australian National University, The Canberra Hospital, Woden, ACT, Australia.

The relationship between leptin and bone metabolism is controversial. The study aim was to investigate leptin-skeletal interactions in older patients with hip fracture (HF), a population not previously studied.

In 207 consecutive patients (mean age 82.1 ± 7.9 years; 75.8% women) with low-energy trauma HF (119/88 cervical/trochanteric) serum concentrations of leptin, 25 hydroxy-vitamin D [25(OH)D], parathyroid hormone (PTH), calcium, phosphorus, magnesium, osteocalcin (OC), bone-specific alkaline phosphatase (BAP) and urine excretion (normalised for urinary creatinine) of free deoxypyridinoline (DPD) and N-terminal cross-linked telepeptide of type 1 collagen (NTx) were measured and clinical data collected prospectively.

Elevated PTH (> 6.5 pmol/L) was present in 53%, 25(OH)D insufficiency (< 50 nmol/L) in 81.6%, excessive bone resorption (increased DPD and/or NTx excretion) in 93.7% and low bone formation (low OC and/or BAP) in 59.2%. Leptin (log-transformed) was significantly and positively correlated with OC ($r = 0.18$; $p = 0.006$) and negatively with NTx ($r = -0.17$; $p = 0.015$) and DPD ($r = -0.14$; $p = 0.037$). In both cervical and trochanteric HF groups, leptin was positively associated with OC, but the association with DPD was significant only in trochanteric HF ($r = -0.30$; $p = 0.009$). Trochanteric compared to cervical HF patients have higher levels of PTH (7.9 ± 6.0 vs 5.9 ± 3.8 pmol/L; $p = 0.005$), but the concentrations of leptin, 25(OH)D and bone turnover markers were similar. Only in cervical HF patients were leptin and PTH positively correlated ($r = 0.26$; $p = 0.005$) and 25(OH)D levels were negatively and significantly correlated with NTx ($r = -0.25$; $p = 0.016$), DPD ($r = -0.31$; $p = 0.002$) and BAP ($r = -0.24$; $p = 0.012$). Other bone metabolism parameters were not associated with leptin in neither group.

These findings suggest that in HF patients there exists a complex relationship between leptin and calciotropic factors, that serum leptin may independently contribute to bone remodelling and is likely to exert different effect on cortical and trabecular bone compartments.

Do Periosteal and Intracortical Responses to Ulmar Fatigue Loading Differ Between Old and Young Rats? J. B. Jones^{*}, R. T. Kitterman^{*}, S. D. Mendenhall^{*}, J. G. Skedros. Dept. of Orthop. Surgery, Univ. of Utah, SLC, UT, USA.

Age-related skeletal deterioration results not only in decreased bone mass but also bone quality. Inadequate modeling responses and/or incomplete infilling of resorption cavities following bone fatigue contribute to this decline in bone mechanical properties. Using the rat ulna fatigue model, we hypothesized that older adult rats would show less periosteal woven bone apposition and resorption space infilling when compared with younger adult rats following mechanical loading. With IACUC approval, 28 male F344 rats (14, 5 month-old, 14, 15 month-old) were obtained from the National Institute on Aging (Bethesda, MD). Eight rats of each age formed the experimental groups and the remaining were used for load/strain calibration. Right forearms were cyclically loaded [Uthgenannt & Silva, J Biomech, 2006] and the contralateral ulnae served as controls. Tetracycline was injected 13 and 3 days prior to sacrifice at 18 days post-loading. Ten transverse sections were then cut from mid-third ulnar diaphyses and mounted on slides. Resorption space areas (Rs.Ar/Ct.Ar), infilling areas (Rs.Inf.Ar/Ct.Ar), and periosteal woven bone area (PWb.Ar/Ct.Ar) were quantified. Kruskal-Wallis ANOVA was employed with significance set at $p < 0.05$. Contrary to our hypothesis that older rats would exhibit less periosteal bone apposition, a larger amount was observed when compared to younger rats (see Table).

Additionally, total resorption area was twice as large in older rats. However, when resorption space infilling area was considered, the older rats showed significantly less infilling than younger rats (33% vs. 55%, see Table). These data suggest that older rats show an imbalance between intracortical resorption and bone formation which leads to net bone loss—a similar phenomenon experienced by aging humans. The finding that older rats exhibit more periosteal woven bone than younger rats implies the possibility of a compensatory mechanism that counteracts the increased cortical porosity. Although a similar interaction between remodeling and modeling has been suggested in humans, the modeling response is relatively subtle [Ural & Vashishth: J Orthop Res 2006]. This demonstrates a limitation when attempting to extrapolate the capacity of bone modeling in 15-month old rats to that in aging humans.

Table: Periosteal modeling, intracortical resorption, and intracortical infilling by age in the rat

	5 month old rats (mean \pm SD)	15 month old rats (mean \pm SD)	
PWb.Ar/Ct.Ar	0.0630 ± 0.0875	0.1578 ± 0.1380	$p < 0.001$
Rs.Ar/Ct.Ar	0.0063 ± 0.0235	0.0129 ± 0.0225	$p = 0.008$
Rs.Inf.Ar/Ct.Ar	0.0035 ± 0.0118	0.0043 ± 0.0065	$p = 0.030$

PWb.Ar/Ct.Ar - periosteal woven bone area / cortical area (mm²/mm²)

Rs.Ar/Ct.Ar - total resorption space area / cortical area (mm²/mm²)

Rs.Inf.Ar/Ct.Ar - resorption space infilling area / cortical area (mm²/mm²)

Increased Active Osteoclasts Are Associated with Acute Cancellous Bone Loss in Adult Mice Exposed to Ionizing Radiation and Musculoskeletal Disuse. H. Kondo¹, R. Mojarrah^{*1}, A. Wang^{*1}, J. Phillips^{*1}, E. A. C. Almeida^{*1}, D. J. Loftus^{*1}, E. Morey-Holton^{*1}, R. K. Globus^{*1}, W. Vercoe^{*1}, C. Limoli^{*2}, N. D. Searby^{*1}. ¹Bone and Signaling Lab, NASA Ames Research Center, Moffett Field, CA, USA, ²Radiation oncology, University of California Irvine, Irvine, CA, USA.

Spaceflight challenges the skeletal health of astronauts by exposure to radiation in microgravity. Hamilton et al. (JAP (2006) 101:789) showed that irradiation alone decreases bone mass in growing mice 4 mo after exposure to 2 Gy vs. controls, as does musculoskeletal disuse. We hypothesize that radiation and disuse share cellular and molecular mechanisms to cause rapid bone loss in the adult. To define dose (1-2 Gy) and time dependence (3 or 10 d) of skeletal responses to radiation, 4 mo old C57/B16 mice were Cs¹³⁷ gamma-irradiated (IR), then marrow cells analyzed for viability by FACS and bones for structure by microCT. In a second study, mice were hindlimb unloaded (HU) or normally loaded (NL) for 7 d; half the mice from each group were IR with 2 Gy 4 d into the unloading period. Bones were analyzed for structure (microCT), osteoclast surface (histomorphometry) and oxidative damage to lipids (peroxidation by malondialdehyde assay). As expected, HU for 7 d decreased cancellous bone compared to NL. Surprisingly, only 3 d after exposure, IR (2 Gy) caused a loss in cancellous BV/TV (~20%), trabecular number, and connectivity similar to 7 d HU. By 10 d after IR, BV/TV was 25% lower than controls at 1 Gy and 35% lower at 2 Gy, showing both dose and time-dependent effects of IR. Cancellous bone loss was similar in mice exposed to IR during HU, compared to mice treated with either IR or HU alone. IR transiently reduced (by 65% at 3 d) numbers of viable marrow cells due to increased apoptosis. IR elevated (by 36%) lipid peroxidation in bone. Osteoclast surface per bone surface increased 113% due to IR, 100% due to HU, and 153% due to both IR and HU compared to NL, indicating stimulated resorption. Hydrogen peroxide treatment of cultured bone marrow cells caused a dose-dependent increase in TRAP+ cells, inhibited by the anti-oxidant, alpha-lipoic acid. Together, these results showed that IR and HU caused similar detrimental effects on cancellous bone structure of adult mice, and shared the cellular mechanism of increasing active osteoclasts. In the short-term, continuous HU did not alter the structural changes caused by radiation, possibly due to depletion of osteoclast precursors by unloading or irradiation alone. Finally, radiation caused oxidative stress in bone tissue that may contribute to increased resorption leading to rapid bone loss. These results have potential clinical relevance to astronauts as well as to cancer patients treated therapeutically with radiation.

The Periosteal and Endosteal Modeling Process Is Affected by Estrogen Differently in Response to Fatigue Loading Than During Development. S. D. Mendenhall*, J. B. Jones*, R. T. Kitterman*, J. G. Skedros. Dept. of Orthop. Surgery, Univ. of Utah, SLC, UT, USA.

Females are "set up" during skeletal development to have fragile bones later in life. This results primarily from the inhibitory effect of estrogen on periosteal modeling during bone mass acquisition, causing women's bones to be less robust than men's. Delayed pubertal development in female rats increases periosteal bone growth, but results in a minor decline in endosteal modeling [Yingling: Tran Orthop Res Soc 2007]. However, little is known about the effects of estrogen on periosteal/endosteal modeling responses to fatigue loading in rats. Using the rat ovariectomy (Ovx) model, we tested the hypothesis that estrogen-deficient rats would exhibit less endosteal modeling and more periosteal modeling following fatigue loading than Ovx rats that were estrogen-repleted (Ovx-Est). With IACUC approval, 36 five-month-old female F344 rats were obtained--6 for load/strain calibration and 15 for each of the experimental groups. Following Ovx, right forearms were cyclically loaded [Uthgenannt & Silva, J Biomech, 2006] and the contralateral ulnae served as controls. The Ovx Est group received daily β -Estradiol (0.05 mg/kg) injections. All animals received tetracycline injections 13 and 3 days prior to sacrifice at 18 days post-loading. Ten transverse sections were cut from mid-third ulnar diaphyses and mounted on slides. Endosteal woven bone area (End.Wb.Ar), periosteal woven bone area (Per.Wb.Ar), and total woven bone area (T.Wb.Ar) were then quantified. Kruskal-Wallis ANOVA was used with significance at $p < 0.05$. As expected, the Ovx rats had less endosteal bone growth when compared to Ovx-Est rats. Surprisingly, the Ovx-Est rats produced nearly twice as much periosteal woven bone than did Ovx rats (see Figure). These results show an interesting interaction between hormone status and fatigue-induced modeling responses in the rat. Although estrogen inhibits periosteal bone growth during development, heavy mechanical stimuli seem to reverse this role, thereby maximizing the amount of new bone growth on periosteal and endosteal surfaces. Similar anabolic effects of estrogen have been reported in women on estrogen replacement therapy [Vedi et al.: Osteoporos Int 1999]. Further work is needed to validate the rat Ovx model for evaluating novel therapeutic agents that target estrogen's actions on bone.

An Acute 7 Gray Dose of Gamma-Radiation Induces a Profound and Rapid Loss of Trabecular Bone in Mice. J. S. Willey*, D. S. Gridley*, M. J. Pecaut*, R. W. Norrdin*, T. A. Bateman*. ¹Bioengineering Department, Clemson University, Clemson, SC, USA, ²Department of Radiation Medicine, Loma Linda University, Loma Linda, CA, USA, ³College of Veterinary Medicine and Biomedical Sciences, Colorado State University, Fort Collins, CO, USA.

Fracture rates of irradiated bones are elevated in patients receiving radiation therapy for a primary tumor as well as palliative care treatment. The mechanism for the elevated risk of fracture is unclear. Osteoblast death and damaged vascularity have been documented in patients as well as animal models, and contribute to atrophy after irradiation. But the effects of radiation on osteoclast number and function are not well defined. We investigated the effects of acute, high-dose radiation exposure on trabecular and cortical bone to document bone quantity and structural properties at an early time-point post-irradiation. Nine-week old C57BL/6 mice (n=6) received 7 Gray (Gy) gamma-radiation, with nonirradiated controls (n=6). Fourteen days after exposure the animals were euthanized, hind limbs removed, and tibiae analyzed via microCT and histomorphometry. Statistical analyses were performed using t-tests to compare the groups. Profound loss of trabecular bone within the metaphysis was observed. Significant reduction in BV/TV (-

54%), Conn.Dens (-69%), and Tb.N (-26%) were observed in irradiated animals compared with control. No differences were observed in cortical parameters. Decreased growth plate cellularity, disorganized chondrocyte arrangement, and a terminal bar of bone along the distal physal border indicated slow growth among all animals. Oc.S/BS and ES/BS were similar between both groups, with TRAP staining confirming presence of multinucleated osteoclasts. The large difference in the amount of bone between groups and evidence together with evidence of slow growth suggests bone loss as opposed to reduced bone growth. Evidence of stabilized resorption at sacrifice indicates that large declines in bone quantity occurred via increased resorption very early after exposure. Radiation-induced reduction in bone quantity and microarchitecture via elevated resorption could reduce bone quality and may provide insight into the nature of increased fracture rates among radiation therapy recipients.

Reduced Levels of Serum Insulin Like Growth Factor 1 in Male with Idiopathic Osteoporosis. J. Dewailly*, I. Legroux-Gerot*, M. D'Herbomez*, X. Marchandise*, D. Dewailly*, B. Duquesnoy*, B. Cortet*. ¹Rheumatology, CHRU Hopital Salengro, Lille, France, ²Service de Médecine nucléaire, CHRU Hopital Salengro, Lille, France, ³Endocrinology, CHRU, Lille, France.

Objective: The pathophysiology of idiopathic male osteoporosis remains unknown. The histomorphometric studies suggest reduction of bone formation. A disturbed secretion of IGF-1 could be involved in male idiopathic osteoporosis since IGF-1 has a stimulative effect on the osteoblastic proliferation and on the bone tissue synthesis. Few studies have evaluated the relationship between the circulating concentrations of IGF-1 and bone mineral density, particularly in osteoporotic men, and the results are controversial. The aim of our study was to evaluate the involvement of IGF-1 in idiopathic male osteoporosis and the relationships between bone density and the serum levels of IGF-1 and sex hormones. **Materials and methods:** Serum levels of IGF-1, estradiol, testosterone, SHBG and bone mineral density at lumbar spine, femoral neck and total hip were compared between 79 men with idiopathic osteoporosis and 26 healthy subjects. Inclusion criteria were a densitometric osteoporosis defined by a T-score ≤ -2.5 SD and/or an osteoporotic fracture. The osteoporotic patients were included after exhaustive work-up excluding the principal causes of secondary osteoporosis.

Results: A significant reduction in the mean serum IGF-1 levels was found in osteoporosis patients ($p = 0.02$) that persisted after adjustment for BMI. However, no correlation was found between bone density and the serum IGF-1 levels. The mean SHBG level was higher in osteoporotic patients ($p = 0.001$) thus yielding a reduction in the mean Free Testosterone Index (FTI, total testosterone / SHBG) ($p = 0.002$). These differences remained significant after adjustment for BMI. After adjustment for the FTI, the mean IGF-1 levels between patients and controls were not significantly different. However, after adjustment for the FTI and the BMI in patients, the IGF-1 level was significantly related to the presence of an osteoporotic fracture, thus indicating an independent effect of the IGF-1 level on fracture risk.

Conclusion: Our study confirms the presence of reduced serum IGF-1 levels in male idiopathic osteoporosis. This could be the cause or the consequence of a disturbance in sex hormones with increased SHBG serum level. This confirms the important role of SHBG in the pathophysiology of male osteoporosis.

Birth Weight Predicts Lean Body Mass and Thus Bmc in Healthy Men at Peak Bone Mass - Results from the Odense Androgen Study. L. Frederiksen*, T. L. Nielsen*, K. Wraae*, H. Claus*, M. Andersen*, K. Brixen*. Endocrinology, Odense University Hospital, Odense, Denmark.

Birth weight has been associated with low bone mass in later life. Previous studies, however, have relied on self-reported data on birth weight, included select populations, or been of a limited size. Moreover, it is unclear if the association between birth weight and bone mass is mediated by body weight, lean body mass, or fat mass.

We hypothesize that birth weight is associated with peak bone mass in men independent of current lean body mass and body weight.

The Odense Androgen Study is a population-based, prospective, observational study on the inter-relationship between endocrine status, body composition, muscle function, and bone metabolism in young men. In brief, 3000 males aged 20-30 years were randomly selected from the civil registration database in Funen County, Denmark, and invited by mail to participate in the study. A total of 2042 men returned the questionnaire, 783 gave written informed consent to participate in the study and the data are presented here. Bone mass measurements (spine, hip, and whole body) were performed using a hologic-4500a densitometer. Data on birth weight, length at birth, and gestational age was retrieved in a national database covering all birth clinics in Denmark in the current period. The relationship between Birth weight, BMC, Lean body mass and fat mass as tested using multiple regression analysis is shown in the table as partial correlation coefficients

Data on birth weight and birth length were available on 754 participants while gestational

age was available on 263 participants (those 20-24 years old). In bivariate analyses, BMC at whole body, spine, and hip were significantly associated with current body weight ($R=0.50$ to 0.30 , $p<0.001$) and birth weight ($R=0.17$ to 0.09 , $p<0.01$). Birth weight was also significantly associated with current body weight ($R=0.09$, $p<0.01$), current lean body mass ($R=0.15$, $p<0.001$) but not current fat mass ($R=-0.04$, NS). No significant difference was found in BMC at any skeletal site in participants born prematurely ($n=26$) and those born at term ($n=237$).

R-values	BMC		
	WB	Spine	Hip
Birth weight	0.08*	-	-
Current fat mass	-0.35***	-0.38***	0.67***
Current lean body mass	0.73***	0.58***	-0.31***
Overall model	0.75***	0.60***	0.67***

* $p<0.05$, ** $p<0.01$, *** $p<0.001$

Birth weight predicts peak bone mass, but this seems to be due to correlation between birth weight and body weight (and lean body mass) in young adult life.

Aberrations in Wnt/ β -Catenin Signaling Driving HAART-induced Bone Loss In Vitro. J. S. Butler¹, P. P. Doran^{*1}, R. T. Moon^{*2}, J. M. O'Byrne^{*3}, W. G. Powderly^{*1}. ¹Mater Misericordiae University Hospital, UCD School of Medicine & Medical Science, Dublin, Ireland, ²Howard Hughes Medical Institute, University of Washington School of Medicine, Seattle, WA, USA, ³Dept of Trauma & Orthopaedic Surgery, Royal College of Surgeons in Ireland, Dublin, Ireland.

The advent of highly active anti-retroviral therapy (HAART) had dramatically decreased the rate of HIV-related mortality and significantly extended the life span of patients with AIDS. A variety of metabolic side effects are associated with these therapies, one of which is metabolic bone disease. A higher prevalence of osteopenia and osteoporosis is reported in HIV-infected patients receiving anti-retroviral therapy relative to patients not on therapy. Thus, we decided to investigate the role played by Wnt/ β -catenin signaling in Protease Inhibitor (PI) induced bone loss in vitro.

Our objectives were to assess the gene expression profile of primary human osteoblasts (HOBs) exposed to PIs with a view to identifying key genes driving HAART-induced bone loss and to assess the effects of silencing the Wnt antagonist Dickkopf-1 (Dkk1) on the bone profile of primary human osteoblasts (HOBs) exposed to $5\mu\text{M}$ of IDV and RTV in vitro.

Primary human osteoblasts (HOBs) were cultured in vitro and exposed to $5\mu\text{M}$ of IDV and RTV over a time course of 4hr, 12hr, 24hr and 48hr. Dkk1 expression was silenced using small interfering RNA (siRNA). Quantitative RT-PCR was performed to confirm gene knockdown. Control and PI-treated HOBs were compared with respect to bone turnover. Markers of bone turnover analyzed included alkaline phosphatase activity, calcium deposition and osteocalcin expression, along with cell proliferation and cellular apoptosis. Global changes in HOB gene expression were elicited by IDV and RTV. Development associated gene pathways were co-ordinately dysregulated with the expression profile of key genes of the Wnt Pathway significantly altered. Dkk1 expression in HOBs was increased in response to IDV and RTV exposure with an associated reduction in alkaline phosphatase activity and calcium deposition. Silencing of Dkk1 expression, as confirmed by quantitative RT-PCR, was associated with an increase in alkaline phosphatase activity and calcium deposition, along with increased cell proliferation and reduced cellular apoptosis.

Dkk1 is an antagonist of Wnt/ β -catenin signaling and plays a key role in regulating bone development and remodeling. Silencing the expression of Dkk1 in primary human osteoblasts has been shown to rescue the effects of PI-induced bone loss in vitro. The pharmacological targeting of the Wnt/ β -catenin signaling pathway offers an exciting opportunity for the development of novel anabolic bone agents to treat HAART associated osteopenia/osteoporosis.

Bone Mineral Density and Prevalence of Osteoporosis and Fractures in Psoriatic Arthritis. M. Romera, N. Busquets*, J. Rodríguez-Moreno*, C. Gómez-Vaquero*, X. Juanola*, J. M. Nolla*. Rheumatology, Hospital Universitari de Bellvitge, L'Hospitalet, Spain.

Systemic diseases, mainly those involving joints, are known to produce secondary osteoporosis. However, there is little information available about bone mineral density (BMD) and the prevalence of osteoporosis and fractures in patients with psoriatic arthritis (PsA).

The purpose of the study is to evaluate BMD and to quantify the prevalence of osteoporosis and clinical fractures in PsA.

BMD was determined by DXA (Hologic QDR 4.500) in all the patients with PsA regularly evaluated in a tertiary university hospital who were willing to participate in the study;

patients with axial involvement were excluded. All patients underwent a physical examination and a general analytics. We gathered demographic and clinical variables related with BMD and risk of fractures. We also recorded the antecedent of clinical low impact fracture. The activity of PsA was assessed by means of the Modified Health Assessment Questionnaire (HAQm) and the Disease Activity Score 28 (DAS28). The population of reference to calculate T-score and Z-score proceeds from a Spanish database. The diagnosis of osteoporosis was made according to the recommendations of the International Society for Clinical Densitometry.

One hundred and fifty-five patients were included (64 postmenopausal women, 26 premenopausal women and 65 men) with a mean age of 62 ± 8 , 39 ± 7 and 55 ± 14 years, respectively. The clinical forms of PsA were: 1% monoarticular, 44% oligoarticular and 55% polyarticular.

BMD in males under 50 years old was lower than BMD of healthy males of the same age ($p < 0.05$); there were no differences in the other groups of patients. BMD related in a statistically significant way to age, body mass index (BMI), time since the beginning of PsA, number of tender joints, HAQm and DAS28.

The prevalence of osteoporosis in postmenopausal women was 28%; in males above 50 years old, 10%. Fifteen percent of the postmenopausal women and 20% of the males under 50 years old had a BMD below the expected range for their age.

Thirteen percent of the patients had had a clinical fracture. The most frequent localization of the fracture was forearm (7%), followed by vertebra (1%) and hip (1%). Clinical and demographic data were similar in patients with and without fracture. Postmenopausal women had a significantly higher prevalence of fractures.

As a conclusion, patients with PsA, mainly postmenopausal women, have a high prevalence of osteoporosis. BMD correlates with age, BMI and activity of the disease. The frequency of clinical osteoporotic fractures is not negligible. The factors associated to fractures in PsA are similar to those in general population.

Associations of Osteoporotic Spinal Deformity with Back Strength Among Elderly Women in Japan and the United States. M. Hongo¹, M. Sinaki², N. Miyakoshi¹, Y. Shimada^{*1}, E. Itoi^{*3}. ¹Department of Orthopedic Surgery, Akita University, Akita, Japan, ²Department of Physical Medicine and Rehabilitation, Mayo Clinic, Rochester, MN, USA, ³Department of Orthopedic Surgery, Tohoku University, Sendai, Japan.

Kyphosis is associated with diminished daily physical function, increased risk of falls, and increased mortality risk. Back extensor strength (BES) is an important factor in maintaining the sagittal alignment of spine and preventing vertebral fractures. When back exercises are prescribed, it is important to know the associations of the sagittal alignment with BES. However, there is a controversy in the literature regarding the influence of the thoracic and lumbar spinal curvatures on BES or quality of life. We hypothesized that the regional or ethnic factor may influence the relationship between thoracic and lumbar sagittal curve, BES and other factors. The purpose of this cross-sectional study was to assess the associations of osteoporotic spinal deformity with back strength in elderly women in Japan and the United States. Using the same inclusion criteria, 104 Asian women residing in Akita, Japan and 102 Caucasian women residing in Minnesota with postmenopausal osteoporosis were selected for this study. Kyphosis angle of the thoracic and lumbar spine were measured with lateral radiographs. Isometric BES was evaluated using a custom-made dynamometer. Correlations between the kyphosis angle, isometric BES, bone mineral density, physical activity score or quality of life score, the number of vertebral fractures, and grip strengths were analyzed. No significant difference was found in thoracic kyphosis between Akita and Minnesota (43.1° and 44.1° , respectively), whereas lumbar kyphosis angle in Akita was significantly larger than in the Minnesota (-15.4° and -54.0° , $p<0.0001$). In Akita, BES showed significant negative correlation with lumbar kyphosis angle ($r=-0.492$, $p<0.0001$), but no correlation with thoracic kyphosis angle ($r=-0.004$, $p=0.97$). In Minnesota, BES showed significant negative correlation with thoracic kyphosis angle ($r=-0.372$, $p<0.0001$), but no correlation was found with lumbar kyphosis angle ($r=-0.087$, $p=0.362$). In addition, quality of life score in Akita demonstrated significant correlation with lumbar kyphosis, but not with thoracic kyphosis. Physical activity score in Minnesota showed significant negative correlation with thoracic kyphosis, but not with lumbar kyphosis. In conclusion, there was a significant difference in lumbar kyphosis angle between the two countries. Lumbar kyphosis angle has more significant influences in maintaining BES and quality of life among women in Akita, Japan compared with those in Minnesota.

Secretion of Adipokines and Hypertrophic Changes in Bone Marrow Adipocytes. A. Hozumi^{*1}, M. Osaki^{*2}, H. Shindo^{*2}. ¹Orthopaedic surgery, Nagasaki Memorial hospital, Nagasaki, Japan, ²Orthopaedic surgery, Nagasaki University, Nagasaki, Japan.

Recent analysis of gene expression in subcutaneous and visceral adipose tissue has shown that 20 to 30% of proteins expressed in adipose tissue are associated with genes coding for secretory proteins, and that adipocytes secrete a series of physiologically active substances such as adiponectin, leptin, tumor necrosis factor alpha (TNF α), and plasminogen activator inhibitor type 1 (PAI-1), regulating vital functions [1-7]. Thus, subcutaneous and visceral adipose tissue is regarded as an endocrine organ, and its importance is emphasized. No study has investigated the physiological function of adipocytes present in the bone marrow.

In this study, we established a simple method for the primary culture of bone marrow adipocytes with a suspension culture line, and quantified adipokine gene expression and secretory proteins released in suspension.

(Subjects) The subjects were 8 patients (8 joints) with coxarthrosis or femur neck fracture, with a mean age of 72 years. Subjects comprised 1 male and 7 females. Bone marrow adipocytes were isolated from bone marrow fluid collected on prosthesis insertion.

(Methods) After bone marrow fluid was treated with an enzyme, adipocytes were isolated by centrifugation, and used as an experimental system employing the floating culture method. These adipose cells were histopathologically examined by oil red O staining and Mayer's hematoxylin staining. In addition, we investigated morphological changes in the adipocytes 7 days after dexamethazone (DEX) administration. We examined PPAR γ , adiponectin, leptin, PAI-1, and TNF α mRNA expressions by RT-PCR 24 hours after culture. Concerning adiponectin, PAI-1, and TNF α release in culture medium, we quantified protein levels by ELISA.

(Results) We confirmed that the isolated adipocytes were histologically mature, and that they comprised a uniform cell population. At the gene expression level, various adipokines were detected in all patients, as demonstrated for subcutaneous and omental adipocytes. We confirmed the secretion of adiponectin, PAI-1, and TNF α in culture medium.

Seven days after DEX administration, hypertrophic change of adipocytes was observed in comparison with the control group.

(Discussion) In this study, we initially established a method for the primary floating culture of bone marrow adipocytes. In addition, various cytokines were detected in bone marrow adipocytes, as demonstrated for subcutaneous and omental adipocytes.

This procedure may be useful for investigating mature bone marrow adipocytes.

RANKL Signaling in Human Osteoclasts: Effect of P62 Mutations. E. Chamoux¹, J. N. Couture^{*1}, B. G. Lemenchick^{*1}, J. P. Brown^{*2}, S. Roux¹. ¹Rheumatology, Faculty of Medicine, Sherbrooke, PQ, Canada, ²GRMO, CHUL Research Center, Quebec, PQ, Canada.

The discovery of mutations in Paget's disease of bone (PDB), characterized by an increased number of overactive osteoclasts (OC), has now targeted p62 as an important player in RANKL signaling. To date, all the mutations identified in p62 prevent its Ubiquitin Binding Associated (UBA) domain from being functional, thus potentially affecting its degradation and/or signaling capacities. Studies on rodent models concluded that p62 forms complexes with the atypical ζ PKC and other partners after RANKL stimulation. However, the precise role of p62 in osteoclast physiology is not clearly understood yet. For our study, we build p-EGFP-C2 plasmids containing p62 wild-type (p62^{wt}), p62 modified with the most common mutation observed in PDB patients (p62^{P392L}) and p62 with a deleted UBA domain (p62^{ΔUBA}). Human OCs differentiated from cord blood monocytes with RANKL were typically able to resorb around 15% of a bone slice surface. This area was more than 3 times larger for osteoclasts transfected with p62^{wt} or p62^{P392L}. Interestingly, OCs transfected with p62^{ΔUBA} did not resorb bone more than non-transfected OCs or OCs transfected with an empty vector. DAPI staining showed that apoptosis occurred in 44.8 \pm 6.1 % of non-transfected OCs 24h after RANKL withdrawal. Similar results were seen in OCs transfected with p62^{wt} or an empty vector. In contrast, apoptosis was decreased in cells transfected with p62^{P392L} or p62^{ΔUBA} (14.1 \pm 5.7% and 8.3 \pm 4.5% respectively), which suggests that p62 mutations increase cell survival. To better understand early events occurring after RANKL stimulation, we used an antibody recognizing ζ PKC when phosphorylated on the Ser410 (hallmark of its activation) in immunofluorescence studies. RANKL stimulation led to the relocalization of P- ζ PKC from the membrane to the perinuclear area (15 min), then within nuclei (1h). If no difference was observed in cells transfected with p62^{wt}, OCs expressing p62^{P392L} in contrast exhibited P- ζ PKC in their nuclei prior to any stimulation by RANKL, and no change was noticed after RANKL addition. We finally determined that RANKL stimulation induced an important intracellular Ca²⁺ mobilization with an amplitude of 356.5 \pm 34.4 pM Ca²⁺, which was not observed in OCs transfected with p62^{P392L}. Our results underline strong relationships between p62 mutations and modified osteoclast behavior resembling to PDB. We also provide new insights in early events occurring after RANKL stimulation of human osteoclasts, noticeably a possible constitutive activation of ζ PKC, which may help to explain the increased survival and resorption observed in mutated OCs.

Functional Consequences of P62 Mutations in PDB Osteoclasts. J. N. Couture^{*1}, E. Chamoux¹, J. Morissette^{*2}, J. P. Brown^{*2}, S. Roux¹. ¹Rheumatology, Faculty of Medicine, Sherbrooke, PQ, Canada, ²GRMO, CHUL Research Center, Quebec, PQ, Canada.

Mutations in the gene encoding SQSTM1/p62 have been linked to Paget's disease of the bone (PDB), a chronic focal skeletal disorder characterized by an increased number of overactive osteoclasts (Ocs), but the functional consequences of these mutations still need to be understood. All the PDB-associated p62 mutations were mapped to the ubiquitin-associated (UBA) domain of the protein. Studies in rodents have shown that p62 forms complexes with signalling partners upon RANKL stimulation but its exact role in the Ocs physiology remains to be elucidated. For this study, we conducted experiments on osteoclast-like cells differentiated from peripheral blood mononuclear cells isolated from PDB patients previously identified with the p62^{P392L} mutation. We compared our results to normal human osteoclasts differentiated from cord blood monocytes (CBMs), a well established model. PDB Ocs were able to resorb cortical bone when differentiated with 25, 50 or 100 ng/mL RANKL during 21 days. The resorbed surface was at least 3 times greater than that for CBMs with the same doses of RANKL added throughout the differentiation. We hypothesized that increased cell survival may in part explain this hyper-resorption so, using DAPI staining, we evaluated PDB Ocs response to some of the major apoptotic signals for human Ocs. PDB Ocs and CBMs were deprived of growth factors for 72h, then a Fas-activating antibody (400 ng/ml), TGF β 1 (2 ng/ml), and M-CSF (25 ng/ml) were added where appropriate for 24h. 58 \pm 2.3% of CBMs vs 12.5 \pm 4.5% in PDB Ocs were apoptotic in controls. This percentage was 75.2 \pm 3.6% for CBMs in the presence of anti-Fas (400 ng/mL) vs 16.3 \pm 4.5% for PDB Ocs. In the presence of TGF β 1 (2ng/mL), apoptotic CBMs were 78.4 \pm 3.6% vs 28.9 \pm 5.6% for PDB Ocs. Finally, 25.1 \pm 5.6% of CBMs were apoptotic with M-CSF (25 ng/ml) vs 17.2 \pm 3.7% for PDB Ocs. To determine if cellular signalisation upon RANKL activation was affected, we conducted immunofluorescence studies on p62, PKC ζ and the activated form of PDK1. In non-treated cells, p62 has a cytoplasmic localisation but reaches the nuclei within 60 minutes after RANKL addition. We also observed that PKC ζ , pPDK1 were present in the nucleus of PDB Ocs prior to any stimulation. In normal human Ocs, these proteins reach the perinuclear region upon stimulation but are cytoplasmic otherwise. Together, these results strongly suggest that PDB Ocs carrying p62^{P392L} are more resistant to apoptosis and display an altered RANKL signaling compared to normal human osteoclasts. This could explain, at least in part, their functional over-activity.

A Randomised, Active-controlled, 6-month Study of Once Weekly 280 mg Oral Buffered Alendronate Solution for Treatment of Paget's Disease of Bone. M. J. Hooper¹, A. Faustino^{*2}, I. R. Reed³, D. Hosking^{*4}, N. Gilcrest^{*5}, P. Selby^{*6}, M. Wu^{*7}, G. Salzmann^{*7}, J. West^{*7}, A. Leung^{*7}. ¹University of Sydney, Sydney, Australia, ²Servimed, Lda, Lisbon, Portugal, ³Auckland Hospital, Auckland, New Zealand, ⁴Nottingham City Hospital, David Evans Medical Research Centre, Nottingham, United Kingdom, ⁵Princess Margaret Hospital, Canterbury Geriatric Medical Research Trust, Christchurch, New Zealand, ⁶Manchester Royal Infirmary, Vitamin D Research Group, Manchester, United Kingdom, ⁷Merck & Co, Merck Research Laboratories, Rahway, NJ, USA.

Although daily doses of oral bisphosphonates are a safe and effective treatment for Paget's disease of bone (PDB), some patients may experience upper gastrointestinal adverse effects (UGI AEs) or find the dosing requirements onerous and become noncompliant. A once weekly (OW) oral dose of bisphosphonate in buffered solution (OBS) may be as effective, better tolerated and more convenient than daily dosing.

During a 6-month, randomized, double-blind, active-controlled trial, we compared an alendronate (ALN) 280-mg OW OBS with an ALN 40-mg/day tablet for treating PDB. Patients were randomized (2:1) to ALN 280-mg OW OBS or ALN 40-mg/day. The primary endpoint was the mean percent decrease in total serum alkaline phosphatase (SAP) from baseline at 6-months.

At Month 6, the mean change from baseline in SAP was -71.76% with a 95% CI of (-76.77, -65.67) in the ALN 280-mg OW OBS group and -73.18% with a 95% CI of (-79.52, -64.89) in the ALN 40-mg/day tablet group. There was no significant difference between groups during the 6-month period. There was a higher incidence of clinical AEs in the ALN 280-mg OW OBS (78.6%) vs. the ALN 40-mg/day tablet group (66.7%), including drug related AEs (47.6% and 9.5%, respectively), that led to study discontinuation (19.0% and 9.5%, respectively). There was a higher incidence of laboratory AEs in the ALN 280-mg OW OBS group (16.7%) vs. the ALN 40-mg/day tablet group (4.8%), including drug related AEs.

Although ALN 280-mg OW OBS was as safe and effective as ALN 40-mg/day in reducing SAP in patients with PDB, ALN 40-mg/day tablet appears to be better tolerated than ALN 280-mg OW OBS.

Long-term Effects of Single Zoledronate or Neridronate Infusion in Paget's Disease of Bone. D. Merlotti, L. Gennari, F. Valleggi, V. De Paola, G. Martini, A. Avanzati*, R. Nuti. Internal Medicine, Endocrine-Metabolic Sciences and Biochemistry, University of Siena, Siena, Italy.

Aminobisphosphonates actually represent the most common treatment for Paget's disease of bone (PDB), with the potential for sustained remission. Intravenous regimens with different compounds demonstrated improved efficacy and compliance with respect to oral regimens. However, there have been few head to head randomized trials comparing intravenous bisphosphonates, and it is not demonstrated if these drugs differ in therapeutic efficacy. We recently performed a randomized study comparing intravenous pamidronate to zoledronate or neridronate in 90 subjects with active PDB. We report the results from the trial and the post-trial follow up of patients. At baseline patients were randomly assigned to receive either a 4 mg infusion of zoledronic acid (n=30) or a 30 mg infusion of pamidronate for 2 consecutive days every 3 months (n=60). After 6 months non-responders to pamidronate were crossed over to zoledronate (n=18) or neridronate (n=15, infusion of 100 mg for 2 consecutive days) treatment. Blood samples were collected at baseline and after 1, 3, 6, 12, 15, 18, and 24 months. No bisphosphonate was given after the cross-over, during the extension study. At 6 months, normal ALP levels were achieved in 93% of patients in zoledronate group and in 35% of patients in pamidronate group. Normalization of ALP levels was maintained in 79% and 65% of patients in the zoledronic acid group, after 12 and 24 months follow-up, respectively, while loss of therapeutic response was observed in 2/30 (6%) at 24 months. Among non-responders patients to pamidronate, 14/15 (93%) in the neridronate group and 17/18 (94%) in the zoledronate group achieved a therapeutic response after 6 months from the cross-over. Similar normalization rates were also observed between neridronate (80%) and zoledronate (83%) treated subjects at 6 months. Moreover, at 18 months from cross-over treatment (corresponding to 24 months from the baseline visit) ALP normalization was maintained in 60% and 77% of patients in neridronate or zoledronate group, respectively. In conclusion, single neridronate and zoledronate infusion produced a rapid and sustained control of bone turnover in up to 90% of PDB patients non-responders to pamidronate. This effect was largely independent of pre-treatment disease activity and prior bisphosphonate therapy.

Measles Virus Nucleoprotein (MVNP) Enhances NFATc1 Activation During Osteoclastogenesis in Paget's Disease. A. Sarmasik*, Y. Hiruma¹, S. Okumura*, J. P. Brown², J. J. Windle³, G. D. Roodman⁴, N. Kurihara¹, D. L. Galson¹. ¹Ctr for Bone Biol, Dept of Med, Univ of Pittsburgh, Pittsburgh, PA, USA, ²Laval Univ, CHUL Res Center, Quebec City, PQ, Canada, ³Human Genetics, Virginia Commonwealth Univ, Richmond, VA, USA, ⁴Univ of Pittsburgh & VA Pittsburgh Healthcare System, Pittsburgh, PA, USA.

The mechanisms responsible for the dramatically increased numbers of hypermultinucleated osteoclasts (OCL) in Paget's Disease (PD) are just beginning to be understood. To explore the role of the critical osteoclast transcription factor NFATc1 in PD, we determined if NFATc1 expression and activity were affected by measles virus nucleocapsid protein (MVNP), which is implicated in PD. Both OCL precursors from PD patients and normal human OCL precursors transduced with MVNP (MVNP-CFU-GM) are hyper-responsive to RANKL and form pagetic-like OCL in vitro. Furthermore, we have found that in the absence of added RANKL, both OCL precursors from PD patients and MVNP-CFU-GM have an increased amount (2-3 fold) of NFATc1 protein. Transient co-transfections of an NFAT-responsive CTR P3 promoter reporter and MVNP- and NFATc1-expression vectors into RAW264.7 cells reveal that MVNP (2 fold alone) and NFATc1 (50 fold alone) cooperate to activate the P3 reporter 250 fold. Additionally, RANKL treatment of RAW264.7 cells co-transfected with the P3 reporter and MVNP demonstrated that MVNP also cooperates with RANKL (2.5 fold alone) to activate this reporter 15 fold. However, MVNP expression could not help NFATc1 overcome lack of the key NFAT-binding site in the P3 reporter, suggesting that NFAT binding is required for MVNP to cooperate with NFAT to activate the P3-reporter. Comparative EMSA analysis of NFAT activation in osteoclastogenesis cultures using bone marrow monocytes (BMM) from wild-type and TRAP promoter-driven MVNP transgenic mice (MVNP-Tg) reveal that both TNF- α and RANKL induction of NFATc1 activation was increased in MVNP-expressing cells. However, CsA blocked MVNP + RANKL from generating multinucleated TRAP+ OCL, implying that MVNP effects require an intact NFAT activation pathway. A constitutively-active NFATc1 (caNFATc1) retrovirus can induce wild-type mouse BMM to differentiate into OCL in the absence of RANKL at a low level with increased differentiation in the presence of suboptimal levels of RANKL. caNFATc1 transduction into BMM from MVNP-Tg mice revealed cooperative enhancement of OCL differentiation by caNFATc1 and MVNP at no and suboptimal RANKL with more and larger OCLs formed than in the presence of either alone. These data demonstrate that NFATc1 is increased in PD and that MVNP can synergize with NFATc1 to upregulate OCL differentiation in PD. Hence, inhibition of NFATc1 activation may be a possible therapeutic target for PD patients.

Enhanced Levels of FGF-2 and SOCS Signaling Modulates RANK Ligand Expression in Patients with Paget's Disease. K. Sundaram¹, J. Senn¹, D. S. Rao², S. V. Reddy¹. ¹Children's Research Institute, Medical University of South Carolina, Charleston, SC, USA, ²Henry Ford Hospital, Detroit, MI, USA.

Paget's disease of bone (PD) is a chronic focal skeletal disorder characterized by excessive bone resorption followed by disorganized new bone formation. We previously reported measles virus nucleocapsid (MVNP) gene expression in patients with PD. MVNP expression in osteoclast lineage results in Pagetic phenotype in osteoclasts and suggested a pathophysiologic role for MVNP in PD. Enhanced levels of IL-6, M-CSF and endothelin-1 have been associated with PD, and are implicated in pathogenesis. Also, RANK ligand (RANKL), a critical osteoclastogenic factor expressed on marrow stromal/osteoblast cells is upregulated in PD. We have recently demonstrated that heat shock factor-2 (HSF-2) is a downstream target of fibroblast growth factor-2 (FGF-2) to induce RANKL expression in stromal/preosteoblast cells. In this study, we hypothesized that FGF-2 modulates suppressors of cytokine signaling (SOCS) levels to induce RANKL gene expression in PD. We found a significant increase (2.5-fold) in serum FGF-2 levels in patients (n=8) with PD compared with normal subjects (n=10). These results are consistent with previous reports that FGF-2 mRNA expression is elevated in pagetic osteoclasts and bone marrow cells. Interestingly, conditioned media obtained from MVNP transduced normal human bone marrow cells showed a significant increase (3.2 -fold) in the level of FGF-2 compared to empty vector transduced cells. Confocal microscopic analysis further demonstrated that MVNP conditioned media (20%) stimulates HSF-2 nuclear translocation in normal human bone marrow stromal/preosteoblast cells, which was blocked by a neutralizing antibody against FGF-2. We further show that FGF-2 stimulation increased SOCS-1 mRNA (5.2-fold) expression in these cells. We next examined if SOCS play a role in FGF-2 signaling to modulate RANKL gene expression in PD. Real-time PCR analysis demonstrated a significant increase in the levels of SOCS-1 (3.4-fold) and SOCS-3 (3.5-fold) mRNA expression in pagetic bone marrow mononuclear cells compared to normal subjects. In addition, co-expression of SOCS-1 with hRANKL gene promoter-luciferase reporter plasmid in marrow stromal cells demonstrated a significant increase (3.0-fold) of RANKL gene promoter activity without FGF-2 stimulation. These data suggest that enhanced levels of SOCS expression, FGF-2 signaling and cross-talk mechanisms may play an important role in modulating RANKL gene expression in PD. The identification of SOCS and FGF-2 involvement in RANKL gene expression may lead to novel therapeutic targets to control excessive bone turnover in PD.

Cardiovascular Manifestations of Primary Hyperparathyroidism. J. Fleischer, M. D. Walker, S. Homma*, T. Rundek*, W. Inabnet*, D. J. McMahon, A. Tineo*, R. Liu*, R. Sacco*, S. J. Silverberg. Columbia University, New York, NY, USA.

Severe primary hyperparathyroidism (PHPT) is associated with cardiovascular (CV) calcification and increased CV mortality. We initiated this prospective observational study of patients who meet NIH surgical criteria and undergo surgery (PTX) to determine whether the mild, frequently asymptomatic PHPT seen today still poses a risk to the CV system, and whether identified abnormalities are reversible. Patients are evaluated pre-PTX and for 2-yr post-PTX. Baseline data on the first 29 patients (72% female; age \pm SD 61 \pm 7 yrs, range: 48-75) and 1 yr post-PTX data (n=5) are available. Baseline serum calcium was 10.5 \pm 0.6 mg/dl and PTH 121 \pm 50 pg/ml. Blood pressure was 121 \pm 15/ 75 \pm 11 mm Hg. Structural changes typical of classical PHPT were uncommon: 5 had valvular calcifications and 4 had increased left ventricular (LV) mass. LV function and wall motion were normal in all. Carotid ultrasound showed plaque in 11 (38%). Carotid intima-medial thickness (IMT), a subclinical marker of atherosclerosis was 0.98 \pm .10 mm in the 75th (\pm 12) percentile of an age/sex/race matched control population. While structural abnormalities were uncommon, functional tests of the heart (diastolic function by mitral pulse wave velocity, deceleration time, tissue doppler E velocity), peripheral vasculature (endothelial function by brachial artery flow-mediated dilation, FMD) and carotid (distensibility [Table]) were revealing. Carotid stiffness and FMD were abnormal. In this small group, FMD improved (4.8 \pm 4.9 to 8.5 \pm 11.7, p=0.08) after PTX. Although mean values for other measures of CV function were normal, 27/29 (93%) had at least one test and 16/29 (55%) had 2 or more tests outside the normal range.

Functional CV Tests			
Functional CV Test	Mean \pm SD	Normal Range	# Abnormal
Mitral Pulse Wave E/A	1.1 \pm .44	.75-1.5	10 (34%)
Deceleration Time (msec)	157.3 \pm 26	>140	8 (28%)
Tissue Doppler E Velocity (cm/sec)	12.3 \pm 3	<15	7 (24%)
FMD (%)	4.8 \pm 3.7	6-10%	19 (66%)
Carotid STRAIN (%)	9.2 \pm 2.9	6-12%	4 (14%)
Carotid STIFFNESS	6.7 \pm 3.4	< 6	14 (48%)

Higher PTH levels were associated with decreased vascular compliance (carotid stiffness: R = 0.37, p=.07; and strain R = -0.61, p=.0009), while serum calcium levels did not predict any CV measures.

In summary, these patients with mild PHPT had abnormal endothelial function and increased carotid stiffness, both of which are risk factors for CV events. Vascular compliance was lowest in those with highest PTH levels. Although the structural CV hallmarks of severe PHPT were not commonly seen, 93% of patients with mild disease had one or more functional CV abnormalities, some of which may improve with PTX. Confirmation and extension of these findings could alter the guidelines for management of PHPT.

Vitamin D Status Is Inversely Associated with Blood Pressure: Results from the Third National Health and Nutrition Examination Survey. S. E. Judd¹, H. M. Blanck^{*2}, M. S. Nanes³, T. R. Ziegler^{*3}, P. W. F. Wilson^{*3}, V. Tangpricha³. ¹Graduate Division of Biological and Biomedical Sciences, Emory University, Atlanta, GA, USA, ²Division of Nutrition and Physical Activity, Centers for Disease Control and Prevention, Atlanta, GA, USA, ³School of Medicine, Emory University, Atlanta, GA, USA.

The prevalence of both hypertension and vitamin D insufficiency are high in the United States. Recent clinical trials and animal studies have suggested that vitamin D insufficiency may be associated with elevated blood pressure. Using cross-sectional data, we sought to determine whether 25(OH)D levels were related to systolic blood pressure in the National Health and Examination Survey (NHANES) III (1988-1994). We excluded individuals currently taking anti-hypertensive medications to minimize the confounding of blood pressure treatment. This study was conducted in adult blacks and whites with available serum 25(OH)D determinations (N=7699). Blood pressure was classified using the 5 categories from the Joint National Committee 7 with a sixth category added to distinguish normotensives (<110 mmHg) from those with high-normal blood pressure (110-119 mmHg). We used predicted marginals to estimate the conditional means of serum 25 hydroxy vitamin D [25(OH)D] and to test for trend across blood pressure categories. Lower 25(OH)D concentrations were significantly associated with a higher blood pressure category in whites (p<0.001). This trend held upon stratification by age, gender, and BMI except in persons <50 years old. Such an association was not seen in black individuals; however, 92% were vitamin D insufficient, thus limiting the range of values with which to detect an association. Vitamin D insufficiency is associated with higher blood pressure in U.S. whites. Such an association was not seen in U.S. blacks given a higher prevalence of vitamin D insufficiency in this population. These data suggest the need for greater testing, detection and treatment of vitamin D insufficiency in U.S. adults for potential cardiovascular benefits. Further, these data suggest a strong interaction between vitamin D and hypertension suggesting that vitamin D repletion may be beneficial in lowering blood pressure.

Molecular Analysis of Histologically Atypical Parathyroid Adenomas: Incipient Malignancies or Fundamentally Benign? K. B. Lauter¹, L. J. Krebs^{*1}, M. R. Rubin², G. G. Fernandez-Ranvier^{*3}, O. H. Clark^{*3}, S. J. Silverberg², A. Arnold¹. ¹University of Connecticut School of Medicine, Farmington, CT, USA, ²Columbia University College of P&S, New York, NY, USA, ³UCSF/Mt.Zion Medical Center, San Francisco, CA, USA.

Whether atypical parathyroid adenomas represent an early stage of parathyroid carcinoma or are fundamentally benign neoplasms is unknown. Atypical parathyroid adenomas possess histological features commonly found in parathyroid cancer (e.g. fibrous bands, mitoses), but lack the definitive diagnostic criteria of distant metastases or invasion of surrounding structures. Mutations of the HRPT2 tumor suppressor gene, encoding parafibromin, are common in clear-cut parathyroid carcinomas and are rare in typical benign parathyroid adenomas. Thus, analysis of non-familial atypical adenomas for HRPT2 mutations could provide insight into their nature and malignant potential.

We examined 13 sporadic atypical adenomas for HRPT2 mutations by direct sequencing of the full 17-exon coding region and splice sites, and for parafibromin expression by immunohistochemistry using antibody 2H1 (Santa Cruz). We found no HRPT2 mutations in any of the 10 fully sequenced atypical adenomas, in striking contrast to the >75% prevalence of inactivating HRPT2 mutations previously detected in definite parathyroid malignancies using identical methodology. Moreover, parafibromin staining was performed in 12/13 atypical adenomas and was strongly or largely positive as quantified with ImageJ software in all 12. This pattern was similar to the positive staining in 21 typical parathyroid adenoma controls and markedly contrasted with the reduced parafibromin staining we observed in three metastatic/invasive parathyroid carcinoma controls.

The absence of detectable HRPT2 inactivating mutations, supported by parafibromin expression patterns, strongly suggests that most non-familial atypical adenomas are fundamentally different from parathyroid carcinomas and, despite their suspicious histologic features, may not share the latter's malignant potential. Our results imply a biological validity for using stringent criteria in defining parathyroid cancer, and suggest caution when considering post-surgical adjuvant therapies for patients with atypical tumors. Our findings also raise the possibility that HRPT2 inactivation might be crucial for conferring the capacity to invade surrounding tissues or to metastasize, whereas histologic features like fibrous bands and mitoses may occur in the absence of HRPT2 inactivation. In summary, disparate patterns of HRPT2/parafibromin status suggest a fundamental difference between atypical sporadic parathyroid adenomas and carcinomas.

Intravenous Administration of Pamidronate Decreases Serum Levels of FGF23 Rapidly in Patients with Osteogenesis Imperfecta. T. Kitaoka¹, N. Namba¹, K. Miura^{*1}, T. Kubota¹, H. Hirai^{*1}, S. Nakajima¹, T. Yamamoto², K. Ozono¹. ¹Department of Pediatrics, Osaka University Graduate School of Medicine, Suita, Osaka, Japan, ²Department of Pediatrics, Minoh City Hospital, Minoh, Osaka, Japan.

Background: Fibroblast growth factor 23 (FGF23) is a recently discovered phosphate (P)-regulating factor responsible for several disorders associated with hypophosphatemia. FGF23 decreases renal P reabsorption by down-regulating sodium P cotransporter type IIa and 25-hydroxyvitamin D-1-alpha-hydroxylase. However, the details of FGF23 regulation and action remain unclear. In this study, we examined the change of FGF23, P, calcium (Ca) and Ca-regulating hormones during the treatment of pamidronate for patients with osteogenesis imperfecta (OI). Subjects & Methods: Six patients with OI (1.4 to 12.1 year old) were included in the study. All patients were treated cyclically with pamidronate for 3 consecutive days, according to the protocol reported by Rauch et al (J Clin Invest 2002). No other medications were taken during intravenous administration. Blood samples were collected at pre- and post-drip infusion of pamidronate at the first and second cycle of treatment. We evaluated the time-course of serum Ca, P, intact PTH (iPTH), 1,25-dihydroxyvitamin D (1,25(OH)₂D) and intact FGF23 (iFGF23) (ELISA, Kainos Laboratories, inc.) values on each cycle. Written informed consent was obtained from the parents. Results: During the first cycle of treatment, serum Ca levels decreased significantly from day 2 post-infusion (-0.84 mg/dl, p<0.05), and serum P levels also decreased from day 1 post-infusion (-0.77 mg/dl, p<0.05). Both iPTH and 1,25(OH)₂D levels increased significantly from day 3 pre-infusion (+140.2 pg/ml and +31.0pg/ml, respectively). In contrast, serum iFGF23 levels decreased from day 2 pre-infusion (-6.75 pg/ml, p<0.05). During the second cycle, iFGF23 declined from the day 1 post-infusion, while serum Ca and P decreased significantly from day 3 pre- and day 1 post-infusion, respectively. Discussion: The reduction in serum Ca and P levels following pamidronate infusion was associated with the inhibition of bone resorption. Interestingly, FGF23 decreased rapidly after pamidronate infusion. It is feasible that the hypophosphatemia attenuated the levels of FGF23. However, it is also possible that pamidronate may directly suppress FGF23 secretion as well as bone resorption, since the decrease in FGF23 at times preceded hypophosphatemia.

A Severe Hypertension: A Possible Complication of McCune-Albright Syndrome. Y. Ohata^{*1}, T. Yamamoto¹, T. Michigami², K. Satomura^{*3}, S. Ida^{*3}, K. Ozono⁴. ¹Pediatrics, Minoh City Hospital, Minoh, Japan, ²Bone and Mineral Research, Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Japan, ³Pediatrics, Osaka Medical Center and Research Institute for Maternal and Child Health, Izumi, Japan, ⁴Pediatrics, Osaka University Graduate School of Medicine, Suita, Japan.

We describe a female case of McCune-Albright syndrome (MAS) complicated by severe hypertension. She had a previous history of Cushing syndrome and was undertaken surgical removal of bilateral adrenal glands when she was 10 months old. An activating mutation of the Gsα protein (Arg 201 to His) was proved in the stored frozen adrenal tissues. We first observed severe hypertension with the systolic blood pressure of 240 mmHg when she was 9 years old. Laboratory investigation revealed that the levels of serum calcium and phosphate were low (8.5 mg/dl, and 2.9 mg/dl, respectively), and serum alkaline phosphatase was extremely high (8720 U/l). Then, urinary excretion levels of norepinephrine and dopamine were extremely increased by 10 and 4 folds compared to the average levels of the age matched controls respectively. Meta-iodobenzylguanidine (MIBG) scintigraphy proved neither pheochromocytoma nor the residual adrenal glands. Iatrogenic hypertension by the supplemental mineral corticoid was implausible because of the normal plasma rennin activity. Hypertension was ameliorated gradually by the combination therapy of several antihypertensive medications including an angiotensin receptor blocker, a calcium blocker, an alpha blocker and diuretics. Since the Gsα protein regulates the norepinephrine synthesis in the sympathetic nodes, it is plausible that an activating mutation of the Gsα protein in MAS complicated by a Cushing syndrome is associated with the cause of hypertension due to the overproduction of norepinephrine, because both of the sympathetic nodes and the adrenal glands in medulla have the similar origins in the process of embryological development. Also this rare case suggested the possible role of Gsα genes in the primary hypertension.

Acro-osteolysis and Calcinosis - Possible Role of the Sympathetic Nervous System (SNS) in Pathogenesis and Treatment with Beta-blockers. M. Patel¹, C. Senger², P. Malleson², S. Ichikawa³, M. J. Econs³, K. Mulpuri². ¹Medical Genetics, University of British Columbia, Vancouver, BC, Canada, ²University of British Columbia, Vancouver, BC, Canada, ³Indiana University, Indianapolis, IN, USA.

A 9 year old healthy girl presented with a 1.5 year history of idiopathic, progressive distal acro-osteolysis of all toes. Dystrophic calcification of adjacent soft tissues caused swelling and pain with periodic rupture of a whitish chalky substance through the dorsal skin of the toes. These findings were associated with slightly tight distal phalangeal skin and distal erythema of the fingers and toes. No systemic abnormalities of bone or mineral ion homeostasis were present, no serologic or histologic findings consistent with rheumatologic disease were present and sequencing of the GALNT3 and FGF23 genes did not reveal mutations in the coding regions or at the intron-exon boundaries. Surgical decompression of one toe demonstrated homogeneous calcification surrounded by reactive macrophages. Analysis of a remnant distal phalanx demonstrated abundant periosteal osteoclasts and absence of osteoblasts. As the cellular findings in bone were consistent with hyperactivation of the SNS, the patient was started on 1.5 mg/kg/day propranolol. This was increased every 2 weeks until beta-blockade occurred, confirmed by an absence of exercise-induced tachycardia, at a final dose of 9 mg/kg/day. Treatment for one year was associated with regression of nascent calcification, arrest of osteolysis and partial regrowth of actively resorbing distal phalanges. The biopsied phalanx re-grew and showed no recurrence of acro-osteolysis on treatment.

Low Total and Bioavailable Testosterone Does Not Play a Role in Renal Bone Disease in Men on Hemodialysis. U. Gruntmanis¹, C. V. Odvina², K. Sakhaee², J. E. Zerwekh². ¹Department of Medicine, Division of Endocrinology, UT Southwestern Medical Center and Dallas Veterans Affairs Medical Center, Dallas, TX, USA, ²Center for Mineral Metabolism and Clinical Research, UT Southwestern Medical Center, Dallas, TX, USA.

In previous studies as many as 60% of men on hemodialysis (HD) are found to be hypogonadal. Yet role of low testosterone in complex pathogenesis of renal bone disease has not been defined. In this cross-sectional study our primary goal was to determine if men on HD with low total testosterone (testosterone below 300 ng/dl) have lower BMD than eugonadal men. Second goal was to find out if there is a difference between serum bone formation and resorption markers (bone specific alkaline phosphatase (BSAP), osteocalcin (OC), type 5b tartrate-resistant acid phosphatase (TRAP5b)) between hypogonadal and eugonadal men on HD. Only BSAP and TRAP5b are not dialyzable and therefore are good markers of bone turnover for this population. We analyzed data on 83 men, 52 African Americans, 20 Hispanic, 9 Caucasians and one Indian American. 50 and 33 men were eugonadal and hypogonadal, respectively. Mean age 52.8±8.2, weight 187.6±40.8 lbs, HD length 30.8±26.1 month and was not different between hypogonadal and eugonadal groups.

Results: BMD at lumbar spine (LS), femoral neck (FN), total hip (TH), distal forearm (DF) and BSAP, TRAP5b, OC levels were not different between hypogonadal and eugonadal groups. 43.8% and 82.1% of men were found to be vitamin D deficient (25-D <20ng/ml) or insufficient (25-D<30ng/ml), yet low 25 hydroxy vitamin D (25-D) level did not correlate with intact PTH, BMD at LS, FN, TH, DF and BSAP, TRAP5b, OC levels in our study.

Length of HD did not correlate with weight, total testosterone, bioavailable testosterone, estradiol, 25-D, BMD or bone turnover markers. Weight had very strong positive correlation for BMD at LS (p=0.01), FN (p<0.0001), TH (p<0.0001) and DF (p=0.068) but negative correlation for BSAP (p<0.009), TRAP5b (p<0.03), OC (p=0.4). Intact PTH (i-PTH), had positive correlation with BSAP (p=0.001), OC (p<0.0001), TRAP5b (p=0.08). BSAP as expected, had negative correlation with BMD at TN (p=0.02), DF (p=0.05), but no correlation at FN (p=0.08), LS (p=0.3). TRAP5b also had negative correlation with BMD at FN and TN (p=0.04) but no correlation at DF (p=0.49) and LS (p=0.07).

Conclusions: Total testosterone level does not appear to play significant role in renal bone disease in our study population. We postulate that men on HD who are heavier have lower bone formation and resorption and as a result have higher BMD. This observation did not change after results were adjusted for total testosterone, bioavailable testosterone, estradiol, i-PTH, 1,25-D and 25-D levels.

Administration of Pravastatin Inhibits Suppressed Osteoblast Dysfunction and Bone Turnover in Uremic Rats. Y. Iwasaki^{*1}, H. Yamato², M. Fukagawa³. ¹Health Sciences, Oita University of Nursing and Health Sciences, Oita, Japan, ²Development, Kureha Special Laboratory Co, Ltd., Fukushima, Japan, ³Nephrology & Dialysis center, Kobe University School of Medicine, Kobe, Japan.

HMG-CoA reductase inhibitors (statins) are widely used for treatment of hypercholesterolemia. Recent studies reveal that statins stimulate bone formation and suppress bone resorption. To evaluate the effect of pravastatin, which is a major statin, on bone formation in low-turnover bone disease with renal failure, we demonstrated bone histomorphometry on our model rats which have low turnover bone. Male SD rats underwent thyroparathyroidectomy (TPTx). The TPTx rats underwent 5/6 nephrectomy (Nx) or sham operations. These rats were continuously infused with rat PTH and injected with L-thyroxine subcutaneously to maintain physiological levels. TPTx-Nx rats simulate adynamic bone disease which is a major type of renal osteodystrophy in chronic dialysis patients. Six weeks after the second Nx, TPTx-Nx rats were assigned to receive pravastatin (Daiichi-Sankyo, Co, Ltd., Japan) at a dosage of 3 or 30 mg/kg body weight per day or vehicle in the diet. By bone histomorphometry, bone formation rate in the TPTx-Nx with vehicle group was reduced to 8% of the TPTx-Sham group. The reduction of bone turnover was ameliorated by pravastatin administration in a dose dependent manner. In the high dose group, the level of osteoblast surface recovered was up to 40% of the TPTx-Sham group. The Serum biochemical parameters, including lipid metabolic parameters, did not change among all the groups. Gene expression of organic anion transporter (OAT)-3, which mediates cellular uptake of pravastatin, was expressed in rat tibiae. In vitro study, we also determined the effect of co-culturing with pravastatin and indoxyl sulfate (IS), which is one of the uremic toxins, on cultured primary osteoblasts. It is known that IS is taken up via OAT-3 and increases free radical production and suppresses cell viability. Free radical production induced by the addition of IS was decreased in the presence of pravastatin in primary cultured osteoblasts. Suppressed osteoblasts cell viability ameliorated in a dose dependent manner. OAT-3 mRNA was expressed in cultured osteoblast. These results suggest that pravastatin ameliorates bone turnover, induced at least in part by suppressed intracellular free radical production and improve osteoblast function.

Tartrate-Resistant Acid Phosphatase Isoforms in End-Stage Renal Disease. A. Jancikla¹, B. Price^{*2}, E. Lederer², L. Yam^{*1}. ¹Medicine, VA Medical Center, Louisville, KY, USA, ²Medicine, University of Louisville, Louisville, KY, USA.

End-stage renal disease (ESRD) is often complicated by chronic inflammation and osteodystrophy. Tartrate-resistant acid phosphatase (TRACP) isoforms 5a and 5b may be suitable serum markers to gauge inflammation and bone resorption respectively.

Methods: Serum was collected from 73 patients (38 male, 35 female) with ESRD just prior to hemodialysis. The mean age was 56±16 years and the mean time on dialysis was 6±5 years. A control group consisted of 36 healthy adults (8 male, 28 female) aged 43±11 years. TRACP 5a and 5b isoforms were estimated by in-house immunoassays. C-reactive protein was estimated by an in-house, high-sensitivity assay using commercially available antibodies and standards. Commercial kits were used to estimate other inflammation and bone markers including fetuin-A, bone-specific alkaline phosphatase (bALP) and cross-linked N-telopeptides of type-I collagen (NTx). Intact parathyroid hormone (iPTH) levels were determined by radioimmunoassay. Bone mineral density (DEXA of calcaneus) was determined at the time of study.

Results: Mean levels of all serum markers were significantly elevated in ESRD except fetuin-A, which was significantly lower than control. Absolute BMD (g/cm²) was no different than control, but the mean T-score was significantly lower in ESRD. TRACP 5a protein correlated with CRP but not fetuin-A or any other bone marker. CRP and fetuin-A were inversely correlated. TRACP 5b correlated positively with all bone markers and inversely with BMD, but not with any inflammation marker. Neither iPTH nor NTx were significantly associated with BMD.

Conclusion: These preliminary data suggest that TRACP isoforms 5a and 5b may be useful markers to estimate the degree of inflammation and bone resorption respectively in ESRD patients on chronic hemodialysis.

Disclosures: A. Jancikla, None.

Albuminuria Predicts Bone Loss in Older Adults: The Rancho Bernardo Study. S. K. Jassal^{*1}, D. von Muhlen², E. Barrett-Connor². ¹Medicine, UCSD & VASDHS, San Diego, CA, USA, ²Family and Preventive Medicine, UCSD, San Diego, CA, USA.

Purpose: There is interest in the association between kidney function and bone health, but prior studies have focused on estimates of creatinine clearance or glomerular filtration rate as predictors. We investigate the cross-sectional and longitudinal association between albuminuria and bone mineral density (BMD), bone loss, and osteoporotic fracture in older community-dwelling adults.

Methods: A cross-sectional and prospective study from the Rancho Bernardo Study. Between 1992 and 1995, 1713 participants (average age 71.3 +/- 11.1 years) completed standardized questionnaires, physical examinations, laboratory testing and bone densitometry; 1023 participants returned for a follow-up visit in 1997-1999, an average of 4.1 (+/-0.9) years later.

Results: Using previously established sex-specific cut-offs, albuminuria (urine albumin/creatinine ratio (ACR) $\geq 17\text{mg/g}$ in men and $\geq 25\text{mg/g}$ in women) was present in 148 men (22%) and 143 women (13.8%) at baseline. In cross-sectional analyses, there was a significant linear association between log transformed ACR (log ACR) and hip BMD in men (Beta (SE) = -0.021 (0.010), $p = 0.034$) and women (Beta (SE) = -0.053 (0.008), $p < 0.001$). These associations were no longer significant after adjusting for age and body mass index (BMI). In prospective analyses, there was an average annual bone loss at the hip of 0.6%. There was a significant association between baseline log ACR and four-year bone loss in men (Beta (SE) = -0.237 (0.089), $p = 0.008$) and women (Beta (SE) = -0.332 (0.0110), $p = 0.003$). These associations persisted after adjusting for age and BMI in both men (Beta (SE) = -0.212 (0.010), $p = 0.018$) and women (Beta (SE) = -0.254 (0.014) $p = 0.026$). At baseline, 180 of 1713 participants (11%) reported at least one clinical fracture of the hip, femur, forearm or wrist; 79 (8%) reported at least one new clinical fractures during follow-up. Log ACR was associated with prevalent clinical fractures in women OR (95% CI) = 1.67 (1.19-2.35), but this did not persist after adjusting for age and BMI. Log ACR was not significantly associated with incident clinical fractures.

Conclusions: ACR was not independently associated with hip BMD in cross-sectional analyses. Baseline ACR, however, predicted four-year bone loss at the hip in both sexes independent of age and BMI. Baseline ACR was associated with prevalent but not with incident clinical fracture, perhaps reflecting the multifactorial etiology of fractures beyond BMD.

Osteopenia and Lipodystrophy in HIV-infected Patients. S. Azriel^{*1}, R. Rubio^{*2}, H. Requejo^{*1}, S. Guadaliu^{*1}, E. Jódar¹, G. Martínez¹, F. Hawkins¹. ¹Endocrinology Service, University Hospital 12 de Octubre, Madrid, Spain, ²HIV Unit, University Hospital 12 de Octubre, Madrid, Spain.

Reduced bone mineral density (BMD) and abnormalities in fat redistribution, glucose homeostasis and lipid metabolism are prevalent among HIV-infected patients on highly active antiretroviral therapy (HAART). The relationship between BMD and changes in regional and whole body composition is unclear.

Patients and methods: This was a prospective cohort study. One hundred HIV-infected caucasian outpatients were recruited during a period of 24 months and were studied over 2 years of follow-up. Exclusion criteria were any condition that could cause loss of BMD and use of medications that interfere with mineral metabolism in the past 6 months. 68% of the patients were males, mean age of the cohort was 40 years (SD: 9), mean BMI was 24 kg/m² (SD: 3.6), 95% had undetectable virus load. 77% were taking a HAART regimen (65% included a protease inhibitor), 18% bitherapy (2 nucleoside reverse-transcriptase inhibitors) and 5% were ART-naïve. BMD (lumbar spine, femoral neck, total hip and radius) and body composition (total body fat mass, percent total fat, trunk fat mass, percent trunk fat, lean mass) were assessed by DXA Hologic QDR 4500. Osteopenia/osteoporosis (op/OP) was defined according to WHO criteria. Lipodystrophy was classified according to clinical criteria (patient's self report and physician's evaluation).

Results: The prevalence of op (at any site) in the cohort was 63.6% and 13.1% of OP. Alterations in body fat distribution were described in 38% of the patients: 35% lipoatrophy, 16% lipohypertrophy and 13% mixed anomalies. In the univariate statistical analysis, patients with low lumbar spine BMD (< -1 SD T-score) showed lower total (kg) and % body fat mass ($p = 0.06$ and $p = 0.049$, respectively), and trunk fat mass (kg, %; $p = 0.039$ and $p = 0.047$). Patients with low femoral BMD (at the femoral neck and total hip) also had lower total body fat mass ($p = 0.013$ and $p = 0.003$, respectively). There was no independent association between op/OP and type or duration antiretroviral therapy and lipodystrophy at any site. In the multivariate logistic regression analysis, the total body fat mass was a protective factor for bone loss at lumbar spine [OR: 0.89, 95% CI: 0.82-0.96, $p = 0.003$, for each additional kg]. No significant changes in BMD and in body composition were found after 2 years of follow-up.

Summary: Prevalence of op in HIV-infected patients is high, irrespective of the antiretroviral therapy. Lumbar op is associated with low total body fat mass. Op does not progress after 24 months.

Anti-TNF Treatment in Rheumatoid Arthritis Patients Does Not Alter the 1-Year Change in Spine and Hip Bone Mineral Density Compared to Control Patients. P. Boyesen^{*1}, E. Haavardsholm^{*1}, G. Haugeberg^{*2}, T. Kvien¹. ¹Dept of Rheumatology, Diakonhjemmet sykehus, Oslo, Norway, ²Dept of Rheumatology, Sørlandet hospital, Kristiansand, Norway.

An increased bone loss is observed in rheumatoid arthritis (RA) patients. Observational uncontrolled studies have suggested that anti-TNF treatment counteract this loss. The aim of this study was to compare one-year change in hip and spine bone mineral density (BMD) between RA patients receiving anti-TNF treatment and historical RA controls.

Twenty-nine RA patients with clinically active disease starting with anti-TNF treatment were included in the intervention group and 253 RA patients were identified as controls from the Oslo RA register. The controls were matched on a group level for disease duration and age. The BMD of hip and spine was measured by dual energy x-ray absorptiometry (DXA) on the same Lunar Expert machine. The anti-TNF group was examined at baseline and 12 months, the controls were assessed in 1996 and 1998 as part of an epidemiologic study.

Mean (SD) age was 52 (6.2) and 55 (6.2) years in the anti-TNF group and control group respectively, disease duration 10 (6.2) and 10 (6.2) years, 82% and 83% were females, 90% and 49% were rheumatoid factor (RF) positive, mean (SD) disease activity score (DAS-28) was 5.3 (1.3) and 4.7 (1.1), Modified Health Assessment Questionnaire (MHAQ) score 1.7 (0.5) and 1.6 (0.4), ESR 31.8 (19.6) and 21.4 (15.8) mm/hr and 28-swollen joint count 9.8 (5.6) and 8.4 (6.0). The only group differences were RF ($p < 0.001$), ESR ($p = 0.02$) and DAS-28 ($p = 0.01$) (Chi square, t-test). 45% and 42% used disease modifying anti-rheumatic drugs, 14% and 22% estrogens and/or bisphosphonates, 52% and 45% were currently using corticosteroids in the anti-TNF group and control group respectively (Chi square test).

At inclusion 55% and 39% were osteopenic, 3% and 13% osteoporotic in the anti-TNF group and the control group respectively. Annual BMD change was computed. BMD of spine and hip were similar between the groups at baseline (t-test). The one-year change was not statistically significant different between the groups. The mean (SD) change in total hip BMD was -0.9% (3.3) and -0.2% (2.6) ($p = 0.17$) and the spine BMD (L1-L4) -1.0% (5.1) and -0.2% (2.8) ($p = 0.17$) for the anti-TNF group and control group respectively. The hip BMD results remained unchanged when correcting for sex, RF, corticosteroids, bisphosphonates, DAS-28 and MHAQ (regression analysis). The adjusted change in BMD at the spine showed an association between increased loss in BMD and anti-TNF treatment ($p = 0.047$).

In conclusion the one-year bone loss of the hip and spine was similar in RA patients treated with anti-TNF and historical RA controls. This finding may suggest that the mechanisms of bone loss in established RA are not halted by TNF blockade.

Small Molecule Inducer of Activated CD4+ T Cell Death Inhibits Disease Progression in Collagen-induced Arthritis Models. J. Han^{*1}, H. Sung^{*1}, J. Park^{*1}, S. Lim^{*2}, S. Lee^{*2}, S. Cho^{*3}, H. Kim^{*3}, S. Shim^{*2}, S. Kim¹, S. Ko⁴, S. Chang^{*1}, J. Kim^{*1}. ¹Pharmacology, OSCOTEC Inc., Cheonan, Republic of Korea, ²Medicinal Chemistry, OSCOTEC Inc., Cheonan, Republic of Korea, ³Pharmacokinetics, OSCOTEC Inc., Cheonan, Republic of Korea, ⁴Oral Biochemistry, Dankook University, Cheonan, Republic of Korea.

Rheumatoid arthritis (RA) is a chronic, systemic, inflammatory autoimmune disorder that affects 1% of the adult population worldwide. RA is characterized by the inflammation of synovial joints infiltrated by CD4+ T cells, macrophages, and plasma cells that play major roles in the pathogenesis of the disease. CD4+ T cells responding to an unknown antigen activate macrophages to produce pro-inflammatory cytokines. Therefore, selective elimination of activated CD4+ T cells, but not naive cells, may slow down disease progression with minimum toxicity. To identify small molecules that selectively induce activated CD4+ T cell death, high-throughput screening (HTS) was conducted on 5,680 compounds. From the Hit compound identified from HTS, we generated lead compound (TCK-O-1). TCK-O-1 was found to induce activated T cell death in a dose-dependent manner. The cytotoxic effects of TCK-O-1 to naïve splenocytes were observed only at high concentrations ($> 10\mu\text{M}$), while selective killing effects on activated CD4+ T cells (up to 60 percent) were observed at low concentrations ($< 3\mu\text{M}$). In addition, TCK-O-1 did not show cytotoxic effect on other immune effector cell lines. To examine the effect of TCK-O-1 on disease progression in RA, time course studies were conducted in collagen induced arthritic (CIA) mice. TCK-O-1 was orally (40mg/kg) or subcutaneously (10mg/kg) administered to CIA mice, once a day for 21 days. Administration of TCK-O-1 significantly suppressed the arthritic index and inhibited the activated CD4+ T cell ratio in peripheral blood mononuclear cells (PBMC), but not other immune cells. Therefore, administration of TCK lead compound effectively inhibited disease progression with minimum toxicity. These results suggest that small molecule inducer of activated CD4+ T cell death may be used for the treatment of rheumatoid arthritis. TCK-O-1 is under development as candidate molecules in search for new anti-rheumatoid arthritis drugs.

Can We Predict Structural Damage Progression at 2 Years in Very Early Arthritis? Value of Bone and Cartilage Markers in the Conservatively Treated Community-based Inceptive VERA Cohort. A. Daragon¹, M. Brazier^{*2}, C. Fèvre^{*1}, R. Daveau^{*3}, O. Mejjad^{*1}, P. Boumier^{*4}, A. Gayet^{*5}, F. Tron^{*3}, C. Zarnitsky^{*6}, O. Vittecoq^{*7}, X. Le Loët^{*7}. ¹Rheumatology, CHU - Hôpitaux de Rouen, Rouen, France, ²Rheumatology, CHU, Amiens, France, ³Immunology Laboratory, Inserm U 519, Rouen, France, ⁴College of Rheumatology Picardie, Amiens, France, ⁵College of Rheumatology Haute Normandie, Rouen, France, ⁶Rheumatology, Groupe Hospitalier, le Havre, France, ⁷Rheumatology, CHU - Hôpitaux de Rouen, Inserm U 519, Rouen, France.

Objective: identification of bone and cartilage markers to predict structural damage progression at 2 years in patients with very early arthritis.

Methods: community -based-recruitment (media campaigns) of 310 adults (mean age: 51.8 years ; 68% females) with swelling of 2 or more joints persisting more than 4 weeks, evolving for less than six months (mean: 4.2 months), DMARD and steroids naïve. Then, they were conservatively treated for 2 years. Assessment was made at entry and comprised clinical data (global pain, Ritchie index and swollen joints / 44), CRP, ESR, auto antibodies rheumatoid factors (RF) by agglutination tests and IgM, IgA, IgG, isotypes by Elisa, anti-CCP II, serum pyridinoline (PYD) deoxypyridinoline (DPD), CTX I, Cartilage Oligomeric Matrix Protéin (COMP), osteoprotegerin (OPG) and RANKL. All patients with ACR RA criteria or undifferentiated arthritis were followed except those classified as having defined rheumatism (DR). Criterion of judgment was structural damage progression of erosion with an increase of at least 1 unit at 2 years (measurement was done according to vdH modified erosion Sharp score by two readers).

Results: At 2 years, 213 patients were assessed (29 refused, 1 lost to follow-up; 1 death, 61 classified as DR, 5 with X ray failure): 42 (19.7%) had erosion progression. With univariate analysis, there was a relationship between erosion progression and COMP (p = 0.017), VS (p = 0.003), IgG and IgA (p = 0.007 and 0.005), and anti-CCP II (p < 10⁻⁴). But OPG, CTX I, PYD, DPD, and CRP were not associated with erosion progression. With principal components analysis 75 % patients are correctly classified as progressive or not progressive with these five markers. COMP give a better sensibility (61.5 %) than other markers (52 %). Results of RANKL will be presented.

CONCLUSION: In patients with very early arthritis, conservatively treated, COMP, anti-CCP II, IgA RF, IgG RF, and ESR, are useful to identify patients who will have structural damage progression at 2 years. This population could be a good target for early aggressive treatment.

Material Properties of Osteoporotic Ewes. E. F. Calton^{*1}, J. MacLeay^{*2}, A. Boskey¹. ¹Hospital for Special Surgery, New York, NY, USA, ²Colorado State University, Fort Collins, CO, USA.

The purpose of this study was to establish baseline material properties for osteoporotic cancellous bone from ovine iliac crest biopsies. Skeletally mature (4-7 yo; 169±29 lb) Rambouillet-Columbia cross-ewes (n=18) were administered a diet to induce metabolic acidosis (MA) and create bone loss similar to that seen in human osteoporosis [MacLeay et al. 2004 J Bone Miner Metab 22:561-8]. Bone densitometry (DXA) measurement of the 4 most caudal vertebrae lumbar spine was performed using a Hologic Delphi QDR dual-energy x-ray absorptiometer (Hologic). Transiliac crest biopsies (8mm dia.) were removed and placed in ethanol. Micro-CT data were collected on the cortical and cancellous regions separately for volumetric bone mineral density measurements. Biopsies were bisected axially with a low-speed saw; half was saved for embedding and histological sectioning and half was prepared for infrared (IR), x-ray diffraction (XRD), and chemical analysis of Ca and PO₄. On the latter half, the cortical ends were removed with the low speed saw. Cancellous bone was defatted using a 1:1 mixture of Chloroform and Methanol and lyophilized 16 hours. The dried and defatted cancellous bone was pulverized using a Spex Mill CertiPrep Freezer/Mill. The XRD line width of the c-axis 002 peak was measured using Cu K α radiation (Bruker AX-8 powder diffractometer, Bruker). FTIR absorbance spectra were collected at 4 cm⁻¹ on pulverized bone formed in KBr pellets (1 wt%). Spectra were baseline corrected and integrated areas were taken for three spectral regions: matrix amide I (1595-1720 cm⁻¹), mineral phosphate v1, v3 (900-1200 cm⁻¹), and carbonate v2 (855-890 cm⁻¹), and area ratios (mineral:matrix and carbonate:phosphate) were calculated. Peak height ratios 1030:1020 cm⁻¹ and 1660:1690 cm⁻¹ were calculated as a measure of crystallinity and collagen cross-linking (maturity), respectively [Paschalis et al. 2001 JBMR 16:1821-8]. Acid hydrolyzed samples were used for phosphate concentration determined by colorimetric assay and for Ca concentration measured by atomic absorption (Perkin Elmer Analyst 100). The values obtained from these measurement methods provide baseline values for cancellous bone from sheep iliac crest biopsies. These values are being used to assess the efficacy of therapeutic interventions on sheep with reduced bone mass and may be useful in determining similar effects in humans with osteoporosis.

Mean Values (n=18)	
Chemical Analysis:	Ca/PO ₄
X-ray Diffraction:	Crystal size (nm)
DXA:	aBMD (g/cm ²)
Micro-CT:	vBMD (mg/cm ³)

Finite Element Models More Accurately Predict Structural Behavior of Human Cancellous Bone When Using Specimen-Specific Tissue Properties. J. H. Cole¹, E. R. Myers^{*2}, M. C. H. van der Meulen¹. ¹Sibley School of Mechanical and Aerospace Engineering, Cornell University, Ithaca, NY, USA, ²Biomedical Mechanics and Materials, Hospital for Special Surgery, New York, NY, USA.

Osteoporosis affects cancellous bone tissue properties through altered mineralization and changes in chemical composition, which may compromise its structural behavior. Experimental assessments of tissue properties are limited primarily to localized in vitro measurements that likely do not fully capture the in vivo spatial variations. Finite element (FE) models that simulate tissue heterogeneity over a larger region of bone can be used to investigate changes in tissue properties non-invasively. This study examined the effect of changes in tissue material properties on the structural behavior of cancellous bone using architecture- and material-based FE models. Cylindrical cores were drilled from the center of the T12 and L2 vertebrae of 13 female and 11 male human cadavers, ages 56-92, and scanned using micro-computed tomography (microCT) at an 11.6- μ m resolution. Cores were fixed in brass endcaps and tested to failure at 0.5% strain/s, and apparent stiffness was computed. MicroCT bone voxels were coarsened to 68 μ m and directly converted to 8-noded linear brick elements for the gage length region of each cancellous core. A variable tissue modulus (E) was assigned for three sets of models: universal homogeneous (Homo) with E = 20 GPa, specimen-specific homogeneous (SS Homo) with E = f(mean microCT mineral content), and specimen-specific heterogeneous (SS Hetero) with E = f(microCT mineral content at each voxel). A uniform compressive strain of 0.25% was applied to the models, and the resulting apparent stiffness and element tissue strains were computed. FE-predicted stiffness was compared to experimentally-measured stiffness using simple linear regression for each set of models. A significance level of 0.05 was used. Repeated measures ANOVA was used to assess the effect of the assigned modulus on the predicted stiffness and tissue strains. Overall, the heterogeneous tissue modulus ranged 5.2-36.6 GPa and averaged 9.9-13.0 GPa over all models. Model-predicted apparent stiffness was 0.13-1.50 GPa for Homo, 0.10-0.79 GPa for SS Homo, and 0.09-0.79 GPa for SS Hetero models. Compared to Homo models, SS Homo and Hetero models predicted cancellous bone stiffness more accurately (slopes = 0.36, 0.78, 0.78) and explained more variability (r² = 0.29, 0.42, 0.42). A virtual biopsy modeling method allows tissue property variations to be examined non-invasively and may help predict bone fragility in the aging population.

Regional Variations in Three-Dimensional Microstructural Properties of Proximal Femoral Trabeculae with Aging. Y. Won¹, B. Min^{*2}, Y. Chung³, W. Cui^{*1}, M. Baek^{*1}, H. Kim^{*4}. ¹Orthopaedics, Ajou University School of Medicine, Suwon, Republic of Korea, ²Orthopaedics, Keimyung University School of Medicine, Daegu, Republic of Korea, ³Endocrinology and Metabolism, Ajou University School of Medicine, Suwon, Republic of Korea, ⁴Orthopaedics, Yonsei University School of Medicine, Seoul, Republic of Korea.

Purpose: The purpose of this study was therefore to explore region-dependent changes in the 3D microstructure of trabecular bone in human proximal femur, with respect to aging.

Materials and Methods: A total of 162 trabecular bone cores were obtained from six regions (femoral head, superior and inferior regions of the neck, and superior/middle and inferior regions of the trochanter) of twenty-seven normal femora of Korean male cadaver donors, aged 40-90 years. These specimens were scanned using high-resolution micro-computed tomography (micro-CT). The following 3D microstructural parameters were calculated: bone volume fraction (BV/TV), trabecular number (Tb.N), thickness (Tb.Th) and separation (Tb.Sp), structure model index (SMI), and degree of anisotropy (DOA).

Results: The results showed that the trabecular morphology changed significantly with age, as well as varied from different regions of the proximal femur. There was a significant decrease in bone volume fraction and an almost identical decrease in trabecular thickness associated with aging at any region. Regional analysis demonstrated a significant difference in BV/TV, Tb.Th, DOA, Tb.Sp, Tb.N between superior and inferior neck, as well as a significant difference in BV/TV, Tb.Sp, DOA, SMI, Tb.N between superior and inferior trochanter.

Conclusions: Age-related changes in bone loss and trabecular microstructure within the male proximal femur are not uniform in this Korean cadaveric population. As a result of mechanical and age-related adaptation, significant regional variations in microstructural properties of trabecular bone are likely to important factors affecting the mechanical properties of the proximal femur.

Calcium Density of Bone Correlates with Trabecular Bone Architecture. N. L. Fazzalari¹, B. Ma^{*1}, P. Sutton-Smith^{*1}, J. S. Kuliwaba¹, R. Phipps², I. H. Parkinson^{*1}, A. Badiei^{*1}. ¹Bone and Joint Research Laboratory, Institute of Medical and Veterinary Science and Hanson Institute, Adelaide, Australia, ²Procter & Gamble Pharmaceuticals, Mason, OH, USA.

Many of the skeletal risk factors for fragility fracture have been defined (bone mass, bone geometry, bone architecture, bone mineralisation and bone remodelling). The amount of bone and the degree of mineralisation have been shown to influence the ultimate failure strength of bone independently. In this study we tested if there was any relationship between calcium density of bone ($D_{Ca} = BV/TV \times \% \text{calcium}$) and trabecular bone architecture.

Intertrochanteric cancellous bone cores were obtained from patients undergoing hemiarthroplasty surgery for a subcapital fragility femoral fracture (N=40; 26f, 14m, mean age \pm SD of 81 ± 9 years), and from controls at autopsy (N=10; 2f, 8m, 76 ± 14 years). All samples were imaged by microCT (Skyscan, Belgium) to determine 3D measures of trabecular bone volume (BV/TV), thickness (Tb.Th), separation (Tb.Sp) and number (Tb.N). An age matched subset of 18 fracture cases (13f, 5m, 82 ± 8 years) and 4 control cases (1f, 3m, 79 ± 9 years) were resin-embedded for quantitative backscattered electron imaging (qBSEI) of the degree of mineralisation.

The trabecular bone architecture of the fracture and nonfracture control group was not significantly different. For the pooled group data, Tb.Sp increased exponentially as BV/TV decreased ($y = 3.2 \times 10^{-5} x^2$, $P < 0.001$). Between each group the rate at which Tb.Sp increased was more than three times greater for the fracture group in contrast to the control group. In the pooled group data of the qBSEI analysis, BV/TV did not correlate with %Ca indicating that the measures of bone volume and tissue level mineralisation were independent variables in the bone structural hierarchy. D_{Ca} did positively correlate with Tb.Th and according to the magnitude of r^2 accounted for greater than 25% of the variability in Tb.Th. In contrast, BV/TV accounted for about 10% and %Ca did not account for any variability in Tb.Th. Collectively, these data suggest that Tb.Th may be reactive to changes in D_{Ca} through an interaction between BV/TV and %Ca. It is understood that increased fragility fracture risk is associated with decreased BV/TV and reduced mineralisation of the bone tissue but possible secondary consequent changes in bone architecture have not been investigated to date. D_{Ca} , a composite bone material property provides a novel perspective of bone quality that might help provide a better understanding of fracture risk and treatment efficacy.

Role of Microarchitecture on Whole-Vertebral Body Biomechanical Behavior. A. J. Fields*, S. K. Eswaran*, T. M. Keaveny. Mechanical Engineering, University of California, Berkeley, Berkeley, CA, USA.

Trabecular microarchitecture can explain variations in biomechanical properties of isolated trabecular bone specimens, yet the role of microarchitecture on whole-bone biomechanical behavior remains unclear. For the spine, the influence of microarchitecture might be obscured by such factors as cortical shell thickness and overall bone size. The purpose of this study was to assess the role of trabecular microarchitecture with and without such factors on whole-vertebral mechanical behavior.

Human T9 whole vertebral bodies (posterior elements removed) from male (n=5) and female (n=13) cadavers (87.4 ± 5.0 years) were micro-CT scanned at 30-micron resolution. Internal regions (approximately $15 \times 20 \times 10 \text{ mm}^3$) of trabecular bone were analyzed for the standard model-independent microarchitectural parameters (Table). An average cortical shell thickness (Ct.Th) was also measured. Linear, isotropic finite element models (60-micron element size), containing 30-80 million elements each and with assumed uniform bone tissue material properties, were created for each whole vertebra from the micro-CT scans and subjected to uniform compression loading to compute whole-vertebral stiffness (K_{FE}).

Results indicated that total bone volume (BV) was the best independent predictor of whole-vertebral stiffness, followed by cortical thickness (Ct.Th) and then trabecular spacing (Tb.Sp) and SMI (Table). BV/TV was not an independent predictor. Using stepwise multiple regression with all parameters, the model included BV, Tb.Sp, and Conn.D ($R^2 = 0.77 \rightarrow 0.86 \rightarrow 0.92$); when BV was excluded, the model included Ct.Th and SMI ($R^2 = 0.45 \rightarrow 0.62$); and when Ct.Th was also excluded, the model included SMI and Tb.Sp ($R^2 = 0.35 \rightarrow 0.55$).

While these finite element models did not contain any tissue mineralization effects and this elderly cohort was limited in size, this study is unique since it included measures of microarchitecture and whole-vertebral mechanical behavior for the same specimens. We conclude that trabecular microarchitectural parameters have the potential to improve predictions of whole-vertebral biomechanical behavior, although their influence interacts with other vertebral features. Ongoing efforts are extending these studies to a larger and younger cohort.

Table: Pearson correlation coefficients (n=18)

Assumptions and Limitations in Image-Based Strength Assessment of Bone. T. N. Hangartner. BioMedical Imaging Laboratory, Wright State University, Dayton, OH, USA.

The goal of many bone measurements is the assessment of the likelihood of future fracture. The most commonly used surrogate for strength is density, which can be measured through the attenuation of x-rays. Mechanical testing of machined bone specimens as well as whole bones usually shows an initial linear behavior between load and deformation, leading to a region of reduced resistance to load and eventually reaching the breaking point. Although the initial slope of these curves is tightly related to the material properties of the bone as well as to the architecture and can be estimated with finite-element models, the breaking point is influenced by non-linear features and differs by age and disease state, usually not taken into account.

Computed tomography, through its three-dimensional representation of the bone, has the highest potential to provide the architectural information needed for accurate mechanical simulation. Although average density of the various compartments like trabecular and cortical bone has proven clinically relevant, strength calculations based on the distribution of the bone material are expected to better represent the strength of an individual bone. It is critical, here, to appropriately convert the CT-measured density values to local elastic moduli, a relationship that almost follows a square law. One specific parameter used by some investigators, the strength-strain index, assumes a linear relationship and may, thus, not adequately represent the strength of the bone.

Dual-energy absorptiometry is a two-dimensional imaging method that reflects the third, collapsed dimension in the density value measured at each point in the image. For purely axial loading, as could be assumed in a simplified model of a vertebra, the resistance to loading would be related to the bone mineral content. In the femur, however, the loads are eccentrically applied to the femoral shaft axis, and, thus, major bending stresses occur in the femoral neck. The resistance to a load applied vertically to the center of the femoral head is dictated by the distribution of the bone material in a vertical plane going through the point of force application and the femoral shaft. The projection image of a properly rotated femur provides just that information, and strength calculations based on dual-energy absorptiometry scans have shown tighter relationships with fractures in vitro than simple density measurements. However, current methods assume a linear relationship of density and elastic modulus. Results might be improved if an appropriate power-based relationship is assumed.

A New Bone Diagnostic Instrument: the Osteoprobe II. P. K. Hansma, P. J. Turner*, B. Drake*, J. Adams*, J. LeLujan*, A. Proctor*, F. Garza de Leon*. Physics, University of California, Santa Barbara, CA, USA.

The Osteoprobe II can measure the material properties of bone even if the bone is covered in tissue because of its novel probe assembly. The probe assembly consists of a reference probe, a 22 gauge hypodermic syringe, and a test probe, a small diameter sharpened rod, which slides through the inside of the syringe. The probe assembly is inserted through the skin to rest on the bone. The distance that the test probe is indented into the bone can be measured relative to the position of the reference probe, which rests on the surface of the bone. Complete force vs. distance curves for bone indentation cycles are automatically generated and analyzed to obtain the material properties of the bone. Cyclic force vs. distance curves reveal differences for bones that differ in their resistance to fracture. The resistance of bone to continuing indentation with cycling is less for bone that has less resistance to fracture, for example, bone that has been baked or irradiated. The resistance of human bone to continuing indentation with cycling is less for bone from an elderly donor than for bone from a young donor. This is consistent with data showing that the fracture toughness is lower for bone from elderly donors compared to bone from young donors². The long range goal is to develop a diagnostic tool to help physicians assess fracture risk in their patients: specifically the contribution to fracture risk due to deterioration of materials properties such as fracture toughness. The availability of this tool could also help in the development of new therapies to mitigate or reverse deterioration.

Lrp5 Gene Expression and Bone Turnover with Disuse. G. K. Alvarez, B. T. Hackfort*, B. McGuckin*, M. P. Akhter, D. M. Cullen. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

The Lrp5 receptor (low density lipoprotein like receptor protein) is associated with canonical Wnt signaling and bone formation. The G171V mutation in LRP5 is associated with high bone mass and greater sensitivity to increase mechanical loading. Conversely, disuse results in bone loss due to increased osteoclast activity and decreased osteoblast activity. The hypothesis for this study was that variation in Lrp5 expression and specifically the G171V mutation are associated with differences in bone response to disuse. We examined the response in adult virgin female (4.5 ± 0.4mo) mice to four weeks of hindlimb suspension in three mice genotypes: WT (wild type C57BL6, Lrp5+/+), KO (single knock out Lrp5-/-), and HBM (high bone mass due to G171V mutation). Mice within each genotype were randomly assigned to suspension (N=46) or control (N= 43). All mice were allowed free access to food and water. The protocol was approved by the University IACUC. Calcein was injected 10 and 3 days before tissue collection and histomorphometry performed on undecalcified femur cortical bone. Measurements included Area (total, cortical), mineralizing surface (MS/BS), mineral apposition rate (MAR), and bone formation rate (BFR/BS). Differences among genotypes and due to disuse were analyzed by GLM in SPSS with P<0.05. There were no differences among groups in initial body weight (25.6 ± 2.6 g). The controls maintained their weight while the hindlimb mice lost an average of 3.6 g over four weeks. Results are presented in the table below. HBM mice had greater total and cortical bone area in the control femur and this difference was maintained after disuse. Only the KO group showed a significant decrease in cortical bone area. Cortical femur after hindlimb suspension had formation two to four fold lower in all genotypes. Mice with the HBM mutation and Lrp5+/+ maintained cortical bone despite a decrease in bone formation with disuse while the Lrp5+/- mice lost bone with the same relative decrease in formation. These results show that Lrp5 gene may protect against bone loss with removal of force. Lrp5 in regulation of osteoclast activity may be a secondary role in addition to the primary role of bone cell proliferation and differentiation. The disuse-related effects of the G171V mutation were not discernable in this study since bone areal changes in control mice were small.

Variable	Trt	HBM (G171V)	WT (Lrp5+/+)	KO (Lrp5+/-)

Effect of Hindlimb Unloading on Bone in Two Strains of Mature Mice. B. M. Boudignon*, P. Kurimoto*, B. Orwoll*, B. Halloran. Endocrine Unit, Veteran Affairs Medical Center San Francisco, San Francisco, CA, USA.

Hindlimb unloading is a good model of to study the effects of loss of weight bearing on bone. Numerous studies have shown that hindlimb unloading induces osteopenia, decreases bone formation and increases bone resorption. These studies, however, focused mostly on rapidly growing animals and only a few mouse strains have been compared in adult animal. To examine the effects of hindlimb unloading and mouse strain on bone in mature mice, male C57BL6 and DBA/2 animals, 6 months of age, were permitted normal ambulation or were unloaded for 1, 2 or 4 weeks using the tail suspension method. The femoral distal metaphysis was analyzed using microCT analysis and histomorphometry. Bone marrow cells were collected to examine calcium nodule and osteoclast formation. Basal BV/TV was 50% lower in DBA/2 than C57BL/6J mice and didn't decrease even after 4 weeks of suspension. C57BL/6J mice lost a significant amount of bone after 2 weeks of suspension and this was maintained through week 4. Calcified nodule number decreased dramatically one week after unloading and remained low through week 4. Osteoclast number increased markedly in both strains of mice and normalized after 4 weeks of suspension in the DBA/2 mice but not in the C57BL/6J. Osteoclasts with more than 50 nuclei, believed to be the most active bone resorbing cells, were most increased (nearly 4 times) the first week after hindlimb unloading. Our results show that hindlimb unloading decreases bone mass in mature C57BL/6J mice but not in DBA/2 mice. That basal bone mass was low in the DBA/2 mice might explain why BV/TV was unaffected by unloading. The cell cultures however demonstrated a dramatic effect of unloading on osteoblasts formation and function and osteoclasts formation in both strains. Our results demonstrate that the loss of bone induced by skeletal unloading is strain dependant and in mature mice is associated with changes in both osteoblast and osteoclast function.

Seasonal Changes in the Bone Mineral Density of a Non-hibernating Arctic Rodent Species: The Northern Red-backed Vole, Clethrionomys rutilus. K. T. Stevenson¹, J. D. Mayfield^{*1}, B. M. Barnes^{*1}, I. G. van Tets^{*2}. ¹Biology & Wildlife, University of Alaska Fairbanks, Institute of Arctic Biology, Fairbanks, AK, USA, ²Biological Sciences, University of Alaska Anchorage, Anchorage, AK, USA.

Arctic rodents use a variety of over-wintering strategies to survive the seasonal arctic environment. Some rodents hibernate. These animals decrease their heart rate, metabolic rate, and body temperature, and in some species may not move, eat, drink, urinate, or defecate for five to seven months. Other rodents, "non-hibernators", maintain a constant body-temperature during winter, but reduce their activity and change their diet, social behavior, and physiology in the months leading up to and throughout winter. Both types of rodents could potentially provide models for studying disuse osteoporosis in humans. However, the coupling of reduced activity with maintained metabolic rate and body temperature in non-hibernators resembles the situation of the human patients more closely. Our aim was to determine whether and how bone mineral density (BMD) changed with season in a non-hibernating arctic rodent, the northern redbacked vole, Clethrionomys rutilus. We used dual-energy X-ray absorptiometry (DXA) to measure seasonal changes in the BMD of adult C. rutilus carcasses collected in Alaska at different times of the year. There was no significant effect of season on the BMD of female voles. The BMD of males, however, was highest in spring and fall and lowest in summer and winter, suggesting a decrease in bone strength in male voles as the result of reduced winter activity and an increase in bone strength associated with the onset of the breeding season. Recruitment of younger adults having lower BMDs and the loss of older adults with higher BMDs in summer is likely to have been responsible for the lower BMD values in summer. This evidence of reduced BMD during times of naturally low activity for male C. rutilus suggests that these non-hibernating arctic rodents could serve as models for studies of disuse osteoporosis in humans. To further test this, we will dissect the bones out of the vole carcasses and repeat our analyses on these isolated bones. We will also use DXA to measure the effect of hibernation on long bone remodeling in captive arctic ground squirrels, Spermophilus parryi, to test the suitability of hibernating rodents for similar research. Continuing research on the effects of season and activity on mineral metabolism and deposition in arctic rodents is likely to improve our understanding of disuse osteoporosis.

A Novel Partial Weight Suspension System Simulating Mars Gravity Leads to Reduced Bone Mass and Strength in Mice. E. B. Wagner^{*1}, W. Tan^{*2}, K. C. Gosselin^{*2}, M. L. Bouxsein³. ¹Division of Health Sciences and Technology, Harvard-MIT, Cambridge, MA, USA, ²Massachusetts Institute of Technology, Cambridge, MA, USA, ³Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA.

The musculoskeletal effects of partial weightbearing, such as expected on the Moon (16%) and Mars (38%), are yet to be quantified. Our novel model of Partial Weight Suspension (PWS) provides the first mechanism for investigating chronic, titrated quadrupedal loading in mice. Suspension is provided by combination of a custom forelimb vest and tail wrap, and can be adjusted to support studies within +/- 5% of a given static loading level. In this study, we examined musculoskeletal adaptation to Mars-analog (38% weightbearing) levels. Adult female BALB/cByJ mice (n=32, 10 weeks old) were randomly assigned to the BASELINE sacrifice group (n=8), MARS suspension group (n=9), JACKET full-weightbearing control group (n=5), or group-housed AGE matched control group (n=10). JACKET mice were singly housed in identical cages and wore the same forelimb vest to mimic any stress induced by the PWS system. JACKET mice were pair-fed based on consumption of MARS, and AGE animals were group housed and fed ad libitum. After 21 days, animals were sacrificed, the gastrocnemius muscle was weighed, and the bone architecture in the distal femur, femoral midshaft, and proximal tibia were assessed by microCT. Femora were tested in 3-point bending to determine biomechanical properties. We found that: 1) Body weight gain did not differ between MARS and AGE-matched controls after an initial adaptation period, suggesting low levels of systemic stress; 2) Gastrocnemius weight and bone architecture did not differ between AGE and JACKET controls; 3) Gastrocnemius weight was significantly decreased in MARS vs AGE-controls (-21.8%, p<0.05); 4) Femoral trabecular BV/TV and mid-shaft cortical thickness were significantly reduced in MARS animals vs controls (BV/TV -20.6%, p<0.01; Cort.Th -8.9%, p<0.001); 5) Bending rigidity and ultimate moment were significantly reduced in MARS animals relative to controls (BR: -13.8%, p<0.005; UltMom: -19.9%, p<0.01). In summary, MARS loading leads to significant muscle and bone loss. Interestingly, trabecular bone loss under MARS weightbearing appears to be attenuated relative to previous reports of bone loss associated with hindlimb suspension.

Fluid Shear Stress and Mechanical Strain Induce a Similar Osteogenic Gene Response via Divergent Signaling Pathways. N. Case¹, Z. Xie^{*1}, B. Sen^{*1}, M. Ma^{*1}, H. Jo^{*2}, J. Rubin¹. ¹Medicine, UNC, Chapel Hill, NC, USA, ²BME, GATech/Emory, Atlanta, GA, USA.

Mechanical loading influences on bone remodeling are well-established with physiologic loading causing net bone gain. The specific forces generated during loading have been postulated to cause equally specific responses: indeed, the few direct comparisons between strain and shear stress have suggested that these forces are not interchangeable. Our previous work has shown that mechanical strain promotes bone formation through repression of RANKL, a necessary factor for osteoclastogenesis, as well as stimulation of Runx2 and osterix, genes that induce osteoblast differentiation and activity. We here ask whether this coordinated regulation of multiple genes associated with bone remodeling is specific to strain: does shear activate the same pattern of osteogenic gene response? Using a modified cone-and-plate shear device, we evaluated the effects of steady fluid flow on regulation of bone remodeling effector genes in the pre-osteoblast CIMC-4 cell line. RANKL mRNA expression was decreased to 0.11 ± 0.03 fold, Runx2 mRNA expression was increased 1.56 ± 0.13 fold and osterix mRNA expression was increased 3.37 ± 0.41 fold in cultures subjected to flow overnight (3 experiments, n=11) as compared to no-flow cultures (p<0.01 all genes). The magnitude of shear-induced changes was \geq strain effects: RANKL repression was 2-3 times lower, Runx2 expression was unchanged and osterix induction was 2 times higher in flow compared to changes observed in strained cultures. We next investigated potential signaling pathways involved in flow-mediated gene regulation. Signaling pathway inhibitors evaluated included MEK inhibitors, PD98059 and U0126, the PI3-kinase inhibitor LY294002, the nitric oxide synthase inhibitor L-NAME and thapsigargin, which empties intracellular calcium stores. While we have previously shown that PD98059 inhibits strain effects on RANKL, Runx2 and osterix, this MEK inhibitor did not affect shear-induced gene changes. As well, shear regulation of RANKL and Runx2 was not altered by treatment with any other inhibitor. Interestingly, shear upregulation of osterix was inhibited by U0126, LY294002 and thapsigargin, but not by L-NAME, indicating that osterix regulation by flow involves at least PI3-kinase and calcium signals. In sum, these data suggest that fluid shear stress and mechanical strain can elicit similar, if not equivalent, cellular responses and that the same biological endpoint can be reached through different means. In conclusion, this work suggests that there is no one dominant biophysical force guiding the response to skeletal loading; rather, a variety of inputs/signaling pathways converge to elicit a summed response that is anti-catabolic and pro-anabolic in bone cells.

A Novel Role for Nuclear Factor of Activated T Cell (NFATc1) in Bone Mechanotransduction. A. B. Celil Aydemir^{*1}, S. Lee^{*1}, T. R. Gardner^{*1}, J. M. Ahn^{*2}, F. Y. Lee¹. ¹Orthopaedic Surgery, Columbia University, New York, NY, USA, ²Hallym University, Chuncheon of Gangwon, Republic of Korea.

Bone adapts to the changes in its microenvironment. It has been shown that osteoblasts alter cytokine expression in response to mechanical stimuli. However, signal transduction pathways that mediate bone cell response to mechanotransduction have not been elucidated at the transcriptional level. One of the early events of mechanotransduction is the elevation of intracellular calcium, which is upstream of calcium/calmodulin and NFAT signaling. Calcium/calmodulin signaling activates NFATc1, which is a transcription factor. Our bioinformatics analysis shows the presence of putative NFATc1 binding motifs in the promoter region of Cox2, a well-known mechanotransduction mediator. We hypothesize that calcineurin/NFATc1 signaling mediates mechanotransduction in osteoblasts. In this study, we show that fluid shear stress (FSS) induces Cox2 and TNF α expression in bone marrow derived human mesenchymal stem cells (hMSC) and mouse preosteoblasts. Osteoblasts and osteocytes are known to be subject to fluid shear stress in vivo. Cells were subjected to a sinusoidal fluid shear stress of ± 10 dynes/cm² at 1Hz for 15minutes. Concurrently, a clinically relevant hydrostatic pressure of 0.138MPa (1380 dynes/cm²), comparable to pressures found in the hip joint space during gait, was applied to the cells. Proinflammatory gene expression and TNF α release in hMSC were both found to increase in this loading environment. Further, NFATc1 translocates to the nucleus in response to fluid shear stress in hMSC. A peptide inhibitor of NFATc1, Vivit, inhibits the FSS-induced proinflammatory gene expression and NFATc1 nuclear translocation. Our results implicate the involvement of the calcineurin/NFATc1 axis as a novel mediator of bone cell response due to mechanical stimulation.

Fluid Flow Shear Stress Promotes Intracellular Assembly and Formation of Connexin 43-forming Channels in Osteocytes. S. Burra¹, A. J. Siller-Jackson¹, L. F. Bonewald², E. Sprague^{*3}, J. X. Jiang¹. ¹Biochemistry, University of Texas Health Science Center, San Antonio, TX, USA, ²Oral Biology, School of Dentistry, University of Missouri, Kansas City, MO, USA, ³Radiology, University of Texas Health Science Center, San Antonio, TX, USA.

Connexin 43 (Cx43) is the major gap junction and hemichannel forming protein in primary osteocytes and osteocyte-like cell line MLO-Y4. Osteocytes are the mechanosensory cells; mechanical signals travel from one osteocyte to other through gap junctions formed at the tips of the dendritic processes of osteocytes. Recent studies by our laboratory and others show that in addition to form gap junction channels, Cx43 forms functional hemichannels, an apposed of halves of gap junctions. Fluid flow shear stress induces the opening of hemichannels associated with the release of prostaglandins. Cx43 protein is abundantly expressed intracellularly as well as along the cell surface. We have previously shown that FFSS appears to enhance the migration of intracellular Cx43 protein towards plasma membrane, resulting in an increase in Cx43 protein on the cell surface. To determine the molecular mechanism of assembly and formation of gap junctions and hemichannels in response to FFSS, sucrose gradient sedimentation analysis was conducted. FFSS induced the assembly of Cx43 into hexamers, the oligomeric forms of Cx43 in forming gap junctions and hemichannels. The localization of Cx43 and its response to FFSS was determined by colocalization analysis with intracellular organelle marker proteins including calnexin (endoplasmic reticulum (ER) marker) and 58K Golgi protein (Golgi marker). Cx43 co-localized with both ER and Golgi markers at static conditions. Cx43 protein plaques, indicative of assembled channels, predominantly localized in the Golgi. Interestingly, upon mechanical stimulation by FFSS, the colocalization of Cx43 plaques in Golgi diminished; instead Cx43 appeared to migrate towards the cell surface. The levels of Cx43 protein on cell surface was quantified by biotinylation approach. When MLO-Y4 cells were subjected to FFSS and the then incubated for various periods of time, surface expression of Cx43 gradually increased over the time and reached maximum after 2 h of incubation. Together, these results combined with functional studies show that FFSS stimulates the assembly and formation of Cx43-forming gap junctions and hemichannels, which will accommodate the response to mechanical stimulation in osteocytes.

In Vivo Tibial Compression Stimulates Bone Formation. D. M. Cullen, G. K. Alvarez, B. T. Hackfort*, B. McGuckin*, M. P. Akhter. Osteoporosis Research Center, Creighton University, Omaha, NE, USA.

Increased exercise stimulates bone formation, but is difficult to model in vivo. Popular noninvasive models include tibial four-point or cantilever bending and ulna compression, but they are limited by the unique load distributions, sample regions, and potential injury. Two papers in Bone 2005, by Fritton and Desousa introduced tibial compression. They presented strain gage data, area, and BMC changes, but did not provide sufficient information to determine appropriate load ranges and sample sites for bone histology. The purpose of this study was to document the bone formation response along the tibia and to demonstrate the load response curve to increasing forces. The load apparatus was modeled after DeSousa with the knee and ankle positioned for force application in the vertical plane with an Enduratec (ELF3200) device. Twenty female C57Bl6 adult mice (5.5±0.4 mo, 30.0±3.2g) were randomized to loads 8, 9, 10, or 11N and then 100 cycles at 2 Hz was applied Mon-Wed-Fri for 3 weeks. Midtibial strains ranged from 1800 to 2500µε. Mice received calcein injections 10 and 3 days before euthanasia to label bone formation for dynamic histomorphometry. Animals loaded from 8-11 N showed no signs of injury. In a test of 12 N loads, 20% of the animals had a stress fracture by day 3 and the group was stopped. Bone sections were selected relative to the tibia fibular junction (TFJ, Fig) with one distal (3 mm) and three proximal (1, 3, 5 mm) sections measured. Differences were seen within animals for loaded and non loaded legs and section location, and among load groups at the periosteal and endocortical surfaces for mineralizing surface (MS), mineral apposition rate (MAR), bone formation rate, and woven bone formation. For all endpoints the responses tended to increase with increased load and the differences in load response were greatest at 3 mm proximal to the TFJ. Difference (Loaded - nonloaded) in periosteal bone formation rate (MS x MAR) is shown in the Figure. Formation increased as applied force increased with the greatest differences seen 3 mm proximal to the TFJ where multiple intergroup comparisons were significant (P<0.01). This study demonstrates that the most load sensitive region for cortical bone histomorphometry is ~ 1 mm proximal to the TFJ, the same region sampled for tibial four-point bending. This area is easily located, reproducible and has a fairly constant shape.

Is Golf a Good Sport for Bone Health in the Elderly? A DPX and High Resolution pQCT Evaluation at both Radius and Tibia Bone Sites. T. Thomas¹, G. Ntougou Assoumou Hourfil², M. Zouch², L. Vico².

¹Rheumatology Department - University Hospital, LBTO INSERM U890, Saint-Etienne, France, ²LBTO INSERM U890, Saint-Etienne, France.

A regular practice of golf may be beneficial for preserving a good bone health in the elderly population, both in the lower limbs because of ground impacts during long walks and in the upper limbs because of impacts transmitted by the club during the swing. Therefore, we conducted a prospective cross-sectional study in men (age range: 60-75) comparing a group of 15 golfers, playing their sport 8 to 12 hours a week for the last 2 years, to a group of 15 walkers, with a similar weekly practice and a group of sedentary men, all appeared for age. Evaluation of bone status was performed using DPX (Hologic Delphi 4500 QDR) and HR-pQCT (Scanco Xtreme CT) for microarchitecture analysis as well as biochemical parameters on fasting blood samples collected early morning. Daily calcium intake and physical activities were assessed by validated questionnaires. The 3 groups were not different in terms of height, weight, BMI and daily calcium intake. Using DPX, we observed that bone mineral content of mid diaphysis radius was significantly higher in the golfer group than in the other groups. There was no statistically significant difference in bone mineral content both at the distal radius and dominant lower limb. The HR-pQCT analysis showed significant differences between groups in central trabecular density (Dtrab), total trabecular density (Dtrab) and trabecular bone volume (BV/TV) both at the dominant radius and tibia. Surprisingly, these parameters were higher in the walker group than in the other groups. On the other hand, cortical density at both bone sites was higher in golfers with a large inter-individual variability. Several factors may partly explain the higher values in trabecular parameters in the walker group. Indeed, total and sport-related annual physical activities were significantly higher in this group compared to the others. Those of golfers were not significantly higher than sedentary group levels. Past physical activity of walker group also was very significantly higher than golfers one while this parameter was significantly lower in sedentary group compared to the others. In addition, testosterone level also was significantly higher in walkers than in other groups and testosterone was significantly and positively related to Dinn ($r = 0.41$, $p < 0.05$).

In summary, our results suggest that golf practice has beneficial effect on the cortical envelope both at the radius and tibia bone sites. The role of past and actual global physical activity seems preponderant on trabecular envelope. Further studies are necessary to confirm a definitive benefit of golf practice on bone health in the elderly.

Eight Months of Twice Weekly Ten Minute Jumping Activity for PE Warm Up Improves Bone in Adolescent Boys and Girls: The POWER PE Study.

B. K. Weeks, C. M. Young*, B. R. Beck. School of Physiotherapy and Exercise Science, Griffith University, Gold Coast, Australia.

High intensity skeletal loading during growth may be an effective strategy to maximise bone accrual and reduce fracture risk in old age. Preventing Osteoporosis With Exercise Routines in Physical Education (POWER PE) was an 8-month randomised controlled school-based exercise intervention designed to apply known principles of effective bone loading to practical opportunities to improve life long musculoskeletal outcomes. We replaced regular warm up activities with jumping in the twice-weekly PE classes of early high school students to observe the effect on bone accrual in adolescent boys and girls. A total of 99 adolescents (46M:53F, 13.8 ± 0.4 years) volunteered to participate in the yearlong study. Most were classified as Tanner IV (53%). Intervention group subjects performed ten minutes of supervised jumping activity in place of regular PE warm up activities. Control subjects performed regular PE warm-up activities directed by their teacher. Anthropometrics, Tanner staging, peak height velocity, muscle strength and power, flexibility, and bone mass (DXA and QUS) were measured at baseline and follow-up. Geometric properties (such as FN cross-sectional moment of inertia and LS index of bone strength) were estimated from DXA measures. Physical activity and dietary calcium were determined by questionnaire. There were no differences in any measured variable between control and intervention groups at baseline. No group differences were detected for 8-month change in anthropometric, maturity, strength, or flexibility variables for boys or girls. At eight months, boys in the intervention group had experienced significant improvements in calcaneal BUA (+5.0%, $p = 0.012$), and fat mass (-10.5%, $p = 0.023$), while controls did not (+1.4% and -0.8% respectively). Girls in the intervention group, however, experienced significant improvements in FN BMC (+13.9%, $p = 0.05$) and LS BMAD (+5.2%, $p = 0.04$), which were not observed in controls (+4.9% and +1.5% respectively). Other bone strength parameters improved significantly for both groups, such that between group comparisons of percent change revealed significant intervention effects only for WB BMC (+10.6% vs +6.3%, $p = 0.029$) for boys. Short duration, regular jumping activity during adolescence appears to improve bone accrual in a sex-specific manner. Boys improved whole body bone mass and BUA, and reduced fat mass, while girls improved bone mass at the hip and spine.

Knee Loading Stimulates Wound Healing in Mouse Femora. P. Zhang, Q. Sun*, C. H. Turner, H. Yokota. Biomedical Engineering, Indiana University Purdue University Indianapolis, Indianapolis, IN, USA.

Knee loading is a recently developed loading modality capable of inducing anabolic responses in murine femora and tibiae. The object of this study was to examine whether this loading modality would be useful in stimulating bone healing in mouse femora. Thirty-seven C57/BL/6 female mice (~14 weeks of age; and a body weight of ~20 g) were used for the study. The procedures performed in this study were in accordance with the Institutional Animal Care and Use Committee guidelines. A surgical hole of 0.5 mm in diameter was generated in the left and right femora. The hole penetrated through the anterior and posterior surfaces at 50% (~8 mm) distant from the distal femoral end. From the fourth postoperative day, knee loading was conducted with a custom-made piezoelectric loader, and 0.5-N loads were laterally applied to the left knee at 15 Hz for 3 min/day for 3 consecutive days. The contralateral femur was used as sham-loaded control. Animals were sacrificed 1, 2, or 3 weeks after the surgery. The healing process was evaluated using μ CT (n = 20), pQCT (n = 7), and histomorphometry with calcein labeling (n = 10).

Compared to sham control, the loaded samples clearly showed load-driven enhancement of wound healing. First, knee loading significantly reduced the size of surgical wounds by 14% (p < 0.05), 24% (p < 0.01), and 32% (p < 0.001) in 1, 2, and 3 weeks after the surgery, respectively. Second, pQCT data showed that the total bone density (BMD) was increased from 571 ± 19 mg/cm² (control) to 686 ± 19 mg/cm² (loading) (p < 0.01), and the total bone content (BMC) was elevated from 3.05 ± 0.12 mg/mm (control) to 3.42 ± 0.11 mg/mm (loading) (p < 0.05). Similarly, the cortical bone density was increased from 1057 ± 19 mg/cm² (control) to 1136 ± 10 mg/cm² (loading) (p < 0.01), and the cortical bone content was elevated from 2.25 ± 0.11 mg/mm (control) to 2.73 ± 0.11 mg/mm (loading) (p < 0.01). Lastly, bone formation near the wound was stimulated by loading. In summary, the current study demonstrates that knee loading is capable of enhancing a healing process in the mouse femur. The described knee loading modality might provide a novel strategy to develop mechanical therapies to accelerate bone healing.

Sex-Specific Bone Surface Changes During Adolescent Growth: pQCT Analysis of the Mid-Tibia. Y. Ahamed*, D. M. L. Cooper, H. A. McKay. Orthopaedics, University of British Columbia, Vancouver, BC, Canada.

The classic studies of Garn and colleagues reported that although growing boys and girls can both exhibit endosteal and periosteal apposition within the diaphysis of the second metacarpal; girls undergo greater endosteal apposition while boys undergo greater periosteal apposition. This suggests a strength advantage for boys as adding bone to the endosteal surface is less mechanically advantageous. Further, this biological "preference" has been viewed as contributing to women's increased bone fragility. Garn's classic studies were conducted using planar measurement techniques and thus were unable to directly assess bone cross-sectional geometry. In a previous study by our group, changes in bone surfaces at the mid-tibia over 20 months (2001-2003) in boys and girls were directly assessed by peripheral quantitative computed tomography (pQCT). This study did not detect any evidence of endosteal formation in either sex in this young sample (mean age = 13.5 (± 0.55) years in 2003) regardless of maturity level. The aim of our current study was to extend this previous work by examining sex-specific changes in bone surfaces across 56 months. We tested the hypothesis that girls add more bone on the endosteal surface compared with boys during adolescence. Subjects were a part of The University of British Columbia Healthy Bones Study. There was no difference between control and intervention groups for pQCT outcomes at the tibia four months after cessation of the exercise intervention. Therefore, both groups were collapsed for the current study which included 69 participants (38 girls, 31 boys) for whom 6 consecutive mid-diaphyseal pQCT (Stratec XCT 2000) scans were available (2001-2006). Mean ages were 12.0 years (± 0.55) at baseline and 16.5 (± 0.56) years as of June 2006. Total bone area (ToA) and medullary canal (MedA) were measured using Stratec XCT software version 5.50. Repeated measures univariate analysis of variance with sex as a factor showed significant increases in ToA and MedA (p < 0.001) in both sexes. Over 56-months ToA increased 42% in boys and 16% in girls. In boys, MedA increased a total of (32%) while the change in MedA for girls was less pronounced (7% increase). Our current findings differ from Garn and colleagues' earlier studies of the second metacarpal but are consistent with our early findings of this cohort when they were less mature that found no evidence of endosteal apposition at the midshaft of either sexes' tibiae. This indicates that endosteal formation of bone does not occur uniformly throughout the skeleton during adolescence and, therefore, may not underlie differences in fragility between the sexes.

Distribution of Bone Measures in Children at 11 Years of Age. J. C. Torner*, M. C. Willing², T. L. Burns*, E. Letuchy*, K. F. Janz*, T. Marshall*, J. M. E. Gilmore*, J. J. Warren*, S. M. Levy*. ¹Epidemiology, University of Iowa College of Public Health, Iowa City, IA, USA, ²Pediatrics, University of Iowa Carver College of Medicine, Iowa City, IA, USA, ³Epidemiology, University of Iowa Carver College of Medicine, Iowa City, IA, USA, ⁴Health and Sports Studies, University of Iowa College of Liberal Arts, Iowa City, IA, USA, ⁵Preventive and Community Dentistry, University of Iowa College of Dentistry, Iowa City, IA, USA.

The purpose of this study is to describe and characterize factors of bone development. A cohort of 481 children (251 girls and 230 boys) was evaluated for bone measures of area, bone mineral content (BMC) and density (BMD) using an Hologic 4500a. The children ranged in age from 10.5 to 12.4 years with a mean of 11.2 years. Even within this restricted age range BMD had a wide distribution.

BMD (gm/cm²) by Site

Location	Mean	Low	High
Hip	0.780	0.535	1.18
Spine	0.700	0.457	1.18

The coefficient of variation was 12.7 for hip BMD and 14.3 for spine BMD. Values for BMC were 21.5 (spine), 22.9 (hip), 17.7 (whole body) and 20.9 (whole body without head). Correlations of BMC between hip and other sites were higher (r=0.801) than correlations for BMD (r=0.659). Hip was more strongly correlated with total body BMC than spine was. Regression models for bone measures with gender, height, weight, and dichotomized Tanner stage as predictors showed that weight and height are the most important predictors of BMC levels. For hip and spine BMC and BMD, gender is also highly significant; Tanner stage is statistically significant (p<0.05) for spine BMC and BMD, whole body without head BMC and hip BMD, and marginally statistically significant (0.05<p-value<0.10) for hip BMC and whole body BMC. Overall, gender, body size and Tanner stage explain 56% of variation in spine BMC, 61% of variation in hip BMC, and 71 and 77% of variation in whole body BMC with and without head; they explain between 36 and 41% of variation in BMD measures. Cross-classification of quartiles adjusted by age, height, weight, gender and Tanner Stage showed that hip BMC and whole body BMC without head had the highest agreement for boys and for girls it was spine and whole body BMC. Quartile agreement for boys for BMD was 41.7% and for girls it was 43.4%. For the lowest quartile the lowest agreement was between hip and spine. These results show disparity in bone measures by site and suggest differential factors may be related to development.

The Independent Contribution of Physical Activity to Bone Mass During Growth. M. Burrows¹, A. Baxter-Jones², H. M. Macdonald*, R. Mirwald², H. McKay¹. ¹Orthopaedics, University of British Columbia, Vancouver, BC, Canada, ²College of Kinesiology, University of Saskatchewan, Saskatoon, SK, Canada.

A few long-term prospective trials have demonstrated the relationship between physical activity and absolute values for bone mass in children. However, the unique contribution of physical activity to the bone gain trajectory (change in bone mass) is not well understood. We assessed bone mineral content velocity (Δ BMC (g/yr), Hologic QDR4500W) at the lumbar spine (LS), proximal femur (PF), femoral neck (FN) and total body (TB) in 361 boys and girls over 7 years (Healthy Bones Study). We obtained parental consent to assess these children aged 9-12 years at baseline. Lean mass (g) and fat mass (g) were obtained from TB scans. Physical activity score (PA score) was determined from a previously validated self-report questionnaire (PAQ-C). To control for the well-documented maturational differences between adolescent boys or girls of the same chronological age, we determined biological age (chronological age at peak height velocity (APHV determined from cubic spline fits) - chronological age at the time of measurement). If APHV had not occurred it was predicted using an anthropometric based regression equation (Mirwald, 2002). We used multi-level modeling to assess the independent contribution of physical activity to change (Δ) in BMC. Table 1 provides significant predictors (with coefficients) for PF and FN BMC Δ . Most notably, in girls each increment increase in PA score was associated with a 21.6g increase in BMC Δ at the FN (p<0.05). In boys, each increment increase in PA score predicted a 0.55g increase in BMC Δ at the PF (p<0.05). PA was a significant predictor of BMC Δ at the TB for girls only (p<0.05) [Δ TB BMC = $324(51) + 2370 + 104(6.5)\text{yrstart}_i + -13.8(2.1)\text{yrstart}_{2i} + -5.9(1.0)\text{yrstart}_{3i} + 7.9(2.3)\Delta\text{height}_{ij} + 0.02(0.003)\Delta\text{lean mass}_{ij} + 21.6(8.9)\text{physical activity score}_{ij} + e_{0ij}$]. Physical activity was an important predictor of bone mineral accrual across 7 years especially at weight bearing sites in boys and girls.

Table 1. Multi-level modeling significant predictors of BMC change in boys and girls

Δ BMC (g)	Boys (n = 183)	Girls (n = 178)
Total proximal femur (PF)	Δ height - 0.15 ± 0.05	Δ height - 0.17 ± 0.04
	Δ lean mass - 0.0006 ± 0.00005	Δ lean mass - 0.0006 ± 0.00005
	Δ fat mass - 0.0001 ± 0.00003	Δ fat mass - 0.0001 ± 0.00003
	Biological age - 0.55 ± 0.31	Biological age - 0.39 ± 0.30
	Physical activity - 0.42 ± 0.21	Physical activity - 0.30 ± 0.17
Femoral Neck (FN)	Δ height - 0.003 ± 0.006	Δ height - 0.002 ± 0.005
	Δ lean mass - 0.00007 ± 0.000005	Δ lean mass - 0.00007 ± 0.000007
	Δ fat mass - 0.000006 ± 0.000003	Δ fat mass - 0.000001 ± 0.000004
	Biological age - 0.04 ± 0.04	Biological age - 0.003 ± 0.006
	Physical activity - 0.09 ± 0.02	Physical activity - 0.02 ± 0.02

Values are estimated mean coefficients ± SEE (Standard Error Estimate); p<0.05 (mean > 2*SEE). Variables that did not enter were weight, ethnicity, calcium intake and years in study.

Determination of Bone Mass and Size in Term, Near-Term, and Preterm Boys. H. Abou Samra^{*1}, D. Stevens^{*2}, T. Binkley¹, B. L. Specker¹. ¹EA Martin Program in Human Nutrition, South Dakota State University, Brookings, SD, USA, ²Pediatrics, Sanford Hospital Medical Center, Sioux Falls, SD, USA.

The purpose of the study was to determine whether there are differences in bone mass and size among prepubertal boys who were born term (> 37 weeks), near-term (NT: 34 to 37 weeks), or at preterm (PT, ≤ 34 weeks gestation) and whether differences in strength or activity explained bone differences. Total body (TB), spine (LS) and hip DXA and pQCT measures of the distal tibia were obtained on 24 prepubertal boys aged 5.7 to 8.3 years. In multiple regression analysis, after adjusting for current weight, height, age, percentage body fat (%BF), and jump power, term boys had greater cortical thickness (p=0.03) and area (p=0.01), higher trabecular volumetric bone mineral density (aBMD) (p=0.05), TB BMC (p=0.01), and total hip BMD (p=0.01) than PT boys and higher TB BMC (p=0.01), TB bone area (p=0.04), total hip BMC (p=0.02) and BMD (p=0.01), and femoral neck BMC and BMD (both, p=0.02) than NT boys. There were no differences in activity measures among gestation groups and no group-by-activity interactions. In conclusion, term boys have greater bone size and mass than PT boys and higher bone mass than NT boys at several bone sites. Activity measures did not differ among gestation groups and did not explain bone differences. Our findings, if confirmed in larger populations, may have significant implications for bone health in near- and preterm children, a group that is thought to represent approximately 11.3% of all births.

Timing of Peak Bone Mass and Bone Mineral Density Are Influenced by High-Level Physical Activity in Young Adults of Both Sexes. S. Breban^{*}, C. Chappard, C. Jaffre^{*}, C. Benhamou. CHR Orleans, INSERM Unit U658, Orleans, France.

Optimization of Peak Bone Mass may help to prevent osteoporosis and sport is known to be beneficial for bone tissue by increasing Bone Mineral Density (BMD). No study has reported effects of physical activity on Peak bone Mass. Thus, the aim of this cross-sectional study was to analyse the influence of physical activity on timing and level of Peak Bone Mass.

70 girls and 90 boys aged 17-28 years participated in this study. The sample included 40 athlete-girls and 60 athlete-boys participating in weightlifting, ball collective sports or judo for more than 6 hours per week (9.6±3.5 hours per week for women and 10.4±3.7 for men). They were age and sex matched with control girls (n=30) and boys (n=30). Bone Mineral Content (BMC, g) and BMD (g/cm²) were measured by DXA (Delphi, Hologic®, Waltham, MA), at lumbar spine (LS) and non dominant femur (total and femoral neck (FN)). We also evaluated whole body (WB) BMC and BMD, with derived analysis of trunk, lower and upper limbs. Height, weight and body composition were derived from these DXA measurements. The timing of Peak Bone Mass was analysed by the inflexions of the age/BMD curves at all bone sites. Our variables were best fitted by second order polynomial regression equations. Thus, the model was expressed as y=ax²+bx+c. The age of maximal bone mass was determined as the maximum of the curve, i.e. when x = -b / 2a. Athletes had higher BMD measurements than controls in both sexes at all bone sites (p<0.05). Consequently all the Peak Bone Mass levels were significantly higher in athletes than controls. BMD peaks were achieved around 21.5 (FN), 22 years (LS), and 24-25 years (WB, upper and lower limbs) in athlete girls; BMD peaks were reached before 17 years for all bone sites except for LS (21.8 years) in control girls. In athlete boys, BMD peaks were reached before 17 years for upper and lower limbs, and ranged from 21.0 years (FN) to 25.5 and 26.0 years respectively for WB and LS. Finally, in control boys, BMD peaks were

reached before 17 years at all bone sites. Timing of Peak Bone Mass was different according to bone sites, sex and athletic or non athletic status. Thus, those results confirm that weight-bearing physical activity lead to a better bone status compared to non athletes, in both sexes and even after puberty. Moreover, our data suggest that the Peak Bone Mass was not reached at all bone sites before 17 years; thus, it is yet possible to optimize BMD and Peak Bone Mass in young adults between 17 and 28 years. High level weight-bearing physical activity seemed to induce a delayed and higher Peak Bone Mass compared to controls.

Fat Mass Is Inversely Related to Subsequent Change in Bone Size and Mass in Young Prepubertal Children. K. S. Wosje¹, P. R. Khoury^{*1}, S. R. Daniels^{*2}. ¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA, ²The Children's Hospital, Denver, CO, USA.

Recent literature suggests that whole body fat mass (FM) may be positively related to periosteal bone formation in children. FM was reported to be positively associated with subsequent 2-year changes in whole body bone area (BA) and bone mass (BMC) in 9 year-olds, but this has not been examined in younger children. We hypothesized that there would be a positive relationship between FM at age 3.5 y and changes in BA and BMC from age 3.5 to 7 y, adjusting for race, sex, socioeconomic status [household income (HHI); N = 104 <\$50,000, N = 117 ≥\$50,000], exact age at baseline, change in whole body lean mass (LM), and change in height. 221 children [176 white (45% girls), 45 black (60% girls)] with data available from whole body DXA (Hologic 4500A) scans done within 3 months of both 3.5 and 7 years of age (interval 3.5 ± 0.2 y) as part of a longitudinal study of adiposity development were included. All 442 scans were confirmed by visual inspection of printed output to have no major limb or trunk movement. For the DXA measures of BA and BMC, the skull was excluded because the skull-inclusive whole body data may be affected by differences in relative head size over time within children. LM, height, BA and BMC were expressed as percentage change (Δ) from age 3.5 to 7 y. Data are mean ± SD. In bivariate analysis, FM at age 3.5 y was inversely associated with ΔBA (p<0.001) and ΔBMC (p<0.01). Blacks had greater ΔBA (32 ± 8 vs. 28 ± 6%, p<0.001) and ΔBMC (91 ± 15 vs. 80 ± 13%, p<0.001) than whites; neither ΔBA nor ΔBMC differed by sex or HHI (all p>0.2). In all children, ΔLM was not associated with ΔBA (p=0.1) but was positively associated with ΔBMC (p<0.001). As expected, exact age at baseline was inversely related to ΔBA and ΔBMC (both p<0.001); and Δheight was positively associated with ΔBA and ΔBMC (both p<0.001). In the final multiple regression model, FM at age 3.5 y remained inversely related to ΔBA (p<0.001) and ΔBMC (p<0.001) after adjusting for race, exact age at baseline, ΔLM and Δheight. There was no FM-by-race or FM-by-sex interaction in relation to ΔBA (both p>0.07) or ΔBMC (both p>0.4). Similar findings were obtained when LM, height, BA and BMC were expressed as absolute rather than percentage change from age 3.5 to 7 y, and baseline BA or BMC was included in the model. Our findings were opposite of our hypothesis and conflict with a prior report of a positive relation between FM and subsequent change in BA and BMC among older prepubertal children. Although our study provides indirect evidence that FM does not appear to be positively related to periosteal bone formation during the younger prepubertal years, studies with measures of cortical bone dimensions using pQCT would provide clarification.

Prostaglandin D₂ in Human Bone Formation and Remodelling In Vivo. M. A. Gallant*, C. Wollén*, E. Chamoux, J. Parent*, S. Roux, A. J. de Brum-Fernandes. Division of Rheumatology, Département de Médecine, Faculté de Médecine et des Sciences de la Santé, Université de Sherbrooke, Sherbrooke, PQ, Canada.

Prostaglandin D₂ (PGD₂) is a lipid mediator implicated in several physiological and pathological events. We have previously showed that human osteoblasts produce PGD₂ and that this mediator decreases osteoprotegerin production through the activation of the DP receptor while it decreases RANKL secretion and increases osteoblast migration through the activation of the CRTH2 receptor, both present on osteoblasts (Gallant et al, JBMR 2005, 20:672-81). These results led to the hypothesis that PGD₂ could be an autacoid implicated in bone remodelling and exerting a positive feedback on osteoblasts. Our objective was to determine, in humans, if the PGD₂ stable metabolite 11 β -PGF_{2 α} was increased in conditions of high bone remodelling and formation in vivo.

We determined the levels of urinary 11 β -PGF_{2 α} and serum bone-specific alkaline phosphatase (BAP) and C-terminal collagen I telopeptide (CTX) in 17 patients with traumatic fracture 6 weeks post-fracture as well as in age- and sex-matched controls. Three patients with active untreated Paget's disease of bone and matched controls were also studied.

The age in patients with fracture varied from 18 to 46 (average 29.4 \pm 11.8 years old). Levels of 11 β -PGF_{2 α} were significantly increased in patients with of bone fractures compared to age- and sex-matched controls (59.86 \pm 6.37 vs 41.26 \pm 5.54 ng/mmol creatinine). No significant increases in BAP or CTX were observed in the whole fracture cohort. Men and women fracture subgroups both showed significantly elevated 11 β -PGF_{2 α} levels compared to their respective controls (62.66 \pm 13.51 vs 35.75 \pm 9.03 and 57.90 \pm 6.02 vs 33.16 \pm 3.74 ng/mmol creatinine for men and women, respectively). The women fracture subgroup presented a significant increase in CTX excretion compared to control (0.499 \pm 0.095 vs 0.239 \pm 0.021 ng/ml) but that was not observed in the men subgroup. Correlation analyses showed no significant correlation between 11 β -PGF_{2 α} levels and BAP or CTX in the whole cohort. In patients suffering from Paget's disease of bone, urinary levels of 11 β -PGF_{2 α} were also significantly higher than the controls, however the sample size prevented us from performing statistical analysis. As expected in PDB patients, the level of BAP was also higher than the controls, indicating a high level of bone formation in these patients. These results support our working hypothesis that PGD₂ could be implicated in the control of bone anabolism and remodelling in vivo in humans. They also suggest that the urinary levels of 11 β -PGF_{2 α} could be a sensitive marker of osteoblast activity.

Bone Turnover in Late Gestation and Six Months Postpartum. J. P. Greeves¹, J. Achten², A. Jeukendrup³, W. D. Fraser⁴. ¹QinetiQ Ltd, Farnborough, United Kingdom, ²Clinical Sciences Research Institute, Coventry, United Kingdom, ³University of Birmingham, Birmingham, United Kingdom, ⁴University of Liverpool, Liverpool, United Kingdom.

Pregnancy and the postpartum period are associated with a loss of bone mass. The aim of the present study was to monitor changes in bone turnover from late gestation to six months postpartum. The study was approved by the North Birmingham Local Ethics Committee.

Early morning blood samples were obtained after an overnight fast in 15 Caucasian pregnant subjects (Preg) at 31 wk gestation (Gest) and at 8, 17 and 26 wk postpartum (PP). Samples were obtained at the same time points in seven non-pregnant controls (Con) during the follicular phase of the menstrual cycle. At 8 wk PP, ten Preg subjects were breast feeding, four were bottle feeding and one was mixed feeding. At 26 wk PP, four Preg subjects were breast feeding and three were mixed feeding. All subjects were non-smokers and followed a standardised diet for 24-h prior to blood sampling. Pregnant and control subjects were matched for age (mean (SD): 30.5 (3.3) vs 29.8 (3.2) y), pre-pregnancy body mass index (22.2 (0.5) vs 24.1 (2.1) kg-m²) and leisure time physical activity (437 (198) vs 409 (196) kcal-d⁻¹, respectively). Blood samples were analysed for markers of bone resorption (β -CTX), bone formation (P1NP and Bone ALP), and OPG.

Mean (1SD) data for Preg and Con are shown in the Table. There was a significant increase in β -CTX and P1NP from Gest to the PP period in Preg (p<0.05) but no change in Con. In Preg, β -CTX increased from Gest to 8 wk PP (p<0.001) and 17 wk PP (p<0.05), and P1NP remained elevated at all PP time points (p<0.05). Bone ALP increased significantly in Preg from Gest to 8 wk PP (p<0.05). OPG decreased during PP compared with Gest (p<0.01), and was unchanged in Con.

In conclusion, bone turnover was significantly elevated during the postpartum period, compared to 31 wk gestation. Elevated bone turnover helps to provide sufficient calcium for breastfeeding. OPG is the decoy receptor for RANKL and the decrease to control levels postpartum be required to allow RANKL to stimulate osteoclast-mediated bone resorption

Table: Markers of bone turnover (β -CTX, P1NP and bone ALP), and OPG at 31 wk gestation (Gest) and during postpartum (PP) (mean (1SD))

The use of Statins to Enhance Bone Mineralisation and Formation in 2D and 3D Tissue Engineered Constructs. S. Griffiths, S. Cartmell. Institute of Science and Technology in Medicine, University of Keele, Stoke on Trent, United Kingdom.

The culture of human bone cells for tissue engineering has great potential as a therapy for patients suffering from bone loss due to disease or trauma. This study has looked at using simvastatin, for the novel use of enhancing human bone cell tissue engineered constructs in vitro. Statins usually prescribed to lower cholesterol, can also enhance bone differentiation, maturation and matrix formation, with increased expression of BMP2 mRNA locally. Our study used simvastatin as a media supplement for in-vitro 2D and 3D primary human osteoblast seeded constructs, utilising gene expression analysis via Real-time RT-PCR, picogreen DNA assays, MicroCT and calcium analysis. Results of 2D cultures show low statin concentrations (0.001 microM) have a significantly increased proliferative effect in 3 (p=4.5E-05) and 7 day cultures (p=2.5751E-05), with a dosage dependent increase in BMP2 mRNA expression. This effect becomes significant after 1microM, though smaller doses also appear to have an enhancing effect (although this may be a result of increased proliferation). Higher optimised simvastatin concentrations (5microM) significantly reduce osteoblast proliferation (p=0.007), whilst gene expression showed significant increases in BMP2 and osteopontin mRNA suggest an increase in osteoblast differentiation and maturation at 7 days. This may be a result of the statin mechanism interacting with cell cycle regulators, pushing the osteoblasts into the maturation stage. 3D scaffold cultures showed increasing volumes of mineralised matrix production per cell in primary human cell cultures, using 5microM simvastatin as a media supplement. Optimised concentration/timing was then used in 2D cell culture, to maximise proliferation and mineralisation of bone constructs. Mineralisation and calcification were analysed using calcium assay/Von-Kossa staining, whilst picogreen DNA analysis was used for quantitative proliferative data. A further extension of this optimised experiment on a 3D hydroxyapatite scaffold is ongoing, with further analysis via MicroCT and microarray. Results suggest that various statin concentrations could be used with non-diseased bone tissue to enhance proliferation, differentiation and maturation of bone cells, when introduced at various culture periods to enhance mineralisation of extracellular matrix in bone tissue engineered constructs

Tartrate-Resistant Acid Phosphatase Is a Negative Regulator of Osteoblast Differentiation. H. C. Roberts^{*1}, R. Crossland^{*1}, T. M. Cox^{*2}, M. J. Evans^{*3}, A. R. Hayman¹. ¹School of Clinical Veterinary Science, University of Bristol, Langford, Bristol BS40 5DU, United Kingdom, ²Addenbrooke's Hospital, University of Cambridge, Cambridge CB2 2QQ, United Kingdom, ³School of Biosciences, University of Cardiff, Cardiff CF10 3US, United Kingdom.

Tartrate-resistant acid phosphatase (TRAP) is a molecule important in both the skeleton and the immune system. It is an iron containing protein expressed by osteoclasts, macrophages, dendritic cells and other cell types including osteoblasts. TRAP is secreted by osteoclasts during bone resorption and its serum activity correlates with the level of resorptive activity in certain bone diseases. We have shown using mice lacking TRAP (-/-) that TRAP is important for the normal development of the skeleton since the gross morphology of the bones in TRAP^{-/-} mice is abnormal. Femoral bones lacking TRAP were stronger and more mineralized and the rate of collagen turnover was increased. Femurs from knockout mice have increased tensile strength, increased MMP-2 activity and contain more total collagen cross-links. Osteoclasts from TRAP^{-/-} animals demonstrate reduced bone resorption in vitro. In this study we aim to determine the role of TRAP in the osteoblast.

We have isolated bone marrow from both TRAP^{-/-} and WT mice and used them in comparative studies. Alkaline phosphatase (ALP) activity was measured enzymatically using p-nitrophenyl phosphate as the substrate, and ALP protein by flow cytometry. Bone marrow cultures were grown to confluency (D-MEM/FCS/antibiotics). The cells were reseeded and the medium supplemented with 50µg/ml ascorbic acid and 50mM β-glycerolphosphate. At selected times cells were analysed for (i) cell viability using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT)-dye reduction assay. (ii) ALP activity, (iii) mineral deposition (iv) cbfa-1 expression.

Single-colour flow cytometry using a monoclonal antibody to ALP showed that the TRAP^{-/-} cultures had increased numbers of ALP positive cells compared to wild-type (2.4 fold, p<0.05). TRAP^{-/-} bone marrow cells showed an increase in ALP activity compared with WT (1.8 fold, p<0.05). The rate of cell growth in the TRAP^{-/-} cultures was significantly reduced (p<0.05) and cellular morphology was altered. In cultures of TRAP^{-/-} osteoblasts ALP levels were higher and mineralisation occurred earlier after 3-4 days compared with 7-10 days for WT osteoblasts. Conventional PCR demonstrated an increase in the expression of cbfa1 and osteocalcin in TRAP^{-/-} osteoblasts.

In conclusion, TRAP^{-/-} mice have abnormal osteoblast function leading to an increased rate of differentiation and enhanced mineralisation. This work suggests that TRAP is a negative regulator of osteoblast activity.

T005

Independent of Their Resorptive Activity, Osteoclasts Secrete an Activity Promoting Bone Formation and Canonical Wnt Signalling in Osteoblastic Cells. K. Henriksen¹, A. V. Neutsky-Wulff^{*1}, K. D. Hausler^{*2}, M. Ciccomancini^{*2}, C. Christiansen³, M. Gillespie², T. J. Martin², M. A. Karsdal¹. ¹Nordic Bioscience A/S, Herlev, Denmark, ²St. Vincent's Institute of Medical Research, Melbourne, Australia, ³Center for Clinical and Basic Research, CCB, Ballerup, Denmark.

Some osteopetrotic mutations lead to low bone resorption, increased numbers of osteoclasts and increased bone formation, whereas other osteopetrotic mutations lead to low resorption, low numbers of osteoclasts and decreased bone formation. These findings indicate that the osteoclasts independent of their resorptive activity could be sources of anabolic signals for the osteoblasts.

The aim of the current study was to investigate whether osteoclasts secrete bone anabolic signals, and to elucidate the signal transduction involved.

Conditioned media from mature human osteoclasts cultured on either bone slices or plastic

were collected. Measuring TRACP and CTX-I validated osteoclast maturity and resorption. Conditioned media were applied to cultures of MC3T3-E1 preosteoblasts, followed by bone formation assessment by Alizarin red and Von Kossa staining after 20 days' culture. We assessed key osteoblast regulatory pathways by using UMR106.01 cells transiently transfected with several reporter constructs. These were the TOPFlash vector, which contains 8 TCF/LEF response elements, the osteocalcin promoter with x6 tandem OSE repeats (6 x OSE), NFAT, AP-1 and NFκB. In each case appropriate positive control stimuli were used.

Conditioned media from osteoclasts cultured on either bone or plastic stimulated nodule formation by the MC3T3-E1 cells to levels comparable to stimulation with 10ng/mL BMP-2. Conditioned media from osteoclasts cultured on both bone and plastic specifically induced activation of the TCF/LEF response system at a level comparable to induction by 20ng/mL of Wnt3A. The Wnt 3a and conditioned medium signals were equally inhibited by addition of either 100ng/mL of DKK1 or sclerostin, consistent with activation of the canonical Wnt signaling pathway. No activation of the OSE, NFAT, NFκB, or AP-1 reporters was detected, suggesting specific wnt activity.

We present evidence that osteoclasts, independent of their resorptive activity, secrete an activity that stimulates osteoblastic bone formation. The same media contains an activity that signals through the wnt activation cascade, indicating a wnt as a possible anabolic product, i.e. a potential coupling factor, produced by the osteoclasts.

Alpha1 and Beta2 Adrenergic Agents Modify RANKL/OPG Expression and Cell Proliferation in Human Osteoblasts and Osteoblastic Cells. H. H. Huang, T. C. Brennan^{*}, M. M. Muir^{*}, R. S. Mason. Department of Physiology and Bosch Institute, University of Sydney, Sydney, Australia.

Previous studies have shown that central control of bone mass is mediated via beta2 receptors of the sympathetic nervous system ⁽¹⁾. Whether alpha adrenergic receptors are expressed in human bone cells is controversial ^(1,2). Takeuchi et al ⁽³⁾ showed that epinephrine increased both RANKL and OPG mRNA expression in murine osteoblast-like cells via beta and alpha adrenergic receptors. The aim of this study is to further investigate alpha and beta adrenergic receptors in human bone cells. Human osteoblastic MG63 cells and primary human fetal bone cells (FBC) were cultured in DMEM with 10% FBS then adapted to serum-free medium for 24 h before treatments were added. Alpha1b and beta2 adrenergic receptors were expressed in MG63 cells and FBC as determined by RT-PCR (alpha1b, beta2) and sequence analysis (alpha1b). In FBC, 10⁻⁵M cirazoline (specific alpha1 agonist) increased OPG and RANKL mRNA expression by 1.43 (p<0.01) and 1.36 (p<0.001) times respectively, while only high-dose cirazoline (10⁻³M) up-regulated OPG (3-4-fold) and RANKL (over 10-fold) in MG63. Fenoterol, (beta2 agonist) at 10⁻⁷M-10⁻⁵M dose-dependently up-regulated OPG mRNA expression (p<0.05) but only 10⁻⁷M fenoterol increased RANKL mRNA expression (p<0.05) in FBC. Phenylephrine (alpha1 agonist) dose-dependently increased cell replication in both FBC (10⁻⁶-10⁻⁴M) and MG63 (10⁻⁶-10⁻⁵M), as did cirazoline in FBC. The beta2 agonist fenoterol suppressed FBC proliferation (10⁻⁶-10⁻⁵, p<0.001). The maximal effects of cirazoline in FBC and phenylephrine in MG63 at 10⁻⁶M on proliferation were partially suppressed by 10⁻⁴M urapidil (alpha1 antagonist). These data indicate that alpha1 adrenergic receptors are present in human bone cells and could play a role in modulation of bone turnover by the sympathetic nervous system in human bone cells.

An Isoform of Fibronectin Is Responsible for Decreased Bone Formation in Patients with Primary Biliary Cirrhosis and this Effect Is Not Exclusively Mediated by beta1 Integrins. N. Kawelke^{*1}, A. Bentmann^{*1}, N. Hackl^{*1}, P. Feick^{*2}, M. V. Singer^{*2}, I. Nakchbandi³. ¹University of Heidelberg, Heidelberg, Germany, ²University of Heidelberg at Mannheim, Mannheim, Germany, ³University of Heidelberg and Max-Planck Institute for Biochemistry, Heidelberg, Germany.

Patients with chronic cholestatic liver disease experience a decrease in bone formation and density associated with an increase in fracture rates. The cause for this bone loss remains elusive. We have reported that oncofetal fibronectin (oFN) is elevated in patients with primary biliary cirrhosis (PBC) and correlates negatively with circulating osteocalcin levels. To determine a causal relationship between the elevation of oFN and bone loss in subjects with PBC we performed in vitro and in vivo experiments in mice.

Fibronectin (FN) was isolated from amniotic fluid (aFN) and characterized as containing both the EIIIA domain and the glycosylated variable region domain (oFN). In vitro experiments showed that mineralization by osteoblasts is diminished to the same degree whether aFN contained the EIIIA domain or not (71% vs. 78% decrease in mineralization using 100 ug/ml FN). This suggests that the presence of the glycosylated variable region was responsible for the decrease in mineralization.

Injection of aFN in CD1 mice for 10 days (1 mg/day/mouse) resulted in a 17% drop in trabecular BMD compared to controls ($p < 0.05$) as measured by pQCT. There was a 30% decrease in mineralizing surface (MS/BS = 44.7 ± 3.1 in controls vs. 31.2 ± 1.6 % in injected mice, $p < 0.005$), and a decrease of 45% in the number of osteoblasts (Ob.N/mm BS = 18.2 ± 1.4 in controls and 10.0 ± 0.8 in injected mice, $p < 0.05$).

In order to determine whether this effect is mediated by beta1 integrins we repeated the experiment in mice in which beta1 integrin was deleted using the collagen alpha1(I)-cre promoter (Beta1 integrin floxed/floxed-Collagen alpha1(I)-cre/+). Similarly to CD1 mice there was a significant decrease of 50% in the number of osteoblasts when aFN was injected over a period of 10 days (Ob.N/mm BS: 25 ± 3 vs. 13 ± 1 , $p < 0.01$; $n = 8$ controls and 4 injected mice).

In summary, we have shown that 1) in patients with PBC the glycosylated variable region of FN as recognized by the FDC-6 antibody correlates negatively with osteocalcin, 2) decreased mineralization by osteoblasts in vitro is caused by the presence of the same domain, and 3) injection of FN containing this domain in mice results in a significant decrease in osteoblasts number that is not exclusively mediated by the presence of beta1 integrins on the surface of osteoblasts expressing the collagen alpha1(I) promoter.

We therefore propose, that oncofetal fibronectin is responsible for decreased bone formation in patients with primary biliary cirrhosis.

Osteogenesis of the Human Ligamentum Flavum by Demineralized Bone Matrix. J. Lee^{*1}, H. Kim^{*2}, C. Lee^{*1}, M. Nan^{*1}, K. Lee^{*2}, S. Moon^{*3}, J. Park^{*3}, H. Kim^{*3}, J. Jahng³, H. Lee^{*3}, H. Kim^{*3}. ¹Orthopaedic Surgery, BK21 Medical Science Graduate School of Yonsei University, Seoul, Republic of Korea, ²Korea Bone Bank, Seoul, Republic of Korea, ³Orthopaedic Surgery, Yonsei University College of Medicine, Seoul, Republic of Korea.

Many attempts have been made to apply demineralized bone matrix for bone regeneration. It has been reported that DBM derived from human tissues induces bone formation and spinal fusion, and that DBM is widely used as a bone graft substitutes in orthopaedic and dental surgery. In addition, Ligamentum flavum (LF) was reported to have osteogenic potential with stimulation of bone morphogenetic protein-2 which is also included in DBM. Although many potential studies for osteogenesis by DBM have been evaluated, osteogenesis of human LF by DBM have not yet been found. In this study, we elucidated the effect of DBM on osteogenesis of human LF. Experimental group (human LF cell culture) was incubated in media solution containing 5mg/ml or 10mg/ml DBM for 2hr, 2day and 7days, and control group was incubated in media which have no DBM. To assess proliferation rate, we performed Alamar blue assay. To assess osteoinductivity, we performed RT-PCR of osteogenic marker gene and von-kossa, alkaline phosphatase (ALP) staining after incubating LF with DBM. DBM, LF and mixture of DBM and LF was implanted to nude mouse. After 28days, H&E staining was performed. Human LF cell cultured with DBM showed increased proliferation without cytotoxicity compared to control in dose-dependent manner. The expression of collagen type I, osteocalcin, osterix, dIIX5, Human MSX2 mRNA demonstrated upregulation of osteogenic phenotype. Also, result of ALP, von-kossa and H&E staining were shown that experimental group, LF by adding the DBM, showed positive osteogenesis compared to control group. We proved that human LF cells cultured with DBM showed increase in proliferation and upregulation of osteogenic phenotypes. Given osteogenic potential of human LF with DBM, autogenous LF can be used for carrier for DBM and bone graft substitute in spinal surgery. The application of mixture DBM and LF will likely be useful in the clinical reconstruction of bone.

Healing of Critical-sized Bone Defects by Endothelial Progenitor Cells. D. Lewinson¹, N. Rozen^{*2}, T. Bick^{*1}, B. Shemian^{*1}, A. Yayon^{*3}, M. Soudry^{*1}. ¹Research Institute for Bone Repair, Orthopaedic Surgery A, Rambam Health Care Campus, Haifa, Israel, ²Research Institute for Bone Repair, Rambam Health Care Campus, Haifa, Israel, ³ProChon BioTech LTD, Ness-Ziona, Israel.

In this study we developed a novel cell therapy method for promoting repair of large bone defects. Our model tested the healing potential of circulating autologous endothelial progenitor cells (EPC) in a critical-sized bone defect created in sheep tibia. Peripheral mononuclear fraction was isolated using LymphoprepTM (Axis-Shield, Oslo, Norway), seeded on fibronectin-coated plates and cultured in EBM-2 media supplemented with EGM-2MV SingleQuote (Clonetics, Cambrex Bio Science, MD, USA). The endothelial nature of adherent colonies was identified by incorporation of Dil-acetylated LDL (Molecular Probes, Oregon, USA), tube formation on Matrigel (BD Labware, MA, USA) and immunostaining for von Willebrand factor (Dako, Glostrup, Denmark). A defect of 3.2 cm was created in the mid-shaft of sheep tibia, partially preserving the periosteum. Two weeks later, a longitudinal wedge was cut along the regenerating tissue filling the gap, 2×10^7 EPC were transplanted into the formed tunnel and covered with the removed scar tissue. Sham-operated sheep served as controls. Bone regeneration was followed during the next three months by x-rays radiography every two weeks. At the end of the experiment, the operated fragment bone was removed and subjected to a detailed qualitative and quantitative 3-D evaluation at a resolution of 36 micrometers using a micro computed tomography (μ CT) imaging system (μ CT 40, Scanco Medical, Bassersdorf, Switzerland). No significant new bone formation was observed radiographically in 4 sham-operated sheep. In contrast, 5 out of six EPC-transplanted sheep showed full bridging at 3 months, starting 2 to 4 weeks post EPC transplantation. Data collected showed an increase of 500% of total tissue volume (TV), 700% of bone volume (BV) in EPC-transplanted gaps vs. sham-operated ones. Material density increased 2-folds both in the entire volume and in the mineralized tissue compartment. We conclude that EPC have a promising potential for healing of large bone defects.

How Does Hypoxia Contribute to the Formation of the External Apical Root Resorption In Vitro? D. Liu, Z. Ou^{*}. Developmental Sciences/Orthodontics, Marquette University, Milwaukee, WI, USA.

Objectives: External apical root resorption (EARR) is commonly seen in orthodontic patients. However, how the EARR is formed under orthodontic force is not known. When a mechanical force is applied to move a tooth, an immediate response is the compression of periodontal ligament, which often leads to occlusion of the capillary blood vessels in it, in turn, forms an ischemia zone within which all the surrounding cells are subjected to hypoxia. Cementoblasts are cementum (first barrier to be attacked during EARR) - forming cells and have been shown to be involved in the repair of EARR. Therefore, we hypothesize that hypoxia plays an active role in the formation of EARR via the regulation of cementoblasts. The purpose of this study is to investigate the effect of hypoxia on the biological responses of cementoblasts in vitro. Methods: OCCM.30 cells - an immortalized murine cementoblastic cell line (from Somerman MJ, U. Washington), were seeded onto glass slides coated with type I collagen ($10 \mu\text{g}/\text{cm}^2$) and grown in α -MEM with 10% FBS. Upon confluent, OCCM.30 cells were starved for 24 hours then subjected to 1% hypoxia challenge while controls were kept under normal culture condition of 95% air and 5% CO_2 . For the early signaling study, after the onset of hypoxia, media were collected at 5 and 15 minutes to determine the release of ATP and PGE_2 . For the long-term functional study, the cells were subjected to 1% hypoxia for 0.5, 1, 3, 6, 12 hours to determine the induction of hypoxia-inducible factor 1- α (HIF-1 α) and production of cyclooxygenase-2 (COX-2) and sclerostin (SOST - a negative regulatory protein for bone formation) by western blot analysis. Paired t test was used to compare hypoxia treated and untreated groups for each parameter with p value being set at 0.05. Results: For the short-term changes, 1% hypoxia induced a drastic release of ATP at 5min followed by increased PGE_2 release at 15min. For the long-term changes, 1% hypoxia significantly induced HIF-1 α production after 3 hours, with a peak reached at 12 hours. COX-2 production was significantly increased after 6 and 12 hours of 1% hypoxia. Interestingly, SOST was for the first time found not only expressed in OCCM.30 cementoblasts but also increased after 6-12 hours of 1% hypoxia. Conclusions: Our data indicate that hypoxia modulates both early molecular signaling and late functional responses of cementoblasts, suggesting its potential role in the modulation of cementum remodeling towards resorption. Clinically, mechanical load exceeding the capillary blood pressure leading to an ischemia-associated hypoxia in periodontal ligament should be avoided to reduce the risk of root resorption during orthodontics. This work was supported by AAOF and EOS research grants.

Indian Hedgehog Is Essential for Postnatal Bone. Y. Maeda^{*1}, R. G. Erben^{*2}, E. Schipani^{*3}, B. Lanske¹. ¹Developmental Biology, Harvard School of Dental Medicine, Boston, MA, USA, ²Department of Natural Science, University of Veterinary Medicine, Vienna, Austria, ³Endocrine Unit, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA.

Indian hedgehog (Ihh) is essential for chondrocyte proliferation/differentiation and osteoblast differentiation during prenatal endochondral bone formation. Recently we

reported the generation and characterization of tamoxifen-inducible conditional *Ihh* knockout mice (*Col2a1-Cre ER**; *Ihh* d/d), in which the *Ihh* gene was successfully ablated from chondrocytes after birth. Our results demonstrated for the first time that *Ihh* expression in postnatal chondrocytes is essential for maintaining a growth plate, and for sustaining trabecular bone, a normal articular surface, and eventual bone growth after birth. We also showed that Wnt signaling was significantly decreased in these mice suggesting that *Ihh* activates osteoblast differentiation via the Wnt signaling pathway in postnatal life. Loss of trabecular bone in the *Col2a1-Cre ER**; *Ihh* d/d mutants could be secondary to their growth plate abnormalities. To examine the direct role of *Ihh* on postnatal bone formation, maintenance of a growth plate in the mutants would be required. We, therefore, induced deletion of *Ihh* in chondrocytes at P14, after a secondary ossification center was formed. At P21, however, the growth plate was completely lost and time course experiments are being performed now to investigate the kinetics of this event. In order to dissect whether the loss of the growth plate or the lack of *Ihh* signaling itself in chondrocytes is responsible for the decrease in trabecular bone, we are now attempting to rescue the growth plate of the *Col2a1-Cre ER**; *Ihh* d/d animals by mating them to *col2a1*-constitutively active *PTH/PTHrP* receptor transgenic mice (*col2a1-Jansen*). Using such compound mutant mice, we anticipate rescue of the growth plate despite absence of *Ihh* signaling. This will allow us to study specific actions of chondrocyte-derived *Ihh* on postnatal bone.

Potential Involvement of Ephrin B2 in the Anabolic Action of PTH in Osteoblasts. E. H. Allan^{*1}, K. D. Hausler^{*1}, J. M. W. Quinn¹, J. Gooi^{*1}, T. Wei^{*2}, J. E. Onyia², N. A. Sims¹, M. T. Gillespie¹, T. J. Martin¹. ¹Bone, Joint & Cancer, St Vincent's Institute, Melbourne, Australia, ²Lilly Research Laboratories, Indianapolis, IN, USA.

The aim was to identify paracrine factors whose production is controlled by PTH and/or PTHrP, using a mouse marrow stromal cell line, Kusa 4b10 that acquires osteoblast features under differentiating conditions. After the appearance of functional PTH1R in Kusa 4b10 cells they were treated with either PTH(1-34) or PTHrP(1-141) for 1, 6 and 24 hours and RNA subjected to Affymetrix whole mouse genome array. The data was analysed statistically by SAM (significance analysis of micro-arrays). Of the 45101 probes used on the micro-array, 4621 probes or 3231 genes with functional annotations were differentially expressed by at least 1.5 fold with false discovery rate < 0.1. These genes were then functionally categorized into 228 groups according to their Gene Ontology. Among genes belonging to the family of Ephrins and their receptors, Ephrin B2 and Eph B2 were up-regulated in response to PTH and PTHrP. The effects were validated using independently prepared RNA samples from differentiated Kusa 4b10 cells, UMR106 rat osteogenic sarcoma cells, and primary mouse calvarial osteoblasts, as well as in vivo using RNA prepared from metaphyseal bone of 3 week-old rats 1.5 and 4 hrs after a single PTH injection. Stimulation of mRNA for Ephrin B2 by PTH and PTHrP was maximal at 4-6 hrs, with a 3-6-fold response. The effect was dose-dependent and the curve shifted to the left with phosphodiesterase inhibition. Western blotting showed a sustained increase in Ephrin B2 protein following treatment of Kusa 4b10 cells with PTH for 6, 12 and 24 hours. Neither IL-11 nor active vitamin D affected Ephrin B2 production. Whereas Ephrin B2 production was clearly regulated in osteoblasts by PTH/PTHrP through a cAMP/PKA mechanism, its baseline production remained unchanged throughout differentiation. No evidence was obtained for regulation by PTH/PTHrP of Eph B4 production, which also remained unchanged throughout differentiation. Eph B2 mRNA was increased 2-fold and Ephrin A5 decreased 2-fold after 6 hrs PTH or PTHrP treatment. Recent evidence implicates osteoclast-derived Ephrin B2 acting through its receptor, EphB4 in osteoblasts, to promote osteoblast differentiation, and through reverse signalling via EphB4 and possibly other members of the receptor family to suppress the formation of osteoclast precursors. The present data raise the possibility that ephrinB2 might act in a paracrine or autocrine manner on the osteoblast under the influence of PTH, and provide a local event related to the anabolic action of PTH.

Acceleration of Fracture Healing via Enhanced Vasculogenesis and Osteogenesis Through SCF/cKit Pathway in Lnk-Deficient Mice. T. Matsumoto¹, H. Nishimura^{*1}, Y. Mifune¹, T. Shoji^{*1}, R. Kuroda^{*2}, A. Kawamoto^{*1}, A. Oyamada^{*1}, M. Horii^{*1}, M. Miwa^{*2}, M. Kurosaka^{*2}, T. Asahara^{*1}. ¹Stem Cell Translational Research, Kobe Institute of Biomedical Research and Innovation / RIKEN Center for Developmental Biology, Kobe, Japan, ²Department of Orthopedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan.

Lnk, with APS and SH2-B, belongs to an intracellular adaptor protein family and was recently proved an essential inhibitory signal molecule of the stem cell factor (SCF)-cKit signaling pathway for self-renewal of stem cells in the findings demonstrating enhanced hematopoietic reconstitution in Lnk-deficient mice. We previously reported that systemic administration of human hematopoietic/endothelial progenitor cell (HPC/EPC)-enriched population induces osteogenesis as well as vasculogenesis and provides a favorable environment for functional bone healing in non-healing fracture model of immunodeficient rat. Therefore, we investigated the hypothesis that a lack of Lnk signaling enhances the regenerative response via vasculogenesis and osteogenesis in fracture healing in Lnk-deficient mice. In radiological and histological evaluations, reproducible model of closed femoral fracture in 10-week-old mice demonstrated more prompt fracture healing in Lnk-

knock out (KO) than wild-type (WT) mice (week2: KO, 70%; WT, 35%, p<0.01, week3: KO, 100%; WT, 90%, n=20). Serial FACS analysis of peripheral blood (PB) demonstrated significantly larger number of Sca1+ Lin- cells, HPC/EPC-enriched fraction (HPC/EPCs), in KO than WT (p<0.05), and significantly increased HPC/EPCs by fracture-stress with the peak at 1 day post-fracture (p<0.05). Among up-regulated gene expressions at the peri-fracture site by cDNA microarray in KO, angiogenesis/vasculogenesis (CD31, VE-cadherin, KDR) and osteogenesis (Osteocalcin, Collagen1A1, Cbfa1/Runx2) related gene expression assessed by real time RT-PCR were significantly enhanced 7 days post-fracture in KO compared to WT (p<0.01). Immunohistochemical staining at the peri-fracture site demonstrated significantly enhanced density of Sca1+ cell-derived endothelial cells (ECs)(Sca1+/CD31+) and osteoblasts (OBs)(Sca1+/Osteocalcin+) 7 days post-fracture in KO compared to WT (p<0.05). Moreover, in addition to a significant higher expression of plasma SCF in KO compared to WT by ELISA (p<0.01), SCF stimulation enhanced these mobilization and incorporation of HPC/EPCs even in WT and more in KO, confirmed by analysis of PB FACS (p<0.05), EC (p<0.05), and OB density (p<0.05). Our data suggest the therapeutic potential of negatively controlling the Lnk system via SCF-cKit pathway for promoting an environment conducive to vasculogenesis and osteogenesis so that fractures can heal promptly.

Bone Plays an Important Role in the Metabolism of Postprandial Lipoproteins in Mice: Impact on Osteoblast Function. A. Niemeier¹, D. Niedzielska^{*2}, R. Secer^{*2}, A. Schilling^{*3}, M. Merkel^{*4}, C. Enrich^{*5}, P. C. Rensen^{*6}, J. Heeren^{*2}. ¹Orthopaedics, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ²Biochemistry and Molecular Biology II: Molecular Cell Biology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ³Trauma- Hand- and Reconstructive Surgery, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ⁴Internal Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany, ⁵Biologia Cellular, Facultat de Medicina, Universitat de Barcelona, Barcelona, Spain, ⁶General Internal Medicine, Endocrinology and Metabolic Diseases, Leiden University Medical Center, Leiden, The Netherlands.

Dietary lipids and lipophilic vitamins are transported by postprandial lipoproteins and are required for bone metabolism. Despite that, it remains unknown whether bone cells are involved in the uptake of circulating postprandial lipoproteins in vivo. The current study was designed to investigate a putative participation of bone in the systemic postprandial lipoprotein metabolism in mice, to identify potentially involved cell type populations and to analyze whether lipoprotein uptake affects bone function in vivo.

As a model for the postprandial state, chylomicron remnants (CR) were injected intravenously into mice. Bone was compared to organs with an established role in CR catabolism. CR organ distribution and cellular uptake was analyzed by immunohistochemistry, confocal laser microscopy and electron microscopy. Radiolabeled CR were used for quantification of organ-specific plasma clearance and uptake into primary osteoblasts and hepatocytes. The effect of vitamin K1-enriched CR on plasma osteocalcin was determined by radioimmunoassay.

Next to the liver, bone appeared to contain the most active cells for the uptake of radioactive and fluorescent CR particles from the circulation in vivo. Immunostaining for apoE proved that intact CR particles were taken up in both liver and bone, but not in other organs. Uptake of CR by primary murine osteoblasts and hepatocytes was in a similar range in vitro. Localization studies in bone showed strongest primary binding to sinusoidal endothelial cells, while particle uptake was also observed into macrophages and osteoblasts. Enrichment of injected CR with vitamin K1 resulted in an increase of the degree of osteocalcin carboxylation in vivo.

In conclusion, bone is an organ of major importance in the postprandial lipoprotein metabolism. Bone function in vivo appears to be directly influenced by CR uptake, which has an impact on the secretory function of osteoblasts. This study uncovers a close functional relation between the systemic lipoprotein metabolism and bone metabolism.

Isolation and Immunohistochemical Analysis of Osteomodulin Expressed in Osteoblast. K. Ninomiya^{*1}, T. Miyamoto², N. Fujita^{*3}, T. Suzuki^{*1}, R. Iwasaki^{*4}, M. Yagi^{*3}, Y. Toyama^{*3}, T. Suda^{*5}. ¹Orthopaedic Surgery and Cell Differentiation, Keio University School of Medicine, Tokyo, Japan, ²Cell Differentiation, Orthopaedic Surgery and Musculoskeletal Reconstruction and Regeneration Surgery, Keio University School of Medicine, Tokyo, Japan, ³Orthopaedic Surgery, Keio University School of Medicine, Tokyo, Japan, ⁴Dentistry and Oral Surgery and Cell Differentiation, Keio University School of Medicine, Tokyo, Japan, ⁵Cell Differentiation, Keio University School of Medicine, Tokyo, Japan.

The bone volume is regulated with the well-controlled balance between bone-resorbing osteoclast and bone-forming osteoblast, which is called coupling. Although coupling is a well-known phenomenon, coupling factor has not been identified. To isolate the coupling factor, we performed microarray and cluster analysis among rat 13 tissues, and isolated osteomodulin (OMD) as a candidate of coupling factor. OMD is an extracellular matrix keratin sulfate proteoglycan that belongs to small leucine-rich repeat proteoglycans (SLRPs). Though OMD is not expressed in osteoclast, the expression of OMD couples with osteoclast markers such as matrix metalloproteinase-9 (MMP-9) and tartrate-resistant acid phosphatase (TRAP) in bone. SLRPs are known to have diverse functions such as regulation of matrix assembly, cell growth, and cell differentiation. In *in vitro*, OMD is expressed in primary osteoblasts and is upregulated during osteoblastic differentiation. To investigate the localization of OMD in *in vivo*, we established an anti-OMD polyclonal antibody. OMD is mainly produced by alkaline phosphatase (ALP) positive osteoblast. The specificity of the anti-OMD antibody was confirmed by the blocked immunoreactivity of the antibody by synthetic peptide. Op/op mice are osteopetrotic because of defective osteoclast formation due to the lack of macrophage colony-stimulating factor (M-CSF) production. Intriguingly, the immunoreactivity of anti-OMD antibody in trabecular bone in op/op mice is weaker than that of wildtype mice. Since osteoblasts do not express c-fms, a M-CSF receptor, the reduced OMD expression in op/op mouse is confirmed based on the lack of coupling due to a defect of osteoclast formation. We also confirmed that expression of OMD in C2C12 cells increased accompanied by an upregulation of ALP activity during osteoblastic differentiation. Because some members of SLRPs inhibit signal of transforming growth factor (TGF), OMD could modulate differentiation of osteoblast and osteoclast by inhibition of TGF signal. Our results suggest that OMD is expressed in osteoblasts especially activated by osteoclast.

Induction of Mineralized Tissues by In Vivo Transplantation of Cultured Rat Dental Pulp Cells in Rat Calvarial Bone Defects. H. Ohba, H. Seto, K. Tokunaga, H. Hama, Y. Inagaki, M. Horibe, E. Takeda, T. Nagata. Health Biosciences, Tokushima, Japan.

Dental pulp tissues have a potency to form mineralized tissues. We investigated the ability of dental pulp cells for mineralized tissue induction *in vitro* and *in vivo*. Dental pulp tissues were extracted from maxillary incisors of male Wistar rats. The tissues were minced and digested with 0.5% trypsin and 0.02% EGTA. Dissociated cells were cultured in Eagle's MEM. After subconfluency, cells were collected and seeded in multi-well plate with or without 2 mM β -GP and 50 μ g/ml ascorbic acid. Alkaline phosphatase (ALP) activity was determined on days 1 and 5 and the von Kossa staining was performed to detect bone nodule (BN) formation on day 20. Also, the association of bone morphogenetic protein (BMP) on such a mineralized tissue formation was determined by ELISA. The subconfluent dental pulp cells were collected and used in the following *in vivo* study. Bone defects were made in male Wistar rat calvaria (hole shape, 3.8 mm diameter). The collected dental pulp cells were transplanted in the defects with collagen sponges including 1% collagen gel (2.5×10^6 cells/ml). After 8 weeks, rat calvariae were taken out and analysed by soft X-ray and histological examinations. Results showed that ALP activity increased and BNs were clearly formed in the dental pulp cell cultures. ELISA assay showed that dental pulp cells produced BMP and the amount of BMP in the condition medium time-dependently increased, showing 3-fold amount of BMP compared to the control on day 15. The soft X-ray and histological examinations revealed that the transplantation of dental pulp cells induced a greater amount of bone-like tissues in the inside of calvarial bone defects than in the controls, showing 4-fold increase of radiopaque area. Hematoxylin and eosin staining demonstrated that there were many osteoblast-like cells around the new-formed tissues. Present findings indicate that bone defects were recovered by the transplantation of dental pulp cells, suggesting that dental pulp cells have a potency to form mineralized tissues in association with BMP production.

Disclosures: H. Ohba, None.

Imatinib Mesylate Inhibits Bone Formation and Decreases Bone Mass In Vivo by Inhibiting PDGFR-Mediated Osteoblast Mitogenesis. S. O'Sullivan^{*1}, D. Naot^{*1}, K. Callon^{*1}, M. Watson^{*1}, G. Gamble^{*1}, M. Karsdal^{*2}, M. Ladefoged^{*2}, J. Cornish¹, P. Browett^{*3}, A. Grey¹. ¹Medicine, University of Auckland, Auckland, New Zealand, ²Nordic Bioscience, Herlev, Denmark, ³Pathology and Molecular Medicine, University of Auckland, Auckland, New Zealand.

Imatinib mesylate, an orally active inhibitor of the c-abl (including bcr/abl), c-kit and platelet-derived growth factor receptor (PDGFR) tyrosine kinases, is in clinical use for the treatment of chronic myeloid leukaemia (CML) and gastrointestinal stromal cell tumours (GIST). Genetic interruption of both c-kit and c-abl signaling in mice induces osteopenia, and treatment with PDGF increases bone mass in rodents, suggesting that imatinib might have adverse effects on the skeleton. *In vitro*, imatinib exerts complex effects in bone cells. It inhibits the proliferation of osteoblast-like cells induced by both low-dose serum and PDGF. Neither addition of SCF, the c-kit ligand, nor siRNA-mediated knockdown of c-abl, alters osteoblast mitogenesis. Imatinib dose-dependently increases osteoblast differentiation, also by inhibiting PDGFR signaling, an observation that might explain the early increase in bone formation markers observed in humans with CML starting therapy with imatinib. In murine bone marrow cultures, imatinib inhibits osteoclastogenesis stimulated by 1,25 dihydroxyvitamin D₃ and partially inhibits osteoclastogenesis induced by treatment with RANKL and M-CSF. Consistent with these findings, imatinib partially inhibits osteoclastogenesis in RANKL-stimulated RAW-264.7 cells. Treatment with imatinib increases the expression of OPG in bone marrow from CML patients, and osteoblastic cells *in vitro*. In order to elucidate the skeletal effects of imatinib *in vivo*, we treated 6 month old Wistar rats with vehicle, imatinib 40mg/kg/day or imatinib 70mg/kg/day, for 5 weeks. Trabecular bone volume, assessed at the proximal tibia by micro-CT, declined by 20% in the imatinib-treated rats ($p < 0.05$ vs vehicle). Serum osteocalcin (Rat-Mid) fell by 40% in response to imatinib therapy ($p < 0.01$ vs baseline). There was no evidence for an anti-resorptive effect of imatinib *in vivo* (CTX-I). Collectively, these results suggest that the dominant skeletal action of imatinib *in vivo* is inhibition of osteoblast mitogenesis by interruption of PDGFR signaling, leading to decreased bone formation and a decline in bone mass. Clinical studies should be undertaken to assess the effect of long-term imatinib therapy on bone mass in humans. These results also suggest that PDGFR signaling in osteoblasts may regulate bone mass *in vivo*.

Expression of Metalloproteinase-14 Is Pleiotropic on Alkaline Phosphatase Expression in Osteogenic Differentiation. D. Palmieri^{*}, S. Soldano^{*}, S. Zanotti^{*}, D. Lombardini^{*}, P. Manduca. DiBio, University of Genoa, Genova, Italy.

It is known that modulation of the expression of AP and MMP-14 are developmentally regulated during osteogenesis.

We here report that in ROB (rat tibia-derived osteoblasts), during early and pre-mineralization stages of osteogenesis, the modulation of the expression of MMP-14 affects that of AP which later jointly condition the formation of nodules and the mineralization of the osteogenic population. We show that the level of expression of MMP-14 affects pleiotropically the expression of AP by up or down modulating, at transcriptional or post-transcriptional levels the expression of either gene in ROB and in cloned derivative lines. Changes in MMP-14 were obtained by activating antibodies or inhibitors or observed in selected clones:

- 1 - Constitutive expression of MMP-14, obtained by exposure to activating antibodies, determines constitutive expression of AP: no nodules form, no mineralization occurs in the population.
- 2 - Inhibitors of MMP-14 inhibit also the expression of AP: no nodules form, no mineralization occurs in the population.
- 3 - Clones constitutive for MMP-14 are constitutive also for AP: no nodules form, no mineralization occurs in the population.

Vice versa, modulation of the expression of AP by GF or fluorides or by inhibitors has no effect on the expression of MMP-14:

- 1 - Over-induction of AP by F compounds, by IGFII and by ET does not affect the expression of MMP-14: enhanced nodule formation and mineralization occur in the population.
 - 2 - Inhibition of AP by Levamisole or by inhibition of endogenous ET, does not affect the expression of MMP-14: nodules form, but their mineralization is reduced.
 - 3 - Inhibition of AP by Levamisole in clones constitutive for MMP-14 and AP, does not affect the expression of MMP-14: no nodules form, no mineralization occurs.
- In conclusion, at the onset of osteogenesis, MMP-14 expression is pleiotropic on AP, not vice versa. Transient up-modulation of both is required for nodule formation and mineral deposition. Down-modulation of MMP-14 is required for nodule formation. Down modulation of both enzymes is associated with mineralization.

Role of PLF in Remodeling of Bone Following Injury. S. Rani^{*1}, M. F. Barbe¹, A. E. Barr^{*2}, J. Litvin^{*1}. ¹Anatomy and Cell Biology, Temple University, Philadelphia, PA, USA, ²College of Health Professions, Temple University, Philadelphia, PA, USA.

Periostin-Like-Factor (PLF) is expressed in developing bone and is up regulated in adult bones that undergo remodeling due to fractures or repeated high force activity which leads to inflammation followed by injury of the bone. PLF over expression by adenovirus in the bone marrow cavity of rats resulted in increased bone formation. Together, these findings suggest that PLF plays an important role in bone formation. To test the hypothesis that PLF promotes bone formation under conditions of remodeling, tissues obtained from the novel model of Upper Extremity-Work-Related Musculoskeletal Disorder (WMSD) in the rat were obtained and subjected to ELISA, immunostaining and Western blot analysis. Twenty two young adult female Sprague Dawley rats were trained to perform a High Repetition High Force (HRHF) voluntary reaching and pulling task, with a food pellet reward. This task entails pulling a lever isometrically at a target rate of 4 reaches/min with 60% max grip force for 2 hrs/day in four 30 min sessions separated by 1.5 hr each, 3days/week and leads to mechanical loading of bone. Loaded bone responds by remodeling and under extreme situations stress fractures and resorptive spaces develop. Tissues from the reach limbs of performing rats and from randomly selected forelimbs of control rats were obtained at various times and subjected to immunostaining and Western blot analysis. To investigate the expression of pro-inflammatory cytokines ELISA assay was done on the bone of performing and control animals.

PLF protein was markedly up regulated in the bone of the performing limb of animals exposed to high force and repetitive motion, and the spatial pattern of PLF expression varied over the course of remodeling. Its expression peaked at 6 weeks, during the 12 week-work regimen. It was detected in the periosteum which contains mesenchymal pre-osteoblasts of the ulna and radius, in osteocytes and osteoclasts. It was secreted from proliferating and hypertrophied chondrocytes. The pro-inflammatory cytokines TNF- α and IL-1, also peaked in the bone at 6 weeks of task performance, suggesting a link between the PLF up regulation and the inflammation process.

The expression of PLF in bones undergoing remodeling, recovery and repair suggests that PLF plays a significant role in formation and maintenance of bone tissue. Its up regulation concomitant with the presences of high levels of pro-inflammatory mediators also suggests that it has a role in the inflammatory processes. In future experiments the role of PLF in remodeling and inflammation mediated processes will be examined in depth in the WMSD and other fracture repair models.

Pitx2 Inhibits Osteoblastic Conversion of Myoblasts Through Interfering the Promoter Activity of Osterix Gene. M. Hayashi^{*1}, S. Maeda¹, H. Aburatani^{*2}, K. Miyazono^{*3}, T. Imamura¹. ¹Department of Biochemistry, The Cancer Institute of the Japanese Foundation for Cancer Research, Tokyo, Japan, ²Genome Science Division, Research Center for Advanced Science and Technology, University of Tokyo, Tokyo, Japan, ³Department of Molecular Pathology, Graduate School of Medicine, University of Tokyo, Tokyo, Japan.

Bone morphogenetic protein (BMP) gives osteoblastic phenotype to myoblast C2C12. The osteoblastic conversion is accompanied by induction of Runx2 and Osterix. However, during the differentiation, C2C12 cannot form calcified bone nodules, which suggests osteoblastic maturation process is inhibited. We have found that induction of Osterix by BMP in C2C12 was transient, which decreased after 24 hours after stimulation. We hypothesized that there may be an inhibitory factor to suppress the expression of Osterix in this period. We screened nuclear proteins of repressors, which were induced late after 24 hours of BMP-stimulation in C2C12, by microarray technique. The expression of paired-like homeodomain transcription factor 2 (Pitx2) up-regulated gradually after 24 hours, and peaked at day four, and remained high level over one week. Since this induction was not seen in osteoblasts and other osteoblastic progenitors, the expression of Pitx2 by BMP may be exclusive to myoblasts. The overexpression of Pitx2 in C2C12 inhibited the induction of Osterix, not Runx2, which was followed by suppressed osteoblastic differentiation. C2C12 cells induced by shRNA for Pitx2, or MEF isolated from Pitx2 null mice showed enhanced induction of Osterix by BMP with elevated expression of ALP, bone sialoprotein and osteocalcin, while no difference on Runx2 was observed. Finally, we found some putative Pitx2 binding elements (PBE) in the promoter of osterix gene, one of which was shown to be functional target for Pitx2 by gel shift and ChIP assays. These results suggest that Pitx2 play a unique role in myoblast to suppress osteoblastic conversion through inhibiting the expression of Osterix. Thus, Pitx2 may be the first therapeutic target for muscle ossifying diseases, such as fibrodysplasia ossificans progressiva, in which cells BMP signaling is tend to be accelerated.

TRP Channels Are Both Present and Functional in Human Osteoblast-like Cells. N. C. Henney^{*1}, B. A. J. Evans², A. K. Campbell^{*3}, K. T. Wann^{*1}.

¹Welsh School of Pharmacy, Cardiff University, Cardiff, United Kingdom,

²Department of Child Health, Cardiff University, Cardiff, United Kingdom,

³Department of Medical Biochemistry & Immunology, Cardiff University, Cardiff, United Kingdom.

Transient receptor potential (TRP) cation channels are currently drawing a lot of interest in many tissues, but relatively little interest in bone. TRP channels are mostly non-selective and are generally widely expressed with increased expression in some malignancies¹, and TRPV1 and TRPM8 ligands, for example, may have potential uses as anti-cancer agents² in prostate malignancy. As prostate cancer cells metastasize to and cohabit with bone cells, this area of research is potentially important and deserves attention. The putative roles of TRP channels include growth, repair, metastasis, apoptosis and cell calcium entry - all of which are relevant to osteoblasts. We aim to show that TRP channels are present and active in osteoblast-like cells.

RT-PCR was carried out using intron-spanning primer pairs for TRPV1, TRPV5, TRPV6, TRPM7 and TRPM8 subunits in MG63 and SaOS-2 osteoblast-like cells. Cell proliferation assays were performed over 72 hours to test the effects of known TRP ligands on cell number, using trypan blue exclusion testing and MTS-conversion assay. Patch-clamp analysis was performed on MG63 and SaOS-2 cells using calcium-free and/or sodium gluconate solutions to minimise the confounding influence of other channel subtypes.

RT-PCR has revealed appropriate sized bands for TRPV1, TRPV5, TRPV6, TRPM7 and TRPM8 in MG63 and SaOS-2 cell lines. In cell proliferation assays, $\geq 10 \mu\text{M}$ capsaicin or capsaizipine significantly reduced MG63 cell number ($P < 0.05$), but $1 \mu\text{M}$ capsaizipine antagonises the effects of $\geq 10 \mu\text{M}$ capsaicin. In addition, resiniferatoxin (TRPV1 agonist), SB366791 (TRPV1 blocker) and anandamide (cannabinoid and TRPV1 modulator) all decreased MG63 cell numbers. Patch-clamp analysis has revealed small conductance channels of 18 - 30 pS in excised inside-out patches, and slightly larger conductance channels in cell-attached and inside-out patches at depolarised and hyperpolarised potentials in MG63 and LNCaP (prostate cancer) cells.

Given our preliminary data, we propose that five members of the TRP channel family are expressed in osteoblast-like cell lines, and we show electrophysiological and pharmacological data which lead us to suggest that at least one TRP channel type is active and functional in bone. TRP channels could therefore be new targets in the battle against bone disorders, and some known TRP channel ligands could be included in that armoury.

A Lymphoid Enhancer Binding Factor (Lef) 1 Isoform Regulates Osteoblast Maturation. L. H. Hoepfner¹, E. D. Jensen^{*2}, J. J. Westendorf³.

¹Graduate Program in Microbiology, Immunology and Cancer Biology,

University of Minnesota, Minneapolis, MN, USA, ²University of Minnesota,

Minneapolis, MN, USA, ³Department of Orthopedic Surgery, Mayo Clinic,

Rochester, MN, USA.

Lymphoid Enhancer Binding Factor (Lef) 1 is a transcription factor linked with the Wnt/LRP5/ β -catenin signaling cascade, which regulates osteoblast proliferation and survival, bone density and skeletal strength. We previously demonstrated that suppression of Lef1 promotes osteoblast mineralization while Lef1 overexpression blocks osteoblast maturation. We also showed that Lef1 blocks Runx2-dependent activation of the osteocalcin promoter. In this study we demonstrate that Lef1 blocks activation from the neighboring Runx2 binding site, even when the sequence is changed from a Runx binding element to a GAL4 DNA binding element. A truncated form of Lef1 (Lef1 ΔN) that lacks the β -catenin binding domain does not repress osteocalcin expression as well as full-length Lef1, even though it retains a functional DNA binding domain. Lef1 ΔN is transcribed from a promoter in the intron between exons 2 and 3 in humans (exons 3 and 4 in mice). Runx2 binds a consensus Runx binding element in this promoter and activates transcription of the Lef1 ΔN transcript. Northern blot analysis indicates that the 2.3 kD Lef1 ΔN transcript is not present in undifferentiated MC3T3-E1 preosteoblasts but becomes detectable after six days of osteogenic stimulation. These data suggest that premature expression of Lef1 ΔN in osteoblast progenitors might block osteoblast differentiation. To test this hypothesis, we stably overexpressed Lef1 ΔN in the murine myo-osteoblast progenitor C2C12 cell line and induced differentiation in osteogenic medium containing ascorbic acid, β -glycerol phosphate, and BMP2. Lef1 ΔN overexpression decreased the rate of alkaline phosphatase production compared to control cells. Together these data suggest that Lef1 ΔN is a Runx2 target gene and an important regulator of osteoblast differentiation. Our model predicts that Lef1 ΔN is normally expressed during the maturation process where it competes with endogenous Lef1 for binding elements and thereby mitigates the Wnt signaling pathway. If expressed earlier, Lef1 ΔN blocks preosteoblast maturation.

Orphan Nuclear Receptor Small Heterodimer Partner (SHP) Promotes Osteoblast Differentiation by Regulation of Runx2 Activity. B. Jeong*, I. Bae*, I. Kim*, J. Koh. Dental Science Research Institution and Brain Korea 21 project, School of Dentistry, Chonnam National University, Gwangju, Republic of Korea.

Orphan nuclear receptor small heterodimer partner (SHP) is an atypical member of the nuclear receptor superfamily, regulating transcription of target genes without a conventional DNA binding domain. This study was undertaken to elucidate roles of SHP in osteoblast differentiation. Primary osteoblasts, mesenchymal progenitor cell lines, and C2C12 were cultured with or without BMP2 (300 ng/ml), and SHP expression was determined by RT-PCR analyses. For evaluation of osteoblast differentiation, alkaline phosphatase (ALP) activity, osteocalcin (OC) production, and Alizarin Red staining assays were done with adenoviral infection of BMP2 and/or siRNA-SHP. To examine transcriptional regulatory actions of SHP, 6XOSE- or OG2 promoter was transfected with Runx2 plasmid. During the BMP2-induced osteoblast differentiation of C2C12 cells, SHP mRNA increased. Transient transfection of SHP significantly promoted the Runx2-dependent stimulation of OG2 or OSE promoter. Knocking down SHP expression by adenovirus siRNA-SHP inhibited BMP-2 induction of ALP activity, OC production, and mineralization with down-regulations of ALP, OC and bone sialoprotein mRNA. These results indicate that orphan nuclear receptor SHP may act as a positive regulator of osteoblast differentiation and mineralization.

Opposing Effects of Glucocorticoids and Wnt Signaling on Krox20 and Mineral Deposition in Osteoblast Cultures. N. Leclerc*¹, T. Noh*¹, J. Cogan*¹, D. B. Samarawickrama*¹, E. Smith*², B. Frenkel¹. ¹Biochemistry and Molecular Biology, University of Southern California, Los Angeles, CA, USA, ²Orthopaedic Surgery, University of Southern California, Los Angeles, CA, USA.

The beneficial anti-inflammatory properties of glucocorticoids (GCs) are associated with inhibition of osteoblast-mediated bone formation, leading to osteoporosis. We previously discovered Krox20 as the transcription factor most strongly repressed by GCs in osteoblast cultures, and showed that GC-inhibition of Osteocalcin (OC) transcription was mediated via suppression of an OC Krox20-binding Enhancer (OKE) located immediately upstream of the Runx2-binding OSE2 site. Because GCs also inhibit Wnt signaling, a major regulator of bone mass, we pursued a possible linkage between GCs, Wnt signaling and Krox20 in osteoblasts.

We first characterized the expression pattern of Krox20 in MC3T3-E1 and primary calvarial osteoblast cultures treated or not with 1 μ M dexamethasone (DEX). RT-qPCR analysis showed that Krox20 expression was the highest during late stages of osteoblast differentiation. DEX decreased Krox20 mRNA to 50 % of control levels within 15 minutes, suggesting a direct effect. Long-term repression of Krox20 by DEX, however, required new protein synthesis, as it was alleviated after a 4 hours cycloheximide treatment. We previously showed that activity of the OKE was absent in undifferentiated osteoblasts and that fibroblasts acquired OKE activity upon forced expression of Runx2. Here, we ruled out the requirement for Runx2 binding in cis -the OKE remained active after the OSE2 site was mutated. We then examined the possibility that Krox20 is regulated by the Wnt signaling pathway. Indeed, Wnt3A stimulated both Krox20 expression and activity of the OKE, whereas two other bone anabolic agents, BMP2 and PTH(1-34), failed to do so. We next addressed the involvement of Wnt signaling in the DEX-repression of Krox20. DEX-inhibition of Wnt signaling was only partially responsible for the 6-fold repression of Krox20 by DEX, as DKK-1 did not completely abolish it but rather reduced it down to 3.7-fold. Finally we asked whether treatment with Wnt3A could antagonize the inhibitory effects of GCs on both Krox20 and the osteoblast phenotype. Wnt3A partially rescued Krox20 expression in DEX-arrested osteoblast cultures and this was associated with rescue of mineralization. However, mineralized nodules only formed when Wnt3A was administered briefly, not chronically, and they were morphologically different from those formed in control cultures.

Our findings are consistent with a role for Krox20 in osteoblast function and suggest that it may contribute to the opposing effects of GCs and Wnt signaling on bone formation.

Vimentin Negatively Regulates Osteoblast Differentiation by Inhibiting the Transactivation Activity of Atf4. N. Lian*, X. Yang. Center for Bone Biology, Department of Pharmacology, Vanderbilt University, Nashville, TN, USA.

Our previous work has identified Atf4 as an osteoblast-enriched transcription factor that is required for osteoblast terminal differentiation and function (Yang et al. 2004; Yang and Karsenty, 2004). Atf4 transactivates gene transcription of osteocalcin, an osteoblast-specific and mature osteoblast marker gene, by binding directly to its osteoblast-specific cis-acting element, OSE1. The transactivation activity of Atf4 is positively regulated by phosphorylation by RSK2, a protein kinase whose mutation causes Coffin-Lowry syndrome (CLS). CLS is characterized by mental retardation and skeletal manifestations. In this study we found, by chromatography and mass spectrometry using purified Atf4 protein and osteoblast nuclear extracts, that Atf4 interacts with vimentin, a member of type III intermediate filament proteins. Interaction between Atf4 and vimentin was confirmed by a reciprocal co-immunoprecipitation in COS1 cells that overexpress both Atf4 and vimentin. Vimentin may play a specific role in osteoblast biology since our RT-PCR and Northern hybridization assay results showed that its mRNA expression is enriched specifically in bone and lung. Consistent with published studies vimentin is localized in both cytosol and nucleus as demonstrated by expressing a fusion protein of green fluorescent protein and vimentin in COS1 cells. To determine whether vimentin affects Atf4's transactivation activity, we performed co-transfection assays using osteocalcin promoter-luciferase reporter constructs and expression vectors encoding Atf4 and/or vimentin. Our results showed that vimentin decreased 80% of the activation of the osteocalcin reporter gene by Atf4. This inhibition is specific because vimentin did not affect the transactivation of a reporter gene by FosB, a transcription factor of the AP1 family. Gel retardation assays showed that this inhibition was caused by the fact that vimentin directly interferes with the binding of Atf4 to OSE1. To further determine the function of vimentin in the osteoblast differentiation process, we have established cell lines that stably overexpress Atf4, vimentin or both. Our results revealed that vimentin affects in osteoblast differentiation and function as shown by measurements of alkaline phosphatase activity, mineralization rate, and expression patterns of osteoblastic marker genes. Together our data suggest that vimentin is not only a structural protein that provides mechanical support for the plasma membrane but also acts as a negative regulator of osteoblast differentiation via its interaction with Atf4.

The microRNA miR-26a Targets the SMAD1 Protein During of Human Adipose Tissue-Derived Stem Cells. E. Luzi*, F. Marini*, S. Carbonell Sala*, I. Tognarini*, G. Galli*, A. Falchetti, M. Brandi. Internal Medicine, University of Florence, Florence, Italy.

Human Adipose Tissue-Derived Stem cells (hADSCs) are a cell population capable to differentiate in adipogenic, osteogenic, chondrogenic, myogenic, and neurogenic lineages. Although different studies suggest a high osteogenic potential for hADSCs, the molecular mechanisms that regulate hADSCs differentiation towards osteogenic precursors and subsequent bone-forming osteoblasts is unknown. MicroRNAs (miRNAs) are a family of naturally occurring, evolutionary conserved, small (approximately 19-23 nucleotides), non-protein-coding RNA molecules that negatively regulate post-transcriptional gene expression. miRNAs are estimated to account for >3% of all human genes and to control expression of thousands of target mRNAs, with multiple miRNAs targeting each mRNA. A role for miRNAs has been identified in both physiological and pathological conditions, encompassing metabolism, proliferation, cell death, differentiation, development, and insulin secretion from pancreatic beta cells, viral infection, and cancer. With few exceptions, physiological targets for miRNAs remain to be identified. Understanding miRNAs function is critically dependent on the identification of its targets. Nucleotides 2-8 (referred to as "seed") of the miRNAs are crucial in determining target specificity. Using osteoblast precursors obtained by subcutaneous human adipose tissue we were able to demonstrate that miR-26a levels increased in differentiating osteoblasts and that the inhibition of miR-26a, by 2'-O-methyl-antisense RNA, increased protein levels of the mothers against decapentaplegic homolog 1 (SMAD1) transcription factor in treated osteoblasts, up-regulating bone marker genes and, thus, enhancing osteoblast differentiation. Our data showed that combined expression and functional data suggest a role for miR-26a in the differentiation of hADSCs towards the osteogenic lineage by targeting its predicted target, the SMAD1 protein.

Osteoblastic Master Regulator Osterix Mediates the Feedback Regulation of BMP-2 Auto-Expression via PI 3 Kinase/Akt Signaling. C. C. Mandal¹, G. Ghosh-Choudhury^{*2}, H. Drissi³, N. Ghosh-Choudhury⁴. ¹Pathology, University of Texas Health Science Center at San Antonio, San Antonio, TX, USA, ²Medicine, UTHSCSA, GRECC, STVHCS, San Antonio, TX, USA, ³Orthopedics, University of Rochester, Rochester, NY, USA, ⁴Pathology, UTHSCSA, STVHCS, San Antonio, TX, USA.

We have recently reported the requirement of phosphatidylinositol 3 kinase (PI3K)/Akt signal transduction in BMP-2-induced osteoblast differentiation and mature bone nodule

formation. BMP-2-inducible Zn-finger transcription factor, osterix (Osx), is required for bone formation during mouse skeletogenesis. The mechanism by which BMP-2 increases Osx expression is not known. BMP-2 increased expression of Osx protein in a time-dependent manner in the cytosol and nucleus of C2C12 cells, concomitant with Osx mRNA expression. PI3K inhibitor, Ly294002, significantly inhibited BMP-2-induced Osx mRNA and protein abundance. Infection of C2C12 cells with adenovirus vectors expressing dominant negative PI3K or PTEN, a negative regulator of PI3K signaling, blocked expression of Osx mRNA and protein in response to BMP-2. Adenoviral-mediated expression of dominant negative Akt kinase (AdDNakt), a target of PI3K, inhibited BMP-2-induced Osx expression. These data for the first time indicate a critical role of PI3K/Akt signaling in osteogenic transcription factor Osx expression during osteoblast differentiation. To investigate the mechanism of Osx expression, we investigated its transcription using reporter construct in which 5'-flanking sequence of Osx gene drives firefly luciferase cDNA (Osx-Luc). Transient transfection of Osx-Luc into C2C12 cells showed increased Osx transcription in response to BMP-2. Analysis of the progressive 5' deletions of the Osx promoter revealed the presence of BMP-2 responsive sequence between -800 bp and -500 bp with respect to the transcription start site. Inhibition of PI3K and Akt kinase activity by Ly294002 or by expression of dominant negative lipid kinase, PTEN and AdDNakt respectively, abolished BMP-2-induced transcription of Osx. BMP-2-induced BMP-2 expression is necessary for sustained osteoblast differentiation. The mechanism is not known. We show that expression of Osx increased the transcription of BMP-2 gene, resulting in BMP-2 protein and alkaline phosphatase protein expression in osteoblasts. Together these results for the first time demonstrate that PI3K/Akt signaling regulates the expression of osteogenic master transcription factor Osx in response to BMP-2. Furthermore, we provide the first evidence that Osx represents the master regulator for BMP-2-induced BMP-2 expression to regulate osteoblast differentiation.

Responses of Bone in ANA Knock-out Mice to Ovariectomy. K. Miyai^{*1}, M. Yoneda^{*2}, F. Mizoguchi¹, T. Hayata¹, Y. Ezura¹, K. Nakashima¹, T. Yamamoto^{*2}, M. Noda¹. ¹Department of Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, ²Division of Oncology, The Institute of Medical Science, The University of Tokyo, Tokyo, Japan.

Tob, a member of BTG/APRO/TOB family protein, has been reported as a negative regulator of BMP signaling on bone. We have identified that ANA, another member of this family, is expressed in skeletal system, including Meckel's cartilage and cartilages of ribs at E12.5 mice suggesting that ANA plays a role in the proliferation and/or chondrocytic differentiation of the cartilage cells (Yoshida et al. 1998 Oncogene). ANA has been reported to interact with Ca²⁺, whose absence did augment the response of bone to BMP similarly to the observation reported in Tob knock out mice. In fact, Tob knock-out mice revealed alteration in the levels of bone mass after ovariectomy. Based on these observations, we examined whether ANA would be involved in the regulation of bone metabolism. To analyze this point, we examined mice deficient in ANA gene. By crossing heterozygous female and male mutants, progeny pups in each genotype were obtained at normal Mendelian frequency. The growth and appearance of knock-out mice were similar to those in wild type littermates. We assumed that this observation was brought about by compensatory mechanisms covering the expected influence, and hypothesized that certain stress on mouse might reveal its role on bone.

It has been reported that Tob knock-out mice are resistant to reduction of bone volume / tissue volume (BV/TV) in femur after ovariectomy, we therefore examined the effect of ovariectomy on bone mass changes in ANA knock-out mice. BMD levels of femur were similar between ANA knock-out mice and wild type littermates. BV/TV levels in femur were tended to decrease in ANA knock-out mice after ovariectomy, and such trends were similar to those in wild type. In conclusion, unlike Tob knock-out mice, ANA deficient mice responded to ovariectomy similarly to wild type mice.

Investigation of KCl Cotransport Expression In Canine Osteosarcoma Cell Lines. H. Ochiai. Research Institute of Biosciences, Azabu University, Sagami-hara Kanagawa, Japan.

K-Cl cotransport, defined originally in erythrocytes as Cl-dependent, ouabain-insensitive bidirectional K transport, encoded by four KCC genes, is recognized as a functional and structural reality in various types of cells. As a functional system, KCC is necessary for ionic and volume homeostasis. Since its discovery by swelling erythrocytes in hyposmotic solutions, KCC has been recognized as one of the key K transport membrane proteins affecting regulatory volume decrease (RVD). Although much information on erythrocytes has been reported, little is known about KCC in osteosarcoma cells. In this study, we investigated KCC of two canine osteosarcoma cell lines, parent canine osteosarcoma cell lines (OS) and highly lung metastasizing canine osteosarcoma which was established from five subcutaneous implantation cycles of lung tumor deposits using parent OS (HM-OS). There was no difference in K-Cl cotransport activity in the physiological condition, while NEM revealed significantly higher Rb (K) uptake in HM-OS than OS. Western blot analysis indicated KCC1, KCC3 and KCC4 were expressed in both cells, and KCC3 was especially abundant in HM-OS compared with OS. Insulin-like growth factor 1 (IGF-1) increased KCC activity and mRNA expression in a dose- and time-dependent manner of the three KCCs. This activation was diminished by addition of DIOA, the specific inhibitor of KCC, along with the inhibitory effect of cell growth in both

cells. Retinoid, the vitamin A derivative, induced morphologic differentiation in both canine osteosarcoma cells and enhanced cell flattening and spreading, as well as reduction in cell overlapping. Alkaline phosphatase (ALP) activity and ALP staining were decreased and induced an increase in production of type I collagen. Retinoid-treated HM-OS indicated KCC3 expression was reduced to level of OS.

Characterization of Regions Upstream of Exon II of the Human CYP19 (aromatase) Gene that Mediate Regulation by cAMP in Murine Osteoblasts. O. K. Oz¹, T. Hasegawa^{*2}, Y. Zhao^{*1}. ¹Radiology, UT Southwestern Medical Center at Dallas, Dallas, TX, USA, ²Pediatrics, Keio University School of Medicine, Tokyo, Japan.

Estrogen is important for the regulation of bone growth and metabolism in humans. Aromatase P450 (aromatase), the product of the CYP19 gene, catalyzes conversion of androgens to estrogens. Aromatase is expressed in human osteoblasts and cultured fetal osteoblast-like cells. In humans, tissue-specific expression of aromatase is regulated in part, by tissue-specific promoters and by alternative splicing mechanisms. In mice, only two promoters, one specific for brain and one for gonads have been described. Little is known regarding the expression and regulation of aromatase expression in murine bone. Thus, we first wanted to determine if aromatase is expressed in murine long bone. Aromatase transcripts were present in whole bone as determined by RT-PCR. Aromatase protein was detected both in osteoblasts and chondrocytes by immunohistochemistry. To ascertain how aromatase expression is regulated in mouse bone, various amounts (-945/-16 bp to -100/-16 bp) of 5'-flanking DNA and promoter of the human CYP19 gene, upstream of exon II (CYP19_h) were linked upstream of the luciferase cDNA (LUC) for transient transfection studies utilizing MC3T3-E1 osteoblast cells. Forskolin-induced reporter activity was greatest with the -517/-16 LUC construct and the response to cAMP was lost upon deletion to -140 bp. Mutation of cAMP-responsive element-like sequence (CLS) and steroidogenic factor-1 (SF-1) element sequence sites markedly decreased the response to forskolin. A probe containing the CLS was used in electromobility shift assays; two complexes were formed with MC3T3-E1 nuclear extracts (NE), and a cAMP-responsive element binding protein (CREB) antibody was able to compete formation of these complexes. A probe specific for the SF-1 element formed a complex with MC3T3-E1 NE and this could be competed through the use of an SF-1 antibody. The results indicate that aromatase is expressed in mouse bone and the 5'-flanking DNA and Promoter II of the human CYP19 gene is capable of driving expression of aromatase in the MC3T3-E1 osteoblast cells. These results suggest a role for SF-1 in bone homeostasis and that the osteoblast is an extraglandular source of local estrogen that may play an important role in bone metabolism.

Snail, a Transcription Factor, Inhibits the Differentiation of Mesenchymal Stem Cells to Osteoblasts. S. Park^{*1}, J. Yook^{*2}, J. Byun^{*1}, Y. Rhee¹, H. Ryoo³, E. Lee^{*1}, S. Lim¹. ¹Internal Medicine, Yonsei University, Seoul, Republic of Korea, ²Oral Pathology, Yonsei University, Seoul, Republic of Korea, ³Cell and Developmental Biology, Seoul National University, Seoul, Republic of Korea.

Mesenchymal stem cells are able to differentiate into several highly specialized cell types, including osteoblasts, adipocytes, myocytes and chondrocytes. Several key transcription factors play a crucial role in commitment process thereby directing the cells along a particular lineage and suppressing the alternative pathways. However, how the key transcription factors in order to specify several distinct lineages are regulated remains a pivotal question. In this study, we examined whether snail, a zinc-finger transcription factor, regulates the differentiation of mesenchymal stem cells. Snail-overexpression decreased the expression of osteoblast marker genes including type I collagen and ALP in C3H10T1/2 mesenchymal cells. And the expression of Runx2, the osteoblast-specific transcription factor, was significantly reduced by Snail-overexpression. The activity of Runx2 was also suppressed by 2 folds after Snail-overexpression in C3H10T1/2 cells. In addition, siRNA against Snail enhanced the activity of Runx2 in C3H10T1/2 cells. Interestingly, osteoblastogenesis was dramatically stimulated after suppression of endogenous Snail expression by siRNA in osteoblastic MC3T3-E1 cells. These results suggested that Snail plays a crucial role in developmental process from the mesenchymal stem cells to osteoblasts.

Disclosures: S. Park, None.

Role of Nuclear Factor I-X Transcription Factor in Regulation of IGFBP-5 and Osteocalcin Expression in Mouse Osteoblasts. L. A. Pérez-Casellas¹, K. E. Govoni², K. D. Howard^{*2}, G. R. Linares³, C. A. Strohbach^{*1}, T. A. Linkhart^{*2}, D. D. Strong². ¹Microbiology, Loma Linda University, Loma Linda, CA, USA, ²Research, Loma Linda VAMC, Loma Linda, CA, USA, ³Physiology, Loma Linda University, Loma Linda, CA, USA.

The Nuclear Factor I (NFI) gene family plays wide reaching roles in viral DNA replication, regulation of gene transcription and development. Gene knockout studies of NFI have shown that nfi-a ^{-/-} mice display mainly neuroanatomical defects, nfi-b ^{-/-} mice show lung and brain defects, nfi-c ^{-/-} caused primarily a disruption of tooth root and underlying mandibular bone development, and nfi-x ^{-/-} mice have brain malformation and also develop a deformation of the spine, due to impaired endochondral ossification and decreased mineralization. We previously reported that the Nuclear Factor I gene family was an important regulator of IGFBP-5 expression in human osteoblast-like cells. Specifically, the isoforms NFI-B and NFI-X significantly activated the IGFBP-5 promoter and siRNA knockdown of NFI-B expression decreased IGFBP-5 mRNA and protein expression. To determine the role of the four NFI isoforms in mouse osteoblast differentiation we evaluated mRNA expression levels in mouse bone marrow stromal cells and mouse osteoblast MC3T3-E1 cells at different stages of differentiation in vitro (αMEM, FBS, Ascorbic Acid and β-glycerolphosphate). We found that all four genes were expressed and their expression levels increased at least 10 fold between day 14 and 21 during differentiation. NFI-x expression was the most abundant in bone marrow stromal cells and differentiated MC3T3-E1 cells and increased the most during differentiation. The increased nfi expression between 14 and 21 days corresponds to previous observations that igfbp-5 expression decreased in MC3T3-E1 cells as the cells fully differentiated and osteocalcin expression increased¹. To determine the role of nfi-x in regulating igfbp-5 expression and osteoblast differentiation, mouse nfi-x expression was inhibited with specific siRNA oligonucleotides in MC3T3-E1 cells. NFI-x mRNA levels were decreased at 48 hrs by 80% and mouse osteocalcin mRNA levels were decreased by 65% compared to non targeting control siRNA. However, nfi-x knockdown caused a 2 fold increase in igfbp-5 mRNA levels. In contrast to stimulating IGFBP-5 promoter activity in human osteoblasts (from an IGFBP-5 luciferase reporter plasmid), nfi-x overexpression in transient transfection experiments did not stimulate promoter activity in MC3T3-E1 osteoblasts. These results suggest an important role for NFI-X in regulating osteoblast differentiation, and that NFI regulation of IGFBP-5 expression may occur by different mechanisms in mouse and human.

Zinc Finger Protein 64 Is a Downstream Target of Runx2 and Regulates Myogenic and Osteogenic Differentiation as a Coactivator of Notch1. K. Sakamoto^{*}, A. Yamaguchi. Section of Oral Pathology, Tokyo Medical and Dental University, Tokyo, Japan.

Runx2 is a crucial transcription factor for osteoblast differentiation. Notch signaling is required for multiple aspects of mesenchymal cell differentiation and it recently has been recognized as an essential regulator of osteogenesis. However, the mechanism to coordinate these signaling pathways is still poorly understood. In this paper, we identified zinc finger protein 64 isoform D (Zfp64) as a novel coactivator of Notch1. Zfp64 was associated with the carboxyl terminal PEST-containing region of Notch1 and was recruited to the promoters of the Notch target genes Hes1 and Hey1, which transactivates these Notch downstream genes. Zfp64 expression, which is under the control of Runx2, was upregulated by direct transactivation of its promoter. During embryo- and organogenesis, Zfp64 is expressed mainly in the mesenchymal cells, including osteoblasts and chondroblasts, but not in myocytes. Zfp64 suppressed the myogenic differentiation of C2C12 cells and promoted their osteoblastic differentiation. Our data demonstrates that Zfp64 is a downstream target of Runx2 and regulates differentiation of osteoblasts and myoblasts as a coactivator of Notch1 by intermediating two signaling pathways between Runx2 and Notch.

Disclosures: K. Sakamoto, None.

Runx2 Transcriptional Activation Domain 3 Supports Synergistic Runx2-MINT Activation of the Osteocalcin FGF Response Element via A DMAT-Sensitive Kinase. O. L. Sierra, S. L. Cheng, D. A. Towler. Bone & Mineral Diseases, Washington Univ Sch Med, St Louis, MO, USA.

MINT, the Mx2-interacting nuclear matrix target protein, is an abundant component of the osteoblastic nuclear matrix. MINT functionally interacts with Runx2 to enhance osteocalcin promoter activity in C3H10T1/2 mesenchymal cells. To study Runx2-MINT interaction in greater detail, we concatamerized the 42-bp element (rat osteocalcin promoter FGF response element; OCFRE) that comprises Runx2 binding sites upstream of the unresponsive RSV minimal promoter (LUC reporter). In co-transfection assays, MINT enhanced Runx2-dependent activation of the OCFRE by 3-4 fold, both in the presence and absence of exogenous FGF2. However, the related family member Runx1 exhibited only 10% the activity of Runx2 in this assay. Deletion of Runx2 N-terminal Activation Domains (AD) AD1 and AD2 did not affect Runx2-MINT interaction. By contrast, Runx2 (1-312) – lacking C-terminal residues 313 to 528 – had significantly reduced activity, indicating that interaction interface with MINT must reside in the C-terminus. A systematic series of Runx1-Runx2 chimeras were generated to

functionally map Runx2-MINT interactions. Runx2 AD1 and AD2 did not convey MINT-dependent activation to Runx1. However, when Runx2 residues 315-402 or 365-402 replaced equivalent domains in the Runx1 C-terminus, both of these Runx1-Runx2 chimeras were capable of augmenting OCFRE activity in the presence of MINT. This region of Runx2, residues 315-402, encodes activation domain 3 (AD3). Inspection of the protein sequence identified multiple potential phosphorylation sites, including cognates for proline-directed protein kinases (PKDs; S319, T326, T407), casein kinase-2 (CK2; S347, S388), and protein kinase C (S330, S364). Alanine scanning mutagenesis was performed in the context of the Runx1-Runx2 chimera. Disruption of S319 and T326 phosphorylation cognates significantly reduced functional Runx2-MINT interactions, indicating that a PDK contributes to transactivation. Other Ala substitutions had no effect. We next examined effects of Ser/Thr protein kinase inhibitors on Runx2-MINT transactivation. Most, including PD98059, had little if any activity. However, the CK2 / Dyrk1 kinase inhibitor 2-dimethylamino-4,5,6,7-tetrabromo-1H-benzimidazole (DMAT) profoundly and dose-dependently abrogated MINT-Runx2 activation and Runx2-transactivation, with an ID50 of 5 uM. By contrast, DMAT did not affect TCF/LEF-dependent transcription. Other CK2 antagonists, such as emodin and apigenin, lacked inhibition. Thus, Runx2 Transcriptional AD3 confers Synergistic Runx2-MINT Activation on the minimally responsive Runx1 protein. MINT-stimulated transcription of AD3 requires the activity of a DMAT sensitive kinase.

LMP-1 Accelerates MC3T3-E1 Osteoblast Differentiation in Part Through Modulation of the IGF System. C. A. Strohbach¹, S. T. Chen^{*2}, S. J. Kleinman^{*2}, T. A. Linkhart², D. D. Strong². ¹Loma Linda University, Loma Linda, CA, USA, ²J.L. Pettis VAMC, Loma Linda, CA, USA.

LIM Mineralization Protein (LMP)-1 is a novel intracellular protein that is believed to be a critical regulator of the osteoblast differentiation program. LMP-1 has been shown to promote bone formation in spinal fusion models and enhance fracture repair. LMP-1 has been proposed to act through the induction of osteogenic factors such as BMPs and Runx2. However, the exact mechanism of action of LMP-1 is still unknown. Previously we found that IGFBP6 (BP6) binds intracellular LMP-1, suggesting that LMP-1 interacting with BP6 may affect osteoblast differentiation. The purpose of this study was to determine the effect of LMP-1 overexpression on MC3T3-E1 osteoblast differentiation, and to further elucidate mechanisms of LMP-1 action focusing on the IGF system. MC3T3-E1 osteoblasts were transduced with an MLV-based retroviral LMP-1 or GFP control vector. Expression of LMP-1 was confirmed by Western blot. After transduction, cells were seeded into 6-well plates and stimulated to differentiate by addition of osteogenic media containing ascorbic acid and beta-glycerolphosphate. The effect of LMP-1 on MC3T3-E1 osteoblast differentiation was determined by Alizarin Red staining and real-time PCR analysis of osteoblast marker gene and IGF system component mRNA levels. At 14 days, Alizarin Red staining demonstrated increased nodule formation in cells transduced with LMP-1 compared to GFP. Real-time PCR analysis revealed that LMP-1 significantly increased the mRNA levels of osteocalcin (7-fold), osteonin (4-fold), bone sialoprotein (19-fold), alkaline phosphatase (7-fold), and Runx2 (4-fold) compared to control. Furthermore at 14 days, LMP-1 significantly decreased mRNA levels of components of the IGF system including IGF-1 (36-fold), IGFBP4 (4-fold), IGFBP5 (14-fold), and BP6 (5-fold). Since LMP-1 is an intracellular molecule, we investigated whether LMP-1 effected transcription using pGL3-promoter reporter constructs. Transient co-transfection revealed that LMP-1 dose-dependently inhibited BP6 promoter activity. Furthermore, we found that retroviral overexpression of BP6 in MC3T3-E1 cells inhibited differentiation and nodule formation normally observed after 21 days of culture in osteogenic media. These results suggest that 1) LMP-1 stimulates the production of osteoblast specific proteins and transcription factors, 2) LMP-1 is involved in regulation of the IGF system, and 3) LMP-1 may have a direct effect on BP6 transcription.

An In Vitro Assay to Assess Secreted Osteogenic Factors from Genetically Engineered Cells. M. Viggswarapu, M. Bargouti^{*}, C. Rogers^{*}, L. Titus, S. D. Boden. Orthopedics, Emory University, Decatur, GA, USA.

LIM Mineralization Protein-1 (LMP-1) is known to induce secretion of osteogenic factors. Optimization of gene transfer protocols, promoter selection, isoform choice and other details have required resource-intensive in-vivo assays to date. The goal of this investigation was to validate an in-vitro assay to measure the osteogenic potential of secreted proteins from genetically engineered cells. To isolate the paracrine effect of secreted osteogenic proteins we chose the non-osteogenic mouse fibroblast (Nor10) cell line as the genetically engineered donor cells. We tested conditioned media (CM) from those cells for their osteogenic potential on freshly isolated rat calvarial osteoblasts (ROBs) and C2C12 pluripotent cells. Nor10 cells were seeded at 2.6x10⁴/cm² in DMEM containing 20% FBS. LMP-1 cDNA was delivered using either a plasmid (pCMV-LMP-1) or Adenovirus (Ad5LMP-1) and grown for 72hrs. CM was collected on day 3 and frozen at -70° until used. The CM was thawed, concentrated 10 fold using 10,000 M_w cut off Centrprep/Centricon concentrators, and sterile filtered. Concentrates were resuspended in fresh complete medium to the original concentration and applied to recipient cells (C2C12 or ROB). C2C12 cells were seeded at 2.1x10⁴/cm² in DMEM containing 10% FBS. Cells were grown for 72 hrs and RNA was harvested. Gene expression was determined by reverse transcription followed by real-time TaqMan PCR analysis. Treatment of C2C12 cells with the CM from Nor10 cells treated with Ad5LMP-1 or pCMV-LMP1 increased BMP2, BMP7 and osteocalcin mRNA

levels. The C2C12 cells, while convenient, do not readily make mineralized bone. Thus, we also tested the osteogenic potential of Nor10 CM on confluent secondary ROB cultures by measuring mineralized nodule formation. Confluent secondary ROB cultures were treated with the CM from LMP-1 overexpressing Nor10 cells and grown for another 14 days. Treatment of ROB with the CM from Nor-10 cells treated with AdLMP-1 or pCMV-LMP1 induced a 5 to 8 fold increase in mineralized bone nodule formation compared with CM from control Nor-10 cultures transduced/transfected with vector alone. In conclusion, these data demonstrate that we can measure the paracrine effects of cells genetically engineered to produce osteogenic factors using a two cell transfer assay. Intermediate markers of osteoblast differentiation (BMPs) and/or mineralized nodule endpoints can be demonstrated.

Osteoblasts Express CSF-1R and Are a Target for CSF-1. Y. Wittrant^{*1}, Y. Gorin^{*2}, K. Woodruff^{*1}, D. Horn^{*1}, S. Mohan^{*1}, H. Abboud^{*2}, S. Werner¹. ¹Pathology, University of Texas Health Science Center and Audie Murphy VA Hospital, San Antonio, TX, USA, ²Nephrology, University of Texas Health Science Center and Audie Murphy VA Hospital, San Antonio, TX, USA.

CSF-1, released by osteoblasts, stimulates the proliferation of osteoclast progenitors via the c-fms receptor (CSF-1R) and, in combination with RANKL, leads to the formation of mature osteoclasts. Whether the CSF-1R is expressed by osteoblasts and mediates specific biologic effects in osteoblasts has not been explored. To examine the CSF-1R in osteoblasts, primary calvarial osteoblasts (OB), isolated from wild-type (wt) and CSF-1 deficient op/op mice, were incubated in the presence and absence of recombinant CSF-1 and analyzed for CSF-1R mRNA and protein by RT-PCR and Western blot, respectively. Wt OB cultures were serum starved for 24 hr and the effect of CSF-1 (0-100 ng/ml) on proliferation and gene expression of RANKL, OPG, CSF-1 and osteocalcin (OC) was determined at 48 hr. In wt bone marrow cultures incubated with 1,25(OH)₂D₃ (10⁻⁸M) and dexamethasone (10⁻⁸M) for 13 days, CSF-1 was tested for its effect on alkaline phosphatase activity (AP), RANKL mRNA and osteoclast formation. Since reactive oxygen species (ROS) influence osteoblast gene expression, studies analyzed the effect of CSF-1 on NADPH oxidase activity, Nox1 and Nox 4 proteins. Results indicate that wt and op/op OB express CSF-1R mRNA and protein and that CSF-1 dramatically reduces CSF-1R protein, but not CSF-1R mRNA, levels. In wt OB, CSF-1 decreased RANKL mRNA in a dose and time dependent manner whereas CSF-1 showed no effect on cell proliferation, OPG, OC or CSF-1 mRNA expression. Incubation of marrow cultures with CSF-1 resulted in a significant decrease in AP activity and RANKL expression and this effect was associated with a decline in TRAP activity and CTR expression. In wt OB, NADPH oxidase activity decreased in response to CSF-1 and correlated with a decline in Nox1 and Nox4 protein levels. Compared to untreated cultures, 1uM DPI (diphenylene iodonium, NADPH oxidase inhibitor) decreased RANKL similar to that observed with CSF-1, and RANKL expression in cultures treated with both CSF-1 and DPI was comparable to each agent alone. These findings provide the first evidence that osteoblasts express CSF-1R and are a target for CSF-1 ligand. CSF-1 may act in an autocrine or paracrine manner to regulate its cognate receptor and osteoblast differentiation. Inhibition of NADPH oxidase activity by CSF-1 likely contributes to the effect of CSF-1 on RANKL. CSF-1-mediated inhibition of RANKL expression on osteoblasts may provide an important mechanism for coupling bone formation/resorption and preventing excessive osteoclastogenesis during normal skeletal growth.

Non-adherent Circulating Progenitor Cells with Osteoblastic Potential Become Adherent in the Presence of Calcium²⁺ and Are able to Mineralize. U. I. Moedder, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Circulating progenitor cells with osteoblastic potential may play an important role both in normal bone remodeling and in mediating vascular calcification. In addition, migration and differentiation of these cells into osteoblasts may be regulated by the release of chemokines, such as stromal cell-derived factor-1 (SDF-1), as well as by increased local calcium²⁺ (Ca²⁺) concentrations, which may be as high as 40 mM at sites of active bone resorption and in areas of vascular injury associated with apoptotic cells. Thus, in the present study, we tested whether non-adherent osteoblast progenitors expressed the SDF-1 receptor, CXCR4, and/or became adherent and formed mineral deposits (as assessed by Von Kossa and Alizarin Red staining) in the presence of Ca²⁺.

Osteocalcin positive cells (OCN^{pos}) were isolated by magnetic activated cell sorting (MACS) and OCN^{pos} cells and mononuclear cells (MNCs) were used as negative controls. Continuous proliferation of the MNCs and OCN^{pos} was observed for up to 7 days in vitro following isolation; however, OCN^{pos} cells failed to proliferate after 24 hours. By flow cytometry, 82% of OCN^{pos} cells coexpressed CXCR4, the exclusive receptor for SDF-1, which is released at sites of vascular injury or fractures. OCN^{pos} cells did not adhere to uncoated culture flasks in the presence of regular growth medium for up to 4 weeks. By contrast, if the culture medium contained an additional 2.1 mM Ca²⁺ for up to 5 days at the beginning of the culture, the cells started to adhere. Subsequently (and following removal of the additional Ca²⁺), these cells mineralized within 21 days in the presence of osteoblast differentiation medium, as determined by Von Kossa and Alizarin Red staining (Figure). By contrast, MNCs and OCN^{neg} cells did not mineralize under these culture conditions. Collectively, these findings support the concept that OCN^{pos} cells may be recruited to sites of bone remodeling and/or vascular injury via the CXCR4-SDF-1 axis and, in the setting of

an increased local concentration of Ca²⁺, be induced to adhere and differentiate into osteoblastic cells.

Human Fetal Bone Cells for Tissue Engineering. M. Montjovent^{*1}, C. Scaletta^{*2}, L. Mathieu^{*3}, D. Pioletti¹, L. Applegate^{*2}. ¹Laboratory of Biomechanical Orthopedics EPFL-HOSR, EPFL, Lausanne, Switzerland, ²Orthopedic Cell Therapy Unit, PAV-03, Centre Hospitalier Universitaire Vaudois and University of Lausanne, Lausanne, Switzerland, ³Laboratory of Composite and Polymer Technology, EPFL, Lausanne, Switzerland.

For clinical bone transplantations, tissue engineering techniques based on the delivery of cells to the defect using scaffold materials are currently investigated. Our aim is to evaluate the possible use of human fetal bone cells for tissue repair. Firstly, fetal bone cells were characterized for their osteoblastic phenotype. Then, fetal bone cells were seeded on scaffolds made of poly-L lactic acid (PLA) and reinforced with b-TCP. Proliferation, ALP enzymatic activity were observed, and in vitro mineralization was assessed. Lastly, scaffolds seeded with fetal cells were tested in vivo in critical size defects in the rat cranial model. The cellular doubling time of fetal bone cells was estimated to be 27 hours, whereas this value was significantly higher for adult bone cells and clearly age dependent. Fetal bone cells receiving a differentiation mix showed a strong induction of ALP activity after 4-6 days of treatment and this observation was also verified at high passage numbers. Adult cells showed a lower induction of ALP enzymatic activity. Extracellular matrix analysis demonstrated that fetal bone cells were able to mineralize PLA/b-TCP scaffolds in vitro. Moreover, repair of craniotomy critical size defect was assessed in vivo and we showed that human fetal bone cells possess a high proliferation potential, are able to differentiate into osteoblasts, and they promote bone repair in vivo when seeded on PLA/b-TCP constructs. The use of fetal bone cells, which have the advantage of a high proliferation capacity, for bone tissue engineering could be an alternative to mesenchymal stem cells.

Modulation of WNT3A Induced Signaling Through Dual-Specificity Phosphatases. P. V. Nantermet^{*1}, P. Hodor^{*2}, O. Flores^{*1}, H. Glantschnig^{*1}.

¹Bone Biology & Osteoporosis, Merck Research Labs, West Point, PA, USA,

²Molecular Profiling, Merck Research Labs, West Point, PA, USA.

There is substantial evidence for a central role of Wnt-signaling in regulating bone mass accrual. Wnt activates a canonical signaling pathway through β -catenin, likely mediated via LRP5 and LRP6. However, other Wnt-mediated non-canonical signaling components like Ca⁺⁺, protein kinase C and mitogen-activated protein kinases (MAPKs) have also been implicated. Using a mesenchymal pluripotent cell (C3H10T1/2), we observed Wnt3A induced early osteoblastic cell differentiation, which can be blocked by DKK-1. To elucidate the signaling pathways engaged in this cell system, we performed a micro-array analysis in C3H10T1/2 cells treated with WNT3A in the presence or absence of exogenous DKK-1.

Among genes regulated by WNT3A, we identified individual temporal responses of eleven members of the dual-specificity phosphatase (DUSP) family. Despite the amount of information on DUSPs in MAPK signaling, limited information exists on the role of DUSPs in Wnt signaling pathway or on further downstream effects. Within this study we have therefore focused on Dusp 1, 4 and 9 representing early (6 hours), delayed (24 hours) and late (72 hours) responders to WNT3A, respectively.

The WNT3A increased Dusp 1/4/9 expression was blocked only partially by simultaneous addition of DKK1. Experiments using bone marrow derived cells from Lrp5^{-/-} mice revealed that the WNT3A induced increase in Dusp 4/9 transcript levels is independent of LRP5. However, over-expression of a HBM-mutant in HEK293-cells (Lrp5-G171R) seemed to augment WNT3A -induced Dusp 4 transcription. To address DUSP involvement in Wnt/LEF/TCF signaling, we transiently over-expressed Dusp 4/9 in HEK293 cells. No effect of either phosphatase on Lef/TCF signaling was observed in absence of WNT3A, however, WNT3A induced signaling was further augmented by about 50% and 20% by Dusp 4 and Dusp 9 over-expression, respectively. Furthermore, in-vitro knockdown of Dusp 4 and 9 by siRNA indicated crucial roles of DUSP-4/9 in WNT3A mediated Lef/TCF signaling.

In conclusion, we have identified DUSP family members responding to WNT3A treatment and importantly, in the case of DUSP 4/9, cross-talking with canonical Wnt/LEF/TCF signaling pathway. By inference, DUSP mediated control of MAPK's through dephosphorylation, thus might play a role in WNT3A induced C3H10T1/2 osteoblastic cell differentiation.

Nondestructive Evaluation of Cell Numbers in Bone Marrow Stromal Cells

/ Biodegradable Scaffold Composites Using Ultrasound. K. Oe¹, M. Miwa^{*1}, K. Nagamune^{*1}, Y. Sakai^{*1}, R. Kuroda^{*1}, T. Hasegawa^{*1}, T. Iwakura^{*1}, N. Shibamura^{*1}, Y. Hata^{*2}, M. Kurosaka^{*1}. ¹Department of Orthopedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan, ²Graduate School of Engineering, University of Hyogo, Himeji, Japan.

Composites of bone marrow stromal cells (BMSCs) and biodegradable scaffold (BS) have been used as a bone graft model. Up to now, the actual number of cells contained in these composites has been difficult to evaluate using nondestructive techniques. In general, ultrasound amplitude through homogeneous material is larger than through heterogeneous material such as BMSCs/BS composites. We developed an ultrasound device to evaluate BMSCs/BS composites.

The ultrasound device has a transmitting probe and a receiving probe attached to the slide gauge frame. Both probes are set to be collinear at opposite sides to propagate ultrasound wave from the transmitting probe to the receiving probe. One of the probes can be moved along the frame to adjust the size of the material to be inserted between them. The ultrasound wave data was recorded by an oscilloscope via an ultrasound pulser/receiver. In this study, we investigated the relationship between the ultrasound amplitude and the actual number of cells, using ultrasound as a nondestructive and quantitative technique. We used BMSCs of S-D rat and examined five experimental groups with different concentrations of BMSCs: 0 (control), 1.0×10^6 , 1.5×10^6 , 2.0×10^6 and 1.0×10^7 cells/ml (n=25). Porous ceramic blocks composed of β -tricalcium phosphate were used as scaffolds. All samples were incubated for 24 hours at 37°C and we evaluated them with the ultrasound device. After measurement by ultrasound device, BMSCs/BS composites were detached with 0.25% trypsin during the destruction of the BMSCs/BS composites for 30 minutes. We counted the BMSCs of all BMSCs/BS composites using a Hemacytometer. We repeated this treatment twice, and considered the total cell count numbers to be the actual number of cells.

Ultrasound amplitude was well correlated to the actual number of cells contained in the BS (r=0.779). The estimation equation ($y=9879x-33290$) was derived from the results. Here, x and y represent the amplitude value and estimated cell number in this study, respectively. The linearity of this estimation equation was validated in the range of seeding cell concentration from 5.8×10^4 to 19.2×10^4 of the cell number. The estimated error for the system was 2.591×10^4 . These results indicate that the ultrasound device we developed is a valuable, convenient, and nondestructive tool for applications in tissue engineering, especially in the generation of artificial bone tissue.

Liganded versus Unliganded Estrogen Receptor: A Potential Explanation for Paradoxical Regulation of Periosteal Expansion by Estrogens. M. Ogita, E. Dworakowski*, J. P. Bilezikian, S. Kousteni. Division of Endocrinology, College of Physicians & Surgeons, Department of Medicine, Columbia University Medical Center, New York, NY, USA.

Many studies in rodents, primates and humans indicate that estrogens suppress periosteal expansion. However, in certain situations, such as in men with aromatase deficiency or in the growing skeleton, low estrogen concentrations may promote directly periosteal expansion or, alternatively, be permissive to the stimulatory effects of androgens or mechanical stimulation. Based on evidence that unliganded and liganded ER α regulate the expression of cytokines like TNF α in an opposite manner, we examined the possibility that ER α may also show different, and opposite, functions to regulate periosteal osteoblast differentiation. We have found that 17 β -estradiol (E₂) has no effect by itself, but attenuates the stimulatory effect of BMP-2 on the expression or activity of alkaline phosphatase and endogenous targets of BMP-2 - and Wnt/ β -catenin-mediated transcription in primary periosteal cells. Dihydrotestosterone (DHT) exerts the opposite effects. However, reduction of ER α expression in primary periosteal osteoblast progenitors using siRNA, dose-dependently attenuates BMP-2 - induced osteoblast differentiation, as measured by AP activity. Pre-treatment with 10^{-8} M of the specific ER inhibitor ICI 182,780, which causes ER degradation, attenuates the stimulatory effect of BMP-2 on AP activity in primary periosteal cells. BMP-2-induced upregulation of Smad1/5/8 phosphorylation is not affected by ICI 182,780; but Smad6 (a transcriptional target of BMP-2), osteocalcin and axin2 (a transcriptional target of Wnt/ β -catenin) expression, measured at 16 days following treatment with ICI 182,780, is attenuated. These results suggest that ER α is a major cellular switch which can either suppress (in the presence of E₂) or stimulate (in the absence of E₂) periosteal bone formation; perhaps by potentiating the beneficial effects of mechanical loading or androgens. We have also found that low doses of E₂ have no effect on periosteal cell differentiation, but in combination with DHT (1-100 pM), induces AP activity in periosteal osteoblast progenitors. Thus, low dose estrogen exposure may mimic the stimulatory actions of unliganded ER α on periosteal expansion. We propose that the dual action of ER α in periosteal osteoblast differentiation may help to explain the apparent paradox of the dose-dependent biphasic response of the periosteum to estrogens.

Characterization of Bone Tumors in a Mouse Model for Carney Complex.

E. Pavel^{*1}, K. Nadella^{*1}, W. Towns^{*1}, L. Kirschner^{*2}. ¹Human Cancer Genetics, The Ohio State University, Columbus, OH, USA, ²Internal Medicine, Subdivision of Endocrinology, The Ohio State University, Columbus, OH, USA.

Carney Complex (CNC) is an autosomal dominant neoplasia syndrome caused by inactivating mutations in PRKARIA, the gene encoding the type 1A regulatory subunit of protein kinase A (PKA). This genetic defect induces skin pigmentation, endocrine tumors, myxomas, schwannomas and bone tumors termed osteochondromyxomas.

In order to study the link between the PRKARIA mutations and tumor formation, we generated a mouse model of this condition. Prkar1a^{-/-} mice develop bone tumors with high frequency, although the associated molecular changes have not been characterized.

Bone tumors observed in Prkar1a^{-/-} mice were heterogeneous, including elements of myxomatous, cartilaginous and bony differentiation which effaced the normal bone architecture. Immunohistochemical analysis had suggested an osteoblastic origin for the tumor cells which we have confirmed using additional markers. These abnormal cells were typically associated with increased bone remodeling as evidenced by increases in osteoclasts number.

Analysis of primary culture of the tumors confirmed that the tumor cells were derived from the osteoblast lineage; however, fully differentiated functions such as mineralization were impaired and tumor cells exhibited an increase in migratory capability. At the biochemical level, we observed the expected reduction in Prkar1a protein and an increase in PKA activity in tumor cells. Moreover, primary tumor cells demonstrated an increased sensitivity to the growth-promoting effects of PKA activation in the cells.

Examination of gene expression in the tumor cells revealed down-regulation of markers of bone differentiation and increased expression of locally acting growth factors, including members of the Wnt signaling pathway. The role of the Wnt signaling pathway has also been confirmed by observing alterations the subcellular distribution of the relevant signaling molecules. In summary, loss of Prkar1a from the mouse leads to the formation of bone tumors analogous to osteochondromyxomas observed in human patients. Dysregulation of PKA leads to the formation of osteoblast-derived bone tumors through dysregulation of differentiation and upregulation of locally-acting factors involved in cell growth and differentiation.

Disclosures: E. Pavel, None.

Effects of PDE7 and PDE8A Inhibition on the Differentiation of Human Mesenchymal Stem Cell-Derived Osteoblasts. M. H. Pekkinen¹, M. E. B. Ahlström^{*1}, U. Riehle^{*2}, M. M. Huttunen¹, C. J. E. Lamberg-Allardt¹.

¹Department of Applied Chemistry and Microbiology, University of Helsinki, Helsinki, Finland, ²Institute for Biological Chemistry and Nutrition, University of Hohenheim, Stuttgart, Germany.

Cyclic adenosine monophosphate (cAMP) is an important second messenger involved in a variety of cellular responses to extracellular agents such as hormones and neurotransmitter, i.e. in PTH signaling via cAMP. cAMP is known to be inactivated by the cyclic nucleotide phosphodiesterases (PDEs), a superfamily of enzymes divided into 11 known families; designated PDE 1-11. PDEs determine the amplitudes of cyclic nucleotide mediated hormonal responses and modulate the duration of the signal. Osteoporosis, bone loss, typically reflects an imbalance in skeletal turnover so that bone resorption exceeds bone formation. It is important to understand the role of the PDEs in bone cells, because the bone metabolism, and especially bone formation, could be affected via PDEs. The aim of this study was to investigate the influence of PDE7 and PDE8A inhibition in the differentiation and function of human osteoblasts.

Osteoblasts differentiated from human mesenchymal stem cells (hMSC) were cultured and treated for 48 h with small interfering RNAs (si-RNAs) generated from PDE7 and PDE8 PCR products. Total RNA was isolated from the cells and gene expression was assayed with cDNA microarray. Quantitative Real-Time PCR was used to confirm the specific PDE inhibition and the cDNA microarray results. bALP measurements were assayed during differentiation and mineralization was determined by quantitative Alizarin red S staining. On the level of mRNA, PDE7 and PDE8 inhibition by RNA interference (RNAi) decreased the gene expression of PDE7A by 60%, PDE7B by 40% and PDE8A by 30%. The silencing of PDE7 increased the expression of several osteogenic genes, such as β -catenin, osteocalcin, caspase 8, and CREB-5 genes and decreased the expression of the 1,25-dihydroxyvitamin D3 receptor gene. The silencing of PDE8A significantly decreased caspase-8, osteoglycin, BMP-1. Mineralization was increased up to threefold in PDE7 siRNA treated cells compared to control and treatment with the PDE7-selective PDE-inhibitor BRL-50481 also increased the mineralization. Silencing with PDE8A siRNAs had no effect on mineralization.

Our results show that specific gene silencing with the RNAi method is a useful tool for inhibiting the gene expression of specific PDEs and that PDE7 upregulates several osteogenic genes and increases mineralization. PDE7 may play an important role in the regulation of osteoblastic differentiation.

Conjugated Linoleic Acid Regulates Osteoblast and Adipocyte Differentiation from Mesenchymal Stem Cells. I. D. Platt^{*1}, L. G. Rao^{*2}, A. El-Soehy^{*1}. ¹Nutritional Sciences, University of Toronto, Toronto, ON, Canada, ²Medicine, University of Toronto, St. Michael's Hospital, Calcium Research Laboratory, Toronto, ON, Canada.

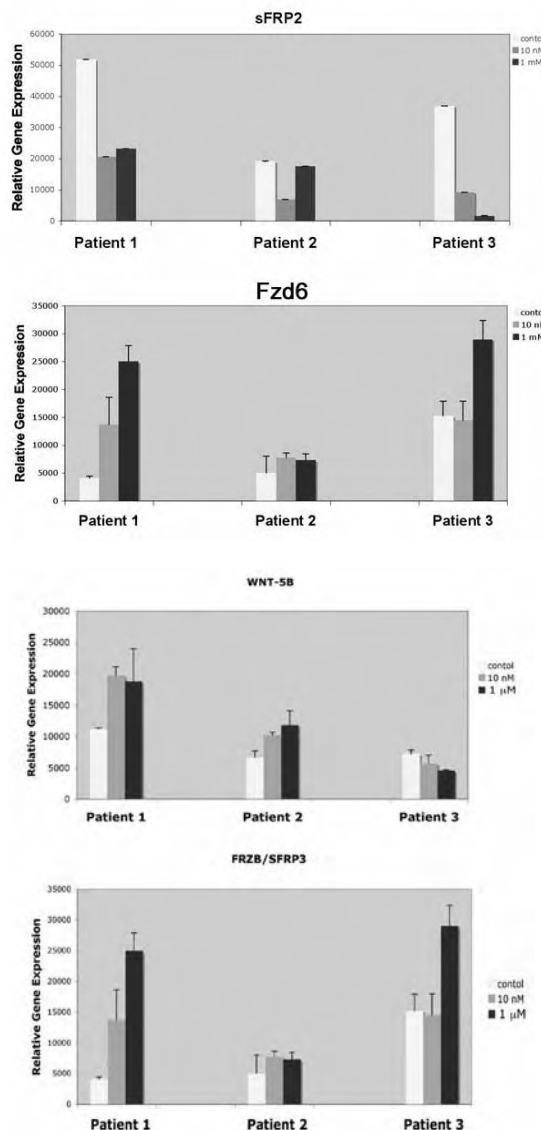

Conjugated linoleic acid (CLA) refers to a group of geometric and positional isomers of linoleic acid. The major isomers are 9cis,11trans (9,11) and 10trans,12cis (10,12) CLA, which are both bioactive and often have different physiological effects. CLA has variable effects on bone formation and on adiposity in vivo and in vitro. Osteoblasts and adipocytes are both derived from mesenchymal stem cells (MSCs), and factors that promote the differentiation of one cell type may inhibit the differentiation of the other type. CLA may be one such factor and the effects of CLA on MSCs are not known. The purpose of this study was to determine whether 9,11 and 10,12 CLA affect markers of osteoblast (alkaline phosphatase (ALP), osteocalcin) and adipocyte (lipid droplet) differentiation from human bone marrow-derived MSCs and alter the expression of genes regulating osteoblast (Wnt10b) and adipocyte (C/EBP α) differentiation from these cells. To determine the effects of CLA on osteoblast differentiation, MSCs were seeded at 3×10^3 cells/cm², and treated 4 days later with 0-50 μ M 9,11 or 10,12 CLA in osteogenic media. Cells were harvested after 11 days in culture for mRNA analysis (Wnt10b, osteocalcin), and for the measurement of ALP activity. Calcium deposition was measured after 18 days in culture. To determine the effects of CLA on adipocyte differentiation, MSCs were seeded at 2×10^4 cells/cm², and treated 4 days later with 0-50 μ M 9,11 or 10,12 CLA in adipogenic media. After 11 days in culture, cells were stained for lipid droplet formation using oil red O, and cells were harvested for mRNA analysis (C/EBP α). Gene expression was determined by real-time RT-PCR and normalized to the expression of β -2-microglobulin. At 12.5 μ M, 10,12 CLA increased Wnt10b expression (~70%), whereas 9,11 CLA decreased its expression (~33%). At 50 μ M, 10,12 CLA increased osteocalcin expression (~85%), calcium deposition (~32%), and ALP activity (~85%), but 9,11 CLA had no effect. At 50 μ M, 10,12 CLA decreased the expression of C/EBP α (~35%), but 9,11 CLA had no effect. However, 9,11 CLA increased oil red O staining at all concentrations and maximally at 50 μ M (~70%). Our results demonstrate that 10,12 CLA increases osteoblast differentiation and decreases adipocyte differentiation from MSCs suggesting that this isomer may prevent bone loss and decrease bone marrow adiposity.

Disclosures: I.D. Platt, None.

Activation of the Non-canonical Wnt Pathway During Human Mesenchymal Stem Cell Osteogenesis: Microarray Expression Analyses to Examine the Effects of Dexamethasone on Cell Differentiation. K. T. Rousche^{*}, A. Derfoul^{*}, J. Helm^{*}, R. S. Tuan^{*}. Cartilage Biology and Orthopaedics Branch, NIH/NIAMS, Bethesda, MD, USA.

Non-canonical Wnts enhance osteogenic differentiation in adult human mesenchymal stem cells (hMSCs). The molecular mechanisms involved in activation of this Wnt pathway during osteoblastic differentiation of hMSCs have yet to be defined. In vitro, glucocorticoids (GCs) are known to maintain differentiation of osteoblasts and to promote osteogenic differentiation of hMSCs. However, administration of high doses of GCs has been shown to suppress growth in children and lead to low bone mineral density and increased fracture risk in adults. To gain insight in the mechanisms of GC action on the differentiation of hMSCs into osteoblasts, we examined the effects of various doses of the GC analog, dexamethasone (DEX), on osteogenic differentiation of hMSCs. The purpose of this study was to identify genes involved in osteogenic differentiation of hMSCs at physiological doses of GCs, as well as genes associated with the inhibition of osteoblast function by therapeutic doses of GCs. We performed DNA microarray analyses of hMSCs cultured in osteogenic conditions in the presence or absence of 10 nM or 1 μ M DEX. Human bone marrow was obtained from the femoral head of patients undergoing hip arthroplasty. hMSCs were cultured in monolayer for 12 days in osteogenic medium in the presence or absence of 10 nM to 1 μ M DEX. Microarray analyses of hMSCs grown in the presence of 10 nM or 1 μ M DEX were performed using Affymetrix human Genome U133 Plus 2.0 chips. Results were analyzed using bioinformatics RAM and MAS softwares. Data suggest that GCs alter expression of non-canonical Wnts, Wnt receptors and Wnt modulators during hMSC osteogenic differentiation. Wnt5b, FRZB (sFRP3), Twist2, and FRZ6, and sFRP2 were differentially expressed during GC-mediated hMSC osteogenesis. Taken together, these data support a distinct role for non-canonical Wnts in MSC osteogenic differentiation. siRNA and functional studies are underway to further support this data.

Cytoplasmic Interaction of p21 with Runx2 During Osteogenic Differentiation of Mesenchymal Stem Cells. P. Muller^{*1}, C. Bergemann^{*1}, U. Bulnheim^{*1}, A. Liebold^{*2}, G. Steinhoff^{*2}, J. Rychly¹. ¹Laboratory of Cell Biology, University of Rostock, Rostock, Germany, ²Department of Heart Surgery, University of Rostock, Rostock, Germany.

Regulating the switch between proliferation and osteogenic differentiation of mesenchymal stem cells is critical for the development of normal bone tissue and more over is of considerable interest in bone tissue engineering using mesenchymal stem cells as vehicles for cell based skeletal therapies. Recent investigations revealed that the protein p21 exhibits multiple functions in addition to its role in cell cycle inhibition. These functions appear to rely on the different cellular localizations and molecular targets. To assess a possible role of p21 in the differentiation of mesenchymal stem cells, we tested the cellular localization of p21 during the osteogenic differentiation of mesenchymal stem cells. Bone marrow derived human mesenchymal stem cells were stimulated to differentiate into osteoblasts by addition of osteogenic differentiation medium (ODM) containing ascorbic acid, glycerolphosphate and dexamethasone. In p21-GFP transfected cells we observed a translocation of p21 from the nucleus to the cytoplasm within 2 hours after addition of ODM. This nuclear export was mediated by CRM1, the major nuclear protein export receptor, because leptomycin B completely blocked the translocation of p21. These experiments further indicated the significance of the CRM1 mediated nuclear export of proteins for the osteogenic differentiation, because inhibition of the export reduced the expression of osteogenic marker proteins and alkaline phosphatase activity. To further assess whether the translocation of p21 is related to known molecules of the cellular machinery that control the osteogenic differentiation we addressed the interaction of p21 with Runx2, the principal osteogenic transcription factor. Coimmunoprecipitation experiments with both nuclear and cytoplasmic fractions revealed that p21 interacts with Runx2 in the cytoplasm during osteogenic differentiation. Blocking the nuclear export of proteins revealed an association of both proteins in the nucleus. We further found that inhibition of the export by leptomycin B with the consequence of blocking osteogenic differentiation did not reduce but rather increased the RNA expression of Runx2. In conclusion, the interaction of p21 with Runx2 in the cytoplasm during osteogenic differentiation suggests that p21 plays a role in the osteogenic differentiation. However, the function of the cytoplasmic interaction of these proteins is not known. We speculate that p21 may act as assembly factor for Runx2 in the cytoplasm to promote or control a nuclear import of Runx2.

Osteogenesis and Adipogenesis Are Differentially Modulated by PTH and the N- and C-Terminal Fragments of PTH-Related Protein. R. Santiago^{*1}, A. Casado^{*2}, I. Herrera^{*3}, A. Torres^{*3}, P. Esbrit^{*4}, G. Dorado^{*5}, J. M. Quesada^{*1}. ¹UMM, Hospital U. Reina Sofía, Córdoba, Spain, ²Sanyres (Grupo PRASA), Hospital U. Reina Sofía, Córdoba, Spain, ³Servicio Hematología, Hospital U. Reina Sofía, Córdoba, Spain, ⁴Laboratorio de Metabolismo Mineral y Oseo, Fundación Jimenez Diaz, Madrid, Spain, ⁵Dpto. Bioq y Biol Mol, Universidad de Córdoba, Córdoba, Spain.

Chronic or intermittent parathormone (PTH) administration plays different roles on bone. We evaluated the effects of different patterns of exposure to either PTH (1-34), parathyroid hormone-related protein (PTHrP) (1-36), or PTHrP (107-139) on adipogenesis and osteoblastogenesis in vitro. Bone marrow stromal cells were differentiated to osteoblasts (dexamethasone, ascorbic acid and glycerolphosphate) or adipocytes (dexamethasone, indomethacin and isobutylmethylxanthine), in the presence of PTH or the PTHrP peptides (100 nM), added at the beginning or at day 6 up to the end of the study period. Differentiating cell cultures were sampled at 6, 18, and 24 days. The differentiating process was evaluated by measuring alkaline phosphatase (AP) activity and gene expression (by real time PCR) of osteogenic (AP, runx2, type I collagen, osteocalcin, osteoprotegerin, and RANKL) and adipogenic (PPAR γ 2 and LPL) markers. Osteoblast mineralization was assessed by alizarin red staining; and adipocyte by oil red staining. Expression of all osteoblastic factors tested decreased with both PTHrP (1-36) and PTH at day 6. However, addition of these peptides, but not PTHrP (107-139), from this day through the end of the culture period increased the expression of these factors at 18 and 24 days, respectively. This was associated with a decrease in PPAR γ 2 and LPL gene expression induced by either PTHrP (1-36) or PTH within the same time period. On the other hand, continuous treatment with PTHrP (107-139) from the start of cell culture induced adipogenesis, as shown by increased PPAR γ 2 and LPL gene expression at day 18, and decreased the expression of various osteoblastic products at day 24. Moreover, at the latter time period, the number of adipocytes was 20 % higher in cultures supplemented with PTHrP (107-139), but 20 % lower in those treated with either PTHrP (1-36) or PTH from day 6, compared with that in untreated cells. In conclusion, our findings suggest that the effects of PTH and these PTHrP peptides on bone marrow stromal cells depend on their differentiation stage. Thus, PTH and, to a lesser extent, the N-terminal PTHrP fragment induce osteogenesis in cells that are already differentiating. On the other hand, PTHrP (107-139) was not found to be osteogenic, but it enhanced adipogenesis, in our experimental setting.

Effect of 1,25-Dihydroxyvitamin D₃, Retinoic Acid, and Dexamethasone on the Osteoblastic Differentiation of Human Adipose-Derived Stem Cells. M. J. Saran^{*1}, P. A. Zuk^{*2}, W. Huang^{*3}, C. K. Huang^{*4}, M. Hakimi^{*1}, D. S. Bischoff^{*3}, G. H. Rudkin^{*5}, D. T. Yamaguchi¹, T. A. Miller^{*3}. ¹David Geffen School of Medicine, UCLA, Los Angeles, CA, USA, ²Regenerative Bioengineering and Repair Lab, UCLA, Los Angeles, CA, USA, ³Research Service, VA Greater Los Angeles Healthcare System, Los Angeles, CA, USA, ⁴Head & Neck Surgery, UCLA, Los Angeles, CA, USA, ⁵Plastic Surgery, UCLA, Los Angeles, CA, USA.

Human adipose-derived stem cells (ASC) are a promising source of cells for bone tissue engineering; however, the factors that stimulate osteogenic differentiation in human ASC have not been well characterized. Most studies have either been done in animal models or in 2-dimensional (2-D) cultures systems. However, human ASC have been shown to respond differently to the osteogenic supplements than animal ASC. Also, 3-D cultures, as compared to 2-D cultures, are a closer approximation to the 3-D matrix that cells encounter in vivo. The purpose of this study was to investigate the supplements that are commonly used to induce osteogenic differentiation in human ASC, and to compare their actions in 2-D versus 3-D cultures. One million human ASC cells were seeded onto 3-D poly(L-lactide-co-glycolide) (PLGA) scaffolds or 2-D PLGA films. Cells were cultured in osteogenic media in the presence or absence of each of the following supplements: 1,25-Dihydroxyvitamin D₃ (VD) [10nM or 100nM], Retinoic Acid (RA) [1 μ M], or Dexamethasone (Dex) [100nM]. Cells were harvested at 7, 10, and 14 days for RNA extraction. Quantitative real-time RT-PCR was performed to measure mRNA expression of the following osteogenic marker genes: Alkaline Phosphatase (ALP), Osteocalcin (OCN), Bone Sialoprotein (BSP), and Collagen I (Col I). VD increased the expression of all 4 osteogenic marker genes in 3-D cultures compared to control. ALP increased 5-fold on day 14. OCN and BSP increased 2-fold on day 14. Col I increased 3-fold on day 14. 2-D cultures treated with VD followed a similar expression pattern. However, treatment with Dex or RA adversely effected expression of these osteogenic markers in both 2-D and 3-D cultures. On day 7, RA treatment resulted in a 4-fold decrease in ALP expression, an 11-fold decrease in BSP expression, and no change in the levels of OCN mRNA. Similarly, Dex caused a 7-fold decrease in BSP expression and no change in ALP or OCN expression compared to control on day 7. In conclusion, we found that for both 2-D and 3-D cultures, 1,25-Dihydroxyvitamin D₃ promotes the expression of osteogenic marker genes; whereas, Retinoic Acid and Dexamethasone treatment, have no effect or can be detrimental to ASC cell osteogenic differentiation. This is an important step to understanding the best supplements to use to promote human ASC osteogenic differentiation in bone tissue engineering.

Microgravity and Bone: Effects of Modeled Microgravity on Osteoblast and Osteoclast Differentiation. R. Saxena^{*1}, G. Pan^{*2}, J. M. McDonald². ¹Department of Cell Biology, University of Alabama at Birmingham, Birmingham, AL, USA, ²Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA.

Prolonged microgravity experienced by astronauts on long term space missions is associated with a decrease in bone mass and an increase in risk of fracture. Studies on astronauts during spaceflight indicate that increased bone resorption by osteoclasts and decreased osteoblast activity, are jointly responsible for bone loss. To investigate the effect of microgravity on differentiation of osteoclasts and osteoblasts from precursor cells in space, we used the Rotary Cell Culture System (RCCS) which is a ground based system that is able to simulate microgravity conditions. Using the RCCS, we have demonstrated that modeled microgravity inhibited the expression of osteoblast differentiation genes and increased adipocyte genes in human mesenchymal stem cells incubated under osteogenic conditions. This transformation involves reduced RhoA activity and cofilin phosphorylation, disruption of F-actin stress fibers, and decreased integrin signaling through focal adhesion kinase. We have recently established a unique system to investigate the effects of modeled microgravity on osteoclastogenesis. The mouse macrophage cell line, RAW264.7 was cultured with microcarrier beads in DMEM supplemented with 10% FBS. Cells attached to beads were placed in the RCCS (microgravity treatment) and rotated at 9 rpm for 8 hours and 24 hours. Bead-attached cells placed simultaneously in culture plates were the gravity controls. After incubations, the cells were detached from beads and stimulated with RANKL (Receptor Activator of NF κ B Ligand, 20ng/ml) and allowed to differentiate for 4 days. Differentiated multinucleated osteoclasts were observed under the microscope followed by TRAcP (Tartrate Resistant Acid Phosphatase) staining. Our results show that multinucleated TRAcP-positive osteoclasts derived from microgravity treated cells were increased nearly two-fold compared to that from gravity-treated cells after treatment with RANKL. RT-PCR further demonstrated that TRAcP expression in MMG-treated cells was increased compared to gravity-treated cells. In conclusion, these data indicate that modeled microgravity directly stimulates osteoclastogenesis and inhibits osteoblastogenesis, consistent with the studies of bone loss in humans in microgravity.

Mesenchymal Stem Cells from Human Adipose Tissue and Bone Marrow: Osteogenic Differentiation and Interaction with Ti6Al4V. I. Tognarini^{*1}, S. Sorace^{*1}, R. Zonfrati^{*1}, G. Galli^{*1}, A. Gozzini^{*1}, S. Carbonell Sala^{*1}, G. Zappoli Thyron^{*1}, A. Carossino^{*1}, S. Ciuffi^{*1}, A. Tanini^{*1}, F. Sbaiz^{*2}, A. Facchini^{*2}, M. Brandi¹. ¹Internal Medicine, University of Florence, Florence, Italy, ²LIMA SpA Medical System, San Daniele del Friuli, Udine, Italy.

In bone tissue engineering and surgery there is a growing need to test the ability of hard biomaterials to control the differentiation of mesenchymal stem cells (MSCs) in order to gain direct bone apposition to implant materials. MSCs, classically used to test implanted biomaterial as Ti6Al4V alloy, are isolated and ex vivo expanded from bone marrow aspirates. Human adipose tissue derived stromal cells may be a better source of MSCs according to their abundance and accessibility. The aim of this study was to evaluate the osteogenic differentiation of adipose tissue and bone marrow-derived MSCs (PA1 and BMC1, respectively) and to compare their response to Ti6Al4V.

The expression of the osteoblastic phenotype was evaluated by monitoring alkaline phosphatase (ALP) activity, expression of osteoblastic markers by quantitative RT-PCR and immunocytochemistry, and calcium mineralization by Calcein staining and Alizarin Red S assay. Cell growth, cytoskeleton morphology and adhesion of differentiated cells on Ti6Al4V were evaluated by cell counting and Laser Scanning Confocal Microscopy analysis (actin, tubulin and vinculin). Human osteoblast-like cells (SaOS-2) were used as control.

Thirty days after the osteogenic induction, near 50% of PA1 cells showed an osteoblastic-like phenotype, whereas almost 100% of BMC1 cells resulted entirely differentiated. BMC1 cells cultured on Ti6Al4V exhibited an increase of ALP activity that was similar to that seen on culture polystyrene (PS), whereas PA1 cells showed a statistically significant increment of this activity on Ti6Al4V compared to that observed on PS. A comparable enhancement of transcript levels of genes involved in osteogenic differentiation was observed in both cell lines on PS and on Ti6Al4V during differentiation. Osteoblastic activity was confirmed at the protein level by osteopontin and osteocalcin immunostaining and at the mineral level by the production of calcium deposits. A good adhesion, cytoskeleton organization, and cell growth on Ti6Al4V were observed in every cell line, but interestingly only PA1 cells showed a higher level of adhesion to Ti6Al4V compared to the control.

In conclusion, the results of this study confirmed that PA1 cells are capable of adhering, proliferating, and differentiating on Ti6Al4V as well as BMC1 cells and support the concept that adipose tissue may represent a valuable alternate source of MSCs to bone marrow for hard tissue regeneration.

Identification of Human Circulating Side Population (SP) Cells Co-expressing the Mesenchymal Stromal Cell Marker, Stro-1. A. H. Undale, U. I. L. Moedder, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Stem cells that stain differentially with vital dyes such as Hoechst 33342 are described as side population (SP) cells, which can be distinguished by their capacity to efflux the Hoechst 33342 dye efficiently and by their unique profiles in Hoechst red versus Hoechst blue bivariate fluorescent-activated cell sorting dot plots. SP cells have been identified in a wide variety of mammalian tissues, including murine and human bone marrow and human peripheral blood. These cells can not only regenerate the cells of the hematopoietic lineage but have also been shown to regenerate several mesenchymal lineages, suggesting their pluripotent potential. Studies conducted by Aubin et al (Bone 2006, 38:662) showed that SP cells isolated from fetal rat calvaria were enriched for osteoprogenitor cells.

We undertook the current study to investigate whether SP cells in human peripheral blood expressed the mesenchymal stromal cell marker, Stro-1, which identifies cells with osteogenic potential in human bone marrow. We examined the SP cell population in human peripheral blood mononuclear cells (MNCs) obtained by Ficoll-gradient centrifugation. The SP cell population (mean \pm SEM, n=4) was identified by flow cytometry based on the ability of these cells to efflux Hoechst 33342 and their typical Hoechst 33342 profile. Flow cytometric analyses identified 0.14 ± 0.01 % of MNCs as SP cells. Further phenotypic characterization of the SP cell population was done using a monoclonal Ab to Stro-1. We found that 1.6 ± 0.4 % of the SP cell population expressed Stro-1, so that the total percentage of Stro-1^{pos}/SP^{pos} cells in MNCs was 0.002%. These results thus demonstrate for the first time the presence of the stromal cell marker Stro-1 on a subset of human peripheral blood SP cells. The circulating Stro-1^{pos}/SP^{pos} cells may represent an early mesenchymal stem cell population that could potentially be expanded and have utility in the treatment of metabolic bone diseases.

β Trcp1 Ubiquitin Complex Regulates Ihh-promoted Osteoblast Differentiation Through Gli2 Ubiquitination. M. Wada^{*1}, T. Matsubara¹, K. Hata^{*1}, T. Imamura^{*2}, R. Nishimura¹, T. Yoneda¹. ¹Osaka University, Osaka, Japan, ²JFCR Cancer Institute, Tokyo, Japan.

Accumulating data indicate that Indian hedgehog (Ihh) promotes the differentiation of mesenchymal stem cells into osteoblasts. It is also suggested that the transcription factor, Gli2, which is activated by Ihh, plays a role in this differentiation process. Recent studies have reported that an ubiquitin ligase complex consisting of β Trcp1 regulates Gli2 expression, suggesting an involvement of β Trcp1 in the osteoblast differentiation. However, the precise role of β Trcp1 in Ihh/Gli2-promoted osteoblastogenesis is currently unknown. Furthermore, it is also unclear whether and how Ihh signaling regulates ubiquitination of Gli2 in conjunction with β Trcp1. In the present study, we investigated the role of β Trcp1 in the osteoblast differentiation stimulated by Ihh signaling and the relationship between Ihh and β Trcp1 ubiquitination system. Overexpression of β Trcp1 together with protein kinase A (PKA) and glycogen synthase kinase 3 (GSK3 β), both of which are shown to be involved in controlling β Trcp1 activity during Gli2 ubiquitination, truncated Gli2 into the repressor form of 78KD. Overexpression of β Trcp1/PKA/GSK3 β also suppressed transcriptional activity of Gli2, suggesting a negative regulatory role of the β Trcp1 ubiquitin ligase complex in Ihh/Gli2 signaling. We next examined the effects of a mutant β Trcp1 (β Trcp1- Δ F-box), which lacks the F-box domain necessary for ubiquitin ligase complex formation on osteoblast differentiation using the mesenchymal cell line C3H10T1/2. Treatment with Ihh or overexpression of Gli2 promoted osteoblast differentiation in C3H10T1/2 cells. Of note, overexpression of β Trcp1- Δ F-box markedly stimulated the Gli2-induced osteoblast differentiation. However, of interest, β Trcp1- Δ F-box had little effects on the Ihh-induced osteoblast differentiation, raising a possibility that Ihh functions through influencing ubiquitination system upstream of β Trcp1. To investigate this, we focused on GSK3 β that functions upstream of β Trcp1. Since GSK3 β activity is known to be negatively-regulated by phosphorylation, we examined the effects of Ihh on GSK3 β phosphorylation and found that Ihh phosphorylated GSK3 β . Moreover, Fused, the serine/threonine kinase which is one of the essential components of hedgehog signaling, also phosphorylated GSK3 β . Collectively, our results suggest that the β Trcp1 ubiquitin complex modulates the Ihh-promoted osteoblast differentiation by regulating Gli2 ubiquitination and that Ihh down-regulates the β Trcp1 ubiquitination system through inactivation of GSK3 β as a consequence of its phosphorylation by Fused.

Ectoderm Neural Cortex 1, a Wnt Target Gene, Is Expressed in Chondrocytic and Osteoblastic Cells. L. E. Worton¹, Y. Shi^{*2}, E. J. Smith^{*2}, D. G. Little^{*3}, J. P. Whitehead^{*1}, E. M. Gardiner¹. ¹Diamantina Institute for Cancer, Immunology and Metabolic Medicine, Brisbane, Australia, ²Garvan Institute of Medical Research, Sydney, Australia, ³Children's Hospital, Westmead, Sydney, Australia.

The canonical Wnt pathway has been implicated in bone mass regulation; however, few Wnt target genes affecting this process have been elucidated. Ectoderm Neural Cortex 1 (ENC1) is a reported Wnt target gene found to be involved in adipocyte differentiation. ENC1 has also been reported to interact directly with retinoblastoma protein (p110 Rb) and with filamentous actin in various cell lines. Therefore, this study was undertaken to establish a role for ENC1 in bone biology. Transcript profiles of fracture callus tissues collected at early stages in a rabbit model of tibial distraction osteogenesis were generated using human ResGen cDNA arrays. ENC1 expression was up-regulated 40-fold between 2 and 4 or 6 weeks post distraction, correlating with a marked change in callus cellular composition. In 2-week callus, fibroblastic and cartilaginous cells predominated. At 4- and 6-weeks, mature osteoblasts and osteocytes were more abundant, coinciding with a notable increase in bone forming activity. ENC1 transcripts were localized to osteoblastic cells and remnant chondrocytes by in situ hybridization of rabbit 4-week fracture callus sections. Furthermore, in normal mouse bone, ENC1 was expressed in growth plate and articular chondrocytes and in mature periosteal osteoblasts. Quantitative RT-PCR analysis confirmed the expression of ENC1 during the differentiation of primary osteoblastic cultures, and of cultured MC3T3-E1 and Kusa-O 4b10 osteoblastic cells. Expression of ENC1 was also confirmed in osteosarcoma and chondrocytic cell lines. Transient expression of epitope tagged ENC1 in MG63 and SaOS2 osteosarcoma cells and stable over-expression in HEK293 and CHO cell lines showed ENC1 to have a cytoplasmic distribution with staining of a subset of nuclei in MG63 cells. There was no evidence of co-localization with filamentous actin. These results indicate that ENC1 is expressed in chondrocytic and osteoblastic cells and may play a role in Wnt stimulated osteoblastic differentiation.

Glucocorticoid-induced Leucine-Zipper (GILZ) Enhances Osteoblast Differentiation of Bone Marrow Mesenchymal Stem Cell by Inhibiting Adipocyte Differentiation. W. Zhang^{*1}, X. Shi². ¹Department of Neurology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China, ²Institute of Molecular Medicine & Genetics, Medical College of Georgia, Augusta, GA, USA.

Mesenchymal stem cells (MSCs) can differentiate into multiple cell lineages including osteoblasts and adipocytes. A recently identified transcription factor, glucocorticoid-induced leucine zipper (GILZ), was shown to inhibit the expression of peroxisome proliferator-activated receptor gamma-2 (PPAR γ 2) and blocks adipocyte differentiation. To investigate the role of GILZ in osteoblast differentiation of MSCs, we isolated bone marrow MSCs from C57BL/6 mice using negative-immuno-depletion and positive-immuno-selection approaches, and overexpressed GILZ in MSCs using retrovirus-mediated gene delivery approach. Our results show that overexpression of GILZ in MSCs increased alkaline phosphatase (ALP) activity and enhanced mineralized bone nodule formation. Consistent to this phenotypic conversion, real-time RT-PCR analysis showed that both basal and differentiation-induced transcripts of the lineage commitment gene Runx2/Cbfa1, as well as osteoblast differentiation marker genes including ALP, type I collagen, and osteocalcin, were all increased in GILZ-expressing cells. In contrast, the mRNA levels of adipogenic PPAR γ 2 and C/EBP α were significantly reduced in GILZ-expressing cells under both osteogenic and adipogenic conditions. In conclusion, results of this study show that GILZ functions as a modulator of MSC differentiation and that GILZ can shift the balance between MSC osteoblast and adipocyte differentiation. These data suggest that GILZ may have therapeutic value for fracture repair and osteoporosis therapy.

Partial Rescue of the Vitamin D Deficient Phenotype of 1 α -hydroxylase Gene Knockout Mice by Transplantation of Wild-Type Non-Adherent Bone Marrow-Derived Mesenchymal Stem Cells. Z. Zhang¹, J. Tong^{*1}, D. Goltzman², D. Miao³. ¹Department of Public Health, Suzhou University, Suzhou, China, ²Medicine, McGill University, Montreal, PQ, Canada, ³Institute of Dental Research, Nanjing Medical University, Nanjing, China.

We previously demonstrated that there are non-adherent mesenchymal stem cells (MSCs) in adult bone marrow and that transplantation of non-adherent bone marrow-derived MSCs (NA-BM-MSCs) can rescue lethal-dose irradiated VDR^{-/-} mice by re-constructing a hematopoietic system and repairing damaged tissues. To determine whether the transplantation of NA-BM-MSCs can rescue the phenotype of 1 α (OH)ase^{-/-} mice, 2x10⁶ NA-BM-MSCs from wild-type mice or vehicle (as a control) were transplanted into lethal-dose irradiated female 1 α (OH)ase^{-/-} mice by tail vein injection. Our results show that all control mice irradiated at a 10 Gy dose died within 2 weeks, however, following transplantation of NA-BM-MSCs, 75% and 70% of lethal-dose irradiated mice were viable at 1 and 2 months, respectively. The phenotype of viable 1 α (OH)ase^{-/-} recipients was compared with that of age-matched, non-irradiated wild-type and 1 α (OH)ase^{-/-} mice. 1 α (OH)ase mRNA in kidney was undetectable by RT-PCR in non-irradiated 1 α (OH)ase^{-/-} mice but was detected in viable irradiated 1 α (OH)ase^{-/-} recipients, although levels were lower when compared to levels in non-irradiated wild-type kidney. Serum 1,25(OH)₂D₃ levels were undetectable in non-irradiated 1 α (OH)ase^{-/-} mice and rose to 24% of non-irradiated wild-type mice (96 \pm 11.3ng/L) in viable irradiated 1 α (OH)ase^{-/-} transplant recipients (23 \pm 8.5ng/L). Serum calcium levels rose to 2.08 \pm 0.25mmol/L in viable 1 α (OH)ase^{-/-} recipients from 1.6 \pm 0.18mmol/L in non-irradiated 1 α (OH)ase^{-/-} mice. Skeletal mineralization improved, but did not reach normal levels in viable 1 α (OH)ase^{-/-} recipients as demonstrated by BMD measurement, micro-CT analysis and von Kossa staining of undecalcified sections. In lethal dose irradiated and non-transplanted control 1 α (OH)ase^{-/-} mice, osteoblasts in the endosteum, periosteum and metaphysis were severely damaged, whereas chondrocytes and osteocytes sustained less injury. Osteoblasts were regenerated in viable 1 α (OH)ase^{-/-} recipients. The number of WBC in the peripheral blood and CD4 and CD8 positive cells in spleen were decreased in non-irradiated control 1 α (OH)ase^{-/-} mice but were normalized in viable 1 α (OH)ase^{-/-} recipients. This study indicates that donor NA-BM-MSCs cells can relocate to multiple tissues where they synthesize 1 α (OH)ase and produce 1,25(OH)₂D₃ that contributes to the improvement of serum calcium and skeletal mineralization and where they produce immune cells that contribute to the viability of irradiated 1 α (OH)ase^{-/-} recipients.

Disclosures: Z. Zhang, None.

Tension Stress/Stain Induced Osteogenesis in Canine Leg Lengthening Procedures. J. J. Zhao, J. A. Jacobson^{*}, Y. Jiang. Osteoporosis and Arthritis Lab, Department of Radiology, University of Michigan, Ann Arbor, MI, USA.

We evaluated distraction osteogenesis under stimulation of mechanical tension stress/strain, and ability of various imaging modalities for detection and monitor its progress, since the rate of distraction depends on the successful production of new bone in the distraction gap. Early evaluation of new bone production is important. Overly fast distraction will inhibit new bone formation and mineralization while overly slow distraction will lead to premature consolidation.

Tibial and fibular midshaft osteotomy was performed in 25 adult canines, distracted at the 7th day post-surgery using Ilizarov's equipment at 1 mm daily till reaching 3 cm lengthening, and examined weekly by ultrasound and radiography. Osteotomy of the left tibia without distraction was severed as control. They were euthanized at 3, 5, 7, 9, and 11 weeks post-surgery. The tibias were examined using DXA, CT, MRI, and processed for histomorphometry.

Ultrasound and DXA detected new bone formation within the distraction site as echogenic foci at 2-3 weeks post-surgery. Serial follow-up sonograms showed that echogenicity increased progressively in number and size till coalesced as echodense bone. Radiographs showed linear streaks of new bone formation in the distracted gap at 3-4 weeks, and a bone bridge formed at about 7 weeks post-surgery. CT showed only bony structure while MRI clearly delineated fibrous, cartilaginous, and bony tissues. Histomorphometry showed location-dependent bone formation and remodeling activity. Both intramembranous and endochondral but mainly intramembranous bone formed linearly oriented columns of interconnecting trabecular plates of woven and lamellar types. Bone formation rate, bone volume, and percentage of bone surface covered cuboidal osteoblast were significantly increased within the distraction and osteotomy callus regions compared with controls. At the original cortical bone, periosteal bone formation and increased bone resorption were found. Imaging modalities were highly correlated with histomorphometric measures of cartilage and newly formed bone, and measures of cortical porosity and increased osteoclasts in the original cortical bone ($r^2 = 0.81-0.88$).

In conclusion, tension stress/stain induced distraction osteogenesis represents an oriented continuum of primary gap healing, associated with enhanced bone formation likely resulting from rapid recruitment and activation of bone forming cells and increased surface area available for matrix deposition and mineralization. Ultrasound and DXA can detect bone formation and monitor mineralization process earlier than radiograph in leg lengthening procedures. The imaging findings are strongly correlated with histomorphometric measurement.

PTH Enhances ATP Induced ERK1/2 Activation via a Competitive Mechanism Involving G-protein Coupled Receptor Kinase 2 in Osteoblastic Cells. Y. Gu^{*}, Y. Xing^{*}, H. J. Donahue, J. You. Division of Musculoskeletal Sciences, Department of Orthopaedics and Rehabilitation, The Pennsylvania State University College of Medicine, Hershey, PA, USA.

In vivo studies show that parathyroid hormone (PTH) enhances mechanically induced bone formation. Previously we and other investigators found that osteoblastic cells responded to mechanical loading induced fluid flow by releasing ATP and activating the P2Y purinergic signaling pathway. In addition, in vitro studies demonstrated that co-activation of P2Y and PTH receptors leads to a profound synergism. However, the molecular mechanism of the synergistic effect of ATP and PTH in osteoblastic cells is unclear. P2Y and PTH receptors are both G-protein coupled receptors (GPCR), which are presumably desensitized by G-protein coupled receptor kinase (GRK). Thus, we hypothesized that PTH enhances ATP induced osteoblastic responses by inhibiting the desensitization of P2Y receptors via a competitive mechanism involving GRK. To test our hypothesis, we first employed osteoblastic MC3T3-E1 cells to examine ERK1/2 activation in response to ATP stimulation in the presence of PTH. Our results indicated that, after pretreatment with 50nM PTH, ATP not only increased the peak activation of ERK1/2 at 5 min, but also extended the activation to 10 min and 15 min compared to those without PTH, demonstrating the synergistic effect of ATP and PTH. Secondly, we over-expressed GRK2 in MC3T3-E1 cells and found that ERK1/2 activation at 5 min was significantly decreased compared with that of MC3T3-E1 cells over-expressing an empty vector (control) in the presence of PTH. In contrast, when we over-expressed a GRK2 dominant negative mutant, GRK2/K220R, in osteoblastic cells, the enhancement of ERK1/2 activation at 5 min was increased further compared with that of control MC3T3-E1 cells in the presence of PTH, suggesting that GRK2 is involved in the synergistic effect of ATP and PTH. Finally, PTH has been shown to induce ERK1/2 activation via PKA signaling pathways. Here we tested whether PKA signal pathways are involved in the synergistic effect by using a PKA activator, forskoline, instead of PTH. Our results showed that activating PKA signaling pathway by forskoline did not enhance ATP induced ERK1/2 activation. Furthermore, we demonstrated that PKA inhibitor did not suppress the synergistic effect of ATP and PTH in osteoblastic cells, suggesting that PKA activation is not required for the synergism. Taken together, our results demonstrate that it is not the PTH downstream signaling pathway (PKA), rather the regulation of PTH and P2Y receptors by GRK2 that is responsible for the synergism, suggesting a competitive mechanism involving GRK2 in MC3T3-E1 cells.

Phosphorylation of Caveolin-1 in Response to Fluid Shear in Osteoblasts Is Mediated by P2X7 Activation. S. Majumdar, K. Czymmek*, E. J. McLaughlin*, R. L. Duncan. Biological Sciences, University of Delaware, Newark, DE, USA.

The anabolic responses of bone to mechanical stimuli are triggered by cellular signaling events that occur within seconds and minutes of initiation of load. One of these early signaling events is the rapid release of ATP, and perhaps other nucleotides, that can bind to purinergic receptors that are essential for mechanotransduction. We have recently shown that the P2X7 receptor is central to the response of bone to exogenous loading, in vivo. We have further shown that binding of the P2X7 receptor activates an entry mechanism capable of cellular uptake of large solutes (>600 Da). Since P2X7 receptors have been associated with lipid rafts in the membrane, we postulated that nucleotide binding to the P2X7 receptor could induce endocytosis via caveolin activation. When 12 dynes/cm² laminar shear was applied to MC3T3-E1 osteoblasts, we found that YO-PRO1, a 629 Da dye, was taken up by the cell within 5 min of the onset of shear, with peak uptake observed at 30 min. Extended application of shear demonstrated that YO-PRO1 uptake subsequently decreased at 45 min. When P2X7 receptors were activated in MC3T3-E1 osteoblasts by the addition of BzATP, the pharmacologic agonist of P2X7, a similar time course of YO-PRO1 uptake was observed. Western blot analysis of MC3T3 cells showed that static controls demonstrated little phosphorylation of caveolin-1 while application of fluid shear stress greatly increased the phosphorylation of caveolin-1. Time course studies demonstrated that phosphorylation of caveolin-1 peaked at 30 min and subsequently decreased at 60 min, which is correlates with our dye uptake experiments. Addition of BzATP also increased caveolin-1 phosphorylation implicating the activation of the P2X7 receptor in the phosphorylation of caveolin. Amino acid sequence analysis of the P2X7 receptor indicates a region which is specific for caveolin binding or interaction, further suggesting an interaction between caveolin and P2X7. These data suggest that caveolin phosphorylation may be a direct function of P2X7 activation and that caveolin phosphorylation triggers an entry mechanism that is large enough to take in large molecules as seen by the dye uptake experiments. Caveolin has been suggested as a scaffold for protein-protein interactions for downstream signaling events. Thus, caveolin phosphorylation may be central to the cellular transduction of a mechanical signal.

Glucocorticoids Stimulate Wnt Expression in Mature Osteoblasts. W. Mak, H. Zhou, C. R. Dunstan, M. J. Seibel. Bone Research Program, ANZAC Research Institute, University of Sydney, Australia.

Differentiation of mesenchymal cells towards the osteoblastic lineage is governed by an array of different factors. Glucocorticoids (GC) have been shown to promote osteoblastic differentiation while Wnt signalling can promote osteoblastogenesis and inhibit adipogenesis. However, whether there is a direct relationship between these signalling pathways has not been fully established. Transgenic (tg) overexpression of 11beta-hydroxysteroid dehydrogenase type 2 (HSD2), a GC inactivating enzyme, under the control of a 2.3kb collagen type I promoter (Col2.3-HSD2) abrogates intracellular GC signalling in mature osteoblasts. We have previously demonstrated that calvarial cell cultures derived from Col2.3-HSD2 tg mice exhibit reduced osteoblastogenesis and retarded Wnt/β-catenin signalling. Here, we have bred Col2.3-GFP mice with Col2.3-11βHSD2 tg mice to generate Col2.3-HSD2-GFP tg and Col2.3-GFP WT mice. We investigated the GC-dependent regulation of Wnts in mature osteoblasts by isolating GFP positive cells using FACS to yield a population of mature osteoblasts. GFP-positive cells were subsequently grown in serum free media. Cultures were treated with a single-dose of 10-8M corticosterone for 0.5, 2, 4, 6 hours. In GFP positive cell cultures derived from WT mice, Wnt7b mRNA expression was up-regulated 4-fold and 3.5-fold following 2 and 4 hrs of treatment, respectively, using real time PCR analysis. Wnt10b mRNA expression was up-regulated 2.5-fold at 2 hrs, and 3-fold at 4 hrs, compared to controls. Up-regulation of Wnt7b and Wnt10b expression was blocked by the addition of cycloheximide, suggesting the requirement for de novo protein synthesis. 10-8M corticosterone had no effect on GFP-positive cells derived from Col2.3-GFP-HSD2 tg mice, with no change in the expression of either Wnt protein. In contrast to mature osteoblasts, enriched precursor cells population (first enzymatic release of the calvaria) derived from either Col2.3-GFP WT or Col2.3-GFP-HSD2 tg calvaria Wnt7b was not detected, while there was only low expression of Wnt10b. We conclude that intact GC signalling in mature osteoblasts, in association with transcriptional regulatory complexes, is essential to stimulate Wnt protein expression and hence osteoblastic differentiation.

Prostaglandin E₂ Acts Through EP2/EP4 Receptors to Upregulate RGS2 Expression in Osteoblasts. C. Nunn*, S. J. Dixon, P. Chidiac*. Physiology and Pharmacology, University of Western Ontario, London, ON, Canada.

Prostaglandin E₂ (PGE₂) can stimulate bone formation in vivo and in vitro. Osteoblasts express multiple subtypes of prostaglandin E₂ (PGE₂) receptors, which are coupled to Gq (EP1), Gs (EP2 and EP4) and Gi/o (EP3). RGS (regulators of G protein signaling) proteins suppress signaling via G protein-coupled receptors (GPCRs). Upregulation of RGS2 expression in osteoblasts mediates cross desensitization between receptors coupled to Gs and those coupled to Gq (J Biol. Chem. 281: 32684, 2006). Thus, RGS2 may play an important role in regulating PGE₂ signaling through its different receptor subtypes. The aims of this study were to determine the effects of PGE₂ on RGS2 expression in osteoblasts, and the receptor subtypes which mediate these effects. Primary mouse calvarial osteoblasts were treated with PGE₂ at different concentrations for multiple time points before extraction and quantification of mRNA using real-time RT-PCR. PGE₂ increased RGS2 expression in a time-dependent manner, which was maximal at 1 h (6 fold increase over control) and decreased to control levels within 6 h. This effect of PGE₂ was concentration-dependent, with an EC₅₀ of 2 μM and maximal effect at 10 μM. To determine the receptor subtypes involved, cells were treated with EP receptor subtype-selective agonists (10 μM) for 1 h. Agonists for EP2/EP4 receptor subtypes (butaprost, 11-deoxy-PGE₂) stimulated RGS2 expression to a similar level as PGE₂, whereas agonists selective for EP1 (17-Ph-ω-trinor-PGE₂) and EP3 (sulprostone) receptor subtypes had little effect on RGS2 expression. Furthermore, isoproterenol (which acts through Gs) dramatically increased RGS2 expression, whereas PGF_{2α} (which acts through Gq) had no effect. Taken together, these data establish that RGS2 is upregulated in osteoblasts by PGE₂, acting through its Gs-coupled receptors. PGE₂ has been shown previously to stimulate bone formation via both Gs-coupled and Gq-coupled receptor subtypes. Our findings suggest a mechanism for cross desensitization between Gs- and Gq-coupled receptors stimulated by the same agonist (PGE₂), in which activation of Gs leads to increased expression of RGS2, which in turn suppresses signaling through Gq.

ATP Modulation of Mitogen-Activated Protein Kinases (MAPKs) and c-fos Expression in Osteoblastic and Breast Cancer Cells. P. Scodelaro, Bilbao*, S. Katz*, R. Boland, A. Russo de Boland*, G. Santillán*. Biología, Bioquímica & Farmacia, Universidad Nacional del Sur, Bahía Blanca, Argentina.

We previously showed that ATP and UTP increase intracellular calcium concentration ([Ca²⁺]_i) in MCF-7 breast cancer and osteoblastic ROS 17/2.8 osteosarcoma cells. The elevation of [Ca²⁺]_i was due to Ca²⁺ release from inner stores through activation of the PI-PLC/IP₃ pathway. In addition, mechanical stimulation after ATP or UTP but not ADP induced a transient Ca²⁺ influx in both cell lines, suggesting that P2Y_{2/4} receptor activation is required for this mechanical stress-activated Ca²⁺ (SAC) influx. Moreover, ATP-dependent SAC influx mediated the phosphorylation of mitogen-activated protein kinases (MAPKs) ERK1/2, p38 and JNK1 only in ROS 17/2.8 cells. In this work, we investigated the expression of P2Y_{(1,2,4)}} subtype purinoceptors and the participation of PKC and Src family kinases in the activation of MAPKs by ATP in both cell lines. The involvement of ATP dependent SAC influx in the regulation of c-fos expression was examined. RT-PCR studies supported the expression of P2Y₂ subtype receptor in the osteoblastic and breast cells in the osteoblastic and breast cells, while P2Y₁ was not detected neither in MCF-7 nor ROS17/2.8 cells, and P2Y₄ was weakly expressed only in MCF-7 cells. The use of Ro 318220, a PKC inhibitor, showed that PKC participates in the phosphorylation of MAPKs by ATP in both cell lines. Otherwise, the use of PP1 or PP2, Src family kinases inhibitors, involved the participation of such kinases in the phosphorylation of MAPKs by ATP only in ROS 17/2.8 cells, although phosphorylation of Src (Tyr 416) was also observed in MCF-7 cells. Maximum levels of c-fos induction were observed after 30 min treatment with ATP in both cell lines, and the use of Gd³⁺, a SAC influx inhibitor, reduced its expression in ROS17/2.8 but not in MCF-7 cells. These results show that P2Y₂ is the main receptor subtype involved in ATP-dependent SAC influx in osteoblasts and breast cells. Unlike MCF-7 cells, Src family kinases and SAC influx, respectively, participate in MAPKs activation and c-fos expression induced by ATP only in ROS17/2.8 cells.

Ubc9 Promotes Stability of Smad4 and Regulates BMP Signaling Pathway in Osteoblastic Saos-2 Cells. K. Shimada¹, N. Suzuki², M. Maeno³, M. Eda^{*1}, K. Yamada^{*1}, K. Ito^{*1}. ¹Department of Periodontology, Nihon University School of Dentistry, Tokyo, Japan, ²Department of Biochemistry, Nihon University School of Dentistry, Tokyo, Japan, ³Department of Oral Health Science, Nihon University School of Dentistry, Tokyo, Japan.

Bone morphogenetic proteins (BMPs) play a specific role in osteoblastic differentiation and maturation. BMPs induce receptor-regulated Smads (R-Smads). The R-Smads form complexes with the common-partner Smad, which is Smad4 in mammals. These complexes translocate and accumulate in the nucleus and regulate the transcription of various target genes. However, the function of Smad4 remains unclear. Here, we performed a yeast two-hybrid screen using Smad4 as bait and a cDNA library from human bone marrow to identify the proteins interacting with Smad4. For this screen, full-length human Smad4 was cloned in pGBKT7 vector to express it as a fusion with the GAL4-binding domain, and the cDNA library was screened. Two cDNA clones of full-length Ubc9 were identified. To analyze the function of Ubc9 in the BMP signaling pathway, endogenous Ubc9 was disrupted in human osteoblastic cell line Saos-2 using a 19-nucleotide siRNA and examined its effectiveness in silencing Ubc9 expression. The gene expression of BMP-induced transcription factor genes, including Runx2, Dlx5, Msx2, and Osterix, was examined using real-time reverse-transcribed PCR and the protein levels of Smad4, Smad1 and phospho-Smad1 were determined with SDS-PAGE and Western blotting. Moreover, to observe whether Smad4 was sumoylated or not, Smad4 was overexpressed using pcDNA3.1 vector in Saos-2 cells and the sumoylated-Smad4 was observed with SDS-PAGE and Western blotting using anti-SUMO1 antibody, because Ubc9 was SUMO-conjugating enzymes E2. The efficiency of silencing Ubc9 mRNA level was approximately 70%. The expression of Runx2, Dlx5, Msx2, and Osterix mRNA was markedly inhibited when Ubc9 was silenced. The protein levels of Smad4 and phospho-Smad1 decreased dose-dependently and the level of Smad1 did not change by siRNA for Ubc9. The sumoylated-Smad4 was detected when Smad4 was overexpressed, and the sumoylated-Smad4 was inhibited by the addition of Senp2, SUMO-protease, was added. In conclusion, it is suggested that Ubc9 promotes stability of Smad4 and Smad4 is sumoylated. Ubc9 should be required the upregulation of BMP signaling pathway because the gene expression of the transcriptional factors and the protein levels of phospho-Smad1 inhibit by siRNA for Ubc9.

Effect of Prostaglandin D₂ on Na-Dependent Phosphate Transport Activity in Osteoblast-like Cells. A. Shogo^{*}, S. Sekiguchi, A. Yokoyama^{*}, K. Inagaki^{*}, H. Kakizawa^{*}, N. Hayakawa^{*}, N. Oda^{*}, A. Suzuki, M. Itoh^{*}. Department of Internal Medicine, Fujita Health University, Aichi, Japan.

Prostaglandins (PGs) are well known to act as autocrine and paracrine factors in microenvironment including bone metabolism. Among them, PGD₂ has been reported to be produced by osteoblasts, and stimulates their proliferation, decreases both osteoprotegerin and RANKL and to induce osteoblast chemotaxis, suggesting the anabolic role of PGD₂ in bone metabolism. We have recently shown that Phosphate (Pi) transporter Pit-1 plays a critical role in the mechanism of the development of the extracellular mineralization of osteoblasts, and Pit-1 has been shown to be expressed in a subpopulation of hypertrophic chondrocyte. The aim of the present study is to investigate the effect of PGD₂ on Pi transport and its intracellular signaling mechanism in mouse calvaria-derived osteoblast-like MC3T3-E1 cells. PGD₂ time- and dose-dependently stimulated Pi transport in MC3T3-E1 cells. A protein kinase C (PKC) inhibitor calphostin C partially suppressed the stimulatory effect of PGD₂ on Pi transport. The selective inhibitors of mitogen-activated protein (MAP) kinases, such as ERK and p38, did not affect PGD₂-induced Pi transport. On the other hand, JNK inhibitor, SP600125, markedly suppressed the enhancement of Pi transport by PGD₂. Both LY294002, a phosphatidylinositol (PI) 3-kinase inhibitors, attenuated PGD₂-induced Pi transport. A selective inhibitor of S₆ kinase, rapamycin, reduced this effect of PGD₂, while Akt kinase inhibitor did not. In summary, these results suggest that PGD₂ stimulates Na-dependent Pi transport activity in osteoblast-like cells. The mechanism responsible for this effect is not mediated by p38 MAP kinase or Akt kinase, but involves activation of PKC, Jun kinase, PI 3-kinase and S₆ kinase.

AKT's Effects on β -catenin Regulate Osteoblasts' Responses to Mechanical Strain and PTH. A. Sinters^{*}, M. Muzylak^{*}, G. Zaman^{*}, V. J. Armstrong^{*}, L. E. Lanyon, J. S. Price. Veterinary Basic Science, Royal Veterinary College, London, United Kingdom.

Two major influences controlling bone mass and architecture are mechanical loading and PTH. One of the pathways implicated in bones' adaptive responses to load is the canonical Wnt pathway. In vitro we have shown that exposing osteoblastic cells to dynamic strain inhibits GSK3 β phosphorylation of β -catenin (β Cat), thereby allowing its translocation to the nucleus where it regulates transcription. Since regulation of β Cat via GSK3 β inhibition can be controlled by AKT we hypothesised that this effect of strain may be mediated through AKT.

To explore this hypothesis the plastic strips onto which monolayer cultures of UMR106 rat

osteoblast like cells had been seeded were subjected to a short period of dynamic 4-point bending engendering levels of strain sufficient to stimulate proliferation. Western blotting demonstrated that this exposure to strain stimulated a transient increase in the expression of phosphorylated AKT (^pAKT) and phosphorylated GSK3 β (inactive) as well as active (de-phosphorylated) β Cat (^p β Cat). Western blots of nuclear/cytoplasmic fractions showed that the strain-mediated nuclear translocation and activation of β Cat were inhibited by pre-treatment with the phosphatidylinositol 3 (PI3)-kinase inhibitor LY294002. Both LY294002 and the AKT specific inhibitor Triciribene also inhibited strain-related proliferation.

Treatment of UMR cells with high continuous concentrations of PTH (100nM) inhibited strain induced proliferation and reduced both basal and strain-induced levels of ^pAKT. PTH also induced the expression of the phosphatase MAP kinase phosphatase-1 (MKP-1) Since PTH signaling acts in part through protein kinase A (PKA), we treated UMR cells with the PKA inhibitor H89 alone, or in combination with PTH and/or strain. H89 treatment increased basal levels of ^pAKT and inhibited MKP-1 induction by PTH. H89 also resulted in a decrease in levels of total β Cat. In strained cells treated with H89 did not influence the increase in ^pAKT but reduced total β Cat levels, and thus failed to increase levels of activated β Cat. However, a combination of H89, PTH and strain resulted in AKT phosphorylation as well β Cat activation with no decline in total β Cat levels. Taken together, these data suggest that PI3K/AKT signaling is a key mediator of the responses to at least two key influences on osteoblasts. Acting through regulation of β Cat, AKT is integral to osteoblasts' responses to mechanical strain associated with bone formation. The responses of osteoblasts to high levels of PTH associated in vivo with resorption may be the result of PTH inhibiting AKT activation.

Regulation of RANKL Expression by Glucocorticoid in Human Osteoblast-like Cells. F. Hirano, N. Maruyama^{*}, K. Komura^{*}, K. Okamoto^{*}, Y. Makino^{*}, M. Haneda^{*}. Medicine, Asahikawa Medical College, Asahikawa, Japan.

Glucocorticoid-induced osteoporosis remains the most common secondary form of metabolic bone diseases. The soluble and transmembrane cytokines, RANKL, are produced by the osteoblast under hormonal and cytokine control and are essential for osteoclastogenesis and bone resorption. In contrast, osteoprotegerin is known to bind to RANKL and to block the interaction between RANKL and its receptor RANK. Glucocorticoid has been reported to induce RANKL mRNA expression in osteoblasts, although circulating soluble RANKL is reduced by glucocorticoid. The reasons of this discrepancy are still unknown. The purpose of this study was to clarify the regulation of RANKL expression by glucocorticoid in human osteoblast-like cells. We used human osteoblast-like cell line MG-63 and examined effect of glucocorticoid on RANKL expression. Quantitative real-time RT-PCR and ELISA methods revealed that 100 nM dexamethasone (DEX) significantly increased RANKL mRNA expression (15-fold, p<0.05) in MG-63 cells for a time-dependent manner and decreased soluble RANKL protein in supernatant, as expected. In addition, we found that DEX did not influence RANKL transcriptional activity by reporter gene assay using human RANKL promoter. Moreover, Treatment with actinomycin D and DEX markedly prolonged the half-life of RANKL mRNA in MG-63 cells, as compared to treatment with actinomycin D alone (T1/2 = over 24h v.s. 10h), presumably indicating that DEX-induced RANKL mRNA expression is due to the stabilization of RANKL mRNA. Next, we investigated effect of glucocorticoid on the expression of TNF converting enzyme (TACE), a known RANKL shedase. The activity of TACE was dose-dependently reduced by DEX. Moreover, 100 nM DEX significantly decreased both mRNA- and protein-expression of TACE by quantitative real-time RT-PCR and ELISA, respectively. Furthermore, 100 nM DEX clearly induced transmembrane RANKL protein in MG-63 cells by flow cytometry and Western blot analysis, suggesting that DEX-reduced soluble RANKL protein expression in supernatant is associated with the decreases of TACE activity and protein expression in MG-63 cells. In conclusion, we presented glucocorticoid up-regulated RANKL mRNA expression via the stabilization of RANKL mRNA and reduced soluble RANKL expression via the decrease of TACE expression, possibly indicating that glucocorticoid-induced transmembrane RANKL expression in osteoblasts mainly played a pivotal role in osteoclastogenesis.

Calcitriol Inhibits Marrow Stromal Cell Differentiation into Osteoblasts in a Manner Cooperative with but Independent of TGF-beta. D. Inoue, H. Ochiai^{*}, R. Okazaki. Third Department of Medicine, University of Teikyo School of Medicine, Ichihara-shi, Chiba, Japan.

Vitamin D is essential to skeletal homeostasis, as impaired action of vitamin D, caused by either vitamin D deficiency or loss-of-function mutations of the vitamin D receptor (VDR), leads to rickets/osteomalacia. However, its direct effect on bone cells has not been fully understood. Recent in vivo studies in mice have shown that the absence of VDR has an anabolic effect on bone, suggesting that vitamin D, at least under physiological conditions, is a negative regulator of bone formation. In the present study, we examined effect of vitamin D on early mesenchymal cell differentiation in our previously established culture system in which a bipotential mouse marrow stromal cell line, ST-2, was induced by BMP-2 to differentiate into osteoblasts and adipocytes.

We found that calcitriol or 1,25-dihydroxyvitaminD3 (1,25D) inhibited the BMP-2-induced ALP activity in a dose-dependent manner with the maximal effect being an almost complete inhibition at 10 nM. A physiological level (0.1 nM) of 1,25D readily caused a significant ALP reduction. Interestingly, in the same culture system, 1,25D also inhibited

the BMP-2-induced adipocytic differentiation as assessed by Oil-Red O-positive cell counts. These results indicate that 1,25D has a negative effect on the early phase of osteoblastic differentiation and that this effect is not a result of reciprocally enhanced adipogenesis.

Given the fact that TGF-beta counteracts the BMP stimulation of osteoblastogenesis and is able to modulate the VDR-dependent 1,25D action, we then tested a hypothesis that TGF-beta lies downstream of the anti-osteoblastogenic effect of 1,25D. As expected, TGF-beta inhibited the BMP-2-induced ALP activity in a dose-dependent manner. Suboptimal concentrations of 1,25D and TGF-beta showed additive effects. SB431542, a TGF-beta receptor kinase inhibitor, completely reversed the suppressive effect of TGF-beta, but showed virtually no effect on the effect of 1,25D. Luciferase assays using Id-1 promoter constructs revealed that TGF-beta, but not 1,25D, inhibited BMP-induced Smad-dependent transcription. We therefore conclude that 1,25D inhibits BMP-2-induced early osteoblastic differentiation in a manner cooperative with TGF-beta through a distinct mechanism. Elucidation of the molecular pathway by which 1,25D inhibits the BMP-induced mesenchymal cell differentiation into osteoblasts and adipocytes will not only help understand its physiological role in skeletal homeostasis but may also provide a theoretical basis for the development of novel selective VDR modulators with bone anabolic effects.

CCN3/NOV Inhibits BMP-2-induced Osteoblast Differentiation by Interacting with BMP and Notch Signaling Pathways. T. Minamizato^{*1}, K. Sakamoto^{*1}, S. Nakamura^{*2}, A. Yamaguchi¹. ¹Section of Oral Pathology, Graduate School of Tokyo Medical and Dental University, Tokyo, Japan, ²Section of Oral and Maxillofacial Oncology, Division of Maxillofacial Diagnostic and Surgical Science, Graduate School of Dental Science, Kyushu University, Fukuoka, Japan.

Several lines of evidence suggest that the CCN family of proteins is involved in regulation of mesenchymal cell differentiation. We demonstrated that CCN3/NOV associated with the Notch1 extracellular domain and inhibited myoblast differentiation through Notch signaling pathway. Further, we reported that Notch signaling is involved in BMP-2-induced osteoblast differentiation. These results prompted us to investigate the role of CCN3 in osteoblast differentiation and its involvement in the BMP and Notch signaling pathways. To explore whether CCN3 participates in regulation of osteoblast differentiation, we first overexpressed CCN3 and/or BMP-2 in MC3T3-E1 cells by adenoviruses. Transduction with CCN3 alone induced no apparent changes in the expression of osteoblast-related markers, whereas cotransduction with BMP-2 and CCN3 significantly inhibited the BMP-2-induced mRNA expression of Runx2, osterix, ALP, and osteocalcin. Immunoprecipitation-western analysis revealed that CCN3 associated with BMP-2. Compared to transduction with BMP-2 alone, cotransduction with BMP-2 and CCN3 attenuated the expression of phosphorylated Smad1/5/8 and the mRNA for Id1, Id2, and Id3, which are target molecules involved in the downstream of BMP signaling. Meanwhile, transduction with CCN3 activated Notch signaling pathway by increasing the expression of cleaved Notch1, an activated form of Notch1, and the mRNA expression of Hes1 and Hey1, the target genes of Notch in MC3T3-E1 cells. Overexpression of CCN3 also increased the promoter activities of Hes1 and Hey1 in C2C12 cells. Since Hey1/Hes1 is reported to inhibit Runx2 promoter activity, we investigated the effects of CCN3 on osteoblast differentiation using Hey1-deficient cells isolated from calvariae of Hey1 knockout mice. The inhibitory effects of CCN3 on the expression of BMP-2-induced osteoblast-related markers were nullified in these cells. Finally, we explored the expression levels of mRNA for CCN3 and proteins for phosphorylated Smad1/5/8 and cleaved Notch1 during bone regeneration in mice. All of these were highly upregulated during bone regeneration. Collectively, the present study indicate that CCN3 exerts inhibitory effects on BMP-2-induced osteoblast differentiation by interacting with the BMP and Notch signaling pathways, and these interaction might be involved in the process of bone regeneration.

High Mobility Group Proteins (HMGs) Coupled with TNF α Production Are Essential for Osteoclastogenesis. A. Brebene^{*1}, K. Yamoah^{*1}, A. Arabi^{*1}, H. Amano², G. Dolios^{*3}, R. Wang^{*3}, R. Yanagisawa^{*1}, E. Abe¹. ¹Endocrinology, Mt. Sinai School of Medicine, New York, NY, USA, ²Pharmacology, School of Dentistry, Showa University, Tokyo, Japan, ³Genetics & Genomics Sciences, Mt. Sinai School of Medicine, New York, NY, USA.

We previously have shown that TSHR (Thyroid stimulating hormone receptor) null mice exhibit osteoporosis due to increased osteoclast formation stemming from TNF α overproduction in osteoclast progenitors. Since the enhanced osteoclast formation in the TSHR null mice was normalized in TSHR and TNF α double null mice, TNF α is concluded to be a crucial factor for osteoporosis in TSHR deficiency. We next examined in detail the regulatory mechanisms of TNF α transcription by identifying the responsive sequence of the murine TNF α promoter and the associated transcription factor. HMG2 (high mobility group 2) was identified by mass spectrometry to bind to a specific sequence of the TNF α promoter and its expression level was increased by IL-1/TNF α , or by RANKL treatment in which TNF α expression was also stimulated. HMG2 in addition to HMG1 not only localized in the nucleus but was also secreted, and stimulated cytokine expression (IL-1, IL-6 and TNF α) and RANKL-induced osteoclast formation in a positive feedback manner. As HMG1 or HMG2 expression was suppressed by siRNA, TNF α and TRAP expression were significantly reduced. We also confirmed the parallel expression of

HMGs and TNF α in osteoclast progenitors from TSHR^{-/-} and TSHR^{+/-} mice, which overexpress TNF α , and TNF α ^{-/-} mice, which underexpress it. These results suggest that the newly identified HMGs are crucial factors in the regulation of TNF α expression and osteoclast formation under pathogenic conditions.

The Suppressive Effect of IL-27 in Osteoclastogenesis. M. Furukawa¹, H. Takaishi^{*1}, S. Sakai^{*1}, M. Yoda^{*1}, H. Takayanagi^{*2}, H. Yoshida^{*3}, Y. Toyama^{*1}. ¹Orthopaedic, Keio university, Tokyo, Japan, ²Department of Cellular Physiological Chemistry, Tokyo Medical Dental University, Tokyo, Japan, ³Department of Biomolecular Sciences, Faculty of Medicine, Saga University, Saga, Japan.

In recent years identification of cytokine of interleukin-12 family advanced, and it became clear to have different point of action depending on a differentiation stage of Th1. Among them, IL-27 is produced from antigen presenting cells and is viewed as inducing initial-phase Th1 differentiation by mediating receptor WSX-1/GP130 as EBI-3 and p28 heterodimers. Bone metabolism and the immune system have a correlative relationship, and both are controlled by various common cytokines in excessive osteoclastogenesis caused by inflammatory diseases, such as autoimmune arthritis. We examined the osteoclastogenesis and participation to Th17 for the purpose of clarifying a role of IL-27 in the inflammatory bone destruction. CD4+T cells were isolated by magnetic cell sorting from mouse spleen cells and were induced to Th17 using the anti-IL-4, anti-IL-12, anti-IFN- γ antibody, and IL-23 after stimulation with immobilized anti-CD3, anti-CD28 antibody. IL-17 expression of Th17 markedly increased by PMA+Ionomycin stimulation, and the stimulation of IL-27 restrained production of IL-17 in induction process from Naive CD4+T cells to Th17. With human and mouse bone marrow macrophages, the expression of p28 was strongly induced by LPS (100ng/ml) stimulation, but no changes were observed in WSX-1. In the mouse primary osteoblasts, IL-27 did not affect for the expression of RANKL, which was induced by D3+ PGE2 or IL-17 stimulation. Human CFU-GM was collected by incubating bone marrow obtained through prosthetic joint replacement surgery in a methylcellulose culture containing GM-CSF and IL-3. In the differentiation process induced by M-CSF+RANKL, IL-27 strongly inhibited the osteoclastogenesis of human CFU-GM in a dose dependent manner. (100ng/ml, 85%). Our study revealed that IL-27 directly inhibited osteoclastogenesis of human CFU-GM. The suppressive effect of IL-27, however, is not selective for IL-17 production in the induction process of Th17, but appears to cover a broad group of proinflammatory cytokines. Therefore, we assume that IL-27 can be used to respond temporally or spatially to the clinical state of an autoimmune disorder, and thus to react with versatility to inflammatory bone destruction.

Cascade of Gene Expression Indicates Chemokine MCP-1 Is Essential for Human Osteoclast Formation. R. M. S. Granfar^{*}, A. S. Stephens^{*}, S. R. J. Stephens^{*}, C. J. Day^{*}, N. A. Morrison. Health Science, Griffith University, Gold Coast, Australia.

The chemokine MCP-1 (CCL2) is essential, in human and mouse, for the formation of foreign body giant cells (FBGC), a multinucleated macrophage cell type similar to osteoclasts. We tested the hypothesis that MCP-1 is necessary for human osteoclast differentiation. On comparing chemokine induction by RANKL with that elicited by LPS or TNF- α , where numerous chemokines are strongly induced, it appeared that RANKL induced a restricted repertoire of chemokines in osteoclasts. MCP-1 and MIP- β (CCL4) were strongly induced by RANKL in human osteoclast progenitors within 24 hours (1200 fold and 40 fold respectively). Other chemokines (MIP- α , RANTES and CCL1) peaked later or were not as potently induced. MCP-1 receptor, CCR2b, was also strongly induced by RANKL (500 fold). As CCR2b expression increased through time, MCP-1 mRNA expression decreased, suggesting a feedback autocrine loop in osteoclast precursors.

A truncated form of MCP-1 with 7 amino acids removed (7ND) acts as dominant negative and blocks FBGC formation in mouse and human. Inhibition of MCP-1 autocrine loop signalling using both neutralising antibody and dominant negative MCP-1 (7ND) dramatically suppressed RANKL mediated osteoclast formation. Neutralising antibody to MCP-1 (4 μ g/mL) reduced osteoclast formation from 240 \pm 16 per cm² (control) to 188 \pm 17 (p=0.01) while 7ND (50ng/mL) suppressed osteoclast number to 21 \pm 1 per cm² (p=4.8 \times 10⁻⁸). Not only did 7ND reagent inhibit osteoclast differentiation, it also suppressed bone resorption activity of purified mature human osteoclasts, reducing dentine resorption from 81 \pm 3 to 18 \pm 3 pits per dentine slice (p=0.0002). The presence of 7ND prevented early RANKL mediated induction of JUN, suggesting that the MCP-1 autocrine loop is necessary for osteoclast transcription factor induction. Following the early 24 hour peak of induction of MCP-1 induction, calmodulin-1 was maximally induced at three days exposure to RANKL. Transcription factors NFAT1 and NFAT2 (thought to be essential for osteoclast formation) reached peak induction six days after MCP-1 induction. The fact that 7ND blocked mature osteoclast bone resorption indicates the surprising fact that chemokine signalling may be required for on-going bone resorption. Indeed, treating mature osteoclasts with MCP-1 enhanced bone resorption activity. Taken together, the data suggest that a highly specific assemblage of inflammatory chemokines is necessary for osteoclast differentiation and that continuous chemokine signalling is required for bone resorption.

G-CSF Enhances Osteoclast Differentiation and Function. R. M. S. Granfar*, C. J. Day*, N. A. Morrison. School of Medical Science, Griffith University, Southport, Australia.

Osteoclasts (OCs) are critical protagonists for the mobilization of the endosteal niche of hematopoietic stem cells. Granulocyte Colony Stimulating Factor (G-CSF) is a widely applied stem-cell mobilization treatment with clinically documented risk of mild to severe bone loss. If OC activity is required for stem cell mobilization, then G-CSF and potentially other stem cell mobilizers should enhance OC differentiation and bone resorption. The standard human mononuclear cell model of OC formation was used. Cells were cultured in MEM supplemented with 25ng/ml M-CSF. In these conditions, RANKL (20ng/ml) treatment results in OC formation in 14 days. OCs differentiated on collagen coated plates were purified over serum gradients to select for giant cells and then this fraction plated onto sperm whale dentine for bone resorption assays. Recombinant G-CSF (Peprotech) was used at doses up to 25 ng/ml. Markers of OC maturity such as dentine-resorption, multi-nucleation, as well as gene expression and protein presence of tartrate resistant acid phosphatase (TRAP), were analysed.

G-CSF treatment had strong effects on OC biology. As well as stimulating bone resorption activity in mature OCs, G-CSF had an early strong effect on OC size and number. Treatment with RANKL and G-CSF resulted in significantly larger OCs by 7 days when compared to RANKL treated cells ($p=0.0004$). Once RANKL treated OCs had matured (at 14 days) they were almost the same size as OCs treated with RANKL and G-CSF, suggesting that exogenous G-CSF accelerates early OC formation. RANKL and G-CSF increased the TRAP+ multi-nuclear cell count when compared to RANKL treated cells (7d $p=0.00005$ and 14d $p=0.013$). Using real time PCR analysis, TRAP mRNA content was significantly greater in G-CSF treated OCs, consistent with the increased number of TRAP positive cells compared to control treatment with RANKL ($p=0.007$). Continual treatment with RANKL and G-CSF over 21 days significantly increased bone resorption activity measured by pits on dentine slices relative to OCs treated with RANKL alone ($p=0.012$). Similarly, addition of G-CSF significantly stimulated bone resorption in mature purified OCs that had no prior treatment with G-CSF, suggesting that G-CSF receptor is present on mature OCs. Gene array showed RANKL induced G-CSF receptor in OCs (12 fold), consistent with the hypothesis that OCs respond to G-CSF as a result of RANKL mediated induction of G-CSF receptor.

In summary, G-CSF increases osteoclast bone resorption, TRAP expression, cell-size and multinucleation. The osteopenic effect of G-CSF therapy and endosteal hematopoietic stem cell mobilization may be regulated by the same phenomenon; G-CSF stimulation of osteoclast differentiation and bone resorption.

M-CSF Stimulates Bone Resorbing Activity of Mature Human Osteoclasts Via Increased Activation of AP-1 and NF κ B. J. M. Hodge*, M. A. Kirkland*, G. C. Nicholson. Clinical and Biomedical Sciences: Barwon Health, University of Melbourne, Geelong, Australia.

The critical role of M-CSF in the differentiation of osteoclasts (OC) is well established. In mature OC, M-CSF has been reported to regulate survival and motility, but no clear role in resorptive function has been established. In this study we investigated the role of M-CSF on resorbing activity of mature human OC.

Human OC were generated by treatment of CFU-GM-derived precursors with soluble hRANKL (125ng/mL) and hM-CSF (25ng/mL) for 14-21d. To quantify resorbing activity, mature OC were dissociated from the plastic substrate using a non-enzymatic buffer, settled onto dentine slices and cultured for 72h. Activation of NF κ B and AP-1 was assessed using a sandwich ELISA technique. I κ B α and ERK were assessed by Western analysis.

Neither M-CSF nor RANKL were required for mature OC survival over 72h. However, resorption function was absolutely dependent on the addition of RANKL. Co-treatment with M-CSF had a concentration-dependent biphasic action, greatly augmenting RANKL-induced resorbing activity (+181%) and actin ring formation (+131%) at 25ng/mL. RANKL alone activated NF κ B (+554%). M-CSF had no effect on NF κ B but potentiated RANKL-induced activation (+42%). In contrast, RANKL alone had no effect on AP-1 activation whereas M-CSF stimulated weakly (+63%) and the combination produced a synergistic effect (+171%). M-CSF activated phosphorylation of ERK 1/2, peaking at 5 min, whereas RANKL had no effect alone or in combination with M-CSF. M-CSF had no effect on I κ B α phosphorylation whereas RANKL alone stimulated, with no additional effect in combination with M-CSF. Time-lapse video-microscopy showed no apparent effect of M-CSF on the motility of OC co-treated with RANKL.

We have demonstrated that M-CSF is not required for survival of mature human OC, but it does potently modulate RANKL-induced resorbing activity via NF κ B and AP-1 activation. The molecular mechanism of this effect remains to be determined although we propose a convergence of RANK and fms signaling ("cross-talk") upstream of the critical OC transcription factors NF κ B and AP-1. These findings have important implications for the clinical management of diseases associated with excess bone resorption.

The Effects of IL-12 Related Cytokines, IL-23 and IL-27, on Osteoclast Formation and T Cell Properties. S. Kamiya*¹, T. Fukawa*¹, C. Nakamura*², T. Yoshimoto*³, S. Wada*¹. ¹Clinical Sciences, Josai International University, Chiba, Japan, ²Bio-analytical Chemistry, Josai International University, Chiba, Japan, ³Intractable Immune System Disease Research Center, Tokyo Medical University, Tokyo, Japan.

A number of evidence has shown that bone remodeling process was affected by host immune reactions. Above all, cytokines which could modulate T cell functions were much focused in this area. Interleukin (IL) -23 and IL-27, IL-12-related cytokines, have been shown to be involved in chronic inflammatory diseases by modulating T cell function and to differentiate naive CD4+ T cells to type 1 helper T. Here, we examined the effects of these cytokines on osteoclast (OC) formation induced by M-CSF/RANKL in the presence of T cells. Mouse Bbone marrow macrophage like cells (BMMs) were prepared through incubating bone marrow cells with M-CSF, and were cocultured with activated T cells, which were partially purified from isolated splenocytes by adhesion properties and were stimulated by anti-CD3 antibody (Ab).

When T cells were activated by 0.2 μ g/ml anti-CD3 Ab, and were cocultured with BMMs in the presence of M-CSF/sRANKL, the number of OC was reduced compared with that of co-cultures with innate T cells. The addition of IL-23 and IL-27 in this culture much strongly and significantly inhibited OC formation. Treatment with these cytokines alone also reduced OC formation minimally even in the absence of activated T cells. To understand this phenomenon more precisely, we explored possible factors which could be produced by the activated T cells and modulate OC formation. Although the production of TNF α , IL-4, and IFN γ , detected by ELISA, was not changed in T cells treated with IL-23 or IL-27, the production of IL-10 was increased by ~200% in T cells treated with IL-27 these interleukins. This was not the case for IL-23. In this process, we found that T treatment with IL-27 also significantly reduced sRANKL production in activated T cells. Furthermore, through FACS analysis revealed we found that treatment with IL-27 suppressed the expression of membrane-bound RANKL on the T cells. These effects of IL-27 could not be found in osteoblasts when stimulated by IL-6. The effects of IL-23 are now under investigation.

In this study, we found that IL-23 and IL-27 inhibited OC formation when cocultured with activated T cells. The effects of these interleukins IL-27 would be associated with modified cytokine-expression profile of the T cells. The findings observed in this study would suggest that IL-12 related cytokines may play crucial roles for OC formation in autoimmune-related skeletal diseases.

Endogenous TNF α in Osteoclast Precursor Cells Promotes Osteoclastogenesis Via c-Fos and NFATc1 Activation. A. Nakao*¹, H. Fukushima*¹, H. Kajiya*¹, F. Okamoto*¹, S. Ozeki*², K. Okabe*¹. ¹Physiological Science & Molecular Biology, Fukuoka Dental College, Fukuoka, Japan, ²Oral & Maxillofacial Surgery, Fukuoka Dental College, Fukuoka, Japan.

Although TNF α is well known to be an important factor for bone resorption, particularly in inflammatory bone diseases, the relevance of RANKL and TNF α in osteoclastogenesis remains unclear. In this study we examined the mechanism of TNF α induced osteoclastogenesis and its downstream signaling using RT-PCR, ELISA, Western blotting and luciferase activity assay. We show that osteoclastogenesis is suppressed by anti-TNF α - and anti-TNF receptor type I (TNFRI)-antibodies and in TNF α - and TNFRI-deficient mice using in vitro culture systems: (1) co-culture of mouse spleen derived osteoclast precursor cells (pOCs) with osteoblasts, (2) pure pOC culture and (3) RAW264.7 cells in presence of RANKL. In co-culture with TNF α - or TNFRI-deficient osteoblasts and wild type (WT) mouse pOCs, the number of osteoclasts was always reduced compared to that in combination with WT osteoblasts and WT pOCs. When pure pOCs without osteoblasts or RAW 264.7 cells were cultured in the presence of RANKL both TNF α and TNFRI neutralizing antibodies significantly inhibited RANKL-induced osteoclastogenesis. In contrast, addition of TNF α increased RANKL-induced osteoclastogenesis in both culture system. Furthermore, fewer osteoclasts were formed in co-culture with WT osteoblasts and pOCs derived from TNF α - and TNFRI-deficient mice. The number of osteoclasts was recovered by addition of TNF α into cultures of TNF α -deficient pOCs, but not TNFRI-deficient pOCs. We also found that RANKL directly induced TNF α expression and secretion in pOCs and RAW264.7 cells in a time-dependent manner. Endogenous TNF α in pOCs induced c-Fos and NFATc1. Expression rates of NFATc1 and c-Fos were significantly delayed and decreased in TNF α - and TNFRI-deficient pOCs compared to WT pOCs during osteoclastogenesis. These results indicate that TNF α is induced by RANKL in pOCs and serves as an autocrine factor promoting osteoclastogenesis through c-Fos and NFATc1 activation.

IL-23-Enhanced Osteoclastogenesis Are Mediated by STAT3 and NF- κ B Via Upregulation of RANKL from CD4+T cells. S. Park*, J. Ju*, K. Kang*, I. Kim*, H. Kim*. Internal Medicine, Division of Rheumatology, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.

Object. IL-23 is a new proinflammatory cytokine which stimulates T cells to subsequently produce inflammatory molecules, resulting in inflammatory arthritis. This study was undertaken to explore the role of IL-23 in CD4+T cells on RANKL expression and

osteoclastogenic activity.

Method. Joint cells, CD4⁺T cells and Fibroblast like synoviocytes (FLSs) were isolated from IL-1Ra^{-/-}mice. The level of RANKL mRNA were measured with realtime PCR after these cells were treated with various cytokines including IL-23, in combination with inhibitors of the intracellular signal pathway. Osteoclasts precursor cells were cocultured with CD4⁺T cells in the presence of IL-23 and subsequently stained for tartrate-resistant acid phosphatase (TRAP) activity. IL-1Ra^{-/-} mice were injected intra-articularly with a recombinant adenovirus expressing mouse IL-23.

Results. Expressions of IL-23, IL-17 and IL-1 β were increased in arthritic joints of IL-1Ra^{-/-} mice. Coexpression of IL-23, CD4⁺T cells and RANKL in pannus of arthritic joints was revealed by immunohistochemical staining. IL-23 increased expression of both RANKL in the mixed joint cells of IL-1Ra^{-/-}mice. IL-23 enhances the expression of RANKL in CD4⁺T cells. TRAP-positive osteoclastogenesis was enhanced by IL-23-stimulated CD4⁺T cells. Interestingly, IL-23 had the potential to induce osteoclastogenesis in itself without the help of CD4⁺T cells. In vivo, intraarticular injection of adenoviral vector carrying IL-23 accelerated the severity of arthritis in IL-1Ra^{-/-}mice and effected high expression of RANKL at inflammatory joints.

Conclusion. IL-23 induces not only joint inflammation but also bone destruction via RANKL expression in arthritic CD4⁺T cells. The various effects of IL-23 in CD4⁺T cells have an important clinical impact in the view point of joint destruction. The interactions among IL-23, CD4⁺T cells, osteoclasts and RANKL expression may be a potential therapeutic approaches in treating bone destruction in inflammatory diseases.

Regulation of Human Osteoclast Precursor Generation by Type II Cytokines and STATs. K. Park-Min^{*1}, M. Humphrey^{*2}, L. B. Ivashki^{*1}.

¹Arthritis and Tissue Degeneration program, Hospital for Special Surgery, New York, NY, USA, ²VAMC, Oklahoma City, OK, USA.

The first step in osteoclastogenesis is M-CSF-mediated generation of osteoclast precursors (pOC) that are responsive to RANKL stimulation from bone marrow progenitors or monocytes. The purpose of this study was to determine if type II cytokines that suppress osteoclastogenesis (IFN- γ , IFN- α/β , IL-10) inhibit human pOC generation and to explore underlying mechanisms. pOC were generated from human monocytes (and in some experiments from murine bone marrow cells) using M-CSF in the presence or absence of IFN- α , IFN- γ , or IL-10, and stimulated with RANKL. OC formation was analyzed by staining for TRAP positive multinucleated cells, OC gene expression was analyzed using real time PCR, and RANK-induced signal transduction was analyzed using immunoblotting. RNA interference and retroviral transduction were used to study the function of OC genes, and the role of Stat1 and Stat3 were investigated using cells from knockout mice. The generation of human pOC was associated with striking increases in expression of RANK and the key costimulatory receptor TREM2. Subsequent RANKL-induced osteoclastogenesis was strongly suppressed by IL-10, IFN- γ , and IFN- α , with concomitant suppression of OC-specific genes such as TRAP and cathepsin K. TREM2 expression in pOC and OC was essentially completely abrogated by IL-10 and IFN- γ ; IFN- γ and IFN- α also suppressed RANK expression. The effects of IL-10 were partially reversed by forced expression of TREM2. IL-10 also suppressed the proximal RANK signaling pathway. Type II cytokines suppress pOC generation by inhibiting expression of TREM2 and RANK. In addition, IL-10 suppresses pOC function by inhibiting signaling responses to RANKL by a mechanism that differs from the previously reported degradation of TRAF6 by IFN- γ . These results yield insights into the molecular regulation of initial steps of osteoclastogenesis by type II cytokines.

Skeletal Muscle-specific Overexpression Pregnancy-associated Plasma Protein-A (PAPP-A) Increases Bone Accretion in Mice. J. Wergedal¹, M. Rehage^{*2}, D. Phang^{*2}, W. Xing², B. Bonafede^{*2}, D. Hou^{*2}, S. Mohan¹, X. Qin^{*1}. ¹Department of Medicine, Loma Linda University, Loma Linda, CA, USA, ²Musculoskeletal Disease Center, J. L. Pettis Veterans Affairs Medical Center, Loma Linda, CA, USA.

We have recently reported that osteoblast-specific overexpression of PAPP-A, a protease for IGF binding protein-2, -4 and -5, increased bone size and bone formation rate in mice. On the other hand, somatic growth was not significantly enhanced, which is consistent with the lack of PAPP-A transgene expression in other non-skeletal tissues and the lack of detectable PAPP-A in circulation. In this study we tested the hypothesis that an increase in PAPP-A concentration in blood, as occurring during human pregnancy, would exert an anabolic effect on bone. Overexpression of PAPP-A in skeletal muscle using the human skeletal muscle alpha actin promoter significantly increased skeletal muscle mass at an age of 10 weeks. The PAPP-A transgene was highly expressed in muscle, leading to a significant increase in PAPP-A concentration and IGFBP-4 proteolysis in the blood. Conversely, PAPP-A transgene mRNA was not detected in bone. Compared with the wild-type littermates, transgenic mice exhibited a significant increase ($P<0.01$) in femur total bone content (26% \pm 4), cortical bone content (28.1 \pm 4.6), and cortical bone area (24% \pm 5) determined by pQCT, calvarial BMD (29% \pm 6) measured by DEXA, and calvaria thickness (39% \pm 6). In conclusion, 1) an increase in PAPP-A concentration in circulation can enhance bone accretion, 2) systemic administration of PAPP-A may be of clinical interest for the treatment of osteoporosis.

IL-33 Inhibits Osteoclast Formation Indirectly Through Osteoblastic Cells. H. Saleh^{*}, J. M. W. Quinn, T. J. Martin, M. T. Gillespie. Bone, Joint and Cancer Group, St. Vincent's Institute, Fitzroy, Australia.

IL-33 is a proinflammatory factor that induces Th2 cytokine production and is produced by endothelial cells in rheumatoid arthritis. Its receptor is ST2, and a natural soluble form of ST2 has anti-inflammatory actions. Since IL-33 is related to IL-18, an inhibitor of osteoclast (OC) formation, we investigated the actions of IL-33 on osteoclastogenesis in vitro.

We studied IL-33 effects on murine OC formation from the following cell populations that contain haemopoietic progenitors: bone marrow cells, M-CSF dependent non-adherent bone marrow macrophages (BMM), spleen cells and RAW264.7 cells. OC formation from these cells was stimulated either by treatment with RANKL (100ng/ml) plus M-CSF (30ng/ml), or by co-culture with 1,25 dihydroxyvitamin D3-stimulated osteoblastic cells.

In RANKL/M-CSF stimulated cultures, IL-33 dose dependently inhibited OC formation from bone marrow cells and spleen cells, with a maximal effect at 20ng/ml. However, these populations contain large numbers of non-hematopoietic cell types such as stromal cells and lymphocytes. OC formation in cultures of RAW264.7 cells or BMM was not inhibited by IL-33, suggesting that IL-33 does not act directly on these two types of immature myelomonocytic cells to block differentiation. In co-cultures of bone marrow, spleen and BMM populations with osteoblastic cells (primary calvarial osteoblasts or Kusa O osteoblastic cell line), dose dependent inhibition of OC formation by IL-33 was observed with a maximal effect also at 20ng/ml. Since OC formation from RANKL-stimulated BMM was not inhibited by IL-33, this suggests an indirect inhibitory action through the mediation of osteoblastic cells. To investigate whether this involved the induction of a soluble osteoblast-derived inhibitor we co-cultured Kusa O cells and BMM separated by a porous membrane in the presence of 1,25 dihydroxyvitamin D3. IL-33 inhibited OC formation in these cultures even when exogenous RANKL and M-CSF were also added suggesting the inhibition is not mediated by osteoprotegerin (OPG).

Our results indicate that IL-33 is a novel OC inhibitor that acts on osteoblastic stromal cells to induce a soluble inhibitor of OC formation that is not OPG. This points to a significant role for IL-33 and, by extension, its decoy receptor ST2 in bone metabolism.

Sonic Hedgehog in Fracture Repair and Osteoclast Formation. T. Shimo^{*1}, T. Yuasa², S. Isowa^{*1}, S. Ibaraki^{*1}, M. Enomoto-Iwamoto^{*2}, A. Sasaki^{*1}, A. Yamaguchi^{*1}, M. Pacifici², M. Iwamoto². ¹Oral and Maxillofacial Surgery, Okayama University Graduate School of Medicine and Dentistry, Okayama, Japan, ²Orthopaedic Surgery, Thomas Jefferson University, Philadelphia, PA, USA.

Sonic hedgehog (Shh) was originally identified as a critical factor in antero-posterior skeletal patterning in developing limb and has since been found to influence other essential developmental processes. In previous studies we found that Shh and other hedgehog proteins are transiently expressed in experimental bone fractures, indicating that the factors may be important in skeletal healing and remodeling. To test this hypothesis, we first monitored hedgehog gene expression in a mouse costal bone fracture model and then tested hedgehog protein functions. RT-PCR analysis showed that gene expression of Shh, hedgehog receptor Patched (Ptc) and its signal transducer Gli1 was strongly and coordinately up-regulated within 12h after fracture and lasted up to 48h. Up-regulation of family member Indian hedgehog (Ihh) was detected after 72h. In situ hybridization revealed that Shh transcripts were broadly distributed within the fracture site field by 6h, indicating that Shh expression is part of an acute response mechanism mounted by several local cell types. To gain insight into the nature of the cells responding to Shh, we created rib fractures in hedgehog reporter mice that harbor β -galactosidase linked to the promoter regions of the Ptc gene, a direct target of hedgehogs. Reporter activity was prominent and well distributed throughout the bone marrow of the fractured bone by 24h. Interestingly, reporter activity was particularly intense in many TRAP-positive and multinucleated cells, suggesting that hedgehog signaling is activated during formation and/or function of osteoclasts. To test this possibility directly, bone marrow-derived osteoclast progenitor cell populations were isolated from 5 week old mice and cultured in the presence or absence of exogenous recombinant Shh and/or RANKL. While Shh itself did not induce osteoclast formation in the absence of RANKL, it markedly enhanced osteoclast formation in RANKL-treated cultures as determined by TRAP staining and dentin pit formation assay. The stimulatory effects of Shh on RANKL-induced osteoclast formation were also observed in CD11b(+) and RAW264.7 cell cultures, were inhibited by treatment with hedgehog pharmacological inhibitor cyclopamine, and failed to occur in primary cultures of bone marrow cells lacking the hedgehog signaling receptor Smoothened. The results of the study provide clear evidence that hedgehog signaling is rapidly activated during bone fracture repair and could be part of mechanisms enhancing bone marrow progenitor cell function and, in particular, osteoclast differentiation and action.

Phenotypical Heterogeneity Between Osteoclasts Involved in the Endochondral Ossification and Bone Remodeling. S. Soeta, Y. Izu, S. Kamiya*, H. Amasaki*, Veterinary Anatomy, Nippon Veterinary Life Science University, Musashino-City, Tokyo, Japan.

Osteoclasts at the chondro-osseous junction of the epiphyseal growth plate play an essential role for replacement of cartilage with bone tissues in the endochondral ossification, and contribute to the longitudinal growth of long bones. Therefore, they are thought to be controlled by a different regulatory mechanism from osteoclasts resorbing bone tissues in the modeling and remodeling process. The purpose of this study is to clarify functional heterogeneity between osteoclasts involved in the endochondral ossification and in the modeling and remodeling process in the long bones. We investigated the expression of RANK, RANKL, Flk-1 (VEGF receptor 1), MMP-9, and MMP-13 immunohistochemically in osteoclasts in the tibiae of new-borne and young male rats. Osteoclasts, detected as TRAP-positive multinucleated giant cells, distributed throughout from epiphysis to diaphysis in the tibiae in rats aged 1 to 42 days. In rats aged 1 to 28 days, osteoclasts at the chondro-osseous junction showed RANK, RANKL and MMP-9-immunoreactivities, but not Flk-1 and MMP-13-immunoreactivities. In rats aged 35 and 42 days, however, osteoclasts at the chondro-osseous junction showed Flk-1 and MMP13-immunoreactivities in addition to RANK, RANKL and MMP-9-immunoreactivities. Osteoclasts on the surface of trabecular bones in the diaphysis showed RANK, RANKL, Flk-1, MMP-9 and MMP-13 immunoreactivities in rats aged 1 to 42 days. From the immunohistochemical observations, osteoclasts may be recruited to the chondro-osseous junction without VEGF-Flk-1 pathway, and absorb the cartilage tissue of the epiphyseal growth plate independent on MMP-13 in the growing period. Therefore, osteoclasts involved in the endochondral ossification in the epiphyseal growth plate may be regulated in a different manner from osteoclasts resorbing bone tissues in the modeling and remodeling process.

Nicotine and Lipopolysaccharide Stimulate the Formation of Osteoclast-like Cells by Increasing Macrophage Colony-Stimulating Factor and Prostaglandin E₂ Production by Osteoblasts. H. Tanaka*, N. Tanabe*, T. Kawato*, T. Katono*, A. Namba*, N. Suzuki*, M. Motohashi*, M. Maeno*, ¹Department of Oral Health Sciences, Nihon University School of Dentistry, Tokyo, Japan, ²Department of Oral and Maxillo facial surgery, Nihon University School of Dentistry, Tokyo, Japan, ³Department of Biochemistry, Nihon University School of Dentistry, Tokyo, Japan.

Several studies have indicated that one of the causes of alveolar bone destruction with periodontitis is lipopolysaccharide (LPS) from the cell wall of Gram-negative bacteria in plaque and that tobacco smoking may be an important risk factor for the development and severity of periodontitis. The present study was undertaken to determine the effect of nicotine and LPS on the expression of macrophage colony-stimulating factor (M-CSF), osteoprotegerin (OPG), and prostaglandin E₂ (PGE₂) in osteoblasts, and the indirect effect of nicotine and LPS on the formation of osteoclast-like cells. Saos-2 cells were cultured with 10⁻³ M nicotine, or 1 or 10 µg/ml LPS and 10⁻³ M nicotine, for up to 14 days. The gene and protein expression of M-CSF and OPG were determined using real-time PCR and ELISA, respectively. PGE₂ expression was determined using ELISA. The formation of osteoclast-like cells was estimated using tartrate-resistant acid phosphatase (TRAP) staining of osteoclast precursors in culture with conditioned medium from nicotine and LPS-treated Saos-2 cells and the soluble receptor activator of NF-κB ligand (RANKL). M-CSF and PGE₂ expression increased markedly in cells cultured with nicotine and LPS compared with those cultured with nicotine alone. OPG expression increased in the initial stages of culture with nicotine and LPS but decreased in the later stages of culture. The conditioned medium containing M-CSF and PGE₂ produced by nicotine and LPS-treated Saos-2 cells with soluble RANKL increased the TRAP staining of osteoclast precursors compared with that produced by nicotine treatment alone. These results suggest that nicotine and LPS stimulate the formation of osteoclast-like cells via an increase in M-CSF and PGE₂ production and that the stimulation is greater than with nicotine treatment alone.

VGLUT1 KO Mice Develop Osteopenia due to an Increase in Osteoclastic Bone Resorption. S. Uehara*, S. Senoh*, M. Nakamura*, T. Ninomiya*, T. Mizoguchi*, Y. Kobayashi*, Z. Hua*, R. H. Edwards*, Y. Moriyama*, N. Takahashi*, N. Udagawa*, ¹Department of Biochemistry, Matsumoto Dental University, Shiojiri, Japan, ²Department of Membrane Biochemistry, Okayama University, Okayama, Japan, ³Institute for Oral Science, Matsumoto Dental University, Shiojiri, Japan, ⁴Departments of Neurology and Physiology, University of California San Francisco School of Medicine, San Francisco, CA, USA.

The vesicular glutamate transporter (VGLUT) is responsible for vesicular storage of L-glutamate, and plays an essential role in L-glutamate-mediated chemical transduction in the central nervous system and some peripheral tissues. We previously reported the role of VGLUT in bone metabolism as follows (EMBO J, 25:4175, 2006): (1) VGLUT1 was expressed in the transcytotic vesicle in osteoclasts, and osteoclasts secreted both L-glutamate and bone degradation products upon depolarization or ATP stimuli in Ca²⁺-and

cAMP-dependent manners. (2) Osteoclasts expressed the metabotropic glutamate receptor (mGluR)8. L-glutamate secreted by osteoclasts inhibited the transcytosis and bone resorbing activity of osteoclasts through the mGluR8 in an autocrine manner. (3) VGLUT1 knock out (KO) mice developed osteopenia. In this study, we investigated the mechanism of L-glutamate secretion from osteoclasts and the cause of osteopenia induced by VGLUT1 deficiency in mice in more detail. The results obtained from this work are as follows: (1) we first examined whether the signaling pathway of cAMP-dependent protein kinase (PKA) is involved in the secretion of L-glutamate from osteoclasts. Osteoclasts obtained from the co-culture of mouse osteoblasts and bone marrow cells were treated with KT-5720, a PKA inhibitor, and stimulated with KCl or ATP to induce L-glutamate secretion. KT-5720 scarcely inhibited the KCl and ATP-induced L-glutamate secretion from osteoclasts. (2) To determine the cause of bone loss in VGLUT1 deficiency in mice, we measured serum levels of TRACP5b (a marker of bone resorption) and alkaline phosphatase (a marker of bone formation) in 8-week-old VGLUT1 KO and wild-type mice. Serum levels of TRACP5b in VGLUT1 KO mice were significantly higher than those in wild-type mice. Serum alkaline phosphatase activities were also increased in VGLUT1 KO mice. These results suggest that osteoclasts secrete L-glutamate through PKA independent pathway, and that bone loss in VGLUT1 KO mice is caused by an increase in bone resorption. The results also suggest that the lack of L-glutamate-mediated signals in bone induces a high turnover bone state. Bone histomorphometry of VGLUT1 KO mice is currently analyzed in our laboratories.

Tumor Cells Metastatic to Bone Express CSF-1 and Support Osteoclast Survival. K. Yagiz, S. R. Rittling, Cytokine, Forsyth, Boston, MA, USA.

Tumors metastatic to the bone produce factors that cause massive bone resorption mediated by osteoclasts in the bone microenvironment. The mechanisms that explain the increase in bone resorption in metastasis are unclear. We have hypothesized that osteoclasts in the vicinity of tumor cells are "superactivated": superactivated osteoclasts are larger than normal osteoclasts with higher resorptive ability. Colony stimulating factor (CSF-1) is strictly required for the formation and survival of active osteoclasts. Aberrant expression of CSF-1, which can be synthesized as a soluble or a membrane-associated protein, has been found in many cancers correlating with disease progression and malignancy. Here we show that r3T cells, a tumor cell line that forms bone metastasis in mice, express abundant CSF-1 in vitro. FACS analysis with an antibody to CSF-1 as well as RT-PCR confirmed that r3T cells express CSF-1 both a secreted and a membrane-associated protein. Murine osteoclast-like cells co-cultured with either mitomycin-c (MMC) treated or glutaraldehyde fixed r3T cells with cytokine RANKL survived in the absence of added CSF-1. In addition, murine osteoclast-like cells were cultured with r3T conditioned medium (CM). Our results showed that r3T cells supported osteoclast formation by providing adequate amounts of CSF-1 protein. Importantly, direct cell-to-cell contact was required for osteoclast survival. Therefore, drugs that could counteract the effect of CSF-1 might be useful for reducing the osteoclast mediated osteolysis. We suggest that tumor cell production of CSF-1 is one of the mechanism by which tumors cause osteoclast superactivation.

Hormonal and Pharmacological Modulation of MT2 Melatonin Receptor Inhibits Osteoclast Maturation and Activity. G. Maillot*, C. Desrochers*, R. Doucet*, E. Levy*, A. Moreau*, ¹Department of Nutrition, Université de Montréal, Research Center CHU Sainte-Justine, Montreal, PQ, Canada, ²Research Center CHU Sainte-Justine, Montreal, PQ, Canada, ³Department of Stomatology & Biochemistry, Université de Montréal, Research Center CHU Sainte-Justine, Montreal, PQ, Canada.

Melatonin (Mel) is known to induce bone formation through osteoblast activation and indirectly through OPG up regulation leading to osteoclast inactivation. However, a direct effect of Mel on osteoclast has never been shown previously. The aim of this study is to investigate the influence of the Mel signaling pathway on osteoclastogenesis and osteoclast activity using in vitro and in vivo models as experimental paradigm. Gene and protein expression of Mel receptor, MT2, were detected in RAW 264.7 cells cultured in presence or absence of RANKL (50ng/ml) whereas MT1 receptor was not detected. Addition of physiological doses of Mel (10⁻⁹ M) decreased by 60% the number of resorption pits and by 69% the total resorbed area although no significant change was observed in the number of TRAP+ cells. Addition of 4-P-PDOT, a MT2 receptor antagonist, blocks the inhibitory action of Mel suggesting that such effect was mediated through Mel signaling activity. Surprisingly, RAW 264.7 cells treated with increasing doses of 4-P-PDOT (10⁻¹⁰ M to 10⁻⁶ M) alone demonstrated a significant decrease in both number of TRAP+ multinucleated cells and resorption pits in a dose dependent-manner. These effects were neither caused by an increased apoptosis nor due to reduced proliferation since no changes were observed between untreated and 4-P-PDOT treated cells. To further investigate the effect of 4-P-PDOT on bone metabolism, we injected 4-P-PDOT (10mg/kg of body weight) after weaning to male C57Bl/6j mice 3 times per week during 4 weeks and performed densitometric (PixiMus II bone densitometer) and histomorphometric analyzes. Preliminary results revealed an increase in bone mineral accretion at the spine and whole body level in treated mice compared to vehicle-injected animals. Overall, these data highlight the importance of the Mel signaling pathway in modulating osteoclast function and show an unrecognized effect of Mel receptor antagonist 4-P-PDOT as a potential anti-osteoporotic drug.

The Osteopetrotic Incisor Absent Rat Exhibits Reduced Osteoclast Activity, Resulting in Normal Endochondral Fracture Union but Delayed Hard Callus Remodeling. M. M. McDonald^{*1}, A. Morse^{*1}, K. Mikulec^{*1}, C. Godfrey^{*1}, S. Tamara^{*2}, D. Little^{*1}. ¹Orthopaedic Research, The Children's Hospital Westmead, Sydney, Australia, ²Science, The University of Technology, Sydney, Australia.

A spontaneous mutation in the incisor absent (ia/ia) rat results in abnormal osteoclasts which display deficient resorption. We investigated the resulting osteopetrotic phenotype to determine the exact age of recovery. Furthermore, we utilized this model to examine fracture repair in the absence of functional osteoclasts.

Samples were harvested from male rats from 3 weeks of age for phenotype analysis. Once the age of recovery was determined, closed fractures were performed in 5 week old male ia/ia and wt/het controls. Harvests were performed at 1, 2 and 3 weeks post fracture, to assess repair within the period of osteoclast dysfunction.

Serum CTX showed decreases up to 9 weeks of age in ia/ia rats ($p < 0.05$), with normalization to control levels at 12 weeks of age. Further, ia/ia primary osteoclast cultures revealed decreased resorption pit formation at 5 and 9 weeks of age compared to control ($p < 0.01$), again normalizing to control levels at 12 weeks.

DEXA scans of tibial metaphyses revealed increases of 40-114% in BMD up to 20 weeks of age in ia/ia rats compared to controls ($p < 0.01$). Histology at this site revealed a constant incline in BV/TV at the proximal region in ia/ia rats such that a 3-fold increase was achieved by 20 weeks compared to controls ($p < 0.01$). In the distal tibial metaphysis however, the BV/TV in the ia/ia rats began to decrease after 9 weeks of age such that it had reduced by half at 20 weeks, suggesting recovery of resorption.

Femur length showed an 11%-14% decrease in ia/ia compared to control rats at all time points examined from 3 weeks of age ($p < 0.01$). However, growth plate height showed a slight increase in ia/ia rats at only 5 weeks of age compared to controls ($p < 0.05$), all other time points showing no differences.

Importantly, initial endochondral fracture union was achieved by 3 weeks post fracture in both ia/ia and controls. QCT revealed significant increases in BMC and volume in ia/ia calluses at 1, 2 and 3 weeks ($p < 0.01$). Controls showed a reduction in callus volume between 2 and 3 weeks, whereas the ia/ia callus volume increased 41%.

In conclusion, the ia/ia rat exhibits a severe osteopetrotic phenotype resulting from reduced osteoclast activity. Recovery from the dysfunctional resorption occurs between 9 and 12 weeks of age. Initial endochondral fracture union was achieved normally in the absence of functional osteoclasts in ia/ia rats, however hard callus remodeling was hindered resulting in a larger, more mineralised callus. This study reveals that osteoclast function is not essential for initial fracture union but is required for hard tissue remodeling.

Normal Endochondral Bone Healing Follows Continuous Bisphosphonate Pre-treatment in a Rat Closed Fracture Model. A. Morse^{*}, M. McDonald^{*}, K. Mikulec^{*}, H. Mai^{*}, C. Munns, D. G. Little^{*}. Orthopaedic Research, The Children's Hospital Westmead, Sydney, Australia.

Long-term Pamidronate (PAM) therapy is the mainstay of treatment for moderate to severe osteogenesis imperfecta (OI). However, these patients can develop a reduced bone turnover state that may affect fracture healing. We aimed to investigate the effects of continuous PAM pre-treatment on bone healing in a rat model of endochondral fracture repair.

9 week old Wistar rats received closed femoral fractures. 4 weeks prior to fracture PAM dosing commenced subcutaneously (SC) at 0.15mg/kg, 0.5mg/kg and 5 mg/kg twice weekly. Harvests were at 2 and 6 weeks post-fracture.

Radiographic union was observed in all 6 week samples and QCT showed increases of 55-92% in callus BMC and 44-77% in callus volume with PAM treatment over saline controls ($p < 0.01$). These increases were attributed to retention of hard callus, with increases in primary callus BV/TV of 68%-84% at 6 weeks compared to saline ($p < 0.01$). In addition, remodeling of the callus was delayed with decreases of 32% and 45% in callus remodeled neo-cortical bone in the 0.5mg/kg and 5mg/kg PAM groups respectively compared to saline ($p < 0.01$).

Histology revealed that endochondral fracture healing followed a normal timeline regardless of PAM treatment. No differences were observed between groups in callus cartilage content at both 2 and 6 weeks post fracture. One 5mg/kg PAM sample showed retained cartilage at 6 weeks, but had no effect on the overall result.

Systemically, PAM dosing lead to increases of up to 4-fold in metaphyseal BV/TV over saline controls at 6 weeks ($p < 0.01$). Endosteal mineral apposition rate (MAR) was reduced by 6 weeks with PAM treatment, the 0.5mg/kg and 5mg/kg groups showing reductions of 30% and 84% respectively compared to saline ($p < 0.01$). Periosteal MAR however showed no changes with PAM treatment at 6 weeks. Small growth deficiencies of 2-5% in femur length were noted with 0.5 mg/kg or 5 mg/kg PAM compared to saline ($p < 0.01$). The growth rate between the 2 and 6 week time points however remained constant, regardless of treatment. Growth plate height was also unaffected by PAM dosing.

In conclusion, continuous PAM pre-treatment was associated with a small decrease in bone formation and a large reduction in bone resorption, leading to a net increase in callus size. However, this lowered bone turnover did not hinder fracture repair, with endochondral union being achieved normally regardless of treatment. These data suggest that long-term BPs, whilst reducing bone turnover, may not interfere with normal endochondral fracture union in healthy individuals, but may hinder long bone growth. Further work is planned with a longer interval of pre-dosing with Pamidronate as well as experiments in animal models of Osteogenesis Imperfecta.

Anti-GGT Antibody Attenuates Osteoclastic Bone Erosion in CIA Mice. Y. Ishizuka^{*1}, S. Moriwaki^{*2}, S. Niida². ¹AC Bio Technologies, Yokohama, Japan, ²Bone & Joint Disease, National Center for Geriatrics & Gerontology, Obu, Japan.

gamma-Glutamyl transpeptidase (GGT/CD224), known as a key enzyme for the catabolism of glutathione and cysteine metabolism, is a newly identified bone-resorbing factor which stimulates osteoclast formation. We found that GGT expression was up-regulated in the inflamed joints of the patients with rheumatoid arthritis (RA). Therefore, we hypothesized that GGT may be involved in the arthritis-related osteolysis. In this study, we demonstrate that the inhibitory effects of anti-GGT monoclonal Ab (GGT-mAb) on the joint destruction in the collagen-induced arthritis (CIA) mice.

Materials and Methods: GGT localization in the synovium of RA patients and CIA mice was determined by immunohistochemistry. In vivo osteoclastogenic activity of GGT was assessed by histological analysis of the rat alveolar bone after infusing the recombinant human GGT (rhGGT) into the jaws. For preparation of CIA mice, DBA/1J mice were immunized with an emulsion containing bovine type II collagen and Mycobacterium tuberculosis in incomplete Freund's adjuvant. GGT-mAbs were generated against rhGGT using BALB/c mice. The GGT-mAbs were administered via i.p. to CIA mice. The therapeutic effects of GGT-mAbs were evaluated by incidence score, arthritic score and histopathological analysis. Role of GGT in osteoclast formation was investigated using cell cultures, microarray analysis and quantitative RT-PCR.

Results: Immunohistochemistry of the inflamed synovium revealed that GGT was detectable in lymphocytes, plasma cells, and macrophages, as well as capillary vessels. The rhGGT-treated rats exhibited marked alveolar bone destruction with an increase in TRAP-positive osteoclasts. Treatment with GGT-mAbs significantly reduced the number of osteoclasts and the severity of osteolysis in CIA mice. In vitro examinations using bone marrow cultures containing 1,25(OH)₂D₃ indicated that the osteoclast development was enhanced through the further up-regulation of RANKL expression mediated by GGT stimulation. Moreover, addition of rhGGT accelerated the osteoclastogenesis in the cultures of bone marrow macrophages maintained with M-CSF and RANKL as compared with those of condition without rhGGT.

Conclusion: This study revealed the involvement of GGT in the bone erosion of CIA mice and contributed to further understanding of the arthritis-related bone loss. Thus, GGT antagonists may be new effective agents for attenuating the joint destruction in RA.

Electroneutral Sodium/Bicarbonate Cotransporter NBCn1 Is Expressed in Rat Osteoclast Ruffled Border Membrane. R. Riihonen¹, I. Song^{*2}, S. Nielsen^{*3}, T. Laitala-Leinonen^{*1}, T. Kwon^{*2}. ¹Bone Biology Research Consortium, Department of Biomedicine, University of Turku, Turku, Finland, ²Department of Biochemistry and Cell Biology, School of Medicine, Kyungpook National University, Daegu, Republic of Korea, ³The Water and Salt Research Center, Institute of Anatomy, University of Aarhus, Aarhus, Denmark.

The aim of this study is to define the expression of the electroneutral sodium/bicarbonate cotransporter NBCn1 in rat osteoclasts and its role for bone resorption. NBCn1 has previously been shown to significantly enhance the cellular uptake of bicarbonate on the basolateral side of the thick ascending limb of the loop of Henle in the kidneys in response to chronic metabolic acidosis, but its function in osteoclasts is unknown.

First, the expression pattern of NBCn1 in bone tissue was determined by analyzing 3-day old rat pup femur and tibia with immunohistochemistry. Additionally, confocal microscopy was utilized to explore the specific localization of NBCn1 in rat osteoclasts. RT-PCR was performed to study NBCn1 mRNA expression in primary rat osteoclasts cultured on bovine bone slices. Moreover, changes of NBCn1 mRNA levels were monitored after exposing osteoclasts to various stimuli such as anoxic conditions, acidic or alkaline culture media and growth factors known to increase the bone resorption rate.

NBCn1 immunostaining was specifically associated with the osteoclast cell membrane facing the bone trabeculae in tissue specimens, and immunocytochemistry revealed a similar expression profile where NBCn1 was exclusively localized in the ruffled border membrane in rat osteoclasts. Using RT-PCR, NBCn1 mRNA expression was detected from rat osteoclast cultures, and the expression levels varied markedly due to changes in the extracellular culture environment.

In conclusion, NBCn1 is localized in the ruffled border membrane of rat osteoclasts and the mRNA expression levels are dependent on the extracellular conditions and the activation status of the osteoclasts. These results suggest a role for NBCn1 in bone resorption, possibly by maintaining an acidic pH in the resorption lacuna by means of bicarbonate uptake during the active bone resorption phase. Thus, we may have found a novel, important player in the osteoclastic bone resorption process and will continue this study by exploring the effects of NBCn1 inhibition on the bone resorption rate.

TSG-6, a New Regulator of Bone Remodelling. D. Mahoney^{*1}, K. Mikecz^{*2}, G. Mabiliau^{*1}, N. A. Athanasou¹, T. Ali^{*3}, C. M. Milner^{*3}, A. J. Day^{*3}, A. Sabokbar¹. ¹Botnar Research Centre, University of Oxford, Oxford, United Kingdom, ²Rush University Medical School, Chicago, IL, USA, ³Faculty of Life Sciences, University of Manchester, Manchester, United Kingdom.

TSG-6 (TNF-stimulated gene-6) is a non-constitutively expressed protein which is up-regulated by inflammatory mediators and growth factors. The protein is composed almost entirely of LINK and CUB domains; to date a wide variety of protein and glycosaminoglycan ligands have been identified as associating with the LINK module. Animal models of arthritic disease have indicated TSG-6 has anti-inflammatory properties and may protect against cartilage degradation and bone erosion. To determine the mechanism by which TSG-6 affects bone we have characterised; (i) the in vitro effect of TSG-6 on osteoclast activity and osteoblast differentiation, (ii) its mode of action and (iii) its levels in the synovial fluids of inflammatory bone disorders.

Using ELISA and BIAcore analysis, we have shown that TSG-6 binds to a mediator of osteoclastogenesis, sRANKL, as well as BMPs-2, 4, 5, 6, 7, 13 and 14 which promote osteoblastogenesis. In vitro assays indicate that TSG-6 inhibits RANKL-induced human osteoclast formation and activity in a dose-dependent fashion, similar in manner to that of OPG. Furthermore, bone marrow cells isolated from the long bones of TSG-6 deficient mice, give rise to markedly increased resorption as compared to cells isolated from control animals. We have also shown that TSG-6 inhibits the BMP-2 induced alkaline-phosphatase activity of an osteoblastic cell line. Full-length TSG-6 inhibits osteoclastogenesis and BMP-mediated osteoblast differentiation to a greater extent than the isolated LINK and CUB domains: affinity analysis suggests sRANKL and BMP2 interact at composite binding surfaces between the LINK and CUB modules. Quantification of TSG-6 in the synovial fluid of patients with rheumatoid arthritis, osteoarthritis, pyrophosphate arthropathy and gout showed varying levels (0.1-200 ng/ml).

These findings indicate that TSG-6 is a regulator of bone metabolism which can synchronise osteoblast and osteoclast biology. We hypothesise dual functions for this protein; a homeostatic role in non-inflammatory bone environments through inhibition of osteoblast differentiation, and a role in inflammatory bone disease through prevention of osteoclastogenesis. As such TSG-6 has a potential role for the development of therapeutic strategies in bone diseases.

Diphyllin, a Novel Potent V-ATPase Inhibitor, abrogates Acidification of the Osteoclastic Resorption Lacunae and Bone Resorption. M. G. Sorensen, K. Henriksen, A. V. Neutzsky-Wulff*, C. Christiansen, M. Karsdal. Nordic Bioscience A/S, Herlev, Denmark.

Dissolution of the inorganic phase of bone by the osteoclasts is mediated through the V-ATPase and ClC-7. Inhibition of the osteoclastic V-ATPase or ClC-7 is a novel approach for inhibition of osteoclastic bone resorption. By testing natural compounds in acidification assays using acridine orange, diphyllin was identified as a potent inhibitor of lysosomal acidification in osteoclasts. We characterized diphyllin with respect to potency in a human osteoclastic bone resorption assay, an acid influx assay, and in a V-ATPase assay. For comparison, diphyllin was tested in an osteoblastic bone formation assay.

Human osteoclasts were generated from CD14⁺ monocytes cultured with 25ng/ml M-CSF and RANKL. The effect of diphyllin on lysosomal acidification in human osteoclasts was investigated using the dye acridine orange. The effect of diphyllin on osteoclastic bone resorption was measured as the release of CTX-I and calcium into the supernatant, and by scoring pit area. The number of osteoclasts, the TRACP activity, and the cell viability were measured. Diphyllin was tested in the acid influx assay and the V-ATPase assay using bovine chromaffin granules isolated from the medullae of bovine adrenal glands. The effect of diphyllin on bone formation was investigated using MC3T3 cells cultured in medium supplemented with ascorbic acid and beta-glycerol phosphate.

We found that diphyllin inhibited human osteoclastic bone resorption measured by CTX-I (IC₅₀=14nM, Figure 1A), calcium release and pit area, in face of increased osteoclast numbers (Figure 1B) and increased levels of TRACP activity. Moreover, diphyllin dose dependently inhibited lysosomal acidification in human osteoclasts. In the acid influx assay, diphyllin potently inhibited influx (IC₅₀=0.6nM), which is similar to the effect of bafilomycin. Furthermore, diphyllin inhibited the V-ATPase with an IC₅₀ value of 17nM, compared to 4nM for bafilomycin. Finally, diphyllin showed no effect on bone formation in vitro, whereas bafilomycin was highly toxic.

We have identified a natural compound that potently inhibits the lysosomal acidification and the V-ATPase in osteoclasts and thereby abrogates bone resorption. These findings are in alignment with osteopetrotic patients where acidification and resorption are attenuated that result in increased numbers of osteoclasts.

Canonical NF-κB Pathway Mediates Osteoclast Bone Resorption Activity.

N. S. Soysa^{*1}, C. N. R. Alles^{*1}, K. Aoki², E. Jimi³, K. Ohya². ¹Center of Excellence for Frontier Research on Molecular Destruction and Reconstruction of Bone, Tokyo Medical and Dental University, Tokyo, Japan, ²Section of Pharmacology, Tokyo Medical and Dental University, Tokyo, Japan, ³Biochemistry, Kyushu Dental College, Kitakyushu, Japan.

NF-κB transcription factor is a key determinant in the orchestration of osteoclast formation, differentiation and survival. Nevertheless the mechanistic basis for NF-κB effect on bone resorbing activity of osteoclast has not fully elucidated yet. Hence the main objective of this study was to find the role of canonical NF-κB pathway in osteoclast resorbing activity using the NBD peptide, an established selective inhibitor of IκB-kinase (IKK). BMM cultured on dentine slices and on cover slips in the presence of RANKL and M-CSF were changed after 3 days with 10µM and 20µM of NBD peptides (Wt). Most of the osteoclasts were fully differentiated when the medium was changed and further cultured for 24 hrs in the presence of the peptides. Osteoclasts were stained for TRAP. Apoptosis was detected by DAPI staining and by TUNEL method and pits were measured by using a confocal microscope system. There was no detectable change in osteoclast numbers after changing the medium. Significant reduction in area of resorption was observed in Wt at 10µM and 20µM concentrations (P<0.01 and P<0.001 respectively). Volume of resorption pit was significantly reduced at 20µM (P<0.001). Volume to area ratio which was independent on osteoclast number was also reduced significantly (P<0.05). No difference in number of apoptotic cells was observed between Wt and control. TRAP was measured in the cell lysate and supernatant to measure the percentage TRAP release. Similarly, Wt significantly reduced TRAP release. Cell migration towards RANKL was reduced in treated samples compared to control assessed by transwell migration assay. Then osteoclasts on cover slips were stained for actin rings. Percentage of osteoclasts with actin rings were markedly reduced in peptide treated group (P<0.001). The levels of TRAP, cathepsin K, MMP-9, NFATc1 and αvβ3 mRNAs analyzed by real-time RT-PCR were significantly reduced in treated samples (p<0.0001). Taken together these results suggest that NBD peptide reduces osteoclast bone resorbing activity, migration and actin ring formation by down regulating above mRNAs and the inhibitory effect on bone resorption was not due to apoptosis, suggesting the vital role of canonical NF-κB pathway in osteoclast activity. Cathepsin K and MMP-9 are NF-κB dependent genes. Also NF-κB binding sites are present within the promoter region of the NFATc1 gene and NFAT binding sites in the TRAP, Cathepsin K, and αvβ3 promoters as well. Therefore the interplay among NF-κB and NFATc1 seems to be crucial in establishment of osteoclast activity.

Disclosures: N.S. Soysa, None.

Dentine Organic Matrix Down-Regulate Osteoclastic Activity in Root Resorption.

W. Sriarj^{*1}, B. J. Varghese^{*1}, K. Aoki², K. Ohya², Y. Takagi^{*1}, H. Shimokawa². ¹Pediatric Dentistry, Tokyo Medical and Dental University, Tokyo, Japan, ²Hard Tissue Engineering, Tokyo Medical and Dental University, Tokyo, Japan.

It has been reported that deciduous tooth roots were more susceptible in resorption than permanent tooth roots, in which resorption did not occur in physiological condition. However, the mechanisms of root resorption are still unclear. Our previous study has shown that osteoclasts cultured on deciduous dentine exhibited a higher level of cathepsin K and MMP-9 mRNA and a higher degree of resorption than cultured on permanent dentine. These could be due to the difference of organic matrices between deciduous and permanent dentine. The purpose of this study is to investigate the effect of organic matrix extracted from bovine deciduous or permanent dentine on the resorptive activity. We extracted dentine organic matrices from bovine deciduous or permanent root dentine using 4M guanidine hydrochloride, pH7.4 (G-ext) then 4M guanidine hydrochloride plus 0.5M EDTA, pH 7.4 (E-ext) sequentially. Osteoclasts, obtained from mouse bone marrow cells co-cultured with osteoblast-rich fraction in α-MEM containing 10% FBS, 1,25-(OH)₂-D₃ and PGE₂, were cultured on the ivory slices

with 500µg/ml of G-ext or E-ext for 48 hours. TRAP positive multinucleated cell number, TRAP activity, resorption pit area and the mRNA level of cathepsin K, TRAP, and MMP-9 were determined. We have found that osteoclasts cultured with both E-ext from deciduous and permanent dentine exhibited lower TRAP positive multinucleated cell number and TRAP activity than G-ext as well as resorption pit area. The mRNA level of cathepsin K, TRAP, and MMP-9 were also down-regulated in osteoclasts cultured with E-ext. Furthermore, permanent dentine E-ext seemed to suppress osteoclastic activity more than deciduous one. These findings suggest that some factors in dentine organic matrices E-ext affect osteoclastic activity in root resorption.

Homogenous Fluorescence-based Calcium Assay for the Rapid Determination of In Vitro Bone Resorption. K. E. Renn*, M. J. Brown*. Lonza Walkersville, Inc., Walkersville, MD, USA.

High-throughput assays for measuring in vitro osteoclast-mediated bone resorption are essential tools in the study of bone related diseases. We have developed a homogenous, fluorescence-based assay for the rapid analysis of in vitro osteoclastic activity. The CalciFluor™ Assay quantitatively measures free calcium released during in vitro bone degradation. Normal human osteoclast precursors (OCP) cultured on a human bone substrate in the presence of macrophage-colony stimulating factor (M-CSF) and soluble RANK ligand (sRANKL) exhibit a linear increase in bone degradation over time when assayed using the CalciFluor Assay. Comparable results are obtained when the bone resorption activity of other primary cell types, such as murine bone marrow mononuclear cells, is measured with the assay. Treatment of human OCP with the bisphosphonate alendronate results in a dose-dependent decrease in the amount of calcium released from human bone coated plates. Likewise, OCP cultured in the presence of osteoprotegerin show decreased calcium release from bone, further illustrating that the free calcium elevations result from osteoclast-mediated bone degradation. Results generated with this fluorescent calcium assay are comparable to those obtained with commercially available enzyme immunoassay (EIA) kits detecting collagen degradation products. When the release of either calcium or collagen fragments is measured, actively resorbing osteoclasts show similar time-dependent trends in the amount of bone degraded as well as comparable inhibition profiles in the presence of pharmacologic agents. The CalciFluor Assay is a more rapid, convenient, and economical assay than the current EIA-based assays for bone resorption, and therefore represents an excellent tool for in vitro analysis of osteoclast activity.

Lack of Bruton's Tyrosine Kinase Results in Osteoporosis, Despite Defects in Osteoclast Function. L. Danks*, S. Workman*, A. D. Webster*, B. M. Foxwell*, M. Feldman*, N. J. Horwood*. ¹The Kennedy Institute of Rheumatology, Imperial College, London, United Kingdom, ²Department of Immunology, Royal Free and University College Medical School, London, United Kingdom.

Bruton's tyrosine kinase (Btk) is a member of the Tec family of kinases and mutations in Btk result in a rare disease known as X-linked agammaglobulinemia (XLA). These patients have an absence of mature B cells resulting in profound hypogammaglobulinemia and recurrent infections. We have previously shown that Btk is not only involved in B cell responses but also plays a role in inflammatory cytokine production in macrophages, however the role of Btk in osteoclast formation and activation is unknown. As the Tec kinases are regulated by the Src family kinases, which are known to have important actions on osteoclast function, we hypothesised that Btk would be a downstream signaling target of Src kinase. Therefore, we investigated the role of Btk in osteoclast differentiation and activation in vitro and examined the effect of Btk deficiency on the bone phenotype of XLA patients.

Human peripheral blood monocytes were differentiated into osteoclasts in the presence of RANKL and M-CSF. Adenoviral overexpression of Btk/GFP during osteoclast culture on hydroxyapatite slides resulted in an unusual actin ring arrangement, the actin rings were smaller and thicker than those of controls. Lacunar pit formation on dentine slices was dose dependently inhibited, whilst there was no effect on TRAP+ osteoclast formation. Osteoclasts derived from PBMC's or CD14+ precursors of XLA patients, compared to control subjects, exhibited a dose dependent and highly significant decrease in bone resorption activity in response to RANKL despite having a dose dependent increase in TRAP+ osteoclast formation. These results suggest that Btk is important specifically for osteoclast resorption activity. The bone phenotype of the XLA patients was examined using serum markers of bone metabolism and bone density analysis. Surprisingly, XLA patients exhibited an osteoporotic bone phenotype with an average 20% reduction in bone density compared to age matched controls.

Our results provide novel evidence that Btk is an important signaling molecule for normal osteoclast activity in vitro however these patients are osteoporotic in vivo. As B cells play a role in the regulation of basal bone turnover, by providing a reservoir of early osteoclast precursors and by direct expression of osteoclast regulatory cytokines, it is likely that the lack of mature B cells in the XLA patients, and the resulting reduction in OPG levels, are able to override the osteoclast defect in vivo. Thus, our novel finding that XLA patients are osteoporotic suggests that absence of B lymphocytes gives rise to an overall decrease in bone density.

NEMO (IKKγ) Modulates Osteoclastogenesis and Bone Erosion. I. Darwech*, S. Dai*, Y. Abu-Amer. Orthopedic Surgery and Cell Biology & Physiology, Washington University School of Medicine, Saint Louis, MO, USA.

The transcription factor NF-κB is essential for osteoclastogenesis and is considered an immune-modulator of rheumatoid arthritis and inflammatory osteolysis. Activation of NF-κB subunits is regulated by the upstream IκB kinase (IKK) complex which contains, among other proteins, IKK1, IKK2, and IKKγ; the latter also known as NF-κB essential modulator (NEMO). The role of IKK1 and IKK2 in the skeletal development and inflammatory osteolysis has been described, whereas little is known about the role of NEMO in this setting. In this regard, several case reports identified point mutations that led to osteopetrosis and hypodontia or anodontia with conical incisors. NEMO facilitates and integrates upstream stimuli and appears to assign, by yet unknown mechanisms, signal specificity. Typically, signals such as RANKL or TNF prompt oligomerization of NEMO monomers through well-defined domains termed the coiled-coil-2 (CC2) and Lucine zipper (LZ) motifs. This step is a prerequisite for binding to IKKs and further relaying signal transduction. In fact, blocking NEMO binding to IKKs perturbs NF-κB activation, abrogates osteoclastogenesis, and diminishes inflammatory bone erosion. In this study, we asked whether NEMO is essential for osteoclastogenesis of murine marrow macrophages and whether interruption of NEMO oligomerization impedes the process of osteoclast differentiation in vitro and in vivo. To this end, we generated short peptides overlapping the CC2 and LZ motifs and fused them with a carrier peptide to enable cell membrane translocation. Our results show that the CC2 and LZ short peptides specifically bind to NEMO monomers, prevent trimer formation, and render NEMO monomers susceptible for ubiquitin-mediated degradation. Further, CC2 and LZ peptides attenuate RANKL and TNF-induced NF-κB signaling in bone marrow-derived osteoclast precursors. More importantly, these peptides potently inhibit osteoclastogenesis, in vitro, and arrest RANKL-induced calvarial osteolysis, in mice. To further ascertain its role in osteoclastogenesis, we were able to block osteoclastogenesis using NEMO siRNA knockdown approach. Collectively, our data establish that NEMO is essential for osteoclastogenesis and provide the novel finding that inhibition of NEMO assembly leads to its degradation. More importantly, inhibition of NEMO expression impedes osteoclast formation and arrests osteolysis. Thus, NEMO present itself as a promising candidate for therapeutic intervention.

NFATc1 Mediates the Stimulatory Effects of Post-translationally Modified Bone Sialoprotein on the Resorptive Activity of Rabbit Osteoclasts. H. H. Chen*, J. A. R. Gordon*, A. Pereverzev*, S. M. Sims*, G. K. Hunter*, S. J. Dixon, H. A. Goldberg. CIHR Group in Skeletal Development and Remodeling, The University of Western Ontario, London, ON, Canada.

Cell-adhesion proteins of bone extracellular matrix such as bone sialoprotein (BSP) promote osteoclastogenesis and resorption; however, their mechanism of action has remained elusive. NFATc1 is a transcription factor that plays a critical role in osteoclast differentiation. Our purpose was to determine whether the effects of BSP on osteoclastic resorption involve NFATc1. Osteoclasts were isolated from the long bones of neonatal rabbits. Native BSP (nBSP) from rat long bones (post-translationally modified) and rat recombinant BSP (rBSP, prokaryotically expressed without post-translational modifications) were purified to homogeneity using FPLC. To quantify resorptive activity, osteoclasts were incubated for 24 hours on dentin slices coated with nBSP or rBSP, or uncoated (control). Samples were stained for TRAP activity to determine osteoclast number and then with toluidine blue to determine total area resorbed. In parallel studies, osteoclast attachment and NFATc1 activation were assessed 3 hours after plating on coverslips coated with nBSP or rBSP, or uncoated (control). Immunofluorescence was used to quantify the percentage of osteoclasts demonstrating nuclear localization of NFATc1, which upon activation translocates from the cytosol to the nuclei. Coating of substrates with nBSP or rBSP did not significantly affect the number of osteoclasts attached at 3 or 24 hours. However, nBSP significantly promoted the resorption of dentin slices (2.26 ± 0.26 fold greater than control, mean \pm SEM, $n = 7$), whereas rBSP had no effect (1.06 ± 0.07 fold). Similarly, nuclear localization of NFATc1 was enhanced in osteoclasts plated on coverslips coated with nBSP (1.68 ± 0.05 fold greater than control, $n = 3$), but not with rBSP (1.05 ± 0.03 fold), suggesting a role for NFATc1 in the activation of resorption. To assess the involvement of NFAT in mediating BSP-induced resorption, we used 11R-VIVIT (a cell-permeable peptide inhibitor of NFAT activation). As expected, 11R-VIVIT decreased NFATc1 translocation in osteoclasts bound to nBSP-coated coverslips. Notably, 11R-VIVIT, but not the inactive control peptide 11R-VEET, blocked the stimulatory effect of nBSP on resorptive activity. These findings establish that interaction of osteoclasts with post-translationally modified BSP enhances NFATc1 activation, which in turn stimulates resorption. This is the first direct demonstration that NFAT regulates the resorptive activity of authentic osteoclasts.

AG490, Jak2 Specific Inhibitor, Regulates Osteoclast Survival via Distinct Signaling Pathways. H. B. Kwak*, H. M. Sun*, D. Yang*, H. Kim*, H. Ha*, J. Lee*, Z. H. Lee. Department of Cell and Developmental Biology, School of Dentistry, Seoul National University, Seoul, Korea, Seoul, Republic of Korea.

Osteoclasts are multinucleated cells with the unique ability to resorb bone. Elevated activity of these cells under pathological conditions leads to the progression of bone erosion, such as osteoporosis, periodontal disease, and rheumatoid arthritis. The regulation of osteoclast apoptosis is important for bone homeostasis. In this study, we examined the effect of AG490 (JAK2 specific inhibitor) on osteoclast apoptosis. We show that AG490 inhibits cytochrome c release into cytosol and in turn suppresses caspase-9 and -3 activation, thereby inhibiting osteoclast apoptosis. Also, AG490 stimulated the phosphorylation of ERK and Akt. Adenovirus-mediated overexpression of dominant negative (DN)-Ras and DN-Akt in osteoclasts inhibited the survival of osteoclast despite the presence of AG490. Thus, osteoclast survival in response to AG490 leads to ERK and Akt pathways. Furthermore, constitutive active (CA)-MEK and Myr-Akt suppress the release of cytochrome c into cytosol and inhibit caspase activity. These results suggest that AG490 inhibits caspase activity by activating Akt and ERK and in turn suppresses the apoptosis of osteoclasts.

Expression and Transcriptional Activity of Microphthalmia-Associated Transcription Factor Isoforms During Osteoclastogenesis. M. Murakami¹, Y. Iwata^{*1}, M. Funaba^{*2}. ¹Laboratory of Molecular Biology, Azabu University School of Veterinary Medicine, Sagamihara, Japan, ²Laboratory of Nutrition, Azabu University School of Veterinary Medicine, Sagamihara, Japan.

Microphthalmia-associated transcription factor (Mitf), a member of the basic helix-loop-helix leucine zipper (bHLH-ZIP) transcription factors, is required for proper development of several cell lineages including osteoclasts, melanocytes, retinal pigment cells and mast cells. Mitf has been implicated to be a key regulator of the later steps of osteoclastogenesis, but the role of Mitf is not fully elucidated; although nine distinct Mitf isoforms, which contain an isoform-specific first exon and are identical exons 2 to 9, have been identified at the RNA level, it is unclear whether any isoforms are unique to the osteoclast lineage cells. The present study examined expression of Mitf isoforms in sRANKL-induced osteoclast-like cells. Previous studies have revealed that tartrate-resistant acid phosphatase (Trap) is a transcriptional target of Mitf in osteoclasts. Thus, we also examined factors affecting Trap gene transcription in HepG2 cells that are responsive to Mitf overexpression. Treatment of RAW264 macrophage-like cells with sRANKL (50 ng/ml) for 72 h resulted in the increase in the number of Trap-positive multinucleated cells. Mitf-A and -J but not the other Mitf isoforms (-B, -C, -D, -E, -H, -M and -mc) were expressed in RAW264 cells, irrespective of the treatment with sRANKL. These results indicate that expression of Mitf isoforms is cell-type specific, and that differentiation of osteoclast lineage cells hardly affects expression pattern of Mitf. In addition, Tfe3, another member of the bHLH-ZIP family, was also significantly expressed throughout the differentiation of RAW264 cells. Transcriptional activation assays using luciferase-based reporter gene containing Trap promoter (-2049 +1) revealed that overexpression of Mitf-J/-D/-E but not Mitf-A slightly increased luciferase expression. The overexpression of c-Jun but not c-Fos and JunB increased expression of Trap reporter gene, and synergistic effects of c-Jun and Mitfs (-A and -J/-D/-E) on Trap gene transcription were detected. In contrast, no synergism was observed between Mitf and the other AP-1 component (c-Fos and JunB). Distinct expression of Mitf isoforms and functional interaction between Mitf and the other transcription factor such as c-Jun during the terminal differentiation of osteoclasts suggests discrete regulation of osteoclastogenesis.

FADD-Caspase-8 aXis Regulates Osteoclast Apoptosis. M. Nakamura, T. Akiyama, K. Nakamura, S. Tanaka. Department of Orthopaedic Surgery, Faculty of Medicine, The University of Tokyo, Tokyo, Japan.

Osteoclasts are terminally differentiated cells and rapidly die through apoptosis in the absence of tropic factors. Apoptosis is genetically programmed cell death to remove unwanted cells from physical status, and is controlled by two distinct signaling pathways; the death receptor-mediated pathway and the mitochondria-mediated pathway. We previously reported that a proapoptotic BH3-only Bcl-2 family member Bim is a key regulator of osteoclast apoptosis, showing the involvement of mitochondrial pathways in the cell death of osteoclasts. On the other hand, the role of the death receptor pathway in osteoclast apoptosis is not fully clarified yet. The death receptor-mediated pathway is activated upon ligand binding to cell surface receptors such as tumor necrosis factor (TNF) receptor that contain cytoplasmic death domains. Ligand binding induces oligomerization of these death domains through ligand-induced receptor trimerization, generates homophilic interaction surfaces for death domain-containing adaptor molecules. FADD (FAS-associated death domain-containing protein) is a universal adapter protein that mediates signaling of death-domain containing members of the TNF receptor superfamily, and plays a critical role in recruiting death-inducing signaling complex and the subsequent activation of initiator caspase-8 and downstream effector caspases. In an attempt to elucidate the role of FADD in osteoclast apoptosis, we constructed an adenovirus vector carrying a dominant negative mutant of FADD (AxFADD-DN), which lacks the death effector domain and therefore cannot activate Caspase-8. Osteoclasts generated in vitro were infected with control adenovirus or AxFADD-DN, which effectively induced FADD-DN expression in the cells, and were subjected to the survival assay. Osteoclasts

overexpressing FADD-DN survived longer than control cells after cytokine depletion, which was associated with the downregulation of Caspase-8 activity. Apoptosis of osteoclasts was also suppressed by a specific inhibitor of Caspase-8, Z-IETD-FMK. These results suggest that death receptor & FADD-mediated pathways are crucial for osteoclast apoptosis. To identify death receptors involving in osteoclast apoptosis, we treated the cells with FasL, TNF- α and TRAIL. However, all of them failed to promote the apoptosis of osteoclasts. Our results suggest that the FADD-Caspase-8 axis critically regulates the apoptosis of osteoclasts, which is activated through previously unknown death receptor ligands.

RANKL-induced Expression of TRPV2, Calcium Permeable Channel, Is Involved in Osteoclastogenesis via Calcium Signaling Activation. F. Okamoto*, H. Kajiya, A. Nakao*, K. Okabe. Physiological Science and Molecular Biology, Fukuoka Dental College, Fukuoka, Japan.

Osteoclast differentiation from hematopoietic precursor cells is stimulated by receptor activator of NF- κ B ligand (RANKL) via activation of transcription factors. Nuclear factor of activated T cells (NFAT) c1 is known to be a crucial transcriptional factor for osteoclastogenesis and is activated by calcineurin, a Ca²⁺/calmodulin-dependent phosphatase. Calcium signaling is considered to be an important regulator during osteoclastogenesis. Although it has been shown that RANKL stimulates PLC γ and then releases Ca²⁺ from intracellular Ca²⁺ stores, little is known which intra- and/or extra-cellular pathways induce osteoclastogenesis. Using a DNA microarray, we found that transient receptor potential V2 (TRPV2), a calcium permeable cation channel, was highly expressed in RANKL treated RAW264.7 cells compared to untreated cells. Thus, the aim of present study was to investigate the expression and role of TRPV2 on osteoclastogenesis via calcium signaling. TRPV2 channels were expressed in RAW 264.7 cells and bone marrow macrophages. RANKL significantly increased TRPV2 expression in both cell types 24 h after treatment. To elucidate the electrophysiological function of TRPV2, non-selective cation currents were recorded from RAW264.7 cells using the whole-cell voltage clamp technique. The current density was significantly increased in RANKL treated cells 24 h after treatment compared to untreated cells. Ruthenium red (10 μ M), an inhibitor of TRPV channels, reduced the current density as well as RANKL-induced osteoclastogenesis. Tetracycline-inducible siRNA targeted TRPV2 completely abolished the RANKL-dependent augmentation of non-selective cation currents. Silencing with TRPV2 siRNA in RAW264.7 cells also suppressed RANKL-stimulated osteoclastogenesis. These results suggest that RANKL up-regulates TRPV2 expression which serves as a calcium influx pathway. TRPV2 is involved in the RANKL-evoked calcium signaling and subsequent activation of calcium-dependent transcriptional factors such as NFATc1 and AP-1 promoting osteoclastogenesis.

Characterization of the Signaling Complex that Mediates Osteoclastic Activation. J. L. Ross*, T. J. Chambers, K. M. Lawrence*. Department of Cellular Pathology, St George's, University of London, London, United Kingdom.

Although the signals responsible for osteoclast differentiation are well characterized, almost nothing is known of those responsible for the activation and modulation of resorption. Confocal microscopy clearly demonstrates that osteoclasts form actin ring structures on mineralized substrates that differ distinctively from those formed on non-mineralized surfaces. Moreover, osteoclasts secrete enzymes when incubated on bone but not on plastic. These findings show that osteoclasts have the ability to distinguish bone from other surfaces, and that mineralized surfaces are essential for the induction of resorptive behaviour.

There is much evidence that the vitronectin receptor (VNR) and c-src are implicated in bone resorption. Recently, it has become clear that in many cases, best exemplified by the immunological synapse of T cells, cell signaling occurs through the formation of large multi-protein complexes that form dynamic physical associations between surface receptors and intracellular signaling molecules. Identifying the components of the multi-protein complex that controls osteoclast resorption may provide new targets for clinical intervention in the treatment of osteoporosis and related diseases.

We therefore performed co-immunoprecipitation experiments, using antibodies to VNR and c-src, to isolate complexes associated with these molecules in resorbing and non resorbing osteoclasts. Osteoclasts were formed on plastic substrates, lifted into suspension, and sedimented onto plastic or bone surfaces. Protein complexes from osteoclasts incubated on bone versus plastic, and with versus without resorption-inducing cytokines, were then compared.

One and 2D gel electrophoresis showed that several proteins were associated with both VNR and c-src under each of the experimental conditions used.

Interestingly co-immunoprecipitates from resorbing cells yielded proteins which were not seen under conditions of no activation. This suggests that in resorbing osteoclasts, additional proteins are recruited to the signaling complex. Furthermore, other proteins appeared to be complexed with VNR and c-src in non-resorbing osteoclasts but absent in activated cells. This implies that some proteins must be removed from the complex in order for resorption to take place, suggesting a novel resorption block mechanism. In order to identify these proteins we used Western immunoblots to probe for known signaling molecules. Using both co-immunoprecipitation antibodies, IL1 receptor, TRAF6, VNR and c-src were found to be present but equal under all conditions, thus eliminating these as differentially-bound candidates. The unidentified novel proteins are currently being identified by mass spectrometry.

Elucidating Mechanisms Leading to Increased Resorptive Activity of Large Osteoclasts in Inflammation. D. P. Trebec¹, A. Gramoun^{*2}, J. N. M. Heersche^{*2}, M. F. Manolson². ¹Department of Biochemistry, University of Toronto, Toronto, ON, Canada, ²Faculty of Dentistry, University of Toronto, Toronto, ON, Canada.

Large osteoclasts (OCs) (≥ 10 nuclei) are prevalent in inflammatory diseases characterized by increased bone resorption (e.g. rheumatoid arthritis and periodontal disease). Previously, we have shown that large OCs express higher levels of the activating receptor interleukin-1 receptor-1 (IL-1R1) while the decoy receptor IL-1R2 was increased in small OCs (2-5 nuclei). In addition, large OCs were found to be more active compared to small OCs in response to interleukin-1 (IL-1 β) (Trebec et al. JCB 101: 205-220, 2007). As a result, our aim was to determine how differential expression of IL-1R1 and IL-1R2 leads to increased resorption in large OCs and if IL-1 α and IL-1 β result in differential effects on OC formation and activity. For all experiments, we used the RAW 264.7 cells differentiated into populations of small and large OCs. In the presence of 50 ng/mL RANKL, RAW cell proliferation rates were unaffected by the addition of IL-1 α/β . IL-1 α (1 ng/mL) and IL-1 β (10 ng/mL) resulted in an increase in TRAP+ cells when added to cultures at day 0 or day 3 but not at day 5. In contrast, TRAP activity revealed no significant differences between the groups. A 2-fold increase in the number of large OCs adopting a "rounded" morphology (indicative of active OCs) was also seen when exposed to 10 ng/mL IL-1 β for 24 hours (less so for IL-1 α) and was reversed with the addition of 50 ng/mL IL-1 receptor antagonist (IL-1ra). Furthermore, similar to previous results shown with 10 ng/mL IL-1 β , large OCs resorbed 3-fold more in the presence of 1 ng/mL IL-1 α . Neither the increase in rounded morphology, inhibition by IL-1ra, nor differences in resorptive activity were evident in small OCs in response to either cytokine. Colocalization of IL-1R1 and the integrin $\alpha v \beta 3$ was observed in OCs, most notably in OCs plated on fibronectin where they adopted a round morphology. Gramoun et al have shown that OCs on fibronectin are hyperactive. In conclusion, there is a differential response between large and small OCs to IL-1, possibly resulting from variations in their IL-1 receptor levels in turn leading to activation of different signalling pathways. IL-1 α was found to be a ~10X more potent than IL-1 β . Colocalization of IL-1R1 and $\alpha v \beta 3$ could also contribute to the differential signalling responses. Elucidating mechanistic differences between large and small OCs may result in novel targets for therapeutics designed to inhibit excessive resorption by large OCs while maintaining normal bone remodelling.

NF- κ B But Not NFATc1 Is Involved in AhR - RANKL Crosstalk in Benzo[a]pyrene-Mediated Inhibition of Osteoclastogenesis. I. Voronov^{*1}, K. Li^{*2}, H. C. Tenenbaum², J. N. M. Heersche^{*2}, M. F. Manolson². ¹Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, ²Faculty of Dentistry, University of Toronto, Toronto, ON, Canada.

Cigarette smoking is a risk factor for impaired bone healing, however, the molecular mechanisms leading to its detrimental effects are not known. Benzo[a]pyrene (BaP) is an environmental pollutant present in high concentrations in cigarette smoke. BaP binds to the aryl hydrocarbon receptor (AhR), a cytosolic transcription factor (TF), and induces expression of several drug-metabolizing enzymes including cytochrome P450 1B1 (CYP1B1). We have demonstrated previously that osteoclastogenesis is suppressed by BaP, and that RANKL, when delivered in high concentration (100 ng/ml) reverses this inhibition and suppresses BaP-mediated gene expression, suggesting possible crosstalk between AhR and RANKL signaling pathways (Voronov et al., Biochem. Pharmacol., 70:300-7, 2005). NF- κ B and NFATc1 are key TFs activated in RANKL-induced osteoclastogenesis. To evaluate the effect of BaP on these TFs, RAW264.7 cells were exposed to 25 or 200 ng/ml RANKL and 10^{-5} M BaP and analyzed by TF activation ELISA kits. TF activity assays demonstrated that BaP inhibited RANKL-mediated NF- κ B activation at 30 min, however, at 60 min, NF- κ B activation levels remained above control levels in BaP-containing groups. In contrast, NFATc1 activity was significantly upregulated by BaP. To determine the effect of BaP on RANKL-mediated nuclear translocation, the cells were analyzed by immunofluorescence (IF) using an anti-p65 or anti-NFATc1 antibodies. IF showed that BaP inhibited RANKL-induced NF- κ B nuclear translocation, but had no effect on NFATc1. To investigate the involvement of NF- κ B and NFATc1 in BaP-mediated gene expression, the cells were cultured in the presence of NF- κ B and NFATc1 inhibitors. RT-PCR revealed that NF- κ B but not NFATc1 inhibitors decreased CYP1B1 expression suggesting that NF- κ B is involved in BaP-mediated CYP1B1 expression. To assess if there is a direct interaction between AhR and NF- κ B, co-immunoprecipitation experiments were performed and revealed an AhR-NF- κ B interaction in the presence of BaP. Based on the above, we speculate that NF- κ B but not NFATc1 is involved in AhR - RANKL signaling crosstalk. We conclude that inhibition of RANKL-induced NF- κ B activation is one of the possible mechanisms of BaP-mediated inhibition of osteoclastogenesis.

Densitometric Derived Structural Indices in HR-pQCT Are Independent of Cortical Geometry. A. J. Burghardt, K. Davis*, S. Majumdar. Radiology, University of California, San Francisco, San Francisco, CA, USA.

High-resolution peripheral quantitative computed tomography (HR-pQCT) has the potential to be a useful method for the longitudinal evaluation of bone quality in human subjects. Current structure analysis methods for this modality calculate BV/TV based on

the apparent mineral density of the trabecular compartment and an assumed compact bone mineral density of 1200 mg HA/cm³. This requires accurate calibration of bone mineral densities and adequate correction for beam hardening effects. Using an equivalent calibration and beam hardening correction in a micro-tomography device, it has been shown that cortical geometry can introduce a non-negligible bias in apparent density measures [1]. In this study we evaluate the error in calculating BV/TV densitometrically as it relates to cortical geometry and corrections for beam hardening for HR-pQCT. Cadaveric distal radii were acquired from 6 donors and a 1cm length was imaged using HR-pQCT (Scanco XtremeCT, 82 μ m isotropic nominal resolution) and μ CT (Scanco μ CT40, 18 μ m isotropic nominal resolution). For both devices custom beam hardening correction factors were determined using a 200mg HA/cm³ wedge phantom. The datasets were registered based on matching cross sectional areas prior to analysis. BV/TV and Ct.Th measures were determined for each dataset in 1mm increments along the long axis of the bone. BV/TV was calculated densitometrically as $vBMD_{trab}/1200$ mg HA/cm³ for the HR-pQCT images, while a simple voxel counting method was used for the μ CT data. Ct.Th was calculated for the μ CT data using direct 3D methods. As reported elsewhere [2], BV/TV determined densitometrically from calibrated HR-pQCT images was somewhat underestimated compared to the reference μ CT values. The absolute error in BV/TV exhibited minimal dependence on cortical geometry. These results suggest that beam hardening effects related to cortical shell geometry are not a significant source of bias in HR-pQCT based measures of trabecular bone structure.

Measurement Protocols for the Non-invasive Assessment of Bone Constituent Properties by Raman Spectroscopy. J. H. Cole¹, M. V. Schulmerich^{*1}, K. A. Dooley^{*1}, J. M. Kriegl^{*2}, E. Daley^{*2}, S. A. Goldstein^{*2}, M. D. Morris¹. ¹Department of Chemistry, University of Michigan, Ann Arbor, MI, USA, ²Department of Orthopaedic Surgery, University of Michigan, Ann Arbor, MI, USA.

Techniques that clinically evaluate bone status may assess the mass and organization of the tissue, but no current method can examine features of bone quality such as mineral and matrix properties in vivo, which contribute vitally to skeletal strength and toughness. Previous studies revealed that bone fragility is associated with changes in composition metrics, such as mineral crystallinity or substitution and collagen cross-linking. We recently developed a non-invasive Raman fiber optic probe that allows us to observe bone spectra through the skin and overlying tissue in animal and human cadaveric limbs. The objective of our study was to improve tissue preparation, optimize probe configuration, and examine our ability to measure bone constituent properties non-invasively in different specimens over a range of overlying tissue depths. Excised limbs from human, mouse, rat, and canine specimens were obtained. For the animal limbs, fur was removed in the region of interest (ROI) using a depilatory agent. Glycerol was applied to the ROI to increase light penetration into overlying tissue, thereby improving the Raman bone spectra. Multiple spectra were acquired on each limb. Following transcutaneous measurements, tissues overlying the bone were removed, and Raman spectra were collected from the exposed bone for validation. The contribution of bone (e.g., mineral and matrix) was separated from that of the overlying tissue (e.g., skin and tendon) using multivariate methods. Standard composition metrics including carbonate/phosphate ratio, mineral/matrix ratio, and collagen cross-link ratio were computed using both band heights and band areas. Band height ratios generally gave better accuracy, because they were less sensitive to errors from baseline correction. Bone composition measurements obtained transcutaneously differed by less than 5% from those obtained on the exposed bone, and the two were not significantly different ($p > 0.05$). The results demonstrate effective measures of bone beneath more than 5 mm of overlying tissue with the expectation of reaching greater depths with further improvements to our system. Non-invasive Raman spectroscopy can accurately assess the contribution of bone composition to bone quality and may prove useful in the clinical assessment of bone fragility.

Within Osteons Infrared Parameters Linked to Specific Bone Properties Vary as a Function of Tissue and Animal Age. S. Gourion-Arsiquaud¹, L. M. Havill², A. L. Boskey¹. ¹Research, Hospital for Special Surgery, New York, NY, USA, ²Southwest Foundation for Biomedical Research, San Antonio, TX, USA.

Fractures are the major problem associated with osteoporosis and represent a major concern of public health. Although BMD is used as a clinical predictor of fracture risk, some patients with fracture incident present normal BMD showing that this is not the only factor affected in osteoporosis. Moreover BMD does not allow understanding the underlying mechanisms involved in these bone diseases. Therefore it was important to find other parameters linked to bone quality. Previous studies on healthy and diseased bones using FTIR spectroscopy have validated parameters that reflect the mineral and matrix organization at a molecular level.

Due to constant bone remodeling, there are tissue age variances within the same bone specimen. In this work we analyze the molecular variations of bone as a function of both tissue and animal age. To address this issue we describe changes of parameters inside osteons from baboons of different ages by FTIR-Imaging and for representative samples also using Raman spectroscopy. The osteon was chosen for this study as it is an active remodeling unit, presenting different tissue ages going from its center to the periphery.

The following parameters were examined across individual osteons in femoral samples from 27 baboons aged 0-30 years: Mineral/matrix ratio, a quantitative assessment of the mineral content; Crystallinity ratio linked to the hydroxyapatite (HA) crystal size; Carbonate to phosphate ratio, and Collagen cross-link ratio which represent, respectively, the incorporation of carbonate into the HA lattice and the maturity of collagen. We found that mineral/matrix ratio and crystallinity ratio increase with tissue age whereas carbonate to phosphate ratio decreases. These data improve our knowledge on the mechanisms involved in bone tissue aging. The Raman data validate and complete these IR results. The parameters show a similar trend within osteons regardless the age of the animal. Only the absolute values of these ratios differed. This work demonstrates not only that FTIR imaging allows the co-localization of important mineral and matrix properties of bone at the microscopic level but also that osteon analysis can provide reproducible characterization of these properties. Indeed, this work set up a basis which will permit using normal osteonal data as a baseline against which those of samples from bone disease subjects can be compared. This should allow characterization of which bone properties are associated with the metabolic bone diseases. On the same way osteonal studies should provide information on the efficacy of therapies used in the treatment of bone diseases.

Assessment of Bone Tissue Mineralization: Evaluation of Polychromatic μ CT Mineralization Measurement by Comparison to Synchrotron Radiation μ CT. G. J. Kazakia, A. Burghardt, S. Majumdar. Radiology, UC San Francisco, San Francisco, CA, USA.

The goal of this study was the quantitative evaluation of micro-computed tomography (μ CT)-based measurement of degree of mineralization of bone (DMB). While μ CT systems are used widely to assess bone structure, beam-hardening effects due to the polychromatic source complicate assessment of DMB. Beam-hardening correction algorithms have recently been introduced to overcome this limitation. Synchrotron radiation μ CT (SR μ CT) is an appropriate standard for spatially-resolved DMB evaluation due to the monoenergetic, high flux, parallel beam that provides high spatial resolution and accurate attenuation measurement. Therefore we proposed to compare μ CT data to those obtained by SR μ CT to evaluate the accuracy of μ CT mineralization measurement.

Cylinders of trabecular bone (8 x 4 mm, n = 14) were harvested from proximal femurs, proximal tibiae, and vertebrae of human cadavers in an effort to include a range of structure and mineralization. Specimens were imaged using a desktop μ CT system (μ CT-40, Scanco Medical AG) at a resolution of 8 microns and energy settings optimized for mineralized human trabecular bone (70 kV, 114 mA). Density-calibrated μ CT reconstructions were created using a hydroxyapatite (HA) phantom.

The specimens were then scanned at a synchrotron beamline equipped with a μ CT stage (National Synchrotron Light Source, BNL) at low energy (26keV) with a voxel size of 7.5 microns. Density-calibrated reconstructions were created using the μ CT HA phantom. SR μ CT data were segmented using a global threshold criterion. Segmentation of the μ CT data was performed by matching the volume fraction (BV/TV) determined by SR μ CT analysis. Mean DMB (g/cc) and BMC (g) were calculated for each specimen from the μ CT and SR μ CT reconstructions. Following imaging, ash weight (g) and density (g/cc) were measured using established gravimetric protocols.

Desktop μ CT DMB measurements were well-correlated to SR μ CT DMB values when anatomic sites were considered individually ($R^2 = 0.80$ tibia & vertebra; 0.99 femur) but not when pooled ($R^2 = 0.21$). At all sites evaluated, μ CT underestimated DMB as compared to SR μ CT (12 to 18 %, $p < 0.001$). At all sites, BMC derived from both μ CT and SR μ CT were well-correlated with ash weight ($R^2 = 0.98$). DMB was correlated to ash density only for proximal femur cores ($R^2 = 0.55$ for both μ CT & SR μ CT).

These results suggest that trabecular bone structure is critical in tomography-based determination of mineral density. We found that bone samples from sites with high BV/TV (proximal femur) produce more accurate DMB measures than low BV/TV samples. Partial volume and segmentation artifacts, which are more prevalent in low BV/TV imaging, likely contribute to errors in DMB.

Analysis of Differing Approaches for the Assessment of Large Scale Transcriptional Profiling of Fracture Healing. J. E. McLean¹, L. J. Silkman¹, T. A. Einhorn¹, T. F. Smith², L. C. Gerstenfeld¹. ¹Orthopaedic Research, Boston University, Boston, MA, USA, ²Biomedical Engineering, Boston University, Boston, MA, USA.

Fracture healing is a synchronous temporal process of one round of endochondral bone formation followed by an extended period of remodeling. The aim of this study was to compare three approaches to the normalization of large scale transcriptional profiling. The methods used were: the profile of unfractured bone as the reference; an exogenously added artificial gene sequence with no known correlate in the mouse genome as reference "alien gene"; and a set of standard genes "housekeeping genes". Standard femur fractures were generated in C57/B6 mice and assessed at days 3, 7, 10, 14, and 21. ~21,000 genes were examined. The hybridization of each spot was assessed using three separate detection channels and spots were measured as a ratio intensities. Separate ratios were determined using the biological reference and the exogenously added Alien gene, which were both co-printed with each gene spot on the chip included with the hybridization cDNAs. Sixty standard genes were empirically compiled based on both their invariant expression from the biological reference and low standard deviation. Sixty genes with the largest ratio differences from their reference for four basic expression patterns increasing, decreasing, and two types of complex behavior over time were used to assess statistical reproducibility of the data. The Alien and biological reference had statistically significant correlation for all sets at ($p < 0.002$). The correlation between the standard genes and the biological reference showed statistical significance (all $p < 0.05$) and was only significant at $p < 0.05$ for two out of four sets of genes that were examined when compared to Alien. The use of the biological reference excludes ratio intensity measurements from being made for all genes that are not actively transcribed in the unfractured bone sample. This analysis method excluded ~2000 mRNAs that are newly transcribed following fracture, as determined via ratio to Alien reference. Using fixed in-spike concentration of Alien also enables absolute ratio intensity measurements of the expressed levels for individual mRNAs to be made. Validation of expressed levels between gene transcripts can be assessed, by examining the ratios of Col1a1 and Col1a2, splice variants of Col2a1 and a selected group of ribosomal subunit proteins. The inherent advantages of using an exogenous reference enables absolute determination of individually expressed mRNAs species to be made and provides the greatest degree of accuracy of both inter-chip and inter-experimental comparisons.

Microscopic Imaging of Bone Composition En Block with Synchrotron Infrared Microspectroscopy. L. M. Miller¹, T. C. Feldman², A. Schirmer³, R. J. Smith¹, S. Judex³. ¹National Synchrotron Light Source, Brookhaven National Laboratory, Upton, NY, USA, ²Materials Science and Engineering, Stony Brook University, Stony Brook, NY, USA, ³Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA.

Understanding changes in the chemical makeup of bone is important for diagnosing and treating bone disease. Fourier transform infrared microspectroscopy (FTIRM) is a well-established imaging technique that provides information on both the mineral and matrix composition of bone. One drawback of the technique is that FTIRM data are typically collected in a transmission geometry, thus requiring plastic-embedding and microtoming of very thin (3 - 5 micrometer) sections of bone. In this work, we have established a new method for collecting FTIRM data in a reflection geometry from the surface of a bone block using synchrotron light. This study will demonstrate the accuracy and quality of reflection FTIRM, while investigating spatially-resolved chemical changes in developing mouse bone. Tibiae of female BALB mice were harvested at 8 time points distributed between 1d and 40d of age and embedded in poly methyl methacrylate (PMMA). Thin sagittal sections (3 micrometers) were cut from the surface of each embedded bone. FTIRM was performed on both the thin section and the surface of the sample block in transmission and reflection geometry, respectively. The results from the two imaging methods were compared using visible landmarks present in both the thin section and the embedded bone. Specifically, the mineralization (phosphate/protein ratio), carbonate accumulation (carbonate/phosphate ratio), crystallinity, and collagen cross-linking were assessed. The results of this work will be presented as a validation of this new methodology, which will increase the applicability of FTIRM by expanding its use to those samples that cannot be processed into thin sections for analysis.

Back-Scattered Electron Imaging of Bone Mineralization in Osteoarthritis. P. Sutton-Smith^{*}, N. Fazzalari, J. Kuliwaba, H. Beard^{*}, B. Ma^{*}. Tissue Pathology, Institute of Medical and Veterinary Science, Adelaide, Australia.

Osteoarthritis affects a large proportion of Western society. There is controversy over the degree and nature of bone changes in this disease with presentation of heterogeneous tissue-level morphology. Studies of sub-chondral bone have shown increased bone volume and decreased bone mineralization, but more distal sites have not been systematically

investigated. We have used a quantitative back-scattered electron imaging technique to analyze inter-trochanteric trabecular bone samples from 22 patients (11 males aged 70±12 years, 11 females aged 68±13 years) undergoing total hip replacement for osteoarthritis. These are compared with a group of 20 skeletally normal post mortem controls (12 males aged 60±14 years, 9 females aged 63±14 years) with both groups including only individuals aged greater than 40 years. Bone samples were fixed and embedded in methylmethacrylate resin for histomorphometry. These blocks were then polished, carbon coated and examined in a Philips XL20 scanning electron microscope which was calibrated with carbon/aluminium standards. Data were pooled to create a mineralization distribution for each of the groups, as well as analyzing the weight percent calcium (wt%Ca) and trabecular bone volume fraction (BV/TV[%]) data for individuals. The mineralization of the osteoarthritis group was less than that of the control group (24.2 wt%Ca versus 25.3 wt%Ca, respectively). The osteoarthritis mineralization distribution was a lower, broader curve consistent with the heterogeneous tissue-level morphology characteristic of osteoarthritis. Statistical analysis of individual's values revealed a significant lowering of the weight percent calcium in osteoarthritis compared to controls (24.4 wt%Ca versus 25.1 wt%Ca, respectively, $p<0.001$) concomitant with a significant increase in BV/TV(%) (10.4% versus 7.6%, respectively, $p<0.02$). These results are similar to those reported for sub-chondral bone in osteoarthritis and imply an increased rate of bone turnover associated with a net positive gain in bone volume. These findings at a site distal to the primary disease process have implications for systemic changes of bone metabolism in osteoarthritis.

Osthoe Stimulates Pre-osteoblast Proliferation and Differentiation Via BMP-2/RUNX2/SMAD1 Pathway. D. Tang^{*1}, S. Cheng^{*1}, Q. Shi^{*1}, D. Chen², Y. Wang^{*1}. ¹Orthopaedics, Institute of Spine, Shanghai University of Traditional Chinese Medicine, China, ²Orthopaedics, Center for Musculoskeletal Research, University of Rochester, NY, USA.

Osthoe, also named 7-methoxy-8-isopentenoxycoumarin, is a coumarin extracted from *Cnidium fructus*. In the present researches, it has various of pharmacological effects, such as anti-arrhythmia, anti-immunity, anti-apoptosis, anti-tumor, anti-inflammation, etc. It was also found that osthoe has effects on osteoporosis using ovariectomized (OVX) rats and human osteoblast-like cell lines. The purpose of this study was to examine effects of osthoe on the pre-osteoblast related with the dose and find its possible mechanisms for anti-osteoporosis. OCT-1 cells (a pre-osteoblast cell line) were used, cultured with 3 dose of osthoe for 48h, or with purified BMP-2 protein. We first determined the effect of osthoe on cell proliferation by MTT assay. alkaline phosphatase (ALP) activity in the cells was also assayed after appropriate treatment periods. The real time RT-PCR was employed to quantify the changes in mRNA levels for bone morphogenetic protein-2 (BMP-2) and RUNX2 of cells. At last we used the Western Blotting analysis to evaluate the expression of Smad1 protein.

As a result, osthoe (10ug/ml) can promote the OCT-1 cells proliferation, but osthoe (30ug/ml) and osthoe (60ug/ml) had no effect on the proliferation of these cells. Various dose of osthoe can increase the ALP activity of OCT-1 cells, the effect of 30ug/ml was the best, and 10ug/ml followed. From the real time RT-PCR analysis, Various dose of osthoe can enhance the BMP-2 mRNA levels, the effect of 10ug/ml was the best, and 30ug/ml followed. In addition, we found that osthoe (10ug/ml) can enhance the BMP-2 mRNA levels significantly, but osthoe (60ug/ml) decreased the BMP-2 mRNA levels significantly. From the Western Blotting analysis, osthoe (10ug/ml) and osthoe (30ug/ml) can stimulate the expression of Smad1 protein, but osthoe (60ug/ml) had the opposite effect. In this study, we demonstrate that osthoe is a promising agent for anti-osteoporosis, but the effect of osthoe is related with the dose. Only suitable dose of osthoe can stimulate bone formation, while exorbitant dose of osthoe may inhibit bone formation.

A New Approach to Assess Bone Formation Rates and Immunohistochemistry / in situ Hybridization in the Same Bone Specimen. J. Zhang, G. E. Gutierrez, M. Zhao, S. A. Munoz*, J. R. Edwards, G. R. Mundy. Center for Bone Biology, Vanderbilt University, Nashville, TN, USA.

Bone formation rate is the key parameter in the in vivo characterization of osteoblast activity and bone growth/remodeling. The standard procedure to assess new bone formation is to use calcium-seeking fluorochromes which are visualized in undecalcified, plastic embedded sections of bone using fluorescence microscopy. Not only is this method time consuming and laborious, more importantly, it limits the application of immunohistochemistry (IHC)/in situ hybridization (ISH) on the same sections/specimens. Consequently, two separate bones (left and right) of an animal must be used for assessing bone formation or IHC/ISH experiments. This is problematic because we have observed that BMD and structural property differ between left-sided and right-sided bones. This suggests that experiments performed on different bones from the same animal may generate different biological information and lead to inaccurate conclusions. Our goal is to develop methods that enable the evaluation of all bone parameters including bone formation rate, bone/osteoid volume, osteoblast and osteoclast numbers, protein and gene expression profiles (IHC, ISH) using one bone specimen. To achieve this goal, the most challenging problem is to assess bone formation rate in decalcified specimens. We have tested three fluorochromes, two fixation buffers and two decalcification solutions. We found that the visualization of calcein green is superior to calcein blue and alizarin red in formalin fixed, EDTA-decalcified paraffin embedded bone sections; the fixation and decalcification times are also critical for preserving calcein green labeling. All three

fluorochromes were not preserved in ethanol or formalin fixation following acid decalcification. Optimizing the time for different specimens, we have effectively assessed mineral apposition rates and other parameters of bone remodeling, as well as IHC and ISH in the same slides/specimens in different developmental stages of tooth and bone. In conclusion, we have successfully developed a simple method to assess new bone formation rates and protein/gene expression profiles in the same bone specimen. This procedure greatly increases the efficiency and reliability of the results.

IGF-1 Regulation of Collagen II and Matrix Metalloproteinase-13 Gene Expression in Rat Endplate Chondrocytes via Distinct Signaling Pathways. M. Zhang^{*1}, Q. Zhou^{*1}, Y. Dong², T. Li², Q. Shi^{*1}, Y. Wang^{*1}. ¹Orthopaedics, Institute of Spine, Shanghai University of Traditional Chinese Medicine, China, ²Orthopaedics, Center for Musculoskeletal Research, University of Rochester, NY, USA.

It is well known that IGF-I exerts positive anabolic effects on chondrocytes in vivo and in vitro. However, little is known on IGF-mediated regulation of collagen II, matrix metalloproteinase-13(MMP13) gene expression and the involved intracellular signaling pathway in endplate chondrocytes. In the present study, chondrocytes isolated from normal rat endplate cartilage were stimulated with IGF-1 in monolayer culture. The technique of real-time PCR was employed to quantify the changes in mRNA levels for collagen IIa and mmp13 in rat endplate chondrocytes in response to IGF. The data were normalized to mRNA levels of β -actin, a constitutively expressed gene. Expression of signaling proteins was evaluated by western blot analysis. Cells were also treated with pharmacologic agents that block PI3K and MAPK signaling pathways. IGF-1 increased the collagen IIa mRNA expression in a time- and dose-dependent manner. With the treatment of IGF-1 (100 ng/ml), the expression of collagen IIa mRNA in rat endplate chondrocytes reached the highest value at 24 h and then decreased gradually along with time. IGF-1 (100 ng/ml) increased collagen IIa mRNA levels in rat endplate chondrocytes by 3.89 fold after treatment 24 h. Additionally, IGF-1 decreased MMP13 mRNA expression in rat endplate chondrocytes. IGF-1 (100 ng/ml) decreased MMP13 mRNA level by 0.55 fold after treatment 24 h. Furthermore, IGF-1 activated (phosphorylation) members of both the PI3K pathway and the ERK/MAPK pathway, Akt and ERK1/2. Coincubation of IGF-1 with PI3K inhibitor wortmannin significantly blocked the stimulatory effect of IGF-1 on collagen IIa mRNA expression, but did not significantly inhibit IGF-induced repression of MMP13 mRNA expression. In contrast, the ERK/MAPK inhibitors PD98059 was able to block partially IGF-stimulated collagen IIa mRNA expression, but significantly blocked IGF-induced MMP13 mRNA repression. These data suggested that IGF-1 stimulation of PI3K signaling pathway is responsible for the ability of IGF-1 to increase collagen IIa mRNA expression, and IGF-1 stimulation of ERK/MAPK signaling pathway is responsible for the ability of IGF-1 to inhibit MMP13 mRNA expression.

Activation ERK1/2 Prevents the FasL-induced Apoptosis Anulus Fibrosus Cells in Insulin-like Growth Factor-1-Treated. Q. Zhou^{*1}, M. Zhang^{*1}, Y. Dong², T. Li², Q. Shi^{*1}, Y. Wang^{*1}. ¹Orthopaedics, Institute of Spine, Shanghai University of Traditional Chinese Medicine, China, ²Orthopaedics, Center for Musculoskeletal Research, University of Rochester, NY, USA.

FasL binds to Fas to induce cell apoptosis. Insulin-like growth factor-1(IGF-1) decreases apoptosis in several cell types. There have been no descriptions showing that through activation Erk1/2, increasing focal adhesion kinase (FAK) expression on anulus fibrosus cells with IGF-1. In this present study, rat anulus fibrosus cell were cultured and treated with antibody FasL, with or without human recombinant IGF-1. Cellular morphology was examined by light microscopy and reverse transcription polymerase chain reaction (RT-PCR). Apoptotic changes were evaluated by transmission electron microscopy, TUNEL staining, and immunostaining of Bax and bcl-2. Real time RT-PCR analysis showed mRNA levels of FAK, collagen II and aggrecan. Values are normalized to β -actin from three independent experiments. Western blot was performed to assay signaling proteins FAK and Erk1/2 phosphorylation and assess its relation to IGF-1. Anulus fibrosus cells expressed collagen II and aggrecan in vitro that maintained cell characteristic in vivo. FasL can induce anulus fibrosus cells apoptosis. TUNEL staining confirmed increased apoptosis ratio in antibody treated cells. Expression of bcl-2 was decreased by FasL, while expression of Bax was increased. FasL treatment caused FAK, collagen II and aggrecan mRNA expression approximately 2.84, 3.43, 3.91-fold down-regulated when compared to untreated controls. Simultaneous treatment with IGF-1 inhibited the effect of FasL on FAK, collagen II and aggrecan mRNA expression, increased 3.63, 11.32, 2.16-fold after treatment 24 hours. FasL treatment inhibited members of ERK/MAPK pathway, Erk1/2 phosphorylation. But not significant affected FAK phosphorylation. Co-treatment of IGF-1 can activate Erk1/2 (phosphorylation) but not significant activate FAK in short time. These data suggested that IGF-1 through activation Erk1/2 and up-regulated the FAK expression protects anulus fibrosus cells from FasL-induced apoptosis.

Dominant X-linked Hypophosphatemic Rickets: A New Mutation of PHEX Gene. L. Masi¹, S. Carbonell Sala¹, A. Gozzini¹, I. Pela², A. Amedei¹, A. Falchetti¹, E. Luzi¹, S. Ottanelli¹, M. L. Brandi¹. ¹Internal Medicine, University of Florence, Florence, Italy, ²Pediatric, University of Florence, Florence, Italy.

Hypophosphatemic rickets is a group of disorders with hypophosphatemia, hyperphosphaturia, normal levels of vitamin D and parathyroid hormone (PTH), bone deformities, osteomalacia/rickets. X-linked hypophosphatemic rickets (XLH) is one of the most common form of the familial hypophosphatemic rickets and in 60-80% of cases bear of mutation in PHEX gene (Xp22.2-p22.1). PHEX encodes for an endopeptidase member M13Zn-metalloproteinase family, involved in the regulation of phosphate homeostasis. PHEX inactivating mutations causes XLH. These mutation enable the accumulation of phosphaturic factors and/or mineralization inhibitors. In the present study we describe a 3 years old female referred to our Center, exhibiting clinical features of a clear hyperphosphaturia, hypophosphatemia, normocalcemia, PTH circulating levels at the upper values of the normal range and normal values for vitamin D. She showed deep asthenia, muscle pain and spasms, bowed legs and cranial deformities. The parents feel well and were not consanguineous. The patient and her parents underwent PHEX mutational analysis upon administration of an informed consent from (in case of minor patient signed by legal tutor). Genomic DNA has been extracted by peripheral blood leukocytes. The 22 exons and the intron-exon boundaries of PHEX have been investigated by PCR and direct-sequencing (ABI-Prism 3100) protocol. It has been identified a hemizygous mutation of PHEX IVS1078+1 position, causing nucleotide change in a splice donor site that may cause an abnormal splicing phenomenon. This nucleotide substitution has been never described on PHEX database (<http://www.phexdb.mcgill.ca/>). Up today, no functional analysis for this mutation has been performed. In the present study a mini-gene analysis is undergoing to evaluate the alternative splicing pattern. Finally, we are planning to use cellular models, either obtained from patients and engineered by transfection methods to evaluate the functionality of the mutated gene. These approaches will be helpful to better understand the molecular mechanism of PHEX action and could provide highlight for future targeted therapies.

Analysis of the Function of the CTCF-binding Site Between the Rxrb and the Col11a2 Genes. J. Murai¹, M. Okamoto¹, H. Yoshikawa¹, N. Tsumaki². ¹Orthopaedic Surgery, Osaka University Graduate School of Medicine, Suita, Japan, ²Bone and Cartilage Biology, Osaka University Graduate School of Medicine, Suita, Japan.

The $\alpha 2(XI)$ collagen chain gene (Col11a2) is specifically expressed in cartilage. The 1st intron sequence of the Col11a2 gene acts as the enhancer that activates expression in cartilage and silencer that inactivates expression in non-cartilaginous tissues. The 5'-end of the Col11a2 gene resides very closely to the 3'-end of the retinoid-X-receptor β gene (Rxrb) which is ubiquitously expressed. We hypothesized the enhancer/silencer blocking elements between these genes. So far, almost all of the characterized enhancer blocking elements identified in vertebrates are bound by the CTCF protein. At the last this annual meeting, we reported the CTCF binding site between the Col11a2 and the Rxrb genes. The purpose of this study is to investigate the function of the CTCF binding site. We prepared three transgene constructs by using the human bacterial artificial chromosome (BAC) DNA clone which is 160 kb in length covering entire COL11A2 and RXRB genes. The wild type (WT) construct was generated by placing the LacZ sequence at the downstream of the RXRB gene promoter in the BAC clone. The mutation construct (Mut) was made by introducing 14 bp-substitution mutation in the CTCF binding site in the WT. The deletion construct (Del) was produced by deleting the 507bp sequence around the CTCF binding site in the WT. We generated transgenic mice bearing these constructs and analyzed LacZ expression patterns by staining the 13.5 d.p.c. founder embryos with X-gal. All of the 4 transgenic mice bearing the WT transgene expressed the LacZ gene in all tissues. This ubiquitous expression pattern of the LacZ was consistent with the expression pattern of the endogenous Rxrb gene. On the other hand, 2 out of 3 transgenic mice bearing the Mut and 2 of 4 mice bearing the Del expressed the LacZ genes specifically in cartilage. Abolition of the CTCF-binding site specifically inhibited expression of the LacZ in non-cartilaginous tissues, suggesting that the CTCF-binding site blocks silencer activities of the Col11a2 regulatory sequences. Next, we established stable transformant clones of rat chondrosarcoma cells bearing the WT, Mut and Del BAC DNA respectively. By the real time RT-PCR, we specifically amplified the human RXRB and COL11A2 mRNA sequences that derived from the transgene. The expression levels of the puromycin resistance gene were used as the internal control. The mean expression levels of the RXRB genes of the Mut and Del clones were significantly higher than that of the WT clones. The abolition of the CTCF-binding site increased expression of the RXRB in chondrosarcoma cells, suggesting that the CTCF-binding site blocks enhancer activities of the Col11a2 in cartilage.

Identification of Hs.43125 as an Articular Chondrocyte-Specific Gene. S. Shin^{*}, J. Chun^{*}. Department of Life Science, Gwangju Institute of Science and Technology, Gwangju, Republic of Korea.

Developmental process of endochondral bones is initiated by chondrogenesis of mesenchymal cells and subsequent hypertrophic maturation. During this developmental process, chondrocytes produce a variety of signaling molecules to coordinately regulate cartilage and bone development. We searched expressed sequence tags (ESTs) cluster library of human normal cartilage in Unigene transcriptome database to identify unrevealed signaling molecules which are produced during limb development. Hs.43125 was identified as a novel cartilage-specific gene and selected for functional characterization. Hs.43125 is composed of four different exons and signal peptide sequence for secretion. When myc-tagged Hs.43125 cDNA was ectopically expressed in primary articular chondrocytes, Hs.43125 encodes a 17 kDa secretory. The molecular weight of secreted Hs.43125 was smaller than cellular protein indicating post-translational modification during secretion. In attempt to examine the role of Hs.43125, expression pattern of Hs.43125 was examined during chondrogenesis of mesenchymal cells and hypertrophic maturing of chondrocytes. Hs.43125 expression was low in mesenchymal cells, increased during chondrogenesis and decreased during hypertrophic maturation of chondrocytes in vitro. In situ hybridization analysis also indicated that Hs.43125 is expressed in proliferating chondrocytes of developing cartilage of mouse embryo at 14.5 day. Our results suggest that Hs.43125 may have a role in chondrogenesis, maintenance of differentiated chondrocyte phenotypes, and/or transition of prehypertrophic chondrocytes to hypertrophic chondrocytes.

Carbonic Anhydrase II Regulates Differentiation and Proliferation of Ameloblast via Intracellular pH-dependent Mechanism. X. Wang¹, T. Suzawa¹, M. Nakamura², B. Zhao¹, R. Yasuhara¹, T. Inoue³, Y. M. Masuda⁴, K. Matsumoto⁴, R. Kamijo¹. ¹Department of Biochemistry, Showa University School of Dentistry, Tokyo, Japan, ²Department of Oral Anatomy, Showa University School of Dentistry, Tokyo, Japan, ³Department of Oral Physiology, Showa University School of Dentistry, Tokyo, Japan, ⁴Department of Clinical Cariology & Endodontology, Showa University School of Dentistry, Tokyo, Japan.

This study aimed to clarify the involvement of carbonic anhydrase II (CAII), a zinc metalloenzyme, on ameloblast differentiation and enamel biomineralization. We identified the expression level of CAII mRNA is strongly up-regulated in differentiated enamel epithelial tissues by means of microarray. Immunohistochemical analysis revealed that CAII was expressed intensively in secretory stage ameloblast in enamel epithelium. In an ameloblast primary culture, the CA enzyme activity measurement showed that activity of CA was increased along with differentiation of ameloblast. RT-PCR indicated that the expression level of amelogenin, a marker for secretory ameloblasts, was enhanced by ethoxzolamide (EZA), a CA inhibitor, as well as by CAII antisense oligonucleotide (CAIIASO). In contrast, expression of EMSP-1, a marker for mature ameloblast, was inhibited by them, suggesting that inhibition of CAII activity could inhibit differentiation of ameloblast. MTS assay also showed they promoted proliferation of ameloblast. Inhibition of ameloblast differentiation by EZA and CAIIASO was confirmed by tooth germ organ culture, since they induced disorderly arrayed ameloblasts with poor polarity. Intracellular pH of ameloblast was labeled with BCECF-AM, and was controlled by the K⁺-nigericin method. EZA and CAIIASO elevated intracellular pH in ameloblast, and an artificial decrease of intracellular pH abolished the effects of CAIIASO on ameloblast. These results suggest the novel role of CAII during amelogenesis, that is, controlling differentiation and proliferation of ameloblast. The results also suggest controlling intracellular pH might be primary mechanism of CAII in ameloblast.

Regulation of Matrix Metalloproteinases Expression by EPAS1 in Articular Chondrocytes. S. Yang^{*}, J. Cho^{*}, J. Chun^{*}. Department of Life Science, Gwangju Institute of Science and Technology, Gwangju, Republic of Korea.

We identified and selected for functional characterization of endothelial PAS domain protein 1 (EPAS1), also referred as a hypoxia-inducible factor 2 α , by screening transcriptome database for expressed sequence tags (ESTs) using osteoarthritic cartilage library in unigene. Because EPAS1 plays essential roles in hypoxia and many pathogenic conditions, this study examined a role of EPAS1 in articular chondrocytes. EPAS1 expression was significantly increased in human osteoarthritic cartilage compared with normal cartilage. In primary culture articular chondrocytes, EPAS1 expression was significantly increased during dedifferentiation of chondrocytes caused by interleukin-1 β , epidermal growth factor (EGF), retinoic acid (RA), or serial subculture as monolayer. Dedifferentiation of chondrocyte accompanies induction of several matrix metalloproteinases (MMPs) such as MMP-1, -3, -9, -12, and -13, without effects on MMP-2, -14, and -15 expressions. Upregulation of EPAS1 during dedifferentiation of chondrocyte occurs prior to MMP expression. We, therefore, examined whether EPAS1 mediates upregulation of MMPs. Overexpression of EPAS1 by adenovirus-EPAS1 (Ad-

EPAS1) induced MMP-1, -3, -9, and -13 expressions, whereas expression patterns of MMP2-, -14, and -15 were not changed. Knockdown of EPAS1 by siRNA blocked IL-1 β -induced expression of MMP-3, -9, and -13. Our results suggest that EPAS1 may play a role in cartilage destruction by modulating MMP expression.

Identification and Characterization of MicroRNAs Expressed During Chondrogenesis of Mesenchymal Cells. S. Yu, J. Chun*. Life Science, GIST, Gwangju, Republic of Korea.

microRNAs (miRNAs) play important roles in regulating the expression of specific mRNAs at both transcriptional and posttranscriptional levels. In attempt to understand more information in on-off of mRNA expression during chondrogenesis, we investigated miRNAs expressed in chondrifying mesenchymal cells derived from mouse embryo limb buds. We identified three new miRNAs from chondrifying mesenchymal cell. Among the identified miRNAs, expression of miRNA 542-3t was decreased during chondrogenesis of mesenchymal cells, and its expression was specifically detected in developing cartilage tissue. By computational analyses, 6130401L20Rik was identified as a potential target gene of miRNA 542-3t. Consistent with the expression pattern of miRNA 542-3t, a target gene expression was increased during chondrogenesis, and its expression was detected in developing cartilage. Our results suggest specific that miRNA 542-3t may regulate transcription of mRNAs such as 6130401L20Rik during mammalian limb development.

Effect of Estrogen Deficiency on Gene Expression Pattern in the Bone Tissue of Postmenopausal Versus Premenopausal Healthy Women. B. Balla*¹, J. Kósa*¹, J. Kiss*², A. Borsy*³, J. Podani*⁴, I. Takács¹, Á. Lazáry¹, Z. Nagy¹, K. Bácsi*¹, G. Speer*¹, L. Orosz*³, P. Lakatos¹. ¹1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary, ²Department of Orthopedics, Semmelweis University, Budapest, Hungary, ³Institute of Genetics, Agricultural Biotechnology Center, Gödöllő, Hungary, ⁴Department of Plant Taxonomy and Ecology, Eötvös Loránd University, Budapest, Hungary.

Estrogen deficiency at the time of menopause results in marked increase in bone resorption and formation leading to rapid bone loss. The aim of our investigation was to determine genes characterized by significantly changed mRNA expression rates in postmenopausal vs. premenopausal healthy bone tissue and describe the interrelationship among these genes using multidimensional data analysis. Ten bone tissue samples from postmenopausal non-osteoporotic female patients (mean age: 53.50 \pm 4.12 years, T-score > -1 SD) and seven bone tissue samples from premenopausal healthy women (mean age: 52.14 \pm 2.34 years, T-score > -1 SD) were examined in our study. Messenger RNA was prepared from each sample and reverse transcribed to cDNA. The expression differences of selected 118 genes were analyzed by TaqMan Gene Expression Assay in Real-Time PCR system. Statistical methods were performed using Mann-Whitney U test, canonical variates analysis and principal components analysis (PCA). Mann-Whitney U test indicated significant differences in the expression of 29 genes between post- and premenopausal healthy individuals ($p \leq 0.05$). Twenty eight genes, including extracellular matrix molecules and digesting enzymes (COL2A1, COL3A1, COL5A1, COL5A2, COL9A1, COL12A1, COL15A1, MGP, BGLAP, FN1, MMP13, BMP1), TGF-beta/BMP pathway (BMP1A, TGF2, TGF3, TGFBR2, SMAD4), transcription factors (RUNX2, SP7, TCF7L2, SOX9), growth factors (PDGFA, FGFR1) and other candidate genes (TNFSF11, IL6, ALPL, IGSF4, TRIB2) were significantly upregulated in postmenopausal women compared to premenopausal ones. Only one gene (ENO1) showed downregulation in the bone tissue after menopause. Applying canonical variates analysis the groups of post- and premenopausal patients are separable by 12 genes coding extracellular matrix molecules which have the best discriminatory power. Based on the multiple mRNA expression profiles of 118 genes, post- and premenopausal states could be differentiated by enhanced postmenopausal gene expression rate using PCA. Significant differences observed in gene expression profiles of estrogen deficient human bone tissue provide further insight into the process of postmenopausal changes of bone metabolism. The menopausal states of bone tissue have been unambiguously defined by their complex gene transcription patterns.

Novel Transcription Factor-like Function of MMP-3/stromelysin-1 that Regulates Connective Tissue Growth Factor (CTGF/CN2) Gene Transcription. T. Eguchi¹, S. Kubota*¹, K. Kawata*¹, Y. Mukudai*¹, T. Yanagita*¹, T. Ohgawara*¹, J. Uehara*², S. Ibaragi*³, M. Takigawa¹. ¹Dept. of Biochemistry and Molecular Dentistry, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan, ²Dept. of Oral & Maxillofacial Rehabilitation, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan, ³Dept. of Oral & Maxillofacial Surgery, Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan.

Connective tissue growth factor (CTGF/CN2) is the second member of CCN protein family and a multifunctional growth factor involved in the development and remodeling of matrix-rich tissues such as cartilage and bone. For example, we have shown that CCN2 promotes endochondral ossification by acting on chondrocytes, osteoblasts and endothelial cells. Its expression is extremely high in chondrocytes especially in hypertrophic chondrocytes. Enhanced production of CCN2 in HCS-2/8 human-derived chondrocytic cells is found to be mediated by the TRENDIC (transcription enhancer dominant in chondrocytes). Matrix metalloproteinases (MMPs) are zinc-dependent endopeptidase also involved in the development and remodeling of cartilage and bone. Here, we report that human MMP3/stromelysin-1 in the nucleus binds to the TRENDIC, and displays a transcription factor-like function. The MMP3 was detected in the nuclear extract of the HCS-2/8 cells in vitro, and also in the nucleus of the normal and osteoarthritic chondrocytes in vivo. Externally added recombinant human MMP3 was internalized into the HCS-2/8 cells and translocated to the nucleus. Also, six putative nuclear localization signals were found in MMP3 and were capable of trans-locating the fused green fluorescent protein to the nucleus. MMP3 interacted with enhancer sequences including TRENDIC in the CCN2 promoter. MMP3 overexpression resulted in activating the CCN2 promoter; whereas, a TRENDIC-mutant of the promoter lost the response. Knocking-down of MMP3 also suppressed CCN2 expression. Notably, an MMP3 inhibitor specifically suppressed the CCN2 promoter activity in the cells. Furthermore, we identified several nuclear MMP3 associated proteins (NuMAPs) in the cells. These finding indicates that MMP3 has dual functions. One is as an extracellular matrix-degrading activity. The other is novel transcription factor-like function for CCN2/CTGF, which results in production of ECM. This extra- and intra-cellular, dual function of MMP3 may play an important role in development and matrix remodeling of cartilage and bone.

Epigenetic Status Monitored by DNA Methylation in the 5'-flanking Regions of CpG-rich Promoters Are Stable During Chondrogenesis in Pellet Cultures of Pluripotent Human Mesenchymal Progenitor Cells. Y. Ezura¹, I. Sekiya*², T. Muneta*³, M. Noda¹. ¹Department of Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan, ²Section of Cartilage Regeneration, Graduate School, Tokyo Medical and Dental University, Tokyo, Japan, ³Section of Orthopedic Surgery, Graduate School, Tokyo Medical and Dental University, Tokyo, Japan.

Developmental skeletogenesis requires multistep cellular events, including progenitor cell recruitment, proliferation, differentiation and multiple interactions of different types of cells. The entire actions of the processes are believed to be programmed in the genomic sequence of the cells; however investigations indicating the additional involvement of "epigenetic" regulation also exist. Here, to investigate the possible involvement of "epigenetic" controls of gene expression during skeletogenesis, we analyzed DNA methylation of CpG-rich promoters for several genes, using genomic DNA samples obtained from the experimental chondrogenesis assay of mesenchymal progenitor cells derived from human synovial tissues. Chondrogenic pellet-cultures were performed according to a standard protocol using rhBMP2 and TGF beta in the medium, and genomic DNA was isolated before and after 3 weeks of pellet-culture. This resulted in highly differentiated chondrocytes producing large amount of cartilage matrix. Candidate genes for the epigenetic control were selected by analysis of expression profiling data accomplished by Affymetrix DNA microarray. By searching dramatically upregulated or downregulated genes during the chondrogenesis, 40 genes were chosen. Among them, genes having extreme CpG-rich promoter were examined at first, for the extent of DNA methylation using bisulfite DNA sequencing method. Consistent with previous studies, most of the CpG-rich promoters were hypomethylated in the progenitor cells before pellet-culture, even for the genes completely silenced before differentiation. We observed stable, similar level of methylation after 3 weeks of pellet-culture in most case. In contrast, we detected highly methylated CpG sites in the promoter region of moderate CpG content, like matrilin-4 gene promoter that is transcriptionally repressed before differentiation; however, the methylation levels were similar even after the induction of chondrogenesis despite apparently detectable levels of the expression. We concluded regarding the genes examined in this study that epigenetic status such as DNA methylation would stably exist during chondrogenic differentiation at least in the context of pellet cultures of the human mesenchymal progenitor cells.

Bone Remodeling after Achievement of Osseointegration by Titanium Implantation in Rat Maxillae. M. Haga^{*1}, N. Fujii^{*2}, K. Nozawa-Inoue^{*3}, K. Uoshima^{*2}, S. Nomura^{*1}, T. Maeda^{*3}. ¹Div. of Oral Health in Aging and Fixed Prosthodont., Niigata Univ. Grad. Sch. of Med. & Dent. Sci., Niigata, Japan, ²General Dentistry and Clinical Education Unit, Niigata Univ., Niigata, Japan, ³Div. of Oral Anat., Niigata Univ. Grad. Sch. of Med. & Dent. Sci., Niigata, Japan.

Osseointegration is regarded as the most appropriate bone-implant interface as it affords a favorable prognosis over an extended period. Previous reports have indicated the existence of pre-existing bone with empty osteocytic lacunae even after achievement of osseointegration. However, little information is available regarding the fate of this injured bone. It is also unclear whether bone remodeling takes place around the implant. The present study was therefore undertaken to examine the response of the surrounding bone around a titanium implant on an animal model using rat maxillae.

Following extraction of the upper first molars of male Wistar rats (4-week-old; n=80), pure titanium implants were installed in the prepared bone cavities by drilling at 1 month after tooth extraction. Under deep anesthesia, the animals were sacrificed at 1 to 12 months after implantation. Decalcified paraffin sections were processed for double staining with alkaline phosphatase (ALP) and tartrate-resistant acid phosphatase (TRAP). For histologic observations, some sections were stained with hematoxylin and eosin (H-E), or Azan. An additional 14 rats were injected with calcein for dynamic labeling of bone formation at 5 and 20 days before sacrifice. Undecalcified sections were prepared in a cryostat with a tungsten knife.

The present animal model achieved osseointegration between the implants and alveolar bone by 1 month post-implantation, but the injured bone with empty osteocytic lacunae remained in the pre-existing bone. Surface analyses showed that the pre-existing bone with empty osteocytic lacunae decreased gradually to disappear completely at 3 months after implantation. Many ALP-positive osteoblasts and TRAP-reactive osteoclasts localized on the surface of the bone along the implant at 1 month post-implantation and remained until 6 months after implantation. The newly-formed bone around the implants thickened and exhibited the same histological features as compact bone at 3 months. Two calcein-labeled lines were recognizable in the newly-formed bone around implants throughout this observation period.

These morphological data suggest the involvement of bone remodeling in replacing newly-formed immature woven bone and injured pre-existing bone with compact bone around titanium implants.

The Increase of the Mechanical Strength of Novel Unidirectional Porous Hydroxyapatite Ceramics In Vivo. M. Iwasashi¹, M. Sakane¹, Y. Shirai^{*2}, Y. Suetsugu^{*2}, T. Tateishi^{*2}, N. Ochiai^{*1}. ¹Graduate School of Comprehensive Human Sciences, University of Tsukuba, Tsukuba, Japan, ²Biomaterials Center, National Institute for Materials Science, Tsukuba, Japan.

Background While the porous Hydroxyapatite (HAp) ceramic has interconnection between the pores, a few osteogenesis occur at the deep area of the HAp material. We have recently developed a unidirectional pores HAp ceramic, which have continuous interconnection through the material.

Purposes The purposes of this study were to observe osteoconductivity of the novel HAp ceramic, and to evaluate the increase of mechanical strength after implantation in the femur of rabbit.

Materials and Methods: Materials for this study were provided by KURARAY CO., LTD. (Kurashiki, Japan).

Animal experiments were carried out in our university and governmental guidelines for proper conduct of animal experiment. Japanese white rabbits were used in this study. Under intravenous injection of thiopental, the knee joint was exposed. Intramedullary, a tunnel was made with drilling of the femur, the cylindrical unidirectional porous HAp (6mm in diameter, 7mm in height) were implanted in the femur. The direction of the interconnected pore is parallel to the axis of the femur. Two, six and twelve weeks after implantation, the femurs were harvested and the 4×4×5mm HAp samples were cut down. The compression strength was measured using a uniaxial mechanical testing apparatus with speed of 0.5mm/s. The same size samples before implantation were measured as a control. For statistical analysis, Tukey-Kramer test were used and P<0.05 was considered statistically significant. Some of the femurs were used for histological evaluation.

Results: The compression strength of samples before implantation was 13.8±1.4MPa, and that of samples at two, six, and twelve weeks was 10.9±3.9, 21.6±9.2, 47.0±12.7MPa. The compression strength at six and twelve weeks increased significantly. Histologically, new bone and osteogenic cells were observed inside of the HAp after two weeks.

Discussion: The microstructure of unidirectional porous HAp is oval pores 100 ~ 300µm in diameter penetrate through the material. The structure is advantageous not only about compression strength but also migration for osteogenic and angiogenic cells inside of the HAp, and contributed to excellent new bone formation at two weeks. The shape of new bone is columns because osteogenesis occurred along the inner wall of the HAp. Beside, early angiogenesis promote bone remodeling. Hence, the mechanical strength at twelve weeks gained 3.4 times as much as before implantation.

Conclusion: Unidirectional porous HAp has excellent osteoconductivity and increase of mechanical strength with time in vivo.

Identification of Calcyclin Expression in Rat Amelogenesis Using Acp Ddrt-pcr Method. Y. Kawano^{*}, S. Kinoshita-kawano^{*}, K. Nozawa-inoue^{*}, A. Suzuki^{*}, T. Maeda^{*}. Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

Ameloblasts are involved in enamel secretion and mineralization. Unmineralized enamel is secreted by secretory ameloblasts and subsequently mineralized by maturation stage ameloblasts. The transformation from secretory into maturation stage ameloblasts during amelogenesis is presumed to be accompanied by changes in gene expression in each cell type. The goal of this study was to identify the genes expressed specifically in ameloblasts that might be involved in ameloblast differentiation, enamel formation or maturation.

Annealing controlled primers (ACP) differential display PCR screening was performed to compare RNA isolated from secretory ameloblasts with those from maturation stage ameloblasts. Using 120 different combinations of primers, we identified and cloned 36 distinct differential display fragments with sizes ranging from 250 to 1000 bp. Seventeen of 39 differentially expressed genes (DEGs) were sequenced and identified. Seven DEGs have significant sequence similarities to already published genes whose functions in the rat incisor are known. The rest is homologous to genes expressed in other tissues, but is not known to be expressed in the incisor. One of the DEGs showed 100% homology to calcyclin (S100A6).

Calcyclin belongs to a family of S100A calcium binding proteins that bind calcium molecules through conserved EF-hand domains. Recently a wide variety of cellular functions has been attributed to the products of this gene family. In particular, calcyclin has been implicated in intracellular calcium homeostasis and signaling, ion transport, and cell proliferation. Quantitative RT-PCR confirmed that calcyclin has specific expression patterns in differentiating ameloblasts during odontogenesis. Calcyclin mRNA was less expressed in secretory stage, but highly in both early and late maturation stages in rat incisor. Immunohistochemistry also showed that calcyclin proteins are expressed in maturation stage of ameloblasts, but not in papillary layer cells. Furthermore, odontoblasts and cementoblasts showed immunopositive reaction for calcyclin, while osteoblasts on alveolar bone were devoid of immunoreaction.

Using ACP, we found 39 DEGs in secretory and maturation stage ameloblasts. Calcyclin was identified to be 100% homologous to one of the DEGs. We confirmed the existence of calcyclin in the differentiating ameloblasts using qRT-PCR and demonstrated its expression in ameloblasts, odontoblasts and cementoblasts by immunohistochemistry. Our findings suggest a role for calcyclin in amelogenesis, especially in enamel maturation, dentinogenesis, and cementogenesis.

The Effects of Heme Oxygenase-1 on Collagen Induced Arthritis Model. H. Kim^{*1}, M. Lee^{*2}, J. Oh^{*3}, J. Kim^{*4}, K. Yun^{*1}. ¹Pathology, Wonkwang University Hospital, Iksan Cholla-bukdo, Republic of Korea, ²Rheumatology, Wonkwang University Hospital, Iksan Cholla-bukdo, Republic of Korea, ³Anatomy, Wonkwang University School of Medicine, Iksan Cholla-bukdo, Republic of Korea, ⁴Orthopaedic Surgery, Wonkwang University Hospital, Iksan Cholla-bukdo, Republic of Korea.

Introduction: Heme oxygenase-1 (HO-1), an inducible heme-degrading enzyme, is expressed by macrophages and endothelial cells in response to various stress. It is also an important mediator of inflammation.

Purpose: To determine the effects of HO-1 modulation on the collagen-induced arthritis (CIA) model and observe the VEGF expression in human synovial fibroblast

Method: DBA/1J mice were treated with an inhibitor of HO-1, tin protoporphyrin IX (SnPP), or with an inducer of HO-1, cobalt protoporphyrin IX (CoPP), from day 1 to day 35 after CIA induction. The clinical evolution of disease was visually monitored. At the end of the experiment, joints were examined for histopathologic changes. VEGF expression in paws were measured by immunohistochemical stain. mRNA expression of VEGF stimulated with TNF- α , CoPP and SnPP, accessed in human synovial fibroblast by RT-PCR

Results: Administration of cobalt protoporphyrin IX significantly induced the inflammatory response, with increased arthritis index and expression of VEGF in paw of arthritis models. Treatment with SnPP significantly reduced the severity of CIA, with inhibition of joint inflammation and cartilage destruction. The expression of VEGF were also significantly reduced by SnPP treatment in paw. CoPPIX as inducer of HO-1, increased VEGF expression dose dependently in synovial fibroblast. In contrast, inhibition of HO-1 activity by SnPPIX reversed CoPPIX-induced VEGF production.

Conclusion: The effects of HO-1 induction in rheumatoid arthritis result in aggravation of arthritis via up-regulation of VEGF. We concluded that inhibition of HO-1 could be a therapeutic target of rheumatoid arthritis

Loss of Annexin VI Affects Endochondral Bone Formation. H. Kim¹, S. E. Moss², T. Kirsch¹. ¹Orthopaedics, University of Maryland School of Medicine, Baltimore, MD, USA, ²Division of Cell Biology, University College London, London, United Kingdom.

Annexin VI is a Ca^{2+} and membrane-binding protein, which is involved in a various cell functions. We have shown that annexin VI is expressed by hypertrophic growth plate chondrocytes and osteoblasts together with other annexins, including annexin II and V. These annexins control Ca^{2+} homeostasis in growth plate chondrocytes and matrix vesicles thereby regulating terminal differentiation and mineralization events (Kirsch 2005 Front Biosci 10:576-581). To determine the exact function of annexin VI in skeletal tissues, we analyzed long bones of annexin VI^{-/-} mice histomorphometrically and analyzed the function of matrix vesicles isolated from long bones of 5 months old mice. Matrix vesicles are released by mineralization-competent growth plate chondrocytes and osteoblasts and these particles initiate the mineralization process. We have shown that annexins II, V and VI have the critical role of mediating influx of Ca^{2+} into the vesicles enabling the formation of the first mineral phase inside the vesicles. Newborn annexin VI^{-/-} mice were ~20% shorter and lighter than wild type littermates. Histomorphometric analysis of the femoral and tibial growth plates of these animals revealed that the lengths of the growth plates (proliferative and hypertrophic zones) were reduced by ~40% in the annexin VI^{-/-} mice compared to the lengths of the growth plates of wild type littermates. The length of the proliferative zone of the annexin VI^{-/-} mice is similar to the length of the proliferative zone of the wild type littermates. However, the length of the hypertrophic zone is markedly reduced in the growth plates of the annexin VI^{-/-} mice. At 4 weeks of age the length of the growth plate in the annexin VI^{-/-} mice was enlarged compared to the length of the growth plates of the wild type littermates, suggesting that endochondral bone formation is delayed in annexin VI^{-/-} mice. At 10 weeks of age the annexin VI^{-/-} mice showed reduced bone volume compared to the bone volume of the wild type littermates. Matrix vesicles isolated from long bones of annexin VI^{-/-} mice contained more annexin II and annexin V than the amount of these annexins in matrix vesicles isolated from wild type littermates. However, vesicles isolated from annexin VI^{-/-} mice contained less Ca^{2+} and P_i than the amount of these mineral ions in vesicles isolated from wild type littermates. In addition, matrix vesicles isolated from annexin VI^{-/-} mice were not able to mineralize in vitro. These findings reveal that annexin VI plays an important regulatory role in terminal differentiation and mineralization events of growth plate chondrocytes and osteoblasts and a loss of annexin VI results in delayed endochondral bone formation and bone loss in older annexin VI^{-/-} mice.

PHD1 and PHD3 Are Expressed in Bone Cells but Are Not Essential for Bone Homeostasis. K. Laperre¹, N. Smets¹, R. Bouillon¹, P. Carmeliet², G. Carmeliet¹. ¹Laboratory of Experimental Medicine and Endocrinology, Katholieke Universiteit Leuven, Leuven, Belgium, ²Center for Transgene Technology and Gene Therapy, VIB, Katholieke Universiteit Leuven, Leuven, Belgium.

Hypoxia induces vascular endothelial growth factor (VEGF) expression, an essential factor for angiogenesis. Signalling occurs via stabilization of hypoxia inducible factor (HIF α) that binds to its response element in the VEGF promoter. During normoxia HIF α activity is inhibited by prolyl hydroxylase domain containing proteins (PHD1, PHD2 and PHD3) targeting HIF α for proteasome mediated degradation. Both the 3 VEGF isoforms and HIF α are essential for bone development by affecting angiogenesis and/or bone cell function. The role of PHDs in bone biology is however not yet elucidated.

In this study, we report that PHDs are expressed in primary murine osteoblast, osteoclast and chondrocyte cell cultures as analysed by quantitative PCR. Abundant mRNA levels were observed for PHD1, less expression was detected for PHD2 whereas PHD3 mRNA levels were very low. Exposure of these cultures to hypoxia for 24 hours resulted in a 3 to 4 fold induction of VEGF mRNA expression in all cell types ($p < 0.001$). In addition, PHD2 and mainly PHD3 mRNA levels were highly induced in the 3 cell types ($p < 0.0001$) whereas PHD1 mRNA expression was not affected by hypoxia.

The role of PHD1 and PHD3 in bone homeostasis was investigated by analyzing the bone phenotype of PHD1 and PHD3 knock out (KO) mice. PHD2 KO mice are early embryonic lethal precluding investigation. PHD1 and PHD3 KO mice are viable and show a normal growth curve. Bone modeling and remodeling were investigated in respectively 4 and 14 week old mice. Femur length was not different between PHD1 and PHD3 KO and their respective wild type (WT) littermates. Trabecular parameters of isolated femurs were analysed by peripheral quantitative computed tomography (pQCT). Trabecular density and content were not different between the genotypes. Histomorphometry on Von Kossa stained sections of PHD3 KO and WT mice confirmed these data. In addition, serum osteocalcin levels also revealed no difference between PHD1 and PHD3 KO mice and their respective WT littermates. A possible explanation for the normal bone phenotype is compensation by the other PHDs. Osteoclasts and chondrocytes lacking PHD1 showed an increased expression of PHD2 and PHD3. This compensatory increase was also observed in PHD3 deficient osteoclasts.

In conclusion, the 3 PHDs are expressed in the major bone cell types but lack of PHD1 or PHD3 has no major impact on bone modeling and remodelling.

The New Surface Modified Demineralized Bone Matrix by rhBMP-2-collagen Hybrid Coating. K. Lee¹, Y. Shim², J. Jang², H. Kim³, Y. Choi², K. Lee², B. Ko², M. Ryu², I. Kim², S. Moon³, H. Lee³. ¹Medical school, Yonsei University, Seoul, Republic of Korea, ²Korea Bone Bank Co., Ltd., Seoul, Republic of Korea, ³Medical School, Yonsei University, Seoul, Republic of Korea.

The use of bone grafts is increasing considerably in orthopaedics and dental practice. Also demineralized bone matrix (DBM) is inherently osteoinductive and it has potential appeal as a bone graft substitute. DBM directly induces new bone formation when implanted subcutaneously or intramuscularly. Allogeneic DBM has intrinsic shortcomings related to procuring, processing and characterizing bone from a human donor pool. Xenogeneic bone represents an unlimited supply of available material if it can be processed to render it safe for transplantation to the human host. Processed xenogeneic DBM still appear a promising alternative to autografts and allografts although several such graft materials were found to be unsatisfactory because of poor histocompatibility which apparently stemmed from the difficulties in manufacturing such a complex material. However, there is lack of consensus about whether DBM from one species can facilitate osteoinduction in a different species, even among lower-order animals. To improve the property of xenogeneic DBM, we modified the surface of DBM by rhBMP-2-collagen hybrid coating. In vitro test, surface modified xenogeneic DBM and human mesenchymal stem cell were cocultured by alginate bead culture. And In vivo test, DBM was implanted in fibular fractured Newzealand white rabbit

Validation of a Simple Isotope Method for Estimating True Calcium Fractional Absorption in Adolescent Girls. W. Lee¹, G. P. McCabe², M. E. Wastney³, B. R. Martin⁴, C. M. Weaver⁴. ¹Agricultural and Biological Engineering, Purdue University, West Lafayette, IN, USA, ²Statistics, Purdue University, West Lafayette, IN, USA, ³Metabolic Modeling Services, Blenheim, New Zealand, ⁴Foods and Nutrition, Purdue University, West Lafayette, IN, USA.

A 5-hr serum oral isotope method has been validated against a classic double isotope or ratio method for assessing calcium absorption in adults (Heaney and Recker Ann Intern Med 103:516, 1985). A simple approach for calculating absorption has not been developed in children. Our goal was to develop an equation to predict absorption using a single serum measurement of specific activity (SA, expressed as the fraction of dose of single oral tracer per gram calcium) and physiological factors and to also identify the best time points to measure SA. Subjects were 45 adolescent girls aged from 10 to 15 yr participating in metabolic studies. Tracer data following oral (^{44}Ca) and intravenous (^{45}Ca) administration of calcium stable isotopes and SA in serum and urine from various time points up to 4 d were used. Absorption was calculated as the ratio of oral to IV tracer in 24-hr urine. In addition to SA, physiological factors (postmenarcheal age and height) were used as predictors in multiple regression analysis. The 4-hr serum SA showed the highest R^2 value with the 24-hr urine ratio. Measured serum SA values between 2.5 and 12 hr can be used with the same equation to predict the 24-hr urine ratio but with lower precision. A similar approach was used to develop equations for urine sampling following oral stable calcium isotope administration. We conclude that the developed equations can be used with a single blood draw or urine collection to evaluate calcium absorption in adolescents.

Does Increased Local Bone Resorption Result in Increased Cartilage Degradation? D. J. Leeming¹, I. Byrjalsen¹, M. G. Sørensen¹, M. Koizumi², P. Qvist¹, M. Fregerlev³, N. Lynnerup³, C. Christiansen¹, M. A. Karsdal¹. ¹Nordic Bioscience, Herlev, Denmark, ²Cancer Institute Hospital, Tokyo, Japan, ³Institute of Forensic Science, University of Copenhagen, Copenhagen, Denmark.

An association between bone and cartilage degradation in osteoporotic and arthritic patients has previously been reported. Breast and prostate cancer patients often develop lesions of locally high bone turnover, when the primary tumor metastasizes to the bone. The objective of the present study was to determine whether increased bone turnover is associated with an increase in cartilage degradation in an aggressive bone disease such as metastatic cancer.

The study population included 132 cancer patients; 90 breast cancer (45 with bone metastasis (BM)) and 42 prostate cancer (17 with BM). Presence of BM was determined by Tc99 scintigraphy and the skeletal involvement was graded according to the Soloway score 1-4. Urine samples were obtained and bone resorption assessed by CrossLaps ELISA (CTX-I), and cartilage degradation by CartiLaps ELISA (CTX-II). Human cortical bones were collected during autopsies and bone slices were prepared. Human osteoclasts were made by isolated of CD14+ monocytes from human peripheral blood, followed by culturing in the presence of 25ng/ml of M-CSF and RANKL in 2% serum for 28 days. Osteoclastic resorption was investigated by CTXI and CTXII in the conditioned medium. Additionally, bone slices were decalcified using EDTA and treated by cathepsin K in-vitro and markers assessed.

Patients with bone metastases revealed significant increased levels of CTXI at all Soloway scores (p<0.001). In contrast CTXII was not elevated until at Soloway score 3 (p<0.01). The ratio CTXI/CTXII decreased at all Soloway scores (score 1-2: p<0.01; score 3-4: p<0.001). The percentage increase in CTXI was 70 and 903% at score 1 and 4, respectively. CTXII was elevated by 99% at score 3; by 128% at score 4. Human osteoclastic bone resorption on human bone resulted in release of CTXI fragments but not CTXII fragments. In alignment, cathepsin K treatment of human bone released CTXI, but not CTXII fragments. Treatment of cartilage did not result in CTXI or CTXII release. Human osteoclasts and cathepsin K were able to release CTXII fragments from human bone. Cartilage degradation was not elevated at high bone resorption levels until the late stage in the pathology of the cancer invasion involving more than 6 skeletal lesions (score 3). This dissociation of localised bone resorption and cartilage degradation in early stages of cancer patients with bone metastases suggests that other metabolic pathways are responsible for the association of bone resorption and cartilage degradation as is seen in osteoporosis and osteoarthritis

Biosynthesis of Menaquinone-4 (Vitamin K2) from Phylloquinone (Vitamin K1) and Menadione (Vitamin K3) in Bone. K. Nakagawa*, Y. Shimomura*, Y. Suhara*, T. Okano. Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan.

Vitamin K is essential for the modification of glutamic acid residues of specific substrate proteins into γ -carboxyglutamic acid (Gla) residues. In bone, osteocalcin, which has three Gla residues, is thought to be involved in the regulation of mineralization. Vitamin K compounds share a common chemical structure consisting of a naphthoquinone nucleus capable of redox cycling. Vitamin K₁ (phylloquinone; PK) has a long phytyl side-chain, whereas vitamin K₂ has an unsaturated side-chain containing 1-13 isoprene unit. Menaquinone-4 (MK-4), vitamin K₂, possesses a significant pharmacological activity on bone formation and is used as a medication for osteoporosis in Japan. The daily dietary intake of vitamin K is mainly (>90%) in the form of PK. MK-4 may be present in low levels in food products. However, MK-4 is found in most tissues. In general, tissue concentrations of MK-4 exceed those of PK except for liver, where relatively low MK-4 levels are found. Therefore, it has been recognized that PK is converted into MK-4 and accumulates in extrahepatic tissues including bone. Menadione (K₃), commonly added to animal diets, is converted into MK-4 when administered to animals. However, the conclusive scientific evidence for the conversion of PK into MK-4 is exiguous. To elucidate the conversion of PK and K₃ into MK-4, we synthesized deuterium-labeled PK, MK-4 and K₃. PK or K₃ with a deuterium-labeled 2-methyl-1,4-naphthoquinone ring was given orally to mice and bone were collected for LC-APCI-MS/MS analyses. Deuterium labeled-PK (PK-d₇) and deuterium labeled-K₃ (K₃-d₈) administration resulted in the accumulation of MK-4-d₇ in tissues, particularly in liver, brain and bone. This is the first direct evidence using deuterium labeled compounds and LC-APCI-MS/MS analysis that PK and K₃ are converted into MK-4 in bone. Moreover, administration of the anticoagulant warfarin, an inhibitor of vitamin K reductase in vitamin K cycle, significantly blocked the conversion of PK-d₇ and K₃-d₈ to MK-4-d₇ in bone. Interestingly, MK-4 epoxide, an oxidized form of hydroxymenaquinone-4 (a reduced form of MK-4) generated by γ -glutamyl carboxylase during the turn-over of the vitamin K cycle, was found at higher concentrations than PK epoxide. This result suggests that in bone, MK-4 is rapidly and remarkably metabolized to the epoxide form via a hydroquinone form. Our results indicate that MK-4 is the true physiologically active form for bone formation and that it is derived from dietary vitamin K.

Plasminogen Activator Inhibitor-1 Increases Femoral Mineralization Independent of Estrogen Status Through Modulation of Fibronectin Matrix. S. M. Nordstrom, J. W. Covington*, D. E. Vaughan*. Pharmacology, Vanderbilt University, Nashville, TN, USA.

Plasminogen activator inhibitor-1 (PAI-1) is a recognized regulator of matrix remodeling in cardiovascular, renal, and tumor biology, while its role in bone matrix is less well characterized. Previously, we reported a gender-specific and age-dependent increase in femoral strength and mineralization in mice that over-express human PAI-1 (PAI-1.stab). In this study, we investigated the female-specificity of this phenotype and the mechanism by which PAI-1 influences bone remodeling. PAI-1.stab and WT females were ovariectomized (OVX) or SHAM-operated (SHAM) at 16 weeks (n=11-12). Total skeletal (tBMD) and vertebral bone mineral density (vBMD) were measured by DEXA at baseline and at 2-week intervals for 12 weeks. Serum osteocalcin and TRACP5b were determined by EIA. Femora were analyzed for trabecular bone histomorphometry. Primary adherent bone marrow cells were evaluated for fibronectin (Fn) matrix deposition by immunocytochemistry while Fn transcription was determined by real-time RTPCR in primary calvarial osteoblasts. PAI-1.stab mice had increased tBMD (p=0.0014) and a differential pattern of remodeling (p=0.0166) from 16-28 weeks of age under basal conditions (SHAM). This phenotype was maintained in the setting of estrogen-deficiency. PAI-1.stab mice exhibited a trend towards increased vBMD with a significant difference in the remodeling pattern (p=0.0022). Genotype did not influence trabecular architecture of SHAM or OVX femora. However, PAI-1.stab mice had significantly reduced osteoid surface and a 1.7-fold greater mineral apposition rate under both SHAM and OVX conditions (p<0.001). Serum osteocalcin was comparable between genotypes in SHAM and OVX, while TRACP5b levels were decreased in PAI-1.stab OVX mice (p<0.001). PAI-1.stab primary adherent bone marrow cells exhibited increased Fn matrix formation from 2-14 days in culture (p<0.0001) and a greater rate of Fn deposition (p=0.0014) compared to WT cells. Fn mRNA was increased 2-fold in PAI-1.stab osteoblasts compared to WT osteoblasts. Taken together, these studies indicate that PAI-1 over-expression results in increased bone mineralization without alteration of bone architecture. This effect is independent of estrogen and occurs in conditions of basal bone remodeling as well as in accelerated remodeling following OVX. Increased mineralization results, in part, from alterations in the Fn component of bone matrix leading to aberrant osteoblast/osteoclast mineralizing activity. This newly recognized role of PAI-1 in matrix synthesis and mineralization suggests novel targets for the prevention and treatment of bone disorders in humans.

The Overexpression of Type III Na-dependent Phosphate Transporter Pit-1 in Rats Develops the Progressive Nephrotic Syndrome. S. Sekiguchi, S. Asano*, K. Nishiwaki-Yasuda*, A. Yokoyama*, K. Inagaki*, H. Kakizawa*, N. Hayakawa*, N. Oda*, A. Suzuki, M. Itoh*. Department of Internal Medicine, Fujita Health University, Aichi, Japan.

Phosphate uptake at the cellular membrane is essential to maintain the cell activity because phosphate has to be supplied for ATP synthesis. Generally, the extracellular signal to stimulate cellular proliferation also induces the enhancement of phosphate uptake, that is, Pi transport activity. On the contrary, accumulating evidence suggests that phosphate overload from the extracellular milieu would be stressful for the cells, because phosphate uptake itself might induce the formation of apoptosome, resulting in the apoptosis of the cells. In the present study, we investigate the effect of overexpression of Pit-1, a type III Pi transporter, on the kidney which is a major phosphate-handling organ in Pit-1 transgenic rats (Tg). Survival was much shorter in Tg rats with death already occurring between the 7 and 9 months of age. The decrease of serum albumin started at the age of 2 months old, and progressively deteriorated. Tg rats developed massive proteinuria at 3 months of age, associated with hyperlipidemia, suggesting the progress of nephrotic syndrome in Tg rats. On the contrary, serum creatinine levels in Tg were not different from those in Wt. At their birth, the difference of electromicroscopic (EM) finding of the glomerulus between Tg and wild type rats (WT) was not apparent, but at 8 weeks after birth, the glomerulus of Tg has started to shrink compared to that of WT. Their glomerular abnormality assessed by EM images were also observed in 8 weeks old Tg rats, that is, glomerulus exhibits diffuse loss of foot processes of visceral epithelial cells (podocytes), thickened basement membrane and the massive deposition of abnormal protein in the glomerulus. These findings suggest that early onset of the development of the damage of glomerulus due to overexpression of Pit-1 phosphate transporter.

In conclusion, Pit-1 overexpression in rats induces the phosphate-dependent cellular stress, which results in the damage of the filtration at glomerulus without affecting renal function itself. This might be a suitable animal model to analyze the pathogenesis of nephrotic syndrome.

Cementoblast Cultured on Fibrin Induces Fibrinolysis and Its Apoptosis. H. Jung*, Y. Choi*, J. Baek, H. Ryoo, K. Woo. Dept. of Cell and Developmental Biology, Seoul National University, School of Dentistry, Seoul, Republic of Korea.

Cementum is a mineralized tissue covering roots of teeth that provide for the attachment of periodontal ligament to roots and surrounding alveolar bone. During periodontal regeneration after disease or surgery, cementum is thought to play a critical

role in the reparative process. However, it has remained a poorly defined tissue at the cellular and molecular level. We intended to examine effect of fibrin, the natural provisional matrix during wound healing, on cementoblast differentiation. A cementoblast cell line OCCM30 was grown on fibrin matrix and the phenotypes were examined. Unexpectedly, it was observed that the fibrin matrix, on which cementoblasts were cultured, was degraded and the cementoblasts on fibrin underwent apoptosis. In contrast, fibrin matrix promoted expressions of osteoblastic phenotypes in MC4 cells without any observable degradation. The degradation of fibrin was quantified through measuring fluorescence-labeled fibrin released to culture medium. The apoptosis was confirmed by TUNEL staining and activation of caspase 3. Next, we surveyed expression of enzymes responsible for fibrin degradation. Tissue-type plasminogen activator was expressed in cementoblasts grown on fibrin. Aminocaproic acid, an anti-fibrinolytic agent, reduced the fibrin degradation and apoptosis of cementoblast in a dose-dependent manner. Taken together, these results imply that fibrin matrix in periodontal wounds may impair regeneration of cementum.

Analysis of In Vivo Responses to Hydrogen Peroxide Purified PHBV Biomaterial Implanted in a Murine Tibial Defect. A. C. K. Wu^{*1}, S. Toulson^{*2}, A. Pettit^{*3}, L. Grøndahl^{*4}, E. J. Mackie^{*2}, A. I. Cassady^{*3}. ¹School of Biomedical Sciences, University of Queensland, Brisbane, Australia, ²Faculty of Veterinary Science, University of Melbourne, Melbourne, Australia, ³Institute for Molecular Bioscience, University of Queensland, Brisbane, Australia, ⁴School of Molecular and Microbial Sciences, University of Queensland, Brisbane, Australia.

The utilization of biomaterials for the repair of critical bone defects has become an emerging field due to the limitations of current therapeutic options. Optimal bone biomaterial should be able to provide structural support for bone regeneration and elicit minimal inflammatory response and toxic effects when implanted. Poly(3-hydroxybutyrate-co-3-hydroxyvalerate) (PHBV) is a naturally occurring biodegradable polymer that possess properties include slow rate of degradation in biological environments and can be tailored into desired building blocks due to its thermoplastic nature. We have previously reported that PHBV is contaminated with bacterially derived impurities and have developed protocol that can eliminate impurities from the material. The purified PHBV have a much improved biocompatibility as tested by the in vitro tissue culture assays. The aim of the current study was to further validate the biocompatibility of purified PHBV under in vivo conditions. Cylindrical blocks of the materials were implanted into a murine tibial cortical defect, consisting of a hole drilled through the diameter of the tibial diaphysis. The defect was either filled with a material plug or left unfilled as a control. The animals were sacrificed at one week and four weeks after surgery and the extracted tibiae were decalcified and paraffin embedded. Bone sections were examined using standard histological staining as well as immunohistochemical staining to determine the extent of the cellular response surrounding the implant. The PHBV implant induced a mild inflammatory response one week after injury, which persisted at four weeks. Granuloma type tissues were formed at the implant tissue interface at the periosteum encapsulating the implants four weeks post surgery. Our data indicate that solid PHBV biomaterials induce a mild tissue reaction with no evidence of osteointegration into the implant at the tissue interface during the study time frame.

Using Replication Competent Avian Virus System to Delivery Short Hairpin siRNA to Silence Gene Expression of Wdr5 in Chicken Limb Bud During Embryogenesis. S. Zhu, E. Gori. Endocrine Unit, Massachusetts General Hospital, Harvard Medical School, Boston, MA, USA.

Wdr5, a WD40 protein, is expressed in chondrocytes and osteoblasts in vitro and in vivo. Targeted expression of Wdr5 to osteoblasts, using the 2.3-kb fragment of the mouse type I collagen promoter results in accelerated osteoblast differentiation during skeletal development. A novel finding in these studies was expansion of the hypertrophic chondrocyte layer, suggesting that Wdr5 expression in the bone collar acts in a paracrine fashion to regulate chondrocyte differentiation. In addition, reduction of endogenous Wdr5 protein levels using plasmid-based small interfering RNAs (siRNAs) markedly inhibits osteoblast differentiation of MC3T3-E1 cells, suggesting that Wdr5 is required for osteoblast differentiation in vitro. To address whether Wdr5 is essential for osteoblast and chondrocyte differentiation in vivo during endochondral bone formation, a replication competent avian virus system (RCAN) is being generated to express short hairpin RNA (shRNA) under the control of the U6 RNA polymerase III (U6 pol III) promoter to specifically silence the expression of Wdr5 throughout the developing chicken limb. Four sites targeting the coding sequence of the chicken Wdr5 were chosen using the Ambion web site algorithm. Four RCAN vectors containing the selected Wdr5-shRNA sequences and one RCAN vector containing a scrambled-shRNA (RCAN-control) to use as a control have been generated. To verify the infection efficiency of RCANs, Green Fluorescence Protein (GFP), driven by cytomegalovirus (CMV) promoter, was cloned into the RCAN constructs upstream the U6 Pol III-shRNA cassette. To examine the role of Wdr5 on limb development in vivo, high-titer RCAN-shWdr5 and RCAN-control retroviral inoculates are being injected into the right wing of E3.5 chick embryos, a stage analogous to mouse embryo E12.5. The contralateral wings will serve as control. The effects of the differing degrees of Wdr5 silencing will be investigated histologically and by in situ hybridization analysis. These studies should offer a rapid and efficient method of analyzing the function of

Wdr5 during embryonic skeletal development. Furthermore, they will allow us to dissect the roles of other genes that interact with Wdr5.

Podocan Affects Cell Proliferation and In Vitro Mineralization Possibly by Inducing Cellular Senescence in MC3T3-E1 Cell. M. Katafuchi¹, Y. Mochida², P. Atsawasuwan^{*2}, M. Sricholpech^{*2}, M. Bahadoran^{*3}, M. Kaku^{*2}, T. Matsuura¹, M. Yamauchi². ¹Department of Oral Rehabilitation, Fukuoka Dental College, Fukuoka, Japan, ²Dental Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, ³School of Dentistry, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA.

Recently we have reported that podocan (Podn), a recently identified small leucine-rich proteoglycan/glycoprotein (SLRP), is expressed in preosteoblastic cell line, MC3T3-E1 cells (MC). In this study, to explore the potential function of Podn in bone biology, MC derived clones stably overexpressing Podn (S clone) were generated and partially characterized by comparing with two control groups, MC and a clone transfected with an empty vector (Ev clone). To establish the S clones, MC was transfected with pcDNA3 Podn HA-tag construct using FuGENE6 transfection reagent. After transfection, cells were cultured and exposed to 400 µg/ml of G418 antibiotics for 4 weeks to select stably transfected clones. The overexpression was confirmed by immunoprecipitation followed by western blot analysis with anti-HA antibody. Seven S clones were selected and analyzed for cell proliferation, in vitro mineralization and cellular senescence. The cell proliferation rate evaluated by cell counting at day 5 of culture was significantly decreased in all S clones in comparison to that of controls (25-58 % of the controls). When cells were cultured in α -MEM in the presence of 10 % FBS, 2 mM β -glycerophosphate and 50 µg/ml ascorbic acid for up to 4 weeks, the onset of mineralization evaluated by Alizarin red staining was significantly delayed in 60-70 % of S clones compared to controls. To investigate the potential cause of these phenotypes, cells (10,000 cells/mL) were cultured for 24 hours and evaluated for cellular senescence by staining for senescence-associated- β -galactosidase (SA- β -gal) activity. In S clones, the number of stained cells was significantly increased when compared to controls (by ~6 fold). These results indicate that Podn may induce cellular senescence in MC resulting in decreased cell proliferation and delayed mineralization in vitro.

Abnormal Collagen Type 1 Production by Human Osteoarthritic Osteoblasts. D. Couchourel^{*}, I. Aubry^{*}, A. Delalandre^{*}, D. Lajeunesse. Rhumatology, Centre Hospitalier de l'Université de Montréal (CHUM), Montréal, PQ, Canada.

Osteoarthritis (OA) is characterized by articular cartilage loss, bone sclerosis and synovial inflammation. Bone sclerosis is due to an abundant osteoid matrix that does not mineralize normally. Here, we prepared primary normal and OA osteoblasts (Ob) from subchondral bone of tibial plateaus to study in vitro the mechanisms responsible for this abnormal sclerosis. The expression of collagen type 1 α 1 chain (COL1A1) and α 2 chains (COL1A2) was determined by real-time PCR in parallel with in vitro mineralization evaluated by alizarin red staining. The SaOS-2 cell model, which shows high rates of mineralization, and OA Ob were used to determine the impact of either COL1A1 or COL1A2 overexpression or siRNA inhibition on the mechanism of mineralization. Last, we determined if a putative factor released by OA Ob could inhibit mineralization using conditioned-media (CM) from OA Ob on SaOS-2 cells while SaOS-2 CM was used to determine if this could correct OA Ob mineralization. In vitro alizarin red staining was significantly reduced in OA Ob compared to normal under basal condition and following BMP-2 treatment indicating a reduced mineralization capacity. Mineralization was reduced in OA Ob due to an increase of COL1A1 expression compared to normal with no significant changes in COL1A2. The COL1A1 to COL1A2 ratio was 7.2 ± 0.2 in OA Ob whereas it was 2.5 ± 0.6 in normal Ob at day 30 post-confluence. The COL1A1 to COL1A2 ratio in SaOS-2 cells varied from 7.5 ± 1.5 at day 0 to 1.5 ± 0.2 at day 14 post-confluence whereas the mineralization progressively increased. Overexpressing COL1A1 in SaOS-2 cells reduced whereas COL1A1 siRNA transiently increased mineralization. In OA Ob, overexpressing COL1A2 increased mineralization by 26% whereas the COL1A1 to COL1A2 ratio decreased by 28.8%. Furthermore, siRNA inhibition of COL1A1 expression in OA Ob increased mineralization by 43.62%. Last, SaOS-2 CM increased the mineralization of OA Ob while OA Ob-CM reduced mineralization of SaOS-2 cells but without any significant changes in the COL1A1 to COL1A2 ratio in either cells. This study suggests that the abnormal mineralization of OA bone tissue observed in vivo may be linked, in part, with the abnormal expression of COL1A1 by OA Ob and their incapacity to down-regulate their COL1A1 to COL1A2 ratio. This assessment is illustrated by the fact that when this ratio is altered in primary OA Ob and in SaOS-2 cells mineralization is not optimal. In addition, this could also be linked with the expression of a putative soluble factor that alters mineralization without altering the COL1A1 to COL1A2 ratio.

An Active Fragment of Secreted Phosphoprotein-24 Enhances but Is Not Indispensable for BMP-Mediated Adult Human Bone Marrow Derived Mesenchymal Stem Cell Differentiation to Osteoblasts. A. Maiti¹, O. Korchynskyi¹, S. C. Ramage², A. P. Pacitti¹, M. J. Beckman². ¹Orthopaedic Surgery, Virginia Commonwealth University, Richmond, VA, USA, ²Biochemistry and Molecular Biology, Virginia Commonwealth University, Richmond, VA, USA.

Mesenchymal stem cells (MSCs) are multipotent cells that can proliferate and differentiate into multiple tissues. The recruitment and differentiation of MSCs into distinct tissues is a precondition for in situ tissue engineering. MSCs play a major role in osteogenesis and their osteogenic potential depends on several factors including BMP/Smad induced transcription and canonical Wnt/ β -catenin signaling. Glucocorticoid signaling is required for normal bone formation, and synthetic glucocorticoids such as dexamethasone (Dex) promote osteoblastic differentiation of MSCs. We examined the osteogenic regulation of secreted phosphoprotein-24 (Spp24), a 24 kDa bone matrix protein hypothesized to possess osteoinductive properties. Adult human bone marrow derived MSCs were isolated by plastic adherence. Both Dex and BMP-2/7 heterodimer accelerated MSC differentiation to osteoblasts (OB) in a 14 day period in the presence of ascorbic acid and β -glycerolphosphate. We used a polyclonal rabbit anti-bovine Spp24 antibody to detect human endogenous Spp24. Gene expression of OB lineage markers were measured by Real-Time RT-PCR and alkaline phosphatase and Alizarin Red staining were performed as measures of an OB-specific marker and OB matrix mineralization, respectively. Western Blot of differentiated MSCs revealed a predominant 18 kDa fragment absent in undifferentiated MSCs. The formation of the 18 kDa fragment of Spp24 in Dex-induced differentiation corresponded with increased gene expression of OB-specific markers (Runx2, Osterix, osteocalcin and collagen I) and alkaline phosphatase staining. Temporal regulation of this putative active form of endogenous human Spp24 was seen at days 7-10 of Dex-induced OB differentiation. To examine the effect of Spp24 on BMP-mediated osteoblastogenesis we replaced Dex with BMP-2/7 as the differentiation mediator and performed adenoviral transduction of Adv5CMV-LacZ control or recombinant Adv5CMV-Spp24 over 12 and 14 day time frames. Expression of full-length mouse Spp24 (mSpp24) enhanced of BMP-mediated matrix mineralization, but without BMP-2/7, Spp24 had only a minor effect at day 12. At day 14 mSpp24 expression induced significant osteoblastogenesis assessed by gene, protein markers and Alizarin Red staining. These results highlight a critical processing step during osteoblastogenesis that produces an activated 18 kDa fragment of Spp24 involved in the enhancement of bone matrix mineralization by its cooperation with BMP.

Cleavage Products of Amyloid Precursor Protein Regulate Osteoblast Function. J. McLeod¹, N. Curtis², M. Fagan², P. Genever¹. ¹Dept. of Biology, University of York, York, United Kingdom, ²Dept. of Engineering, University of Hull, Hull, United Kingdom.

γ -secretase is an intramembrane protease responsible for the cleavage of numerous molecules which regulate osteoblast activity, such as Notch and EphrinB2. Cleavage of its substrates results in release of a fragment into the extracellular space, and a C-terminal peptide into the cytoplasm. Amyloid precursor protein (APP) is also processed by γ -secretase, though its role in bone is unknown. Amyloid- β (A β) peptides are secreted into the extracellular space as a result of γ -secretase activity on APP, and in the brain can aggregate to form the plaques characteristic of Alzheimer's disease (AD). The amyloid intracellular domain (AICD) binds to the nuclear adaptor protein Fe65 in the cytoplasm, and translocates to the nucleus to form a transcriptionally active AFT complex with Tip60. In this study the expression, cleavage and potential function of APP were investigated during osteogenesis. By qRT-PCR and western blot analysis, expression of all γ -secretase subunits (PS1, PS2, APh-1 α , APh-1 β , Nct, PEN-2) was confirmed. A specific fluorimetric assay showed significant increase in enzyme activity during osteogenic differentiation of human bone marrow stromal cells (MSCs). Using RT-PCR we identified expression of a longer isoform of APP in osteoblasts compared to neuronal APP, which contained an additional Kunitz protease inhibitory domain that promotes aggregation of A β peptides. Western blot analysis confirmed expression and processing of APP throughout osteogenesis, and treatment of samples with γ -secretase inhibitors confirmed that this enzyme specifically cleaves APP within differentiating MSCs. Expression of Fe65 and Tip60 throughout in vitro osteogenesis was confirmed by RT-PCR and western blot analysis. Using confocal microscopy we showed that over-expression of both AICD and Fe65 in C3H10T $\frac{1}{2}$ stromal cells resulted in colocalisation within discrete domains of the nucleus. A specific chemiluminescent immunoassay demonstrated secretion of A β during osteogenesis. MSCs showed a significant increase in adhesion to extracellular matrices containing aged A β plaques compared to non-aged A β peptide controls and A β plaques were localized to the endosteal and periosteal surfaces in sections of adult rat ulna. By μ CT analysis (15 μ m resolution) of vertebrae from a 12 month old AD mouse model, Tg2576, which over-expresses a mutant APP resulting in increased γ -secretase cleavage, we showed a 20% decrease in bone volume compared to wild type controls (10.60mm³ vs. 8.47mm³; wild type vs. transgenic). These findings indicate that APP may function as a novel regulator of osteoblastic activity both in vitro and in vivo, with functions ranging from adhesion to regulation of gene transcription.

The Effect of IL-6 and sIL-6R on the Expression of Cartilage Matrix Proteins. A. Namba¹, Y. Aida², Y. Watanabe², H. Tanaka³, O. Shimizu¹, N. Suzuki⁴, M. Maeno³. ¹Departments of Oral and Maxillofacial Surgery, Nihon University School of Dentistry, Tokyo, Japan, ²Department of Fixed Prosthodontics, Nihon University School of Dentistry, Tokyo, Japan, ³Department of Oral Health Sciences, Nihon University School of Dentistry, Tokyo, Japan, ⁴Department of Biochemistry, Nihon University School of Dentistry, Tokyo, Japan.

Elevated concentrations of interleukin-6 (IL-6) and soluble IL-6 receptor (sIL-6R α) in the synovial fluid of the temporomandibular joint (TMJ) have been implicated in the joint cartilage destruction associated with TMJ disorders. Recently, we demonstrated that IL-1 β promotes the resolution system of cartilage matrix turnover through an increase in inflammatory cytokine production by chondrocytes and that it also may promote the autocrine action of IL-6 through an increase in IL-6R α expression in human chondrocytes (Life Sci 79, 764-771, 2006). In the present study, we examined the effect of IL-6 and sIL-6R α on cell growth and alkaline phosphatase (ALPase) activity. We also examined the expression of Sox-9, cartilage matrix proteins (including type II collagen, aggrecan core, and link protein), bone morphogenetic protein (BMP)-7, and BMP receptors (BMPR) in human chondrocytes. The cells were cultured with or without 50 ng/mL IL-6 and/or 30 ng/mL sIL-6R α for up to 28 days. The levels of mRNA expression for Sox-9, the cartilage matrix proteins, BMP-7, and BMPR were determined using real-time PCR; protein levels were determined using ELISA. The proteoglycans of the extracellular matrix were stained with Alcian blue. Cell proliferation increased slightly in the presence of both IL-6 and sIL-6R α after 7 days of culture. ALPase activity, a marker enzyme used to differentiate osteoblasts and chondrocytes, decreased markedly in the presence of both IL-6 and sIL-6R α after 10 days of culture. The expression of Sox-9, aggrecan core, and Alcian blue-positive proteoglycans in the extracellular matrix did not change in the presence or absence of IL-6 and sIL-6R α , whereas the expression of type II collagen, link protein, BMP-7, and BMPR increased in the presence of both IL-6 and sIL-6R α after 7 days of culture. These results suggest that IL-6 in the presence of sIL-6R α suppresses the differentiation of chondrocytes and induces the repair of arthrodial cartilage through the increased expression of cartilage matrix proteins, BMP-7, and BMPR.

Histological and Biochemical Characterization of Mandibular Bones in Senile Osteoporotic Mice. K. Tokutomi¹, T. Matsuura¹, Y. Daigo¹, M. Katafuchi¹, K. Toh¹, H. Sato¹, M. Yamauchi². ¹Oral Rehabilitation, Fukuoka Dental College, Fukuoka, Japan, ²Dental Research Center, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA.

The quantity and quality of jaw bone are an important determinant for the outcome of many aspects of dental treatment. However, relatively little is currently known about the age-related changes of jaw bone. In this study, the mandibular bones of SAMP6 mice, a senile osteoporosis mouse model, were partially characterized and compared to those of SAMR1 mice as control. A total of twelve 6 month-old male mice of each strain were used. Static bone morphometric analysis was performed using 6 mice from each strain to assess cortical thickness index (CTI) at the mandibular ramus, bone area (B.Ar / T.Ar), trabecular width (Tb.Wi), trabecular number (Tb.N) and trabecular separation (Tb.Sp) at the interradicular septum between the distal root of the first molar and the mesial root of the second molar. Using other 6 mice from each strain, bilateral condylar necks and mandibular rami were dissected, pulverized, weighed, hydrolyzed with 6N HCl and subjected to amino acid analysis to determine collagen content (μ g/mg bone powder) and the extent of lysine hydroxylation (moles of hydroxylysine/mole of collagen). Statistical analysis was performed by Student t-test. Both CTI and B.Ar/T.Ar values of SAMP6 (20.1 \pm 1.3 % and 62.9 \pm 4.6 %) were significantly lower than those of SAMR1 (21.9 \pm 1.4 % and 77.0 \pm 4.8 %) (p=0.046 and p<0.001). The values of Tb.Wi (75.9 \pm 16.1 μ m) and Tb.N (8.62 \pm 1.79/mm) of SAMP6 showed a trend of decrease but not statistically significant comparing to those of SAMR1 (81.6 \pm 15.1 μ m and 9.72 \pm 1.28/mm, respectively) (p=0.542 and p=0.248). The Tb.Sp value of SAMP6 (45.6 \pm 14.2 μ m) was significantly higher than that of SAMR1 (23.5 \pm 2.8 μ m) (p=0.004). Biochemical analysis revealed that collagen content of SAMP6 (126.4 \pm 9.7 μ g/mg) was significantly lower than that of SAMR1 (149.6 \pm 10.3 μ g/mg) (p<0.001) and that the extent of lysine hydroxylation of SAMP6 (51.10 \pm 0.39) was higher than that of SAMR1 (48.54 \pm 1.42) (p=0.040). These results indicate that the mandible of SAMP6 exhibits not only reduced bone mass but also altered quantity and quality of collagen matrix. The latter may contribute to a mineralization defect seen in osteoporotic patients.

Enamel Phenotype and Sexual Dimorphism in Dentin of dspp-null Mouse Molars. K. Verdelis¹, J. T. Wright², N. Haruyama³, A. Kulkarni³, L. Lukashova¹, A. L. Boskey¹. ¹Research, Mineralized Tissues Laboratory, Hospital for Special Surgery, New York, NY, USA, ²School of Dentistry, University of North Carolina, Chapel Hill, NC, USA, ³NIDCR, NIH, Bethesda, MD, USA.

The dentin phenotype in dentin sialophosphoprotein (dspp) depleted 70 day-old mice resembles that in humans with dentinogenesis imperfecta type III. Our purpose was to quantitatively compare the dentin and enamel mineral density and the amount of dentinal

and enamel tissue formed in normal(WT) and *dsp^{-/-}* (KO) male and female mature molars.

Extracted 1st (m1) and 2nd (m2) lower molars from 8 WT and 9 KO 7-8 mo-old male and female mice (n total=33) were analyzed on a 1172 (Skyscan, Be) μ CT system at 8 μ m isotropic voxel resolution. Parameters calculated from the resulting mineral distributions (1st molars presented in Fig. 1) were: average mineral density (dentin-enamel), mineralized tissue volume (dentin), heterogeneity index (calculated by width at half height of mineral density distribution peaks- dentin).

WT molar crowns had a lower mineral density in both male and female animals (male m1 and m2=-11 to -16%, $p<0.01$, female m1 and m2=-6 to -7%, $p<0.01$). The total volume of dentin was, as initially described, much lower in male KO (-16 to -36%, $p<0.05$), while in female KO this volume was the same (m2) or there was a trend for increased volume ($\pm 8\%$, $p=0.06$ - m1), probably due to enlarged pulp space. Dentin heterogeneity was also sex-dependent, agreeing with the earlier results in KO male (+20 to 28%, $p<0.05$), but lower in female KO animals (-18 to -22%, $p<0.05$). Root dentin showed similar results. Enamel presented phenotypic differences between KO and WT mice that were not sex-dependent, both in mineral density (male=-5%, $p<0.05$, female=-2 to -4%, $p<0.05$) and volume of tissue (male=+21 to 29%, $p<0.05$, female=+22%, $p<0.05$). In KO males only (5 of 8 animals) dystrophic calcification of the pulp and root canals was present.

The results showed that the described dentinogenesis imperfecta III dentin phenotype of the *dsp^{-/-}* mice is sex-dependent, implying possible X-chromosome located protein partners for *dsp^{-/-}* in its signaling function in dentin and possibly in the pulp. They also showed that the final mineral density difference of KO dentin is moderate and that there are some enamel changes as well in the *dsp^{-/-}* mice.

Supported by NIH grants DE 04141 and AR-46121.

Bone Sialoprotein-Mediated Osteoblast Differentiation and Mineralization Is Principally Dependent on the Intrinsic Characteristics of Responding Cells. J. G. Yost*, Q. Lu*, M. Rodova*, J. Wang. Orthopedic Surgery, The University of Kansas Medical Center, Kansas City, KS, USA.

Bone sialoprotein (BSP) is one of the major non-collagenous phosphoproteins in bone and tooth, which stimulates matrix mineralization and osteogenesis in surgically created rat calvarial defects, but not in rat thoracic subcutaneous tissue (Calcif Tissue Int 2006; 79:179). This has raised an important question of whether BSP-mediated osteogenesis is dependent on local environment and/or cellular conditions. This study tests our hypothesis that the effect of BSP on osteoblast differentiation and function is principally dependent on the characteristics of responding cells. We first examined the origins of BSP-responsive cells at the cranial defect site by using a nitrocellulose membrane to separate BSP-collagen implants from the host bone/periosteum, the dura that is located at the bottom of the defect, and the skin flap covering the defect. The results demonstrated that bone-forming cells observed in the mid-portion of BSP-treated defects are primarily derived from the dura and to a much lesser extent from the host bone and periosteum. Cells derived from the skin flap do not differentiate into osteoblasts or mineralize. To eliminate the effects of local environment on BSP function, primary cells isolated separately from the dura, cranial subcutaneous or thoracic subcutaneous tissues were cultivated in the same conditions of α -MEM media. When the cells reached 75-80% confluence, they were transfected with a BSP expression lentiviral vector with the addition of 10% FBS, 50 μ g/ml ascorbic acid and 5 mM β -glycerolphosphate. Transfection of rat dural cells with a lentiviral BSP expression vector, but not an empty vector, led to the expression of osteocalcin and matrix mineralization at 14 days after transfection; while transfection of rat cranial and thoracic subcutaneous cells with a lentiviral BSP expression vector did not result in osteocalcin expression or mineralization even by 21 days. Quantitative real-time PCR analyses demonstrated that the expression levels of Runx2 and Osterix were significantly higher in normal dura than in normal cranial and thoracic subcutaneous tissues, while there were no significant differences in the expression levels of osteocalcin, BSP and osteopontin between these tissues. These results suggest that the dura-derived cells, at least some of them, are Runx2/Osterix expressing osteoprogenitors or preosteoblasts, which can be further differentiated into functional osteoblasts upon BSP treatment, and that BSP-mediated osteoblast differentiation and mineralization is principally dependent on the intrinsic molecular and cellular characteristics of responding cells.

Focal Bone Loss in Mice with Transient Muscle Paralysis. B. J. Ausk*, P. Huber*, S. Srinivasan, T. S. Gross. Orthopaedics and Sports Medicine, University of Washington, Seattle, WA, USA.

The mechanisms by which muscle function locally mediates bone homeostasis are unclear. We have previously reported that transient muscle paralysis rapidly induces osteoclast mediated trabecular and cortical bone loss in bones nearest the paralyzed muscles. Given this spatial relation, we hypothesized that resorption within a given bone would be focused on the cortex adjacent to the paralyzed muscle. Ten female C57B6 mice (16 wk) received IM injections of Botox (2.0 units/100 g) in the right calf immediately following a μ CT scan of a 2 mm mid-diaphyseal region of the tibia. At 21 d, a second μ CT scan of the same region was obtained. Pre- and post-scans of individual mice were aligned and changes in cross-sectional area determined at three 2-D cross-sections located at the distal (A, 1.4 mm proximal to the tib-fib junction), middle (B, 2.4 mm proximal) and proximal end (C, 3.4 mm proximal) of the scanned volume. Composite 2-D images at each location were partitioned to identify focal bone loss in the posterior third of bone (i.e., adjacent to paralyzed calf muscle; Calf) compared to the remainder of the cross-section (Non-Calf). Mean (\pm s.e.) whole cross-sectional bone area was significantly reduced throughout the scanned volume (A: -0.073 ± 0.009 mm²; B: -0.071 ± 0.012 mm²; C: -0.051 ± 0.009 mm², all $p < 0.001$). Bone loss arose entirely via endocortical expansion and the magnitude of the loss did not differ statistically across the scanned volume ($p > 0.3$). While bone loss at the most distal location (A) was focused in the Calf Sector ($18.8 \pm 2.2\%$ vs $8.3 \pm 1.3\%$, $p = 0.001$), bone loss at the most proximal location (C) was primarily associated with the Non-Calf Sector ($9.4 \pm 1.6\%$ vs $3.1 \pm 0.9\%$, $p = 0.004$). The center of the scanned region (B) demonstrated bone erosion in both cortical sectors ($13.7 \pm 2.4\%$ vs $9.2 \pm 1.9\%$, Calf vs Non-Calf, respectively, $p > 0.15$). These data clearly indicate that the endocortical resorption induced within the bone by transient muscle paralysis, though focal and highly reproducible across mice, was not exclusive to cortical areas adjacent to the paralyzed muscle. As the paralyzed calf spanned the entire scanned bone volume (no muscle insertions within 6 mm of scanned volume), the shift of resorption from anterior predominant to posterior predominant within this region suggests that the dynamics governing focal bone loss have complexities beyond that originally hypothesized. Instead, the data suggest that osteoclast recruitment to bone surfaces is not a random process but is either the result of active osteoclast chemotaxis or focal inhibition of osteoclast attachment.

The Increased vBMD and Bone Area due to Mechanical Loading Gradually Decreased Following Cessation of Loading. C. Kesavan, D. J. Baylink*, P. Gifford*, S. Mohan, MDC, J.L. Pettis VAMC, Loma Linda, CA, USA.

Dynamic loads lead to increases in volumetric (v) BMD and cross sectional area. However, the issue of how long these gains are maintained after cessation of loading has not been fully understood. To address this question, we performed a long term study in which skeletal changes were monitored every 2-4 weeks for a 12 week period following cessation of external loading. A four-point loading device was used to apply external loading (9N at a frequency of 2Hz for 36 cycles once per day for 12 days) to the right tibia of 10-week old female mice. Skeletal changes were monitored by in vivo pQCT. The value of the left non-loaded tibia was subtracted from the value of the right loaded tibia to determine the changes associated with loading at each time point. Two-weeks of four-point loading caused a drastic 40% increase in total area (TA) and 15% increase in total vBMD. However, the increase in size due to external loading did not continue once the external loading was stopped. Furthermore, cessation of loading resulted in a continuous loss of both bone size (TA) and vBMD. The vBMD returned to normal at 12 weeks with a half life of 6 weeks. The TA declined with a half life of 8.5 weeks and was still significantly elevated at 12 weeks. Thus, the decline in elevated TA proceeded at a much slower pace than the loading induced increases in vBMD. Conclusions: 1) External loading-induced increases in bone are lost over a period of time but at a much slower pace than the induction of the increases; 2) While a single burst of external loading provides increased bone mass temporarily, periodic loading may be necessary to maintain long term bone strength.

Values are given as mean \pm SE, * $p<0.05$ vs. non-loaded bones, n = 5

Identifying Mechanical Loading QTL by Gene Expression Changes for Alkaline Phosphatase and Bone Sialoprotein in C57BL/6J (B6) X C3H/HeJ (C3H) Intercross. C. Kesavan, D. Baylink*, S. Kapoor*, S. Mohan. MDC, J.L. Pettis VAMC, Loma Linda, CA, USA.

Previous studies have shown that mechanical loading (ML) 1) produces a more robust skeletal anabolic response in B6 mice than C3H mice, which is largely mediated by genetic differences and 2) induces greater expression of bone formation (BF) marker genes in the bones of B6 mice compared with C3H mice. We, therefore, tested the hypothesis that the variation in skeletal anabolic response to ML in the F2 mice of B6 and C3H intercross is largely due to changes in BF response. To examine this, we measured expression changes in two BF markers, namely bone sialoprotein (BSP) and alkaline phosphatase (ALP) in the loaded and non-loaded bones of 10-week F2 female mice (n=241). Loading was performed daily on the right tibia by four-point bending using a 9 Newton at 2Hz, 36 cycles, for 12 days. The left tibiae were used as internal controls. The expression levels of ALP and BSP were quantitated after normalization with two house keeping genes, actin and PPIA. The mean increase in gene expression in the F2 mice, expressed as fold change, ranged from 3.0 ± 2.8 for BSP and 2.7 ± 2.8 for ALP, and showed significant correlation ($r=0.25$ to 0.36 , $p<0.01$) with changes in BMD and bone size. A genome-wide search using 111 microsatellite markers with 15 cM intervals in the

*determined using MapQTL program; ^a $p<0.01$, ^b $p<0.05$, ^c $p<0.1$

F2 mice revealed QTLs on Chrs 8, 9, 17 and 18, which corresponded to ML QTLs we previously identified using changes in BMD and bone size as end points. We identified two new ML QTLs on Chrs 16 and 19 using gene expression data. In conclusion: 1) Identification of several common QTL for BMD, BSP and ALP phenotypes suggests that the skeletal response to ML is largely mediated by increased BF; 2) Identification of genes that are involved in regulating BSP and ALP expression in response to ML will lead to improved understanding of the molecular pathways regulating the bone response to ML.

Comparative Analysis of Expression Profile in the Anatomically Separated Parts of Femurs Prepared from Unloading Induced Bone Loss Model of Tail-suspended Mice. J. Nagata, Y. Ezura, M. Noda. Department of Molecular Pharmacology, Medical Research Institute, Tokyo Medical and Dental University, Tokyo, Japan.

In vivo experimental analysis for disuse osteoporosis has been effectively carried out by rodent experiment of hindlimb unloading obtained by "tail-suspension". Applications of knock-out mice for this experiment unveiled molecular involvement of several genes such as osteopontin, for the unloading induced bone-loss. However, the entire process of the molecular events involved in this phenomenon is largely unknown. To obtain insights into the integrative understandings of the molecular events, we performed DNA microarray analysis on tissues prepared from unloaded femurs of the tail-suspended mice. Tail suspension was carried out using 8-week old C57Bl6 mice (n=5) for 2-weeks, and we compared them with normally loaded mice (n=5). Whole femora were dissected out from left hindlimbs, and separated into three parts; (A) bone marrow flushed out from mid shaft 1/3, (B) mid shaft cortex, and (C) distal and proximal epiphyses and metaphyses. Total RNA was isolated from these samples, and only the quality checked samples were used for expression analyses. Micro-CT analysis on contralateral femora confirmed significant decrease of bone volume in the distal end. Expression profile for up to 39,000 transcripts was analyzed by Affymetrix DNA microarray (Mouse Expression 430_2.0 Array) for three different parts of femurs (A to C). The analyses displayed significantly different patterns. Partial resemblance and reasonable shift observed in the expression pattern of some genes indicated a possibility for analytical reconstruction of changes in proportion of different types of cells and/or changes in expression levels of the gene in specific type of cells in the tissue. For this sake, we first specified significantly up-regulated and down-regulated genes in each type of anatomical site origins (A to C), considering data conceivability regarding flag indication for the spot signal and consistency between the triplicated samples, as well as the statistical significance of the differential expression between loaded and unloaded samples indicated by p-values for Student's t-test. Up-regulated 102 and down-regulated 83 genes were selected from the data for tissue preparation (A). Similarly for preparation (B) and (C), 91 and 46 upregulated and 121 and 50 down-regulated genes were selected. Comparative analysis of these genes among the data obtained from different tissue preparation should clarify the specific cellular events occurring in the unloaded bones in vivo.

Collagen and Osteopontin Upregulation by Mechanical Loading of Bone Cells in Porous 3D Scaffolds. A. Sittichokechaiwut, L. E. Brown*, G. C. Reilly. Engineering Materials, University of Sheffield, Sheffield, United Kingdom.

Previously, we showed that polyurethane foam scaffolds seeded with osteoblastic cells and loaded in a biodynamic chamber attached to a mechanical testing machine (Bose ElectroForce 3200) provide a good model for analysis of mechanotransduction in 3 dimensions. Under static culture conditions MC3T3-E1 and MLO-A5 cells settled throughout the scaffolds and were shown to be viable up to 15 days of culture. Since MLO-A5s have been demonstrated to be rapid matrix producers (Kato et al. JBMR 2001) we used these cells to investigate the effects of compressive loading in the 3D system. Cell-seeded scaffolds were loaded in compression with a sine wave at 1Hz, 5% strain for 2 hours per day at days 5, 7 and 9 of culture. Collagen content, as assayed by colorimetric analysis of sirius red staining, was significantly ($p<0.05$) higher in loaded scaffolds even if the loading was reduced to days 5 and 7 only. There was no effect of 2 hrs of loading on cell number. However, reducing the length of the loading period to 0.5 or 1 hr eliminated the difference in collagen content but caused an increase in the final number of viable cells in loaded scaffolds. To assess loading induced changes in matrix gene expression 2 types of culture were set up. 1) MLO-A5 cells in polyurethane foams (BritishVita). 2) MC3T3-E1 cells in collagen sponges (BD biosciences). In both experiments cells were cultured until day 5 then subjected to a single bout of 2 hours of loading at 5% strain, 1 Hz. In both experiments an increase in osteopontin mRNA was detectable in loaded samples by PCR. Positive effects of mechanical loading on bone matrix production can clearly be demonstrated in 3D porous scaffolds..

Continuous Local Infusion of Basic Fibroblast Growth Factor Enhances Consolidation of the Bone Segment Lengthened by Distraction Osteogenesis in Rabbit Experiment. A. Abbaspour, S. Takata, K. Sairoy*, S. Katoh*, K. Yukata*, N. Yasui*. The University of Tokushima, Tokushima, Japan.

Experimental tibial lengthening was achieved in 52 rabbits to examine the effect of continuous local infusion of recombinant human fibroblast growth factor-2 (rhFGF-2) on bone regeneration during distraction osteogenesis. The tibia was separated by osteotomy and was subjected to slow progressive distraction (rate:0.35 mm/12h) using a monolateral external fixator. The lengthening process consisted of a lag phase for one week after osteotomy, a distraction phase for two weeks, and a consolidation phase for five weeks in this experiment. At various stage of the distraction, rhFGF-2 was infused continuously for two weeks into the lengthened segment [rate:14.28 µg/day(60 µl/day)] using an osmotic pump implanted under the skin. Bone healing was significantly accelerated when rhFGF-2 was infused in the beginning of consolidation phase, but not in the distraction phase nor in the lag phase. Infusion of normal saline (N/S) using the same osmotic pump had no effect. Dual energy X-ray absorptiometry (DXA) and peripheral quantitative computerized tomography (pQCT) studies demonstrated that rhFGF-2-treated tibia had higher bone mineral density (BMD), higher bone mineral content (BMC) and increased cortical bone thickness (CBT) than N/S-treated tibia. In addition, three-point bending test demonstrated that rhFGF-2-treated bone had significantly stronger mechanical properties than N/S-treated bone. Finally, distribution of the infused materials was checked by using Indian ink or Urographin. The dyes distributed widely but exclusively in the lengthened segment. Based on these results we conclude that direct delivery of rhFGF-2 into the lengthened segment can shorten the consolidation phase of limb lengthening and the method is applicable to the clinical treatment.

Limited Collagenase Digestion Increases Solubility and Induction Potential of Human Demineralized Bone Matrix (DBM) In Vitro. H. Tang, L. Shanahan*, M. Diegmann*, N. Forsyth*, D. Knaack*, K. Behnam R&D, Osteotech, Inc., Eatontown, NJ, USA.

When processed in a manner consistent with the preservation of native growth and differentiation factor activity, human demineralized bone matrix has the ability to induce the formation of endochondral bone heterotopically in athymic rodents. Histological demonstration of the formation of ectopic mineralized bone, bone marrow, osteoid, and cartilage is generally considered to be the gold standard for the measurement of osteoinductive activity. While quantitative and semiquantitative histomorphometric methods for defining the osteoinductive potential of DBM have been previously proposed, for the purpose of testing lots of DBM produced from individual donors a predictive in vitro alternative would be desirable. Previously, quantitative in vitro methods for the measurement of the induction of osteoblastic markers in clonal cells have been proposed. We find that a significant limitation of many of these assays is the relative insolubility of the collagenous matrix in the cell culture media. Limited digestion of human demineralized bone matrix with purified bacterial collagenase increases both the solubility of DBM in cell culture media and the ability of the residual matrix to upregulate alkaline phosphatase activity in clonal C2C12 myoblasts. Partial digestion of DBM for 60 minutes increases the ability of the material to induce AP activity in C2C12 cells more than 10 fold 4 days post-treatment but the same treatment has no effect on the activity of guanidine hydrochloride inactivated DBM. The partially digested DBM begins to dissolve into the cell culture medium within 4 to 5 hours, with scant amounts of residual DBM remaining after 48 hours. Complete solubilization of the matrix is dependent on the presence of cells but direct cell contact with the matrix is not required. The capability of DBM to induce alkaline phosphatase activity is dependent both on the dose of the DBM added and the duration collagenase digestion [data not shown]. These results indicate that the solubility of DBM in cell culture media influences the release kinetics of native growth factors which reside within the collagenous matrix.

Continued Enhanced Fgfr2 Function Delayed Fracture Healing in Mice. L. Yin, X. Du, Z. Liu, N. Su, H. Qi, J. Yang, L. Zhao, L. Chen Trauma Center, Research Institute of Surgery, Daping Hospital, Third Military Medical University, chongqing, China.

To evaluate the role of FGFR2 in fracture healing, this study was conducted using twelve-week-old female mice carrying gain-of-function substitution (Ser252Trp) in Fgfr2 or their wild-type littermates. After been anesthetized, mice were subjected to an open mid-diaphyseal fracture of its right femur, a 0.5-mm-diameter metal pin was inserted through the patellar tendon into the medullary canal of the tibia to fix the fracture. Mice were sacrificed at day 5, 7, 10, 14 and 21 after fracture. Digital radiographs of right hind limbs were obtained. After been demineralized, embedded and sectioned, H.E. staining and safranin O/fast green staining were undertaken to show the histological structure of the callus. In situ hybridization using digoxigenin-labeled probes were performed to detect the expression of Fgfr2, Col2(Collagen 2), Ihh(Indian hedgehog) and BMP4(bone morphogenetic protein 4) in callus. The results showed that all the wild-type mice had radiographic evidence of bone union compared with delayed fracture union in mutant-type mice. At 7 days post-fracture, marked chondrogenesis appeared in callus of wild-type mice but not in mutant-type mice. By 21 days, fracture healing was completed in wild-type mice. In contrast, at this time, the fracture healing was not finished in mutant-type mice, with persistence of fibrous scar and cartilage in the fracture gap and bone marrow cavity. The expression of Fgfr2 was present in both wild-type and mutant-type calluses. The initiation of Ihh and Col2 expression in callus was delayed in mutant-type mice than that in wild-type mice. No significant difference in the expression of BMP4 between two groups was observed. Therefore, this study indicated that constitutively activated Fgfr2 function will suppress the endochondral ossification in fracture callus and delay the healing of fracture through the inhibition of the Ihh expression in fracture site.

FGF-23 Controls NaPiIIa Trafficking via Crosstalk Between the PI-3 kinase and MAP kinase Pathways. M. Khan*, S. M. Jan de Beur Medicine, Johns Hopkins Medical Institute, Baltimore, MD, USA.

Fibroblast Growth Factor 23 (FGF-23) is an important physiological regulator of phosphate homeostasis and its excess or deficiency has been implicated in several human disorders of phosphate homeostasis. FGF-23 exerts its phosphaturic action by promoting internalization of the type IIa and type IIc sodium-phosphate co-transporters (NaPiIIa, NaPiIIc) from the renal brush border membrane and preventing the compensatory increase in 1,25(OH)₂D₃ by reducing renal 1 α hydroxylase expression. FGF-23 can bind several known FGF receptors (FGFR) and activate MAP kinase signaling. However, it is not known which of FGF signaling pathways mediate the diverse actions of FGF-23. We sought to distinguish which FGFR signaling pathway regulates FGF-23-mediated NaPiIIa internalization. Previously, we reported that FGF-23 stimulates ERK1/2 (ERK) phosphorylation and that inhibiting ERK signaling with U0126 abolished FGF-23-mediated NaPiIIa internalization in opossum kidney cells (OK/e). To interrogate other FGFR signaling pathways such as the phosphatidylinositol-3 kinase (PI-3 kinase) pathway, we measured phosphorylation of Akt by immunoblot but observed no increase in pAkt upon stimulation with FGF-23 (0.1 ng/ml-100ng/ml). Yet, surprisingly, inhibition of PI-3 kinase with LY294002 partially blocked FGF-23-mediated NaPiIIa internalization. In tyrosine kinase receptor signaling in general and FGFR signaling specifically, the MAP kinase pathway may be activated by a number of upstream molecules including Ras, phospholipase C γ (PLC γ) via protein kinase C (PKC), and PI-3 kinase via PDK-1. In order, to further dissect the inputs to the MAP kinase pathway, we measured pERK by immunoblot in FGF-23 stimulated OK/e cells treated with the farnesyl transferase inhibitor (FTI-277) that induces accumulation of non-farnesylated cytoplasmic Ras to form inactive Ras/Raf complexes. OK/e cells were preincubated with 2 μ M FTI-277 for 1-24 hrs and then stimulated with FGF-23 (10 ng/ml) or PTH (1-84, 10⁻⁸M). MAP kinase activation was measured by immunoblot of whole cell lysate with a pERK antibody. In OK/e cells treated with FGF-23, FTI-277 did not appreciably reduce pERK compared to untreated FGF-23-stimulated cells. In contrast, PTH-stimulated ERK phosphorylation was completely abolished with FTI-277 treatment. U0126 blocked both FGF-23 and PTH-stimulated ERK phosphorylation. Taken together, these data suggest that the PI3 kinase pathway regulates FGF-23-mediated NaPiIIa internalization through crosstalk with the MAP kinase pathway and that this is a distinct signaling pathway from PTH-mediated NaPiIIa trafficking.

Age-Dependent Regulation of FGF23 Production in Murine Bone. T. Masanori¹, B. Yuan², Y. Xing^{2*}, K. Aya¹, T. Morishima¹, M. K. Drezner², H. Tanaka¹ ¹Department of Pediatrics, Okayama Univ., Okayama City, Japan, ²Department of Medicine, Univ of Wisconsin and GRECC, William F. Middleton VAMC, Madison, WI, USA.

The detailed physiological regulation of FGF23 production remains unknown. However, the principal location of the hormone in osteoblasts and variation in the amount present during matrix mineralization suggests FGF23 production may be age-dependent (Bone. 2007 Feb 8 [pub ahead of print]). Thus, in the present study, we examined the influence of age on FGF23 production in mice. Initially, we measured serum FGF23 (s-FGF23) in wild type (WT) C57BL/6J mice at 2, 4 and 12 weeks of age. s-FGF23 was highest at 2 weeks and declined thereafter (516.5 \pm 48.3, 373.3 \pm 56.4 and 106.8 \pm 8.4 pg/ml, respectively; p<0.05). In accord, FGF23 mRNA expression in WT-mice significantly (p<0.05) decreased at 4 (41.5 \pm 9.1%) and 12 (77.9 \pm 8.4%) weeks of age. Interestingly, hypomimetic with a pathological abnormality of FGF23 metabolism, had superimposed on this defect a progressive age-dependent decrease in FGF23 mRNA production, significantly (p<0.05) declining by 42.2 \pm 9.6% at 4 weeks and 89.9 \pm 5.3% at 12 weeks. Accordingly s-FGF23 similarly decreased (4811.8 \pm 184.6, 3391.2 \pm 158.1 and 1367.4 \pm 59.2 pg/ml; p<0.05). To examine if the age-dependent modulation of FGF23 expression is PHEX independent, we established an in vitro system using osteoblasts derived from SV40 Tg mice (SV-Ob). Cells were maintained in α MEM containing 10% FBS, ascorbate and β -glycerolphosphate (VC-GP). The SV-Ob cells proliferated and reached sub-confluence at day 6 of incubation and after 12 days, mineralization of extra-cellular matrix was evident. After 3 days of incubation proliferating cells displayed abundant FGF23 mRNA expression, which decreased with maturity at 6 days (97.4 \pm 1.2%; p<0.05) and 12 days (99.1 \pm 0.2%; p<0.05) of incubation. Incubation of SV-Ob cells in conditioned medium from SV-Ob cells at day 6, but not day 12, of culture significantly elevated FGF23 mRNA expression compared to that in cells incubated with fresh VC-GP medium (4.86 \pm 0.90 fold; p<0.05), indicating that a factor(s) produced by immature osteoblasts plays an important role in regulation of FGF23 production. Interestingly, exposure of SV-Ob cells to d6 medium, containing the phex inhibitor, MH2-64-C, did not modulate the effect on FGF23 expression. Moreover, SV-Ob cells, transfected with pcDNA/phex-WT vector encoding the mouse phex protein, displayed FGF23 mRNA expression no different than that in SV-Ob cells transfected with an empty vector. Our observations clearly indicate that FGF23 production in murine osteoblasts is regulated by an age-dependent mechanism, which results in a PHEX independent decline of FGF23 mRNA with maturity.

Overexpression of Low Molecular Weight Isoform of FGF2 partly prevents Bone Loss in Ovariectomized Mice. L. Xiao¹, J. D. Coffin², M. M. Hurley¹. ¹University of Connecticut Health Center, Farmington, CT, USA, ²The University of Montana, Missoula, MT, USA.

In humans, there are multiple high molecular weight (HMW, 22, 23, 24kDa) nuclear isoforms of basic fibroblast growth factor (FGF2) and a low molecular weight (LMW, 18kDa) isoform that is exported from cells. We previously reported that targeted over-expression of the LMW FGF2 isoform in preosteoblasts and mature osteoblasts increased bone mass in vivo and in vitro. To determine whether LMWFGF2 protects against ovariectomy induced bone loss, female Col3.6/GFP transgenic mice (VectorTg) and Col3.6/LMWFGF2/GFP transgenic mice (LMWTgFGF2) were ovariectomized (OVX) or sham-operated (sham) at 14 weeks of age and sacrificed 6 weeks post surgery. Six weeks after OVX, there were significant reductions in uterine weight in both VectorTg-OVX and LMWTgFGF2-OVX groups compared to the sham group. Body weight was significantly increased only in the VectorTg-OVX group compared with VectorTg-sham group. DEXA analysis showed a 4.6% and 9% significant reductions in femoral bone mineral density (BMD) and bone mineral content (BMC) in VectorTg-OVX group compared with VectorTg-sham group ($p < 0.05$). There was no significant reduction in BMD and BMC in LMWTgFGF2-OVX group compared with LMWTgFGF2-sham group. Micro-CT analysis revealed that femoral trabecular bone volume/total volume (BV/TV), connective density (Conn-Den) and trabecular number (Tb.N) were significantly decreased by 32%, 38% and 18% respectively in VectorTg-OVX compared with the VectorTg-sham group. However, there were only 24%, 22% and 13% decrease in femoral BV/TV, Conn-Den and Tb.N respectively in LMWTgFGF2-OVX group compared with LMWTgFGF2-sham group. At 2 and 3 weeks mineralized bone nodules were increased in ex vivo bone marrow stromal cell cultures from LMWTgFGF2-sham mice compared with VectorTg-sham and was further increased in cultures from LMWTgFGF2-OVX mice compared with VectorTg-OVX. Northern analysis showed that mRNA for Osteocalcin (OC); a late marker of differentiated osteoblasts; was similar between VectorTg-sham and VectorTg-OVX in 3 week cultures. However there was a 1.75 fold increase in LMWTgFGF2-sham compared with Vector-sham and a 1.91 fold increase in LMWTgFGF2-OVX compared with Vector-OVX group. Similar data was observed in two independent lines of LMWTgFGF2 mice. These data indicate that targeted over-expression of LMW isoform of FGF2 protein in preosteoblasts and osteoblasts partially protected against OVX-induced bone loss in vivo and in vitro.

Bone Regeneration with Local Controlled Application of Granulocyte Colony-Stimulating Factor (G-CSF) in a Bone Defect of Rabbit Ulna. K. Ishida^{*1}, R. Kuroda^{*1}, K. Sasaki^{*1}, Y. Mifune^{*1}, K. Tei^{*1}, M. Miwa^{*1}, T. Matsumoto^{*1}, Y. Tabata^{*2}, M. Kurosaka^{*1}. ¹Department of Orthopaedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan, ²Department of Biomaterials, Field of Tissue Engineering, Institute for Frontier Medical Sciences, Kyoto University, Kyoto, Japan.

It is recognized that re-establishment of vascularity is an early event in fracture healing and the appropriate vascularization is emerging as a prerequisite for bone regeneration. G-CSF is a cytokine known to have an angiogenesis-promoting effect by recruitment of bone marrow cells. In this study, we investigated that the local applied G-CSF enhances bone regeneration via revascularization and osteoblast mobilization by controlled release from gelatin hydrogel. Methods: We have designed a biodegradable catonized gelatin (CG) hydrogel as the drug delivery system for G-CSF. All animal procedures were approved by the Animal Research Committee of Kobe University Graduate school of Medicine. 24 Japanese white rabbits were used in this study. A segmental bone defect (20 mm) was created at the diaphysis of rabbit ulna. The defects were treated in two groups as follows: Group G0: defects were filled with CG hydrogel only, Group G5: defects were filled with CG hydrogel with G-CSF (5µg). Every defect of the radiographs was obtained at 2, 4, and 8 weeks after surgery. Semiquantitative radiographic evaluations were performed using Image J and the radiographic healing was graded according to modified Cooks' grading scale. Toluidine blue staining was performed to see endochondral ossification. Histochemical staining for isolectin B4 was performed as an assessment of capillary invasion and immunofluorescent staining for osteocalcin were performed as an osteoblast marker. Results: Radiographic semiquantitative assessment revealed that there were more bone formation in group G5 than in group G0 at every weeks. Radiographic grading also revealed that bone formation was significantly promoted in group G5 at 4 and 8 weeks. Toluidine blue staining revealed that more cartilaginous matrix was seen in group G5 at as early as 2 weeks. Histochemical staining for isolectin B4 showed that capillary density was significantly increased in group G5 at 2 weeks. Osteoblast density was also significantly increased in group G5 at 2 weeks and these results revealed that revascularization and osteoblast mobilization into the bone defects were promoted in group G5. Conclusions: The present study demonstrates that local controlled application of G-CSF promotes rabbit bone regeneration. The reasons seemed that the G-CSF promoted revascularization and osteoblast mobilization. G-CSF had further possibility to apply other situations that needs both bone repair and neovascularization.

Immunoregulatory Role of RANKL-stimulated Dendritic Cells on Autoimmune Arthritis in MRL/lpr Mice. T. Izawa^{*1}, N. Ishimaru^{*2}, K. Moriyama³, Y. Hayashi^{*2}. ¹Department of Orthodontics and Dentofacial Orthopedics, Institute of Health Biosciences, Tokushima University, Graduate School, Tokushima, Japan, ²Department of Oral Molecular Pathology, Institute of Health Biosciences, Tokushima University, Graduate School, Tokushima, Japan, ³Department of Maxillofacial Orthognathics, Tokyo Medical and Dental University, Graduate School, Tokyo, Japan.

Recent studies have established that receptor activator of NF-κB(RANK)/RANKL signaling plays a key role for maintenance of dendritic cells (DCs) in the periphery. However, the association of the RANKL signaling for DCs with autoimmunity has been obscure. In this study, we investigated the immunoregulatory role of DCs through RANKL signaling on autoimmune arthritis using MRL/lpr mice.

The phenotypes and functions were analyzed using DCs of spleen and lymph nodes, or bone marrow-derived DCs (BMDCs) from MRL/lpr and MRL/+/+ mice. The surface markers on the peripheral DCs and RANKL-stimulated BMDCs were analyzed by flow cytometer. Apoptosis- and cell cycle-related molecules of the DCs were detected by Western blot analysis. In addition, the adaptive transfer of RANKL-stimulated BMDCs was performed into MRL/lpr mice as recipients to modulate the arthritis lesions.

We found that the number of CD11c⁺CD11b⁺CD8a⁺ myeloid DCs in the periphery from MRL/lpr mice was significantly increased comparing with that from control mice, and that the MRL/lpr DCs could survive much longer than control DCs. In addition, the expressions of Bcl-x and Bcl-2 and the nuclear transport of NF-κB of RANKL-stimulated BMDCs from MRL/lpr mice were considerably upregulated compared with those from control mice. On the other hands, Fas expression of normal BMDCs was significantly increased by RANKL stimulation. Moreover, the adoptive transfer of RANKL-stimulated BMDCs resulted in accelerated and severe autoimmune arthritis of MRL/lpr recipients. These findings suggest that the crosstalk between RANKL and Fas signaling in DCs might influence the maintenance of DCs in the periphery and the development of autoimmunity.

SDF-1/CXCR4 Is Essential for In Vivo Endochondral Bone Repair. T. Kitaori^{*1}, H. Ito¹, E. M. Schwarz², T. Nakamura¹. ¹Orthopaedic Surgery, Graduate School of Medicine, Kyoto University, Kyoto City, Japan, ²The Center for Musculoskeletal Research, University of Rochester, Rochester, NY, USA.

INTRODUCTION A chemokine, SDF-1, and its receptor, CXCR4, have been well known to play a crucial role in homing of hematopoietic stem cells (HSCs) to bone marrow niche. Additionally accumulating data have shown that SDF-1 is highly expressed in some damaged organs, such as myocardial infarction and brain injury, and recruits circulating mesenchymal stem cells (MSCs) to the damaged lesion, allowing them to start normal organ repair. But it is still unknown whether SDF-1 is involved in bone repair. Using murine autograft and allograft models, we tested the hypothesis that SDF-1 is essential in endochondral bone repair. **METHODS** We used in-vivo 4-mm segmental femoral autograft and allograft model of C57Bl/6 mice. For autograft model, the freshly removed bone was transplanted back to the same mouse, and secured by a metal pin. For allograft model, graft bones, which had been harvested from ICR mice and kept frozen for at least 24 hours, were applied to the defects. For a loss of function study in autograft model, mice received anti-SDF-1 neutralizing antibody or control IgG injection peritoneally after the implantation. For a gain of function study in allograft model, rmSDF-1 protein or adeno-SDF-1 was loaded locally around the graft bones. For an in-vivo chemotaxis assay, pre-cultured bone marrow stromal cells (BMSCs) were labeled with BrdU and transplanted through tail vein at the end of the surgery. Bone grafts and surrounding tissue were harvested at days 0.5, 1, 2, and 3 after transplantation for RNA extraction and at days 7, 14, and 28 for histological analysis. The expression of SDF-1 mRNA was measured by RT-PCR. To detect the labeled-BMSCs immunohistostaining using anti-BrdU antibody was examined. **RESULTS & DISCUSSION** In this study we demonstrated the involvement of SDF-1 in endochondral bone repair. The mRNA expression of SDF-1 was increased in autograft at days 2 after transplantation, while no increase was detected in allograft. The transplanted BMSCs were detected around the grafted bones at days 7. Moreover the new bone formation around the autograft was significantly inhibited by the injection of anti-SDF-1 antibody. These data indicated that SDF-1 had an essential role in the acute phase of normal bone repair. The gain of function study, however, showed no remarkable increase in the bone formation, suggesting that SDF-1 may need to collaborate with other molecules to have a successful effect.

Intracellular Cytokine Profile of RANKL Expressing Lymphocytes. D. Krenbek, U. Semrad*, M. Rauner*, D. Stupphann*, J. Patsch, M. Willheim*, P. Pietschmann. Department of Pathophysiology, Medical University of Vienna, Vienna, Austria.

Cytokines play an important role in regulation of bone mass by influencing Receptor activator of NF κ B (RANKL). For example, TNF α increases bone resorption by elevating RANKL expression while IFN γ suppresses osteoclastogenesis by inhibiting RANK/RANKL signalling. Lymphocytes are major producers of cytokines and as they express RANKL, they are thought to be involved in bone destruction in a number of diseases including rheumatoid arthritis, parodontitis and possibly osteoporosis. Yet their function in bone metabolism is still poorly understood. Therefore we studied expression of surface and intracellular RANKL in lymphocytes as well as cytokine production by flow cytometry.

Peripheral blood mononuclear cells were isolated from young healthy subjects and stimulated for 4 hours with ionomycin (1.25 μ M), phorbol 12-myristate 13-acetate (10 ng/ml) and brefeldin A (10 μ g/ml). Harvested cells were incubated with an anti human RANKL specific monoclonal antibody followed by saponin treatment and further incubation with antibodies against IFN γ , TNF- α and CD4. To detect intracellular RANKL cells were permeabilised prior to staining.

Data was acquired on a FACSCalibur flow cytometer (Becton Dickinson) and analysed with the CellQuest Pro Software. RANKL positive cells were gated to illustrate their intracellular cytokine pattern.

In most of the cells intracellular RANKL was detected whereas only few cells were positive for surface RANKL. The latter were predominantly negative for IFN γ (80 \pm 7%) but expressed TNF α (47 \pm 26%). By gating on CD4 positive lymphocytes a similar pattern in RANKL and cytokine expression was observed.

Our data suggest that lymphocytes are involved in regulation of bone mass predominantly by the secretion of RANKL, rather than regulatory interaction of surface-expressed RANKL with target cells. Yet a small sub-population of lymphocytes expressing surface RANKL but not IFN γ may act on osteoclasts and their precursors directly via cell-cell contact.

TNF-alpha Dependent Redox Signals Upregulate Msx2 Gene Transcription via Stress Activated Protein Kinases in Arterial Myofibroblasts. C. F. Lai-Huang, J. S. Shao, E. Huang*, Z. Al-Aly*, S. L. Cheng, D. A. Towler. Internal Medicine - Bone and Mineral Diseases, Washington University School of Medicine, St. Louis, MO, USA.

Aortofemoral calcification is prevalent in type II diabetes (T2DM), tracking metabolic syndrome parameters and increasing the risk for lower extremity amputation. LDLR $^{-/-}$ mice fed high fat diets (HFD) develop T2DM, and accumulate aortic calcium, mediated via BMP2 and Msx2-Wnt osteogenic mechanisms that resemble craniofacial mineralization. Low-grade inflammation - including elevated serum TNF-alpha -- is characteristic of T2DM. TNF-alpha upregulates myofibroblast BMP2, a potent stimulus for aortic Msx2 expression. We wished to determine if TNF-alpha augmented Msx2 expression in arterial myofibroblasts, potentially via autocrine BMP2 signals. TNF-alpha (10 ng/ml) upregulated both BMP2 and Msx2 mRNA accumulation 4-fold in aortic myofibroblasts following 6 hours of treatment. However, detailed time course reveals that Msx2 induction actually precedes BMP2 expression, with 2-fold Msx2 induction observed within 1 hour of treatment. Moreover, addition of 250 ng/ml recombinant noggin, an inhibitor of BMP2 and BMP4, did not inhibit Msx2 induction, providing further evidence of regulation independent of autocrine BMP2 signals. Msx2 induction was maximal by 3 hours, and dose-response studies revealed an ED50 for TNF-alpha of 2 ng/ml. Induction was completely abrogated by actinomycin treatment, and dose-dependently prevented by DRB, indicating Msx2 induction was transcriptionally regulated by TNF-alpha. Inhibition of the IKK-NF-kappaB pathway with BAY 11-7082 did not inhibit (actually enhanced) Msx2 induction. However, the JNK/SAPK inhibitor SP600125 significantly reduced TNF-alpha actions. JNK/SAPK is a critical component of the oxidative stress signaling cascade downstream of NADPH oxidase. Therefore we examined the effects of apocynin (NADPH oxidase inhibitor), SIN-1 (superoxide and nitric oxide precursor) and H202 on Msx2 expression. Apocynin reduced both basal and TNF-alpha stimulated Msx2 expression, indicating a role for NADPH oxidase redox signaling in aortic myofibroblasts. SIN-1 treatment had no effect. However, H202 dose-dependently upregulated Msx2 mRNA accumulation, phenocopying the response to TNF-alpha. Finally, mice with vascular TNF-alpha augmented by a SM22- TNFalpha transgene exhibit higher levels of aortic Msx2 gene expression vs. non-transgenic sibling cohorts, providing further evidence for a vascular TNFalpha - Msx2 regulatory axis in vivo. Thus, arterial myofibroblast Msx2 gene transcription is directly stimulated by TNF-alpha, entraining vascular Msx2 expression to inflammation via redox-regulated JNK/SAPK signal cascades.

The Role of Wnt3A Signaling in Maturation of Rat Osteoblasts. L. Ling*, C. Dombrowski*, L. M. Haupt*, V. Nurcombe*, S. M. Cool. Stem Cells and Tissue Repair, Institute of Molecular and Cell Biology, Singapore, Singapore.

Recent studies have indicated that heparan sulfate (HS) sugar-dependent Wnt signaling is crucial to bone formation. These sugars are manufactured in the Golgi, and are heavily reliant on the HS-synthesizing enzymes glucosaminyl N-deacetylase/N-sulfotransferase-1 (NDST-1) and HS 2-O-sulfotransferase (HS-2-OST). NDSTs and HS-2-OST are responsible for HS N-sulfation and O-sulfation, respectively; NDST1 is also a key enzyme directing further HS modifications including O-sulfation. Recent studies have indicated that HS regulates proliferation and differentiation of osteoblasts and improves bone healing. The work here was designed to investigate the function of Wnt3A during the maturation of primary osteoblasts derived from new-born rat calvaria. Sequential digests of rat calvaria were able to release cells characteristic of the various stages of osteogenic development. Preosteoblasts (fraction 3) were most sensitive to 1,25 α -vitaminD3 and parathyroid hormone, whilst more mature osteoblasts (fraction 5) exhibited the greatest alkaline phosphatase (ALP) activity as well as collagen I α 1 and osteocalcin (OC) expression. The osteogenic potential of F3 and F5 were further demonstrated by Alizarin Red and von Kossa staining. The mRNA level of target genes and the expression of target proteins were determined by RQ-PCR and Western Blot analysis, respectively, and cell proliferation determined by the GUAHA PCA-96 Viacount system. We found that the levels of NDST1 and HS-2-OST were at least 5-fold higher in F3 than F5, suggesting that HS sugars are intimately involved in the maturation of pre-osteoblasts to osteoblasts. We further demonstrated that Wnt3A increased NDST1 expression in F5 (2.7-fold) and F3 (1.4-fold). Wnt3A and LiCl (an activator of Wnt signaling) both inhibited cell proliferation while increasing ALP activity and OC expression in both fractions, inducing a higher ALP activity in F3 (2.1-fold) than F5 (1.5-fold) but a higher OC expression in F5 (5.0-fold) than F3 (1.7-fold). Heparin dose-dependently increased Wnt3A-stimulated ALP activity in F3, but decreased it in F5. We also observed that activation of Wnt signaling dramatically increased noggin expression, a BMP inhibitor, while decreasing RUNX2 expression. In conclusion, Wnt3A signaling regulates the maturation of calvaria osteoblasts by switching the cells from proliferation to differentiation. As Wnt3A is known to interact with BMP2 signaling which is also mediated by HS, the sugar may be orchestrating the availability of these factors to precursor cells.

Osteoprotegerin as Cardiovascular Risk Marker in Patients with Type 2 Diabetes Mellitus. P. Rozas-Moreno*, M. Muñoz-Torres, G. Alonso*, D. Fernández-García*, I. Luque-Fernández*, A. Sebastian-Ochoa*, F. Escobar-Jiménez*. Bone Metabolic Unit. Department of Endocrinology, University Hospital San Cecilio, Granada, Spain.

Background: Type 2 diabetes mellitus patients have a high prevalence of cardiovascular disease. The classic cardiovascular risk factors seem not to completely explain such increase in vascular disease in type 2 diabetes mellitus. Hyperhomocysteinemia and enhanced carotid intima-media thickness (CINT) are both predictors of cardiovascular disease in diabetic patients. It has been postulated that osteoprotegerin (OPG) could be the physiopathologic link between osteoporosis and vascular disease. On the other hand, elevated serum levels of OPG, a key cytokine in the bone remodelling process, have been related to an increased mortality due to cardiovascular events in type 2 diabetes mellitus patients.

Objective: To analyze the association between serum OPG and some of the cardiovascular risk factors observed in type 2 diabetes mellitus (Arterial hypertension [HT], hyperlipidemia, obesity, smoking, hyperhomocysteinemia, CINT).

Patients and methods: 72 patients with type 2 diabetes mellitus were studied. All of them attended to the Endocrinology Service of University Hospital "San Cecilio" of Granada, Spain. Arterial hypertension was defined as blood pressure \geq 140/ 90 mmHg and/or actual anti-hypertensive treatment. Serum levels of homocystein, LDLc, HDLc and OPG were measured (OPG ELISA BI-20402, BIO-MEDICA-GRUPPE WIEN, Austria). Hyperlipidemia was defined according to the ATPIII criteria (statins treatment, LDLc \geq 130 mg/dl, HDLc $<$ 40/50 mg/dl in males and females respectively). Obesity was graded using the Body Mass Index (BMI: Kg/m 2). The CINT was determined by means of vascular Eco-doppler (TOSHIBA Vision 6000) of both carotid arteries at the level of 10 mm proximal from the carotid branch off using a mode B, 7.5 MHz probe. A value \geq 0.9 mm was considered as pathologic.

Results: The study population included 41.7% females and 58.3% males, mean age 57.9 \pm 6.3 years-old. Males showed smaller serum levels of OPG than females (4.70 \pm 1.8 vs 5.98 \pm 2.6 pmol/L respectively, p=0.02). Serum levels of OPG were positively related to age in both genders (r=0.31, p=0.01). In female patients OPG levels were not significantly related to none of the studied variables. In males the serum levels of OPG were significantly related to presence of HT (Yes/No: 5.59 \pm 2.3 vs 4.06 \pm 1.5 pmol/L, p=0.01), CINT = 0.9 mm (Yes/No 5.09 \pm 1.6 vs 3.9 \pm 1.9 pmol/L, p= 0.03), presence of carotid plaque (Yes/No: 5.46 \pm 1.6 vs 4.22 \pm 1.8 pmol/L, p= 0.047) and BMI (r= 0.3, p= 0.05).

Conclusion: Our results suggest that the serum levels of OPG could contribute additional information about the cardiovascular risk in males with type 2 diabetes mellitus.

Local CNP Clearance System as a Regulator of CNP-GC-B System for Bone Growth. Y. Nakatsuru*. Endocrinology and Metabolism, Kyoto University, Kyoto, Japan.

Natriuretic peptide family consists of three endogenous ligands, ANP, BNP and CNP. They exert their biological actions by producing intracellular cyclic GMP through two subtypes of membranous guanylyl cyclase (GC), GC-A and GC-B. The third natriuretic peptide receptor is called clearance receptor (C-receptor), which has no GC activity and is involved in the clearance of ligands. ANP and BNP are widely known as regulators of cardiovascular homeostasis through GC-A, whereas recent studies elucidated that CNP plays pivotal roles in the regulation of endochondral bone growth via GC-B. A previous study demonstrated that C-receptor deficient mice exhibit skeletal overgrowth like transgenic mice with targeted overexpression of CNP in cartilage. Here we examined the significance of natriuretic peptide clearance system in the growth plate using fetal mouse tibial organ culture. A specific agonist for C-receptor, C-ANF, increased the production of intracellular cGMP dose-dependently, and accordingly, elongated the tibial explants and their cartilaginous primordium significantly. Histological examination revealed that the width of the growth plate is widened in the C-ANF treated group. On the other hand, C-ANF did not increase the length of tibial explants from CNP depleted mice. These results suggest that C-ANF raised local CNP concentration in the growth plate cartilage. We conclude that local CNP clearance system is essential for the regulation of growth promoting effect of CNP-GC-B system in the growth plate.

Involvement of Connexin43 in Interleukin-1 β -induced Osteoarthritis-Associated Changes in Synovial Fibroblasts. C. Nigier, F. D. Howell*, J. P. Stains. Orthopaedics, University of Maryland, Baltimore, MD, USA.

Interleukin-1 beta (IL-1 β), produced by activated synovocytes, has been reported to play a prominent role in the pathology of osteoarthritis (OA). In vivo studies have shown an enhancement in connexin43 (Cx43)-mediated gap junctional intercellular communication between synovial lining cells as one of the changes observed in OA. The purpose of this study is to examine the role that Cx43 plays in the IL-1 β -induced changes in OA-associated gene expression observed in synovial fibroblasts.

We show that treatment of a rabbit synovial fibroblast cell line (HIG-82) with IL-1 β stimulates the synthesis of Cx43 protein in a dose- and time-dependant manner. Additionally, by immunocytochemistry, we observe a large scale redistribution of Cx43 from the cytosol to the plasma membrane, following treatment with 1 ng/ml IL-1 β for 16h. By real time PCR, we detect that IL-1 β treatment or transient transfection of Cx43 in synovial fibroblasts were both effective at increasing gene expression of several OA-associated genes, including matrix metalloproteinases (MMP-1 and -13) and cyclooxygenase-2. Similar results for secreted MMP activity in conditioned media were also observed. Surprisingly, overexpression of Cx43 is as effective, if not more effective, than IL-1 β treatment at inducing the expression and/or activity of OA-associated genes. Thus, it appears that IL-1 β increases Cx43 levels and alters localization, and that this change in Cx43 is sufficient to induce OA-associated gene expression and MMP activity. In order to elaborate on these findings, we examined the signal transduction cascades downstream of IL-1 β treatment. We show that IL-1 β potentially activates the extracellular signal regulated kinase (ERK) cascade. Furthermore, inhibition of the ERK cascade with U0126 abrogates the upregulation of Cx43 expression, the cellular redistribution of Cx43 to the plasma membrane, and the associated changes in gene expression and MMP activity. Importantly, Cx43 overexpression in conjunction with IL-1 β does not synergize to increase transcription of OA-associated genes, nor does Cx43 overexpression potentiate ERK activation by IL-1 β .

Together, our data show that Cx43 is a major target of IL-1 β action on synovial fibroblasts. The data suggest that IL-1 β acts on Cx43 expression and cellular distribution in an ERK-dependent manner, and the subsequent effects of these changes on Cx43 are sufficient to induce OA-associated changes in the phenotype of these cells.

Role of Interleukin-6 Signalling in c-Src-mediated Osteoblast Differentiation. B. Peruzzi*¹, M. Longo*¹, N. Rucci¹, F. De Benedetti*², A. Teti¹. ¹Experimental Medicine, University of L'Aquila, L'Aquila, Italy, ²Ospedale Pediatrico Bambino Gesù, Rome, Italy.

The non-receptor tyrosine kinase c-Src plays unique roles in the regulation of bone cell activity. In osteoblasts (OBs) c-Src maintains an "immature" state in which cell proliferation is very active and further differentiation is inhibited. In a large-scale transcriptome study of mouse primary OBs treated with the c-Src inhibitor PP1, we noted a ~60% expression decrease of the pro-inflammatory cytokine interleukin-6 (IL-6), confirmed by RT-PCR and ELISA assay. Our previous work had shown that NSE/hIL-6 transgenic mice, which have high levels of circulating IL-6, display reduced OB activity, therefore we hypothesized that c-Src and IL-6 could be functionally associated in regulating OB function and that they could contribute to imbalanced bone remodelling in pathologic situations. In a time-course experiment in which we treated mouse primary OBs with PP1, we investigated IL-6 expression and found a time-dependent reduction of IL-6 mRNA in PP1- vs. vehicle-treated OBs, also confirmed at level of secreted protein by ELISA assay. The same result was also obtained in OBs in which c-Src was inhibited by

siRNA treatment for 48 hours and by retroviral infection with a dominant-negative-Src isoform. In order to explain how c-Src inhibition influenced IL-6 expression, we tested the involvement of "Signal Transducer and Activator of Transcription" (STAT) proteins, among which STAT3 is described to drive the transcription of the IL-6 gene and to be a c-Src substrate. In the PP1 time-course experiment we showed that STAT3-phosphorylation at the tyrosine 705 (a c-Src substrate) was decreased following c-Src inhibition, suggesting involvement of this transcription factor in the c-Src-dependent regulation of IL-6 expression. We then tested a possible role for STAT3 on c-Src signalling. We inhibited STAT3 by siRNA and found a reduced c-Src-activating phosphorylation and increased osteoblast differentiation markers. Consistent with our hypothesized IL-6 role, we observed a time-dependent increase of c-Src activating phosphorylation in primary OBs treated with recombinant human IL-6 (rhIL-6) for 1 week. In conclusion, we have obtained evidence of a relevant interplay between c-Src and IL-6 in OB differentiation, partly based on STAT3-dependent transcription.

Characterization of a New Traumatic Mouse Model of Heterotopic Ossification. B. E. Rapuano*¹, A. Grose*², E. Tomin*¹, J. M. Lane*³, D. Helfet*³. ¹Research, Hospital for Special Surgery, N.Y., NY, USA, ²Orthopedics, Upstate Medical Center, Syracuse, NY, USA, ³Orthopedics, Hospital for Special Surgery, N.Y., NY, USA.

Purpose: To develop a physiologically relevant traumatic model of heterotopic ossification (HO) in the mouse, quantify the amount of ectopic bone which forms in the model, and begin to characterize the molecular regulators that mediate the formation of HO.

Methods: Mice from the C57BL/6J strain underwent a surgical procedure in which the quadriceps in recipient mice were subjected to surgical trauma by clamping and bone marrow cells from donor mice were transplanted into a pouch created surgically in the clamped area in recipient mice. Some recipient mice were sacrificed 42 days following surgery, the femurs with attached quadriceps were removed from the operated hindlimbs, and HO was quantified by microCT analysis. Other recipient mice were sacrificed at 2, 7 and 14 days following surgical induction of HO and femur / muscle samples were removed, fixed, embedded in paraffin and sectioned for histology. The expression of bone morphogenetic protein (BMP) 2, 4 and 7 was analyzed immunohistochemically in deparaffinized sections.

Results: HO (1.47 +/- 0.3 mm³; mean +/- S.E.) formed in the quadriceps of all of the operated limbs (12 of 12). Bone mineral density, tissue mineral density and bone volume fraction were 273 +/- 55 mg/cc, 504 +/- 75 mg/cc and 0.42 +/- 0.02, respectively (N = 12 mean +/- S.E.). BMP positive cells were found at the site of tissue injury several weeks before the development of HO.

Conclusions: By transplanting bone marrow containing stromal cells into a site of muscle injury, traumatic HO can be formed reproducibly in an animal model in which putative molecular regulators of the human disorder are expressed prior to the formation of ectopic bone. Therefore, we have developed a new mouse model of traumatic HO that may be more physiologically relevant than previous models that rely on exogenous BMP's or demineralized bone matrix.

Connective Tissue Growth Factor Induces NFAT and Osteoblastogenesis In Vitro. A. Smerdel-Ramoya, S. Zanolli, E. Canalis. Research, Saint Francis Hospital and Medical Center, Hartford, CT, USA.

Connective Tissue Growth Factor (CTGF) is a member of the CCN family of secreted proteins that regulates multiple cellular functions. Previously, we demonstrated that osteoblasts express CTGF, but its role in osteoblastic differentiation and function remains unclear. To define the function of CTGF, ST2 stromal cells were transduced with a retroviral vector expressing CTGF under the control of the cytomegalovirus promoter. Overexpression of CTGF induced osteoblastogenesis, increased mineralized nodule formation, alkaline phosphatase activity and osteocalcin mRNA levels. Although, CTGF can interact with BMPs, it did not enhance the effect of BMP-2 on Smad signaling or the effect of Wnt3a on Wnt/ β -catenin signaling. To investigate alternate mechanisms involved in the osteoblastic differentiation induced by CTGF, we examined CTGF activity on the nuclear factor of activated T cells (NFAT), a transcription factor that cooperates with osterix in the formation of bone. CTGF increased the transactivation of a transiently transfected IL-4-9xNFAT-Luc construct, where 9 repeats of NFAT sites direct luciferase expression. The effect was reduced by FK506, an inhibitor of calcineurin, suggesting that CTGF acts on the calcineurin dependent pathway to activate NFAT. In addition, CTGF increased the transcription of Hes-1, a transcription factor known to regulate osteoblastogenesis and NFAT expression. Down regulation of Hes-1 using RNA interference (RNAi) resulted in a decrease of NFAT activation by CTGF, indicating that the induction of Hes-1 by CTGF explains in part its effect on NFAT transactivation. Although, hes-1 is a Notch target gene, its induction by CTGF cannot be explained by activation of the canonical Notch RBPJk/CSL signaling pathway, since CTGF opposed Notch signaling. Down-regulation of CTGF expression by RNAi suppressed NFAT and Hes-1 transactivation confirming that both, NFAT and Hes-1, are dependent on CTGF expression. In conclusion, CTGF overexpression induces osteoblastic differentiation possibly by enhancing NFAT and Hes-1 signaling.

NOX Expression in Odontoblasts and Cementoblasts of NOS Knock-out Mice. Y. Sugawara, H. Watanabe, T. Yanagisawa*. Ultrastructural Science, Tokyo Dental College, Chiba, Japan.

Reaction systems of nitric oxide (NO) and reactive oxygen species (ROS) are intricately combined and are involved in the control of many cell functions such as tissue homeostasis, as well as tissue damage and diseases. Oral tissues are sensitive to the effects of their gas environment, but there are a few reports on these effects. In this study, we performed the following experiment to evaluate the protein levels of ROS synthetase, superoxide dismutase (SOD), and nitric oxide synthetase (NOS) in the dental pulp, odontoblasts, periodontal ligament and cementoblasts of normal and NOS1 (n-NOS), NOS2 (i-NOS), and NOS3 (e-NOS) knock-out (KO) mice and to clarify the interrelations of the kinetics of various enzymes in the absence of n-, i-, e-NOS. After anesthetizing 5-week-old normal and NOS1, 2, and 3 KO mice, immunohistochemical evaluation were performed using NOXA, NOXA, NQO, and Mn-SOD antibodies. The expression of NOXA, NOXA, and NQO in odontoblasts and cementoblasts were weakly positive in the control mice and strongly positive in the NOS2KO and NOS3KO mice. The Mn-SOD expression in odontoblasts and cementoblasts were weakly positive in the control mice and strongly positive in the NOS2KO and NOS3KO mice. From these results, ROS were considered to be generated by NOX1 in odontoblasts and cementoblasts, and this ROS generation to be affected by i-NOS and e-NOS. Furthermore, as Mn-SOD and NOX were strongly positive in the same areas, increases in ROS are considered to be accompanied by increases in Mn-SOD.

Adiponectin, Anabolic to Bone In Vitro but Negative Effects In Vivo. G. A. Williams*, K. E. Callon*, J. Lin*, M. Watson*, D. Naot*, Y. Wang*, A. Xu*, J. Cornish*, I. R. Reid*. ¹Medicine, University of Auckland, Auckland, New Zealand, ²Genome Research Center, University of Hong Kong, Hong Kong, Hong Kong, ³Medicine, University of Hong Kong, Hong Kong, Hong Kong.

Adiponectin, the most abundant adipose-specific protein, regulates energy homeostasis as well as glucose and lipid metabolism. Adiponectin is reduced in obesity, insulin resistance and type 2 diabetes, and plasma concentrations are inversely related to body weight.

Body weight is an important risk factor for vertebral and hip fractures, ranking in importance alongside that of age. There is now an accepted positive association of fat mass with the secretion of bone active hormones from the pancreatic beta cell and from the adipocyte.

We have investigated the effect of adiponectin on bone cells in vitro as well as to determine the bone phenotype of adiponectin knockout mice. Adiponectin significantly stimulated osteoclastogenesis by 21% at 0.1 µg/mL, but markedly inhibited this process by 26% and 54% at 1 and 5 µg/mL, respectively. It had no effect on bone resorption in the isolated mature osteoclast assays. Adiponectin was dose-dependently mitogenic to primary osteoblasts (24% increase at 5 µg/mL).

Male adiponectin-deficient (Ad-KO) and wild-type (WT) C57BL/6J mice were examined at 8 and 14-weeks of age. We scanned the left proximal tibia using micro-CT at 5µm resolution and analysed bone micro-architecture by 3D analysis. We found significant increases in trabecular bone volume (BV/TV) (15.92±1.63% in Ad-KO vs 12.19±0.72% in WT, p=0.02) and trabecular number (3.20±0.18mm⁻¹ in Ad-KO vs 2.32±0.12mm⁻¹ in WT, p=0.0009) in 14-week old Ad-KO mice compared to controls. Similar differences between WT and Ad-KO were present in 8-week old animals, but these did not reach statistical significance.

Our results demonstrate that although adiponectin can be anabolic in vitro, adiponectin-deficient animals have increased number and volume of trabeculae, indicating that adiponectin is inhibitory to bone accrual in vivo. The latter data concur with the observations from epidemiological studies in humans that adiponectin negatively correlates with both fat mass and bone mass. Therefore, adiponectin may be a contributor to the link between fat and bone mass.

The actions on bone of novel hormones related to nutrition are an important area of further research. An understanding of this aspect of bone biology may open the way for new treatments of osteoporosis. The role of weight maintenance in the prevention of osteoporosis is an important public health message that needs to be more widely appreciated.

EGF-like Ligands Stimulate Osteoclastogenesis by Regulating Expression of Osteoclast Regulatory Factors by Osteoblasts: Implications for Osteolytic Bone Metastases. J. Zhu¹, X. Jia¹, G. Xiao², Y. Kang³, N. C. Partridge¹, L. Qin¹. ¹Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA, ²Medicine, University of Pittsburgh, Pittsburgh, PA, USA, ³Molecular Biology, Princeton University, Princeton, NJ, USA.

Epidermal growth factor (EGF)-like ligands and their receptors constitute one of the most important signaling networks functioning in normal tissue development and cancer biology. In vivo mouse models suggest this signaling network plays an important role in bone metabolism. Previous studies found that EGF stimulates bone resorption in organ cultures but the mechanism was unknown. Here we report that EGF-like ligands stimulate formation of TRAP-positive osteoclastic cells in a coculture system containing bone marrow macrophage and osteoblastic MC3T3-E1 cells. Western blots and [125I]EGF ligand binding experiments revealed that MC3T3-E1 cells express EGF receptor (EGFR) while osteoclasts do not, indicating EGF-like ligands do not function directly on osteoclasts. Conditioned medium from EGF-treated MC3T3-E1 cells generated more multinucleated TRAP-positive osteoclasts in the primary osteoclastic culture than conditioned medium from control-treated MC3T3-E1 cells, suggesting that EGF-like ligands regulate the production of secretory factors from osteoblasts. Using quantitative RT-PCR and ELISA, we identified that EGF-like ligands have no effect on RANKL expression but decrease its decoy receptor osteoprotegerin (OPG) expression and increase monocyte chemoattractant protein 1 (MCP1) expression in both MC3T3-E1 and mouse bone marrow primary osteoblastic cells. MCP1 is a chemokine that recruits osteoclasts and stimulates their fusion. Addition of exogenous OPG completely inhibited osteoclast formation stimulated by EGF-like ligands in the coculture system, while addition of a neutralizing antibody against MCP1 exhibited partial inhibition. Coculture with bone metastatic breast cancer cells, MDA-MB-231, which express significant levels of EGF-like ligands, had similar effects on the expression of OPG and MCP1 in the osteoblastic cells and these effects could be partially abolished by EGFR inhibitor PD153035. In summary, we demonstrate that EGFR signaling stimulates osteoclastogenesis indirectly by regulating OPG and MCP1 expression in osteoblasts. Since a high percentage of human carcinomas express EGF-like ligands, our findings suggest a novel mechanism for osteolytic lesions caused by cancer cells metastasizing to bone.

Glucocorticoid Enhances the Expression of a Wnt Antagonist, Secreted Frizzled-Related Protein 3, in Cultured Human Osteoblasts. K. Ohnaka*, Y. Matsuzaki*, M. Tanabe*, M. Adachi*, H. Kawate*, R. Takayanagi*. ¹Department of Geriatric Medicine, Kyushu University, Fukuoka, Japan, ²Department of Medicine and Bioregulatory Science, Kyushu University, Fukuoka, Japan.

Glucocorticoid-induced osteoporosis (GIO) is one of the most frequent and serious problems of long-term glucocorticoid therapy. Although the major cause of GIO is considered to be impairment of bone formation, detailed mechanism underlying GIO remains to be fully elucidated. Recently, the Wnt signal emerged as a novel key pathway for promoting bone formation. In this study, we investigated the effect of glucocorticoid on a Wnt antagonist, secreted frizzled-related protein (sFRP), in cultured human osteoblasts and an osteosarcoma-derived cell line, MG-63 cells. The expression of mRNA for secreted frizzled-related protein 3 (sFRP3) was markedly induced by dexamethasone among sFRP families. The expression of sFRP3 was also enhanced by hydrocortisone and prednisolone, but not by 17-β estradiol, dehydrotestosterone or 1, 25-dihydroxyvitamin D₃. Similar effect of dexamethasone on sFRP3 expression was observed in MG-63 cells.

To examine the effect of sFRP3 on osteoblast function, we then generated an expression vector containing entire coding region of human sFRP3 cDNA (pcDNA-sFRP3-HA). Transient transfection of pcDNA-sFRP3-HA suppressed the Wnt3a-induced accumulation of cytosolic β-catenin in MG-63 cells. Transfection of sFRP3 also decreased the Tcf/Lef-dependent transcriptional activity in MG-63 cells. Furthermore, sFRP3 suppressed the proliferation of MG-63 cells.

These data suggest that glucocorticoid may impair osteoblast function and bone formation by enhancement of sFRP3 in human osteoblastic cells, which may be involved in the pathogenesis of GIO.

Identification and Functional Involvement of Lipocalin 2 in Glucocorticoid-induced Growth Retardation. H. C. Owen^{*1}, S. F. Ahmed², C. Farquharson¹. ¹Bone Biology Group, Roslin Institute, Edinburgh, United Kingdom, ²Bone and Endocrine Research Group, Royal Hospital for Sick Children, Glasgow, United Kingdom.

Glucocorticoids (GC) are commonly used for immunomodulation and steroid replacement. Long-term use can, however, result in side effects including growth retardation in children. This is thought to be due to their actions on growth plate chondrocytes. To gain an insight into the mechanisms involved in GC-induced growth retardation, we performed Affymetrix microarray analysis of the murine chondrogenic cell line ATDC5, incubated with 10⁻⁶M dexamethasone (Dex) for 24h. Differential expression of selected genes was confirmed by qRT-PCR. Genes confirmed as down-regulated included secreted frizzled-related protein and IGF-I, whilst upregulated genes included serum/GC-regulated kinase, connective tissue growth factor, and lipocalin 2. Lipocalin 2 is an acute phase transport protein which we have shown is expressed in proliferative chondrocytes within the growth plate. In this study, qRT-PCR analysis confirmed that lipocalin 2 gene expression increased in ATDC5 cells by 40-fold after 24h Dex. Expression further increased after 48h (75-fold) and 96h (84-fold) Dex and this response was Dex concentration-dependent. Western blotting confirmed that Dex also increased lipocalin 2 protein expression. The lipocalin 2 response was not blocked by cycloheximide or the p38 inhibitor SB203580, but was blocked by the GC-receptor antagonist RU-486 and the Nuclear-Factor kappa B (NFkB) inhibitor TLCK. The lack of a cycloheximide effect implies a direct action of Dex on lipocalin 2 expression, which is consistent with the presence of a glucocorticoid response-element on the lipocalin 2 promoter. Dex also caused an increase in lipocalin 2 expression in primary murine chondrocytes at 6h (2.5-fold, p<0.05), and this was maintained for up to 72h. Proliferation in ATDC5 cells stably transfected to overexpress lipocalin 2 was slower than control cells (49%, p<0.05) and lipocalin 2 overexpression caused an increase in proteoglycans (66%, p<0.05) and collagen type-X expression (4-fold, p<0.05). Alkaline phosphatase activity and expression was unaffected. The effects of lipocalin 2 overexpression on chondrocyte proliferation (64%, p<0.05) and collagen type-X expression (8-fold, p<0.05) were further exacerbated with the addition of 10⁻⁶M Dex. This synergistic effect may be explained by a further increase in lipocalin 2 expression with 10⁻⁶M Dex in transfected cells (45%, p<0.05). These results suggest that lipocalin 2 may mediate Dex effects on chondrocytes through an NFkB-dependent pathway, and therefore provides a potential novel mechanism for GC-induced growth retardation.

The Temporal Feature of Bone Marrow Fat Cells in the Process of Steroid-Associated Osteonecrosis Development. H. Sheng^{*1}, G. Zhang^{*1}, L. Qin^{*1}, W. Cheung^{*1}, C. Chan^{*1}, Y. Wang^{*2}, H. Wang^{*3}, K. Lee^{*4}, K. Leung^{*1}. ¹Orthopaedics & Traumatology, the Chinese University of Hong Kong, Hong Kong, Hong Kong, ²Diagnostic Radiology and Organ Imaging, the Chinese University of Hong Kong, Hong Kong, Hong Kong, ³Fudan University, Shanghai, China, ⁴Lee Hysan Clinical Research Laboratory, the Chinese University of Hong Kong, Hong Kong, Hong Kong.

The fat volume of bone marrow in steroid-associated osteonecrosis (ON) increases greatly, but the dynamic change of fat cells in the process of ON development is still unknown. This study aimed to explore the time course change of bone marrow fat cells using our established ON model. Thirty-two rabbits were divided into control (n=16) and steroid-treatment group (n=16). Each of group was further divided into the early (n=8) and late group (n=8) in terms of sacrifice time. The rabbits in steroid-treatment groups were injected with once lipopolysaccharide and three times of methylprednisolone to induce ON. The rabbits in control groups were injected with normal saline accordingly. The blood perfusion function of the femoral heads were measured by dynamic contrast magnetic resonance imaging (MRI) at week 0, week 2 and week 4. The rabbits were sacrificed at week 2 and week 4, the bilateral femurs were harvested and processed for bone marrow fat cell density, fat cell diameter and fat cells area percentage analysis histomorphometrically and ON evaluation histopathologically. The dynamic MRI showed the blood perfusion function decreased continuously in steroid-treatment group, the maximum enhancement decreased from 55% in week 2 to 30% in week 4. The ON incidence increased from 25% (2/8) in week 2 to 87.5% (7/8) in week 4. The fat cells area percentage in steroid-treatment early and late group increased by 44% and 83.4% compared with control group. The fat cells density in early and late group increased by 67.1% and 54.4% than control group, but there is no significant difference between the treatment groups; The fat cells diameter in late group was much larger than control group, but the fat cell diameter in early group was smaller than control group; The fat cells size profile showed most of the increased fat cells were small size cells ranging from 30 to 40µm in diameter in early group, but large size cells ranging from 50 to 60µm in the late group. The marrow fat cells featured increase in number of small size fat cells in the early stage and enlargement in size of fat cells in the late stage in ON development. These imply the active adipogenesis in the early stage and excessive lipogenesis in the late stage in the process of steroid-associated ON development. The forming new hypothesis is inhibiting adipogenesis in early stage and decreasing fat cells lipogenesis in late stage would prevent steroid-associated ON development.

Transcription Factor E4bp4 Is Induced by Glucocorticoids and Represses Promoter Activity in Osteoblasts. S. M. Woo^{*1}, I. C. Ozkurt^{*2}, S. Tetradis¹. ¹UCLA School of Dentistry, Los Angeles, CA, USA, ²Ankara University, Ankara, Turkey.

Chronic, systemic use of glucocorticoids (GCs) dramatically inhibits bone formation. GCs mediate their effects by binding to and activating the glucocorticoid receptor to regulate downstream gene expression. GCs profoundly repress osteoblastic genes. However, the molecular mechanisms mediating GC repression of osteoblastic gene expression remain largely unknown. E4bp4, a transcription factor acting as a transcriptional repressor in osteoblasts, is induced by GCs in fibroblasts. Thus, we hypothesize that E4bp4 participates in the GC repression of osteoblastic genes. Here, we study GC-induced E4bp4 gene expression and explore E4bp4 involvement in GC regulated promoter activity in osteoblasts. Calvariae-derived murine osteoblasts (MOBs), calvarial cultures, and 6-8 day old CD-1 mice were treated with Dexamethasone (Dex), and E4bp4 expression was measured by Northern and Western blot assays and quantitative real-time PCR. Protein-DNA binding was evaluated by electrophoretic mobility shift assays and promoter activity by luciferase assays. MOBs were infected in vitro with an adenovirus overexpressing E4bp4, and transcriptome profiling was completed using the Affymetrix GeneChip 430A 2.0 Mouse Array and GeneSifter microarray analysis software. Dex increased E4bp4 mRNA and protein expression that peaked at 4-6 h and 1µM Dex, with elevated levels even at 24 h. Pre-treatment with the protein synthesis inhibitor cycloheximide did not prevent E4bp4 induction, showing that E4bp4 is a Dex-induced primary response gene. Nuclear proteins from MOBs treated with Dex specifically bound the E4bp4 response element (EBPRE), but not mutated EBPREs. Co-incubation with E4bp4-specific antibodies showed that the Dex-induced EBPRE-bound nuclear proteins contained E4bp4 protein. Furthermore, Dex treatment attenuated activity of a chimeric promoter containing three tandem repeats of wild-type but not mutant EBPRE, suggesting that E4bp4 protein mediates promoter repression by Dex. Adenoviral-mediated E4bp4 overexpression upregulated 415 and downregulated 337 genes more than 1.8 fold. Gene ontology (GO) grouping summarized the molecular function, biological process, and cellular component of regulated genes. Interesting GO groups with z-score >2 included multicellular organismal development, cell surface receptor linked signal transduction, extracellular space, extracellular matrix, receptor binding, and receptor activity. We are currently investigating direct regulation of individual genes by both GCs and E4bp4. These results support a role of E4bp4 in mediating glucocorticoid-induced gene repression in osteoblasts.

A Novel Mechanism of Glucocorticoid Action-Inhibition of Cox-2 Transcription by Glucocorticoid Induced Leucine Zipper (GILZ). N. Yang^{*}, X. Shi. Institute of Molecular Medicine & Genetics, Medical College of Georgia, Augusta, GA, USA.

Cyclooxygenase-2 (COX-2) plays an important role in rheumatoid arthritis (RA) and therefore, it has been a major target for anti-arthritis therapies. The expression of COX-2 is induced by inflammatory cytokines such as TNF-α and IL-1β, and inhibited by glucocorticoids (GCs). However, the molecular mechanisms underlying the anti-inflammatory and immune suppressive actions of GCs are not well defined. Importantly, long-term GC therapy causes, among other adverse effects, rapid bone loss resulting in osteoporosis, therefore, their use is limited. Here we report that a recently identified GC-inducible protein, GILZ, mimics GC action and inhibits inflammatory cytokine-induced COX-2 expression in bone marrow mesenchymal stem cells (MSCs), the cells that have been recently implicated in the pathogenesis and progression of RA. Using a retrovirus-mediated gene expression approach we demonstrate that overexpression of GILZ inhibits TNF-α and IL-1β-induced COX-2 mRNA and protein expression and knockdown of GILZ by shRNAi abolishes GC inhibition of cytokine-induced COX-2 expression. Consistent to these results, overexpression of GILZ also inhibits NF-κB- and AP-1-mediated COX-2 promoter activity. Finally, we show that GILZ inhibits COX-2 expression by blocking NF-κB nuclear translocation and by inhibiting AP-1 binding to the COX-2 promoter region. Our results suggest that GILZ is a key GC effect mediator and that GILZ may have pharmacotherapeutic value for novel anti-inflammation therapies.

Glucocorticoid Excess in Mice Leads to Early Activation of Osteoclastogenesis and Prolonged Suppression of Osteogenesis Through Gene Expression Profiling. W. Yao, Z. Cheng, C. Busse*, S. Rao*, N. Lane. Center for Healthy Aging, UC Davis Medical Center, Sacramento, CA, USA.

Glucocorticoid (GC) excess induces alterations in bone metabolism that weakens bone structure. We performed genome-wide cDNA microarray on whole bone RNA (Affymetrix Mouse Genome 430 2.0 array) to identify genes associated with bone metabolism in GC-treated mice. Long bones from mice exposed to GC excess were collected at 0, 3, 7, 28 and 56 days (5mg prednisolone 60-day slow release pellet, n=8-12/group). The success of this animal model was confirmed by changes in bone turnover markers as well as bone microarchitecture measured by microCT. Differences in gene expression with time were calculated by unequal-variance ANOVA with a threshold of > 2fold and $p < 0.01$. The significantly expressed 1179 transcripts were then further grouped by Gene Functions using GeneShifter Software. Quantitative real-time PCR was performed on selected genes to confirm microarray results.

Results: Compared to placebo treated mice, GC-treated mice lost trabecular bone volume at the distal femur (16% by d28 and was unchanged at d56). Serum measurements of osteoclast maturation, TRAP5b, increased by 18% at d7 and d28, and increased by 15% at d56; and osteoblast maturation, osteocalcin decreased by 50% from d28-d56. Compared to placebo treated mice, GC excess was associated with increased expression of genes involved with osteoclast activation (csf1, c-fms, c-fos, adam8, Trem2, Oscar, Nfatc1) that peaked at d7; osteoclast cytoskeleton reorganization (β 3, Ibsp, c-src, vav3, ATPase) and genes associated with matrix degradation peaked at d28 (cathepsins, mmps and proteases). At d28 and d56, genes associated with osteoblast activation and function had decreased expression (BMPs 2,5, 8, 12, 13, TGF β 1) and Wnt inhibitors such as Wif1, Dkk1 and Sost had increased expression compared to placebo treated animals. In addition, with GC excess, genes expressed by osteocytes and associated with bone mineralization, DMP1 and PheX, had increased expression at d28 and d56. RT-PCR confirmed our microarray findings in selected genes.

In conclusion, GC excess is associated with early activation of osteoclastogenesis and delayed but prolonged suppression of osteogenesis and matrix mineralization. These rapid and sustained alterations in bone cells maturation and activity help to explain the significant deterioration in bone strength in the presence of GCs.

Osteoblast-Targeted Disruption of Glucocorticoid Signalling Delays Intramembranous Bone Development In Vivo. H. Zhou, W. Mak, Y. Zheng, C. R. Dunstan, M. J. Seibel. Bone Research Program, ANZAC Research Institute, University of Sydney, Sydney, Australia.

Transgenic (tg) expression of 11 β -hydroxysteroid dehydrogenase type 2 (HSD2), a glucocorticoid (GC) inactivating enzyme, under the control of a 2.3kb collagen type I promoter (Col2.3-HSD2) abrogates intracellular GC signalling in mature osteoblasts. Adult Col2.3-HSD2 tg mice exhibit a mild osteoporotic phenotype but the skeleton otherwise appears normal (1). To investigate the effects of osteoblast-targeted disruption of GC signalling on early skeletal development, calvaria and tibiae of wild-type (WT) and Col2.3-HSD2 tg mice aged 0, 1, 7, 10 and 14 days were analysed.

HSD2 mRNA and protein expression was present in the calvaria and long bones of tg mice but absent in the bones of WT mice. Calvaria from tg mice demonstrated a markedly altered phenotype: compared to their WT littermates, tg mice had poorly formed parietal bones with large amounts of cranial cartilage still present at day 0. A similar picture was seen at day 1, with the extent of parietal bones being reduced by 33% relative to WT mice. The cranial cartilage plate was present in all tg mice but absent in WT mice. In 7-day old mice, the cranial cartilage plate was reduced in size but still present in tg animals, but formation of parietal bones was complete and bone area was similar to WT mice. Calvaria appeared normal at 2 weeks of age. Immunohistochemical analyses showed reduced protein expression of MT1-MMP, an enzyme essential for calvarial cartilage removal in the cranial cartilage of tg mice. TUNEL staining indicated reduced chondrocyte apoptosis. In contrast, no phenotype was observed in the long bones (tibiae) of tg mice.

Our results indicate that osteoblast-targeted disruption of GC signalling results in delayed calvarial (intramembranous) development, without affecting the (endosteal) formation of long bones. These findings further suggest that in neonatal mice, osteoblasts regulate

cranial cartilage removal, a function that appears to be GC-dependent and mediated through activation of chondrocytic MT1-MMP expression. Our studies point to a novel role for both GC and osteoblasts in intramembranous bone development.

Transgenic Disruption of Glucocorticoid Signalling in Mature Osteoblasts Attenuates KRN Serum-induced Arthritis In Vivo. H. Zhou¹, F. Buttgeriet², T. Gaber², R. Kalak³, R. Dragovic¹, D. Huscher², R. H. Straub³, J. Modzelewski⁴, C. R. Dunstan¹, M. J. Seibel¹. ¹Bone Research Program, ANZAC Research Institute, Sydney, Australia, ²Dept. of Rheumatology & Clinical Immunology, Charité (CCM) and DRFZ, Berlin, Germany, ³Dept. of Internal Medicine I, University Hospital, Regensburg, Germany, ⁴Dept. of Endocrinology & Metabolism, Concord Hospital, Sydney, Australia.

Transgenic (tg) overexpression of 11 β -hydroxysteroid dehydrogenase type 2 (HSD2), a glucocorticoid (GC) inactivating enzyme under the control of a 2.3Kb collagen type I promoter (Col2.3-HSD2), abrogates intracellular GC signalling exclusively in mature osteoblasts. Since GC are important immune modulators, we investigated the impact of osteoblast-targeted disruption of GC signalling on joint inflammation and bone catabolism using the KRN serum transfer model of autoimmune arthritis.

KRN arthritis was induced in 5-week-old male Col2.3-HSD2-tg mice (tg-KRN, n=28) and their wild-type (WT) littermates (WT-KRN, n=27). Twelve tg and 13 WT mice served as controls (CTR) receiving either normal serum or PBS. Body weight and paw swelling (ankle size, clinical arthritis, scored 0-6) were assessed daily from induction (day 0) to day 14. Serum levels of IL-1 β , IL-2, IL-4, IL-6, IL-10, IL-12, TNF- α , IFN- γ , G-CSF, M-CSF and corticosterone (CS) were determined in CTR, and in KRN animals on days 7 and 14. Micro-CT of the tibia and the paw skeleton was employed to assess for morphological changes.

Both tg-KRN and WT-KRN developed acute arthritis. However, the inflammatory response was significantly blunted in tg mice from day 7 onwards (Fig. 1). Compared to CTR, tibia bone volume (BV/TV) was significantly reduced in WT-KRN but not in tg-KRN on day 14. As compared to day 7, mean serum M-CSF levels were significantly lower on day 14 in tg-KRN but not in WT-KRN. Compared to CTR, serum TNF- α , IL-6 and IL-12 levels were significantly lower in tg-KRN on day 14. However, there were no differences in cytokine or CS levels between tg-KRN and WT-KRN at any time point, suggesting that in HSD2-tg mice the inflammatory process was attenuated through local mediators.

We conclude that osteoblasts are able to significantly modulate local inflammatory responses via a glucocorticoid-dependent pathway.

Regulation of Oxidative Stress and Osteoblast Apoptosis by Estrogens Is Preserved in Mice in which the ER Cannot Directly Interact with DNA. M. Almeida, M. Martin-Millan*, L. Han, A. Warren*, V. Lowe*, R. S. Shelton*, A. DeLoose*, R. S. Weinstein, T. Bellido, C. A. O'Brien, R. L. Jilka, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

To investigate the role of the ER α , and in particular its non-ERE-mediated signaling, in skeletal homeostasis we have crossed knock-in mice in which classical ER α signaling through ERE sites has been selectively eliminated while preserving non-classical signaling (ER $\alpha^{\text{NERK1-/-}}$), with heterozygous mice of the ER α gene, to generate ER $\alpha^{\text{NERK1-/-}}$ mice. We report that 17 β -estradiol (E $_2$) at 10 $^{-8}$ M stimulated apoptosis of mature osteoclasts in bone marrow cultures from ER $\alpha^{\text{NERK1-/-}}$ mice as effectively as in cultures from wild-type control mice. Likewise, E $_2$ prevented etoposide-induced apoptosis in osteoblastic cultures derived from calvaria of either type of mouse. In agreement with the in vitro data, ovariectomy (ovx) upregulated osteoclastogenesis in wild type as well as in ER $\alpha^{\text{NERK1-/-}}$ mice as measured in ex vivo bone marrow cultures. OvX also caused an increase of osteoblast apoptosis in ER $\alpha^{\text{NERK1-/-}}$ and wild-type mice; and E $_2$ replacement prevented the phenomenon in both. Further, ovx led to an increase in reactive oxygen species (ROS) levels and a decrease in glutathione reductase activity in the bone marrow; as well as an increase in the phosphorylation of p66 $^{\text{shc}}$ (a key component of a signaling cascade that is activated by ROS and stimulates apoptosis) in vertebral lysates from both wild-type controls and ER $\alpha^{\text{NERK1-/-}}$ mice. E $_2$ replacement prevented all these changes in both type of mice. Lastly, there was a progressive decrease in baseline BMD in the femur and spine from ER $\alpha^{+/+}$, to ER $\alpha^{+/-}$, to ER $\alpha^{\text{NERK1-/-}}$, to ER $\alpha^{\text{NERK1-/-}}$ mice. Moreover, ER $\alpha^{\text{NERK1-/-}}$ mice exhibited a decrease in bone size and osteoblastogenesis as measured by the number of colony forming units-osteoblasts in ex vivo bone marrow cultures; as well as a decrease in osteocalcin levels in the serum. These results strongly suggest that the antioxidant properties of estrogens, as well as their ability to control osteoblast and osteoclast apoptosis and osteoclastogenesis do not require classical DNA binding of the ER α ; and are consistent with evidence that trabecular (but not cortical) bone mass remains estrogen responsive in the ER $\alpha^{\text{NERK1-/-}}$ mice. The decrease in bone size, BMD and osteoblastogenesis in the ER $\alpha^{\text{NERK1-/-}}$ mice may be explained by evidence presented elsewhere in this meeting that the unliganded wild type ER α (presumably through its ability to bind directly to DNA) is a co-activator of BMP-induced osteoblastogenesis and thereby bone formation and growth during development.

Disclosures: M. Almeida, None.

Estrogens or Androgens Attenuate p66 $^{\text{shc}}$ Phosphorylation via an ERK and PKC β Signaling Cascade: a Critical Mechanism of their Protective Effects Against Oxidative Stress and Bone Loss. M. Almeida, M. Martin-Millan, L. Han, A. Warren*, V. Lowe*, T. Bellido, R. L. Jilka, C. A. O'Brien, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Phosphorylation of the adapter protein p66 $^{\text{shc}}$ is not only required for transduction of oxidative stress signals leading to apoptosis but also amplifies such stress by generating reactive oxygen species (ROS) in the mitochondria. Based on this and evidence that ovariectomy (ovx) or orchidectomy of 5 month-old C57BL/6 mice increases the phosphorylation of p66 $^{\text{shc}}$ in vertebral lysates, while replacement with 17 β -estradiol (E $_2$) or DHT prevent this phenomenon as effectively as the antioxidant N-acetyl-L-cysteine (NAC), we have investigated the molecular basis of the effects of sex steroids on p66 $^{\text{shc}}$. We report that exposure of several osteoblastic cell lines as well as primary cultures of calvaria osteoblasts to H $_2$ O $_2$ stimulated the phosphorylation of p66 $^{\text{shc}}$ within 5 min, and that pre-treatment of all these cells for 1 h with either E $_2$ or DHT prevented this effect. Further, overexpression of p66 $^{\text{shc}}$ in C2C12 cells induced apoptosis both under basal condition and in the presence of H $_2$ O $_2$. The suppressive effect of sex steroids on H $_2$ O $_2$ -induced phosphorylation of p66 $^{\text{shc}}$ was inhibited by the ERK-specific inhibitor PD98059 indicating that this is a kinase-mediated action of the ER. Consistent with this finding E $_2$ inhibited the pro-apoptotic effect of H $_2$ O $_2$ as well as p66 $^{\text{shc}}$ phosphorylation in calvaria derived osteoblast cultures from ER $\alpha^{\text{NERK1-/-}}$ mice, a knock-in mouse mutant of the ER α that lacks classical DNA binding on ERE elements. Moreover, the increase in osteoblast apoptosis and p66 phosphorylation in the vertebra following ovx was suppressed by E $_2$ replacement in both wild-type and ER $\alpha^{\text{NERK1-/-}}$ mice. To further dissect the mechanism by which sex steroids antagonize p66 $^{\text{shc}}$ phosphorylation induced by oxidative stress we searched for and found that PKC β activity was required for H $_2$ O $_2$ -induced p66 $^{\text{shc}}$ phosphorylation, as it was blocked by the specific PKC β inhibitor hispidin. Furthermore, activation of PKC by PMA induced p66 $^{\text{shc}}$ phosphorylation and stimulated apoptosis in C2C12 cells; and both effects were prevented by hispidin. Finally, both phosphorylation of p66 $^{\text{shc}}$ as well as apoptosis induced by PMA were prevented by E $_2$ suggesting that modulation of PKC β activity might mediate the anti-apoptotic effects of sex steroids in osteoblastic cells. These results strongly suggest that sex steroids attenuate osteoblast apoptosis induced by oxidative stress by modulating a cascade of cytoplasmic kinases culminating with inhibition of p66 $^{\text{shc}}$ phosphorylation.

Disclosures: M. Almeida, None.

Estrogens Attenuate IL-6, and TNF α Production in Osteoblastic Cells by Decreasing Oxidative Stress and its Effects on NF κ B Activation. M. Almeida, L. Han, M. Martin-Millan, V. Lowe*, A. Warren*, R. L. Jilka, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Reactive oxygen species (ROS) may play a critical pathogenetic role in osteoporosis, and the anti-osteoporotic effect of estrogens may result from the ability of these hormones to protect against oxidative stress. Indeed both aging and estrogen deficiency increased oxidative stress in the bone of both male and female C57BL/6 mice as well as the number of osteoclast progenitors in the bone marrow. Based on this and the well known relationship among IL-6, TNF α , osteoclastogenesis, and estrogens we tested the hypothesis that estrogens exert their anti-osteoclastogenic effects by enhancing defense against ROS. We report that increasing levels of ROS, decreasing GSR activity, and increasing phosphorylation of p66 $^{\text{shc}}$ between 8 and 31 month of age in C57BL/6 female mice were temporally associated with a progressive increase in the expression of the osteoclastogenic cytokines TNF α and IL-6, as measured by RT-PCR in calvaria. Consistent with the notion that the in vivo changes in oxidative stress and cytokine production were causally related, H $_2$ O $_2$ up-regulated the expression of both TNF α and IL-6 in cultures of the UAMS32 osteoclast supporting stromal cell line. And, 17 β -estradiol (E $_2$) at 10 $^{-8}$ M potentially attenuated the effects of H $_2$ O $_2$ on the production of both cytokines. In line with this finding, H $_2$ O $_2$ strongly activated NF κ B within 1 h, as determined by the phosphorylation of the NF κ B inhibitor kinase I κ B, by Western blot. Consistent with the inhibitory effect of E $_2$ on the expression of IL-6 and TNF α upon H $_2$ O $_2$ stimulation, pre-treatment with E $_2$ for one hour abrogated the effect of H $_2$ O $_2$ on NF κ B activation. Finally, to determine whether the increase in osteoclastogenesis that follows estrogen deficiency is mediated by the anti-oxidant actions of estrogen, we treated ovx mice with E $_2$ or the anti-oxidant N-acetyl-L-cysteine (NAC). NAC was as effective as E $_2$ in preventing the increase in the number of osteoclast progenitors as determined by ex vivo bone marrow cultures. Consistent with this, administration of L-buthionine-(S,R)-sulfoximine (BSO), a specific inhibitor of glutathione synthesis, for 6 weeks, or the oxidant-producing herbicide paraquat for 4 weeks, to 5 month-old C57BL/6 mice increased both ROS levels as well as the number of osteoclast progenitors in the bone marrow. Taken together with evidence that estrogens directly suppress p66 $^{\text{shc}}$ phosphorylation, presented elsewhere in this meeting, these results suggest that estrogens attenuate IL-6 and TNF α production in stromal/osteoblastic cells by decreasing oxidative stress and its effects on NF κ B activation.

Premenopausal Women with Short Luteal Phase Length Have Reduced vBMD, but Normal Bone Bending Strength at the Tibial Midshaft. B. C. Kaufman*¹, R. J. Wetzsteon¹, M. S. Kurzer*², J. C. Prior*³, M. A. Petit¹. ¹Kinesiology, University of Minnesota, Minneapolis, MN, USA, ²Food Science and Nutrition, University of Minnesota, Minneapolis, MN, USA, ³Vancouver General Hospital, Vancouver, BC, Canada.

Progesterone is hypothesized to have an important influence on bone metabolism, which could influence bone health in women with a shortened luteal phase. The purpose of this cross-sectional study was to explore the relationship between luteal phase length (LPL) and bone parameters in healthy, sedentary, pre-menopausal women. We used baseline data from a subset of women (n = 32, aged 18-30yr; mean BMI = 22.9 \pm 3.1) enrolled in a study of physical activity and ovulation (WISER). Menstrual cycle characteristics were assessed by questionnaire and confirmed with ovulation kits over 5 menstrual cycles. Volumetric bone mineral density (vBMD, mg/mm 3), bone geometry (Total Area), and estimated bone strength (polar strength strain index, SSI) were assessed by pQCT (XCT 3000) at a distal (8%) and midshaft (50%) site of the left tibia. Participants were split into two groups based on average luteal phase length of < 10.9d (short LPL, n = 12) or > 11.0d (normal LPL, n = 20). Groups were similar in age, height, weight, %fat and %lean mass. There were also no differences between groups in physical activity (assessed by questionnaire), total calorie intake (from 3d food records), or average menstrual cycle length (29 and 30d respectively). At the tibial midshaft, total vBMD was significantly lower (-5.9%, p = 0.005) in the women with short LPL, while total bone area was significantly higher (+13%, p = 0.013) resulting in a non-significant difference in SSI between groups (p > 0.05). Similar trends were seen at the distal site, but differences in bone parameters were not significant. Results remained significant after adjusting for tibial length and body weight. These data suggest that sedentary women with shortened luteal phase length may have reduced vBMD that seems to be compensated for by increased bone area, resulting in bone bending strengths similar to sedentary women with normal luteal phase length at the tibial midshaft.

Disclosures: B.C. Kaufman, None.

Identification of Primary Target Cells for the Classical Genomic Effects of Estrogen and Raloxifene in Bone. C. Håkansson^{*1}, P. T. van der Saag^{*2}, J. Å. Gustafsson^{*3}, H. Carlsten^{*1}, C. Ohlsson⁴, M. K. Lagerquist⁴. ¹Dept. of Rheumatology and Inflammation Research, Inst. of Medicine, Gothenburg, Sweden, ²Hubrecht Lab., Netherlands Inst. for Developmental Biology, Utrecht, The Netherlands, ³Dept. of Bioscience at NOVUM, Karolinska Institute, Huddinge, Sweden, ⁴Dept. of Internal Medicine, Inst. of Medicine, Gothenburg, Sweden.

Estrogen, as well as the selective estrogen receptor modulator raloxifene, has bone protective effects, but the mechanism behind these effects is still not completely characterized. Recently, immune cells in the bone marrow have been implicated to be involved in estrogenic effects on bone. The aim of this study was to identify primary target cells in bone marrow for the classical genomic effects of estrogen and raloxifene in an attempt to clarify the mechanism behind the bone protective effects of these compounds. For this purpose we have used a reporter mouse with a luciferase reporter gene under the control of three estrogen-responsive elements (EREs). These mice enable detection of in vivo activation of gene transcription via binding of estrogen receptors (ERs) to ERE-elements. Three-month-old ovariectomized (ovx) mice were given a single dose of 17 β -estradiol (E2) (50 μ g/kg, s.c.) or the raloxifene-analog LY117018 (3mg/kg, s.c.) and the experiment was ended after 10h. The doses were chosen because of their equipotent effects on bone mass.

Bone marrow was flushed from femur and sorting of various cell populations was performed using FACSaria, resulting in cell populations with >95% purity. In total bone marrow, E2 increased luciferase activity to 12000 RLU/10⁶ cells and raloxifene to 700 RLU/10⁶ cells (p<0.01). In the B cell fraction (CD19⁺ cells), E2 increased luciferase activity slightly (1600 RLU/10⁶ cells), while raloxifene had no effect. No effect of either E2 or raloxifene was found in the T lymphocyte or the granulocyte population, while the cell fraction lacking both lymphocytes and granulocytes exhibited the greatest luciferase activity/10⁶ cells (40000 RLU for E2 and 6000 RLU for raloxifene). In conclusion, neither lymphocytes nor granulocytes are primary targets for the classical genomic effects of E2 or raloxifene in bone marrow. Furthermore, raloxifene can activate gene transcription via ER binding to EREs in the bone marrow, but not to the same extent as E2 at doses that give equipotent effects on bone mass.

Estrogen Receptors in Adolescent Idiopathic Scoliosis (AIS). D. Leboeuf^{*1}, K. Letellier^{*2}, B. Azeddine^{*2}, G. Grimard^{*3}, S. Parent^{*3}, H. Labelle^{*3}, A. Moreau⁴, F. Moldovan^{*4}. ¹Sciences Biomédicales, Université de Montréal, Montréal, PQ, Canada, ²Biologie Moléculaire, Université de Montréal, Montréal, PQ, Canada, ³Hôpital Sainte Justine, Montréal, PQ, Canada, ⁴Centre de Recherche de l'Hôpital Sainte Justine, Montréal, PQ, Canada.

AIS occurs and progresses during puberty, a period greatly influenced by hormones. This, and the fact that most severe cases of scoliosis affect girls, points to a possible role for estrogens in the onset and the progression of AIS. Estrogen signaling occurs mainly via two nuclear receptors, ER α and ER β . Here we investigate the expression of ER α and ER β in AIS and control (trauma) patients. RNA extracted from osteoblasts of AIS and control patients was investigated by RT-PCR using primers covering all 4 domains of ER α and ER β (protein-protein interaction, hinge, ligand-binding and DNA binding domains). In addition, ER α and ER β were detected by immunohistochemistry on spinal biopsy tissues and on osteoblasts exposed in vitro to 17 β -Estradiol.

All AIS patients (n=10, age=14 \pm 2.02, Cobb=59.37 \pm 20.9) and controls (n=8, age=14.7 \pm 3.0,) show transcripts of many isoforms of ER α . However, the expression of ER β varied between patients and controls, and results suggest the presence of various isoforms in human osteoblasts. We also identified by sequencing an insert specific to isoform h-ER β S1, in 6/10 AIS patients and 8/8 controls. Immunohistochemistry revealed high levels of ER α and low levels of ER β . Finally, osteoblasts of AIS patients exposed to 17 β -Estradiol show increased nuclear expression of ER α , which was not observed in control osteoblasts. It is already known that ER α and ER β have overlapping roles in regulating growth and differentiation of bone tissues. However, ER β is the dominant receptor in many ER-dependent signaling pathways in bone cells, and some isoforms exhibit an antagonistic effect on ER-mediated transcriptional activity. Surprisingly, the level of ER β was very low in AIS cells, compared to ER α . In addition, the lack of the isoform h-ER β S1 in some AIS patients, as well as the altered balance between ER α and ER β , appears to be critical for estrogen-dependent functions of osteoblasts, which could impact bone homeostasis and lead to decreased bone mineral density and osteopenia in AIS.

The Unliganded ER α or β , but not the AR, Potentiates BMP-induced Transcription and Osteoblastogenesis. M. Martin-Millan, L. Han, A. Warren^{*}, V. Lowe^{*}, C. A. O'Brien, M. Almeida, S. C. Manolagas. Center for Osteoporosis and Metabolic Bone Diseases, University of Arkansas for Medical Sciences and Central Arkansas Veterans Healthcare System, Little Rock, AR, USA.

Whereas estrogens suppress osteoblastogenesis and estrogen loss increases it, female or male mice with ubiquitous ER α deletion (ER α ^{-/-}) exhibit decreased osteoblast number and bone formation rate. Based on this and recent evidence for distinct roles of the unliganded versus liganded ER in the transcriptional repression of the TNF gene, we have tested the hypothesis that the ER may have two opposite effects in osteoblast generation: attenuation in the presence of 17 β -estradiol (E₂) and potentiation in the absence of E₂. We report that E₂ at 10⁻⁷ to 10⁻⁸ M suppressed BMP-2-induced osteoblast progenitor commitment and differentiation in two cell lines, the uncommitted mesenchymal C2C12 and the pre-osteoblasts 2T3, as well as in primary cultures of murine bone marrow, as measured by alkaline phosphatase (AP) activity. Consistent with a suppressive effect on osteoblastogenesis, E₂ also attenuated BMP-2-induced osteocalcin secretion, as well as the expression of the BMP-2 responsive gene Smad6. Importantly, ER α co-immunoprecipitated with Smad1 and Smad4 in all these cell models. Further, treatment of C2C12 or 2T3 cells with ICI182,780 (10⁻⁷ M), an antagonist of ER that promotes its degradation, also attenuated BMP-2-induced AP activity, osteocalcin secretion and the expression of Smad6. In support of the contention that the inhibitory effect of ICI on osteoblastogenesis was indeed due to ER degradation, silencing ER α in C2C12 cells using specific siRNA oligonucleotides abrogated AP activity induced by BMP-2. In agreement with these observations, transfection of C2C12 cells with increasing amounts of plasmids encoding the ER α or the ER β , dose-dependently increased BMP-induced transcription, as measured by a Smad6-luciferase reporter construct. This effect was also evident in cultures not treated with BMP, indicating that the unliganded ER α or β potentiated the effect of both endogenous as well as exogenous BMPs. Transfection with the same amounts of a plasmid expressing the androgen receptor had no effect on basal or BMP-stimulated transcription of the reporter construct. These findings strongly support the hypothesis that the unliganded ER stimulates BMP target genes, perhaps by acting as a co-activator of Smads, and that binding of E₂ antagonizes this effect. Opposite effects of the unliganded versus the liganded ER on osteoblastogenesis can explain why, in spite of the well-known suppressive effect of estrogens on osteoblastogenesis as well as osteoclastogenesis, and thereby on remodeling, bone formation is decreased in mice with ER α deletion.

Serum Testosterone in Elderly Men Measured by Liquid Chromatography-Tandem Mass Spectrometry and Radioimmunoassay: Concordance and Effect on Epidemiologic Association. T. V. Nguyen¹, C. Meier², D. J. Handelsman^{*3}, M. Kraenzlin², M. M. Kushnir^{*4}, A. L. Rockwood^{*4}, A. W. Meikle^{*5}, J. R. Center⁶, J. A. Eisman⁶, M. J. Seibel². ¹Bone and Mineral Research Program, Garvan Institute of Medical Research, St Vincent's Hospital and UNSW, Darlinghurst, NSW, Australia, ²Bone Research Program, ANZAC Research Institute, Concord, NSW, Australia, ³Andrology, ANZAC Research Institute, Concord, NSW, Australia, ⁴ARUP Institute for Clinical and Experimental Pathology, Salt Lake City, UT, USA, ⁵Department of Medicine and Pathology, University of Utah, Salt Lake City, UT, USA, ⁶Bone and Mineral Research Program, Garvan Institute of Medical Research, St Vincent's Hospital and UNSW, Darlinghurst, NSW, Australia.

Serum testosterone (T) is used as a measure to define androgenic status and its association with health outcomes. Established radioimmunoassays (RIA) have been used to measure T; however, liquid chromatography-tandem mass spectrometry (MS) has increasingly become a reference method for measuring T. The present study assessed the concordance between T measured by RIA and MS, and the effect of this concordance on the association between serum T and fracture risk in men.

T was measured by direct RIA (RIA-T; Delphia, Perkin-Elmer) and liquid chromatography-tandem mass spectrometry (MS-T) in 593 men aged 60+ years, who had participated in the Dubbo Osteoporosis Epidemiology Study between 1989 and 2005. Low-trauma fractures were recorded during the study period. The concordance between the two methods of measurement was assessed by the coefficient of concordance and the limit of agreement method. The association between each measured T and fracture risk was analyzed within the framework of the Cox's proportional hazards model.

The coefficient of concordance between RIA-T and MS-T was 0.67 (p18 pmol/L). RIA-T tended to underestimate MS-T by 25%. In the Cox's model, each SD of log MS-T was significantly associated with fracture risk (hazard ratio [HR] 1.37; 95% CI: 1.15, 1.6), which was slightly higher than the association between log RIA-T and fracture risk (HR: 1.19; 95% CI: 1.02, 1.40).

These data suggest that there was a modest concordance between MS-T and RIA-T, with minor effects on the assessment of associations between serum T and fracture in epidemiologic studies in men.

Down-Regulation of Klotho Protein Expression by Estrogen. O. K. Oz¹, A. Hajibeigi¹, W. Siyambalapitiyage¹, K. Korach², M. Kuro-o³. ¹Radiology, UT Southwestern Medical Center at Dallas, Dallas, TX, USA, ²NIEHS, NIH, Research Triangle Park, NC, USA, ³Pathology, UT Southwestern Medical Center at Dallas, Dallas, TX, USA.

Klotho is a glycoprotein predominantly expressed in distal tubules cells of kidney. Low klotho gene expression in mice leads to multiple disorders, such as arteriosclerosis, skin atrophy, abnormal calcium homeostasis and shortened life span. More recently klotho has been shown to regulate activity of the calcium channel TRPV5 in the kidney. Estrogens are also regulators of calcium homeostasis. In this study we investigated a potential regulatory role for estradiol in klotho expression. The effect of estradiol treatment on klotho expression in vitro was tested in the renal tubule cell line MDCK grown in estrogen depleted (charcoal stripped) or repleted serum. Lysates of the treated cells were prepared and klotho expression quantified by western blot (WB). To determine the effects of estrogen in vivo, we used wild type (WT), aromatase deficient mice (ArKO), and ArKO mice treated with estradiol (20ug/mouse 3x/week) or vehicle for 3 weeks. RNA and protein were prepared from the kidneys for real time PCR and WB analysis, respectively. MDCK cells grown in charcoal stripped FBS (csFBS) showed higher klotho protein expression than cells grown in 10%FBS. However, klotho expression in cells grown in 10% csFBS supplemented with 10(-5)M and 10(-8)M estradiol was decreased to the same level as cells grown in 10%FBS. Kidneys from ArKO mice showed significantly higher expression of klotho, both at the mRNA and protein levels in ArKO animals compared to WT and estrogen treated ArKO mice. Similarly, protein extracts from estrogen receptor alpha knockout mice kidneys showed higher klotho levels than WT extracts. Based on these observations we conclude that estrogen, acting through ERalpha, down-regulates the klotho protein in the mouse kidney.

High Dose Estrodiol Treatment Causes Destruction of Cortical Bone and Is Associated with an Increased Death Rate in Old Wild Type and ERKO Male Mice. Z. Peng¹, P. Härkönen², K. Väänänen³. ¹Pharmatest Services Ltd, Turku, Finland, ²Department of Laboratory Medicine, Tumor Biology, Lund University, Malmö, Sweden, ³Department of Anatomy, University of Turku, Turku, Finland.

Estrogen plays an important role in maintaining bone mass in males as well as in females. The purpose of this study was to learn how estradiol and testosterone treatments influence bone metabolism in very old ERKO male mice. Sham-operated or orchidectomized (ORC) 10-25 mo old ERKO mice and their wild type (WT) littermates were implanted with a pellet of testosterone (Te) (0.21mg/mouse/day), or estradiol (E₂) (3µg/mouse/day or 12µg/mouse/day) and sacrificed after 4 weeks. Bone analysis of the animals showed that ORC decreased the tibial and femoral ash weight of WT mice, which was reversed by Te treatment. The lower dose E₂ treatment increased bone ash weight, TBV, BMD and bending strength of both tibia and femur in wild type but not in ERKO mice. In contrast, a high dose E₂ treatment caused a very high bone turnover rate with enhanced bone formation and an increased number of osteoclasts both in WT and in ERKO mice. TBV was clearly elevated but cortical bone revealed local areas with enhanced bone resorption leading to foci with an almost complete local loss of cortical structures. The mechanical strength of cortical bone was clearly decreased due to the local destruction of cortical bone. T treatment of ORC animals reversed the ORC-induced bone changes both in WT and ERKO mice. However, in intact old animals T treatment did not significantly improve measured bone parameters. Generally, all sham-operated animals, both WT and ERKO, survived the whole 4-week experiment whereas 4 out of 22 ORC WT mice (19.2%) and 16 out of 21 ORC ERKO mice (76.2%) died, and most of them were at 5 to 19 days after operation. However, in Te-treated ORC mouse groups, only 3 out of 21 WT (14.3%) and 2 out of 15 ERKO (13.3%) died. Both low and high dose E₂ treatment of ORC WT and ORC ERKO male mice was associated with an increased death rate. Only 3 out of 39 WT (7.7%) and 5 out of 35 ERKO (14%) survived in E₂-treated groups until the end of the study. Similarly, in E₂-treated intact old WT and ERKO mice groups 5/14 and 4/16 animals died during the experiment, respectively. No deaths occurred in the control or Te-treated groups during the same time period. In conclusion, E₂ treatment was associated with an increased death rate both in intact and ORC old WT and ERKO mice. ORC also increased death rate in old ERKO males which could be decreased by Te treatment of ORC mice. The reason for increased, delayed deaths after ORC or E₂ treatments remains currently unknown since the routine histological examination of major organs did not reveal any obvious cause of death.

Activation of MAPKs by 17 beta-Estradiol Is Mediated by PKC and c-Src in Skeletal Muscle Cells. A. C. Ronda¹, C. Buitrago¹, E. Roldan², R. Boland¹. ¹Biología, Bioquímica & Farmacia, Universidad Nacional del Sur, Bahía Blanca, Argentina, ²Gador S.A., Buenos Aires, Argentina.

The classical mechanism of action of 17β-estradiol (E2) involves its binding to the intracellular estrogen receptors (ER) α or β. These ligand-activated receptors stimulate mRNA synthesis and de-novo protein expression, for hours to days. Additionally, E2 is also known to exert rapid non-genomic effects on target tissues. Some of these effects involve activation of intracellular signalling pathways. We have previously shown in C2C12 skeletal muscle cells that 10⁻⁸M E2 stimulates ERK1/2 and p38 MAPK at 15 min and that the hormone promotes phosphorylation of CREB and Elk-1 transcription factors in an ERK1/2 and p38-dependent manner. In the present work, we demonstrate that E2 activates c-Src in C2C12 cells within the same time interval as ERK1/2 and p38 MAPK phosphorylation. E2-induced ERK1/2 and p38 activation was abolished by the c-Src specific inhibitor PP2, involving c-Src in hormone stimulation of MAPKs. Treatment of the muscle cells with the specific PKC inhibitor Ro318220 demonstrated that activation of ERK 1/2 and p38 in response to the estrogen is also mediated by PKC. Moreover, E2 modulates Src activation in a PKC-dependent manner, possibly through a Src protein tyrosine phosphatase. The data altogether suggest that the steroid hormone 17β-estradiol triggers upstream at PKC/Src the signalling MAPK cascades leading then to phosphorylation of CREB and Elk-1 transcription factors in the C2C12 skeletal muscle line.

Estrogen Preferentially Suppresses Osteogenic Gene Expression in Mice Lacking Classical ERE Signaling. V. Rudnik^{*}, F. A. Syed, D. G. Fraser^{*}, D. G. Monroe, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Studies with female mice in whom the only functional estrogen receptor α (ERα) is one which cannot bind DNA (ERα-/NERKI) have shown that these mice gained cortical bone mass following ovariectomy (ovx), and E dose-dependently suppressed this increase; these changes were the opposite of those seen in wild type (WT) mice. These paradoxical effects of ovx and E on cortical bone in ERα-/NERKI mice could be due to an alteration of the balance between classical (through EREs) and non-classical (through protein-protein interactions) signaling of ERα in osteoblastic cells. To identify the potential signaling pathways involved in these effects of the NERKI receptor, 3 month old female WT and ERα-/NERKI mice were ovx'd or sham operated (n = 3 per group) for 1 week and then euthanized and the femurs extracted. The metaphyses were removed and bone marrow was flushed in order to isolate RNA purely from cortical bone. Following synthesis of cDNA, QPCR arrays were performed using mouse osteogenesis platforms (SuperArray). Fold differences (following normalization to 5 different housekeeping genes) were compared within the WT and ERα-/NERKI groups between E+ (sham) and ovx (E-) animals. Of particular interest, mRNA levels of TWIST1, which is a known inhibitor of osteoblast differentiation and of runx2 activity, were lower in the cortical bones of E+ as compared to E- WT and ERα-/NERKI mice (by 2 fold for both, P = 0.06 and 0.006, respectively). By contrast, mRNA levels for BMP1, BMP3, and LEF1 (a downstream target gene in the Wnt signaling pathway) were similar in the bones of the E+ and E- WT mice, but were lower (by 2, 2, and 4-fold, respectively, all P < 0.05) in the bones of the E+ as compared to the E- ERα-/NERKI mice. These in vivo data thus demonstrate that (1) TWIST1 may be a novel E-regulated target gene and suggest that suppression of TWIST1 may play a role in the stimulation of osteoblast differentiation by E; and (2) suppression by E of BMP1, BMP3, and Wnt signaling in ERα-/NERKI mice may explain their paradoxical cortical bone response (i.e., gain in bone mass) following ovx.

17beta-Estradiol Abrogates Apoptosis in Skeletal Muscle Cells Through Extra-Nuclear Estrogen Receptors. A. Vasconsuelo^{*}, L. Milanese^{*}, A. Russo de Boland^{*}, R. Boland. Biología, Bioquímica & Farmacia, Universidad Nacional del Sur, Bahía Blanca, Argentina.

Although there is evidence showing that estrogens regulate apoptosis in various cellular systems, the underlying molecular mechanism is not well understood. The present study demonstrates that 17β-estradiol, at physiological concentrations, abrogates apoptosis in mouse skeletal muscle C2C12 cells through estrogen receptors (ERs) with non-classical localization. Specific antibodies against ER α or β and silencing of ERs with ER α and β short interference RNAs (siRNAs) inhibited this protective action, which involved PI3K/Akt activation and BAD phosphorylation. Apoptosis inhibition by 17β-estradiol was stronger when ER β was blocked, suggesting that the β isoform mediates to a greater extent than the α isoform the antiapoptotic effects of the steroid hormone. Expression and subcellular distribution of ER α and β in extra nuclear compartments (mitochondria, endoplasmic reticulum and Golgi) of C2C12 cells were confirmed by competitive binding assays, conventional and confocal fluorescence microscopy, silencing of ERs with siRNAs and RT-PCR using specific primers.

These results indicate that 17β-estradiol exerts antiapoptotic effects in skeletal muscle cells mediated by estrogen receptors with extra nuclear localization.

Bone Formation Is Predicted by Resting Metabolic Rate and Leptin in Exercising Women with Hypothalamic Amenorrhea. J. L. Scheid*, S. L. West*, J. D. Vescovi, S. Awdishu*, M. J. De Souza. Exercise Science, University of Toronto, Toronto, ON, Canada.

The purpose of this study was to assess metabolic factors that impact bone formation and bone resorption in exercising women with hypothalamic amenorrhea. For this observational study, subjects were divided according to menstrual status into one of three groups: 1) Ovulatory (OV, n= 21), 2) Anovulatory (ANOV, n=9), 3) Amenorrheic (AMEN, n=21). Menstrual status was assessed by daily urinary ovarian steroid measurements for 2-3 menstrual cycles, or 30-day monitoring periods if AMEN. Serum was analysed for type I procollagen amino-terminal propeptide (PINP), triiodothyronine (TT3), ghrelin, peptide YY (PYY), leptin, and 24 hour urinary samples for C-terminal telopeptide (CTX). Resting metabolic rate (RMR) was assessed by indirect calorimetry and bone density by dual-energy x-ray absorptiometry. As an indicator of energy deficiency, a measured RMR:Predicted RMR (pRMR) was defined as less than 0.90. All groups were similar (p>0.05) with respect to age (23.3±0.5yr), height (1.65±3.22m), weight (58.0±1.0kg), and BMI (21.2±0.3kg/m²). As expected, Z-scores were lower (p=0.002) in the AMEN (-0.614±0.175) compared to both the OV (0.747±0.352) and ANOV (0.500±0.389) groups at the lumbar spine L2-L4. RMR was suppressed (p=0.023; 28.7±0.7, 31.4±0.8, and 31.1±0.8kcal/day*kg FFM) in the AMEN compared to the OV and ANOV groups, respectively. RMR:pRMR was below 0.90 in the AMEN group, indicative of energy deficiency. Suppressed TT3 (p=0.030), elevated ghrelin (p=0.038) and elevated PYY concentrations (p=0.039) were observed in the AMEN compared to the OV group, but similar to that observed in the ANOV group. Leptin concentrations were similar (p=0.667) among groups (4.83±0.45ng/ml). PINP was similar (p=0.440) among groups (121.5±7.8 ug/L), while CTX was increased (p=0.034) in the AMEN (291.1±39.7ng/ml) compared to the OV (174.8±18.7ng/ml) group, and similar to that observed in the ANOV (224.2±31.4ng/ml) group. Variables in a regression model predicting PINP included RMR:pRMR and leptin which accounted for 28.6% (R²=0.327, p=0.001) of the variance in PINP. However, in the AMEN group, 55.8% (R²=0.626, p=0.004) of the variance in PINP was accounted for by RMR:pRMR and leptin. Variables in a model predicting CTX included the duration of amenorrhea, leptin and PYY concentrations and accounted for 39.9% (R²=0.454, p<0.001) of the variance in CTX. Exercising women with hypothalamic amenorrhea are energy deficient, as depicted by suppressed RMR, RMR:pRMR, TT3, elevated ghrelin, and PYY levels compared to their ovulatory counterparts, and their bone marker profile is predicted by their energy status.

The Role of Androgen Receptor in the Lineage Commitment of Bone Marrow Stromal Cells. C. Shyr¹, T. Meng-Yin^{*2}, H. Ko-En^{*2}, C. Chang^{*3}. ¹Chinese Medicine, Chang-Gung University, Niao-Sung, Taiwan, ²Obstetrics and Gynaecology, Chang-Gung Hospital, Niao-Sung, Taiwan, ³Pathology, University of Rochester, Rochester, NY, USA.

Androgen receptor (AR) mediates androgen action to affect bone, muscle and fat tissue metabolism through controlling cellular events like differentiation process. However, the molecular control by AR on the making of specialized cells such as osteocytes and adipocytes from progenitor cells and more primitive stem cell remain unclear. To determine the role of AR in stem cell fate decision and differentiation, we conducted experiments on bone marrow stromal cells (BMSC) obtained from wild type (WT) and AR knockout (KO) mice, which contain mesenchymal stem cells with pluripotency to give rise all types of cells. We found that ARKO mice had higher numbers of colony formation unit-fibroblast, (cfu-f) and colony formation unit-osteoblast, (cfu-o) than WT mice did. Gene expression profile determined by oligoarray chips revealed that the genes related to osteogenic differentiation decreased, but genes involved in adipogenic differentiation increased in ARKO mice compared to those in wt mice. The Q-RT-PCR results verified the findings obtained from microarray analysis with lower expression of genes linked to osteogenesis and higher expression of adipogenesis-related genes in ARKO mice. Furthermore, cell surface epitope analysis by flow assay demonstrated that ARKO BMSCs exhibited different characteristics to WT BMSCs.

The study on ARKO mice is a direct and evident approach to investigate the role of AR in stem cell fate determination and lineage commitment. Our findings in this study imply that AR may accelerate the use of stem cells from their pool and direct them into differentiation because the loss of AR caused the increased progenitor cell numbers. For stem cell differentiation, we suggest that AR plays a role in promoting the stem cell differentiation decision for osteogenesis other than adipogenesis based on the gene expression profile. By understanding the role of AR on adult stem cell biology, we can find a precise and efficient way to control stem cell self-renewal and differentiation, resulting in a therapeutic application in treating illnesses such as osteoporosis and obesity through the regulatory role of AR on stem cells.

The UGT2B7 H²⁶⁸Y Polymorphism Is Associated with Serum Sex Steroid Levels and Cortical Bone Size in Young Adult Men. C. Swanson¹, M. Lorentzon¹, L. Vandenput¹, F. Labrie^{*2}, A. Rane^{*3}, J. Jakobsson^{*3}, S. Chouinard^{*2}, A. Belanger^{*2}, C. Ohlsson¹. ¹Center for Bone Research at the Sahlgrenska Academy, Department of Internal Medicine, Gothenburg University, Göteborg, Sweden, ²Laboratory of Molecular Endocrinology and Oncology, Laval University Hospital Research Center and Laval University, Quebec, PQ, Canada, ³Department of Laboratory Medicine, Division of Clinical Pharmacology, Karolinska Institutet at Karolinska University Hospital, Stockholm, Sweden.

Androgens stimulate periosteal bone expansion in males during sexual maturation and the androgen receptor (AR) is required for this effect. The bio-active androgens testosterone (T) and dihydrotestosterone (DHT) can be inactivated directly by conjugation with glucuronic acid. An alternative pathway is the transformation of DHT in two main metabolites, namely androstane-3 α ,17 β -diol (3 α -diol) and androsterone (ADT). Conjugation of 3 α -diol and ADT with polar cofactors, such as glucuronic acid, is an irreversible step, abolishing its affinity for the AR. Conjugation of androgens with glucuronic acid has been suggested to play a role in the regulation of the intracellular levels of unconjugated steroids as well as their biological activities in tissues. It is now well established that UDP glucuronosyltransferase (UGT) 2B7 is one of three major enzymes responsible for the glucuronidation of all androgens and their metabolites in humans. The in vivo role of UGT2B7 for the regulation of circulating, as well as local, levels of androgens, estrogens and their metabolites is unknown. A H²⁶⁸Y polymorphism has been described in the UGT2B7 gene.

Our aim was to determine the impact of the UGT2B7 H²⁶⁸Y polymorphism on serum levels of sex steroids and cortical bone dimensions in the population-based GOOD-study, which includes 1068 young adult men at the age of peak bone mass.

Serum levels (measured by GC-MS) of T (YY 9% over HH, p<0.01), DHT (YY 10% over HH, p<0.01) and estradiol (YY 8% over HH, p<0.01) were associated with the UGT2B7 H²⁶⁸Y polymorphism (genotyping performed by Real-Time PCR). The polymorphism was associated with the metabolites (measured by LC-MS/MS) 3 α -diol-17-glucuronide and 3 α -diol-3-glucuronide (p<0.01) but not with ADT-glucuronide levels in serum. In addition, the UGT2B7 H²⁶⁸Y polymorphism was an independent predictor of cortical bone size (measured by pQCT) as reflected by periosteal circumference and cortical moment of inertia (p<0.01) in both the weight bearing tibia and the non-weight bearing radius.

In conclusion, the UGT2B7 H²⁶⁸Y polymorphism is independently associated with cortical bone size and serum sex steroid levels in young adult men. Subjects homozygous for the Y-allele had higher serum T and larger cortical bone size than subjects homozygous for the H-allele.

Increased Caloric Intake Is Associated with Reversal of Amenorrhea and Favorable Changes in Metabolic and Bone Markers: A Case Study Report.

S. L. West^{*1}, J. L. Scheid^{*1}, N. I. Williams², J. D. Vescovi¹, S. A. Jamal¹, G. A. Hawker¹, S. Awdishu^{*1}, M. J. De Souza¹. ¹University of Toronto, Toronto, ON, Canada, ²Penn State University, State College, PA, USA.

Physically active women can develop exercise associated menstrual cycle disturbances (EAMD) such as amenorrhea secondary to a chronic energy deficiency. EAMD is frequently associated with low bone mass and stress fractures. Here we report data from an ongoing 12 month randomized controlled trial to determine if increased caloric intake would reverse amenorrhea, and improve energy and bone marker status. Subjects were categorized by ovulatory status into either an ovulatory control or EAMD group. After a one month run in period subjects in the EAMD group were randomly assigned to an EAMD control or EAMD+calories group that was required to increase daily caloric intake (20-30%) above their baseline energy needs. Resting energy expenditure (REE), dietary intake, daily energy expenditure, body composition (by DXA), serum markers of bone formation (PINP) and resorption (CTX), metabolic status (ghrelin and triiodothyronine [TT3]), and daily urinary ovarian steroids (E1G and PdG) were assessed over the study period. Presented is a case study of one participant randomized to the EAMD+calories group who has completed 6 months of the study protocol. The 24 year old subject had been amenorrheic for 2 years. She participated in over 300 minutes of exercise per week (primarily dance and aerobic exercise), and had a V_O max of 43.5 ml/kg/min. At study entry she weighed 54.5 kg, her BMI was 19.8 kg/m² and she had 20% body fat. REE at baseline was 1171 kcal/day and represented 87% of predicted REE, indicative of an energy deficiency. Supplemental caloric intake averaged 300 kcal/day over the study period. After 6 months of increased calories the subject reported resumption of menses, confirmed by daily ovarian steroid profile (E1G cycle area under the curve increased 79.6% from 435.6 to 782.4). There was a 1.9 kg increase in body mass, a 0.7 kg/m² increase in BMI, and endocrine alterations indicative of a move toward energy surplus including a 5.0% increase in REE, a 2.0% increase in TT3, and a 1.7% decrease in ghrelin. PINP increased 26.4% from 73.89 to 93.39 ug/L, while CTX remained unchanged (0.64 ng/ml vs. 0.69 ng/ml). Our data suggest that, in this subject, increased caloric intake results in resumption of menses, as well as more favourable metabolic, energy, and bone marker profiles.

Deficiency of the G protein-coupled Estrogen Receptor GPR30 Leads to Reduced Bone Growth and Bone Mineral Density in Female Mice. S. H. Windahl¹, N. Andersson¹, U. E. A. Mårtensson^{2,3}, C. Owman^{2,3}, C. R. Rosen³, M. L. Adamo⁴, B. Olde^{2,3}, F. Leeb-Lundberg^{2,3}, C. Ohlsson¹. ¹Center for Bone Research at the Sahlgrenska Academy, Gothenburg, Sweden, ²Unit of Drug Target Discovery at Lund University, Lund, Sweden, ³The Jackson Laboratory, Bar Harbor, ME, USA, ⁴Department of Biochemistry, The University of Texas Health Science Center, San Antonio, TX, USA.

Estrogens are important regulators of bone growth and adult bone metabolism. There are two known nuclear receptors for estrogen (ER α and ER β). ER α is the most important nuclear ER for bone in both males and females while the role of ER β mainly is to modulate ER α activity in female but not male mice. Recent in vitro studies have suggested that the G-protein-coupled receptor GPR30 is a functional ER but the impact of GPR30 in vivo is unknown. The aim of the present study was to investigate the in vivo role of GPR30 for the skeleton and for reproductive tissues. We therefore developed a mouse model in which the GPR30 gene locus was disrupted. GPR30^{-/-} mice are viable and serum levels of estradiol and testosterone as well as the uterine weight were unchanged in GPR30^{-/-} mice compared with wild type mice. Interestingly, after sexual maturation, the female GPR30^{-/-} mice displayed a reduced body weight (22.6 \pm 0.4g, n=25) compared to WT mice (24.7 \pm 0.6g, n=26; p<0.01). The reduced body weight in female GPR30^{-/-} mice was associated with a reduced skeletal growth, including both the axial skeleton (crown-rump length, p<0.05) and the appendicular skeleton (femur length, p<0.05). The magnitude of the skeletal growth disturbance was similar in the appendicular and the axial skeleton, indicating that it was a proportional skeletal growth disturbance. In contrast, male GPR30^{-/-} mice displayed a normal skeletal growth. Because the growth disturbance became significant after sexual maturation and only was seen in female mice, one may speculate that sex steroid-dependent pubertal growth is affected in female GPR30^{-/-} mice. The GH/IGF-I axis is a major determinant of skeletal growth. Serum IGF-I levels were reduced in female (-11%, p<0.05) but not male GPR30^{-/-} mice, indicating that reduced serum IGF-I levels might be involved in the growth disturbance seen in female GPR30^{-/-} mice. Initial screening of BMD using total body DXA showed that the female but not the male GPR30^{-/-} mice displayed reduced BMD (-3%, p<0.05) compared with wild type mice. In conclusion, deficiency of the proposed novel ER GPR30 results in reduced bone growth and total body BMD associated with reduced serum IGF-I levels in female mice.

DHT Treatment Reverses Gonadectomy-induced Changes in Fat and Lean Mass in Male but Not Female Mice. A. A. Semirale, X. Zhang, K. M. Wiren. VA Medical Center, Oregon Health & Science Univ, Portland, OR, USA.

Androgens have pervasive effects on target tissues including muscle, fat and bone. To characterize the role of androgen receptor (AR) signaling on body composition, an experimental paradigm of protracted hormone ablation followed by steroid replacement was employed. B6D2F2 control mice were sham operated or gonadectomized at 3 months of age. The effect of nonaromatizable dihydrotestosterone (DHT) was determined after an 8 week delay, to provide time for gonadectomy-induced changes in body composition to develop before intervention. The effect of androgen was assessed by dual energy x-ray absorptiometry (DXA) following 6 weeks of treatment with either DHT or placebo pellets. In control males (n = 8-11), lean mass as a % of body weight was significantly reduced (7.7 %, p < 0.001) following orchietomy (ORX) while conversely, % fat mass increased (7.6 %, p < 0.001) vs. sham controls. DHT treatment was beneficial, improving or fully restoring body composition changes induced by ORX compared to placebo. In females (n = 4-10) a similar trend was observed with increased fat (2.2 %) and reduced lean mass (2.3 %) after ovariectomy (OVX). Surprisingly, females were resistant to the effects of DHT to restore body composition. To determine whether changes in bone metabolism contribute to body composition differences, transgenic mice with skeletally-targeted AR overexpression in mature osteoblasts (driven by the 2.3 kb fragment of type I α 1 collagen promoter) were characterized. AR2.3-tg mice demonstrated changes in body composition after gonadectomy that mirrored wild types (n=3-9). Again similar to wild-type controls, DHT improved ORX-induced alterations in % fat and % lean mass in AR2.3-tg males but not females. In contrast to gonadectomized models, DHT treatment in intact wild type mice had a negative impact on body composition in both males and females. Males (n = 14-23) lost 4.4 % lean mass (p < 0.05) and increased fat mass by 4.3 % (p < 0.05) compared to placebo, with similar but less dramatic changes observed in females (n = 14-26). These results show both males and females increase fat and lose lean mass following gonadectomy. In the bone-targeted AR-overexpression model, enhanced androgen signaling does not influence the response to DHT suggesting that circulating factors derived from bone likely do not play a role in the body composition response to androgen therapy. Combined, these data indicate that systemic DHT positively influences body composition changes after a prolonged hypogonadal state in males but is ineffective in females over the same time frame. Furthermore, DHT treatment in the intact animal results in detrimental changes in body composition and should be approached with caution.

Dissection of Androgen Receptor Signaling: Reconsideration of Direct Anabolic Action in Mature Bone. X. Zhang, A. A. Semirale, K. M. Wiren. VA Medical Center, Oregon Health & Science Univ, Portland, OR, USA.

The effects of androgen on bone remain poorly characterized and understudied. To develop insight into the cell types important in mediating androgen action, we constructed and compared two distinct transgenic lines employing different α 1(I)-collagen promoter fragments to control skeletally-targeted AR overexpression. The col3.6 AR-transgenic (AR3.6-tg) mice demonstrate AR overexpression throughout the osteoblast lineage including the periosteum, while col2.3 (AR2.3-tg) mice have more restricted overexpression in mature osteoblasts and osteocytes. Complex skeletal analysis using morphological characterization by μ CT, dynamic and static histomorphometric analysis, dual-energy x-ray absorptiometry (DXA), biomechanical testing and gene expression studies all indicate that androgen signaling in mature osteoblasts during growth produces a low turnover state, and the consequences are detrimental to overall matrix quality and bone strength. To determine the consequences of androgen treatment in the adult and whether nonaromatizable dihydrotestosterone (DHT) may be effective for treatment of post-menopausal bone loss in an animal model, 3 month old male and female B6D2F2 control mice were gonadectomized. Six weeks of treatment with DHT or placebo pellets was delayed until age 5 months to allow rapid bone turnover to stabilize, thus minimizing the impact of anti-resorptive effects of androgen. DXA demonstrated that systemic DHT administration significantly increased BMD and BMC in both sexes, to reverse loss sustained after a prolonged hypogonadal state (n = 14-26). To test the consequences of enhanced androgen signaling targeted to bone in the adult, male and female AR3.6-tg and AR2.3-tg mice were treated in the same manner. In both AR-tg families and in contrast to wild-type mice, DHT replacement did not improve either measure versus placebo pellet (n = 3-14). Taken together, these results indicate that improvements in bone mass with androgen treatment after gonadectomy in wild-type mice are likely mediated through effects on extra-skeletal tissues, not osteoblasts. Consistent with detrimental effects of enhanced androgen signaling on bone quality, DHT treatment in intact controls significantly reduced bone mass in both males and females. These findings demonstrate that after a sustained hypogonadal period, androgen effectively treats bone loss but that enhanced androgen signaling directly in bone is not anabolic in either male or female adults. The data suggests that targeting androgen response to mature osteoblasts is not beneficial for bone formation, and raise concerns regarding androgen administration or anabolic steroid abuse in healthy individuals in both sexes.

Genetic Variation in Post-Natal Skeletal Growth Defines Functional Interactions among Adult Bone Traits and Fragility. K. J. Jepsen¹, B. Hu^{*1}, M. A. Cordova^{*1}, S. M. Tommasini², C. Price¹, H. W. Courtland¹, J. H. Nadeau^{*3}. ¹Mt Sinai School of Medicine, NY, NY, USA, ²CUNY Graduate Center, NY, NY, USA, ³Case Western Reserve University, Cleveland, OH, USA.

Prior work revealed that several adult bone traits are functionally related, such that the small cross-sectional size of slender bones was compensated by increased cortical thickness and tissue-mineral density. The set of traits for slender bones, although sufficiently stiff for daily activities, performed poorly under extreme load conditions. Because slenderness is a key determinant of fracture risk, identifying the biological controls responsible for functional interactions among adult traits should advance our understanding of how genetic background influences fracture risk. Femora from 20 female AXB/BXA Recombinant Inbred (RI) mouse strains were analyzed to test the hypothesis that functional interactions among adult traits are determined during early post-natal growth. Femoral mid-diaphyseal traits analyzed at 1 and 28 days of age were compared to adult traits measured at 112 days. Z-transformed data were analyzed using Path Analysis, which uses conditional covariances to establish causal relationships among multiple traits. Path Analysis (Fig 1) revealed a significant correlation between the rate of increase in total area (periosteal expansion) and marrow area (endosteal expansion) from 1 to 28 days, indicating that expansion of the periosteal surface relative to the endosteal surface was biologically controlled. Further, the rate of increase in total area (periosteal expansion) showed a net negative relationship with adult TMD and CtTh, such that variable post-natal periosteal expansion rates defined the degree of matrix mineralization and the relative rate of marrow expansion (and thus cortical thickness). The functional interactions between post-natal surface expansions and the set of adult traits indicated there are adaptive processes, superimposed on allelic variation, that co-adapt traits to match loading demands. These adaptive processes appear to accommodate allelic variation affecting periosteal expansion (i.e., slenderness) by allowing mechanically functional structures to be constructed in different ways. This study provided important new evidence that the set of adult traits which define bone strength and fragility are determined in large part by genetic factors affecting post-natal skeletal growth patterns.

Fig 1. Path Analysis showing causal (straight arrows) and non-causal (curved arrow) relationships among post-natal body weight gain (ΔBW_{1-28}), periosteal expansion ($\Delta TtAr_{1-28}$), marrow expansion ($\Delta MaAr_{1-28}$), and adult tissue-mineral density (TMD_{112}) and cortical thickness ($CtTh_{112}$). Path coefficients calculated based on Z-transformed data.

Cells Cultured from Bone Lesions of Patients with Paget's Disease Show No Evidence of Measles Virus RNA or Somatic Mutations in SQSTM1. B. G. Matthews^{*1}, U. Bava^{*1}, K. Callon^{*1}, M. A. Afzal^{*2}, J. Cornish¹, I. R. Reid¹, D. Naot¹. ¹Medicine, University of Auckland, Auckland, New Zealand, ²Division of Virology, National Institute for Biological Standards & Control, Potters Bar, United Kingdom.

Paget's disease is a focal condition of bone of uncertain etiology. The disease appears to be associated with a combination of genetic and environmental factors. SQSTM1 mutations have been identified in familial Paget's and in a minority of sporadic cases, and several groups have suggested long-term infection with a paramyxovirus is associated with the disease. However, the mechanisms for the focal nature of Paget's disease are not understood. In this study, we used cells obtained from pagetic bone lesions to investigate local changes that could possibly account for the characteristic focal pathology.

We have collected RNA from cultured osteoblasts and bone marrow samples taken from both pagetic lesions and unaffected bone from a group of 22 patients with Paget's disease, and from control patients. Differential gene expression, analyzed by real-time PCR, identified several changes in these samples, including increased Dkk1 and IL-6 and a reduced RANKL/OPG ratio in pagetic cells compared with controls.

Somatic mutations within the pagetic lesion have been suggested to be responsible for the focal nature of the disease. In order to investigate the possibility of somatic SQSTM1 mutations, exons 7 and 8 of the SQSTM1 cDNA were sequenced in all the patients with Paget's disease, in some cases using samples from both pagetic and unaffected tissue. The wild-type sequence was found in all but one patient, who was heterozygous for the P392L mutation. DNA from peripheral blood in this subject had an identical sequence of SQSTM1, indicating that this was a germ-line mutation. We conclude that somatic mutations for SQSTM1 are not commonly present in Paget's disease.

The RNA was also used to look for evidence of measles virus involvement in Paget's disease. Nested RT-PCR analysis at the National Institute for Biological Standards and Control in England did not detect measles virus nucleocapsid or matrix genes in any of the pagetic or control samples. This suggests that long term measles virus infection is not commonly present in New Zealand patients with Paget's disease.

The results indicate that pagetic lesions are different from normal bone in terms of gene expression, but do not commonly contain somatic SQSTM1 mutations or measles virus infection.

A Mouse Model for Diabetes-mediated Osteoporosis. Z. Wang^{*1}, K. Ding^{*2}, M. W. Hamrick³, H. He^{*1}, S. Yan^{*4}, L. Zhou^{*1}, C. M. Isles⁵, Q. Mi¹. ¹Center for Biotechnology and Genomic Medicine/Dept. of Pathology, Medical College of Georgia, Augusta, GA, USA, ²Dept. of Medicine, Medical College of Georgia, Augusta, GA, USA, ³Dept. of Cellular Biology and Anatomy, Medical College of Georgia, Augusta, GA, USA, ⁴Dept. of Endocrinology, The Medical School Hospital of Qingdao University, Qingdao, China, ⁵Dept. of Orthopedic Surgery, Medical College of Georgia, Augusta, GA, USA.

Decreased bone mass, osteoporosis, and increased fracture rates are common skeletal complications in patients with type 1 diabetes (T1D). There is a considerable amount of clinical data to link osteoporosis with T1D. However, very little basic research has delved into this phenomenon, and few have directly addressed the influence of diabetes on the skeletal system of mice, an animal model that is amenable to genetic manipulation. Recently, a streptozotocin (STZ)-induced T1D mouse model was used to examine the influence of T1D on bone. However, STZ-induced diabetes causes some diversity among individual animals in terms of the extent of severity and the onset of diabetes. In addition, STZ may directly affect bone function. Here, we employed a novel genetic approach by which T1D would be most stably induced in RIP-iNOS mice as early as 1 week after birth due to the iNOS-mediated selective destruction of insulin-producing pancreatic beta cells. Pixus densitometric analysis showed a significant decrease in bone mineral density of whole bones in 3-month-old male RIP-iNOS mice compared with that of age- and strain-matched wild-type mice. The radiographic analysis also showed a significant lower bone mass in RIP-iNOS mice. However, the body weight was invariant between the two groups during the 3-month observation period. Our study demonstrated that diabetic RIP-iNOS mice can spontaneously develop osteoporosis, and could be served as a novel mouse model for studying T1D-related osteoporosis.

GLP-1 Action on Bone Turnover in Normal and Type 2 Diabetic State. B. Nuche-Berenguer^{*1}, V. Sancho^{*1}, J. Cancelas^{*1}, D. Lozano^{*2}, P. Esbrit², M. L. Villanueva-Peñacarrillo^{*1}. ¹Metabolism, Nutrition & Hormones, Fundación Jiménez Díaz, Madrid, Spain, ²Laboratory of Bone & Mineral Metabolism, Fundación Jiménez Díaz, Madrid, Spain.

An insulin-independent antidiabetic action of GLP-1 (glucagon-like peptide 1) is widely documented, as well as its insulin-like effect upon glucose metabolism in liver, muscle and fat, and neurotrophic and anorectic properties. It was suggested that incretins could participate in bone turnover changes occurring after absorption of nutrients. We have explored the possible in vivo effect of GLP-1 on bone remodeling in normal and diabetic state. Type 2 diabetic model was developed by streptozotocin injection in neonatal Wistar rats (STZ-T2D). Adult rats, normal (n=6) and STZ-T2D (n=6), were treated -3 days through an osmotic pump- with GLP-1 (0.86 nmol/kg/h). In fed conditions, plasma samples were taken before (basal) and by the end of the treatment, when also tibias were collected. MC3T3-E1 osteoblasts were incubated for 24 hours in α -MEM with 5 or 25mM D-glucose (or mannitol), and in absence and presence of 10^{-9} M GLP-1. Measurements: in plasma, osteocalcin (OC), tartrate-resistant acid phosphatase (TRAP) -ELISA-, insulin -RIA- and glucose; in bone and cells, gene expression of OC, osteoprotegerin (OPG) and RANK ligand (RANKL) -RT-PCR-. Untreated rats of both groups (n=6, each) were included as respective controls. In plasma: GLP-1 did not modify normal basal OC (440.5 \pm 6.0 ng/ml), while in STZ-T2D group, initially showing an apparently lower than normal level, GLP-1 induced a reduction (-10.9 \pm 0.9% Δ of basal, p<0.001); TRAP was slightly increased by GLP-1 in normal (2.87 \pm 0.24 U/l vs basal 2.64 \pm 0.27) and also in STZ-T2D (2.88 \pm 0.29 U/l vs basal 2.45 \pm 0.27); glucose and insulin were not significantly affected in either group. In bone: OC mRNA level in STZ-T2D was 1.65 \pm 0.26 times that of normal rats; treatment with GLP-1 induced an increase in normal (2.35 \pm 0.50 times control) and also in STZ-T2D (1.99 \pm 0.44 times control); OPG mRNA was higher in STZ-T2D (4.87 \pm 0.30 times that of normal), but while GLP-1 raised the value in normal (2.73 \pm 0.30 times control, p<0.005), it reduced that in STZ-T2D (0.44 \pm 0.05 times control); RANKL mRNA was slightly higher in STZ-T2D (1.63 \pm 0.19 times that of normal), and was similarly increased by GLP-1 in both groups (normal: 1.97 \pm 0.29 times control; STZ-T2D: 1.38 \pm 0.13 times control). In control STZ-T2D, RANKL/OPG mRNA ratio was 0.326, and GLP-1 treatment raised it to 2.98, similar to the 2.20 value obtained in MC3T3-E1 cells incubated with GLP-1 and high glucose. In conclusion, these novel findings show that GLP-1 directly modulates bone turnover markers in both normal and type 2 diabetic rats, and suggest that this hormone might favor bone resorption.

Investigating the Role of Mecp2 in the Epigenetic Regulation of Bone Mineral Density. R. D. O'Connor¹, A. L. Ham^{*1}, A. M. Wolff^{*1}, M. Zayzafoon², N. C. Schanen³, M. C. Farach-Carson¹. ¹Department of Biological Sciences, University of Delaware, Newark, DE, USA, ²Department of Pathology, University of Alabama at Birmingham, Birmingham, AL, USA, ³Laboratory for Human Genetics, Nemours/Al duPont Hospital for Children, Wilmington, DE, USA.

Rett Syndrome (RTT), a neurodevelopmental disorder, is most often caused by inactivating mutations in the X-linked gene encoding a regulator of epigenetic gene expression, methyl CpG binding protein, MeCP2. Clinical data show that, along with neurological defects, females with RTT frequently have marked decrease in Bone Mineral Density (BMD) beyond that expected from disuse atrophy. Preliminary studies with a Mecp2 knock-out mouse model reveal a difference between the wild-type and knock-out mice, with the knock-out mice having a reduced skeletal size and altered bone mineral content compared to their wild type littermates. Histological analyses revealed a noticeable morphological difference in femur and tibia growth plate apparent by 3 weeks of age, prior to the onset of neurological symptoms. We speculate that Mecp2 deficiency leads to a primary dysregulation of genes critical for regulation of bone growth, differentiation and mineral homeostasis. To test this hypothesis, we have utilized a chromatin immunoprecipitation assay (ChIP) on chip strategy to identify specific targets of Mecp2-regulated expression in bone. Several genes essential to proper bone formation and maintenance of bone and calcium homeostasis have been identified as likely targets of Mecp2 in a differentiating osteoblast cell system. Current studies are underway to determine the specific regions of Mecp2 binding, and the functional significance of Mecp2 deficiency on candidate gene expression and function.

Dwarfism: Body Composition and Bone Mineral Density Analysis. M. G. B. Pippa^{*1}, D. C. Andrade^{*2}, S. R. Eis³, C. A. Brandao⁴, C. F. Zerbinini¹. ¹Rheumatology, Hospital Heliopolis, Sao Paulo, Brazil, ²Clinical Research, Centro Paulista de Investigação Clínica, Sao Paulo, Brazil, ³Clinical Research, Centro de Diagnóstico e Pesquisa da Osteoporose do Espírito Santo, Vitória, Brazil, ⁴Bone Densitometry, Fleury Medicina e Saude, Sao Paulo, Brazil.

Dwarfism is a medical condition which result in short stature. Characteristically, the arms are shorter than the forearms and the thighs are shorter than the legs. Little is known about bone mass adjusted for body size and body composition (BC) compartments in dwarfism. Our objective was to evaluate bone mineral density (BMD), BC and X-Ray alterations in this population. 24 females and males dwarfs were studied. All of them were submitted to dual-energy X-ray absorptiometry (DXA) in order to analyze BMD of lumbar spine, proximal femur (PF), total body BMD (TBBMD), radio 33% (R33%) and BC as well. Total Lean mass (TLM), Total Fat Mass (TFM), percentage of adiposity (% adp), arms lean mass (ALM), legs lean mass (LLM), and body fat distribution (BFD) were also determined. Areal BMD was measured and reported in g/cm². Adjusted BMD (Adj BMD) was calculated by the relation between bone mineral content (BMC)/height and results were given in g/m². Apparent BMD was calculated according to Bachrach. Sarcopenia was also determined according to Baumgartner classification. AP and lateral Plain X-Ray of dorsal / lumbar spine were performed. Variables were evaluated as descriptive patterns. The adherence to normal curve was evaluated by Kolmogorov Smirnov test. Data were analysed using the statistical computer program Minitab version 15.0%. Twelve male and 12 female dwarfs from 6 to 53 years old were studied. Average age was 34.5 years (SD = 11.9), average weight 18 Kg (SD = 12.1), average BMI 33.9 Kg / m² (SD = 9.2) and average height 1.20 m (SD = 0.12). Areal BMD L1-L4 mean was 0.991 g/cm², App L1-L4 BMD 0.304 g/cm³ and adjusted L1-L4 BMD was 0.0274 g/cm². TBBMD mean was 1.047 (SD = 0.20) BMD, and AdjBMDT mean was 0.616 (SD = 0.52). R33% BMD mean was 0.616 and its Z-score -1.92 (SD = 1.02). According Z-score areal L1-L4 BMD, low bone mass was found in 5 dwarfs (20.8%). When we used Z-score TBBMD no low bone mass was shown. Using Z-score R 33% BMD, low bone mass was present in 52.6%. Five male presented sarcopenia (20.8%) and 3 female (12.5%). Mean age sarcopenic dwarfs was 26.7 (SD = 13.2). All sample had 1 or more X-Ray alterations (scoliosis, scoliosis, hyper lordosis, platyspondyly, narrow AP spinal canal, squared iliac wings, hypoplastic ("bullet nose") T-L vertebrae, mild and severe vertebral crush). Low bone mass was very frequent, particularly when R 33% Z-score was used. We concluded that dwarfism should be submitted to DXA analysis earlier than normal height people.

Skeletal Development Analysis by Two-Dimensional Electrophoresis (2-DE) in White Bream (Diplodus sargus), Fed with Different Diets. P. M. L. Rodrigues^{*}, O. Cordeiro^{*}, T. S. Silva^{*}, L. E. C. Conceição^{*}. FCMA, Universidade do Algarve, Faro, Portugal.

Although high larval survival rates are commonly observed in aquaculture production of *D. sargus*, skeletal deformities are one of the main constraints. Diets with poor protein content and amino acid deficiencies have been related to the development of skeletal deformities. The central objective of this study is to evaluate the possibility of minimizing the skeletal deformity problems commonly found when *D. sargus* are cultured, through the

use of amino acid supplements. It is also intended to verify how the expression of key proteins involved in skeletal development are affected, in order to better understand the mechanisms present in development of skeletal deformities. The fish used in this study were previously fed since the larval stage with diets containing different amino acid profiles. The effect on skeletal deformities and bone proteins expression of larval *D. sargus* of a well balanced diet in the different indispensable amino acids (group 1 - control), or the same diet supplemented with amino acids involved in skeletal formation (group 2 - trp supplement and group 3 - lys supplement), was studied. Bone and cartilage were removed from *D. sargus* and proteins extracted. Protein expression changes in the three groups for normal and deformed fish were characterized by 2D gels analysis. Triplicates were done for each different condition with a total of eighteen gels. Gels with separated protein spots were analyzed on an imaging densitometer. Qualitative and quantitative analysis was done with PDQuest 2-D analysis software, which enables detection, matching and quantification of protein spots. After spot detection and matching, the intensity volume of each spot was normalized by comparison with a reference set of non-differentially expressed spots. Evaluation of the statistical significance of spot variation between groups was performed using a non-parametric test (Mann-Whitney U test, p < 0.05). The above figure representing the spots differentially expressed shows that the 2-DE technique allows the identification the key proteins involved in skeletal development and deformities. This information may be used for the development of better balanced diets, leading to fewer individuals with skeletal deformities in fish culture.

An ENU Mutation Mapped to a Distal Region of Chromosome 11 Is Major Determinant of Bone Size Independent of Body Growth. V. Chest^{*}, S. Mohan, J. E. Wergedal, A. K. Srivastava. JLP VA Medical Center & Loma Linda University, Loma Linda, CA, USA.

Using a phenotype driven N-ethyl-nitrosourea (ENU) screen in growth hormone (GH) deficient mice, we have identified a mutant (named 14104) that exhibited 40% decreased bone size independent of body weight. The mutation is inherited as an autosomal dominant trait in a C57BL/6J background and magnitude of the bone size phenotype is modulated by GHRHR gene (7% lower bone size, p < 0.05 by post Hoc analysis). Measurement of bone size in tibia, femur, and humerus by pQCT, μ CT (Figure-1A), and histology showed 20% low (p < 0.001) periosteal circumference (PC) in mutant mice as compared to control mice. The unique feature of the 14104 mutant mice is that the cortical thickness is not decreased in the same proportion as cross-sectional area due to a greater (40-50%, p < 0.01) decrease in endosteal circumference (EC). This opposing movement of PC and EC is due to 25% decreased bone formation (p < 0.05) at the periosteal surface and a much larger 45% decreased bone resorption (p < 0.05) at the endosteal surface (Figure-1B), determined by histomorphometry. The osteoblasts from 14104 mice showed 40-50% (p < 0.05) reduced proliferation rate and lower induction of ALP activity (p < 0.05) in response to differentiating agents. To identify the chromosomal location of the mutation, we backcrossed the mutant 14104 mice with DBA mice and generated about 140 F2 mice. Employing a selective genotyping and phenotype based DNA pooling method we scanned the genome for linkage using 60 markers. We identified linked markers on chromosome 11 with peak LOD scores of 9.8 and 10.5 (p < 0.000001) for PC and EC, respectively. The 95% confidence interval of the locus involves 52-66 cM region of Chr 11. The allelic distribution of B6 (n = 18) and DBA alleles (n = 15) confirmed that linked locus was contributed by mutant gene because homozygous B6 allele contributed to 21% low PC (p < 0.001) and 53% low EC (p < 0.001) as compared to homozygotes for DBA alleles. In conclusion, we report mutant allele that dramatically reduced bone size independent of bone size by interacting with GH/IGF signaling pathway. The mutation is mapped to a Chr 11 region that includes several important QTLs regulating bone density and size. Since disruption of none of the known genes in this region (GH, Igfbp1, Colla1, Integrin, Noggin) produced phenotype similar to 14104 mutant mice, we believe that mutation is in a novel gene.

Serum Alkaline Phosphatase QTLs Provide Evidence that Genes on Chromosome 5 and 11 Regulate Bone Formation and Affect Bone size and Strength. J. E. Wergedal¹, C. L. Ackert-Bicknell², W. G. Beamer², S. Mohan¹, D. J. Baylink³, A. K. Srivastava¹. ¹JLP VA Medical Center & Loma Linda University, Loma Linda, CA, USA, ²The Jackson Laboratory, Bar Harbor, ME, USA, ³Dep. of Med., Loma Linda University, Loma Linda, CA, USA.

We have previously shown that the RF/J (RF) inbred mouse line has a greater femur cross sectional size associated with a higher bone formation rate than the NZB/B1NJ inbred mouse line. We sought to test the hypothesis that genetic loci that regulate bone formation contribute to variation in bone size and strength in the RF and NZB intercross. We analyzed serum alkaline phosphatase (ALP), as a surrogate marker for bone formation phenotype, to obtain evidence for the concordant loci regulating bone strength parameters and bone formation marker. Surprisingly, the mean serum ALP level was higher in the low bone formation mouse strain, NZB (n=8, Mean±SD 151±39 U/L) as compared to RF (n=16, 119±29 U/L, P<0.05 vs NZB). A genome-wide scan was carried out using 94 polymorphic markers and serum from 542 F2 female mice (Fig. 1). Total ALP levels in serum were measured by kinetic assay using a fully automated clinical chemistry analyzer. Interval mapping for co-segregation of genetic marker data with ALP activity revealed five significant QTL on chromosome (Chr) 3 (LOD 4.74, peak location 36 cM), Chr 5 (LOD 3.82, 64 cM), Chr 9 (LOD 5.1, 48 cM), Chr 11 (LOD 3.48, 40 cM), and Chr 12 (LOD 5.04, 4 cM). A suggestive QTL was observed on Chr-17 (LOD 3.00, 56 cM). Combined together, these QTLs explain 29% of the F2 variance in ALP levels. Three of these loci on Chr 5, Chr 9, and Chr 12 represent novel ALP loci that have not been identified in any previously published crosses. The allelic distribution of ALP at the peak marker was compared with values for bone size (periosteal perimeter) and bone bending strength. Two of the ALP QTL (Chr 5 and 11) corresponded with size and strength QTL and had the allele from the RF strain as the high allele. Two additional ALP QTLs corresponded with size or strength QTL but did not have the same strain as the high allele. It is possible that these loci regulate ALP levels by influencing the ALP metabolism. In conclusion, five Chr loci have genes that affect ALP and may affect bone formation. Two Chr loci on 5 and 11 have genes that affect femur size and strength, possibly by regulating bone formation.

FDPS, GGPS1 and FDFT1 Gene Polymorphisms as Pharmacogenetic Markers for the Response to Bisphosphonates. S. Carbonell Sala¹, V. Martinetti¹, F. Del Monte¹, I. Tognarini¹, S. Silvestri¹, F. Marini¹, L. Masi¹, A. Tanini¹, A. Falchetti², M. Brandi². ¹Internal Medicine, University of Florence, Florence, Italy, ²Internal Medicine, University of Florence, Florence, Italy.

The therapy of metabolic bone diseases is characterized by variability in the response with limited prediction on a patient-by-patient basis. This is relevant in osteoporosis, where therapy is required long-term before outcomes' evaluation. Our aim was to study how genetic traits influence efficacy and acute response to amino-bisphosphonates (N-BPs), key components for the therapy of high turnover metabolic bone diseases. N-BPs can specifically inhibit mevalonate pathway enzymes required for protein prenylation. As the response to N-BPs is highly variable among treated patients, the individual genetic variability could be an explanation.

In this study we analyzed the farnesyl pyrophosphate-synthase (FDPS), the geranylgeranyl pyrophosphate-synthase (GGPS1) and the squalene synthase (FDFT1) gene polymorphisms to assess genetic aspects of N-BPs response. The genotype distribution for FDPS A/C polymorphism (intron 1) in the Italian population corresponded to an A-allele frequency of 0.82, and C-allele frequency is 0.18, with a heterozygosity index of 0.2981 (χ^2 Test: p=0.29). The Polymorphism Information Content of this marker is informative (PIC=0.29). After the evaluation of the PIC value of GGPS1 and FDFT1 selected polymorphisms, our future goal is to perform a cohort study with patients involved in clinical trials with N-BPs, searching for correlations between genotype/haplotype and response to therapy. In a cohort study including a group of 200 Caucasian postmenopausal women was observed no statistically significant association between FDPS polymorphism and baseline-BMD, with a tendency of lowest response to therapy in patients with CC-genotype.

Our final goal is to identify the segregation of clinical response to N-BPs with genetic profile of their targets in chronic metabolic bone syndromes; and to provide models for N-BPs pharmacogenetic functionality studies. Some studies demonstrate the presence of osteoclast precursors in peripheral blood in the mononuclear cell fraction. Future studies will attempt to isolate peripheral human osteoclast precursors obtained from patients with FDPS, GGPS1 and FDFT1 opposite genotypes to perform "in vitro" functionality studies. Altogether these data can contribute to the selection of optimal therapeutic guidelines in patients treated with N-BPs.

Disclosures: S. Carbonell Sala, None.

Genome-wide Haplotype Association Mapping (HAM) in Mice Leads to an Identification of a Genetic Variant in CER1 Associated with Bone Mineral Density in Premenopausal Women. C. L. Cheung¹, P. L. Tang², P. C. Sham³, P. McClurg⁴, S. Chan², D. K. Smith², A. I. Su⁴, K. S. Cheah², A. W. Kung¹, Y. Song². ¹Medicine, The University of Hong Kong, Hong Kong, Hong Kong, ²Biochemistry, The University of Hong Kong, Hong Kong, Hong Kong, ³Genome Research Centre, The University of Hong Kong, Hong Kong, Hong Kong, ⁴Genomics Institute of the Novartis Research Foundation, San Diego, CA, USA.

Bone Mineral Density (BMD) is a complex trait likely determined by multiple genes. We attempted to identify the quantitative trait loci (QTL) for BMD in mouse genome and to replicate the findings in human. Information on single nucleotide polymorphisms (SNPs) (1) and whole body BMD of 18 weeks female mice (2) were gathered from 30 mouse strains. The Haplotype Association Mapping (HAM) program which utilized a sliding window of 3 SNPs in the grouping of a haplotype block was applied (1). A modified F-test was used to query for the existence of some haplotypes structure that can partition mice with high BMD and low BMD. The positional candidate gene was then replicated in 1,083 young southern Chinese women aged 20-40 years having extreme high (BMD Z score > +1 at either the spine or hip) and low BMD (Z score < -1.28, equivalent to the lowest 10th percentile of the population). The association was examined using binary logistic regression with adjustment of age, height and weight. 22 blocks in the female mice genome were identified to contain genes for BMD variation. Chromosome 4, 82.2-87.9 Mb and Chromosome 12, 26.9-28.6 Mb had two peaks in close proximity. No genes can be found in the gap in Chromosome 12, 26.9-28.6 Mb. 27 genes were found in that of Chromosome 4, 82.2-87.9 Mb. Examination of the gene list identified Cer1 as a positional candidate gene in chromosome 4 QTL. Cer1 is a homolog of Cerberus in Xenopus, which belongs to a cysteine knot superfamily containing a cysteine knot motif in a C-terminal cysteine-rich region. Genotyping of 10 SNPs in human CER1 gene in 1,083 high and low BMD subjects revealed a non-synonymous SNP (rs3747532) was associated with an increased risk of low BMD in premenopausal women (odds ratio 2.2; 95% confidence interval: 1.0 - 4.6; p < 0.05). Our successful identification of an association of CER1 with BMD variation in both young mature female mice and humans suggested that CER1 is one of the genes associated with peak bone mass. Our study highlights the utility of publicly available databases for rapidly surveying the genome for QTL.

Association Study of CLCN7 Polymorphisms and Areal Bone Mineral Density in White or Black Women or White Men. K. Chu¹, S. Ichikawa¹, D. L. Koller², R. Snyder¹, L. Curry¹, X. Xuei³, H. J. Edenberg³, T. M. Foroud², M. Peacock¹, M. J. Econs¹. ¹Medicine, Medical School of Indiana University, Indianapolis, IN, USA, ²Medical and Molecular Genetics, Medical School of Indiana University, Indianapolis, IN, USA, ³Biochemistry and Molecular Biology, Medical School of Indiana University, Indianapolis, IN, USA.

Mutations in the Chloride Channel 7 (CLCN7) gene result in autosomal dominant osteopetrosis (ADO) or autosomal recessive infantile osteopetrosis. Previously, we found that polymorphisms in CLCN7 were associated with disease severity of ADO. A SNP (single nucleotide polymorphism) in CLCN7 (rs12926089; V418M) was also found to be associated with femoral neck BMD in Scottish women. To determine whether CLCN7 SNPs are associated with normal variation in peak areal BMD we genotyped 6 SNPs distributed throughout CLCN7 in a sample of 1704 premenopausal white women, 517 premenopausal black women or 717 white men. The SNPs were tested for association with lumbar spine and femoral neck BMD in these three samples. We found SNP rs2235579 to be associated with femoral neck BMD ($P=0.03$) in white women; however, only a small proportion (0.52%) of the total variation in femoral neck BMD was explained by rs2235579. No significant association was found in white men or black women. We did not detect significant evidence of association ($P>0.92$) with the SNP rs12926089 (V418M) in our samples. In conclusion, variation in CLCN7 is not a major contributor to the observed variability in peak BMD at either the femoral neck or lumbar spine in white or black women or white men.

Influence of the Gene Polymorphisms of Collagenase-1 in Osteogenesis Imperfecta. P. Román-García¹, C. Gomez¹, M. Rodríguez-García¹, D. Álvarez-Hernández¹, I. Rodríguez-García², M. Muñoz-Torres³, N. Guanyabens-Gay⁴, J. Cannata-Andía¹. ¹Bone and mineral research unit, Hospital Universitario Central de Asturias, Oviedo, Spain, ²Molecular Genetics Laboratory, Hospital Universitario Central de Asturias, Oviedo, Spain, ³Endocrinology, Hospital Universitario San Cecilio de Granada, Granada, Spain, ⁴Rheumatology, Hospital Clinic de Barcelona, Barcelona, Spain.

The osteogenesis imperfecta (OI) is an inheritable disease, characterized by extreme bone fragility, and several extraosseous clinical manifestations. Recent results have revealed that mutations in genes not related with collagen synthesis are the cause of the new OI types. Thus, mechanisms not related to collagen synthesis might explain the different severity of the disease. The matrix metalloproteinases (MMPs) are implicated in the collagen digestion in the bone turnover process.

The aim of this study was to investigate if the functional polymorphism +1519 T/- in the MMP-1 gene (Collagenase I) was associated to the development of the disease and to the number of fractures. We studied the new T/T > T/- polymorphism, at the +1519 position in the MMP-1 gene in 30 patients with clinical diagnosis of OI and healthy controls using PCR-SSCP technique. The OI patients were 10 males and 20 females, 37.08 ± 16.4 years old (8 to 70). As reference population we used 450 people, age and sex matched from a large sample of our community hematological donors.

The frequency of the T/- genotype in OI was 3 fold higher than the observed in control population. Table 1. The clinical picture in patients with OI and T/- genotype was not different with regard T/T patients in mean number of fractures (11.3 ± 5 vs. 11.7 ± 9), presence of blue esclerae. By contrast in T/- patients we did not observed any vertebral fractures whereas in T/T patients, the prevalence of vertebral fractures was 95%. None of T/- patients had familiar history of OI versus 61% in the T/T patients. In terms of BMD we found a trend to have a higher BMD in lumbar spine and total hip in T/- patients.

There is an association between the genotype T/- and the disease. The allele (-) implicates a "frameshit reading" change and the patients with the (-) allele may have a modified collagenolytic activity. These data supports the theory that there are other molecules are affecting the disease or its manifestations or even the possibility of a misclassification in patients with clinical diagnosis.

Table 1 (* $p<0.05$ compared to control)

	T/T	T/-	Total
Controls	450 (97.0%)	14 (3.0%)	464
Osteogenesis Imperfecta	27 (90.%)	3 (10%)*	30
Lumbar-spine (Z-Score)	-3.14 ± 1.21	-1.16 ± 1.24	
Total hip (Z-score)	-1.56 ± 1.04	-0.5 ± 0.21	
Prevalence of lumbar OP	76%	0%	
Prevalence of total hip OP	20%	0%

Common Variant of SOSTDC1 Is Associated with Increased Risks of Fractures and Osteoporosis--A Novel Candidate Gene Revealed by Fine Mapping from Anhui Genome-Wide Scan. Y. H. Hsu¹, T. Niu², H. Terwedow², C. Rosen³, X. Xu², J. Brain². ¹Hebrew SeniorLife and Harvard Sch Public Health, Boston, MA, USA, ²Harvard Sch Public Health, Boston, MA, USA, ³Maine Center for Osteoporosis Research and Education, St. Joseph Hospital, Bangor, ME, USA.

Previously, we have revealed three novel QTLs (LOD > 3.65) on Chr 7p21 for femoral neck (FN) BMD, Chr 2q24 for total hip BMD and Chr 5q21 for BMDs combined at different skeletal sites in a genome-wide scan of 3093 adult Chinese siblings selected based on their extreme hip BMD. To narrow down the QTL region, we first genotyped 10-20 microsatellite markers (~2 cM per marker) in each of the QTLs in the same 3093 siblings. Fine mapping of the Chr 7p21 QTL narrowed to a 8 cM region (LOD = 3.72). Among 23 known genes in this region, twist homolog 1 (TWIST1) and sclerostin domain-containing protein 1 (SOSTDC1) have been known functionally relevant to bone metabolism. TWIST1 inactivation reduces the binding ability of CBFA1/RUNX2 to the osteocalcin promoter. SOSTDC1 belongs to a class of bone morphogenetic protein (BMP) antagonists. To test whether polymorphisms in the TWIST1 and SOSTDC1 are associated with BMDs in our cohort, we genotyped tag SNPs in an independent set of 2392 extreme low FN BMD cases (T-score < -1) and extreme high FN BMD controls matched by age and sex, selected from a study of 23,327 Chinese men and women. Tag SNPs were chosen from HapMap dataset (5 tag SNPs with pairwise mean $r^2 = 0.98$ to un-tag SNPs for SOSTDC1; 4 tag SNPs with $r^2 = 0.94$ for TWIST1). Multiple logistic regression with additive genetic model was used, adjusted for age, height, weight, physical activity, smoking, and menopause (women). First, the adjusted odds ratios (ORs) for extreme low FN BMD was associated with three adjacent SNPs located in exon 1 and intron 1 of SOSTDC1 (ORs 1.4-1.6, p -values 0.004- 4×10^{-5} , p -values by permutation test 0.041- 5×10^{-4}) in men. A weak association was found in women for the SNP located in exon 1 of SOSTDC1 ($p=0.017$). No association was found between TWIST1 SNPs and BMD. Second, the ORs (95%CI) for men carrying the polymorphic allele A for the strongest associated SNP (rs16878762, MAF: 28.6%) of SOSTDC1 were 1.7 (1.3-2.4) for osteoporosis, and 2.0 (1.1-3.7) for osteoporotic fractures. Third, men carrying AA genotype had 54 and 80 mg/cm² lower whole body and Lumbar Spine BMD, respectively. Finally, SNP rs16878762 was significantly associated with SOSTDC1 gene expression in men ($p=0.004$) and women ($p=0.049$). Notable, despite the close homologue to sclerostin (SOST), no significant association was found for SOST polymorphism (SRP9) in our study population. In sum, results from linkage, population-based association, and gene expression studies all suggest SOSTDC1 variants may causally reduce BMDs and increase risks of osteoporotic fractures.

An AluI Polymorphism in ESR2 Is Associated with Reduced Risk of Osteoporotic Fractures. L. B. Husted, N. Gonzalez-Bofill, L. Stenkjær*, M. Carstens*, B. L. Langdahl. Research Lab. C, Aarhus University Hospital, Århus, Denmark.

Estrogen is important for acquisition and maintenance of bone mineral density (BMD) and therefore also for the development of osteoporosis. It acts by binding to estrogen receptors, which are transcription factors belonging to the nuclear receptor hormone superfamily. Two types of estrogen receptors, ERα and ERβ, have been identified. We have previously found that a TA-repeat polymorphism in the gene encoding ERα, ESR1 is associated with osteoporotic fracture risk. In this study we investigated the effect of three polymorphisms in the ERβ gene (ESR2): a synonymous RsaI polymorphism (rs1256049), an AluI polymorphism in the 3'UTR (rs4986938) and a CA-repeat polymorphism (D14S1026) in intron 5 on BMD and risk of vertebral fractures in a case-control study including 466 osteoporotic patients and 336 normal controls.

Prevalence of the CC and CT + TT genotypes of the RsaI polymorphism was 94.5% and 5.5% in patients with vertebral fractures, respectively, and 95.0% and 5.0% in normal controls, respectively, $\chi^2 = 0.071$, ns. BMD at the lumbar spine was 0.844 ± 0.190 g/cm² in carriers of the T allele vs 0.836 ± 0.178 g/cm² in individuals with the CC genotype, ns. Likewise, no differences in BMD between the genotypes were found at any of the hip sites. The AluI polymorphism was associated with reduced risk of vertebral fractures. Distribution of the CC, CT and TT genotypes in patients with vertebral fractures and normal controls was 44.3%, 45.3% and 10.4% and 34.9%, 49.1% and 16%, respectively, $\chi^2 = 7.05$, $p = 0.029$. BMD at the lumbar spine was 0.828 ± 0.179 g/cm², 0.837 ± 0.176 g/cm² and 0.866 ± 0.182 g/cm² in individuals with the CC, CT and TT genotypes, respectively, ns. Similar results were found at the hip. In men, however, the difference in BMD at the total hip between the genotypes was significant ($p = 0.003$).

The distribution of the number of CA-repeats was bimodal and therefore the CA-repeat alleles were divided into a low (≤ 21 repeats) and a high repeat number group (> 22 repeats) for statistical analyses. The prevalence of the CA genotypes was similar between patients with vertebral fractures and normal controls, and there was no difference in BMD between the genotypes.

Because the CA-repeat polymorphism and the RsaI polymorphism were in linkage disequilibrium haplotypes could be estimated. We found no effect of the three common haplotypes on BMD or fracture risk.

By examining the TA-repeat polymorphism in ESR1 and the CA-repeat polymorphism in ESR2 there seemed to be an additive effect of the two polymorphisms on fracture risk.

In conclusion, we found that the AluI polymorphism in ESR2 is associated with reduced risk of osteoporotic fractures.

Disclosures: L.B. Husted, None.

ENPP1 as a Candidate Gene for Femoral Bone Geometry. Y. K. Cho¹, S. Demissie^{*1}, G. Livshits^{*2}, J. B. Meigs^{*3}, L. A. Cupples^{*1}, J. C. Florez^{*3}, J. McAteer^{*3}, D. P. Kiel⁴, D. Karasik⁴. ¹Biostatistics, BU Sch Public Health, Boston, MA, USA, ²Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel, ³Mass General Hospital and Broad Inst, Boston-Cambridge, MA, USA, ⁴Hebrew SeniorLife and Harvard Med School, Boston, MA, USA.

Secondary mineralization in bone is a controlled process with a tight balance between the levels of extracellular phosphate ions and inorganic pyrophosphate (PPi), which inhibits hydroxyapatite crystal growth and therefore prevents excessive calcification. Ecto-nucleotide pyrophosphatase phosphodiesterase 1 (ENPP1) generates PPi. It is uncertain to what extent ENPP1 may be involved in appendicular skeletal mineralization.

We examined the association of polymorphisms in the ENPP1 gene with femoral geometry measured with Hip Structural Analysis (HSA), in 789 women and 704 men from the Framingham Offspring Cohort (mean age \pm SD: 61.3 \pm 9.1 years), who had DXA and DNA available. HSA measures included femoral neck length (FNL), neck-shaft angle (NSA), and subperiosteal width at the narrowest section of the femoral neck (NN_WID) and shaft (S_WID).

Thirty one single nucleotide polymorphisms (SNPs) were genotyped on an iPLEX Sequenom platform, these SNPs captured 69% of common variants in ENPP1 (minor allele frequency >5%) with an r^2 >0.8. We performed sex-specific ANCOVA using 2 models adjusted for covariates: age (model 1) and age, height, BMI, smoking status, as well as estrogen history in women (model 2).

In men, we found 6 SNPs with nominally significant associations with the age-adjusted bone geometry traits. Intronic SNP (rs775386) was associated with FNL at $p = 0.0009$. Other SNPs (rs9493100, rs1044498, rs9493116, rs7768480, and rs1510) were also associated with bone geometry traits ($p < 0.008$). In women, no nominally significant associations were found. After adjustment for additional covariates, including body size, in general, magnitude and direction of the association did not change. To correct for multiple testing, we performed 10,000 random permutations of phenotypes and covariates while keeping the genotype LD and phenotype correlation information intact. The corrected p -value for rs775386 and FNL was 0.10, suggesting that the observed association may be due to chance.

In conclusion, this is the first study which examined a fairly comprehensive set of common variants in ENPP1 in relation to bone geometry. Nominally significant associations between ENPP1 polymorphisms and femoral geometry in Caucasian males generate the hypothesis that the observed genetic associations are not mediated by body size. These results require improved coverage of ENPP1 polymorphisms and confirmation in larger samples.

Association of ADIPOR1 and ADIPOR2 Gene Polymorphisms with Bone Mineral Density in Postmenopausal Korean Women. H. Y. Kim¹, B. Oh^{*2}, J. Y. Lee^{*2}, B. L. Park^{*3}, H. D. Shin^{*3}, T. H. Kim^{*4}, E. K. Park^{*4}, S. Y. Kim^{*4}, J. M. Koh⁵, G. S. Kim⁵. ¹Division of Endocrinology and Metabolism, University of Wonkwang College Medicine, Sanbon Medical Center, Gunpo, Republic of Korea, ²National Genome Research Institute, National Institute of Health, Seoul, Republic of Korea, ³Department of Genetic Epidemiology, SNP Genetics, Inc., Seoul, Republic of Korea, ⁴Skeletal Disease Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea, ⁵Division of Endocrinology and Metabolism, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Republic of Korea.

Obesity is associated with both higher fat mass and higher bone mineral density (BMD). Adiponectin is circulating peptide derived from adipose tissue. It mediates its insulin sensitizing and anti-atherogenic effects on target tissue through two known receptors, adiponectin receptor 1 and 2 (ADIPOR1; ADIPOR2). Recently, the expression of both adiponectin and its receptors in the bone forming cells of human was reported. The possibility was suggested that interaction between adiponectin and receptor might have an effect on bone metabolism. Therefore, we examined the associations between ADIPOR1 and ADIPOR2 gene polymorphisms and bone mineral density (BMD) in postmenopausal Korean women.

All exons, their boundaries, and the promoter region (approximately 1.5 kb) of ADIPOR1 and ADIPOR2 were sequenced in 24 individuals. Among identified polymorphisms, three polymorphisms in ADIPOR1 and three polymorphisms in ADIPOR2 were selected based on LDs and frequencies and genotyped in all study participants ($n = 729$). BMD at the lumbar spine and femur neck was measured using dual energy X-ray absorptiometry.

The mean age of the study subjects was 58.7 ± 7.5 years and the mean years since menopause was 9.5 ± 7.8 years. Multivariate analysis showed an association of the +5843 G > A in ADIPOR1 with lumbar spine BMD. Individual with +5843 A allele had lower BMD at the lumbar spine compared with those without A allele (0.90 ± 0.18 vs 0.86 ± 0.16 g/cm², $P = 0.005$) after adjustment age, years since menopause, weight, and height. There was significant association between the -64243T > G in ADIPOR2 with femur neck BMD. Individual with -64243 G allele showed lower BMD at femur neck than those without G allele (0.74 ± 0.12 vs 0.71 ± 0.13 g/cm², $P = 0.005$). However, we did not find any association with fractures.

These finding suggests that the +5843 G > A in ADIPOR1 and -64243T > G in ADIPOR2 gene may be one of the genetic determinants of osteoporosis in Korean postmenopausal women.

Disclosures: H.Y. Kim, None.

T221

Associations of Paraoxonase Gene (PON1) Promoter Polymorphisms with Vertebral Fracture Risk Independently of Bone Mineral Density in Postmenopausal Women. B. Kim^{*1}, S. H. Lee^{*1}, Y. Chung^{*2}, B. Oh^{*3}, J. Lee^{*3}, J. Lee^{*3}, B. L. Park^{*4}, H. D. Shin^{*4}, T. Kim^{*5}, E. K. Park^{*5}, S. Kim^{*5}, J. Koh¹, G. S. Kim¹. ¹Division of Endocrinology and Metabolism, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, ²Department of Internal Medicine, Seoul Veterans Hospital, Seoul, Republic of Korea, ³National Genome Research Institute, National Institute of Health, Seoul, Republic of Korea, ⁴Department of Genetic Epidemiology, SNP Genetics, Inc., Seoul, Republic of Korea, ⁵Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea.

There is increasing evidence of a biochemical link between oxidative stress and bone metabolism. Paraoxonase (PON1) is associated with high density lipoprotein and has the antioxidant effect by both preventing the formation of oxidized low density lipoprotein (LDL) and inactivating LDL-derived oxidized phospholipids once they are formed. Therefore, PON1 could be an important candidate gene for the modulation of bone metabolism. In order to investigate the effects of PON1 polymorphisms, especially promoter polymorphisms, on the risk of osteoporotic fractures (OFs) and bone mineral density (BMD), we directly sequenced the PON1 gene in 24 Korean individuals, and identified 30 sequence variants. In the present study, we selected 3 promoter polymorphisms of them, and they were genotyped in a larger-scale study of postmenopausal women ($n = 729$). Areal BMD (g/cm²) of the anterior-posterior lumbar spine and the non-dominant proximal femur was measured using dual energy X-ray absorptiometry. Lateral thoracolumbar (T4-L4) radiographs were obtained in all subjects. Multivariate analyses showed that all three promoter polymorphisms were not associated with BMD at the both sites. However, we found that the PON1-1741A > G and -909G > C promoter polymorphisms were associated with vertebral fracture risk independently of BMD before and after adjustment for age, years since menopause, height, weight, and/or BMD. After the adjustments for all covariates, the subjects with the GG homozygote of -1741A > G and the CC homozygote of -909G > C were significantly related with higher vertebral fracture risk (odds ratio = 2.37, 95% CI 1.36-4.15, $P = 0.002$ in the recessive model; and odds ratio = 2.35, 95% CI 1.35-4.07, $P = 0.002$ in the recessive model, respectively). When we categorized the subjects into four levels according to the number of vertebral fractures, we found that the rare alleles of PON1-1741A > G ($P = 0.004$) and -909G > C ($P = 0.006$) increased, as the number of OFs did. These findings suggest that PON1 could be one of the genetic predictive markers for osteoporotic fracture risk and severity in postmenopausal women.

The Association of Bone Mass with SNPs of Frizzled Genes in Wnt System and Circulating Osteoprotegerin (OPG) - Receptor Activator of NF- κ B Ligand (RANKL) System. J. Kim, H. Kim^{*}, S. Chae^{*}, C. Suh^{*}, S. Kim, Y. Choi, S. Moon. Dept. of Obstetrics & Gynecology, Seoul National University Hospital, Seoul, Republic of Korea.

The aim of this study was to investigate the association between single nucleotide polymorphisms (SNPs) in frizzled (FZD)s gene in Wnt signal pathway, and circulating osteoprotegerin (OPG), soluble receptor activator of NF- κ B ligand (sRANKL) levels, bone turnover markers, and bone mineral density (BMD) in postmenopausal Korean women. The SNPs in FZD1 (rs3752146), FZD5 (rs1056614), FZD6 (rs17855053; rs12549394), FZD7 (rs12546413), and FZD9 (rs17852398; rs17856756; rs17856757; rs17852397) gene were analyzed by direct sequencing in 371 Korean postmenopausal women. Levels of serum OPG, sRANKL, osteocalcin (OST), C-telopeptide of type I collagen (CTX), calcium (Ca), phosphorus (P), parathyroid hormone (PTH) and calcitonin, and BMD at the lumbar spine and proximal femur were measured. The SNPs in FZD1, FZD5, FZD7, and FZD9 gene, and in exon 2 of FZD6 gene were not observed. The distributions of C345A SNP (rs17855053) in the exon4 and A664C SNP (rs12549394) in the exon 8 of FZD6 gene were as follows: CC 36.4%, AC 43.7%, AA 19.9%, CC 95.7%, and CA 4.3%. No significant differences in the adjusted BMD of lumbar spine and proximal femur were noted among the genotypes of C345A and A664C SNPs in FZD 6 gene and the distributions of these genotypes were not different according to the status of bone mass. No significant differences in serum levels of OPG, and sRANKL, and their ratios, and bone markers such as OST, CTX, Ca, P, PTH and calcitonin were observed according to these genotypes of FZD 6 gene polymorphisms. In conclusion, the FZDs gene polymorphisms was not associated with BMD of the lumbar spine and proximal femur, bone turnover markers, and circulating OPG-sRANKL levels in Korean women.

Association Study of Catalase Gene Polymorphisms with an Osteonecrosis of Femoral Head in Korean Population. J. Hong^{*1}, X. Dai^{*1}, T. Kim^{*1}, J. Park^{*1}, J. Jung^{*1}, E. Park^{*2}, S. Kim^{*3}. ¹Skeletal diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea, ²Pathology and Regenerative Medicine, School of Dentistry, Kyungpook National University, Daegu, Republic of Korea, ³Department of Orthopedic Surgery, Kyungpook National University Hospital, Daegu, Republic of Korea.

Osteonecrosis of femoral head (ONFH) frequently leads to progressive collapse of the femoral head followed by a degenerative arthritis of the hip joint. Various theories have been proposed regarding the pathogenic mechanisms of osteonecrosis (ON). Oxidative stress, which has been implicated in many pathological conditions, including vascular injury, has been recently suggested to play a part in the development of ON. In addition, tissue oxidation is known to induce apoptosis, which has also been suggested to be involved ON. Recently, oxidative stress has been also suggested to participate in the development of osteoporosis. Some in vitro and animal studies have suggested that oxidative stress decrease bone formation by modulating the differentiation and survival of osteoblasts and stimulating bone resorption.

Catalase (CAT) is a major antioxidant enzyme that detoxifies hydrogen peroxide by converting it into water and oxygen, thereby preventing cellular injury by oxidative stress. Individuals with reduced catalase activity have an increased incidence of oxidative stress-related disease, such as atherosclerosis, diabetes, and dyslipidaemia. To examine the associations between the CAT gene polymorphisms and ON in Korean population, we selected nine polymorphic sites of CAT from public databases (dbSNP, KSNP and HapMap), and genotyped in 460 ONFH patients and 300 control subjects. The CAT genotype did not deviate from Hardy-Weinberg equilibrium in any of the case or control groups. We classified the patients according to etiology: alcohol-induced, steroid-induced, and idiopathic ONFH subgroup. We found that -89A>T, -20T>C, +14539A>T, and +22348C>T polymorphisms of CAT gene were significantly associated with the risk of ONFH in all alternative analysis model (p range; 0.0003-0.047, OR; 0.56-3.57). However, the minor allele of -89A>T and -20T>C had protective effect on ONFH with significant p-values (p range; 0.004-0.047, OR; 0.56-0.75). Further analysis based on pathological etiology (alcohol-, steroid- or idiopathic) and sex showed that the genotype of -89A>T, -20T>C, +14539A>T, and +22348C>T were also associated with the risk of ONFH in each subgroup with significance. Our results provide, for the first time, evidence supporting the association of CAT gene polymorphisms with the risk of ONFH in Korean population, and suggest that oxidative stress may play an important role in the pathogenesis of ONFH.

Association of Lipoprotein Lipase Hind III Polymorphism with Lumbar Bone Mineral Density in Korean Premenopausal Women. S. Lee¹, O. Kim^{*2}, J. Kim^{*2}, K. Lee^{*2}, H. Baik^{*2}, Y. Jo^{*3}, H. Kim^{*3}, B. Kim^{*3}, K. Park^{*3}, H. Choi^{*4}. ¹Biochemistry-Molecular Biology/Internal Medicine, School of Medicine, Eulji University, Daejeon, Republic of Korea, ²Biochemistry-Molecular Biology, School of Medicine, Eulji University, Daejeon, Republic of Korea, ³Internal Medicine, School of Medicine, Eulji University, Daejeon, Republic of Korea, ⁴Family Medicine, School of Medicine, Eulji University, Daejeon, Republic of Korea.

The association between serum levels of lipid and bone mineral density (BMD) remains debatable. The lipoprotein lipase (LPL) plays a key role in lipid metabolism. Association of LPL Hind III polymorphism with BMD has not been studied. In the present study, we attempted to examine the association between LPL Hind III polymorphism and lumbar BMD in pre- and post-menopausal women, respectively. 201 Korean women (130, premenopausal women; 71, postmenopausal women) were recruited at the Eulji University Hospital, South Korea. We measured lumbar spine L₁-L₄ BMD using DXA. We determined LPL gene polymorphisms affecting Hind III polymorphism site in intron 8 using PCR techniques. The polymorphic allele displaying the restriction site was referred to as (+) and the allele without the site as (-). The (-) allele was less common. We compared the anthropometric parameters, blood lipid levels, and lumbar BMD between women with H(+/+) and H(+/-) genotype in pre- and post-menopausal women, respectively. Frequencies of H(+/+), H(+/-) and H(-/-) genotype were 60.8 %, 33.8 %, and 5.4 %, respectively, in premenopausal women. Frequencies of H(+/+), H(+/-) and H(-/-) genotype were 57.8 %, 39.4 %, and 2.8 %, respectively, in postmenopausal women. There were no differences in total cholesterol levels (184±31 vs 184±37 mg/dL), triglyceride levels (100±56 vs 106±91 mg/dL), HDL-cholesterol levels (54±10 vs 54±11 mg/dL), LDL-cholesterol levels (111±28 vs 109±32 mg/dL), waist circumference (74±7 vs 74±7 cm), and body mass index (22.5±2.5 vs 22.7±2.6 kg/m²) between women with H(+/+) and H(+/-) genotype in premenopausal women. However, there was a difference in lumbar BMD (0.970±0.111 g/cm² vs 1.015±0.108 g/cm²) between women with H(+/+) and H(+/-) genotype in premenopausal women. In postmenopausal women, there were no differences in blood lipid levels, obesity and lumbar BMD between women with H(+/+) and H(+/-) genotype. Our data indicate an association between LPL Hind III polymorphism and lumbar BMD in premenopausal women and suggest that the effect of LPL Hind III polymorphism on lumbar BMD is different between pre- and post-menopausal women at Korea.

Associations of TSH Receptor Gene (TSHR) Polymorphisms with Bone Mineral Density (BMD) in Postmenopausal Women. S. H. Lee^{*1}, B. Kim^{*1}, W. G. Kim^{*1}, Y. Chung^{*2}, B. Oh^{*3}, J. Lee^{*3}, J. Lee^{*3}, B. L. Park^{*4}, H. D. Shin^{*4}, T. Kim^{*5}, E. K. Park^{*5}, S. Kim^{*5}, J. Koh^{*1}, G. S. Kim^{*1}. ¹Division of Endocrinology and Metabolism, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea, ²Department of Internal Medicine, Seoul Veterans Hospital, Seoul, Republic of Korea, ³National Genome Research Institute, National Institute of Health, Seoul, Republic of Korea, ⁴Department of Genetic Epidemiology, SNP Genetics, Inc., Seoul, Republic of Korea, ⁵Skeletal Diseases Genome Research Center, Kyungpook National University Hospital, Daegu, Republic of Korea.

It is well known that hyperthyroidism is associated with lower bone mass as well as higher fracture risk. Not only high thyroid hormone level but also low thyroid stimulating hormone (TSH), is associated with lower bone mass. We selected TSH receptor gene (TSHR) as a candidate gene and investigated the genetic effects of selected TSHR polymorphisms on the bone mineral density (BMD) in postmenopausal Korean women with normal thyroid function. Four SNPs were selected in the Oriental SNP data, and genotypes for the selected SNPs were determined in 729 healthy postmenopausal women. Areal BMD (g/cm²) of the anterior-posterior lumbar spine and the femoral neck was measured using dual energy X-ray absorptiometry. Serum concentrations of TSH and free thyroxin were measured using immunoluminometry and radioimmunoassay, respectively. Mean age of the studied subjects was 58.7 ± 7.5 year old, and years since menopause was 9.5 ± 7.8 years. We found that TSHR +140974T>C polymorphism was significantly associated with BMDs at the lumbar spine and the femoral neck. After adjustment for age, year since menopause, weight and height, the subjects with the TT homozygotes had lower BMD at the lumbar spine (p = 0.01 and 0.01, respectively) and femoral neck (p = 0.003 and 0.001, respectively) in co-dominant and dominant models. When we divided the subjects into the two groups according to the serum TSH concentrations, the significant associations of the polymorphism with BMDs were persistent at the lumbar spine (p = 0.019) and femoral neck (p = 0.007) in the higher TSH group (1.8-5.0 μU/ml), but not in the lower TSH group (0.4-1.7 μU/ml) (p = 0.491 and 0.667, respectively). These results suggest +140974T>C polymorphism in TSHR is a possible genetic factors for BMD values in the postmenopausal women with normal thyroid function, and the association was more prominent in those with higher serum TSH concentration.

Multiplex SNP Genotyping and Data Analysis on 360 Hungarian Postmenopausal Women. G. Speer^{*}, Á. Lazáry, J. Kósa^{*}, B. Tóbiás^{*}, T. Mez^{*}, K. Bácsi^{*}, B. Balla^{*}, I. Takács, Z. Nagy, P. Lakatos. 1st Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Many single nucleotide polymorphisms were described as risk factors for osteoporosis (OP) but there are only a few reports in the literature about more complex genomic analyses such as haplotypes and gene-gene interactions. The aim of this study was to test the associations between SNPs or haplotypes of OP-related genes and the quantitative and qualitative traits of bone loss in Hungarian postmenopausal women. Thirty-eight SNPs found in OP-related genes were genotyped with GenomeLab SNPstream Genotyping system (Beckman Coulter) from DNA isolated from blood samples of 360 unrelated postmenopausal women. Associations between individual SNPs and traits of OP in three measured skeletal site (hip, spine and radius) were tested by MANOVA adjusted for BMI and years since menopause. We applied Multifactor Dimensionality Reduction (MDR) software for detecting gene-gene interactions and THESIAS software for validating them. Among individual SNPs showing the strongest association with OP were those found in RANKL, OPG and COL1A1 genes, respectively. We could not confirm the association with OP in cases of some previously reported SNPs, however, some new individual relationships have been determined. MDR analysis has shown the best models built by 2, 3, 4 or 5 SNPs for the estimation of OP that have been validated later. "TA" haplotype of RANKL (rs9533156) and VDR (rs1544410) was associated with OP risk on lumbar site (p<0.05) while "AC" haplotype of CYP19 (rs12901187) and IL1B (rs1143634) was associated with total femoral T-score and OP at the femoral site (p<0.05). Two models of three SNPs were determined; the "TAA" haplotype of COL1A1 (rs2857396), IL6 (rs1800797) and VDR (rs1544410) has strong association with the lumbar BMD (p<0.01) and T-score (p<0.05). The "GCA" haplotype of CYP19 (rs12901187), RANKL (rs3742257) and CASR (rs9740) was also associated with OP at the lumbar site (p<0.05). Our results suggest that multiplex SNP analysis can increase the force of genetic studies and can reveal new contexts of the genetic background of OP.

Relationship between Variation in the PTH, PTH Related Peptide and the PTH Receptors 1 and 2 Genes and BMD and Fracture in Elderly Women. M. Tenne^{*1}, P. Gerdhem^{*1}, H. Luthman^{*2}, K. Åkesson¹, F. Mc Guigan^{*1}.¹Orthopaedics and Clinical Sciences, Malmö University Hospital, Lund University, Malmö, Sweden, ²Medical Genetics, Clinical Sciences, Malmö University Hospital, Lund University, Malmö, Sweden.

The aim of this study was to evaluate the relationship between genetic variations in 4 key genes of the PTH regulatory pathway and fracture and BMD in 75-year old women. Parathyroid hormone (PTH) plays a key role in calcium homeostasis and skeletal integrity whereas parathyroid hormone related peptide (PTHrP) contributes to skeletal development. Secretion of PTHrP has also been observed in tumors. PTH and PTHrP act through the same receptor, the PTH/PTHrP receptor (PTHrR). In addition, a second receptor, PTHR2 has been identified. We have previously reported on variation in the PTH and PTHrP genes in this cohort. However, we have extended the analyses to also include the receptor genes; PTHR1 and PTHR2.

The study group included 1044 elderly women, all 75-yr old at baseline, from the Malmö Osteoporosis Prospective Risk Assessment study (OPRA). This is an extensively phenotyped cohort which has been followed for up to 9 years. Three single nucleotide polymorphisms (SNPs) at the PTHR1 locus on chromosome 3 and three at the PTHR2 locus on chromosome 2 have been analysed, in addition to six SNPs at the PTH locus on chromosome 11 and three at the PTHrP locus on chromosome 12. Furthermore, for the PTH gene, after verifying LD between the SNPs, we analysed 5 common haplotypes identified using the PHASE program. We found no association between BMD, fracture or serum-PTH and PTHR1 SNPs. Neither did we find any association with PTHR2, a gene relatively unexplored in relation to osteoporosis. There was no association between SNPs in the PTH and PTHrP genes after adjusting for confounders.

Analysis revealed an association between a common haplotype of the PTH gene; Hap 5 occurring in 37% of the population and risk of fracture between age 50 and 75 ($p=0.018$), an association that was strengthened by adding prospectively occurring fractures i.e. from age 75 onwards ($p=0.011$). For Hap 1 (13%) the association was lower ($p=0.02$) for fractures age 50 to 75. In addition, PTH Hap 9 (19%) was associated with risk for any fracture sustained since childhood ($p=0.011$). We did not find any association between PTH haplotypes and BMD. A shift towards increasing PTH levels in the elderly may lead to fracture and genetic variation in the components of the PTH pathway may play a role. The absence of an association with the receptor genes could reflect that they are less important in the elderly. In this study the association between variation in PTH genes and fracture is evaluated for the first time. In our population of elderly women the effect of PTH gene variation, however modest, appears to be independent of BMD.

No Role for Polymorphisms in the Gene Encoding RANKL in the Development of Sporadic Paget's Disease of Bone in Contrast to Some OPG Polymorphisms. G. Beyens^{*1}, F. de Freitas^{*1}, F. Vanhoenacker^{*2}, L. Verbruggen^{*3}, H. G. Zmierzak^{*4}, R. Westhovens^{*5}, J. Van Offel^{*6}, J. Devogelaer⁷, W. Van Hul¹. ¹Department of Medical Genetics, University of Antwerp, Antwerp, Belgium, ²Department of Radiology, University of Antwerp, Antwerp, Belgium, ³Department of Rheumatology, University Hospital of Brussels, Brussels, Belgium, ⁴Unit of Osteoporosis and Metabolic Bone Diseases, University Hospital of Ghent, Ghent, Belgium, ⁵Department of Rheumatology, Catholic University of Leuven, Leuven, Belgium, ⁶Department of Rheumatology, University of Antwerp, Antwerp, Belgium, ⁷Department of Rheumatology, Saint-Luc University Hospital, Brussels, Belgium.

Paget's disease of bone (PDB) is a metabolic bone disease characterized by focal lesions of increased bone turnover and affects between 1% and 5% of individuals older than 55 years in Western countries. Epidemiological studies have shown that PDB patients can be divided into two groups, a familial patient group and a sporadic group, with at least partially divergent pathogenic mechanisms. In a previous study, we have shown that polymorphisms in the TNFRSF11B gene encoding OPG have a gender-specific influence on the development of sporadic PDB in both Belgian and UK study populations [1]. With the current research we wanted to investigate whether a similar effect could be observed for SNPs in TNFRSF11 encoding RANKL.

Based on HapMap data and using an r^2 -based tagging strategy, we selected 10 SNPs and 2 multi-marker tests that cover all known common (minor allele frequency > 5%) genetic variation in a 44.57kb region surrounding TNFRSF11. These SNPs were genotyped in a population of 159 sporadic Belgian PDB patients and 186 Belgian control individuals. After genotyping one SNP, rs633137, turned out not to be in Hardy-Weinberg equilibrium in controls and was excluded. The remaining 9 SNPs in combination with the 2 multi-marker tests fail to cover 6 informative SNPs in the selected region (resulting in 85.4% coverage). However, these SNPs are all located intronic or at the 3' end of the gene. Genotyping and testing the selected SNPs and multi-marker tests in our Belgian study population indicated that none of them is associated with PDB and no gender-specific effects were observed.

This indicates that in contrast to OPG polymorphisms, RANKL polymorphisms do not play a role in the development of sporadic PDB. Analysis of other populations is necessary to confirm this result.

Multifactor Dimensionality Reduction Reveals Antagonistic Epistasis Between ESR1 and ESR2 with BMD Variation in Southern Chinese Women. S. M. Xiao, C. L. Cheung, A. W. C. Kung. The Department of Medicine, The University of Hong Kong, Hong Kong, China.

Osteoporosis is a complex disease, which is affected by both genetic and environmental factors. Epistasis is thought to be a critical genetic architecture underlying complex disease, which allows genetic buffering, i.e. to stabilize the trait through the interaction of polymorphisms in different loci in the gene network. A recent study demonstrated that multifactor dimensionality reduction (MDR) is one of the best ways to study epistasis. In this study, we applied MDR in studying the epistasis between two closely related candidate genes for BMD variation, ESR1 and ESR2.

To study the relation of ESR1 and ESR2 polymorphisms in hip BMD variation in southern Chinese women, 827 subjects with either low BMD (defined by a BMD Z score less than -1.28 at either the femoral neck or total hip) or high BMD (score greater than +1) were studied. A novel CA repeat polymorphism (D6S440) in ESR1 and 8 SNPs in ESR2 were genotyped. We previously reported CA repeat size of 18 was most discriminative for hip BMD in a population cohort. Multifactor dimensionality reduction was applied to test the epistatic effect, with subsequent confirmed by binary logistic regression (at least one allele >18 CA repeats vs <18 repeats) with adjustment of age, height and weight.

Carriers of 18 CA repeats of ESR1 were associated with higher BMD at the femoral neck (OR: 2.4, $p=0.001$) or hip (OR: 3.2, $p<0.001$). Variant allele of T-1213C of ESR2 was associated with lower BMD at the femoral neck (OR: 1.7, $p=0.042$) and variant allele of T-1213C and rs3742641 was associated with low BMD at the total hip (OR: 2.2, $p=0.011$ and OR: 2.2, $p=0.013$ respectively). MDR revealed significant epistasis between 18 CA repeats of ESR1 with several polymorphisms of ESR2 for 2-way, 3-way and 4-way interactions (testing accuracy > 50%). These results were confirmed by binary logistic regression model. Interestingly, when 18 CA repeat interacted with rs944052, rs3742641 and rs928554 of ESR2, the OR resulted from gene-gene interaction was 1.0 ($p=0.038$) at femoral neck and 1.1 ($p=0.004$) at hip.

The epistasis between ESR1 and ESR2 significantly altered the single gene effect of either ESR1 or ESR2. We have demonstrated the epistasis between genes in the same gene network significantly altered the single gene effect. Testing for gene epistasis in association with BMD variation is a powerful approach to understand the pathophysiology of low bone mass in the general population.

The Association between Peak Hip Axis Length and Polymorphisms of the Vitamin D Receptor and Estrogen Receptor 1 genes in Chinese Healthy Men. Z. Zhang, J. He*, J. Gu*. The Department of Osteoporosis, Osteoporosis Research Unit, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China.

To investigate the possible relationship between peak hip axis length (HAL) and polymorphisms of the vitamin D receptor (VDR) and estrogen receptor 1 (ESR1) genes in Chinese healthy men. A total of 252 healthy men aged from 20 to 40 (29.9 ± 5.9 years) of Han nationality in Shanghai were recruited and were measured for hip axis length (HAL, cm) using DXA (Lunar-Prodigy). The VDR Apa I and Fok I genotype and ESR1 Pvu II and Xba I genotype were determined by PCR-RFLP. The distribution of Apa I genotype was as follows: aa 54.4%, Aa 38.5%, AA 7.1%, respectively. Frequencies of Ff, FF, and ff genotype were 52.4%, 25.4%, and 22.2%, respectively. The distribution of Pvu II genotype was as follows: Pp 46.0%, pp 41.3%, PP 12.7%, respectively. Frequencies of xx, Xx and XX genotype were 71.0%, 25.4% and 3.6%, respectively. After phenotypes were adjusted for age, height, and weight, a significant association was found between VDR Apa I genotype and HAL ($P=0.04$). The HAL of subjects with aa genotype (111.5 ± 0.5) were significant higher than that of Aa genotype (109.8 ± 0.5) ($p=0.015$). Moreover, significant association was found between VDR Fok I genotype and HAL ($P=0.002$), and The HAL of subjects with ff genotype (112.6 ± 0.7) were significant higher than that of Ff genotype (110.8 ± 0.5) ($p=0.031$) and that of FF genotype (109.1 ± 0.7) ($p=0.000$). Neither Pvu II genotype nor Xba I genotype was significantly associated with HAL. The study suggested that Apa I and Fok I polymorphism in VDR gene may have influence on variation of peak HAL in Chinese men, but Pvu II and Xba I polymorphism in ESR1 gene is not the quantitative trait loci (QTL) underlying peak HAL variation.

Paclitaxel-loaded Hydroxyapatite-alginate Beads for Local Chemotherapy of Metastatic Spine Cancer in Rats. T. Abe^{*1}, M. Sakane¹, T. Ikoma^{*2}, T. Yoshioka^{*3}, J. Tanaka^{*3}, N. Ochiai^{*1}. ¹Orthopedic Surgery, University of Tsukuba, Tsukuba, Japan, ²Biomaterials Center, National Institute for Materials Science, Tsukuba, Japan, ³Metallurgy and Ceramics Science, Tokyo Institute of Technology, Tokyo, Japan.

Breast cancer is one of the most common cancers to develop metastasis to bone. Of these, spine is the most frequent site. As therapy for systemic cancer improves, local control of metastatic site is becoming important. Among patients with breast cancer that had metastasized to bone, 5-10% did not respond to treatment and developed metastatic epidural spinal cord compression. Paralysis caused by spinal cord compression is directly associated with survival and quality of life of breast cancer patients. We have shown successful loading of the Hydroxyapatite (HAP)-alginate carrier with paclitaxel (PTX) previously. This study was made to clarify the effects of the PTX-loaded HAP-alginate beads administered therapeutically in a rat model of metastatic spine cancer. Rat's mammary adenocarcinoma (the CRL-1666 cell line) and female Fischer 344 rats (8 weeks old) weighing 130-150 grams were used. The PTX-loaded HAP-alginate beads were available by the spray-drying method and the gelation of alginate acid. A 7.4 wt% of PTX (0.13 mg) was contained in each HAP-alginate bead with a diameter of 2.2 mm. We made in vivo biocompatibility test by implantation in the paravertebral muscle, performed surgery to obtain metastatic spine cancer model. Thirty rats with metastatic spine cancer were divided into 3 groups. We checked hind-limb motor function and survival time using the BBB scale. The mean time before onset of paralysis of the local-treatment group (n = 12) was 17.45 days, which was significantly longer than 9.0 days of the control group (n = 8). The effect of the systemic-treatment group (n = 10) that administered intravenously was not evident despite 3 times of 6-fold higher dosage of PTX. In addition, the HAP-alginate carrier and local administration of the PTX-loaded HAP-alginate beads showed no toxicity, whereas intravenous administration of PTX showed severe complications including phlebitis of tail vein and sudden death. This report documents that the local administration of the PTX-loaded HAP-alginate beads showed significant delay in the mean time before onset of hind-limb paralysis. The results indicate local chemotherapy offers promise as less invasive treatment for metastatic spine cancer to delay the potential problem of onset of paralysis.

Both N- and C-terminal Fragments of PTHrP exert Pro-Survival Effects on Human Prostate Cancer Cells Through Transcription Factor Runx-2. V. Alonso^{*1}, F. C. Pérez-Martínez^{*2}, F. J. Calahorra^{*2}, P. Esbrit¹. ¹Bone and Mineral Metabolism Laboratory, Fundación Jiménez Díaz, Madrid, Spain, ²Urology Department, Fundación Jiménez Díaz, Madrid, Spain.

The propensity of prostate cancer (PCa) to metastasize to bone seems to be related to the osteomimetic properties of PCa cells. In the present study, we analyzed the putative mechanisms whereby the osteoblast-like features of these cells can promote their survival. Human prostate cancer PC-3 cells were treated with a high dose (50 µM) of the phytoestrogens genistein and daidzein or 17β-estradiol for 24-48 h. Cell death was analyzed by trypan blue exclusion and flow cytometry (propidium iodide staining). Bone-related factors that are expressed by PC-3 cells: parathyroid hormone-related protein (PTHrP) and the PTH1 receptor (PTH1R), osteoprotegerin (OPG), receptor activator of NF-κB ligand (RANKL), and Runx2, as well as apoptosis-related proteins were evaluated by Western blot. Our results show that genistein induces apoptosis (2-fold vs basal) in PC-3 cells; this effect does not appear to be dependent on estrogen receptors, since the same dose of either daidzein or 17β-estradiol failed to affect PC-3 cell death. The pro-apoptotic effect of genistein was unchanged by a neutralizing anti-OPG antibody. However, PTHrP (7-34), a PTH1R antagonist, induced PC-3 cell death in the presence or absence of each phytoestrogen. Moreover, PTH1R protein expression was significantly increased (2-fold vs basal) by both genistein and daidzein in these cells. In addition, pre-treatment (1 h) with 100 nM of either PTHrP (1-36) or PTHrP (107-139) -which does not interact with the PTH1R- abrogated the pro-apoptotic effect of genistein in PC-3 cells. This effect of each PTHrP peptide was associated with an increase in RANKL protein expression. However, blockade with a neutralizing RANKL antibody or stimulation with exogenous RANKL (50 ng/ml) failed to modify genistein-induced PC-3 cell death. We found that each PTHrP fragment triggered Runx-2 nuclear protein internalization, and Bcl-2/Bax ratio (1.5-fold vs basal; at the expense of a Bcl-2 protein increase) in PC-3 cells. Interestingly, PC-3 cells transfected with a dominant negative Runx2 construct abolished these protective effects of both PTHrP peptides.

In conclusion, the present in vitro findings support the anti-apoptotic action of both N- and C-terminal PTHrP fragments in PCa cells. Our data also indicate the pivotal role of Runx-2 on this protective effect of these PTHrP fragments on these cells.

Progression of Osteonecrosis of the Jaw in Breast Cancer Patients even with Discontinuation of Intravenous Bisphosphonate Therapy. C. Barragan-Adjemian^{*1}, L. Lausten^{*2}, M. L. Johnson¹, J. O. Katz^{*3}, L. F. Bonewald¹. ¹Oral Biology, University of Missouri Kansas City, Kansas City, MO, USA, ²Special Patient Care, University of Missouri Kansas City, Kansas City, MO, USA, ³Oral Pathology, Medicine and Radiology, University of Missouri Kansas City, Kansas City, MO, USA.

Intravenous bisphosphonate (BP) therapy has become the standard of care for the treatment of cancers that metastasize to bone. BPs have been associated with osteonecrosis of the alveolar bones, a condition known as bisphosphonate-related osteonecrosis of the jaw (BRONJ). The incidence or pathogenesis of BRONJ is largely unknown. The lesions are characterized by exposed necrotic bone with no evidence of healing after 8 weeks in the absence of radiation to the head and neck. BRONJ lesions have been recalcitrant to conventional therapies. The current recommendation is to proceed with non invasive dental treatment with patients on BP therapy. If an ONJ lesion has been diagnosed discontinuance of IV infusion of BPs is recommended if systemic conditions permit. We hypothesized that discontinuation of the intravenous BPs in breast cancer patients does not prevent further evolution of the lesions as detected using cone-beam computerized tomography (CBCT), although soft tissue may appear healed. Six subjects with breast cancer in remission that had discontinued BP therapy were followed for at least two years. Dental evaluations and CBCT were performed to follow the progression of the BRONJ lesions. BRONJ lesions were clinically observed and diagnosed during the period of 1 month to 2 years after discontinuation of BP. In all cases, there was exposed, necrotic bone. Two of the BRONJ lesions were associated with an extraction, one lesion was associated with an adjacent periradicular abscess and subsequent root canal and three lesions occurred spontaneously. All of the subjects received the appropriate treatment for the lesions. None of the lesions had completely healed even after discontinuation of BP therapy for up to 2 years. In one subject, the baseline CBCTs revealed a large sequestrum on the mandibular ridge with a surrounding sclerotic area. After vigorous treatment with antibiotics and local surgical debridement of the sequestrum, the gingival tissue healed leaving a small fistula. A CBCT taken one year after diagnosis demonstrating further progression of the diseased state; sclerotic bone and small sequestrums were still present 2 years on CBCT after cessation of the BP therapy. In conclusion, BRONJ lesions can persist for up to 2 years after cessation of BP treatment and CBCT is a technology that can identify and follow the progression of lesions in BRONJ patients allowing better diagnosis and assessment of disease status.

PTHrP Regulation of Aldo-Keto Reductase 1C3 and Growth in Prostate Cancer Cells. T. M. Downs^{*1}, R. H. Hastings^{*2}, F. Araiza^{*3}, D. Burton^{*4}, A. Stolz^{*5}, L. J. Defos^{*4}. ¹Surgery, Veterans Administration San Diego Healthcare System and University of California, San Diego, CA, USA, ²Anesthesiology, Veterans Administration San Diego Healthcare System and University of California, San Diego, CA, USA, ³Moore's Cancer Center, San Diego, CA, USA, ⁴Medicine, Veterans Administration San Diego Healthcare System and University of California, San Diego, CA, USA, ⁵Medicine, University of Southern California, San Diego, CA, USA.

Parathyroid hormone-related protein is involved in prostate tumor development, growth, progression and metastasis to bone, but the molecular mechanisms that PTHrP uses are not well defined. We previously demonstrated that DU 145 prostate carcinoma cells upregulated aldo-keto reductases (AKR1C1-3) mRNAs when stably transfected to express PTHrP. The goal of this study was to explore the role of PTHrP on prostate cancer growth and its interactions with AKR1C3 and the regulation of androgen and prostaglandin metabolism. We studied the effects of PTHrP on AKR1C3 levels in DU 145 human prostate cancer cells with quantitative PCR, western, and enzymatic studies. We also evaluated the effects of PTHrP, androgens, and prostaglandins on cell proliferation and apoptosis. PTHrP treatment demonstrated significant increases in AKR1C3 mRNA levels in DU 145 cells, increased AKR1C3 protein expression up to 5-fold, and augmented cellular reductase activity. Furthermore, PTHrP promoted prostate cancer cell proliferation and protected the prostate cancer cells against UV and gamma irradiation induced apoptosis. 5α-dihydrotestosterone and 5-androstane-3α-17β-diol had no stimulatory activity on cell proliferation in the androgen receptor-negative cells, but the androgens stimulated the androgen-dependent LNCaP cells. Prostaglandin D2, an AKR1C3 substrate, inhibited prostate cancer cell proliferation, but its metabolite, 9α-11β-prostaglandin F2, had no effect on growth. In summary, PTHrP stimulates the growth, apoptosis, and AKR1C3 expression of androgen-independent prostate cancer cells. These effects could be mediated through AKR1C3-catalyzed reductions in the levels of prostaglandin D2.

Wnts Increase Osteoblast Activity in Prostate Cancer Through Bone Morphogenetic Proteins. J. Dai, C. L. Hall*, J. Escara-Wilke*, E. T. Keller. Department of Urology, University of Michigan, Ann Arbor, MI, USA.

Our previous studies have shown that bone morphogenetic proteins (BMPs) promote prostate cancer (PCa) osteoblastic activity, but upstream inducers of BMP expression in PCa are unknown. Wnts are mediators of osteogenesis. In this study, we investigated a potential role of Wnts in PCa osteoblastic lesions.

To investigate whether Wnts regulate the expression of BMPs in PCa cells, C4-2B cells were treated with Wnt3a and Wnt5a. Wnt3a increased BMP4 mRNA and protein expression, whereas Wnt5a increased BMP6 mRNA and protein expression. To investigate whether Wnts activate BMP promoters, C4-2B cells were transfected with BMP4 or BMP6 promoter. Wnt3a increased mainly BMP4 promoter activity, whereas Wnt5a only increased BMP6 promoter activity. DKK-1 and sFRP-1, inhibitors of Wnt binding to Wnt receptors, blocked Wnt3a-induced BMP4 promoter activity. To elucidate whether Wnt canonical pathway or non-canonical JNK-dependent signaling pathway mediate Wnts-induced BMP promoter activity, C4-2B cells transfected with BMP4 or BMP6 promoter were treated with Axin-2, a negative regulator of the canonical Wnt pathway, or a JNK inhibitor. Axin-2 blocked Wnt3a-induced BMP4 promoter activity, and the JNK inhibitor diminished Wnt5a-induced BMP6 promoter activity. To define how Wnts mediate osteoblast activity, MC3T3-E1 cells were treated with Wnt3a or Wnt5a. Wnt3a and Wnt5a increased alkaline phosphatase activity and osteocalcin level. Dkk-1 completely, whereas Noggin, a BMP inhibitor, partially blocked Wnt3a-mediated osteoblast activity, both together did not show further inhibition. DKK-1 and Noggin partially blocked Wnt5a-mediated osteoblast activity and both together showed further inhibition. To investigate whether the secreted proteins from PCa cells mediate osteoblast activity, MC3T3-E1 cells were treated with C4-2B cells or LuCaP23.1 cells conditioned medium (CM). C4-2B cells and LuCaP23.1 CM increased ALP activity and osteocalcin level. Dkk-1 and sFRP-1 partially blocked CM-mediated pro-osteoblast activity. DKK-1 and Noggin together block CM-mediated osteoblast activity. To further elucidate whether C4-2B cells or LuCaP23.1 cells CM-mediated osteoblast activity through BMPs, MC3T3-E1 cells were treated with CM from C4-2B or LuCaP23.1 cells pretreated with DKK-1 and/or Noggin. DKK-1 completely, whereas Noggin partially, blocked CM-mediated pro-osteoblast activity. DKK-1 and Noggin together had no further inhibition on the CM-mediated pro-osteoblast activity. Taken together, we conclude that PCa cells promote osteoblastic activity through both direct Wnt3a and Wnt5a activity on pre-osteoblasts, as well as through induction of BMP4 and BMP6 expression that occurs through both the canonical and non-canonical pathways.

Urinary Excretion of ^{41}Ca in Mice: Application of ^{41}Ca in Cancer-induced Bone Disease. R. L. Fitzgerald¹, D. W. Burton², T. Griffin^{1*}, L. J. Defetos², D. A. Herold^{1*}, D. J. Hillegonds³. ¹Pathology, VAMC/UCSD, San Diego, CA, USA, ²Endocrinology, VAMC/UCSD, San Diego, CA, USA, ³AMS, Lawrence Livermore National Laboratories, Livermore, CA, USA.

Background: ^{41}Ca is novel tracer technique that promises a direct measure of net bone calcium balance in both humans and in animal models.

Purpose: To establish a timeline for the excretion of ^{41}Ca in normal mouse urine and to show the feasibility of monitoring prostate cancer induced bone disease.

Methods: 6 week old male mice were injected i.p. with 10 nCi ^{41}Ca and 24 hour urines were collected once per week for 7 weeks. Feasibility of monitoring prostate cancer induced bone disease was demonstrated by dosing three groups of male immunocompromised mice (1=saline/saline, 2=tumor/saline, and 3=tumor/bisphosphonate) with 10 nCi ^{41}Ca . Three weeks later, the mice were injected i.p. with saline or zoledronate (5 ug/mouse). Four weeks after ^{41}Ca dosing, the mice were injected intra-tibially with saline or 10^6 PC-3-GFP cells. The saline or zoledronate injections were repeated every 4 weeks. Urine and fluorescent images were collected weekly from each mouse for 10 weeks.

Results: Steady-state $^{41}\text{Ca}/\text{Ca}$ ratios were reached at 14 days after ^{41}Ca injection and the $^{41}\text{Ca}/\text{Ca}$ ratios were approximately 10,000-fold above baseline (see Figure 1). In the prostate cancer model, initial results demonstrate that the tumor can be visualized 2 weeks after prostate cancer cell injection and that zoledronate significantly reduces the severity of the bone lesion, as quantitated by x-ray scoring.

Conclusion: Successful implementation of a ^{41}Ca assay in cancer patients with metastatic bone disease could have wide benefits, including improved risk assessment, monitoring treatment, and early detection of metastasis.

Figure 1. Mean (+/-SEM) of urinary $^{41}\text{Ca}/\text{Ca}$ following a 10 nCi dose of ^{41}Ca (N= 2 or 3). Note y axis is logarithmic.

Breast Cancer Cells Inhibit Osteoblast Differentiation. J. E. Fong^{1*}, D. Le Nihouannen¹, O. Hussein¹, P. M. Siegel², S. V. Komarova¹. ¹Dentistry, McGill University, Montreal, PQ, Canada, ²Medicine, McGill University, Montreal, PQ, Canada.

Skeletal metastasis is a major complication of advanced breast cancer which results in bone fractures and considerable pain burden. Osteoclasts recruited to the site of metastasis lead to the destruction of bone and formation of osteolytic lesions. Osteoblasts are known to contribute to osteoclast activation by producing a key pro-resorptive cytokine RANKL, however the effects of cancer cells on osteoblasts are not fully understood. We have studied the effects of MDA-MB-231 human breast carcinoma cells on proliferation and differentiation of primary osteoblast precursors. MDA-MB-231 cells were cultured until 80% confluent, and conditioned medium was collected after 24h of culturing. Bone marrow cells were isolated from the long bones of C57BL/6J mice, and treated for 5 days with ascorbic acid (50 µg/ml) in the presence or absence of MDA-MB-231 conditioned medium (10%). As a control, we used medium conditioned by MC3T3-E1 cells. Cell numbers were assessed in samples labeled with nuclear stain DAPI, and processed using image analysis. Treatment with ascorbic acid alone led to formation of 390 +/- 90 cells/mm². Addition of MDA-MB-231 conditioned medium to osteoblastic cultures led to a 2-3 fold increase in cell number, whereas treatment of cultures with MC3T3 conditioned medium had no effect, indicating that MDA-MB-231 cells produce factors that stimulate proliferation of osteoblastic cells. To assess osteoblast differentiation, the cultures were stained for alkaline phosphatase (ALP) and the labeled area was quantified using image analysis. Even at this early cultures, treatment with ascorbic acid alone led to significant increase in APL-positive cells, compared to untreated cultures. Addition of MDA-MB-231 conditioned medium to ascorbic acid-treated cultures resulted in a 5-fold decrease in ALP expression. Thus, our data indicate that soluble factors produced by breast cancer cells stimulate proliferation and inhibit differentiation of native osteoblasts. Since it has been previously shown that immature osteoblast precursors represent a major source of RANKL, compared to mature osteoblasts, our findings suggest a novel mechanism for osteoblast-mediated stimulation of osteoclasts that potentially contributes to the establishment and progression of metastatic lesions in bone.

TGF- β Increases Osteolytic Prostate Cancer Bone Metastases and Expression of Pro-metastatic Genes. P. G. J. Fournier, G. A. Clines, J. M. Chirgwin, T. A. Guise. Internal Medicine, University of Virginia, Charlottesville, VA, USA.

Prostate cancers commonly metastasize to bone, where high concentrations of TGF- β are released by osteoclastic resorption. TGF- β stimulates production of PTHrP, IL-11 and CTGF, which are central factors in bone metastases due to breast cancer and melanoma. We hypothesized that TGF- β would also promote prostate cancer bone metastases.

First, we showed that a specific inhibitor of the TGF- β type I receptor (T β RI) kinase, SD-208, inhibited TGF- β -dependent Smad2 phosphorylation in PC-3 prostate cancer cells in vitro. Mice were inoculated with PC-3 cells via the left cardiac ventricle. In both prevention and treatment protocols, SD-208 (50mg/kg/d) decreased osteolytic metastases and increased survival. To determine downstream targets of TGF- β in prostate cancer, we analyzed PC-3 cells treated with TGF- β (24h, 5ng/mL) by Affymetrix gene array with DMT and dCHIP data analyses. Significantly upregulated genes included known TGF- β targets PTHrP, CTGF, MMP-13, TSP-1 and ADAM19, which function in bone remodeling or are dysregulated in cancer.

The most increased gene was PMEPA1 (23.2-fold, P<0.03), a protein highly expressed in breast, colon and prostate cancers. Using real-time qPCR of RNA from PC-3 cells treated with TGF- β (5ng/mL, for 0 to 48h), we confirmed that PMEPA1 mRNA was rapidly induced and peaked at 24h (16.7-fold, P<0.05). TGF- β also increased PMEPA1 mRNA in prostate, breast and lung cancer lines. PC-3 cells were treated with SD-208, the transcription inhibitor actinomycin D, or the translation inhibitor cycloheximide; the results showed that TGF- β directly activates PMEPA1 transcription. TGF- β also increased PMEPA1 protein production in PC-3 by Western blot; the induction was prevented by SD-208. We cloned and made deletion mutants in 3.7kb of the PMEPA1 promoter, which contains 5 putative Smad binding elements. Dual-luciferase assays and overexpression of Smad2, -3 and -4, indicated that PMEPA1 transcription is regulated by TGF- β via both Smad-dependent and independent pathways.

PMEPA1 interacts with the E3 ubiquitin ligase Nedd4, which is related to the Smurfs. These proteins inhibit TGF- β signaling by targeting Smads and T β RI for proteasomal degradation. PMEPA1 could prevent proteasomal inhibition of the TGF- β pathway by suppressing Nedd4/Smurf activity, leading to sustained TGF- β signaling in bone metastases. Our data indicate that TGF- β promotes osteolytic bone metastases by stimulating known prometastatic factors, as well as novel factors that may enhance TGF- β signaling in the tumor cell. Thus, TGF- β inhibitors should be effective treatments for osteolytic prostate cancer bone metastases.

Serum TRACP 5b Increases with Advancement of Osteolysis in a Nude Mouse Model of Breast Cancer Bone Metastasis. M. I. Suominen, R. Käkönen*, J. P. Rissanen, S. Ylönen*, J. M. Halleen. Pharmatest Services Ltd, Turku, Finland.

Serum tartrate-resistant acid phosphatase isoform 5b (TRACP 5b), a marker of osteoclast number, is significantly elevated in breast cancer patients with bone metastases. We investigated if elevated TRACP 5b values would indicate the development of bone lesions in a mouse model of breast cancer bone metastasis. MDA-MB-231(SA) breast cancer cells (n=19) or PBS (n=11) were inoculated into the left cardiac ventricle of five-week-old female nude mice. Serum samples were collected before the inoculation (day 0), at days 6, 9, 13, 16, and at sacrifice (day 23). Bone lesions were quantitated by radiography at days 16 and 23. Bone samples were collected for histomorphometric analysis at day 23, and osteoclasts were counted from TRACP-stained sagittal sections. Statistical analysis was performed using Student's t-test with necessary transformations after checking the assumptions for normality and homogeneity of variances. A p-value <0.05 was considered statistically significant. Pearson's correlation coefficients were calculated for cancer-inoculated mice. Body weight of the tumor-bearing animals was significantly lower compared with the PBS-controls at sacrifice due to tumor-induced cachexia. Osteolytic foci were found in 47.4% of the cancer cell-inoculated mice already at day 16, and all animals had lesions at sacrifice. Because the animals were growing rapidly during the study, their TRACP 5b values decreased in both groups during the first two weeks. At day 16, the TRACP 5b values reached a plateau in the control mice inoculated with PBS. However, in the cancer cell-inoculated mice, TRACP 5b values were elevated on day 16, and a sharp increase was observed between days 16 and 23. The changes in TRACP 5b values were significantly different in the cancer cell-inoculated mice than in the control mice on days 16 and 23. The TRACP 5b values correlated with osteolytic area determined by radiography on day 23. Furthermore, the TRACP 5b values correlated reversibly with body weight in tumor-bearing mice at sacrifice, whereas no correlation was observed in control mice. The histomorphometrically determined number of osteoclasts was radically increased, as expected based on the increased TRACP 5b values, and bone volume was decreased in the cancer cell-inoculated mice. Of note, large numbers of osteoclasts were found residing inside the tumor, with no bone surface nearby. These results demonstrate that TRACP 5b correlates with osteolysis and tumor-induced cachexia and is therefore a useful marker in the nude mouse model of breast cancer bone metastasis.

Calcium Enhances Anti-tumor Effects of Ibandronate in Breast Cancer Cells. F. Journe¹, N. Kheddoumi*¹, C. Chaboteaux*¹, G. Laurent*², J. J. Body¹. ¹Institut Bordet, Brussels, Belgium, ²Université de Mons-Hainaut, Mons, Belgium.

Bisphosphonates now constitute standard therapy for the management of breast cancer-induced skeletal complications. Although their therapeutic effects mainly result from an inhibition of osteoclastic bone resorption, in vitro data indicate that bisphosphonates may also act directly on breast cancer cells by inhibiting their proliferation and inducing their apoptosis. This study examined the effects of Ca++ on the growth inhibitory activity of ibandronate in MDA-MB-231 and MCF-7 breast cancer cell lines. In presence of 0.6 mM Ca++, 30 µM ibandronate had no effect on MDA-MB-231 cell growth, and only a borderline effect on MCF-7 cell growth (13.6±6.6% inhibition). By contrast, in presence of 2 mM Ca++, ibandronate dramatically inhibited cell culture growth by 55.5±7.8% and 76.1±4.6% (p<0.01) in MDA-MB-231 and MCF-7 cells, respectively. Moreover, dose-response curves revealed that increasing Ca++ concentrations from 0.6 to 1.6 mM decreased ibandronate IC50 values of from 100 to 30 µM in MDA-MB-231 cells and from 60 to 10 µM in MCF-7 cells. In addition, whereas 30 µM ibandronate did not markedly induce cell apoptosis in presence of 0.6 mM Ca++, it significantly increased the percentage of apoptotic cells (annexin V-PE-positive) in presence of 1.6 mM Ca++ (11.4 and 32.9% in MDA-MB-231 and MCF-7 cells, respectively). Of note, Ca++ chelation by EGTA at a concentration which did not affect cell growth (0.5 mM) significantly reduced the growth inhibitory effect of 30 µM ibandronate in culture medium containing 1.6 mM Ca++. To address the effects of Ca++ on cell drug accumulation, cells were cultured in medium containing 0.6 or 1.6 mM Ca++ and were exposed to [14C]-ibandronate for 4 hours. In presence of 1.6 mM Ca++, cells accumulated much more [14C]-ibandronate than cells cultured in presence of 0.6 mM Ca++ (about 4.6 and 11.4-fold increases in MDA-MB-231 and MCF-7 cells, respectively). Finally, when evaluating the inhibition of protein prenylation, we found that high Ca++ level increased the intracellular activity of ibandronate. Thus, in both cell lines, 10 µM ibandronate were sufficient to produce a detectable inhibition of Rap1A prenylation in presence of 2 mM Ca++, while 100 µM ibandronate were required to achieve a similar effect in presence of 0.6 mM Ca++. In conclusion, our data indicate that extracellular Ca++, likely through its binding to ibandronate, modifies its cellular pharmacokinetics and increases its inhibitory activity on tumor cells. Thus, Ca++ released during the process of tumor-induced osteolysis could enhance the anti-tumor effects of bisphosphonates.

Heparin-like Polysaccharides Markedly Reduce Osteolytic Bone Destruction and Tumor Growth in a Mouse Model of Breast Cancer Bone Metastasis. R. S. Kakonen*¹, S. Kakonen², K. S. Mohammad*³, J. P. Rissanen¹, J. M. Halleen¹, A. Warri*⁴, L. Nissinen*⁴, M. Pihlavisto*⁴, J. M. Chirgwin³, M. Salmivirta*⁵, A. Marjamäki*⁴, T. A. Guise³. ¹Pharmatest Services Ltd, Turku, Finland, ²Department of Anatomy, University of Turku, Turku, Finland, ³University of Virginia, Charlottesville, VA, USA, ⁴BioTie Therapies Corp, Turku, Finland, ⁵Turku Centre for Biotechnology, Turku, Finland.

Heparin treatment effectively prevents venous thromboembolism, but may also prolong survival in patients with malignant disease. Experimental studies support the hypothesis that cancer progression can be influenced by heparin and heparin-like glycosaminoglycans (HLGAGs), but their widespread use is hindered by their high anticoagulant activity. We have evaluated the therapeutic potential of two HLGAGs with low anti-coagulant activity, a low-molecular-weight synthetic heparin (fragmin), and a high-molecular-weight K5-derived heparin-like polysaccharide (K5-NSOS), to inhibit osteolytic bone destruction and tumor growth in an experimental mouse model of breast cancer bone metastasis. MDA-MB-231 breast cancer cells were inoculated into the left cardiac ventricle of athymic nude mice, which were then administered with Fragmin, K5-NSOS or vehicle once daily for 4 weeks. HLGAG-treated animals had significantly increased body weight when compared to vehicle. In addition, osteolytic lesion area as measured by radiography was significantly decreased by both HLGAGs. Histomorphometric examination revealed that both HLGAGs significantly reduced tumor burden in bone. In vitro studies showed that both HLGAGs inhibited significantly cancer cell adhesion, and K5-NSOS inhibited significantly bone resorption activity of human osteoclasts. Our data demonstrate that HLGAGs can efficiently reduce osteolytic lesion area and tumor burden in bone. K5-NSOS HMW is a potential antimetastatic and antiresorptive agent with low anticoagulant activity, and it could be further optimized as an anti-tumor agent.

Human Breast Stem Cell Transformation and Invasiveness Is Mediated Upregulation of IL-8 by TWIST Interactions with NFκB. S. E. Kendall*¹, K. S. Aboody*², S. D. Flanagan*³, C. A. Glackin¹. ¹Molecular Medicine, City of Hope/Beckman Research Institute, Duarte, CA, USA, ²Hematopoietic Cell Transplantation/Neurosciences, City of Hope/Beckman Research Institute, Duarte, CA, USA, ³Neurosciences, City of Hope/Beckman Research Institute, Duarte, CA, USA.

Interleukin (IL-8), a prototypical chemokine has been shown to play an important role in tumor growth, angiogenesis and metastasis. Transcriptional activation of IL-8 is critically dependent on NFκB, but can be modulated by several transcription factors, i.e. AP-1, C/EBP and NRE. TWIST, a basic helix-loop-helix transcription factor has been shown to bind to NFκB and transcriptionally repress two pro-inflammatory cytokines, IL-1β and TNFα at E-box consensus sites on their respective promoters. We have previously demonstrated that TWIST over-expression in benign human breast cancer cells (MCF-7) significantly enhances their growth and invasiveness through an epithelial to mesenchymal transition (EMT) process. In our current studies, designed to delineate these early transformation events, we over-expressed TWIST in the MCF10A human breast luminal epithelial cell line. Results display a phenotypic change in their cell surface marker expression (ESA, Muc1, CD49f), reminiscent of breast stem cells. Affymetrix microarray analysis confirmed EMT associated differential gene expression where epithelial markers such as Keratins and E-cadherins were down regulated and mesenchymal markers such as vimentin were upregulated. Western blot analysis also reflected EMT related changes, such as the E- to N-cadherin switch. However, elevated levels of cytokines (IL-1α, IL-8, uPAR?) and their target genes (NFκB, MMP9, uPA) were observed, indicating that alterations in these inflammatory signaling pathways were being affected by TWIST overexpression. Protein array screening of conditioned media from TWIST over-expressing cells confirmed significantly elevated levels of IL-8. Moreover, TWIST and NFκB form a transcription factor complex that interacts to enhance IL-8 expression through the NFκB consensus site on the IL-8 promoter. The signals produced through CXCR1 and CXCR2 binding activate MMP9 gene expression. Importantly, TWIST over-expressing cells show a significant level of MMP9 activity that facilitates their invasion towards osteocytes. Collectively our results suggest that TWIST over-expression in breast epithelial cells promotes their transformation to a stem cell-like state and enhances their invasive capabilities through the creation of an IL-8 feedback loop. Thus, TWIST may play a significant role in the transformation of normal/benign breast cells towards malignancy.

Zoledronic Acid Delayed the Wound Healing of Tooth Extraction Socket but Failed to Cause Osteonecrosis of the Jaw in Mice. Y. Kobayashi^{*1}, T. Hiraga^{*2}, A. Ueda¹, R. Nishimura¹, H. Yatani^{*3}, T. Yoneda¹. ¹Biochem, Osaka Univ Grad Dent, Suita, Japan, ²Oral Anat, Matsumoto Dent Univ, Matsumoto, Japan, ³Fixed Prosth, Osaka Univ Grad Dent, Suita, Japan.

Bisphosphonates (BPs), particularly nitrogen-containing BP such as zoledronic acid (ZOL) and pamidronate, have been widely- and beneficially-used for the treatment of cancer patients with bone metastases and/or hypercalcemia. However, observations are accumulating that cancer patients who have received these BPs occasionally show osteonecrosis of the jaw (ONJ) following dental treatments, especially tooth extraction. To understand the underlying mechanism of ONJ, we examined the effects of ZOL on the wound healing of tooth extraction socket. C57BL/J mice (6 week-old, male) were given ZOL (5µg/mouse, ip) once a day. After 7 days, the upper right first molar was extracted under anesthesia. Administration of ZOL was continued until 5 days after the tooth extraction. There was no marked histological difference in the wound healing of extraction sockets between control and ZOL-treated group until day 3. At day 5, histomorphometrical analysis revealed active new bone formation and substantial numbers of CD3-positive blood vessels in control mice. In contrast, the amount of new bones and the numbers of TRAP-positive osteoclasts and CD31-positive blood vessels were significantly decreased in ZOL-treated mice, indicating the delay of the socket healing. The non-nitrogen-containing BP etidronate (ETI, 5µg/mouse, ip) showed no effects on the healing. In the dorsal air sac (DAS) assay in which Millipore chambers containing VEGF and/or ZOL were implanted in the skin at the back of mice, ZOL significantly inhibited the angiogenesis promoted by VEGF. Moreover, ZOL (5-50µM), but not ETI, inhibited the proliferation of bone marrow endothelial cells and human endothelial-like cells in monolayer and collagen gel in a dose-dependent manner. ZOL also inhibited the capillary tube formation of human umbilical vessel endothelial cells on matrigel. Finally, we examined the effects of ZOL combined with doxorubicin (100µg/mouse, ip) and/or dexamethazone (400µg/mouse, ip) as a clinically-relevant setting. Contrary to our expectation, however, combination of these agents did not further delay the healing than ZOL alone. Of note, we did not observe ONJ following the treatment with each or combination of these agents. In conclusion, our results suggest that ZOL delays the wound healing of tooth extraction sockets through inhibiting new bone formation and angiogenesis. However, ZOL alone or combined with steroid and/or anti-cancer agent failed to cause ONJ in our model. Additional unknown factors may be involved in the pathogenesis of ONJ seen in cancer patients who have been treated with BPs.

Osteoblast - Prostate Cancer Cell Signaling: Role of Hedgehog Pathway. M. L. G. Lamm, T. Douglas^{*}. Pediatrics, Northwestern University Feinberg School of Medicine, and Children's Memorial Research Center, Chicago, IL, USA.

The key to understanding the proclivity of metastatic prostate carcinoma to bone lies in unraveling unique interactions between invading prostate cancer cells and host bone stroma including bone cells and extracellular matrix. The purpose of the present study is to test the hypothesis that Sonic hedgehog signaling between prostate cancer cells and osteoblasts promotes osteoblast differentiation, a requisite step toward metastatic prostate tumor formation in bone. Sonic hedgehog (Shh) is a secreted ligand that mediates epithelial-mesenchymal interactions critical to normal morphogenesis of many developing organs including the prostate. Shh signaling activates the expression of genes for the transcription factor Gli1 and the Shh receptor Ptc1 in target cells. The genes for Shh, Gli1, and Ptc1 are expressed in human prostate cancer specimens including prostate metastatic carcinoma. We have previously shown that human prostate cancer cells, LNCaP, which are genetically-engineered to express high levels of Shh (designated LNCaP-Shh cells) upregulate Gli1 and Ptc1 expression in stromal cells and promote xenograft prostate tumor growth in a mouse model.

In the present study, LNCaP-Shh cells and vector-transfected control LNCaP cells were co-cultured with mouse calvaria-derived non-transformed osteoblast precursor cells MC3T3-E1. Cells were co-cultured for varying periods of time either as mixed populations within the same culture chamber or separate populations in two chambers that share the same culture medium. Gene expression analysis was performed by real time quantitative RT-PCR using species-specific primers to differentiate gene expression between human and mouse cells. Staining for alkaline phosphatase activity was used as a marker of osteoblast differentiation.

Data show that Shh-expressing prostate cancer cells upregulate Gli1 and Ptc1 expression in osteoblasts and, this effect is inhibited by cyclopamine and dependent upon Gli transcriptional activity. Shh signaling in osteoblasts increases alkaline phosphatase activity and upregulates expression of osteopontin indicative of osteoblast differentiation. These results demonstrate that Shh signaling between prostate cancer cells and osteoblasts promotes osteoblast differentiation, and implicate the hedgehog signaling pathway in the development of osteoblastic prostate cancer metastasis.

Non-isomerized C-telopeptides of Type I Collagen (ALPHA CTX) for Early Detection and Treatment Monitoring of Bone Metastases Secondary to Prostate Cancer. D. J. Leeming¹, A. Hegele^{*2}, M. A. Karsdal¹, P. Qvist¹, P. Olbert^{*2}, C. Christiansen^{*1}, I. Byrjalsen¹. ¹Nordic Bioscience, Herlev, Denmark, ²Department of Urology, Philipps University, Medical School, Marburg, Germany.

Skeletal spread of metastasis represents a devastating event, which should be detected as early as possible prior to that of traditional imaging techniques. The objective of this study was to compare a novel biochemical marker of cancer mediated bone resorption, ALPHA CTX, to that of prostate specific antigen (PSA) and total alkaline phosphates (tALP) in patients with prostate cancer.

Two studies were performed. 1) Cross-sectional study of 170 prostate cancer patients without bone metastases (-BM) prior to radical prostatectomy, including 24 patients with lymph node metastases (+LN), compared to 68 controls. 2) Prospective study of 40 hormone refractory stage prostate cancer patients including 20 with bone metastases (+BM). Patients received four treatment cycles during four months of 35mg/m2 docetaxel in week 1, 2, and 3 (all patients) and 4mg zoledronate in week 1 (only +BM). Urine samples were collected at 0, 1, 2, 3 and 4 months and assessed in ALPHA CrossLaps (ααCTX) (Nordic Bioscience), PSA and tALP (Roche Diagnostics). Presence of bone metastases was determined by bone scans and verified by X-ray. Adjacent bone metastases sections from prostate cancer patients were stained for the presence of tumor cells (anti-cytokeratin antibody), osteoclasts (TRAP activity) and αCTX (anti-αCTX antibody).

PSA was elevated in both -LN and +LN patients compared to controls (p<0.001), ααCTX was only elevated in +LN patients (p<0.01); in contrast no difference in tALP was detected. In the prospective study, only ααCTX decreased significantly, -52% (p<0.05) and 62% (p<0.01) in the combined zoledronate/docetaxel group at week 4 and 16, respectively. The suppression of PSA and tALP in the +BM group was similar to the suppression induced by docetaxel in the -BM group. Immunohistochemistry revealed accumulation of TRAP+ osteoclasts and intense staining for αCTX epitopes in the proximity of tumor cells.

ααCTX was increased in +LN, indicating that these patients already had sustained skeletal spread as detected prior to that of imaging techniques, representing a high-risk group that need to be closely monitored. ααCTX in these patients predicts presence of skeletal spread of the malignancy, presently undetected by bone scans, and may thus be of great benefit for early detection of metastasis. In the prospective study, ααCTX decreased in zoledronate/docetaxel treated +BM patients to levels below docetaxel-treated -BM patients, emphasizing the skeletal specificity of this markers in contrast to PSA and tALP.

The α_vβ₃ Integrin Inhibitor MK-0429 Is Generally Safe and Decreases Bone Turnover in Men with Hormone-Refractory Prostate Cancer (HRPC) and Bone Metastases (MBD). M. Rosenthal^{*1}, P. Davidson^{*2}, F. Rolland^{*3}, A. Lombardi⁴, Y. Berd^{*4}, W. He^{*4}, L. Wehren⁴. ¹Melbourne Comprehensive Cancer Centre, Parkville, Australia, ²CURT Medical Trials Trust, Christchurch, New Zealand, ³Centre Gauducheau Medecine Oncologie, Saint Herblain, France, ⁴Merck & Co., Inc., Rahway, NJ, USA.

Background: Osteoclast adhesion to bone surface, essential for bone resorption, is mediated by α_vβ₃ integrin. Inhibition of this activity might slow the development or progression of MBD. MK-0429 is an oral α_vβ₃ inhibitor being evaluated in MBD in patients (pts) with HRPC.

Materials and methods: This multicenter Phase 1 study enrolled 21 pts with HRPC and MBD. Pts were randomized to receive either 200 mg (n=5) or 1600 mg (n=16) b.i.d. of MK-0429 for 4 weeks, with an optional open-label extension of 48 weeks. The study examined the toxicity and pharmacokinetics of MK-0429 in this population, as well as its effect on markers of bone turnover, urinary cross-linked N-telopeptides of type I collagen to creatinine ratio (uNTx), and bone-specific alkaline phosphatase (BSAP).

Results: Eighteen pts (86%) completed 4 weeks of treatment. All pts in the 200-mg group and 8 pts (50%) in the 1600-mg group subsequently entered the extension study. Nausea (Grade 1 or less commonly Grade 2) occurred in 11 pts in the 1600-mg group, and 1 pt in the 200-mg group. Only 1 Grade 3 event (anemia) occurred. Two pts in the 1600-mg group discontinued treatment (1 due to spinal cord compression, the other to nausea), and an additional pt withdrew consent. At 4 weeks, the mean AUC_{0-12hr} and C_{max} values were 210 µM•hr and 42 µM in the 200-mg group and 673 µM•hr and 154 µM in the 1600-mg group, respectively. Baseline and end-of-treatment values of the biochemical markers are displayed in the table.

Conclusions: In this Phase I study, MK-0429 was generally safe in pts with HRPC and MBD, with the most common side effect being nausea. There was evidence of an early reduction in biochemical markers of bone turnover.

Biochemical Marker*	200 mg b.i.d.		1600 mg b.i.d.	
	Baseline	% Change from Baseline	Baseline	% Change from Baseline

PTHrP-induced MCP-1 Production by Human Bone Marrow Endothelial Cells and Osteoblasts Promotes Osteoclast Differentiation In Vitro: A Novel Role in Prostate Cancer Bone Metastasis. Y. Lu¹, G. Xiao¹, Z. Cai^{*1}, X. Chen^{*1}, D. L. Galson¹, Y. Nishio^{*2}, A. Mizokami^{*3}, J. Zhang¹. ¹Medicine, University of Pittsburgh, Pittsburgh, PA, USA, ²Medicine, Shiga University of Medical Science, Shiga, Japan, ³Urology, Kanazawa University, Kanazawa, Japan.

Prostate cancer (PCa) preferentially metastasizes to bone resulting in osteolytic lesions with underlying osteolytic activities. The mechanisms by which PCa cells promote osteolytic activities and subsequent osteoblastic bone formation remain poorly understood. Parathyroid hormone-related protein (PTHrP), produced by bone cells and PCa, binds to receptors on osteoblasts and stimulates bone formation and resorption. We have previously reported that MCP-1 acts as a paracrine and autocrine factor for PCa progression. However, the role of PTHrP in regulating MCP-1 expression in bone microenvironment, specifically by human bone marrow endothelial cells (HBME) and osteoblasts (hFOB), as well as by PCa cells, has not been studied. Accordingly, we determined the effect of PTHrP on MCP-1 expression by bone cells and PCa cells. PTHrP induced both MCP-1 protein and mRNA expression by HBME and hFOB cells, but not by PCa LNCaP and PC3 cells. To further determine the mechanisms of PTHrP-induced MCP-1 transcription, analysis of the MCP-1 promoter was performed. MCP-1 promoter activity was induced by PTHrP. Both C/EBP β and NF- κ B binding elements are required for PTHrP-induced MCP-1 transcription. Finally, when a constitutively-active PTH receptor construct was transfected into HBME and hFOB cells, MCP-1 production was increased. The conditioned media collected from these cells induced osteoclast differentiation and PC3 proliferation and invasion in vitro. These effects were partially inhibited by MCP-1 neutralizing antibody. We conclude that PTHrP-induced MCP-1 production by HBME and hFOB cells promotes osteoclast differentiation in vitro and such induction may play a critical role in PCa development in the bone microenvironment.

Activation of MCP-1/CCR2 Axis Promotes Prostate Cancer Invasion and the Tumor-induced Osteoclast Activity In Vitro. Y. Lu¹, Z. Cai^{*1}, X. Chen^{*1}, G. Xiao¹, A. Mizokami^{*2}, G. D. Roodman¹, J. Zhang¹. ¹Medicine, University of Pittsburgh, Pittsburgh, PA, USA, ²Urology, Kanazawa University, Kanazawa, Japan.

When prostate cancer (PCa) metastasizes to the skeleton, bidirectional interactions between tumor cells and the bone microenvironment occur. Both the tumor cells and cells from the bone microenvironment produce growth factors, angiogenic factors, and chemotactic factors which enhance tumor growth. These factors may account for the increased frequency of bone metastasis in PCa. Monocyte chemotactic protein-1 (MCP-1) is a member of the CC chemokine superfamily that plays a critical role in recruitment and activation of monocytes during acute inflammation and angiogenesis. We previously showed that MCP-1, produced by PCa epithelial cells, stroma/osteoblasts, and bone marrow endothelial cells, is chemotactic for PCa cells. More recently, we reported that CCR2 expression correlates with Gleason score and clinical pathological stages as determined by immunohistochemistry. We hypothesized that the MCP-1/CCR2 axis plays a critical role in PCa invasion and the tumor-induced osteoclast activity. Accordingly, to determine whether the expression of CCR2 on PCa cells play a fundamental role in PCa invasion and proliferation, CCR2 or control shRNAs were transfected into human C4-2B or PC3 cells using lipofectamine reagents and individual clones were selected and evaluated. CCR2 knockdown in both C4-2B and PC3 cells significantly diminished the MCP-1-induced cell invasion in matrigel assays. Furthermore, to determine whether MCP-1 knockdown in PCa cells alters the PCa conditioned media (CM)-induced osteoclast formation, MCP-1 or control shRNA were generated and transfected into C4-2B or PC3 cells. CM were collected from 4 clones and evaluated for their capacity to induce osteoclast formation. Non-adherent mouse bone marrow cells were cultured for 7 days with M-CSF (10ng/ml) and/or RANKL (50ng/ml) or 10% CM collected from the stable clones. We found that MCP-1 knockdown significantly diminished the capacity of PCa CM to induce osteoclast formation. Taken together, we have demonstrated that activation of MCP-1/CCR2 axis promotes prostate cancer invasion and the tumor-induced osteoclast activity in vitro. Our data suggest that MCP-1/CCR2 axis may serve as a therapeutic target.

The Constitutive Activity of the NF- κ B p65/p50 Transcriptional Complex is Critical for Bone Metastasis in Breast Cancer. C. Menaa^{*1}, A. Moscovitz^{*2}, S. Kim^{*1}, C. J. Froelich^{*1}, S. M. Sprague¹. ¹Department of Medicine, Evanston Northwestern Healthcare, Northwestern University Feinberg School of Medicine, Evanston, IL, USA, ²Department of Medicine, Hadassah University Medical Center, Jerusalem, Israel.

Long-term breast cancer (BC) survival decreases dramatically in patients with bone metastases and represents a major challenge for treatment. This is due in large part to the capacity of tumor cells to induce osteoclastogenesis. How tumor cells acquire this capacity and the mechanism(s) involved are not yet defined. We previously reported that NF- κ B is a

key pathway for bone metastasis. Here we demonstrate that the NF- κ B p65/p50 transcriptional complex controls the capacity of BC cells (MDA and MCF7) to support OC formation in vitro and tumor growth and bone metastasis in vivo. The over-expression of p65 DN significantly reduced the production of osteoclastogenic factors (OF), including PTHrP expression in vitro. Furthermore, the p50 subunit is necessary to form the active transcriptional complex with the p65 subunit in BC. The transdominant negative form of p50, where the DNA binding capacity has been disrupted, significantly reduced the constitutive activation of NF- κ B in BC and the transcriptional activity of the p65 as measured by gel shift and reporter gene assays. Moreover, stable BC cells expressing p50 mutants where (A56/L-F57/A) or (Y59/A-V60/S) are unable to support osteoclastogenesis and PTHrP production in vitro. The intra-cardiac injection of the wild type cells into nude mice results in diffuse bone metastasis, whereas the injection of the p50 mutant cells do not lead to osteolytic lesions as assessed by X-Rays and histological analyses. This effect was not due to a reduction in cell viability and/or proliferation, since p50 mutant cells form tumors similarly to the WT cells when injected subcutaneously, but lack the ability to induce osteoclastogenesis. In addition, BC p50 mutant cells are less invasive and aggressive compared to the WT. We specifically found that the transcriptional factor snail is down-regulated in non-bone metastatic BC (MCF7) as well as MDA-p50 mutant cells compared to MDA WT cells. These data suggest that snail could be the down stream factor for NF- κ B that is responsible for bone metastases.

In summary, we found that the NF- κ B p65/p50 transcriptional complex is essential for the NF- κ B constitutive activation and the capacity of BC to form osteolytic metastasis by controlling expression and secretion of osteoclastogenic factors such as PTHrP which could be mediated by snail transcription factor. In conclusion, these data further highlight the role of NF- κ B in bone metastasis in breast cancer. Thus, NF- κ B (p65/p50 complex) could be a suitable therapeutic target for bone destruction in breast cancer.

High Extracellular Calcium Directly Stimulates MDA-MB 231 Human Breast Cancer Cell by a Mechanism Involving the Calcium Sensing Receptor. R. Mentaverri^{*}, R. Abdoune^{*}, J. Lion^{*}, M. Brazier^{*}, S. Kamel^{*}. Pharmacy, INSERM, ERI-12, Amiens, France.

Bone is the most common site of breast cancer metastasis and skeletal metastases greatly contribute to the morbidity and mortality associated to the disease. Over the past several years, significant effort has been focused on elucidating the molecular mechanisms that govern bone metastasis. However, so far, the factors that regulate the preferential metastasis of breast cancer cells in bone are not well identified. Recently, it has been demonstrated that cancer cells invade preferentially the bone microenvironment subjected to high bone remodeling suggesting that some factors released during high bone turnover can accelerate the development of cancer cell in bone. Here we show that high extracellular calcium concentrations ([Ca]_e) can trigger migration of human MDA-MB 231 breast cancer cells, in Boyden's chambers. Thus, when breast cancer cells were exposed to different concentrations of calcium (from 1.8 to 7.5 mM) the mobility of the cells was dose-dependently stimulated. The maximum effect was obtained at 5mM where the cell mobility was approximately three fold increased compared to cell submitted to control medium ([Ca]_e = 1.8 mM). Using pharmacological inhibitors known to selectively block the ERK1/2 and phospholipase C pathway (i.e. U-0126 and U-73122), we completely abrogated the [Ca]_e-induced effect, suggesting the implication of a G Protein Coupled Receptor. Because these two pathways are known to be triggered by the calcium sensing receptor (CaR), we first confirmed that breast cancer cell expressed both at transcriptional and at protein level the CaR. Finally, confirming the role played by the CaR in this process, we demonstrated that small interfering RNA (siRNA) targeting of the CaR almost completely reversed the effects of calcium on cancer cell mobility. Taken together, these data demonstrate that high [Ca]_e, such as those seen in the bone microenvironment, can directly stimulate the breast cancer cell mobility by a mechanism involving the CaR. From these results, it can be hypothesized, that high [Ca]_e may participate to processes allowing tumor cells which express the CaR to invade and proliferate into the bone.

Skeletal Effects of 2-Methoxyestradiol in Combination with other Prostate Cancer Therapies. K. S. Mohammad¹, V. Duong^{*1}, L. Kingsley¹, C. R. McKenna^{*1}, H. Walton^{*1}, X. Peng^{*1}, L. J. Suva², T. A. Guise¹, J. M. Chirgwin¹. ¹Internal Medicine, University of Virginia, Charlottesville, VA, USA, ²Orthopaedic surgery, University of Arkansas for Medical Sciences, Little Rock, AR, USA.

The majority of patients with hormone-refractory advanced prostate cancer develop bone metastases, in which the characteristic disorganized new bone formation results from the paracrine stimulation of osteoblasts by tumor cells. Many of the secreted proteins that activate osteoblasts are regulated by the hypoxic response pathway via induction of HIF-1 α . We hypothesized that anti-hypoxic therapy would be effective against bone metastases and tested this idea with 2-methoxyestradiol (2ME2), an inhibitor of microtubule polymerization and the Hif-1 α pathway that is currently in phase II clinical trials in cancer patients.

2ME2 was used alone and in combination with two established treatments for bone metastases: zoledronic acid (ZA), and the endothelin A receptor antagonist, atrasentan. We assessed the skeletal effects of treatments on tumor-free bones in 8 groups of nude mice: vehicle control, 3 single-treatment groups, 3 double-treatment groups and 1 triple-

treatment group. Mice were treated for 20wks, followed by X-ray and Piximus for bone mineral density and analyzed after euthanasia by histomorphometry and micro-CT of selected bones. Atrasentan (20mg/kg/d) had no substantial effect on bone parameters when used alone or in combination with ZA or 2ME2 as determined by X-ray, histomorphometry and micro-CT. Histomorphometric analysis of mice treated with ZA (5ug/kg/3x/wk sc) showed an increase in trabecular bone volume fraction (BV/TV%). Micro-CT revealed a similar increase in BV/TV, with a parallel increase in trabecular number and a reduction in trabecular separation. Across all single, double and triple treatment groups, we observed that 2ME2 (150mg/kg ip) increased bone mass. Histomorphometric analysis showed increased BV/TV and more osteoclasts in 2ME2-treated mice. Micro-CT demonstrated a similar increase in BV/TV and a parallel increase in trabecular thickness and reduction in trabecular separation. The groups in which 2ME2 and ZA were combined showed significant additive effects on bone mass, with even greater increases in BV/TV and trabecular thickness and decreased trabecular separation and osteoclast number. The data demonstrate that 2ME2 increased bone mass and osteoclast number. Inhibition of osteoclasts with ZA further increased bone mass. Preclinical studies are underway to see if these additive therapeutic effects also reduce prostate cancer tumor burden in bone. The experiments will test if 2ME2 is selectively active against bone metastases and if it is more effective in combination with ZA than either agent alone.

Tissue Engineered Bone: Components of Native Bone Environment Involved in Breast Cancer Metastasis. J. E. Moreau¹, K. Anderson^{*1}, M. Reagan^{*2}, D. L. Kaplan^{*2}, M. Rosenblatt¹. ¹Physiology, Tufts University School of Medicine, Boston, MA, USA, ²Biomedical Engineering, Tufts University, Medford, MA, USA.

Challenges in breast cancer (BrCa) treatment are due to the migration of primary tumor cells to the skeleton, initiating osteolysis, formation of metastases, and the entry of the disease into an incurable phase. Tissue engineered bone constructs afford a controllable microenvironment and have been confirmed as efficacious targets for metastatic spread using a mouse model of metastasis originating from the orthotopic site. We continued assessment of the contribution of individual components of engineered bone present upon initiation of metastasis cells, scaffold, and protein to begin characterizing the metastatic bone environment. Specimens of porous silk-based tissue engineered bone and native human bone (controls) were prepared for subcutaneous implantation in immunodeficient (NOD/SCID) mice. Orthotopic injection of the luciferin-expressing human epithelial breast cancer cell line, SUM1315, for assessment of cell migration was subsequently performed one month following implantation. Four groups of scaffolds untreated silk, bone morphogenic protein 2 (BMP2) coupled, bone marrow stromal cell (BMSC) seeded, and BMP2/BMSC treated were prepared and implanted subcutaneously over the left shoulder, with native human bone controls cored from discarded femoral heads over the right. BMSC were administered to scaffolds one day prior to implantation in their respective treatment groups. One month following implantation, SUM1315 cells were injected into mouse mammary fat pads and monitored over the course of 12 weeks. Luminescent imaging of implants at final harvest revealed the presence of metastases in 0 of 6 untreated scaffolds, 4 of 4 with BMSC treatment, 4 of 4 with BMP2 treatment, and 1 of 6 with BMP2/BMSC treatment. Metastatic spread to engineered scaffolds and the progression of bone remodeling was further confirmed through immunohistochemistry, labeling cytokeratin 5/6 for BrCa identification, trichrome for collagen I and early bone development, and von Kossa staining of calcium deposit. All metastatic spread was exclusive to the implants, with no invasion of the mouse skeleton, as confirmed via luminescent imaging. These findings provide impetus for continued research to explore the roles of bone proteins in breast cancer recruitment, the nature of the developing bone scaffold as a homing site, and the differentiation/influence of adult stem cells in creating a niche for metastatic spread.

Disclosures: J.E. Moreau, None.

Metastasis-Associated Protein 1 (MTA1) was Highly Expressed and Localized in Nucleus in Prostate Cancer Bone Metastasis. J. Wang, A. Levenson*, J. Jarrett*, W. Laskin*, R. Satcher*. Northwestern University, Chicago, IL, USA.

Bone is the most frequent target site for prostate cancer metastasis. The preferential metastasis to bone suggests that bone microenvironment provides suitable conditions for tumor growth and survival. Bone marrow stromal cells (BMSC) play an active role in regulating colonization and progression of metastatic malignant epithelial cells through diffusible factors and cell-cell contact. The molecular mechanism responsible for stromal-epithelial crosstalk in bone microenvironment remains largely unknown.

We established a novel co-culture system with direct heterotypic cell-cell contact. Five different prostate cancer cell lines (PC3, DU145, LNCaP, C4-2, MDA-PCa2b) were labeled with fluorescence and co-cultured with BMSC respectively. Two types of cells were then separated by fluorescence-activated cell sorting. Gene expression profiles were analyzed using cDNA microarray. Among the most significantly modified genes, metastasis-associated protein 1 (MTA1) was found to be highly up-regulated in multiple prostate cancer cell lines during the co-culture. The expression of MTA1 was further studied in normal prostate tissue, primary prostate tumor, and bone metastasis tissue using tissue microarray and immunohistochemistry. The results showed that in normal prostate tissue (n=15) there was weak staining in cytoplasm (Intensity=0.8±0.4, Frequency=1.1±0.7) but no staining in nucleus. In contrast, in primary prostate cancer tissue (n=72) there was moderate staining both in cytoplasm (I=1.8±0.7, F=3.3±1.2,

P=0.00002 vs normal tissue) and in nucleus (I=2.1±0.6, F=3.6±0.8). There was no significant correlation between MTA1 expression level with Gleason score, TNM grade or PSA level. In bone metastasis tissue (n=8), there was no staining in cytoplasm, but strong staining in nucleus (I=2.6±0.5, F=3.4±0.5, P=0.04 vs primary tumor).

We concluded that MTA1 was differentially expressed in normal prostate tissue, primary tumor and bone metastasis tissue. The differential localization in cytoplasm and nucleus of MTA1 may indicate the degree of metastasis potential. As a member of nucleosome remodeling complex, the translocation of MTA1 between cytoplasm and nucleus in primary tumor and bone metastasis may conduct different function on transcription regulation and signaling transduction.

Regulation of Protein Synthesis Factors in Estrogen Metabolite-Mediated Inhibitions of Osteosarcoma Cells. K. L. Shogren^{*1}, M. J. Yaszemski¹, T. E. Hefferan¹, M. C. Charlesworth^{*2}, B. J. Madden^{*2}, R. T. Turner³, A. Maran¹. ¹Orthopedic Research, Mayo Clinic, Rochester, MN, USA, ²Proteomics Research Center, Mayo Clinic, Rochester, MN, USA, ³Nutrition and Exercise Sciences, Oregon State University, Corvallis, OR, USA.

Protein biosynthesis is one of the fundamental processes involved in both the regulation of normal eukaryotic cell growth and tumorigenesis. Previous studies show that a natural metabolite of 17 β -estradiol, 2-Methoxyestradiol (2-ME) can induce growth inhibition and cell death in human osteosarcoma cells. 2-ME treatment leads to the induction of apoptosis and the activation of RNA dependent protein kinase (PKR). Here, we have further investigated the molecular mechanisms associated with 2-ME-dependent cell death in human osteosarcoma cells. We employed 2-dimensional gel electrophoresis followed by trypsin digestion of the 2D spots. Subsequent analysis of the peptides by nano-LC-ESI tandem mass spectrometry combined with the Swiss-Prot database identified several proteins that participate in the mammalian protein synthesis. Western blot analysis using MG63, KHOS and SAOS2 osteosarcoma cells, further validated the proteomic results and revealed a significant down-regulation of proteins involved in translational regulation. Another protein synthesis initiation factor, EIF5A-2, which has been implicated in tumorigenesis was down-regulated by 2.5-fold within 24hrs of 2-ME treatment. These findings are consistent with the studies showing that 2-ME treatment results in the activation of PKR and subsequent phosphorylation of the initiation factor EIF-2. Taken together, these studies suggest that multiple translational control pathways are modulated by 2-ME treatment and the deregulation of factors catalyzing the various steps of polypeptide chain synthesis contributes to apoptosis and anti-osteosarcoma effects of 2-ME.

Tyrosine Kinase Inhibitors Slow Motility of Osteosarcoma Cells In Vitro. P. J. Messerschmitt*, E. M. Greenfield. Orthopaedics, CWRU, Cleveland, OH, USA.

We determined whether tyrosine kinases regulate osteosarcoma cell motility, a critical component of metastasis. Three genetically-related human osteosarcoma cell lines were used: TE85: non-tumorigenic and non-metastatic; MNNG: tumorigenic, non-metastatic; and 143B: tumorigenic, highly metastatic. Motility assays measured migration distance, the width between two converging cell fronts, in a scrape created in confluent cultures. All tyrosine kinase inhibitors were tested at maximally effective concentrations based on the literature. In vitro motility correlated with metastatic ability as the 143B cells migrated 65% (p<0.001) faster than the non-metastatic cells. These differences are not due to proliferation, since aphidicolin, a DNA polymerase inhibitor, did not affect migration, but completely blocked proliferation.

Inhibitors of HER-2, NGF-R, PDGF-R, and JAK had little effect on the motility of all cell lines. In contrast, the EGF-R inhibitor (Calbiochem #324674) slowed motility of all cell lines by 50-75% (p<0.001). The met inhibitor (SU11274) slowed motility of MNNG cells by 80% (p<0.001), while only slowing motility of the 143B and TE85 cells by 20% (p<0.001). This is consistent with the finding that tumorigenesis in the MNNG cells is due to a chromosomal translocation resulting in overexpression of met. Suramin slowed motility of the MNNG and TE85 cells by 60% (p<0.001) and 41% (p<0.001), but only slowed motility of the 143B cells by 11% (p=0.012). Suramin prevents growth factor binding and thereby inhibits activation of many receptor tyrosine kinases, including activation of met by Hepatocyte Growth Factor (HGF). The preferential inhibition of MNNG motility suggests that met-dependent motility in these cells is due to autocrine production of HGF. The molecular basis for inhibition of TE85 motility remains to be identified. 3,4-Methylenedioxy- β -nitrostyrene (MNS), a newly identified tyrosine kinase inhibitor, preferentially slowed motility of the metastatic 143B cells by 53% (p<0.001), while only slowing motility of the MNNG cells by 25% (p<0.001) and not detectably affecting motility of the TE85 cells. MNS inhibits the tyrosine kinase activity of both Syk and Src. However, other inhibitors of Syk and Src, either alone or in combination, had no detectable effect on 143B motility. Thus, it is likely that MNS slows motility by inhibiting another, as yet unidentified, tyrosine kinase. Nonetheless, MNS is an attractive, potential therapeutic agent for further study as it preferentially slowed motility of the metastatic cell line. Our results also show that inhibitors of EGF-R and met are attractive therapeutic agents for patients with osteosarcoma that overexpress those receptors.

Fracture Risk Is Increased in Danish Men with Prostate Cancer. A Nationwide Register Study. M. F. Nielsen¹, K. Brixen², S. Walter^{3,4}, J. Andersen⁴, P. Eskildsen⁵, B. Abrahamsen⁶. ¹Dept. of Endocrinology, Odense University Hospital, Odense, Denmark, ²Dept of Endocrinology, Odense University Hospital, Odense, Denmark, ³Urology, Odense University Hospital, Odense, Denmark, ⁴Dept. of Urology, Roskilde Hospital, Roskilde, Denmark, ⁵Dept. of Internal Medicine, Koege Hospital, Koege, Denmark, ⁶Dept. of Medicine, Copenhagen University Hospital Gentofte, Copenhagen, Denmark.

The purpose of this study was to examine the effect of prostate cancer on fracture risk and calculate the national impact of prostate cancer on hip fracture incidence, while taking into account any modifying effects of orchiectomy and androgen deprivation therapy (ADT). Data from the National Hospital Discharge Register, the National Bureau of Statistics, and the National Prescriptions Database were merged. The analysis covered 15,716 men aged 50+ years presenting with a fracture at any hospital in the country in the year 2000 and 47,149 age-matched controls. A prior diagnosis of prostate cancer had been recorded in 1.3% of controls and 2.5% of fracture cases, with a median time span between the first consultation for prostate cancer and the index fracture of three years. In 75 percent of the patients, the time span was less than five years. Prostate cancer was associated with significant increase in all-fracture risk, OR 1.8 (95% CI 1.6-2.1), and hip fracture risk, OR 3.7 (3.1-4.4) whereas no impact on vertebral fracture risk was found, OR 1.0 (0.7-1.5). The effects were undiminished by adjustment for age, prior fracture, living circumstances and income. In men aged 50-65 years, prostate cancer increased the risk of hip fracture by as much as nine-fold, OR 9.2 (4.8 - 17.5).

After adjustment for previous fracture, cancer diagnosis, and age, both ADT and orchiectomy significantly increased overall fracture risk, OR 1.7 (1.2-2.5, $p < 0.01$) and 1.7 (1.2-2.4, $p < 0.01$), respectively. ADT also increased hip-fracture risk (OR 1.9, 1.2-3.0, $p < 0.05$), but prostate cancer therapy was not associated with demonstrable increases in vertebral fracture risk.

In conclusion, prostate cancer was associated with an increase in all-fracture risk as well as hip-fracture. The increased fracture risk became apparent early after diagnosis and remained pronounced even in long-term survivors. In total, 3.1% of hip fractures in men aged 50+ were attributable to prostate cancer. The risk of hip fracture was not confined to the very old, neither was fracture risk made negligible by the excess mortality in patients with advanced prostate cancer.

Role of CXCL13 Chemokine Ligand 13 in Squamous Cell Carcinoma Associated Osteolysis in Athymic Mice. S. N. M. Pandravad¹, X. Liu², J. S. Norris², K. Sundaram¹, S. Shanmugarajan¹, W. L. Ries¹, S. D. London³, S. V. Reddy¹. ¹Charles P. Darby Children's Research Institute, Charleston, SC, USA, ²Department of Microbiology and Immunology, Medical University of South Carolina, Charleston, SC, USA, ³College of Dental Medicine, Medical University of South Carolina, Charleston, SC, USA.

Head and neck squamous cell carcinoma is the most common malignant neoplasm estimated to be more than 40,000 cases per year in the US. These malignant tumors are known to have a potent activity of local bone invasion; however the molecular mechanisms of SCC associated osteolysis are unknown. In this study, we identified high level expression of chemokine ligand, CXCL13 and RANK ligand (RANKL) in squamous cell carcinoma (SCC) derived cell lines. SCC 14a cell conditioned media (20%) induced osteoclast differentiation which was inhibited by addition of OPG in human peripheral blood derived monocyte cultures indicating that SCC cells produce soluble RANKL. In addition, recombinant CXCL13 (10 ng/ml) significantly enhanced RANKL stimulated osteoclast differentiation in these cultures. Trans-well migration assay further identified that CXCL13 induces (7-fold) chemotaxis of peripheral blood monocytes in vitro which was inhibited by addition of anti-CXCR5 receptor antibody. Zymogram analysis of conditioned media obtained from RAW 264.7 macrophage cells stimulated with CXCL13 for 48 hr demonstrated a significant increase (4.0-fold) in the level of MMP-9 expression. Real-time PCR analysis of total RNA isolated from human bone marrow derived stromal cells stimulated with CXCL13 for 48 hr showed a significant increase (4-fold) in RANKL mRNA expression. Interestingly, CXCL13 treatment to SCC 14a cells induced CXCR5 receptor and MMP-9 expression suggesting an autocrine regulatory function in SCC cells. To further examine the molecular mechanisms associated with SCC tumor cell invasion and osteolysis of bone, we established an in vivo model for SCC by subcutaneous injection of SCC 14a cells (7×10^6 cells in PBS) onto the surface of calvaria in NCr-nu/nu athymic mice, which developed tumors in 4-5 weeks. Immunohistochemical analysis confirmed CXCL13 and MMP-9 expression in the tumor cells and invasion of bone/osteolysis in vivo. Histochemical staining further demonstrated a significant increase in the numbers of multinucleated TRAP positive osteoclasts at the tumor bone interface. Thus, our data implicate a functional role for CXCL13 in SCC tumor cells invasion/osteolysis of bone and may be a potential therapeutic target to prevent osteolysis associated with SCC in vivo.

Balloon Kyphoplasty in the Treatment of Osteolytic Lesions in the Thoracic and Lumbar Spine Due to Cancer - 2 Years Prospective Follow-up. R. Pflugmacher*. Centrum für Muskuloskeletale Chirurgie, Charité - Universitätsmedizin Berlin, Berlin, Germany.

Purpose: Balloon Kyphoplasty is a minimally invasive stabilization procedure for osteoporotic and osteolytic vertebral fractures. The purpose of this prospective study was to evaluate this operative procedure in the treatment of osteolytic vertebral fractures in reduction of pain and functional improvement of these patients and further to evaluate the restoration of vertebral height postoperatively and over a time period of 24 months.

Materials and methods: In this prospective study, 96 patients (45 patients with multiple myeloma, 51 patients with metastatic disease) with osteolytic vertebral fractures (176 vertebrae) were treated with Balloon Kyphoplasty. We were able to collect 2 year follow up data for 82 patients. 38 patients (30 male, 8 female) with 83 osteolytic vertebral fractures due to multiple myeloma and 44 patients (26 male, 18 female) with 78 osteolytic vertebral fractures due to metastatic disease. Preoperatively conventional radiographs in lateral and a.p. view, CT and / or MRI were performed. Pre- and postoperatively, pain (Visual Analogue Scale) and disability (Oswestry disability index) were evaluated. Radiographs were performed pre- and postoperatively and after 3, 6, 12 and 24 months. Vertebral height and endplate angles were measured.

Results: Clinical results for the patients with multiple myeloma and metastatic disease improved significantly. The median pain scores (VAS) decreased significant from pre- to post-treatment ($p < 0.001$) as well as the Oswestry disability index ($p < 0.001$). Balloon Kyphoplasty led to a significant and sustained reduction of pain resulting in a significant functional improvement of the patients. In the radiological evaluation a significant restoration of vertebral height ($p < 0.05$) and reduction of the kyphotic angle ($p < 0.05$) could be achieved in the patients with multiple myeloma. In patients with metastatic disease only a slight restoration of vertebral height and reduction of the kyphotic angle was achieved. Balloon Kyphoplasty was able to stabilize the vertebral height and avoid a further kyphotic deformity in the long term for both patient groups. Radiation therapy and / or chemotherapy could be performed without any loss of time.

Conclusion: In the treatment of osteolytic vertebral fractures Balloon Kyphoplasty led to a quick and sustained reduction of pain and functional improvement. Balloon Kyphoplasty was able to stabilize the fractured vertebrae in the long-term and was able to prevent an increase of kyphotic deformity. Balloon Kyphoplasty is an outstanding alternative in comparison to the established therapeutic concepts in the treatment of osteolytic vertebral fractures.

Chondrostatin: A New Inhibitor of Angiogenesis, Tumor Invasion and Osteoclast Activity. L. J. Sandell¹, Z. Wang¹, C. Franz¹, N. Havioglu², J. Bryan³, B. El³, A. Rapraeger³. ¹Orthopaedic Surgery, Washington University, St. Louis, MO, USA, ²Pathology, St. Louis University, St. Louis, MO, USA, ³Pathology and Laboratory Medicine, University of Wisconsin, Madison, WI, USA.

Cartilage tissue is avascular and resistant to tumor invasion: the molecule mechanism of is unknown. We have recently shown that a normally produced fragment of the predominant cartilage collagen, called chondrostatin, is responsible for exquisite targeting of inhibition of cell migration and for cell death. The cells targeted are endothelial cells, osteoclasts and tumor cells. The targeting is based on the specific binding of the chondrostatin to integrins $\alpha_v\beta_3$ and $\alpha_v\beta_5$, expressed on osteoclasts, endothelial and tumor cells but not on normal chondrocytes. The chondrosarcoma cell line, Ch-1 and the breast cancer cell line MDA-MB 231 were used to establish the proof of concept. First, we demonstrated that Ch-1 cells adhere to chondrostatin dependent on binding to an RGD sequence. Next, we established that Ch-1 and MDA cells express the $\alpha_v\beta_3$ and $\alpha_v\beta_5$ integrins and that these integrins are responsible for adhesion. Confocal microscopy studies showed that chondrostatin is internalized into the cells. Inside the cells, it is able to induce cell death in a dose and time-dependent manner. Inhibition of α_v integrin by RNA interference eliminated adhesion and cell killing. In further studies, we examined the ability of chondrostatin to inhibit angiogenesis. Two well accepted assays were used: formation of tubes from HUVEC endothelial cells, and outgrowth of endothelial cells from explants of aorta. Chondrostatin inhibited angiogenesis in both of these assays reducing angiogenesis by 50% at a concentration of 100 nM. In conclusion, naturally occurring chondrostatin inhibits angiogenesis and kills tumor cells mediated by the $\alpha_v\beta_3$ and $\alpha_v\beta_5$ integrins. This molecule may be useful in the treatment of neo-vascular disease, cancers and osteoporosis.

Development of Small Molecule Adrenomedullin Antagonists for Treatment of Bone Metastases. V. A. Siclari¹, K. S. Mohammad², A. Martinez^{*3}, C. Gineste^{*4}, H. M. Geysen^{*4}, T. A. Guise², J. M. Chirgwin².

¹Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA, USA, ²Internal Medicine, University of Virginia, Charlottesville, VA, USA, ³Instituto Cajal, Madrid, Spain, ⁴Chemistry, University of Virginia, Charlottesville, VA, USA.

Adrenomedullin (AM) is a 52 amino acid peptide of the calcitonin/CGRP gene family secreted by cancers such as breast, lung, and prostate, where it can stimulate angiogenesis and autocrine signaling and may cause cancer-associated pain. AM also dose-dependently stimulates new bone formation at picomolar concentrations, by binding to the calcitonin-receptor-like receptor plus RAMP2 or 3 and stimulating adenylyl cyclase. It stimulates osteoblast proliferation, although the molecular pathways activated in bone cells by AM are poorly understood. When we treated primary mouse osteoblasts with AM, the mRNAs encoding bone matrix proteins (bone sialoprotein, type I collagen, osteocalcin, and osteopontin) were not increased. However, AM stimulated IL-6 mRNA expression by primary osteoblasts. We previously reported increased or decreased bone metastases due to AM overexpression and siRNA knockdown in prostate and lung cancer models respectively. These observations identify AM as a significant target for therapeutic intervention against bone metastasis.

Small molecules have been identified that function as agonists or antagonists of the action of AM to increase cAMP, by binding to the AM ligand rather than the receptor. One of the antagonists, NCI 16311, binds with $K_d = 8\text{ nM}$ to AM without altering ligand:receptor binding affinity. We added 100nM 16311 to neonatal mouse calvarial organ cultures. Increases in new bone and osteoblast number caused by 1nM AM were completely blocked by 16311, without cellular toxicity or blockade of new bone formation due to IGF1 receptor activation. Two additional antagonists were tested in the same assays. NCI 28086 was ineffective, but the methylene-bis- benzoic acid derivative NCI 37133 was as effective as NCI 16311 at blocking AM-induced new bone formation. The two lead compounds may be effective bone-selective antagonists of tumor-secreted AM. NCI 16311 and 37133 are aromatic carboxylic acid derivatives that act extracellularly, offering attractive pharmacological properties without needing to be cell-permeant. Further development of these compounds into higher affinity, second-generation derivatives should be possible. Small molecule AM antagonists may provide improved treatment for osteoblastic bone metastasis and associated cancer bone pain.

Synthesis and Biological Evaluation of Vitamin K₂ Metabolites. Y. Suhara^{*}, A. Murakami^{*}, M. Kamao^{*}, S. Mimitsu^{*}, K. Nakagawa^{*}, N. Tsugawa^{*}, T. Okano. Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan.

Vitamin K is an essential nutrient and a cofactor for the carboxylation of specific glutamyl residues of proteins to gamma-glutamyl residues, which activates osteocalcin related to the bone formation. Recently, the metabolism of vitamin K has been studied in humans and rats, and urinary metabolites as glucuronides of K acid I, II, and omega-carboxylic acid have been detected. However, their biological activities have hardly been evaluated so far. We anticipated that if those metabolites were studied in detail, they would provide insight into the biological significance of vitamin K and valuable information for the development of new drugs. In this study, we synthesized six kinds of "predictable" vitamin K metabolites. They were introduced vitamin K₂ (menaquinone-2, 3, and 4) molecule to omega-hydroxyl group or omega-aldehyde group instead of omega-carboxylic acid because the metabolites including omega-carboxylic acid were unstable and unable to use for assay. The requisite analogues were synthesized by coupling the naphthoquinone derivative and side-chain moiety. For the synthesis of side-chain part, we chose geraniol, farnesol and geranylgeraniol as the starting material. While the naphthoquinone part was prepared from 1,4-diacetoxy-2-methylnaphthoquinone. After coupling reaction, deprotection of protective group gave omega-hydroxyl derivative, and additional oxidative reaction yielded omega-aldehyde derivative. To investigate the biological activities of those analogues, we focused on the apoptosis-inducing activity against HL-60 cells (human leukemia cells). Samples of 5 and 10 μM analogues were successively added to HL-60 cells. After 72 h, the cells were collected and treated with propidium iodide, and then apoptosis activity was determined with a fluorescence-activated cell sorter (FACS). As a result of biological evaluation, omega-hydroxylation of the side-chain part of menaquinone-4 increased apoptosis-inducing activity for HL-60 cells compared to menaquinone-4. Our results indicated that metabolites of vitamin K might have potential as biologically active compounds and can provide useful information to develop new drugs based on vitamin K with modification of the terminal alkyl group. A more detailed examination is currently undergoing based on these findings.

Benign and Malignant Bone Tumors Express the Melatonin Receptor Isoform 1 (MT1). M. Svoboda^{*1}, C. D. Toma^{*2}, F. Arrich^{*2}, C. Ekmekcioglu^{*3}, O. Assadian^{*4}, T. Thalhammer^{*1}. ¹Department of Pathophysiology, Medical University Vienna, Vienna, Austria, ²Department of Orthopaedic Surgery, Medical University Vienna, Vienna, Austria, ³Department of Physiology, Medical University Vienna, Vienna, Austria, ⁴Clinical Department of Hygiene and Medical Microbiology, Medical University Vienna, Vienna, Austria.

The indolamine melatonin is synthesized and secreted by the pineal gland during night time and is well known for its role in the regulation of circadian rhythms. Recent studies showed that melatonin exhibits potent anti-tumor activity in vitro as well as in vivo and it is produced in extrapineal tissues, e.g. the bone marrow. Melatonin acts by receptor independent and dependent pathways. The latter is mediated through high-affinity G-protein receptors (MT1 and MT2) signaling.

To account for a possible role of MT1/MT2 in bone homeostasis, we investigated whether MT1/MT2 are expressed in malignant and non-malignant human bone lesions and osteosarcoma cell lines (HOS, MG-63). By RT-PCR, Western blot and immunofluorescence we found that MT1, but not MT2 was detectable in the tumor cell lines. By TaqManPCR, we analyzed 30 specimens from osteosarcoma and 11 from benign bone tumors for MT1-mRNA expression and determined mRNA expression (relative to a control specimen) of the osteoclast activity stimulating receptor activator of nuclear factor- κ B ligand (RANKL) and its opponent osteoprotegerin (OPG).

We found that MT1 was similarly expressed in malignant (4.39 ± 4.98 -fold) and benign samples (4.64 ± 6.81 -fold). Also, mean RANKL- and OPG-mRNA levels were comparable in malignant and benign samples (RANKL: 7.38 ± 9.61 -fold vs. 3.57 ± 3.11 -fold, $p=0.207$; OPG: 23.45 ± 32.76 vs. 8.07 ± 7.23 -fold, $p=0.13$). Expression of MT1-mRNA was also found in normal human osteoblasts (hOB), and bone marrow stromal cells (BMSC). High expression levels of MT1-mRNA together with low OPG-mRNA were found in both cancer cell lines, while in normal hOB and BMSC, high OPG-mRNA levels were associated with low MT1-mRNA levels.

In summary, we found that MT1-mRNA is abundantly expressed in human malignant and benign bone tumors and in osteosarcoma cells lines. Despite our finding that the relative expression levels of MT1 mRNA in malignant and non-malignant bone tumors did not differ significantly, the highest MT1 levels were detected in individual osteosarcoma specimens, i.e., in two specimens from patients with a local recurrence of the tumor. Whether this may be a prognostic parameter remains to be established in further work.

TGF-beta Inhibition Suppresses Myeloma Cell Growth via Enhancement of Osteoblast Differentiation. K. Takeuchi^{*1}, M. Abe¹, A. Oda^{*1}, H. Amou^{*1}, M. Hiasa^{*2}, O. Tanaka^{*1}, S. Fujii^{*1}, S. Nakamura^{*1}, A. Mihara^{*1}, H. Miki^{*1}, J. Asano^{*1}, K. Kagawa^{*1}, K. Kitazoe^{*1}, K. Yata^{*1}, T. Hashimoto^{*1}, S. Ozaki^{*1}, S. Kido¹, T. Matsumoto¹. ¹Dept of Medicine and Bioregulatory Sciences, Univ of Tokushima Graduate Sch of Med Sci, Tokushima, Japan, ²Dept of Orthodontics and Dentofacial Orthopedics, Univ of Tokushima Graduate Sch of Dent Sci, Tokushima, Japan.

Multiple myeloma (MM) enhances osteoclast formation and suppresses stromal cell differentiation into osteoblasts (OBs). Because both osteoclasts and undifferentiated stromal cells enhance MM cell growth and survival, such effects of MM create a microenvironment suitable for MM expansion in the bone marrow, which can be called as myeloma niche. TGF-beta, an inhibitor of terminal OB differentiation, is released from the bone matrix through enhanced bone resorption by MM. We previously demonstrated that TGF-beta inhibition is able to restore OB differentiation suppressed by MM. However, it is not known whether the restoration of OB differentiation by TGF-beta inhibition affects MM growth. We therefore aimed to clarify the role of TGF-beta inhibition on MM growth in relation to the induction of OB differentiation. Terminally differentiated MC3T3-E1 osteoblastic cells with mineralized nodules secreted a factor(s) with potent apoptosis-inducing activity in 5TGM1 and RPMI8226 MM cells. The anti-MM activity was elaborated exclusively by terminally differentiated MC3T3-E1 cells with mineralized nodule formation, whereas untreated MC3T3-E1 cells with pre-osteoblastic phenotypes enhanced MM growth. SB431542, a TGF-beta type 1 receptor kinase inhibitor, facilitated OB differentiation as well as the production of MM cell growth inhibitory activity in MC3T3-E1 cells. Although interaction of MM cells with stromal cells/undifferentiated OBs gives rise to drug resistance in MM cells, terminally differentiated OBs potentiated the cytotoxic effects of doxorubicin on MM cells. These results demonstrate that, in contrast to stromal cells/undifferentiated OBs, terminally differentiated OBs inhibit MM cell growth and survival, and that inhibition of TGF-beta actions enhances OB differentiation, suppresses MM cell growth and potentiates responsiveness to cytotoxic agents. It is suggested that suppression of OB differentiation by MM not only accelerates bone destruction but also enhances MM growth to create myeloma niche, and that induction of OB differentiation by TGF-beta inhibition may provide a novel approach to disrupt myeloma niche.

Surgical Treatment for Benign Bone Tumors with Fully Interconnected Porous Hydroxyapatite Ceramics. N. Tamai*, A. Myoui*, T. Ueda*, H. Yopshikawa*. Dep. of Orthopaedics, Osaka University Graduated School of Medicine, Osaka, Japan.

PURPOSE: Large bone defects remaining after curettage of benign bone tumors should be filled with a substitute to restore mechanical strength. We have utilized several kinds of CHAs available in Japan for massive bone defect after curettage of benign bone tumors and have reported our follow-up study. In 2000, we have developed a fully interconnected porous calcium hydroxyapatite ceramics (NEOBONE) and have utilized them as bone substitute. The purpose of this study is to evaluate the clinical outcomes with the use of NEOBONE as bone substitute after curettage of benign bone tumors.

METHODS: We reviewed the results of 27 patients with benign bone tumors sequentially treated by curettage followed by implantation of NEOBONE™ between 2000 and 2004. There were 8 women and 19 men, with the mean age of 29 years. The locations were as follows: phalanx (11patients), femur (6), pelvis (3), tibia (2), radius (1), calcaneus (1), humerus (1), talus (1). The histological diagnoses included enchondroma (9patients), solitary bone cyst (6), chondroblastoma (4), giant cell tumor of bone (3), fibrous dysplasia (3), intraosseous ganglion (2). The mean follow-up period was 30 months. Assessment was based on plain radiography at the final follow-up. Radiographic findings were classified into four grades: Grade1, slight bone formation in NEOBONE; Grade2, moderate bone formation in NEOBONE and their openings; Grade3, consolidation phase; Grade4, absorption phase.

RESULTS: Radiographs at the final follow-up were graded as follows; Grade1 in 6 patients; Grade2 in 4; Grade3 in 13; Grade4 in 4. The mean periods required to reach each grade were as follows; Grade1 in 2.5 months (2-9 months); Grade2 in 6 months (2-12 months); Grade3 in 18 months (6-31 months); Grade4 in 41 months (27-55 months). There were two local recurrences, observed in each one case of solitary bone cyst and giant cell tumor of bone.

CONCLUSIONS: NEOBONE (pore size: 150-300µm, porosity: 75%) has a finely-organized, 3-dimensional interconnecting pore structure. The large interconnecting channels (average diameter: 40 µm) permit the easy penetration of tissue into the deep pores and, therefore, NEOBONE can itself induce local bone repair processes. In the present study, we utilized NEOBONE as a bone substitute after curettage of benign bone tumors, and demonstrated its superior osteoconductivity. We conclude that NEOBONE is an excellent next generational bone substitute in surgery for benign bone tumors.

Mediation of Cell Proliferation and Tumorigenicity of Musculoskeletal Tumor Cells by an Interferon Inducible IFI16 Protein. Y. Zhang*, R. D. Howell*, L. Kong*, C. Liu. Orthopaedic Surgery, New York University, New York, NY, USA.

IFI 16, a member of an interferon-inducible p200-protein family, modulates cell proliferation, differentiation, apoptosis and cellular senescence. It has also been implicated in the pathophysiology of autoimmune diseases and antitumor activity of several kinds of cancer cells. In this study we showed that the level of IFI 16 was dramatically reduced in the primary human osteosarcoma compared to normal bone. Overexpression of functional IFI 16 in human osteosarcoma and chondrosarcoma cell lines significantly inhibited cell growth. This IFI16-mediated inhibition on musculoskeletal tumor cells is overcome by a siRNA that specifically knockdown the expression of IFI16, suggesting that certain level of IFI16 is critical for controlling musculoskeletal tumor growth. In addition, ectopic expression of IFI 16 in musculoskeletal tumor cell lines markedly inhibited colony formation and was associated with a senescence-like phenotype, production of senescence-associated beta-galactosidase. Further, upregulation of p21 and inhibition of cyclin E, cyclin D1, c-Myc and Ras accompanied inhibition of cell growth by IFI 16 in musculoskeletal tumor cell lines. Taken together, our observations provide insight into the process of musculoskeletal tumors regulated by IFI16, and more importantly, our findings also provide evidence indicating that IFI16 has great potential to be employed as a therapeutic target for treating musculoskeletal tumors, including both osteosarcoma and chondrosarcoma.

Longitudinal Changes in Bone Density and Management in Men with Osteopenia. R. A. Adler, X. Samaropoulos*, M. I. Williams*, V. I. Petkov*. Endocrinology, McGuire VAMC, Richmond, VA, USA.

Until 10 year fracture risk can be easily calculated from DXA and clinical factors, patients with osteopenia (low bone mass but not osteoporosis) by DXA usually receive recommendations to take calcium, vitamin D, exercise and repeat DXA in two years. We identified 78 men who had participated in a screening program based on the OST (Osteoporosis Self-Assessment Tool) equation, which identifies risk for osteoporosis by DXA based on age and weight only. The men had at least 1 T-score in spine, total hip, femoral neck, total forearm, or distal 1/3 forearm between -1 and -2.5, except for 4 men who had a T-score of ≤ -2.5 but not given pharmacologic treatment. The men had a second DXA at least 2 years after the first. At first DXA, mean age was 70.7 yrs, mean weight 76.4 kg, mean OST score 1 (moderate risk). Low bone mass was found in 33% of spine, 46% of total hip, 78% femoral neck, 51% total forearm, and 40% distal 1/3 forearm DXA measurements. 37/78 men were prescribed calcium and 21/78 Vitamin D (beyond a

multivitamin). After an average of 998 days, weight was down an average of 1.2 kg. The overall diagnosis worsened to osteoporosis in 3 men, but in only one man was the change in DXA statistically significant. Interestingly, after the second DXA, calcium and/or vitamin D supplementation was started in 17 men. Thus, while the second DXA only identified 3 more men with osteoporosis, an additional group had conservative treatment of osteopenia started for the first time. In conclusion, a second bone density test for men at risk of osteoporosis seldom changes the diagnosis. However, the second DXA may spur providers to start preventive methods.

Solid-State ^{31}P MRI Quantifies Decreased Mineralization Density in OVX Rat Bone. S. Anumula*, S. L. Wehrli*, J. Magland*, F. W. Wehrli*. ¹Radiology, University of Pennsylvania, Philadelphia, PA, USA, ²NMR Core Facility, Children's Hospital of Philadelphia, Philadelphia, PA, USA.

Osteoporosis is characterized by rapid bone turnover resulting in decreased mineralization density of bone (MDB), a parameter that cannot currently be measured in vivo. Here we examine the hypothesis that 3D ^{31}P solid-state magnetic resonance imaging (SS-PH) is able to quantify cortical bone phosphorus content in situ in a rat model of osteoporosis in view of possible future application of the technique to humans in vivo. The study involved six ovariectomized rats (4 months old, OVX) compared to six sham-operated rats of the same age (NO). After the surgery all the animals were given standard chow and water ad libitum for 50 days after which they were euthanized and cortical bones extracted from the right and left femurs. In order to optimize the imaging parameters, the spin lattice relaxation time T_1 was measured in the specimens using inversion-recovery sequence. 3D SS-PH was performed at 9.4 Tesla (~162 MHz) using a sequence with non-selective excitation followed by sampling of the free induction decay in the presence of a readout gradient whose K-space data were reconstructed off-line yielding an isotropic resolution of 177 µm (Fig. 1). Specimens were co-imaged with a reference phantom of 2M K_2HPO_4 in order to quantify the mineral phosphorus. The sequence was implemented on a vertical-bore superconducting system (DMX-400, Bruker Instruments, USA) in conjunction with a home-built solenoid coil. Quantitative MRI results were compared with micro-CT derived MDB values using calibration samples made of various concentrations of K_2HPO_4 . Phosphorus concentration obtained by SS-PH was lower in the OVX than in the NO group (6.7 ± 0.9 vs $7.5 \pm 0.7\%$; $p=0.01$) (Fig. 2a). This result was paralleled by lower MDB measured by $\mu\text{-CT}$ in the OVX group (1199 ± 24 vs 1225 ± 10 ; $p=0.02$) (Fig. 2b). In conclusion our data suggest that ^{31}P SS-PH may have potential for studying changes in mineral metabolism nondestructively and noninvasively, i.e. without the use of ionizing radiation.

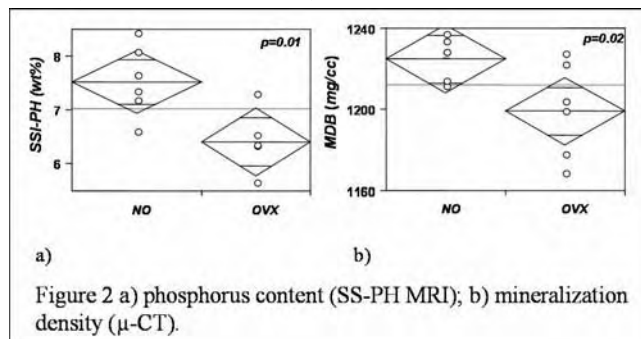

Figure 2 a) phosphorus content (SS-PH MRI); b) mineralization density ($\mu\text{-CT}$).

Accuracy and Precision of Adipose Tissue Cross-sectional Area Measured Using Peripheral Quantitative Computed Tomography (pQCT). C. Gordon¹, D. Inglis^{2*}, L. Giangregorio³, J. M. Zmuda⁴. ¹Radiology, McMaster University, Hamilton, ON, Canada, ²Civil Engineering, McMaster University, Hamilton, ON, Canada, ³Kinesiology, University of Waterloo, Waterloo, ON, Canada, ⁴Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA.

Purpose: Using magnetic resonance images (MRI) as the gold standard to quantify adipose tissue cross-sectional area (CSA), this study assessed the accuracy of quantifying sub-cutaneous fat, marrow fat, and fat in and around muscle from pQCT images of the calf. The precision errors for each of the fat components were also determined.

Methods: Twenty-five subjects participated in this study. Ten subjects were scanned with MRI and pQCT at a calf location corresponding to 66% of the distance up from the medial malleolus to the medial condyle of the tibia. pQCT scans were acquired with a STRATEC XCT 2000L scanner (Orthometrix Inc., White Plains, NY) at a voxel size of 0.4 mm³ and scan speed of 10 mm/sec. The MRI images were acquired on a 1.0 T peripheral magnet (ONI Corp, Wilmington, MA) using a fast spin echo sequence that acquired 10 contiguous 2 mm slices around the 66% location. CSAs of the adipose tissue components in the pQCT image were determined using various edge tracking and threshold steps available within the pQCT analysis software. To reduce noise, median filtering was applied before segmentation. Custom software was used to extract the CSA of the adipose tissue components in the MRI calf images. Least squares analysis was used to compare pQCT and MRI fat areas. To assess precision, 15 subjects had pQCT scans done on the same day, with repositioning between scans. Precision error was calculated as percent coefficient of variation.

Results: There was good agreement between pQCT and MRI derived areas for total fat ($R^2=0.98$, $p<0.0001$), subcutaneous fat ($R^2=0.96$, $p<0.0001$) and marrow fat ($R^2=0.61$, $p<0.03$). CSA of the fat in and around the calf muscles was not well defined with pQCT ($R^2=0.12$, $p=0.8$). pQCT defined adipose tissue at the calf with precision errors of 10% for total fat, 4% for subcutaneous fat, and 16% for marrow fat. The precision error for the area of fat in and around the calf muscle exceeded 100%.

Conclusion: Adipose tissue CSAs in the calf can be accurately derived from pQCT images. The fatty infiltration between and within the calf muscles may have to exceed a threshold to be accurately detected with pQCT or be best characterized by an index such as muscle density.

Comparison of QCT and DXA Derived Areal Bone Mineral Density. B. C. C. Khoo^{1*}, S. Henzell^{2*}, S. Gustafsson^{2*}, K. Zhu², R. I. Price¹, R. L. Prince³. ¹Medical Technology and Physics, Sir Charles Gairdner Hospital, Nedlands, Australia, ²Department of Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Nedlands, Australia, ³School of Medicine and Pharmacology, University of Western Australia, Crawley, Australia.

WHO guidelines, promulgated in 1994, considered that a gold standard for diagnosis of bone fragility in the clinical setting should be areal bone mineral density (aBMD, gcm²) measurements of the proximal femur using DXA. Recently there has been a return to the use of quantitative computed tomography (QCT) in clinical diagnosis to facilitate the understanding of bone fragility and structural analysis in individuals. aBMD is one of many variables that can be generated in such QCT studies. A critical question arises is how similar are the aBMD measurements derived from QCT and DXA?

This study compared the aBMD and T scores of 91 elderly female subjects aged 82.8 (2.5) years [mean (SD)], height 157.4 (6.0) cm, weight 63.6 (12.4) kg. All subjects were scanned on a Hologic Discovery DXA and a Phillips Brilliance CT scanner. The DXA aBMD was measured using Hologic software version 12.6 and QCT aBMD using Mindways software version 4.1.3. Using the QCT data aBMD data a "Hologic aBMD equivalent" can be calculated using manufacturer data which then allows calculation of an NHANES equivalent T score. The data was compared using linear regression and Bland-Altman (B-A) plots.

In linear regression the R^2 for total hip (TH), femoral neck (FN), inter-trochanter (IT) and trochanter (T) aBMD comparisons were 0.88, 0.84, 0.84 and 0.85 respectively, the regression coefficients were 0.87, 0.83, 0.90 and 0.83 respectively. The B-A plots showed that the QCT aBMD measurement under estimated the DXA aBMD (TH 0.13 (0.05) g/cm², FN 0.09 (0.04) g/cm², IT 0.14 (0.07) g/cm² and T 0.10 (0.05) g/cm²) with no bias as the mean increased.

These data confirm that QCT hip areal structural values are highly correlated with DXA aBMD. However there is an offset which needs further consideration.

A New CUSUM Method for Simultaneous Quality Control of BMD, BMC, and Area for DXA Scanners. Y. Lu, S. Zhao*, B. Fan, J. Shephard. Department of Radiology, University of California, San Francisco, San Francisco, CA, USA.

CUSUM method has been used in longitudinal quality control (QC) of bone mineral density (BMD) by dual X-ray absorptiometry (DXA) scanners. It identifies significant deviations from the baseline as breakpoints for further investigations. With an increase of pediatric and whole body studies, a new QC method is necessary to monitor BMD, bone mineral contents, and area simultaneously. In this paper, we presented a new multivariate CUSUM method. After a log-transformation of variables ($\ln(BMD)=\ln(BMC)-\ln(Area)$), we normalized and rotated variables $\ln(BMD)$ and $\ln(BMC)$ into two linearly unassociated variables X and Y based on their observed covariance matrix. A modified univariate CUSUM was then performed on X and Y separately in both increasing and decreasing directions. Multivariate (2-D) CUSUM parameters were selected to assure a false alarm rate similar to the univariate CUSUM of one variable. Simulation studies were conducted to evaluate performance comparing to our previously proposed 2-D Shewhart. $\ln(BMD)$, $\ln(BMC)$, and $\ln(Area)$ were generated by multivariate normal distribution using mean and covariance matrix derived from a whole body QC study. We simulated the in-control condition with 365 scans. We then generated 365 off-control data in the following conditions: (1) Case 1: both log BMD and BMC increased 1 SD and Area was relative stable; (2) Case 2: BMC increased in 1SD but not BMD, and area increased accordingly; and (3) Case 3: BMC increased 1 SD but BMD decreased 1SD. Each condition was repeated for 2000 times. Table 1 showed simulation results. When a scanner was in control, the median running length for the 1st false alarm was 213 and 31 scans, respectively, for the 2-D CUSUM and Shewhart methods. When a scanner was out of control, CUSUM identified the breakpoints within 5 to 20 scans on average similar to Shewhart. In conclusion, multivariate CUSUM method can be used for QC of BMD, BMC, and Area simultaneously for whole body phantom data with satisfactory false and true positive rates.

Table 1: Simulation Results for Bivariate QC Methods (n=2000)

Case	Median # of Scans	for the 1st Alarm	% Simulations Alarmed	Within the 1st 100 scans
Case Control	Shewhart	CUSUM	Shewhart	CUSUM
In Control	31	213	92%	42%
Case 1	6	8	98%	98%
Case 2	9	20	98%	95%
Case 3	7	5	98%	99%

Vitamin D Status/insufficiency May Predict Physical Performance in a Group of Osteopenic/osteoporotic Women. Preliminary Study. S. R. Mastaglia*, M. Seijo*, D. M. Muzio*, B. Oliveri. Sección Osteopatías Médicas, Hospital de Clínicas. Universidad de Buenos Aires, Buenos Aires, Argentina.

Hypovitaminosis D is frequent in population over 65 years of age, producing a secondary hyperparathyroidism, increase of bone remodeling, bone loss and osteoporotic fractures, loss of the muscle force function. The aim of this study was to assess the vitamin D (25OHD) nutritional state in osteopenic/osteoporotic women >65 and the relationship with muscle force and function. To date, forty women were assessed, with an average age ($X \pm DS$) 71.2 \pm 5.3, body mass index (BMI) 27.5 \pm 4.2, with a bone mineral density (BMD) (DXA-LUNAR) of femoral neck (FN) 0.752 \pm 0.71 (T-1.9). The exclusion criteria applied were: having received vitamin D during the year preceding the study, pathology or medication affecting mineral metabolism, neurological and/or motor-function disease. The physical performance of lower limbs (walking speed, balance, standing-up and sitting-down) and the hip force with a dynamometer was assessed. The population sample was divided into two groups, taking as cut point 20ng/ml of 25OHD (Lips P Endocr Rev 2001): Group 1 (G1): > 20 ng/ml, Group 2: (G2) \leq 20 ng/ml. The results obtained are shown in the table. A lower score in the physical performance and a tendency to a lesser left hip abduction in women with 25OHD \leq 20ng/ml was observed.

Preliminary data show that the levels of insufficient vitamin D could predict physical performance in osteopenic/osteoporotic women >65.

Table

	25OHD (ng/ml)	Left Hip Flexion	Left Hip Abduction	Physical Performance
G1 (n=20)	31.85 \pm 6.4	13.8 \pm 1.8	7.33 \pm 1.66	11.1
G2 (n=20)	12.9 \pm 3.9	14.01 \pm 2.4	6.74 \pm 2.09	9.6
p	0.000	NS	0.1>p>0.05	0.02

In Vivo and In Vitro Comparison of DXA Scanners. T. K. Omsland^{1*}, N. Emaus^{2*}, C. G. Gjesdal^{1*}, J. A. Falch^{3*}, G. S. Tell^{3*}, L. Forsen^{4*}, G. Berntsen^{2*}, H. E. Meyer¹. ¹University of Oslo, Oslo, Norway, ²University of Tromsø, Tromsø, Norway, ³University of Bergen, Bergen, Norway, ⁴Aker University Hospital, Oslo, Norway, ⁵Norwegian Institute of Public Health, Oslo, Norway.

When comparing BMD measured by different DXA scanners in multi-centre studies, the agreement between scanners is essential for the quality of the data obtained. In-vivo calibration is considered the "gold standard" when assessing agreement, but phantoms are frequently used instead. The European Spine Phantom (ESP) is an imitation of human vertebrae developed for comparison between scanners. The aim of this study was [1] to assess the agreement between in-vivo measurements (total femur) on three scanners (one GE Lunar DPX-IQ and two GE Lunar Prodigy scanners) and [2] to determine whether the ESP was able to reproduce the in-vivo variability in hip measurements on the different scanners.

The data were collected as part of the Norwegian Epidemiological Osteoporosis Studies (NOREPOS). The scanners compared in this study were located in three different cities, and the study subjects travelled between the cities. 6 men and 10 women aged 28-66 years had three repeated scans (with repositioning) on each machine. Body weight ranged from 58 to 100 kg. The ESP was scanned at least 40 times on each machine. Bland & Altman plots and multilevel linear regression analyses were used to analyse the data.

Mean difference between hip measurements on the two Prodigy scanners was small (<0.001 g/cm²) and insignificant ($p=0.97$). The differences between the scanners were not dependent on BMD level. The ESP was able to reproduce the in-vivo findings.

Mean difference between hip measurements on Prodigy and DPX-IQ was also small (0.007 g/cm²) and insignificant ($p=0.10$). However, the differences between the scanners changed over the range of BMD. The ESP did not fully reproduce the in-vivo difference between the scanners. The mean difference between ESP and measurements in humans was 0.010 g/cm² ($p=0.02$).

In conclusion, there were little overall differences between the in-vivo measurements. The ESP is a valid substitute when assessing agreement between Prodigy scanners. However, when assessing agreement between Prodigy and DPX-IQ, substitution of in-vivo with in-vitro measurements should be made with caution.

Disclosures: T.K. Omsland, None.

T273

The Effect of Bone Mineral Density (BMD) Measurement of Hip Bilateral in Clinical Practice. J. B. Lopes*, C. F. Danilevicius*, Y. F. Caparbo*, L. Takayama*, R. M. Pereira. Rheumatology Division (Bone Metabolism Laboratory), University of São Paulo, São Paulo, Brazil.

The aim of this study was to determine the effect of adding BMD measurement of contralateral hip on osteoporosis (OP) treatment based on NOF (National Osteoporosis Foundation) criteria. Sixty hundred and five consecutive elderly people community-dwelling (374 women/ 231 men) with 65 years-old or more (73.28 ± 5.40 yr) were evaluated. Subjects with a stroke causing hemiplegia, confined to a wheelchair, or with conditions resulting in immobilization of one limb were also excluded from the study. Densitometry of both hips and lumbar spine was evaluated using dual-energy X-ray absorptiometry (DXA) with HOLOGIC Discovery scanner. Precision errors and least significant change (LSC) were determined for each site: left/right hip (femoral neck and total femur) and lumbar spine. Clinical and anthropometric data were obtained by specific questionnaire and physical examination. The lowest T-score analyzed by DXA was considered in three distinct circumstances: lumbar spine+right hip; only hips and lumbar spine+hips. The risk factors were associated to the lowest T-score in these 3 situations and NOF criteria were applied to point out pharmacological treatment. Person's coefficient was used to assess the correlation between the 2 hips and McNemar's test to assess the differences using the NOF treatment criteria adding BMD measurement of contralateral hip.

There was a highly significant correlation between BMD of the two hips at femoral neck and total femur ($r = 0.93$ and 0.95 , respectively; $p < 0.0001$). Using the lowest T-score in the sites (lumbar spine, right/left femoral neck, right/left total femur) and WHO classification, osteoporosis was found in: 48.6% ($n=294$) analyzing lumbar spine+right hip; 31.2% ($n=189$) analyzing only hips and 49.75% ($n=301$) analyzing lumbar spine+hips. Similarly, pharmacological treatment using NOF criteria differed compare all analysis situations. Treatment indication occurred in 65.4% (396) analyzing lumbar spine+right hip versus 55.0% (333) analyzing only hips with a significant discordance treatment ($p < 0.0001$). Comparing lumbar spine+right hip BMD analysis and lumbar spine+hips analysis, the pharmacological therapy was indicated in 65.4% vs. 69.3% respectively with a significant discordance in treatment suggestion ($p=0.028$). This study indicate that the added of the both hips at the lumbar spine scan; can expand the number of people with the osteoporosis diagnosis and treatment indication. Furthermore, although of the artifacts such as osteoarthritis and osteophytic calcification influence in the lumbar spine BMD in elderly people, this site should be consider in the OP diagnosis and treatment.

The Relationship Between the Knowledge on Osteoporosis in Females and Bone Mineral Density at Hip, Spine and Forearm. W. Pluskiewicz*, B. Drozdowska*, A. Grodzki*. ¹Metabolic Bone Diseases Unit, Silesian School of Medicine, Zabrze, Poland, ²Silesian School of Medicine, Zabrze, Poland, ³Central Clinical Hospital, Medical University in Warsaw, Warsaw, Poland.

The study assessed the thesis that better knowledge on osteoporosis ought to be related with better results of bone mineral density (BMD) measurements.

The study group included 859 females (aged 18-88 y.) without prior treatment for osteoporosis and fractures. The knowledge of osteoporosis and attitude towards methods for preventing the disease were assessed using a questionnaire consisting of ten questions. BMD was measured at femoral neck, spine or forearm.

The level of knowledge and its duration did not influence BMD of spine, femoral neck and forearm either in the whole group and in subgroups divided according to the level of education. Mean number of correct answers was 7.25 ± 1.73 , and was significantly higher in better than in less educated women (7.93 ± 1.06 versus 6.39 ± 2.01 , $p < 0.0001$). In the whole group, the majority of women (63.7%) declared an increase in calcium intake (Chi-square test=74.5, $df=3$, $p < 0.00001$), and only 44.5% declared modification of physical activity (Chi-square test=44.3, $df=3$, $p < 0.00001$).

In less educated women an increase in calcium intake declared 54.7% versus 71.3% for better educated women (Chi-square test=15.0, $df=1$, $p < 0.001$). An increase in physical activity declared 37.6% versus 50.4%, respectively (Chi-square test=8.34, $df=1$, $p < 0.01$). Concluding, the level of knowledge on osteoporosis is not related with skeletal status in female population.

Level of knowledge (Number of correct answers)	Z-score spine L1-L4	Z-score femoral neck	Z-score forearm
0-5 (poor)	-0.11 +/- 1.49	-0.12 +/- 0.9	-0.77 +/- 0.96**
6-7 (moderate)	-0.52 +/- 1.41*	-0.22 +/- 1.1	-1.09 +/- 0.88**
8 (good)	-0.58 +/- 1.17*	-0.03 +/- 0.93	-1.52 +/- 0.98
9-10 (very good)	-0.34 +/- 1.26	0.05 +/- 0.76	-1.33 +/- 0.87

*significantly lower than poor result, $p < 0.05$

**significantly higher than good result, $p < 0.05$

no significant differences between Z-score values for femoral neck

Z-score values in whole group in regard to an increase (answer A) or no change (B) in calcium intake

The Qualitative Method and the Method Based on the Concept of 10 Years Probability of Bone Fracture in Qualifying Patients for Pharmacological Treatment of Osteoporosis. J. Przedlacki, K. Ksiezopolska-Orlowska*, A. Grodzki*, T. Bartuszek*, D. Bartuszek*, A. Swirski*, J. Musiał*, E. Luczak*, E. Loth*, P. Teter*, A. Lasiewicki*, A. Walkiewicz*, I. Drozdowska-Rusinowicz*. Krajowe Centrum Osteoporozy, Warsaw, Poland.

Introduction: The lack of generally accepted guidelines for osteoporosis in Poland obliges the specialist centers to perform free diagnostic procedures for each referred patient. The one worked out and used in Krajowe Centrum Osteoporozy (KCO) is a qualitative method based on the data from the specialist literature. It combines the assessment of the clinical risk factors with the results of DXA test. Another method, which considered for introduction to Poland, is that worked out by the Canadian authors derived from the concept of 10 years probability of bone fracture.

Purpose of study: The aim of the study was to compare both methods in terms of qualifying patients for the pharmacological treatment of osteoporosis.

Material and methods: The diagnostic tests were done on 908 patients (108 men and 800 women) aged over 50 years (64.7 +/- 8.3 years). They were referred to KCO mainly by GPs, for the diagnosis and treatment of osteoporosis from 21.03.2006 to 20.03.2007. The tests leading to the diagnosis were conducted separately according to each method.

Results: According to the method used in KCO 250 patients were qualified for pharmacological treatment of osteoporosis (27.5% of all, 16 men and 234 women). According to the Canadian authors' method 334 patients would have been qualified for the pharmacological treatment (risk of bone fracture >20%). The decision to introduce pharmacological treatment was unanimous in both methods in the case of 243 patients. In the group of women <65 years old and men <70 years old according to the Canadian authors' method there would have been qualified 95 patients out of 483 (19.7%), and

according to the KCO method 44 patients (9,1%) - conformity 46,3%. In the group of 55 patients that were not qualified for the pharmacological treatment 41 (74,5%) didn't have an indication for DXA test. In the group of men and women in older age according to the Canadian authors' method there would have been 239 patients out of 425 (56,2%) qualified for treatment, and according to KCO method 205 (48,6%) - conformity 84,5%. In the group of 37 patients not qualified for treatment 18 had a T-score > -2,0.

Conclusion: There was a moderate general agreement of implication for treatment in both methods, significant in older patients, smaller in younger ones. The authors think that the method currently used in KCO can be continued with. Interpretation of the differences in both methods is not explicit. The obtained results will be taken into account in preparing a periodical actualisation of our method.

Evaluation of Bone Area in the BMIL QA/QC Phantom on the Norland System. T. V. Sanchez¹, J. M. Wang², G. Ekker^{*3}, K. M. Dudzek^{*4}. ¹Research and Development, Norland--a CooperSurgical Company, Socorro, NM, USA, ²Research and Development, Norland--a CooperSurgical Company, Beijing, China, ³Engineering, Norland--a CooperSurgical Company, Fort Atkinson, WI, USA, ⁴Customer Service, Norland--a CooperSurgical Company, Fort Atkinson, WI, USA.

Bone area assessment using DXA varies with bone edge detection algorithms and equipment. Phantoms offer a tool by which to evaluate equipment performance when examining bone area. The current study evaluated DXA-based measurement of bone area on the BMIL QA/QC Phantom using AP Spine, Research and Small Subject Software to determine instrument response.

The commercially available BMIL QA/QC Phantom was evaluated on the Norland XR-46 using AP Spine Software at 1.5 x 1.5 mm and scan speeds of 65mm/s or 130mm/s and both Research and Small Subject Software at 1.0 x 1.0 mm with a scan speed of 15mm/s. The Phantom was scanned 25 times on each setting and operator set region of interest were analyzed for the total individual vertebrae (L1, L2, L3 and L4) on each scan. Regression analysis evaluated instrument performance.

When analyzed the studies done using AP Spine at 130 mm/s resulted in Bone Area for L1, L2, L3 and L4 of 13.526 cm², 17.484 cm², 21.648 cm² and 26.668 cm², respectively. Regression analysis between AP Spine mode at 130 mm/s and AP Spine mode at 65 mm/s ($y = 0.9928x + 0.3621$, $r = 0.9815$), Research mode ($y = 1.0812x - 6.399$, $r = 0.9909$) or Small Subject mode ($y = 0.9777x - 4.4908$, $r = 0.9991$) indicated strong relationships.

In summary, this study demonstrates that the Norland scanning system is able to assess the four segments of the BMIL QA/QC Phantom and that the operating software modes produce similar bone area results. Phantoms, like the BMIL QA/QC Phantom, can prove to be powerful tools for evaluating the performance of a DXA system.

Limits for Exclusion of Individual Vertebra from the L2-L4 AP Spine Assessment. J. M. Wang¹, T. V. Sanchez². ¹Research and Development, Norland--a CooperSurgical Company, Beijing, China, ²Research and Development, Norland--a CooperSurgical Company, Socorro, NM, USA.

Evaluation of the AP Spine L2-L4 region assumes that the individual vertebrae are free of defects that will skew the L2-L4 result. When evaluating the Norland AP Spine study, methodology calls for examining the individual vertebrae for a spread of less than 10% to insure that group value is not skewed. The current study examines the effect of spread on the L2-L4 result to establish if the criteria are valid.

A population of 424 AP Spine studies were pulled from clinical achieves. T-score results of studies were divided into four groups based on the spread of the L2, L3 and L4 percent young normal value_Group 1 (n = 115) with ≤5% variation, Group 2 (n = 167) with variation over 5% to 10%, Group 3 (n = 78) with variation over 10% to 15% and Group 4 (n = 64) with variation over 15%. To assess the effect of variation on the clinical findings, we examined discordance in T-score based diagnosis obtained from individual vertebrae and the L2-L4 region. The number of discordant diagnosis moved from 21% and 27.5% in Group 1 and Group 2 to a substantial 49% and 59% in Group 3 and Group 4.

The study demonstrates that as spread of the percent young normal increases in individual vertebrae beyond ten percent the population experiences a substantial increase in the number of discordant diagnosis. A limit in spread of ten percent or less among individual vertebrae is justified.

T278

Reliability of Two Consecutive Prodigy Densitometers. M. C. Schoeller^{*1}, S. Mehle^{*2}, C. Simonelli¹. ¹Internal Medicine, HealthEast Osteoporosis Care, Woodbury, MN, USA, ²HealthEast Research and Education, HealthEast Medical Research Institute, Woodbury, MN, USA.

Evaluation of long-term stability of DXA devices is important for assessing precision and maintaining quality control of bone mineral density measurements in longitudinal studies. Quality control procedures generally use spine phantoms with known values provided by manufacturer. We evaluated long-term precision over a 4-year and 9-month period of

measurement of a single Lunar spine phantom on two consecutive Lunar Prodigy (GE Healthcare) scanners located in an osteoporosis clinic.

The phantom consisted of an aluminum spine with increasing density from L2 to L4 embedded in a plastic that mimics human tissue (%fat=30%). The original Prodigy scanner was replaced 3.5 years into the study with a Prodigy Advance scanner. Six versions of enCORE operating software were used during the study. In addition to routine service on both scanners, two service interventions (tube head replacement) occurred on the first scanner. Both Prodigy scanners were used heavily (more than 160 scans/week on average). A total of 785 measurements of the spine phantom (L2-L4) were analyzed.

Long-term BMD precision was 0.4% and a regression of BMD on date showed no significant trend ($p(t)=0.08$, $R^2=0.004$). The average individual measurement change from baseline (first 5 measurements) was -0.31%. Minitab run chart evaluations of BMD for trends and oscillation around the mean were not significant ($p=0.20$ and 0.80 , respectively). The average change seen in phantom BMD measurements was insignificant at 0.0002 g/cm^2 per year and there were no significant trends.

We conclude that spine phantom measurements over a 4-year 9-month period on Lunar densitometers involving service interventions, multiple software versions, and a complete scanner exchange revealed highly stable values with average BMD shifts of -0.31%. The excellent BMD precision error of 0.4% for these densitometers demonstrated reliable system performance, long-term stability of results, and enhanced confidence in longitudinal studies.

	Prodigy Long-term Precision Error Measured with Phantom	
	BMD (g/cm ²)	BMC (g)
Mean	1.265	52.52
SD	0.005	0.323
CV	0.40%	0.67%

Phalangeal BMD Assessment Using Radiographic Absorptiometry From Hand X-rays Taken With Digital Mammography. S. L. Silverman¹, X. Bi^{*2}, L. Al-Dayeh^{*2}. ¹Cedars-Sinai/UCLA, Beverly Hills, CA, USA, ²CompuMed, Inc, Los Angeles, CA, USA.

Osteoporosis is under diagnosed and under treated. Recent guidelines from the US Preventive Systems Task Force recommend bone density screening for women over age 65 or women above age 60 with risk factors. Yet only 22.9% of Medicare recipients have had a BMD test in the 3 years after Medicare reimbursement for osteoporosis screening began¹. Breast cancer risk increases steadily with age. Mammography is recommended yearly for women over age 50.

We hypothesized that the availability of software to measure phalangeal BMD with digital mammography equipment would allow at risk postmenopausal women to have their BMD assessed when a routine mammogram is performed.

Radiographic Absorptiometry (RA) measures volumetric BMD of the middle phalanges from a standard AP x-ray of the non-dominant hand (with an aluminum reference wedge placed near the hand). We conducted a feasibility study to validate the use of Full Field Digital Mammography (FFDM) system to acquire the required hand x-ray for RA analysis, and to assess the accuracy of the results from the mammography system as compared to the results from standard x-ray films.

A customized module of the OsteoGram® (CompuMed Inc., Los Angeles, CA) which uses RA, has been developed to accept digital images from a Hologic - LORAD Selenia digital mammography system. The module accounted for normalizing the radiographic optical density response of the mammography system to the standard radiographic response of standard x-ray equipment.

50 volunteers, age between 40 to 78 seen for routine mammography at University of California, San Diego (UCSD) Medical Center were recruited to assess their phalangeal BMD by taking two hand x-rays. One x-ray was taken with the Hologic FFDM system with the settings at 35 kVp, 5 mAs; and another using standard x-ray equipment with mammography films. The exclusion criterion was a history of diagnosed osteoporosis.

To analyze the two data sets of radiographs, the customized module was used for the FFDM data and a standard OsteoGram system was used for standard film data (using standard flatbed scanner). Regression analysis of the results showed a significant ($p<0.001$) Pearson correlation coefficient of 0.94 between the two methods validating the results from FFDM.

Of the 50 volunteers, 16 had a phalangeal BMD T-score of less than -1.0 and 4 had a T-score below -2.5 (T-score calculated using OsteoGram's normative database). This finding calls for assessing the prevalence of low bone density amongst females scheduled for mammogram.

We conclude that the availability of phalangeal BMD testing during breast cancer screening with FFDM may provide an opportunity for BMD screening for osteoporosis.

Clinical Evaluation of Jaw Bone Density with a Newly Developed “Jaw Bone Density Evaluation System” - Relationship with Osteoporosis Evaluation. Y. Takaishi¹, A. Kamada², T. Ikeo², T. Miki³. ¹Takaishi Dental Clinic, Himeji-city, Japan, ²Biochemistry, Osaka Dental University, Osaka, Japan, ³Geriatric medicine, Osaka City University, Osaka, Japan.

<Background> The relationship between osteoporosis and changes in alveolar bone has become a target of interest, as the formation and resorption processes of the bone structure and periodontal structure are analogous. The number of osteoporosis patients increases in accordance with age. The same trend is observed in patients with periodontal diseases or with teeth loss. Therefore, osteoporosis may be one of the risk factors of the teeth loss due to reduction of the alveolar bone. Unfortunately clinical methods to evaluate alveolar bone have yet to be established and medical proofs are still insufficient.

<Objective> We estimated alveolar bone density using a new “mandibular bone density evaluation system” and examined the relationship with osteoporosis to determine whether jaw bone evaluation is clinically useful in assessing osteoporosis.

<Method> Thirty four postmenopausal female subjects (age: 50-69, average age: 59.9) participated in the experiment. In a simple X-ray scan of mandibular bone, standard substance (aluminum step wedge) was also scanned. The bone density was estimated based on the difference in their rates of transmittance. The correlations among bone mineral density (BMD) by DXA, cortical bone of proper alveolar bone portion and cancellous bone of support alveolar bone portion in mandibular bone were examined.

<Results> Cancellous bone density of support alveolar bone (A) and cortical bone density of proper alveolar bone (B) were 87.0 ± 18.1 (SD) and 89.9 ± 26.7 , respectively. Significant correlation between (A) and (B) was observed ($r=0.736, p<0.01$). The correlations of lumbar BMD by DXA and BMD (A) and (B) were significant, respectively ($r=0.638, p<0.01$, $0.414, p<0.05$).

<Conclusion> Both cancellous bone density of support alveolar bone (A) and cortical bone density of proper alveolar bone (B) correlated with lumbar BMD; however, the correlation with (A) was greater. These results suggest alveolar bone BMD by the jaw bone density evaluation system can be utilized as one of the screening tools for osteoporosis. This system may also utilized in a large scale screening of osteoporosis in the dental fields because of low cost and short period for the evaluation. This system may provide great contributions for osteoporosis patients.

Body Composition Measurements with Lunar iDXA: Precision Evaluation. E. Toussiot^{*1}, C. Semon^{*2}, F. Penfornis^{*2}, D. Wendling¹. ¹Rheumatology, University Hospital, Besancon, France, ²Endocrinology, University Hospital, Besancon, France.

Dual-energy x-ray absorptiometry (DXA), widely used for osteoporosis assessment, is increasingly used for measurement of body composition. Body composition is an important issue in metabolic diseases, pediatric patients but also in rheumatological conditions such as inflammatory rheumatic diseases, osteoarthritis and osteoporosis.

Precision error is a measure of the ability of a DXA system to detect small changes in a patient's body composition and bone mineral density (BMD). Lower precision error reduces the least significant change (LSC), allowing a smaller change in BMD or fat and lean mass to be identified as biological rather than related to instrument variability. Precision error is related to technology as well as the subject population; precision may degrade in thicker subjects due to decreased x-ray flux and the effect of thicker tissue on edge detection.

We evaluated precision error of total body BMD, bone mineral content (BMC), %fat, fat mass, and lean mass.

We scanned 24 women and 7 men for a total of 31 subjects (mean age 56.9 yrs, SD 13.1; mean BMI 28.4, range 17.3 - 39.6). 13 subjects had BMI values in the obese category (above 30), with a mean total %fat of 38% for the entire group. Each subject's total body was scanned two times, with repositioning between scans. Precision (%CV) was calculated as the root-mean-square standard deviation.

Precision values for Lunar iDXA total body BMD and BMC were 0.56% and 0.57% respectively. Body composition precision values were 0.63% for %fat, 0.59% for fat mass, and 0.45% for lean mass.

We conclude that the Lunar iDXA provided excellent precision for total body measurements, including BMD, BMC and body composition.

n=31	IDXA	Mean	CV
	BMD (g/cm ²)	1.065	0.56%
	BMC (g)	2318	0.57%
	%Fat	38%	0.63%
Total Body	Fat (g)	28779	0.59%
	Lean (g)	42783	0.45%

An Evaluation of Forearm BMD Measurement for Diagnosis and Treatment Monitoring in Men. N. Vallarta-Ast, D. Krueger, N. Binkley. University of Wisconsin, Madison, WI, USA.

Degenerative disease commonly confounds lumbar spine (LS) DXA assessment in older men, as such, forearm measurements are often appropriate. The ISCD recommends that the 1/3rd or “mid” radius site be utilized as the forearm region of interest (ROI) for diagnosing osteoporosis. It is therefore logical that this site would also be utilized for monitoring therapy. However, as the 1/3rd radius ROI is small and comprised primarily of cortical bone, it is plausible that use of the “total” radius ROI, which contains a higher proportion of cancellous bone, would be preferable for monitoring response to therapy. This report investigates the utility of routine forearm measurement in men and explores the utility of using the 1/3rd vs. the total radius ROI in monitoring BMD change over time in men. Between November 2003 and September 2006, 1599 men had clinically-indicated DXA scans performed at the Middleton VAMC. LS, proximal femur and non-dominant forearm images were obtained in all. Thirty-two percent (516/1599) of these predominately white men (97%, 2% Black), of mean age 68 years and mean BMI 28.3 kg/m², were osteoporotic by lowest T-score. The 1/3rd radius was equal to the spine ($p = 0.9$) in ability to detect low BMD in the group as a whole. However, in men age 80 and over, the 1/3rd radius was superior in low BMD detection ($p = 0.007$). Moreover, in men age 70+, osteoporosis was uniquely identified at the lumbar spine in only 2%, but at the 1/3rd radius in 14%.

From November 2003 to September 2006, 141 men had a repeat DXA scan performed, of whom 49 had initiated bisphosphonate (BP) therapy. As such, evaluation of non-response to BP therapy (defined here as a BMD decline greater than the LSC) is feasible. As might be expected, a BMD increase greater than the LSC was observed in 43%, 27%, 12% and 14% at the L1-4 spine, total femur, 1/3rd and total radius respectively. However, significant BMD declines were observed in none of these men at the LS, 4% at the total femur, 6% at the 1/3rd radius and 16% at the total radius.

In conclusion, the 1/3 radius is useful in identifying men with osteoporosis. However, “non-response” to BP therapy will be more common at the total radius than the 1/3rd radius, total femur or LS. DXA interpreters should be aware of this phenomenon when utilizing the total radius as a site to monitor therapy. Evaluation of the clinical significance, if any, of this “non-response” is indicated.

Skeletal Health between Two Different Groups of Hispanic American Women. J. Vargas-Jerez*, M. D. Walker, C. Gagel*, D. J. McMahon, R. A. Lantigua*, J. P. Bilezikian. College of Physicians and Surgeons, Columbia University, New York, NY, USA.

Osteoporosis is common in non-Caucasian women, particularly Hispanic Americans. Multiple studies suggest obvious racial differences in bone mineral density (BMD) and fracture risk. It is unclear whether fracture risk in non-Caucasian individuals should be assessed using race-specific referent BMD databases. A Hispanic referent BMD database for the hip, comprised of BMD values from Mexican Americans, is available from the third National Health and Nutrition Examination Survey (NHANES III). It is not known if this Mexican American database is applicable to other Hispanic groups. The purpose of this study is (1) to develop a local referent BMD database for Dominican American women who make up the majority of our local Hispanic population; and (2) to compare these data to referent values for Mexican and Caucasian American women.

560 women, 80 per decade from 20 to 90, are being recruited. Along with DXA of the total hip (TH), femoral neck (FN) lumbar spine (LS) and forearm, demographic, familial, medical, nutritional and behavioral information is being obtained. To date, 332 women have been recruited. Preliminary data suggest that Dominican American women have significantly higher mean BMD values at the TH for the decades beginning at age 50 (0.927 ± 0.113 vs. 0.859 ± 0.134 g/cm²; $p < 0.001$), 60 (0.876 ± 0.131 vs. 0.815 ± 0.134 g/cm²; $p = 0.04$), and 70 (0.830 ± 0.109 vs. 0.720 ± 0.134 g/cm²; $p < 0.001$) but not at the younger decades up to 40, or over 80 as compared with the NHANES III database for Mexican Americans. Femoral neck (FN) values were similar between the Dominican and Mexican American groups.

Dominican American women have higher bone density at the TH compared to Caucasian women for the decades beginning at age 40 (0.985 ± 0.125 vs. 0.922 ± 0.122 ; $p < 0.001$), 50 (0.927 ± 0.113 vs. 0.886 ± 0.122 g/cm²; $p = 0.04$), 60 (0.876 ± 0.131 vs. 0.827 ± 0.122 g/cm²; $p = 0.07$), 70 (0.830 ± 0.109 vs. 0.759 ± 0.122 g/cm²; $p < 0.001$), & 80 (0.780 ± 0.081 vs. 0.691 ± 0.122 g/cm²; $p = 0.04$) but not for the 2 younger decades (20-40). Mean FN values were also greater in the Dominican American group compared to Caucasians across most age ranges. Mean LS BMD values were similar between groups.

These data suggest major differences in BMD between two Hispanic American subgroups and in comparison to the standard Caucasian database. The data also suggest that a single Hispanic American referent database may not be applicable to all Hispanic American women. How these differences relate to fracture risk among different Hispanic American groups is an important next investigative step.

Disclosures: M.D. Walker, None.

Comparison of pQCT-based Measures of Radial Bone Geometry and Apparent Trabecular Structure Acquired Using Different Algorithms. N. J. MacIntyre*, D. Inglis². ¹School of Rehabilitation Science, McMaster University, Hamilton, ON, Canada, ²Department of Civil Engineering, McMaster University, Hamilton, ON, Canada.

The purpose of this study was to compare methods of analyzing peripheral quantitative computed tomography (pQCT) images using different software and/or algorithms aimed at evaluating similar bone characteristics in the distal radius. The sensitivity of variables to changes in positioning in the region of the 4% site was also assessed.

Seven left cadaveric forearms (mean age (SD) 74.13 (7.09) y) were imaged at 0.5 mm intervals around the 4% site using pQCT (10 slices, 0.2 mm × 0.2 mm, 2.5 mm thick; Stratec XCT2000L). We analyzed the images for total and cortical cross-sectional areas (B.Ar, Ct.Ar), mean cortical thickness (Ct.Th) and its variation in terms of SD using both commercial software (Stratec v6.00 B) and an in-house developed program (pQCT Pro). pQCT Pro not only quantifies a variety of bone geometry variables, but also provides estimates of apparent trabecular structure, including number (App.Tb.N), thickness (App.Tb.Th) and spacing (App.Tb.Sp) using two different stereological approaches: the parallel plate model and mean intercept length (MIL) analysis. Measures of similar bone characteristics (mean values for 10 slices) were compared using Bland Altman plots and the absolute mean differences were expressed as percentages. We assessed the effect of slice position using one-way repeated measures ANOVA ($p < 0.05$).

The percent difference in measures varied from 3.5% (B.Ar) to 64.7% (App.Tb.Sp). As the mean value for App.Tb.Sp increased, the difference between the measures increased. The other measures did not differ systematically. Comparable methods produced mean values that ranked the seven specimens similarly with few exceptions (Ct.Th, specimen 3; App.Tb.Th, specimen 7; App.Tb.N, specimens 1, 3, 5, 6).

Measurements of B.Ar at the 4% site differed from those acquired more than 0.5 mm proximal and all more distal positions ($p < 0.001$). Ct.Ar at the 4% site differed only from positions that were at least 2 mm more proximal or distal ($p < 0.001$). Parallel plate model measurements of App.Tb.Sp at the 4% site differed from those 2 mm more proximal ($p < 0.02$). For the other variables, positioning did not have a significant effect.

Excellent agreement in B.Ar measures was observed. Differences between the other measures reflect differences in the algorithms used to derive them and these differences need to be considered when selecting outcome measures. Parallel plate derived measures are more influenced by anatomic variation than MIL based measures of apparent structure which makes the latter measure more desirable for cross sectional study designs. With the exception of B.Ar, measures acquired within 2 mm of the 4% site are consistent.

Longitudinal Change in Bone Strength Indices: The Framingham Study. S. Menn, Y. H. Hsu, D. P. Kiel, D. Karasik. IFAR, Hebrew SeniorLife, Boston, MA, USA.

Bone strength is a valid predictor of bone's ability to resist fracture. Metacarpal bones have been routinely measured in previous research studies to predict fractures and quantify bone loss. Since change in metacarpal bones geometry over time may characterize the other long bones in the body, we evaluated effect of age, height and weight, as well as change in height and weight over a time interval of 22.5 ± 0.8 yrs on change in radiographic metacarpal Bone Strength Indices (BSIs).

Convenience sample of digitized hand x-rays (208 out of ~800) participants of the Framingham Study Original cohort (54±5 yrs old at baseline, BL), was used. At both BL (1967-1970) and follow-up, FU (1992-1994), the following indices as well as changes in them, Δ, were measured at the midshaft: Metacarpal Cortical Index (MCI), Cortical Thickness (MCT), and Section Modulus (MZ). Second (Met2) and third (Met3) metacarpals were studied.

All analyses were done by gender. We calculated correlation coefficients between ΔBSIs and BL age, height, weight, Δheight, and Δweight. Subsequently, we performed regression analysis to estimate effect of the above variables on ΔBSIs over time.

In final analysis, 79 men and 129 women were included. Changes in Met2 and Met3 BSIs were normally distributed and evident in both sexes, ranging from -45.6 to 38.5% in men and -63.6 to 42.4% in women.

In Met2, age at BL significantly negatively correlated with ΔMCI and ΔMCT in women only ($r = -0.25$ to -0.29 , $p < 0.005$). Height on BL significantly negatively correlated with ΔMCI and ΔMCT in men, while weight on BL and Δheight correlated with ΔMZ in women. Δweight positively correlated with ΔMCI, ΔMCT, and ΔMZ of both Met2 and Met3 in women ($r = 0.17$ to 0.24 , $p < 0.05$).

In regression analyses of Δheight and Δweight (with BL age, height, and weight in the same model), BL weight and Δheight were marginally significant predictors of Met2 ΔMCI in men, whereas in women, BL weight, height and Δheight predicted Met2 ΔMZ (beta = -1.17, 8.74 and 26.20, $p < 0.05$). In women, Δweight was significant predictor of both Met2 and Met3 ΔMCI and ΔMCT (beta = 0.07 to 0.11, $p < 0.05$).

In conclusion, in this pilot study, change in metacarpal bone geometry and strength was observed over an interval of 22 yrs, mostly in women. There was a wide range of changes with age, from loss to gain of bone strength indices. Weight and height at baseline, as well as change in weight and height, predicted the longitudinal change in BSIs in women, less strongly in men. Age-related change in metacarpal bone strength indices may reflect general behavior of long bones.

Correlations Between HR-pQCT & High-Field MR In Vivo Bone Imaging. G. J. Kazakia¹, B. Hyun¹, A. Burghardt¹, R. Krug¹, D. Newitt¹, A. DePapp², T. Link¹, S. Majumdar¹. ¹Radiology, UC San Francisco, San Francisco, CA, USA, ²Merck & Co., Inc., Bryn Mawr, PA, USA.

The purpose of this study was to compare bone structural measures obtained via high-resolution peripheral QCT (HR-pQCT) to those obtained by high-field MRI in a cohort of post-menopausal females enrolled in a longitudinal pilot study comparing the effects of alendronate to placebo on bone microarchitecture.

Fifty-two early post-menopausal women classified as osteopenic by lumbar and/or hip DXA T-score underwent HR-pQCT (XtremeCT, Scanco Medical AG) and MR imaging of the distal radius and tibia. For HR-pQCT imaging a 9 mm axial length was imaged, with isotropic 82 micron voxels. Bone volume fraction (BV/TV) was derived assuming a density of 1200 mg HA/cc for mineralized bone. The 3D distance transform (DT) method was used to assess trabecular number (Tb.N). Following cortical segmentation using a Gaussian blur and a fixed intensity threshold, cortical thickness (Ct.Th) was calculated as the cortical volume divided by the periosteal area.

MR imaging was performed at 3 Tesla (GE Medical) using a balanced steady state free precession sequence. Spatial resolution of the resulting images was 156 x 156 x 500 micron. Regions of interest corresponding to the HR-pQCT regions were used to calculate structural parameters. Each image was binarized using a global threshold, and BV/TV, apparent Tb.N and other structural parameters were calculated using 2D histomorphometric methods. Cortical boundaries were defined manually and Ct.Th was derived using the DT method.

Despite the distinct differences between analysis techniques, significant correlations between HR-pQCT and MR parameters were found. The correlation was strongest for Tb.N ($R^2 = 0.52$) and Ct.Th ($R^2 = 0.43$) and weaker for all other parameters. However, MR and HR-pQCT provide statistically different measures of structure parameters. BV/TV was significantly higher in the MR analyses (mean MR/pQCT = 3.2 radius; 3.9 tibia) while Tb.N was lower (mean MR/pQCT = 0.9 radius & tibia). Tb.Th and Tb.Sp values were therefore higher and lower, respectively, as calculated by MRI. MR analysis resulted in higher values of Ct.Th (mean MR/pQCT = 2.0 radius; 1.3 tibia). In terms of correlations with DXA measurements, significant relationships were found only between HR-pQCT parameters at the distal radius and radius T-score ($R^2 = 0.19-0.58$).

The XtremeCT system uses a unique density derived analysis technique, necessitating the careful investigation of relationships between HR-pQCT and MR measures. Our results demonstrate discrepancies in absolute values and moderate correlations between modalities, suggesting that differences in the analysis techniques must be taken into account when comparing and interpreting the results of these imaging modalities.

High-Resolution CT Images Yield Accurate Microstructural Information if Processed by 3-D Extensions of Standard Histomorphometric Analysis or Fuzzy Segmentation Approaches. A. Krebs¹, C. Graeff¹, I. Frieling^{2,3}, B. Kurz³, W. Timm⁴, C. C. Glüer¹. ¹Med. Phys., Diagn. Radiology, UKSH, Kiel, Germany, ²Osteoporose-Praxis Neuer Wall, Hamburg, Germany, ³Anatomisches Institut, CAU, Kiel, Germany, ⁴Synarc, Hamburg, Germany.

In vivo assessment of trabecular bone microstructure is limited by image quality and radiation exposure. We investigated whether microstructural information can be accurately extracted from High Resolution CT (HRCT) images of human vertebrae.

Microstructural variables can be defined by 3-D adaptation of 2-D stereological methods used in histomorphometry. However, binarization of bone structures is affected by image resolution and image noise. Fuzzy segmentation approaches may overcome these limitations. For bone voxels exceeding a minimum gray level, a minimal weighted distance to the bone marrow background, named fuzzy distance, is calculated as measure of local thickness. A complementary process based on the marrow phase yields a measure of trabecular separation. Both the stereologic and the fuzzy methods were implemented on StructuralInsight, our imaging software developed in house and yield estimates of microstructural variables, defined analogously to histomorphometry, including bone volume fraction (BV/TV), trabecular thickness (Tb.Th), and trabecular separation (Tb.Sp).

16 vertebral biopsies of 8mm diameter (Set 1, training) and 8 whole vertebrae (Set 2, validation) embedded in PMMA were measured by HRCT (Siemens Somatom 16, 120 kV, 360 mAs, pixel size 156 x 156 μm^2 , slice thickness 400 μm) inside a CIRS abdomen phantom to emulate in vivo conditions. Reference measurements on micro-CT systems were obtained on a Scanco $\mu\text{CT}40$ (voxel size 24 μm^3) for Set 1 and a Scanco Xtreme CT (voxel size 82 μm^3) for Set 2.

The table lists residual root-means-square (RMS) errors (in% of the reference mean) and coefficients of determination for regression of reference systems against HRCT.

Reference results [mean \pm SD(in mm, %)]		BV/TV 0.08 \pm 0.02 (26%)	Tb.Th 0.12 \pm 0.02 (17%)	Tb.Sp 0.94 \pm 0.13 (14%)
Set 1	Stereol.	19%, $r^2=0.48$	13%, $r^2=0.45$	13%, $r^2=0.20$
	Fuzzy	16%, $r^2=0.61$	11%, $r^2=0.63$	9%, $r^2=0.61$
Reference results [mean \pm SD(in mm, %)]		BV/TV 0.33 \pm 0.08 (25%)	Tb.Th 0.37 \pm 0.04 (12%)	Tb.Sp 0.79 \pm 0.21 (27%)
Set 2	Stereol.	17%, $r^2=0.58$	8%, $r^2=0.66$	20%, $r^2=0.55$
	Fuzzy	21%, $r^2=0.40$	5%, $r^2=0.88$	21%, $r^2=0.49$

Both methods estimate structural variables with RMS-errors substantially smaller than the sample SD, demonstrating that microstructural information could be extracted from the HRCT images with acceptable residual accuracy errors of 5-21% under in vivo like conditions. HRCT has value for the assessment of vertebral microstructure in patients.

Disclosures: A. Krebs, None.

Hip Structural Geometry and Incidence of Osteoporotic Fractures in the Women's Health Initiative-Bone Mineral Density (WHI-BMD) Cohort. A. Z. LaCroix¹, Z. Chen², D. Sherrill^{3,4}, T. Beck³, J. Cauley⁴, C. E. Lewis⁵, R. Jackson⁶. ¹Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ²University of Arizona, Tucson, AZ, USA, ³Johns Hopkins University, Baltimore, MD, USA, ⁴University of Pittsburgh, Pittsburgh, PA, USA, ⁵University of Alabama, Birmingham, AL, USA, ⁶Ohio State University, Columbus, OH, USA.

While the relationship between bone mineral density (BMD) as measured by dual-energy x-ray absorptiometry (DXA) and risk of hip and osteoporotic fractures is well established, much less is known about how the amount and distribution of underlying bone tissue relate to fracture. We studied 10,432 postmenopausal women ages 50-79 at baseline enrolled in the WHI Observational Study or Clinical Trial who had a hip BMD scan by DXA at baseline at one of three WHI clinical centers in Pittsburgh, PA, Tucson, AZ, or Birmingham, AL. The hip DXA scans were analyzed using a validated program developed by T. Beck which yielded the following measurements for this analysis: section moduli at the narrow neck and proximal shaft (cm^3); Buckling ratios at the narrow neck; and shaft (dimensionless). For each of these parameters measured at baseline, time to first fracture was studied using Cox Proportional Hazards models adjusting for age, ethnicity, history of falls, hip BMD and hormone therapy intervention. All fractures were physician-adjudicated at the local clinical centers and hip fractures were also centrally reviewed and adjudicated. During an average follow-up time of 8 years, 1599 clinical fractures occurred with 161 of these at the hip. Hazard ratios (HRs) are expressed for a 1 standard deviation change in each parameter. HRs for all four parameters indicated associations with increased risk of hip fracture, which were statistically significant for three out of four measurements. The strongest association was seen for section modulus at the shaft (HR=1.79; 95% CI 1.43-2.24), whereas the other HRs were in the range of 1.2-1.3. Hazard ratios were lower for prediction of total fracture, ranging from 1.0-1.2, but still statistically significant for all except for the section modulus at the narrow neck. These results show that geometric measurements of hip bone strength predict future hip fracture even after adjustment for hip BMD. An interesting result is that the direction of the effect of section modulus is reversed after adjustment for hip BMD, such that a higher bending resistance is associated with greater fracture risk for a given BMD level. The theoretical reasons for the change in the direction of the effect on risk will be presented.

The Spinal Curvature Irregularity Index Discriminates Hip Fractures: Comparison with Femur BMD. G. Maalouf¹, R. Zebaze², N. Maalouf³, S. Maalouf⁴, A. Nehme⁵, Z. Tannous⁶, J. Wehbe⁷, G. Adib⁸, M. Gannagé-Yared⁹, E. Seeman². ¹St George Hospital, Beirut, Lebanon, ²Austin Hospital, U. Melbourne, Melbourne, Australia, ³U Texas Southwestern Medical Center, Dallas, TX, USA, ⁴General Company for Technical Services, Beirut, Lebanon, ⁵Italian Hospital, Damascus, Syrian Arab Republic, ⁶Hotel Dieu de France, Beirut, Lebanon.

Vertebral and hip fractures (fx) are common consequences of osteoporosis. The Spinal Curvature Irregularity Index (SCII) gives a quantitative estimate of the regularity of spinal curvature that is a robust, simple, and independent indicator of the presence of vertebral fx. SCII is calculated by comparing the ratio of the anterior to the posterior vertebral heights of one vertebra to that of adjacent vertebrae throughout the thoracolumbar spine (T4-L4). SCII is the integrated average of these calculations for all pairs of adjacent vertebrae in an individual. A perfectly regular spine has an SCII of zero percent.

We compared the ability of SCII to discriminate between patients with and without hip fx. Vertebral heights from the Vertebral Fracture Assessment application, and spine and femur bone mineral density (BMD) values, were measured with a Lunar Prodigy (GE Healthcare) in 420 Lebanese women (age 22 - 89 years, total femur (TF) BMD 0.446 - 1.305 g/cm^2). 27 subjects had previous hip fx; 393 subjects without hip fx served as controls. The average SCII was 14.6% (SD=4.1%) for hip fx cases and 7.5% (SD=3.4%) in controls. ROC analysis tested the ability of SCII, L1-L4 spine BMD, TF BMD, femur neck (FN) BMD, hip axis length (HAL) and Femur Strength Index (FSI) to discriminate between hip fx and control subjects. SCII was the strongest discriminator (AUC=0.941) and was superior to FN BMD ($p=0.0023$). An SCII cut-point of 11.2 yielded 90% sensitivity and specificity in identification of hip fx subjects. We conclude that SCII in this population discriminated between subjects with and without hip fx better than FN and TF BMD.

Model Effects in the Ovariectomized Rhesus Monkey as Measured with pQCT. P. J. McCracken¹, R. Y. Jayakar¹, L. T. Duong², R. Hargreaves³, T. N. Hangartner³, D. S. Williams¹. ¹Imaging Department, Merck Research Laboratories, West Point, PA, USA, ²Department of Molecular Endocrinology, Merck Research Laboratories, West Point, PA, USA, ³Department of Biomedical, Industrial and Human Factors Engineering, Wright State University, Dayton, OH, USA.

Preclinical evaluation of disease burden and treatment efficacy is critical to the development of new therapies for osteoporosis. Clinically translatable imaging modalities beyond DEXA, such as pQCT and hrMRI, give us the advantage of studying in-vivo macro- and micro-architectural parameters relevant to bone strength. We have quantified pQCT endpoints of the ovariectomized (OVX) rhesus monkey as compared to intact

animals to examine potential technological and model-based measurement limitations. pQCT (XtremeCT, Scanco Medical) of the distal radius, one-third radius, distal tibia, and one-third tibia in OVX and intact monkeys (n = 10/group, aged 14-20 years) was performed at 12 months post-OVX to assess cortical and cancellous bone at the distal bone sites. BMD was also measured using a Hologic QDR Discovery DXA. With the midpoint of the distal endplate as reference, scanning started proximally at a distance of 2mm, 3mm, and 50-70mm for the distal radius, distal tibia, and one-third proximal locations, respectively, with the slice pack for 1/3 locations chosen according to the length of the shaft. Both model-derived and direct measurements in each relevant site included Cortical Thickness (CtTh), Bone Volume Fraction (BVf), Trabecular Number (TbN), Trabecular Thickness (TbTh), Trabecular Separation (TbSp), Structure Model Index (SMI), Total Density (D100) and Cortical Density (Dcomp). After precalibration and scout imaging at each location, anesthetized animals were scanned using: 9mm slice pack, 220 slices, 1500 projections, 3072 points per projection, 3000x3000 matrix, 200 ms integration time, 40 μ m voxel size, 8.3 min measurement time. Total imaging time was under 40 minutes. The data were reconstructed at a 100 μ m voxel size and processed using the manufacturer's 'clinical' and 'research' analysis protocols. One animal was scanned ten times per site to quantify test-retest variability. Results showed significant differences in radial and tibial BVf (-8%, -13%), 1/3 CtTh (-25%, -37%), and Dcomp (-4.5%, -6%) between the OVX and intact groups. There were trends in measures of TbTh, CtTh, TbSp and TbN consistent with the estrogen deficient model, and test-retest variability estimates indicated adequate precision for monitoring longitudinal changes. Density measurements by DEXA correlated with comparable XCT measurements. Our quantification of the results of OVX in rhesus monkeys as measured with pQCT encourages its further investigation in disease-modifying therapies.

DXA and QCT Geometric Structural Measurements of Proximal Femoral Strength. C. Muschitz¹, L. Milassin^{*1}, T. Pirker^{*1}, R. Waneck^{*2}, H. Resch^{*1}.

¹Medical Department II, St. Vincent Hospital, Vienna, Austria, ²Department of Radiology, St. Vincent Hospital, Vienna, Austria.

Hip fracture results mainly from loss of femoral strength associated with aging. Femoral strength is a function of bone mineral density (BMD) and distribution of bone mass in the proximal femur. Geometric measurements known to relate to femoral strength and fracture risk include cross-sectional moment of inertia (CSMI), cross-sectional area (CSA) and hip axis length (HAL). BMD contributes only half the variation in strength estimated by CSMI, indicating that CSMI contributes additional information (Yoshikawa 1994). These variables are measured with both dual-energy X-ray absorptiometry and quantitative computed tomography (QCT). We measured 93 Caucasian clinic patients from 37-91 years of age (mean 67.6 yrs; SD 11.97) with femur BMD 0.452-1.171 g/cm² (mean 0.795 g/cm²). We compared DXA (Lunar iDXA, software version 11.2, GE Healthcare) measurements with CT (Phillips MX8000 4-slice CT, 3.2mm slices). The iDXA automatically measures CSMI as the minimum CSMI in the neck region of interest (ROI), and CSA of the minimum CSMI line in the neck ROI. These are often found in narrowest section of the neck, but may occur further up the neck due to individual variation in location of center of mass. We used a commercial QCT application (QCT PRO version 4.1, Mindways Software Inc) that generated measurements from cross-sectional images at the narrowest portion of the femoral neck to most closely duplicate the DXA measurement site. QCT values were adjusted by the ratio of DXA/QCT reference for average density of bone (1.85/1.05 g/cm³). Results showed high correlations for CSMI (r 0.91) and CSA (r 0.87), although the reported values were not equal, possibly due to different measurement location. HAL was highly correlated (r=0.94) with a slope not significantly different from identity. Femoral neck BMD values were also highly correlated (r=0.91). We conclude that structural measurements made at the femoral neck with DXA were highly correlated with similar QCT measurements.

CSMI DXA vs QCT

CSMI (cm ⁴)	CSMI (QCT) = 0.7955 CSMI (DXA) + 0.1343	0.1414	0.91
CSA (cm ²)	CSA (QCT) = 0.8032 CSA (DXA) + 0.0790	0.1210	0.87
HAL (mm)	HAL (QCT) = 0.9957 HAL (DXA) + 4.1492	2.8522	0.94
Femur Neck BMD (g/cm ³)	BMD (QCT) = 0.8551 BMD (DXA) - 0.0837	0.0486	0.91

MRI-based Measurement of Vertebral Shape in Japanese Women. T. Nakano^{*1}, A. Harada², H. Hagino³. ¹Department of Orthopaedic Surgery, Tamana Central Hospital, Kumamoto, Japan, ²Department of Restorative Medicine, National Center for Geriatrics and Gerontology, Aichi, Japan, ³Rehabilitation Division, Tottori University Hospital Faculty of Medicine, Tottori University, Tottori, Japan.

We propose the cutoff values for diagnosing a previous vertebral fracture by determining the dimensions of the normal vertebral body, as expressed by the anterior-posterior (A/P) ratio, central-posterior (C/P) ratio, and other indices. The subjects were 56 female volunteers, and their age distribution was as follows: 20-29 years (n=13), 30-39 years (n=14), 40-49 years (n=15), and 50-59 years (n=14). T1-weighted magnetic resonance imaging (MRI) scan of 14 vertebral bodies from T4 to L5 revealed that measured values of L4 and L5 were remarkably different from those of the remaining vertebral bodies. No age-related tendency was observed. The A/P ratios obtained from images of the thoracic and upper lumbar spine were below 1.00, showing a slight wedge or rectangular deformity. The A/P ratios obtained from images of the lower lumbar spine exceed 1.0 with an inverse wedge deformity. Few differences were found in C/P ratios obtained from images of the parts from the upper thoracic spine to the upper lumbar spine. The levels of -3.0 SD of the A/P and C/P ratios of the parts from T4 to L3 were 0.82 and 0.79, respectively, therefore it is reasonable that the A/P ratio below 80% and the C/P ratio below 75% are considered as the cutoff values for diagnosing a vertebral fracture based on vertebral body measurement from T4 to L3.

Sclerosis of the Principal Medial Compressive Trabeculae in the Osteoporotic Femur May Mask The Bone Mineral Loss of the Femoral Cortex. S. Okamoto¹, H. Noguchi^{*2}, H. Suzuki^{*3}, N. Ohtsu^{*1}, T. Okamoto^{*1}, S. Okamoto^{*4}, A. Itabashi⁵. ¹SORF Okamoto Clinic, Oita, Japan, ²Noguchi Thyroid Clinic and Hospital Foundation, Beppu, Japan, ³Suzuki Orthodontic Office, Nagasaki, Japan, ⁴KS Okamoto Clinic, Shimabara, Japan, ⁵Saitama Center of Bone Research, Saitama, Japan.

We have examined three dimensional CT of the osteoporotic femurs and found substantial mineral loss in the femur cortex in the neck region. Meanwhile, there was significant sclerosis in the principal medial compressive trabeculae extending from the femoral head to the medial cortex of the femur. This gross rearrangement of bone structure may be a risk factor for femur fracture and may serve to explain the lack of correlation between femur neck BMD and bone fracture frequency. Femur neck BMD is said to be the parameter of osteoporosis most responsive to therapy, yet is more variable than trochanter or total femur BMD. In some cases, neck BMD rises or drops in ways that conflict with the direction of the systemic bone mineral loss or gain. This paradoxical behavior may in part be explained by the increasing sclerosis of the principal compression trabeculae of the femur that progresses in tandem with the thinning of the femoral cortex. Radiological measurements may pick up the increased density of the principal compression trabeculae and present a falsely high value of the weakened femur. To test this theory, TV-X ray fluoroscopy with the postural adjustment was performed in 134 normal volunteers and 2600 female osteoporosis patients. Lumbar and Femur BMD were measured (QDR 4500 or Discovery, Hologic) and PQCT of the radius (Stratec) was assessed in all patients. 3-D figures of bilateral femurs were performed by Helical CT (Asteion Super 4 edition Toshiba) analysis in 55 cases. We found a number of cases where femur neck BMD did not correlate with trochanter and total femur BMD and observed gross increase in the density of the principle compression trabeculae. This change in bone structure may be the result of adaptation of the trabeculae to increased load due to the weakened cortex. A collection of cases will be presented.

Over-adaptation of principal compressive trabeculae.

Regional Thinning of Cortical Bone in the Femoral Neck with Age: Interim Analysis of a Study of Women from the Second to the Eighth Decade. K. Poole¹, C. Rose²*, S. Kaptoge¹, K. Brown², N. Loveridge¹, P. Bearcroft²*, J. Reeve¹. ¹Clinical School, University of Cambridge, Cambridge, United Kingdom, ²Mindways Software, Austin, TX, USA.

In the superoposterior (SP) region of the female femoral neck, cortical thinning occurred at 10% per decade in a post mortem study (Mayhew et al Lancet 366:129 2005). This may be sufficient that elderly hips fracture in a sideways fall through local cortical buckling, when SP suffers the hip's maximal loading. Improved estimation of risk would then require estimation of cortical thickness (C.Th), measurable with whole body Computed Tomography (WCT) but not DXA. Women were recruited aged 20 to 80 (IQR 39-65) to investigate C.Th using Siemens 64 WCT and Mindways software (v4.1.3). They were a sample of 56 healthy volunteers attending for routine clinical WCT scans including the pelvis (exclusions; corticosteroid use, carcinomatosis), and they consented to a slightly caudal extension to include both hips (1mm slice thickness, 0.59 mm pixel size). Bone architecture was assessed using a contour-tracking algorithm after automatic calibration of greyscale CT images to BMD equivalents (using a K2HPO4 phantom). A single cross-section of the femoral neck was automatically extracted at a reproducible location (ratio of 1.4:1 'in plane' to 'out of plane' diameter) for analysis of regional C.Th. in octants defined using the centre of mineral mass and principle axes. Combining octants resulted in four anatomical quadrants; SP, supero-anterior, infero-posterior and infero-anterior. Overall intra-operator CV (6 subjects measured twice) was 5.85% and was independent of subject age (p=0.1), octant (p=0.6) and any interaction between the two (p=0.6). There were no differences in C.Th between right and left hips so the data were measured for the analysis. Longitudinal drift by phantom measurement was <2%. In the SP quadrant, there was a marked decline with advancing age, amounting to loss in thickness of nearly 60% between the age of 20 and 80. The superior quadrants were better fitted log-linearly and age accounted for 60% of the variance in cortical thickness at SP. The exponential rate was highest at SP, more than two-fold more than that in the inferior quadrants. Ageing was associated with relatively much faster thinning of the SP cortex of the femoral neck than BMD decline, confirming Mayhew's results. Local femoral neck cortical thickness can be quite reliably estimated in vivo by WCT. Better-than-DXA estimation of hip fracture risk might be achievable using whole body CT and calibrated measurement of proximal femur geometry.

Laws' Masks Descriptors Applied to Bone Texture Analysis: An Innovative and Discriminant Tool. M. Rachidi¹*, A. Marchadier¹*, C. Gadois²*, E. Lespessailles³, C. Benhamou¹, C. Chappard¹. ¹Inserm u 658, CHR Orleans, Orleans, France, ²D3A, Orleans, France, ³CHR Orleans, Orleans, France.

Bone micro-architecture evaluation in vivo is not largely available at present. A few techniques of texture analysis were developed to assess trabecular bone micro-architecture. Laws' masks are known as one of the best methods for texture analysis in image processing, and are used in various applications, but not in bone tissue characterization. This method is based on masks aiming to filter image. From each mask, five parameters can be calculated namely Mean, Standard Deviation, Skewness, Kurtosis and Energy. The objective of this study was to explore a new method of texture analysis to characterize bone micro-architecture.

This study was performed on 182 healthy post menopausal women with no fracture and 114 age-matched women with fractures (26 Hip fractures (HF), 29 vertebrae (VF), 29 wrist (WF) and 30 other fractures (OF)). For all subjects the radiographs were obtained on calcaneus using a new high resolution X-ray device with direct digitisation (BMATM, D3A[®] France). The lumbar spine, femoral neck, and total hip BMD were assessed by DXA.

In terms of reproducibility, the best results were obtained with E5E5 mask especially for two parameters: "Mean" and "Standard Deviation" with respectively in vitro RMSCV%=1.0 and 1.5%, in vivo short term RMSCV%= 2.0 and 3.6, and mid term RMSCV%= 1.8 and 4.2. The Mean parameter had a better reproducibility but Standard Deviation had a better discriminant power (cf table).

After multivariate analysis with adjustment for age and total hip BMD, for "Standard Deviation" parameter the difference remained statistically significant between Control group versus HF and VF groups (p<5.10⁻³, and p=4.10⁻² respectively).

No significant correlation between these two Laws' masks parameters and BMD measured at different sites was obtained. The data suggest that this analysis can be useful for assessing fracture risk independently from BMD. Thus, Laws' masks may constitute one of the best methods for bone texture analysis.

Mask E5E5 Controls	Parameter "Mean" 0.693 ± 0.102	Parameter "Standard Deviation" 0.112 ± 0.016
HF	0.629 ± 0.115 (p=0.003)	0.095 ± 0.017 (p<10 ⁻³)
VF	0.669 ± 0.122 NS	0.105 ± 0.017 (p=0.02)
WF	0.702 ± 0.097 NS	0.113 ± 0.017 NS

Iliac Cortical Bone Structure in Osteoporotic Women. S. Bare¹*, K. McCon²*, R. Recker¹, D. B. Kimmel². ¹Osteoporosis Research Center, Creighton University, Omaha, NE, USA, ²Molecular Endo and Bone Biology, Merck Research Laboratories, West Point, PA, USA.

Evaluation of small features in cortical bone of living humans is limited by the available biopsy sites. An intact transiliac biopsy specimen (TIBx) has two cortices around a trabecular area. Our purpose is to use TIBxs to study cortical thickness (Ct.Th), cortical porosity (Ct.Po), and pore diameter (Po.D) of osteoporotic women.

TIBxs (7.5mm diameter) were obtained via a lateral approach from 42 untreated post-menopausal osteoporotic women (T-score<-1.8; age 69±6yrs, range 60-85yrs). 6µm sections from plastic-embedded TIBxs were stained with toluidine blue.

For each cortex, the endocortical surface (ES) was the boundary between trabecular and cortical bone. The distance from the ES to the periosteal surface (PS) was measured (6-7 sites) to find Ct.Th. Total cortical area (Ct.Ar) and pore area (Po.Ar) were measured. Pores were non-marrow containing voids in bone tissue between the ES and PS, with area >500µm². Ct.Po was Po.Ar/Ct.Ar. Po.D was calculated from Po.Ar and pore number.

32 TIBxs had two cortices. Cortices of each TIBx were grouped as "thick" or "thin." Thickness of the single cortex from the other ten was equal to the thick cortex from the 32; the ten were deemed "thick." Differences between the two cortices for Ct.Po and Po.D were tested (Mann-Whitney U). Pearson's correlation coefficient (r) was calculated among age, Ct.Po, Ct.Th, and Po.D.

Summary: The thick cortex is more porous with pores of larger diameter than the thin cortex (P<0.0001). More porous cortices have larger pores, rather than greater pore number. Cortices exhibit age-related thinning.

Conclusion: The interrelationships of cortical porosity with age and cortical thickness revealed in untreated post-menopausal osteoporotic women suggest that cortical porosity in the ilium, and perhaps at all anatomic sites, is a complex issue. Thick cortices are more porous than thin cortices, regardless of age. Techniques with resolution of 85-100µm may miss 30-50% of cortical pores. Approximately 70 additional TIBxs are under analysis.

A Newly Developed Quantitative Ultrasound Scanner for the Proximal Femur: First Data of Hip Fracture Discrimination. R. Barkmann¹, S. Dencks¹*, P. Laugier²*, F. Padilla²*, C. Glüer¹. ¹Medizinische Physik, Diagnostische Radiologie, UKSH, Kiel, Germany, ²Laboratoire d'Imagerie Paramétrique, Université Paris, Paris, France.

Calcaneal Quantitative Ultrasound (QUS) has similar power as DXA for the prediction of osteoporotic fracture risk. However, femur DXA shows best performance in the prediction of hip fractures. We developed a QUS scanner for the proximal femur (femur ultrasound scanner, "FEMUS") and present first results of the power of this new method to discriminate between women with and without hip fractures.

Patients who had visited the traumatology for surgery after osteoporotic hip fracture within the last half year were asked to participate in the study. Controls without hip fractures were recruited from the OPUS study. The study was approved by the local ethical committee and informed consent was given. Fracture patients were older (78 ± 6 vs. 72 ± 10 years) and had lower weight (62 ± 7 vs. 68 ± 17 kg), however, differences were not significant. Height did not differ between groups (1.60 ± 0.05 m). All participants were measured using DXA and the FEMUS. QUS signal transmission through the center of the greater trochanter was evaluated and QUS variables SOS and BUA were calculated. SOS was adjusted for variations in hip width using transit times of signals reflected from both anterior and posterior surfaces of the hip. Correlations of QUS variables with trochanteric and total hip BMD were calculated. The ability of discriminating between women with recently fractured hips and controls without fractures was calculated for QUS and DXA using logistic regression analysis and expressed as standardized odd's ratios, per one SD decrease of population variance, adjusted for age (confidence intervals in brackets).

Both SOS and BUA correlated significantly with trochanteric BMD (SOS: R²=0.66, p<0.0001, BUA: R²=0.54, p<0.001) and total BMD (SOS: R²=0.59, p<0.0001, BUA: R²=0.36, p<0.01). Odd's ratios were 3.9 (2.0 - 7.6) for trochanteric BMD, 7.8 (2.9 - 20.7) for total BMD, 8.7 (3.3 - 22.8) for SOS and 2.2 (1.3 - 3.7) for BUA. Weight and height did not contribute significantly to any of these associations.

First measurements on patients using our new FEMUS device demonstrated similar power of QUS and BMD in the discrimination between women with and without fractures. Total hip BMD and SOS showed best performance. Femoral QUS might become an additional tool for osteoporosis assessment.

Associations Between Bone Mineral Density and Speed of Sound: Canadian Multicentre Osteoporosis Study. K. S. Davison¹, J. D. Adachi², D. A. Hanley³, J. P. Brown¹, W. P. Olszynski⁴, ¹U. of Laval, Quebec, PQ, Canada, ²McMaster U., Hamilton, ON, Canada, ³U. of Calgary, Calgary, AB, Canada, ⁴Saskatoon Osteo. Centre, Saskatoon, SK, Canada.

The objective of this investigation was to compare bone mineral density (BMD) attained from dual-energy x-ray absorptiometry (DXA) with speed of sound (SOS) data attained from a Sunlight Omnisense quantitative ultrasound (QUS) in a large sample of randomly-selected community-based individuals from the Canadian Multicentre Osteoporosis Study (CaMOS). In year 5 of CaMOS 4124 men and women were assessed by both DXA and QUS in one of six centres from CaMOS equipped with both instruments. BMD (g/cm²) was assessed at the lumbar spine (L1-4; LS), femoral neck (FN), total hip (TH), Ward's triangle (WT) and the greater trochanter (GT) by DXA. The DXAs were cross-calibrated among centres using a common phantom and a calibrated BMD was used for all analyses. SOS (m/s) was assessed at the distal radius (DR), tibia (TIB) and phalanx (PX) sites by Sunlight Omnisense QUS. Pearson product-moment correlations were performed between measures of BMD and SOS for men and women separately. Alpha was set at $p < 0.05$ for all analyses. In this subset of CaMOS data there were 2948 women and 1176 men included with a mean (SD) age of 66.5 (11.49) and 63.7 (13.04) years, respectively, and a range of 30-96 years of age. For the women, DR SOS was significantly ($p < 0.0001$) positively correlated with LS ($r = 0.24$), FN ($r = 0.29$), TH ($r = 0.28$), WT ($r = 0.36$), and GT ($r = 0.24$) BMD. TIB SOS was significantly ($p < 0.0001$) positively correlated with LS ($r = 0.21$), FN ($r = 0.20$), TH ($r = 0.20$), WT ($r = 0.25$), and GT ($r = 0.19$) BMD, and PX SOS was significantly ($p < 0.0001$) positively correlated with LS ($r = 0.24$), FN ($r = 0.29$), TH ($r = 0.27$), WT ($r = 0.31$), and GT ($r = 0.21$). For the men, DR SOS was significantly ($p < 0.05$) positively correlated with FN ($r = 0.08$), TH ($r = 0.07$), WT ($r = 0.14$), and GT ($r = 0.07$), but not LS ($r = 0.05$) BMD. TIB SOS was significantly ($p < 0.05$) positively correlated with BMD only at the LS ($r = 0.07$), FN ($r = 0.04$), TH ($r = 0.03$), WT ($r = 0.05$), and GT ($r = 0.03$). PX SOS was only significantly ($p < 0.05$) positively correlated with BMD at the FN ($r = 0.07$), TH ($r = 0.06$), and WT ($r = 0.09$); LS (0.003) and GT (0.02). Despite the differences in significance between the men and women for a number of comparisons, the greatest r^2 attained indicates that there is at best 13% of the variance shared between the measures; most associations were far weaker. While the power of this sample allowed for statistically significant results to be found between the methods it can be safely assumed that they are measuring different attributes of bone which may have important implications for fracture prediction that need to be further assessed with prospective trials, particularly with QUS.

Disclosures: K.S. Davison, None.

T299

Ultrasound and Dual-energy X-ray Absorptiometry Comparisons at the Distal Radius. S. Grzybowski¹, K. S. Davison², D. Hein¹, W. P. Olszynski¹. ¹Saskatoon Osteo. Centre, Saskatoon, SK, Canada, ²U. of Laval, Quebec, PQ, Canada.

The primary objective of this study was to determine how the speed of sound (SOS) at the distal radius using the Sunlight Omnisense Quantitative Ultrasound (QUS) correlates to the bone mineral density (BMD) of the distal radius using dual-energy x-ray absorptiometry (DXA). Sixty women were enrolled into the study in three different stratum levels with twenty participants in each strata: ages 20-40, 41-60 and 61-80 years. DXA BMD (g/cm²) measurements were performed at the ultra-distal (UD), mid-shaft (MID), one-third (OT) radius using the Hologic Delphi W. A composite total radius (TOT) BMD was also calculated for the three regions. QUS (m/s) measurements of the distal radius were performed using the Sunlight Omnisense. Measurements were performed on the left radius, however, if a patient had a previous fracture of the left radius, then the measurements were performed on the right. T-scores and z-scores were provided from both machines using manufacturer-specific databases. Pearson product-moment correlations were performed between DXA BMD and QUS SOS measures. Alpha was set at $p < 0.05$. The mean (SD) age of the women was 50.4 (17.2) years. Mean BMDs were 0.394 (0.08), 0.564 (0.08), 0.658 (0.11) and 0.543 (0.08) g/cm² at the UD, MID, OT and TOT sites, respectively. The mean SOS was 4113.2 (148.2) m/s. The mean t- and z-scores ranged from -0.38 to -0.57 and 0.22 to 0.62 for the DXA assessed-sites and -0.55 and 0.41 for QUS-assessed radius, respectively. SOS was significantly ($p < 0.01$) correlated with BMD measures from all four sites: UD $r = 0.40$, MID $r = 0.63$, OT $r = 0.62$, TOT $r = 0.63$. The correlations between SOS and BMD T-scores were also all significant ($p < 0.001$): UD $r = 0.53$, MID $r = 0.68$, OT $r = 0.73$ and TOT $r = 0.68$. Similar, yet weaker, correlations were seen with z-scores. These results suggest that at the distal radius 16-40% of the variance in SOS and BMD is shared. While this is a significant relationship the inverse needs to be also stressed in that 60-82% of the variance is not shared between these measures indicating that the majority of bone characteristics each machine is measuring are unique to one another.

Bone Health of Vegans. H. J. Hinkley*, I. P. Drysdale. British College of Osteopathic Medicine, London, United Kingdom.

Public health strategies aimed at preventing osteoporosis through modifiable factors such as diet are currently under review. Vegans usually have a substantially lower calcium intake due to their lack of consumption of dairy products, unless they consume calcium-rich plant foods, which may result in lower bone mineral density and greater risk of osteoporosis. However, optimal acid/base balance may be a beneficial consequence of the

absence of dietary meat and fish protein due to the reduction in acid load, which results in decreased mobilization of bone mineral, which lowers excretion of calcium in the urine and preserves the integrity of bone despite lower calcium intakes. Therefore, it is unclear as to whether or not the bone health of vegans is better or worse than that of comparable omnivores. A pilot study recruited age-matched females (20 to 44 years) to assess calcaneal Broadband Ultrasound Attenuation (BUA; McCue CubaClinical), a measure of bone mineral density and structure of cancellous bone, in 60 vegans of mean body mass index (BMI) 23.1 (sd 5.9) kg/m² and compared this group with 110 female omnivores of mean BMI 22.0 (sd 2.7) kg/m². The hypothesis tested was that the vegan diet was not detrimental to bone health as assessed by calcaneal BUA. Data were analysed using t-test and multiple regression analysis. Despite the slightly lower mean BUA of the vegans, no significant difference was observed in BUA between vegans (78.3 (sd 16.5) db/MHz) and omnivores (82.2 (sd 16.8) db/MHz). However, these preliminary findings were potentially confounded by large inter-individual variability in both BUA and weight, found previously to influence BUA, and weight was also observed to be slightly higher (non-significant) in the vegans (vegans, 63.0 (sd 15.8) kg; omnivores, 60.1 (sd 8.1) kg). Therefore, BUA was adjusted for weight. However, no significant difference was observed between the groups. The mutually exclusive variables of vegan and non-vegan were entered stepwise with weight, height and age into a multiple regression model. The vegan category was found to be an independent significant predictor of BUA along with weight, but not height or age. In conclusion, the hypothesis that the vegan diet does not adversely affect bone health is supported in part, although slightly confounded, by the results of this cross-sectional study, possibly due to the large extent of biological variability (BUA measurement variability, in house CV 2.3%). This indicates that further work would be of value to establish potential longitudinal effects of the vegan diet and any mechanisms involved in maintaining a healthy balance in bone metabolism. On the basis of this pilot study, a larger study is currently being undertaken in which a number of indices of bone mineral density are assessed along with other measures of health in general.

A New Through-Transmission Approach for Ultrasonic Assessment of the Radius. J. J. Kaufman¹, G. Luo², R. S. Siffert². ¹CyberLogic, Inc., New York, NY, USA, ²Orthopedics, The Mount Sinai School of Medicine, New York, NY, USA.

The overall objective of this study was to develop a new ultrasonic system for estimating bone mineral density (BMD) at the forearm. Estimation of BMD is an important component in diagnosis and managing osteoporosis. The use of BMD is based on the well-established thesis that bone strength is strongly related to the amount of bone material present and that a stronger bone in a given individual is associated generally with a lower fracture risk. Radiological densitometry (e.g., DXA), which measures the BMD at a given site is currently the accepted indicator of fracture risk. Because of its expense, inconvenience, and associated x-ray exposure, ultrasound has been proposed as an alternative to DXA.

This study used both empirical ultrasound measurements and data generated in computer simulations. In vitro measurements were conducted on a set of 6 plastic rods, 7 plastic tubes, and 20 human radii. A 3.5 MHz source and receiver in a through-transmission configuration were used within a water tank, between which the plastic or bone samples were placed. The received waveform was stored for subsequent processing. A set of ultrasound simulations of analogous models was also carried out using a commercial software package (Wave2000 Pro, CyberLogic, Inc., NY).

The ultrasound data obtained from both the bench-top experiments and the computer simulations were processed to obtain an ultrasound parameter known as net time delay (NTD), associated with each sample. Results obtained show extremely close correspondence between the simulated and empirical results, validating the use of the software for further development. Moreover, the results obtained show correlations of NTD with overall rod, wall, or cortical thicknesses, respectively, of 0.99, 0.99, and 0.97. The figure below displays the results for ten of the radial bone specimens.

In conclusion, this study suggests that ultrasonic transmission measurements at the forearm may be a useful, simple, and radiation-free alternative to DXA for assessing bone mass and fracture risk.

T302

Calcaneal Broadband Ultrasound Attenuation and Risk Factors for Osteoporotic Fractures in Postmenopausal South Asian and Caucasian Women. S. R. Mitra¹, P. Foster^{*1}, P. Judd^{*2}, B. Ellahi^{*3}, I. Bhojani^{*4}, J. F. McCann^{*5}, N. Lowe^{*1}. ¹Biological Sciences, University of Central Lancashire, Preston, United Kingdom, ²Lancashire School of Health and Postgraduate Medicine, University of Central Lancashire, Preston, United Kingdom, ³Biological Sciences, University of Chester, Chester, United Kingdom, ⁴Bangor Street Health Centre, Blackburn, Blackburn, United Kingdom, ⁵Medical Rehabilitation Centre, Royal Preston Hospital, Preston, United Kingdom.

Managing postmenopausal osteoporosis involves measuring bone mineral status and assessing clinical risk factors for osteoporotic fractures. Early onset of menopause, personal history of fracture after 50 and sedentary lifestyle are among the key risk factors. The purpose of this study was to investigate risk factors for osteoporotic fractures in postmenopausal South Asian compared to Caucasian women living in Blackburn, U.K.; using calcaneal broadband ultrasound attenuation (BUA) measurements and known or suspected risk factors.

BUA of the calcaneus was determined by contact ultrasound sonometry (McCue CUBA Clinical Ultrasonometer) in 76 South Asian women and 47 Caucasian women. Relevant life-style factors, including physical activity level were assessed in all the participants using an interviewer administered structured questionnaire.

The mean age of the South Asian and Caucasian participants was (mean±SEM) 55.9 y (±0.50) and 59.9 y (±0.53) respectively, with a BMI of 31.1 kg/m² (±0.63) for South Asians, significantly higher than the Caucasians at 28.0 kg/m² (±0.78) (p=0.002). The mean age of menopause was not significantly different in the two groups, 48.0y (±0.61) and 48.6y (±0.86), (p=0.55) respectively.

There was no significant difference in BUA measurements between the South Asian and Caucasian women (68.5 dB/MHz (±1.8) and 66.8 dB/MHz (±2.0) respectively). We classified 38.3% of Caucasians and 31.6% of the South Asians as 'at risk' for the development of osteoporosis (BUA T score ≤ -1.7) and 29.8% Caucasians and 26.3% South Asians as osteoporotic (BUA T score ≤ -2). A significant difference was observed in 'personal history of fracture above the age of 50', 12.8% of the Caucasians with this risk factor as compared to 2.6% of South Asians (p=0.05). There was significant positive correlation between current body weight and BUA in both groups, r=0.44, p=0.002 (Caucasian); r=0.31, p=0.006 (South Asian).

Analysis of our study data reveals that, South Asian and Caucasian women in this population have comparable calcaneal BUA scores. High BMI may have contributed to the maintenance of a healthy bone mass in both groups of women. We are currently investigating the role of vitamin D status and secondary hyperparathyroidism in the skeletal status of this population.

Canadian Normative Data for Sunlight Omnisense Quantitative Ultrasound: Canadian Multicentre Osteoporosis Study. W. P. Olszynski¹, J. P. Brown², J. D. Adachi³, D. A. Hanley⁴, K. S. Davison². ¹Saskatoon Osteo. Centre, Saskatoon, SK, Canada, ²U. of Laval, Quebec, PQ, Canada, ³McMaster U., Hamilton, ON, Canada, ⁴U. of Calgary, Calgary, AB, Canada.

The objective of this investigation was to generate a normative database of speed of sound (SOS) measures for Canadians as provided from Sunlight Omnisense quantitative ultrasound (QUS) in a large sample of randomly-selected community-based individuals from the Canadian Multicentre Osteoporosis Study (CaMOS). In year 5 of CaMOS 4124 men and women were assessed by QUS in one of six centres from CaMOS equipped with a Sunlight Omnisense QUS (Calgary, Halifax, Hamilton, Saskatoon, Ste-Foy, St. John's). SOS (m/s) was assessed at the distal radius (DR), tibia (TIB) and phalanx (PX) sites by Sunlight Omnisense QUS. For the normative data creation, data was separated for men and women and into age groups from 30-39y, 40-49y, 50-59y, 60-69y, 70-79y and 80+y and reported for each of the three sites investigated. The mean and standard deviation (SD) from both the men's and women's 30-39y group was used as the reference point and assigned a t-score of 0. The means of all other groups were then reported as a t-score based on these sex-specific reference values ((sex-specific 30-39y mean - mean for age group)/SD for 30-39y group)). In this subset of CaMOS data there were 2948 women and 1176 men included with a mean (SD) age of 66.5 (11.49) and 63.7 (13.04) years, respectively, and a range of 30-96 years of age. The mean (SD) SOS for the women at 30-39y of age was 4192 (111), 3877 (163), and 4005 (200) m/s at the DR, TIB and PX, respectively (n=87). The mean (SD) SOS for the men at 30-39y of age was 4137 (113), 3949 (135), and 3949 (181) m/s at the DR, TIB and PX, respectively (n=70).

T-scores for mean SOS of each age group (women:men)

Age Group (n)	DR t-score	TIB t-score	PX t-score
40-49 y (119:94)	-0.28:-0.47	0.29:0.01	-0.07:-0.12
50-59y (611:277)	-0.80:-0.36	-0.01:-0.10	-0.48:0.00
60-69 y (853:303)	-1.35:-0.54	-0.21:0.00	-0.98:-0.30
70-79y (981:334)	-1.98:-0.81	-0.43:-0.21	-1.54:-0.64
80+y (297:98)	-2.52:-0.98	-0.66:-0.43	-1.90:-1.03

The t-scores showed that there was a steady decline in SOS m/s for women with age at the DR and PX, with a slower decline at the TIB. A similar, yet smaller magnitude, trend was observed in the men. This relative preservation in TIB may be a consequence of greater

maintenance of load bearing on the legs as compared to the arms with aging. While there was a large overall pool of data to study the change of SOS in three sites over time, the sample size for the reference group needs to be larger to allow for a greater determination of the mean and particularly the SD, which has a large impact on t-scores.

Improved Standardization of Calcaneal Speed-of-Sound Measurements: Results in 73 Women. K. A. Wear^{*}. Center for Devices and Radiological Health, US Food and Drug Administration, Silver Spring, MD, USA.

Although calcaneal speed of sound (SOS) is an effective predictor of osteoporotic fracture risk, the SOS measurement exhibits substantial dependence on measurement system hardware and analysis algorithm software. Accordingly, improvement in standardization methods will be required before quantitative ultrasound can play a major role in clinical practice (C. C. Gluer, "Quantitative ultrasound: It is time to focus research efforts," Bone, 40, 9-13, 2006).

The purpose of this study was to develop and validate a method for reducing variability in calcaneal SOS measurements.

A compensation formula that corrects for the dependence of SOS measurements on center frequency, bandwidth, broadband ultrasound attenuation (BUA), and transit-time marker (e.g. zero-crossing) was derived. The formula predicts that variations in SOS measurements (i.e. deviations from group velocity) are approximately proportional to 1) BUA, and 2) the square of the fractional bandwidth of the ultrasound data acquisition system. To test the formula, SOS data from 73 women and from a bone-mimicking phantom were acquired using a GE Lunar Achilles Insight bone sonometer.

Compensation of SOS measurements using the formula reduced 1) average transit-time-marker-related SOS variability by 75% in 73 women and 2) bandwidth-related SOS variability by 80% in the bone-mimicking phantom. Transit-time-marker-related variations in SOS were found to decrease as the transit-time marker was moved toward the pulse center. Therefore, compared with other time-domain measures of SOS, group velocity (which is measured using the pulse center as a transit-time marker) exhibited the minimum system dependence.

This new method of compensating SOS measurements will enable a substantial improvement in consistency in bone sonometry.

Improved Accuracy of Broadband Ultrasound Attenuation Measurement Using Phase Insensitive Detection: Results in 73 Women. K. A. Wear^{*}. Center for Devices and Radiological Health, US Food and Drug Administration, Silver Spring, MD, USA.

Although calcaneal broadband ultrasound attenuation (BUA) is an effective predictor of osteoporotic fracture risk, the BUA measurement exhibits substantial inter-system variability. As Gluer recently emphasized, improvement in standardization methods will be required before quantitative ultrasound can play a major role in clinical practice (C. C. Gluer, "Quantitative ultrasound: It is time to focus research efforts," Bone, 40, 9-13, 2006). Typical clinical BUA measurements are performed with phase sensitive (PS) receivers and therefore can be corrupted by phase cancellation artifacts. In bone sonometry, phase cancellation results from the ultrasound beam propagating through cortical plates. Cortical plates have a relatively high speed of sound and uneven thickness. Therefore, the lateral phase profile of the ultrasound beam becomes distorted as it propagates through cortical plates. This produces phase cancellation artifact when the beam is converted to an electrical signal by the piezoelectric receiver.

The purpose of this study was to investigate phase insensitive (PI) detection, which suppresses phase cancellation artifacts, as an alternative to conventional PS detection for the measurement of BUA.

Through-transmission data from 73 women and from phantoms with acrylic wedge phase aberrators were acquired using a GE Lunar Achilles Insight bone sonometer with a two-dimensional receiver array. Radio frequency data from 52 central elements of the receiver array were digitized and stored individually. Radio frequency data were processed off-line using both PI and PS algorithms. Calcaneal bone mineral density (BMD) was measured on all 73 women using a GE PIXI dual-energy x-ray absorptiometer. Their x-ray T-scores ranged from -3.2 to 2.5 (mean: -0.4, standard deviation: 1.1).

PI BUA measurements on phantoms with acrylic wedge phase aberrators were found to be far more resistant to phase cancellation artifact than PS BUA measurements. In data from 73 women, the means (standard deviations) for BUA measurements were 81.4 (21.4) dB/MHz (PS) and 67.2 (9.7) dB/MHz (PI).

This study is the first investigation of PI BUA on a clinically-relevant population with a commercial bone sonometer. On the average, phase cancellation artifacts accounted for at least 17% of clinical PS BUA values. Because of superior accuracy and lower coefficient of variation, PI BUA is a promising alternative to PS BUA for diagnosis of osteoporosis. The mention of commercial products, their sources, or their use in connection with material reported herein is not to be construed as either an actual or implied endorsement of such products by the Department of Health and Human Services.

Precision Study of Quantitative Ultrasound(QUS) and DXA in Korean Female. S. Yang¹, D. Kim², Y. Chung³, Y. Lee⁴. ¹Radiology, Eulji University Hospital, Daejeon, Republic of Korea, ²Nuclear Medicine, Kyunghee University Hospital, Seoul, Republic of Korea, ³Internal Medicine, Ajou University Hospital, Suwon, Republic of Korea, ⁴Internal Medicine, Yonsei University Hospital, Seoul, Republic of Korea.

Quantitative ultrasound(QUS) is one of the major tools for evaluating osteoporosis. The appropriate role of QUS in osteoporosis is not clear and diagnostic cut-off value for the specific QUS devices are not determined, so confusion is existing to diagnose using QUS compared with DXA(dual energy x-ray absorptiometry) results. Purpose of this study is to establish the precision data among five different QUS devices and DXA, and correlation coefficients between QUS parameters and DXA results of the L-spine.

Precision of QUS devices was taken by duplication of the test in 30 examinees or triplication of the test in 15 examinees according to the hospital. All the precision for DXA was made using European Spine Phantom(ESP) which is made up of water equivalent plastics and epoxy resins and bone-equivalent tissues are simulated by adding calcium hydroxyapatite to the water-equivalent materials. It is composed of three vertebrae which vary in mineral density and cortical thickness.

Results are as follows:

1. Precisions of DXA using ESP among the four University Hospitals varied from 0.44 to 1.10%.
2. Precisions of speed of sound(SOS) in five QUS devices in-vivo varied 0.20 to 2.76%.
3. Precisions of broadband ultrasound attenuation(BUA) in three QUS devices in-vivo varied 1.71 to 3.51%.
4. Correlation coefficients between L-spine BMD and SOS varied 0.194 to 0.526.
5. Correlation coefficients between L-spine BMD and BUA varied 0.242 to 0.516.

Certain QUS device showed very low correlation and poor precision, so accurate assessment of the device quality is mandatory to enhance the accuracy of osteoporosis diagnosis. Clinical role of QUS and diagnostic criteria should be determined after including more normal volunteers and patients with osteoporosis by nationwide prospective study.

Disclosures: S. Yang, None.

Intake of Calcium and Other Minerals Through Water: Health Implications. À. Martínez-Ferrer*, P. Peris, R. Reyes*, N. Guàrdia. Rheumatology, Hospital Clínic de Barcelona, Barcelona, Spain.

Calcium (Ca) intake through diet is mainly obtained from dairy products. However, there are other sources of Ca, like water, which can significantly contribute to this intake. Moreover, water also contains other minerals, such as magnesium (Mg) and sodium (Na), with potential implications for health. Thus, Mg has been associated with a reduction of sudden death, whereas Na contributes to the occurrence of hypertension. The rise in the consumption of bottled water in the general population clearly indicates the necessity of knowing the possible effects on health. Indeed, there is a great variation in the content of these minerals depending on the type of water.

Methods: We obtained the mineral content of Ca, Mg y Na from tap water of 475 Spanish towns and cities (through data given by autonomous communities, city/town halls or municipal water companies) and from 128 commercially available bottled waters (108 available in Spain, 20 available in Europe). The results were compared with the recommended dietary allowances of these minerals (minimum daily required intake for Ca of 800 mg, and for Mg of 350 mg; and maximum intake of 2400 mg for Na).

Results: There is a great variation in the mineral content among the different bottled water and also among tap waters. Thus, among bottled waters in our country the Ca concentration ranges between 0.5-367 mg/l; 16% of these waters had a concentration > 100 mg/l and only one > 300 mg/l; some European waters showed high concentrations of Ca (459-546 mg/l); Na concentrations ranged between 0.1-1138 mg/l, and Mg between 0.1-70.5mg/l. In tap water Ca concentrations ranged between 0-440 mg/l, Na between 1.0-240mg/L, and Mg between 0.3-200mg/L. 34% of the analysed tap water the Ca concentration was > 100 mg/l, in 3 of them it was > 200 mg/l. One village (Albox [Almería]) showed a marked increase of Ca and Mg concentrations, 440 mg/l and 200 mg/l, respectively.

Conclusion: Water, even bottled water or tap water, has a great variability in the concentrations of Ca, Mg and Na. In some occasions, water may even supply the minimum recommended allowances of Ca and Mg and can exceed the Na content. These data should be considered when selecting one for consumption.

Bone Mineral Density in Japanese Adolescent Girls with Anorexia Nervosa. K. Matsuzaki¹, T. Hasegawa², H. Takaishi³, Y. Toyama³. ¹Dept. of Orthopedic Surgery, National Hospital Organization Tokyo Medical Center, Tokyo, Japan, ²Dept. of Pediatrics, Keio University, Tokyo, Japan, ³Dept. of Orthopedic Surgery, Keio University, Tokyo, Japan.

Anorexia nervosa (AN) present with severe body weight loss and amenorrhea caused by decrease in food intake with psychological problem. Malnutrition, low body weight, decrease in gonadal steroid followed by insufficiency of ovary and high cortisolemia are considered to be the cause of low BMD. Osteoporosis or osteomalacia in young onset cases have been increasing and getting big issue because they should attain peak bone mass in their adolescent. However, data about BMD in young onset AN in Japan is insufficient, although there are a few report about BMD in adult onset AN. We report here the effect of nutritional status and gonadal steroid on BMD in young onset AN in Japan.

We studied 22 Japanese girls (12-17 years old) who admitted to Keio Univ. Hospital for the treatment of incipient AN prospectively. Dual energy x-ray absorptiometry (DEXA) was performed to determine lumbar spine (L2-4) BMD. The effects of nutritional status and gonadal steroid on BMD were evaluated. We used obesity index, BMI and serum IGF-1 level for the index of nutritional status and the duration of amenorrhea for the index of gonadal steroid effect.

12 cases (55 %) showed BMD lower than -1SD and 10 cases (45 %) showed BMD lower than -2SD. Their obesity index were -51.3~ -21.6% (median: -34.4). Their BMIs were 9.7~ 15.9kg/m² (median: 12.9). Serum IGF-1 level were -5.17~ 0.986 SD (median: -2.694). 9 girls had not started their menstrual periods. In 11 girls with their menstrual periods, age at menarche were 10~ 13 (median: 11) and duration of amenorrhea were 1~ 15 months (median: 5). A significant correlation was found between obesity index and BMD. A significant correlation was also found between BMI and BMD. On the other hand, the correlation between serum IGF-1 and BMD approached, but did not reach, significance. There was not a correlation between duration of amenorrhea and BMD.

These results suggest that nutrition status may have stronger contribution on BMD than the effects of gonadal steroid. Therefore increasing body weight may be the most effective way of prevention and treatment for AN in Japanese adolescent girl.

Disclosures: K. Matsuzaki, None.

Net Endogenous Acid Production (NEAP) and Bone Mineral Density in Men and Women: The Framingham Offspring Study. R. R. McLean¹, C. E. McLennan², N. Qiao³, K. E. Broe², K. L. Tucker³, L. A. Cupples⁴, M. T. Hannan¹. ¹Hebrew SeniorLife & Harv Med Sch, Boston, MA, USA, ²Hebrew SeniorLife, Boston, MA, USA, ³USDA HNRC, Tufts Univ, Boston, MA, USA, ⁴BU Sch of Public Health, Boston, MA, USA.

In the short term, bone may buffer excess acid by releasing calcium. It has been proposed that diets high in protein, which have high potential renal acid load, may contribute to low BMD. In contrast, some evidence indicates higher protein intake may be beneficial for bone health, possibly by enhancing calcium absorption. NEAP is the daily amount of net acid produced by the metabolic system and can be estimated using the ratio of average dietary intakes of protein to potassium. We hypothesized that NEAP is directly associated with BMD, but only among individuals with dietary calcium intakes <800 mg/day. We examined the cross-sectional relation between NEAP and BMD among 1287 men and 1581 women (mean age 61 yrs, range 29-86) of the Framingham Offspring Study who completed the Willett food frequency questionnaire between 1996-2001. We also determined whether the association between NEAP and BMD differed by dietary calcium intake. Estimated NEAP (mEq/day) was calculated as [62.1 x protein / potassium(mEq)] - 17.9, standardized to 10.46 MJ and adjusted for energy using the residual method. BMDs (g/cm²) of the proximal femur (neck, trochanter) and lumbar spine (L2-L4) were measured using a Lunar DPX-L. Multivariable linear regression was used to calculate the association between NEAP and BMD for men and women separately and within dietary calcium intake groups (<800 mg/day: y/n). Analyses were adjusted for age (yrs), height (in), weight (lbs), smoking (c/t/n), physical activity, daily intakes of alcohol (g), caffeine (mg), dietary vitamin D (IU), dietary calcium (<800 mg: y/n) and total calories (MJ), vitamin D supplement use (y/n), calcium supplement use (y/n), and in women, estrogen use (c/t/n) and menopause status (y/n). Mean NEAP (±SD) was 47.4 (14.9) for men and 45.2 (14.5) for women. For both men and women, NEAP was not associated with BMD at the femoral neck (p≥0.7), trochanter (p≥0.4) or lumbar spine (p≥0.1). 65% of men and 61% of women had dietary calcium intake <800 mg/day. NEAP was not associated with BMD at any site among men with calcium intake ≥800 mg/day (p≥0.5). Among men with calcium intake <800 mg/day, higher NEAP tended to be associated with increased lumbar spine BMD (p=0.06), but not with femoral neck or trochanter BMD (p≥0.3). NEAP was not associated with BMD among women regardless of dietary calcium intake. Although these cross-sectional results suggest diets with high potential acid load, such as those high in protein, may not contribute to low BMD in community-dwelling men and women, further studies of longitudinal bone loss are needed.

Disclosures: R.R. McLean, None.

Physical Activity in Young Adulthood Is an Independent Predictor of Bone Mineral Density in Elderly Swedish Men. M. Nilsson^{*1}, C. Ohlsson¹, M. Karlsson^{*2}, Ö. Ljunggren^{*3}, D. Mellström¹, M. Lorentzon¹. ¹Center for Bone Research at the Sahlgrenska Academy, Dept. of Internal Medicine, Gothenburg University, Sweden, Gothenburg, Sweden, ²Clinical and Molecular Osteoporosis Research Unit, Dept. of Clinical Sciences, Lund University, Dept. of Orthopaedics, Malmö University Hospital, Sweden, Malmö, Sweden, ³Dept. of Medical Sciences, University of Uppsala, Sweden, Uppsala, Sweden.

Physical activity (PA) is believed to have a positive influence on bone mineral density (BMD) accrual, especially during the attainment of peak bone mass. However, whether or not the positive effects of PA on BMD during young adulthood remain at old age is still unclear. The purpose of this study was to investigate if previous PA was associated with present BMD in elderly Swedish men. The 498 subjects, with a mean age of 75.2 ± 3.3 (mean \pm SD), included in the present study were randomly selected from the population based Mr OS Göteborg study. BMD of the total body, femur trochanter, femoral neck, and lumbar spine (L1-L4) was assessed using Dual X-ray Absorptiometry (Hologic). Data concerning patterns of PA, including both competition (CS) and recreational sports (RS), and occupational physical load in a lifetime perspective (divided into years of age: 10-20, 21-35, 36-50, 51-65, and 66-) were collected at interview.

Subjects training with the highest intensity (n=81) of CS during ages 10-20, had 3.3% higher BMD of the total body (p=0.01) and 6.5% higher BMD of the trochanter (p<0.01) than subjects not participating in CS during this time period (n=319).

In order to determine the independent role of current and previous PA as well as of occupational physical load on present BMD, a stepwise linear regression analysis was used. In this regression model, present age, height, weight, calcium intake, smoking status (yes/no), present PA (daily walking distance), and CS and RS as well as occupational physical load for all the investigated time periods were included. Intensity of CS between ages 10-20 was an independent positive predictor of present BMD at the total body ($\beta=0.11$, p=0.01) and trochanter ($\beta=0.09$, p=0.03), while intensity of CS between ages 21-35 predicted present BMD at the femoral neck ($\beta=0.09$, p=0.03) and lumbar spine ($\beta=0.11$, p=0.01).

Neither current PA, intensity of CS in any of the later time periods (51-65 and 66-), nor intensity of RS, or occupational physical load for any time period investigated, independently predicted BMD at any bone site measured.

In conclusion, our results demonstrate that PA in CS during adolescence and in young adulthood is associated with areal bone mineral density in 75-year-old Swedish men, suggesting that high intensity PA early in life could aid in preventing osteoporosis in elderly men.

A Nutrition Survey about the Status of Fat-soluble Vitamins in Japanese Women. T. Okano¹, M. Kamano^{*1}, N. Tsugawa^{*1}, Y. Suhara^{*1}, K. Tanaka^{*2}, K. Uenishi³, H. Ishida⁴. ¹Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, ²Department of Nutrition, Kyoto Women's University, Kyoto, Japan, ³Laboratory of Administrative Dietetics, Kagawa Nutrition University, Tokyo, Japan, ⁴Laboratory of Physiological Nutrition, Kagawa Nutrition University, Tokyo, Japan.

Dietary habits are an important risk factor for lifestyle-related diseases. To carry out a nutrition survey of fat-soluble vitamins, we developed novel determination methods for fat-soluble vitamins using liquid chromatography-atmospheric pressure chemical ionization/tandem mass spectrometry or high-performance liquid chromatography with fluorescence detection. In these methods, stable isotope-labeled compounds or vitamin K analogues with a saturated side-chain were used as internal standards. These methods have high sensitivity and sufficient accuracy. We applied them in a nutrition survey about the status of fat-soluble vitamins in Japanese healthy women. Plasma concentrations of 25-hydroxyvitamin D₃ [25(OH)D₃] and 25-hydroxyvitamin D₂ [25(OH)D₂] in healthy postmenopausal women (n=98) were 20.5 ± 7.9 and 0.4 ± 1.4 ng/ml, respectively. A significant negative correlation in plasma levels between 25-hydroxyvitamin D [25(OH)D] and parathyroid hormone was observed. For vitamin K homologues, plasma levels of phyloquinone, menaquinone-4 and menaquinone-7 in Japanese women of various ages (n=1409) were 1.03 ± 0.90 ng/ml, 0.12 ± 0.28 ng/ml and 6.71 ± 13.6 ng/ml, respectively. The mean total vitamin K intake of Japanese young women was about 130 µg/day, and 94% of participants met the Adequate Intake of vitamin K for women aged 18-29 years in Japan, 60µg/day. Moreover, we determined fat-soluble vitamins in breast milk collected from Japanese lactating women and revealed that the contents of all-trans-retinol, vitamin D₃, 25(OH)D₃, α-tocopherol, phyloquinone and menaquinone-4 in breast milk were 0.39 ± 0.14 ng/ml, 0.10 ± 0.15 ng/ml, 0.08 ± 0.04 ng/ml, 3.96 ± 1.84 ng/ml, 3.56 ± 2.19 ng/ml and 1.77 ± 0.68 ng/ml, respectively. Those levels except for vitamin D₃ and 25(OH)D₃ were within reference values set for breast-fed infants in Japan. In contrast, Daily intake of vitamin D calculated from an infant's consumption of breast milk, 780 ml/day was 0.47 µg/day, which did not meet current Japanese Adequate Intake of 2.5 µg/day.

Nutrient Intakes Related to Bone Mineral Density in Brazilian Men and Women- The BRAZILIAN Osteoporosis Study (BRAZOS). M. M. Pinheiro¹, N. O. Jacques^{*2}, P. S. Genaro^{*2}, R. M. Ciconelli^{*3}, M. B. Ferraz^{*3}, L. A. Martini². ¹Reumatology, UNIFESP, Sao Paulo, Brazil, ²Nutrition, USP, Sao Paulo, Brazil, ³Paulista Center of Economy in Health, CPES, UNIFESP, Sao Paulo, Brazil.

Dietary calcium, vitamin D and K, phosphorus and magnesium are important determinants of bone mineral density. The purpose of the present study was to evaluate mean dietary intakes of Brazilian men and women older than 40 y. A total of 2392 subjects (1693 women) were enrolled in the nutritional evaluation at the BRAZILIAN Osteoporosis Study - BRAZOS, undertaken in 120 cities across 5 regions (North, Northeast, Central, Southeast and South) of the country, and included people from five categories of economical level (from A to E). The sampling was based in the census data from IBGE (Brazilian Institute of Statistics and Geographic) 2000 and PNAD (National Research of Home Sampling) 2003 and it was calculated accordingly with to the probabilistic and representative sample of Brazilian population. The coefficient of variation is 2.2% with 95% confidence interval. Dietary intakes were evaluated by a 24h Food Record. For the nutrient analysis the Nutrition Data System software (Minneapolis, MN 2005) was used. Statistical analysis was performed by SAS (SAS Institute Inc, Cary, NC, USA, v 8.02). Student T test was used for gender comparison and One way ANOVA for comparisons between regions and economical level. Three was ANCOVA was used for interactions between gender, economical level and regions. Significance was considered as p<0.05. The mean calcium intake in the entire population was 411 (249) mg/d, vitamin D 2.2 (1.9) µg/d, vitamin K 69 (117) µg/d, phosphorus 759 (397) mg/d and magnesium 197 (111) mg/d. A significant difference was observed between genders for calcium (F_{1,2333}=15.19, p<0.001), vitamin K (F_{1,2333}=18.65, p<0.001), phosphorus (F_{1,2333}=44.85, p<0.001) and magnesium (F_{1,2333}=67.44, p<0.001), being men higher than women. Mean vitamin D intake (F_{4,2333}=8.15, p<0.001) and phosphorus (F_{4,2333}=7.29, p<0.001) was significantly higher in the North region. Magnesium was similar in North and Central regions, instead higher than other ones (F_{3,2333}=7.77, p<0.001). Significant differences were observed between economical levels, being higher in people from level A, for all nutrients evaluated. Calcium, vitamin D, K and magnesium was under recommended levels for age in all regions and economical levels. The present data suggests that an improvement in nutrients related to bone mineral density should be recommended in Brazilian population.

The Association of Dietary Calcium, Bone Mineral Density and Biochemical Markers of Bone Turnover Among Rural Thai Women. C. Pongchaiyakul¹, V. Kosulwat^{*2}, N. Rojroonwasinkul^{*2}, S. Charoenkiatukul^{*2}, L. Chailurkit^{*3}, R. Rajatanavin^{*3}. ¹Division of Endocrinology and Metabolism, Department of Medicine, Faculty of Medicine, Khon Kaen University, Thailand, ²Institute of Nutrition, Salaya campus, Mahidol University, Bangkok, Thailand, ³Division of Endocrinology, Department of Medicine, Faculty of Medicine, Mahidol University, Bangkok, Thailand.

Objective: To investigate the relative contribution of dietary calcium intake on biochemical bone turnover markers and bone mineral density (BMD) in Thai women.

Materials and Methods: A cross-sectional investigation was designed in 255 rural Thai women. Usual dietary calcium intake was determined by quantitative food frequency questionnaire. BMD were measured by DXA. Three markers for bone turnover: type I collagen C-telopeptide, serum N-mid osteocalcin, serum total alkaline phosphatase including serum calcium were determined.

Results: An average daily calcium intake in this study was 265 mg/day. Of 233 (87%) women consumed dietary calcium less than half of the recommended value and only 3% of women (n = 7) had calcium intake >800 mg/day. After controlling for age and body mass index, women who consumed higher amount of dietary calcium had significantly higher BMD at all sites. Moreover, marked increasing of bone turnover markers was observed in those who were in lowest quartile of calcium intake. Women with osteopenia and osteoporosis were older, lighter weight, consumed less calcium and had significantly higher values of all biochemical markers for bone turnover than those who had normal BMD.

Conclusion: This study indicated that habitual diet of the northeastern population might not provide enough calcium needed for bone retention and for prevention of bone loss during the later years. Modification of eating pattern by promotion of increased consumption of locally available calcium rich food together with adopting other protective healthy lifestyle may be beneficial in prevention of osteoporosis among this population.

Gender Related Differences in Bone Mineral Quality. D. Porter^{*1}, M. Faugere^{*2}, D. Pienkowski³, H. H. Malluche^{*2}. ¹Biomedical Engineering, University of Kentucky, Lexington, KY, USA, ²Nephrolog, Bone and Mineral Metabolism, University of Kentucky, Lexington, KY, USA, ³Orthopaedic Surgery, University of Kentucky, Lexington, KY, USA.

Gender related differences in adult fracture risk are well known, but the etiology of this differential remains unclear. To identify the contributing variables, most studies have focused on extrinsic factors, e.g. fall risk, bone shape, etc. Except for bone mineral density, few studies have addressed the relationship between gender and the intrinsic material properties of bone. Therefore, this study sought to determine if gender is related to bone mineralization or bone mineral perfection.

Bone specimens were obtained in this IRB approved study from 23 males (56.7 ± 8.0 yrs) and 21 females (55.9 ± 7.7 yrs) that had iliac crest biopsies for workup of renal bone disease. Subjects treated with medications known to affect bone metabolism, or those with stable bone aluminum, diabetes, or a kidney transplant were excluded. Bone specimens were sectioned and analyzed by Fourier Transform Infrared Spectroscopy to quantify the mineral-to-matrix and carbonate-to-phosphate ratios. These measures of bone mineral quality were analyzed for gender differences.

The mean relative mineral content of bone (mineral/matrix ratio) was 7.5% greater (p<0.05) in males than in females. No difference was detected in the carbonate/phosphate ratio (a measure of the degree of mineral perfection), but the diminutive values of this parameter (>2 orders of magnitude less than the mineral/matrix ratio) may have obscured detection of true differences.

Given that a 6% increase in density can produce a 3-fold increase in fatigue life [2] and that fracture toughness peaks when the mineral/matrix ratio is within ± 1% of the peak value (i.e., 65%) [3], the observed 7.5% greater mineral/matrix ratio may be clinically significant. This finding extends our knowledge of gender related differences in bone and advances our understanding of bone mineral beyond that available from BMD. We conclude that gender has a role in determining the relative mineral content of bone; this in turn merits further study to determine its role in fracture risk.

Mineral Quality vs Gender			
	Male	Female	p - value
Mineral/matrix	3.88 ± 0.32	3.61 ± 0.39	< 0.05
Carbonate/phosphate	0.010 ± 0.001	0.010 ± 0.002	NS

Vitamin D Status in Postmenopausal Japanese-American Women Living in Hawaii: A Population-Based Study. P. Pramyothin^{*1}, S. Techarurongkul^{*1}, J. Lin^{*2}, H. Wang^{*2}, A. Shah^{*2}, P. D. Ross², R. Puapong^{*1}, R. D. Wasnich¹. ¹Hawaii Osteoporosis Center, Honolulu, HI, USA, ²Merck Research Laboratories, Rahway, NJ, USA.

Apart from its role in calcium metabolism, vitamin D has also been shown to have a beneficial role in neuromuscular function and fall prevention. Fall and hip fracture rates in native Japanese and Japanese-American females in Hawaii have been reported to be half of those of Caucasians living in both Hawaii and other parts of the United States. Differences in the vitamin D status and the seasonal variation in serum vitamin D levels among these populations may contribute to this finding. Contributors to vitamin D status include both cutaneous synthesis of vitamin D from sunlight exposure and dietary vitamin D intake. In this study, we examine serum 25(OH)D levels and their seasonal variation in a cohort of community-dwelling postmenopausal Japanese females living in Hawaii. Data for these analyses came from 495 women of Japanese ancestry living in Hawaii who participated in the 8th examination of the Hawaii Osteoporosis Study (HOS) conducted from January 1992 through September 1994. All participants gave signed informed consent, and the study was reviewed and approved by an Institutional Review Board. Serum specimens were collected and preserved at -70 degrees. Serum 25(OH)D assays were performed at the Nichols Institute using liquid chromatography tandem mass spectrometry. The mean age of the subjects was 74±5 years. The mean serum total 25(OH)D was (mean ± SD) 79.9±23.7nmol/L (31.9±9.5ng/mL); 43% of women (n=216) had values <75nmol/L (30ng/mL), 8% (n=41) <50 nmol/L (20ng/mL), 0.60% (n=3) <30 nmol/L (12ng/mL), and none had <25 nmol/L (10ng/mL). There was little evidence of seasonal variation, with mean serum 25(OH)D levels of ~28 ng/mL during January and February, and 31 to 34 ng/mL during most other months. The current study has several limitations. Analyses were cross-sectional in design, and vitamin D levels were measured at a single point in time. When compared to published data for ambulatory Caucasians in the US and Europe, as well as other populations, low serum 25(OH)D level in our cohort was somewhat less prevalent. For example, the prevalence of 25(OH)D <20ng/mL in one US study of women with osteoporosis was 18%, compared to 8% in our study. In contrast to studies conducted at more northerly latitudes, there was little evidence of seasonal serum 25(OH)D variation in Hawaii. Although the prevalence of very low vitamin D was lower in Hawaii than in other parts of the world, a substantial proportion (43%) had serum 25(OH)D values less than the 75nmol/L (30ng/mL) considered optimal by some experts, despite the abundant sunshine in this tropical latitude.

Low Calcium Intake and Insufficient Serum Vitamin D Status in Treated and Non-Treated Postmenopausal Osteoporotic Women in Spain: The Previcad Study. J. M. Quesada Gómez¹, J. M. Mata Granados^{*1}, J. Delgadillo^{*2}, E. Ramírez^{*3}. ¹Unidad de Metabolismo Mineral, Servicio de Endocrinología, Hospital Universitario Reina Sofía, Córdoba, Spain, ²Medical Department, Procter & Gamble Pharmaceuticals Iberia, Barcelona, Spain, ³Medical Writing, Infocencia, Barcelona, Spain.

The purpose of the present study was to assess the calcium intake and serum vitamin D level in postmenopausal women treated and non-treated for osteoporosis, and to evaluate the influence of sunlight exposure on vitamin D status.

This observational epidemiologic and cross-sectional study was conducted at Spanish hospitals and primary care centres, which were categorized on basis of their sunlight exposure (above or below 2500 sunlight hours/year). The participant investigators collected demographic and clinical data from postmenopausal women diagnosed of osteoporosis, including their history of prior fractures, pharmacological treatment, and dietary calcium intake. In addition, measures of 25OHD and other bone metabolism markers were determined from a blood sample. All the patients gave their written signed informed consent to participate in the study, which followed the Declaration of Helsinki principles and was approved by the local institutional human research committee.

A total of 336 postmenopausal women aged 71.2 ± 4.9 were enrolled, 190 of which were under osteoporosis treatment. Among them, the bisphosphonate drugs were the first choice therapy (69.5%), followed by the use of selective estrogen receptor modulators (11.1%), while only 1.6% received a combination of both. A high percentage of insufficient dietary calcium intake (<1500 mg/day) was observed, with an average value of 1018.6 mg/day in the whole sample and without differences between treated and untreated.

Mean serum 25OHD concentration was 25.5 ng/ml, and a 68.9% exhibited vitamin D insufficiency (<30 ng/ml), 76.4% in non-treated and 63.2% in treated women. In contrast, no significant benefit of the sunlight exposure was found when patients from areas receiving more or less than 2500 sunlight hours/year were compared. Furthermore, the calcium intake did not appear to influence either 25OHD or PTH levels.

In conclusion, strikingly even in a sunny country such as Spain, there is a large prevalence of vitamin D insufficiency amongst untreated osteoporotic women, regardless of the sun hour's availability. Moreover, 63.2% of Spanish women under osteoporosis therapy have vitamin D insufficiency and a low calcium intake. Hence, it is important to highlight the need for improving physician and patient's knowledge about the optimization of vitamin D status and calcium intake in this population segment in order to improve the therapeutic response.

Lack of Association of Carotenoid Intake with Bone Mineral Density (BMD) in Older Adults: The Framingham Osteoporosis Study. S. Sahni¹, M. T. Hannan², J. Blumberg^{*1}, L. A. Cupples³, D. P. Kiel², K. L. Tucker¹. ¹JM USDA HNRCA, Tufts Univ., Boston, MA, USA, ²Hebrew SeniorLife, Boston, MA, USA, ³Boston Univ. SPH, Boston, MA, USA.

In vitro and in vivo studies suggest that carotenoids may inhibit bone resorption and stimulate bone formation. One study of BMD showed positive and negative associations for specific carotenoids, and a fracture study showed interaction by smoking. Thus, we evaluated intakes of total and individual carotenoids (α -carotene, β -carotene, β -cryptoxanthin, lycopene, lutein+zeaxanthin) and BMDs at hip, spine and radius in the Framingham Osteoporosis Study.

277 men and 476 women had hip and spine BMDs (g/cm², Lunar DP3), radius BMD (Lunar SP2) and food frequency questionnaires (FFQ), all obtained in 1988-89. Carotenoid intakes were estimated with Willett FFQ and adjusted for total energy (residual method). Least squares mean BMDs were estimated for men and women separately by quartile of carotenoid. Linear regression models were adjusted for age, BMI, height, total energy, physical activity, alcohol, smoking, calcium, vitamin D, caffeine, & estrogen (women). We tested interaction with pack-years of smoking (male mean: 26.2 ± 3.9; female mean 12.7 ± 19.0).

Mean age was 75y ± 5.0. For women, no associations were seen between total carotenoids, α -carotene, β -carotene, β -cryptoxanthin and BMD at any site. Men had similar results except β -carotene showed borderline positive association with radius BMD (P for trend=0.08). Women in lowest quartile (Q1) of lycopene had significantly lower trochanteric BMD compared to Q2, Q3, Q4 (adjusted mean BMD=0.62±0.01 in Q1 vs 0.66±0.01, 0.66±0.02 and 0.67±0.02 g/cm² in Q2-4, P<0.05, P for trend=0.009). For men, lycopene and BMD was modified by smoking (P for interaction term =0.003 for femoral neck; P=0.002 for trochanter). Male smokers (not non-smokers), in Q1 of lycopene had significantly higher trochanteric BMD compared to other quartiles (adjusted mean BMD=0.89±0.01 in Q1 vs 0.82±0.01, 0.82±0.01 and 0.80±0.01 g/cm² in Q2-4, P<0.05, P for trend=0.005). No associations were seen with lycopene and other BMD sites. Women in Q1 of lutein+zeaxanthin intake had significantly lower trochanteric BMD compared to Q4 (adjusted mean BMD=0.63±0.01 in Q1 vs 0.66±0.02 g/cm² in Q4, P<0.05, P for trend=0.062), while no associations were seen in men.

In sum, few associations were seen between carotenoids and BMDs in our study: none for total carotenoids, α -carotene or β -cryptoxanthin, and marginal results for β -carotene, lycopene and lutein+zeaxanthin. As these results were inconsistent across BMD sites and gender and no results were sufficiently strong to rule out chance, we believe our findings indicate lack of association between carotenoids and BMD in this elderly population.

The Single Nucleotide Polymorphism R325Q in the Vitamin K-Dependent Gamma-Glutamyl Carboxylase Gene Has Effects on the Correlation Between Dietary Vitamin K Intake and Gamma-Carboxylation of Serum Osteocalcin in Young Males. N. Sogabe^{*1}, N. Tsugawa^{*2}, R. Maruyama^{*1}, M. Kamao^{*2}, T. Okano², T. Hosoi³, M. Goseki-Sone¹. ¹Department of Food and Nutrition, Japan Women's University, Tokyo, Japan, ²Department of Hygienic Sciences, Kobe Pharmaceutical University, Kobe, Japan, ³Department of advanced Medicine, National Center for Geriatrics and Gerontology, Aichi, Japan.

Vitamin K is a cofactor for gamma-glutamyl carboxylase (GGCX), which is an essential enzyme for the gamma-carboxylation of vitamin K-dependent proteins such as osteocalcin (OC). Associations among dietary vitamin K intake, vitamin K status, and bone metabolism have not been thoroughly investigated. Recently, it has been reported that single nucleotide polymorphisms (SNPs) of GGCX (R325Q, 974G>A) were associated with age-related bone loss. We investigated the associations among dietary vitamin K intake, the level of serum vitamin K, and the ratio of undercarboxylated OC (ucOC) to intact OC. The subjects were 60 healthy young male volunteers (mean age, 22.6 y; standard deviation, 1.7). Dietary nutrient intake was assessed by consecutive, individual 3-day food records before the day of blood examinations. Serum concentrations of vitamin K (phylloquinone: PK, menaquinone 4: MK-4, and menaquinone 7: MK-7), ucOC, intact OC, calcium, phosphorus, and bone-specific alkaline phosphatase were measured. All subjects were genotyped for polymorphism (R325Q). Dietary vitamin K intake from vegetables was significantly correlated with the level of serum PK ($p=0.009$), and vitamin K intake from fermented beans, natto, was also significantly correlated with the level of serum MK-7 ($p<0.001$). The ratio of ucOC to intact OC showed a negative association with the total vitamin K intake or MK-7 intake from natto. Interestingly, grouped by the GGCX genotype, a significant interaction between the ratio of ucOC to intact OC with serum MK-7 was observed in 325R homozygotes ($p=0.003$), but not in heterozygotes, nor in 325Q homozygotes. In the present study, we revealed that the single nucleotide polymorphism R325Q in the GGCX gene had effects on the correlation between dietary vitamin K intake and gamma-carboxylation of serum osteocalcin in young males. Our data may be useful for planning nutritional strategies for preventing osteoporosis.

Effects of Weight Reduction on Bone Mass and Structure in Obese Women. K. Uusi-Rasi, H. Sievänen, P. Kannus*, M. Pasanen*, K. Kukkonen-Harjula*, M. Fogelholm*. The UKK Institute for Health Promotion Research, Tampere, Finland.

Obesity is associated with obvious health risks, such as hypertension, type 2 diabetes, atherosclerosis and osteoarthritis, while it is also connected with greater bone mass. Therefore, one deleterious consequence of weight loss may be bone loss and increased bone fragility.

This pilot study was a non-controlled, prospective 3-mo study of women treated in weight loss groups by the general primary health care. The groups used conservative energy restrictive diet or VLED products (Cambridge Diet) in reducing body weight. Totally 54 of 60 recruited women completed the study. All assessments were done at baseline (0 month) and after 12 weeks' weight reduction.

Waist circumference, body composition by DXA-based and bone mineral content (BMC) of the right proximal femur were assessed. Cortical (shaft CoD) and trabecular bone density (distal TrD) of the radius and tibia was measured with pQCT. As markers of bone turnover, serum tartrate-resistant acid phosphatase isoform 5b (S-TRACP 5b), serum C-telopeptide of collagen cross-links (S-CTX) and serum amino-terminal propeptide of type I procollagen (S-PINP) were determined. Linear regression analysis was used to analyze associations of weight loss with bone characteristics.

At baseline, mean age (SD) was 45 (7) years, and mean BMI 34.4 (4.8). The mean weight loss was 4.0 (4.1) kg ranging from -14.8 kg to +2.1 kg. Waist circumference decreased by 4.0 (4.2) cm. The change in S-CTX was negatively associated with weight change ($r = -0.314$; $p=0.022$), while changes in S-TRACP5b and S-PINP were not associated with weight change. There were correlations of borderline statistical significance between changes in biomarkers and bone mass. S-PINP and S-CXT correlated negatively with trochanter BMC ($r=-0.262$; $p=0.058$ and $r=-0.262$; $p=0.058$), respectively.

The correlation between weight change and change in femoral neck BMC was negative ($r=-0.280$; $p=0.042$), the β -coefficient of weight change being -0.009 for femoral neck BMC. There was also a negative correlation between weight change and radial CoD ($r=-0.291$; $p=0.036$) and radial TrD ($r=-0.247$; $p=0.077$) suggesting increased bone loss at the radius. For radial bone changes, change in body fat mass was a better predictor than change in lean mass (significant for CoD only). A 1 kg change in fat mass was associated with 0.001 mg/cm³ mean decline in the radial CoD ($p=0.004$). As the radius is a nonweight-bearing bone, changes in bone loading due to reduced body weight cannot explain this association.

These findings suggested that changes in body mass influence bone metabolism to some extent, apparently in a complex fashion. Therefore the possibility of harmful effects of weight loss on bone cannot be ruled out. Further research is definitely needed.

Disclosures: K. Uusi-Rasi, None.

Serum 25(OH)D Levels and Falls, Frailty, and Fractures among Postmenopausal Women in the Hawaii Osteoporosis Study. S. Techaturunkul^{*1}, P. Pramyothin^{*1}, J. Lin^{*2}, H. Wang^{*2}, A. Shah^{*2}, P. D. Ross², R. Puaopong^{*1}, R. D. Wasnich¹. ¹Hawaii Osteoporosis Center, Honolulu, HI, USA, ²Merck Research Laboratories, Rahway, NJ, USA.

In this study we investigate the relationship of serum 25-hydroxyvitamin D (25(OH)D) levels to measures of physical performance and muscle strength, and to subsequent falls and fractures in the Hawaii Osteoporosis Study (HOS). Using liquid chromatography tandem mass spectrometry, 25(OH)D levels (D3 and total) were measured in serum stored at -70 degrees that had been collected from 495 postmenopausal women during the 8th examination of the HOS cohort in 1992-94. In the primary analyses, the relationship of total 25(OH)D to performance-based measurements (walking speed, timed get-up-and-go, chair stand, hand & foot reaction time, functional reach), and muscle strength (grip, triceps, and quadriceps) was explored using multivariate regression models, adjusted for age, height, and weight. Logistic regression analyses adjusted for age, height, and weight were also performed to evaluate the relationship of total 25(OH)D to falls and to the incidence of vertebral and non vertebral fractures during a mean 2.7 year follow-up. Secondary analyses were performed: 1) using vitamin D3 as the predictor variable, 2) using vitamin D (D3 and total) with adjustment only for age, and 3) including quadriceps strength as an additional covariate in models of falling. The mean serum 25(OH)D level was 79.9 (SD=23.7 nmol/L; n=495). After adjustment for age, height, and weight, only quadriceps strength had a significant association ($p=0.0002$) with 25(OH)D. No significant association of 25(OH)D was found with either vertebral or non-vertebral fractures, or with the incidence of one or more falls. There was a borderline significant ($p = 0.05$) association of total 25(OH)D with two or more falls after adjustment for age alone, but there was no association in the model adjusted for age, height, weight, and quadriceps strength, suggesting that an effect on falls may be partly mediated by quadriceps strength. The current study has several limitations. Analyses were of cross-sectional design, and vitamin D levels were measured at a single point in time. Although prospective data were available for falls and fractures, the numbers of fracture events were relatively small. Also, the interpretation of tests for statistical significance are less straightforward due to the large number of endpoints studied. The lack of association with fractures and falls, or with most physical performance measures, might be related to the fact that very low levels of 25OHD are less common in this population than in other studies.

Association between Urinary Potassium and Hip Bone Mass in a Prospective Cohort Study of Elderly Postmenopausal Women. K. Zhu¹, A. Devine^{*2}, J. Beilby^{*3}, R. L. Prince⁴. ¹Department of Endocrinology and Diabetes, Sir Charles Gairdner Hospital, Nedlands, Australia, ²School of Exercise, Biomedical and Health Science, Edith Cowan University, Perth, Australia, ³Pathcentre, Sir Charles Gairdner Hospital, Nedlands, Australia, ⁴School of Medicine and Pharmacology, University of Western Australia, Nedlands, Australia.

Dietary potassium intake, best evaluated by potassium output in the urine, has been suggested to be beneficial for bone structure perhaps because of its relationship to fruit and vegetable intake.

The association between urinary potassium and hip bone mass was evaluated in 266 elderly postmenopausal women selected from the population who participated in a 5-year calcium intervention study in which subjects were randomised to calcium 1.2 g or placebo (the CAIFOS study). Twenty-four hour urine samples were collected at baseline and urinary potassium (Urine K) measured by autoanalyzer (Roche Diagnostics Hitachi 917). Dietary intake was assessed by a validated food frequency questionnaire (Victorian Anti Cancer Council) and Net Endogenous non carbonic Acid Production (NEAP) calculated. One year later total hip DXA BMD was assessed (Hologic 4500A).

At baseline subjects mean age was 75.0 ± 2.7 years and mean calcium intake was 959 ± 338 mg/day. In correlation analysis there was a positive relationship between the urine K and total hip BMD ($r = 0.188$, $P = 0.002$). Subjects in the highest quartile of urine K had a total hip BMD 5% higher of those in the lowest three quartiles after adjustment for age, weight, height and calcium treatment group. There were no significant differences between the four groups in intakes of calcium and protein or NEAP. The effects remained after further adjustment for these variables.

	24 hour Urine Potassium (mM/day)			
	1 st quartile <41	2 nd quartile 42 - 57	3 rd quartile 58-76	4 th quartile >76
Total hip BMD mg/cm ²	789 ± 142 (0.02)*	794 ± 127 (0.03)*	805 ± 126 (NS)	857 ± 112
Hip BMD % df from 4 th quartile	-9.0 ± 2.8 (0.002)*	-8.0 ± 2.8 (0.004)*	-6.6 ± 2.8 (0.020)*	-
Hip BMD adjusted % df from 4 th quartile	-5.1 ± 2.4 (0.037)**	-5.0 ± 2.4 (0.038)**	-5.1 ± 2.4 (0.035)**	-
Calcium intake mg/day	947 ± 382	955 ± 308	984 ± 317	950 ± 351
Protein intake g/day	80 ± 29	78 ± 23	86 ± 32	83 ± 29
NEAP mEq/day	51 ± 17	50 ± 11	53 ± 20	52 ± 17

Results mean \pm SD, % results mean \pm SEM, * P value of 4th quartile ** P value of 4th quartile adjusted for age, weight, height and treatment. These findings suggested that increase the intake of food rich in potassium, such as fresh fruit and vegetables may have a substantial beneficial effect on the maintenance of bone mass at the hip.

Secondary Causes of Osteoporosis in Fracture Patients. E. R. Bogoch¹, V. I. M. Elliot-Gibson^{*2}, R. Wang^{*3}, R. G. Josse⁴. ¹Department of Surgery, St. Michael's Hospital, Toronto, ON, Canada, ²Mobility Program Clinical Research Unit, St. Michael's Hospital, Toronto, ON, Canada, ³Orthopaedic Resident, Department of Surgery, St. Michael's Hospital, Toronto, ON, Canada, ⁴Department of Medicine, St. Michael's Hospital, Toronto, ON, Canada.

This analysis was performed to report the prevalence of vitamin D deficiency and other secondary causes of osteoporosis (OP) in patients with fragility fracture. A chart audit of 399 patients referred from an inner city orthopaedic unit to the Metabolic Bone Disease Clinic (MBDC) over a three year period was conducted. A total of 117 males, average age 64.6 (SD 12.8) and 282 females, average age 63.5 (SD 14.6) were reviewed. Fracture locations and etiology: 90 hip (76 fragility), 161 wrist (135 fragility), 8 vertebral (6 fragility), 77 shoulder (62 fragility) and 62 other sites (45 fragility) and one with both hip and shoulder (fragility). Thirty percent (42 males and 78 females) of patients had a total of 149 secondary causes of OP recorded in their MBDC note. Secondary causes included medication use (oral steroids, anti-seizure), rheumatic, gastrointestinal and endocrine conditions (RA, IBD, Graves disease, Type 1 DM, hyperparathyroidism), hypogonadal states (premature ovarian failure, hypogonadism), genetic conditions (hypophosphatasia), hematological conditions (thalassemia) and miscellaneous causes (smoking, renal impairment). A total of 308 patients completed blood work, including 269 patients who had a 25-OH vitamin D measurement: seven patients were deficient at ≤ 25 nmol/L, 137 were insufficient at 26 to 74 nmol/L and 125 were sufficient at ≥ 75 nmol/L. There were no differences between males and females ($p=0.457$), or among fracture locations ($p=0.246$). Over 75% of the blood/urine analyses were within the normal range for: 1,25 vitamin D ($n=18$), ALP ($n=266$), ALT ($n=75$), AST ($n=105$), bilirubin ($n=19$), creatinine ($n=247$), T3 ($n=173$), T4 ($n=229$), homocysteine ($n=3$), magnesium ($n=74$), phosphorus ($n=249$), platelets ($n=220$), serum calcium ($n=269$), protein ($n=282$), albumin ($n=282$), globulin ($n=281$), TSH ($n=254$), tissue transglutaminase ($n=49$), Vit B12 ($n=17$), WBC ($n=220$), and 24 hour urine calcium ($n=52$) and phosphorus ($n=34$). Between 50 and 74% of the blood/urine analyses were within the normal range for: CRP ($n=30$; 30% elevated), ESR ($n=173$; 43% elevated), testosterone ($n=53$; 25% of men below normal), bioavailable testosterone ($n=52$; 40% of men below normal), N-telopeptide ($n=5$; 30% of women elevated), PTH ($n=130$; 19% elevated), RBC folate ($n=12$; 33% elevated), 24 hour urine creatinine ($n=51$; 27% below normal). A standardized blood test protocol for all fracture patients is now being used.

Osteoporosis Post-Fracture Screening Program. V. I. M. Elliot-Gibson^{*1}, R. Jain^{*2}, F. Jiwa^{*2}, D. E. Beaton¹, E. R. Bogoch³, S. Richie^{*4}, F. Samji^{*5}. ¹Mobility Program Clinical Research Unit, St. Michael's Hospital, Toronto, ON, Canada, ²Osteoporosis Canada, Toronto, ON, Canada, ³Department of Surgery, St. Michael's Hospital, Toronto, ON, Canada, ⁴Department of Surgery, McMaster University and Brantford General Hospital and Ontario Orthopaedic Association, Hamilton, ON, Canada, ⁵Ministry of Health and Long-Term Care, Government of Ontario, Toronto, ON, Canada.

In 2005, the Ontario Government, committed up to \$5 million per year towards an Osteoporosis (OP) Strategy with the primary goal to prevent OP through early detection and education. One of the five main components of this program is the creation of a province-wide fracture clinic program with the goals to improve OP diagnosis and treatment in this population, prevent future fractures, improve OP knowledge among health professionals and patients and increase collaboration between orthopaedic surgeons and family physicians. The Ministry of Health and Long-Term Care (MOHLTC) has commissioned Osteoporosis Canada (OC) to develop, implement and evaluate this program. The Post-Fracture OP Program has been designed as a multifaceted intervention program aimed at orthopaedic surgeons, health care professionals, administration and staff at the hospital level, family physicians, and individuals who have sustained a fragility fracture. For this program, OC will deploy 14 OP Screening Coordinators (OSCs) in 35 medium to high volume fracture clinics across the province of Ontario. In these clinics, the OSCs will screen and identify fragility fracture patients, educate them on OP and their risks and recommend follow up with the family physician for further investigation and treatment of the patients bone health. Family physicians will also receive a standardized form letter recommending follow up with their patients. Quality assurance self-report data is collected on all patients. This includes OP risk factors, prior OP treatment and adherence, prior bone mineral density (DXA) testing, OP knowledge and beliefs and socio-demographics characteristics. Patient review at three months will evaluate their follow-up with their family physician, DXA testing and self-report of these results, new OP diagnosis, treatment and adherence to treatment and assessment of OP knowledge and beliefs. This data will be collected using touchscreen technology. A website is being developed to support the ongoing training of the OSCs. The Ontario Orthopaedic Association (OOA) will identify an 'Orthopaedic Osteoporosis Champion' in each hospital to support the deployment of these coordinators and promote the program strategy. Educational materials for patients have been developed for this program by OC.

The Pattern of Fractures in Men: Geelong Osteoporosis Study. S. Korn^{*}, J. Pasco, M. Henry^{*}, M. Kotowicz, G. Nicholson. Department of Clinical and Biomedical Sciences: Barwon Health, University of Melbourne, Geelong, Australia.

Using radiology reports at the Geelong Hospital, all men aged 20+yr with incident fracture in 2005-6 were identified; approximately 90% of fractures in the region can be ascertained by this method. We aimed to describe fracture epidemiology by age, fracture site and trauma. Low trauma fracture included spontaneous fracture and those resulting from falls <standing height or unspecified, overexertion or strenuous movement. We identified 2,103 men aged 20-97yr sustaining at least one incident fracture (Figure). Trauma level was determined for 1088 cases: 401 low and 687 high. Among men aged <60yr, 80% (599/748) of fractures were attributable to high trauma whereas among men aged >60yr only 26% (88/340) were high trauma.

In a subset of 217 fracture cases, total-hip BMD (Lunar Prodigy) for high trauma ($n=130$, median age 46yr IQR 34-59) and low trauma ($n=87$, median age 56yr IQR 38-73) was compared with controls from a random population-based sample ($n=879$, 54yr IQR 33-75). Mean age- and weight- adjusted BMD was statistically lower according to trauma level (mean \pm SE: low trauma 0.995 ± 0.015 vs high trauma 1.040 ± 0.012 vs controls 1.068 ± 0.004 g/cm², all $p<0.05$).

One-third of the fracture burden arose from men aged >60yr, with age-related increases in traditional osteoporotic fractures (forearm, spine and hip) and relatively few high trauma. In contrast, high trauma fractures at non-osteoporotic sites predominated in younger men. Despite differences in trauma patterns between younger and older men with fracture, BMD was consistently lower for fracture cases compared with controls across all ages.

Chronic Kidney Disease Stages Classified by Serum Cystatin-C and Incidence of Hip Fracture in the Women's Health Initiative Observational Study (WHI-OS). A. Z. LaCroix¹, J. Lee², L. Wu^{1*}, J. Cauley³, M. G. Shlipak^{4*}, S. M. Ott⁴, J. Robbins⁵, J. D. Curb^{6*}, M. LeBoff⁷, R. Jackson⁸, C. Kooperberg^{4*}, D. C. Bauer², S. R. Cummings². ¹Public Health Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA, USA, ²University of California at San Francisco, San Francisco, CA, USA, ³University of Pittsburgh, Pittsburgh, PA, USA, ⁴University of Washington, Seattle, WA, USA, ⁵University of California at Davis, Irvine, CA, USA, ⁶University of Hawaii, Honolulu, HI, USA, ⁷Harvard University, Boston, MA, USA, ⁸Ohio State University, Columbus, OH, USA.

Recent epidemiological studies have investigated associations between impaired renal function and hip fracture with inconsistent results. None have evaluated the recently defined KDIGO Chronic Kidney Disease (CKD) Stages using serum cystatin-C, a measure of renal function that is not dependent on lean body mass. We conducted a nested case-control study within the WHI-OS among 400 cases of incident adjudicated hip fracture and 400 controls matched on baseline age, race/ethnicity and date of blood draw (average follow-up time=7.1 years). Subjects were selected from 39,795 eligible postmenopausal women without previous hip fracture, not using estrogen, androgens or osteoporosis treatments and not on kidney dialysis. Cystatin-C levels were measured on baseline serum using the Dade Behring BN-II nephelometer with a particle-enhanced immunonephelometric assay (interassay co-efficient of variation=5.7%, sensitivity=0.02 mg/L). Estimated glomerular filtration rates (eGFR) were calculated with a validated equation ($76.7 \times \text{cystatin-C}^{-1.18}$) and categorized into CKD Stages of 0-1 (eGFR>90 ml/min/1.73 m²; n=133), 2 (60-90; n=517), or 3-4 (30-59; n=138; <30; n=6). Compared to women with CKD Stages 0-1, conditional logistic regression models adjusting for body mass index, parental hip fracture, smoking, alcohol, and physical function revealed an odds ratio (OR) of 2.50 (95% confidence interval (CI) 1.32-4.72) for Stages 3-4 CKD, but no association was seen for Stage 2 CKD (OR=1.04; CI 0.66-1.64). These associations were not affected by adjustment for other indicators of poor health status (frailty score, # of chronic conditions); hemoglobin level; or serum 25 hydroxy vitamin D level. Recent experimental data show that eGFR by cystatin-C is an important determinant of homocysteine level independent of vitamin B12 and folate status. Adjustment for plasma homocysteine levels ($r=0.45$ for cystatin-C & homocysteine) reduced the OR for Stages 3-4 CKD to 1.83 (CI 0.93-3.61) suggesting that reduced renal function may increase hip fracture risk partly through raising homocysteine levels. These results indicate that women with cystatin-C eGFR levels <60 have a substantially increased risk of hip fracture.

Low Levels of 25 hydroxyvitamin D Associated with Moderate/Severe Vertebral Fractures. J. B. Lopes^{1*}, C. F. Danilevicius^{1*}, L. Takayama^{1*}, E. Bonfá^{1*}, V. F. Caparbo^{1*}, P. R. Menezes^{2*}, R. M. Pereira¹. ¹Rheumatology Division, University of São Paulo, São Paulo, Brazil, ²Preventive Medicine Department, University of São Paulo, São Paulo, Brazil.

The aim of this study was to determine the possible relevance of serum vitamin D levels as a parameter for the presence of vertebral fracture. Eighty-five women with moderate/severe vertebral fracture and 85 women without vertebral fractures were consecutively selected in a well established elderly community in the city of São Paulo, a subtropical area, located at 23°34'S. All of them collected 25-hydroxyvitamin D (25-OHD) during the same period of the year. None had received vitamin D supplementation. Clinical and anthropometric data were obtained by specific questionnaire and physical examination. Vertebral fractures were evaluated by thoracic and lumbar X-ray using a semi-quantitative assessment (Genant et al.). The levels of serum 25-OHD [immunoradiometric assay (DiaSorin, Stillwater, MN, USA)], intact parathyroid hormone (intact PTH), serum calcium and estimated glomerular filtration rate (Cockcroft-Gault equation), were examined in both groups. Patients with vertebral fractures compared to those without fractures had a higher mean age (73.4 ± 4.9 vs. 71.8 ± 4.4 years, $p=0.032$), and lower weight (62.51 ± 12.47 vs. 68.01 ± 12.84 Kg, $p=0.005$) and height (1.49 ± 6.36 vs. 1.51 ± 6.22 m, $p=0.029$). Of interest, serum levels of 25-OHD in the group with fractures were significantly lower compared to the other group (17.6 ± 7.5 vs. 24.9 ± 13.3 ng/ml, $p<0.0001$). Reinforcing this finding, hypovitaminosis D (25-OHD<20 ng/ml) was more frequently observed in patients with fractures than in those without this complication (67 vs. 42.5%, $p=0.001$). Accordingly, intact PTH were significantly higher in the group with fractures compared to those without vertebral fractures (50.21 ± 36.23 vs. 40.27 ± 17.25 pg/ml, $p<0.024$). Serum calcium and glomerular filtration rate were comparable in both groups ($p>0.05$). Logistic regression analysis, using 25-OHD, age, weight, height, intact PTH revealed that only 25-OHD remains a significant factor for the presence of moderate/severe vertebral fracture. In our study, serum levels of vitamin D have an emerged promising index of vertebral fracture in elderly community-dwelling women.

Prevalence of Asymptomatic Vertebral Fractures in Postmenopausal Women with Osteoporosis in Buenos Aires. Z. Man, M. S. Larroude^{*}, M. P. D. Yantorno^{*}, M. S. Moggia^{*}, R. D. Diaz^{*}, M. G. Torres Cerino^{*}, G. A. Macías^{*}, J. C. Morgenstern^{*}, M. Pérez Sáinz^{*}. Centro TIEMPO, C.A.Buenos Aires, Argentina.

Introduction: Underdiagnosis of vertebral fractures (VFX) is a common problem. The semiquantitative evaluation provided by the Genant Method is a very useful tool in the assessment of these fractures, by means of plain lateral thoracic and the lumbar radiographs.

Objective: To determine the prevalence of asymptomatic VFX in the postmenopausal women (PMW) with the osteoporosis diagnosed by the DXA scans performed at our center, located in Buenos Aires, Argentina, who attended for control. Material and method: After ruling out history of VFX through medical interrogatory, 337 PMW [mean age, 67 years (range, 51-85)] with at least five years postmenopausal, had plain lateral thoracic and lumbar X-rays done. A reduction >20% of the vertebral body height was considered for the diagnosis of VFX.

Results: We found 146 VFX, of which 103 VFX (70%) and 43 VFX (30%) were located in the thoracic and lumbar spine, respectively. 94 PMW with osteoporosis (27.89% of the total sample) had VFX; 31 of these (33%) had more than one VFX.

Conclusion: It is well known that the presence of a VFX is a predisposing factor for the future fractures. Their diagnosis represents a useful tool for the establishing risk groups. Plain radiographs of the spine are accessible and inexpensive imaging methods, whose benefits are important in terms of public and the individuals health.

A Novel, Integrated Approach to the Management of Patients Following Hip Fracture: The Hip Fracture Integrated Intervention Program (HIIP). V. Nanci^{1*}, G. Berry^{2*}, E. Harvey^{3*}, D. Goltzman³, S. N. Morin³. ¹McGill University, Montreal, PQ, Canada, ²Orthopedics, McGill University Health Center, Montreal, PQ, Canada, ³Medicine, McGill University Health Center, Montreal, PQ, Canada.

Clinical guidelines recommend that patients having sustained a fragility fracture be considered for osteoporosis treatment to reduce the risk of recurrent events. Because of their frailty and inability to comply with follow-up appointments, patients with hip fractures receive therapy less than 30% of the time.

The purpose of this study was to evaluate the feasibility of implementing an integrated approach to the delivery of care to patients having sustained a hip fracture. Specific objectives were to describe the characteristics and current care of patients who survive to hospital discharge, to characterize patients lost to follow-up and to evaluate the applicability of evaluation tools.

Patients admitted to our institution for a hip fracture from November 15th 2005 to October 21st 2006 were scheduled for a bone mineral density and pertinent blood tests while in hospital. Upon discharge, patients were given a 6 week follow-up conjoint appointment with the treating surgeon and a bone metabolism specialist, at which time a comprehensive treatment plan was elaborated. A summary letter was sent to the patient's primary care physician, who was asked to follow-up on the recommendations.

154 patients with hip fractures were admitted during the study period. 74 patients were seen in follow up (78% women, age = 80.0 years [SD=3.1], 22% men, age = 76.8 [SD=10.6]). Amongst the patients seen in clinic, 30% had sustained a previous fracture, 45 % were receiving some calcium or vitamin D and 19% were on an antiresorptive agent at the time of the fracture. 79% underwent BMD and blood tests while in hospital; of those, 67% had a Femoral Neck T score of -2.5 or less and 34% had evidence of secondary hyperparathyroidism. Factors associated with inability to undergo the prescribed tests were: short hospital stay and medical deterioration. Failure to return to clinic was related with dementia and travelling distance. All patients who returned for follow-up received recommendations on fall prevention and appropriate prescriptions for calcium, vitamin D and pharmacological therapy. Patients' satisfaction level with this approach was high.

We conclude that this novel, integrated program is well suited for the hip fracture population and fosters collaboration between health care professionals. We propose to address the following questions: 1) evaluation of the impact of our interventions on adherence to therapy at 6 and 12 months, 2) development of a treatment pathway for patients who do not return to clinic for the initial follow-up and 3) development and validation of fracture-reduction strategies.

Disclosures: S.N. Morin, None.

Using a Case-Manager to Improve Osteoporosis Treatment after Hip Fracture: Results of a Randomized Controlled Trial. D. W. Morrish^{*1}, S. R. Majumdar^{*1}, L. A. Beaupre^{*2}, N. R. Bell^{*3}, J. G. Cinats^{*4}, D. A. Hanley^{*5}, C. H. Harley^{*1}, A. G. Juby^{*1}, D. A. Lier^{*6}, W. P. Maksymowych^{*1}. ¹Medicine, University of Alberta, Edmonton, AB, Canada, ²Rehabilitation Medicine, University of Alberta, Edmonton, AB, Canada, ³Family Medicine, University of Alberta, Edmonton, AB, Canada, ⁴Surgery, University of Alberta, Edmonton, AB, Canada, ⁵Medicine, University of Calgary, Calgary, AB, Canada, ⁶Institute of Health Economics, University of Alberta, Edmonton, AB, Canada.

Purpose: Patients having hip fracture frequently have osteoporosis, yet osteoporosis diagnosis and treatment rates remain inappropriately low at 10-20%. Therefore, we designed a randomized controlled trial to determine the cost and effectiveness of using a case manager to achieve diagnosis and appropriate treatment for this patient group.

Methods: The protocol was approved by the institutional Health Research Ethics Board. We recruited patients from all hospitals in Capital Health, Edmonton. Inclusion criteria were age over 50 years, not receiving active osteoporosis treatment other than calcium/vitamin D, and not living in long-term care facilities. The intervention consisted of a case manager who educated, arranged bone mineral density (BMD) testing by DEXA, provided bisphosphonate prescriptions to patients with low bone mass and communicated with primary care physicians. The control arm was "usual care", which did not include these measures.

Results: We screened 2219 patients and allocated 110 patients randomly to each of control or intervention. 88 intervention patients (80%) versus 32 (29%) controls had BMD performed ($p<0.001$). Of the 120 patients who had a BMD, 27 (23%) had normal bone mass. At 6 months, 56 (51%) of intervention patients versus 24 (22%) of controls were treated with bisphosphonates (adjusted odds 4.7, 95% CI 2.4-8.9, $p<0.001$). Intervention patients were more likely to receive appropriate care (defined as prescribed bisphosphonate therapy if BMD was <-1.5 SD t-score) than controls (67% versus 26%, adjusted $p<0.001$). The intervention cost was \$52 CDN per patient.

Conclusions: We conclude that a case manager substantially increases rates of osteoporosis testing and treatment in hip fracture patients for a modest cost.

T330

Vertebral Fractures in Patients with Chronic Obstructive Pulmonary Disease Patients: The EOLO Study. R. Nuti¹, S. Maggi^{*2}, G. Guglielmi^{*3}, G. Martini¹, C. Caffarelli^{*1}, S. Batucci^{*4}, T. De Feo^{*4}, G. Crepaldi², S. Gonnelli¹. ¹Institute of Internal Medicine, University of Siena, Siena, Italy, ²CNR Aging Branch, University of Padua, Italy, ³Institute of Internal Medicine, Department of Radiology, Scientific Institute Hospital, Casa Solievo della Sofferenza, San Giovanni Rotondo, Italy, ⁴Procter & Gamble, Roma, Italy.

Osteoporosis has been recognized as one of the systemic effects associated with chronic obstructive pulmonary disease (COPD). In particular there is a growing concern about the risk of vertebral fractures (VFs) which in COPD patients lead to a notable worsening of the respiratory condition. The aetiology of osteoporosis in COPD is complex and many factors may contribute to its pathogenesis, in particular the role of glucocorticoids (GCs) is still being debated.

The E.O.L.O. (Evaluation of Obstructive Lung disease and Osteoporosis) is a national study aimed to evaluate the prevalence of osteopenia, osteoporosis and VFs in a large sample of patients affected by COPD. Moreover E.O.L.O. study aimed to evaluate the impact of the use of oral and inhaled GCs and the severity of COPD on VFs. A total of 3030 ambulatory COPD patients (1768 men and 1262 women) aged 50+ yrs were enrolled. The patients underwent an evaluation of bone status by using a Quantitative Ultrasound device (Achilles, GE-Lunar) and a lateral chest X-ray for thoracic spine evaluation. X-ray films were locally and centrally digitized and morphometry software (MorphoXpress) was used for measuring vertebral heights.

Both in men and in women VFs are more frequent ($p<0.001$) in osteoporosis patients (72.8% and 78.3%) than in osteopenics (52.2% and 62.9%) or in normals (50.1% and 55.8%). The number of patients with osteoporosis or osteopenia is significantly influenced by COPD severity but not by COPD duration or GCs. The logistic regression model showed that the frequency of VFs is associated to the COPD severity and higher rates of VFs are observed in patients treated with oral or inhaled GCs. (see below)

LOGISTIC REGRESSION MODEL FOR VERTEBRAL FRACTURES

$n=2934$ (no fractures =1072, one or more fractures = 1862)

	OR	95% C.I.	
GENDER (Men)	0.547	0.464	0.644
AGE (yrs) *	1.034	1.024	1.044
BMI (<26.7)	1.448	1.239	1.692
COPD	1.000		
Mild	1.307	1.070	1.595
Moderate	1.426	1.137	1.790
Severe + Very Severe			
GC	1.000		
No TR.	1.350	1.028	1.774
No CS	1.593	1.029	2.466
O-CS	1.418	1.145	1.756
I-CS	2.018	1.449	2.810
O-CS + I-CS			

* 5 years increase in age

Variables in the model: gender, age, BMI, smoke, GCs, COPD severity

In conclusion the E.O.L.O. study confirms that COPD patients are at higher risk of having osteoporosis and of developing VFs. COPD severity and the use of GCs (both oral and inhaled) seem to play a crucial role in determining VFs.

Disclosures: R. Nuti, None.

The Chaos Clinic - A Randomized Controlled Trial of a Falls Clinic for Prevention of Falls and Related Fractures. M. Palvanen^{*1}, P. Kannus^{*1}, J. Parkkari^{*2}, J. Rintala^{*3}, M. Järvinen^{*4}, M. Fogelholm^{*1}. ¹UKK Institute, Tampere, Finland, ²The Sports Medicine Centre of Tampere, Tampere, Finland, ³Suomen Terveystalo, Tampere, Finland, ⁴Tampere University Medical School and University Hospital, Tampere, Finland.

The purpose of this preliminary report of a falls clinic is to determine the number of falls and fall-related injuries (fractures) among our Finnish Chaos Clinic participants.

The Chaos Clinic is a falls clinic for prevention of falls and related injuries among elderly people. All persons aged 70 years or more with high-risk for falling and fractures are first interviewed and examined carefully at the Chaos Clinic to evaluate all individual intrinsic and extrinsic risk factors for falls and fall-induced injuries such as fractures. After the comprehensive and individual assessment of the risk factors for falling, the participants are randomized to the intervention group and control group. Thereafter, the personnel of the Chaos Clinic decide, on individual basis, the falls prevention measures needed and supervise their execution in the intervention group (a multifactorial preventive approach). All the participants are then followed-up for 12 months (in three months intervals) for falls and related injuries. Our hypothesis is that persons in the intervention group will have 30% less falls and related injuries than their counterparts in the control group.

The trial started in January 2005 and is still in process. So far, 400 participants have been followed for 12 months. At the one-year follow-up, 202/400 (51%) of the participants had fallen at least once having altogether 490 falls. These falls caused 262 injuries, 15 of them (5.7%) being fractures. The mean age of the participants was 76 years at baseline and 87% of them were women.

The randomized study evaluating the effect of the Chaos Clinic in falls prevention of older adults has started well and the number of falls and related injuries have been at expected level. The coming years will show the true efficacy of the falls prevention intervention of the Clinic.

Disclosures: M. Palvanen, None.

X-ray Ordering Improves in Patients with Height Loss or Kyphosis Following an Osteoporosis Educational Intervention: Canadian Quality Circle (CQC) National Project. A. Papaioannou¹, G. Ioannidis¹, B. Kvern^{*2}, A. Hodsman³, L. Thabane^{*1}, A. Gafni^{*1}, D. Johnstone^{*4}, L. Salach^{*5}, F. Jiwa^{*6}, J. D. Adachi¹. ¹McMaster University, Hamilton, ON, Canada, ²University of Manitoba, Winnipeg, MB, Canada, ³University of Western Ontario, London, ON, Canada, ⁴Procter and Gamble Pharmaceuticals, Toronto, ON, Canada, ⁵Ontario College of Family Physicians, Toronto, ON, Canada, ⁶Osteoporosis Canada, Toronto, ON, Canada.

The CQC National Project is an integrated disease management study designed to improve family physicians' (FPs) adherence with the Osteoporosis Canada 2002 guidelines. The project consists of five phases: wave I data collection, 1st educational intervention, wave II data collection, 2nd educational intervention, and wave III data collection. During the educational intervention QC's met to discuss physician profiles on how they managed osteoporosis and to participate in an osteoporosis workshop. This interim analysis (wave I & II) examined the change in x-ray ordering in patients with kyphosis or height loss. The guidelines recommend that x-rays should be ordered in all patients with kyphosis or height loss. A total of 340 (wave I) and 301 (wave II) PCPs formed 34 QCs. For each wave, PCPs collected data from different patients via chart reviews and a standardized collection form. There were 8376 (wave I) and 7354 (wave II) patient records selected at random and analyzed. All patients were women 55 years and older. The generalized estimating equations (GEE) technique was used to evaluate differences in x-ray ordering in patients with kyphosis or height loss before and after the educational intervention. The cluster variable for the GEE model was physician and the analysis was adjusted for other clinical risk factors. An exchangeable correlation matrix was used for the analysis. Odds ratios (OR) and 95% confidence intervals (CI) were calculated. A total of 54.3% (662/1220), 56.2% (654/1163) and 53.1% (958/1804) of patients with kyphosis, height loss, or either kyphosis or height loss during wave I and 63.9% (726/1136), 61.0% (834/1367) and 60.2% (1130/1877) of patients with kyphosis, height loss, or either during wave II had a x-ray ordered, respectively. The likelihood of x-ray ordering increased following the educational intervention for patients with kyphosis (OR: 1.35; 95% CI: 1.07, 1.70), height loss (OR: 1.28; 95% CI: 1.04, 1.57) or either (OR: 1.32; 95% CI: 1.12, 1.55). In conclusion, more patients with kyphosis or height loss had x-rays done following the educational intervention. Appropriate x-ray ordering may result in a greater number of vertebral fractures detected. Patients with vertebral fractures may benefit with osteoporosis therapies.

A Five Year Longitudinal Study of Health Related Quality of Life in Individuals with and without Incident Fractures: The Canadian Multicentre Osteoporosis Study (CaMos). A. Papaioannou¹, G. Ioannidis¹, C. Kennedy¹, L. Pickard¹, A. Tenenhouse², J. P. Brown³, R. Josse⁴, A. M. Sawka⁵, S. M. Kaiser⁶, T. Anastassiades⁷, W. Hopman⁸, J. D. Adachi¹. ¹McMaster University, Hamilton, ON, Canada, ²McGill University, Montreal, ON, Canada, ³Laval University, Sainte-Foy, PQ, Canada, ⁴University of Toronto, ON, Canada, ⁵University of Toronto, Toronto, ON, Canada, ⁶Dalhousie University, Halifax, NS, Canada, ⁷Queen's University, Kingston, ON, Canada.

CaMos, is a nation-wide, random sample of Canadian that provides a unique longitudinal opportunity to determine the relationship between incident fractures on health related quality of life (HRQL) over a 5 year period. A total of 4820 women and 1783 men 50 years of age and older were examined. The Health Utilities Index (HUI) Mark II and III systems were used to assess HRQL. The Mark II and III consist of a multi-attribute utility function score; Mark II has 6 attributes (sensation, mobility, emotion, cognition, self-care, and pain), and Mark III, 8 attributes (vision, hearing, speech, ambulation, dexterity, emotion, cognition, and pain). Multivariable linear regression analyses were conducted to examine changes in utility functions in patients with incident fractures versus those without fractures during a 5 year period. The analyses were adjusted for baseline covariates and were conducted for men and women separately. Parameter estimates and 95% confidence intervals (CI) were calculated. During the course of the study 8.0% (141/1766) of men and 11.8% (556/4773) of women had at least one incident fracture. For women, the differences between those with and without incident fractures for the Mark II were -0.06 (95% CI: -0.10, -0.02), -0.04 (95% CI: -0.07, -0.004), -0.04 (95% CI: -0.07, -0.01) and -0.10 (95% CI: -0.15, -0.04) for the multi-attribute utility function; and mobility, self-care, and pain attributes, respectively. For the Mark III, the differences were -0.07 (95% CI: -0.13, -0.01), -0.05 (95% CI: -0.09, -0.01) and -0.12 (95% CI: -0.18, -0.06) for the multi-attribute utility function; and ambulation and pain attributes, respectively. For men, the differences between those with and without incident fractures were -0.06 (95% CI: -0.11, -0.02) for the sensation domain of the Mark II; and -0.09 (95% CI: -0.16, -0.02), -0.03 (95% CI: -0.06, -0.001), -0.05 (95% CI: -0.10, -0.01), and -0.06 (-0.12, -0.01) for the multi-attribute utility function, vision, ambulation, and pain attributes of the Mark III. In conclusion, incident fractures are associated with reduced HRQL in both men and women. These impairments should be addressed to improve patient outcomes.

A Randomized Controlled Assessment for Effectiveness of an Evidence-based Guideline for Osteoporosis and Osteoporotic Fracture Prevention: Design and Pre-intervention Assessment. M. Iki¹, Y. Nakatani², M. Komatsu³, J. Tamaki¹, E. Kajita³. ¹Public Health, Kinki University School of Medicine, Osaka-Sayama, Japan, ²Community Nursing, Hamamatsu University School of Medicine, Hamamatsu, Japan, ³Public Health and Home Nursing, Nagoya University School of Health Sciences, Nagoya, Japan.

Background: Many evidence-based clinical guidelines have been published for the treatment of patients with osteoporosis and for its prevention. However, only a little evidence for the effectiveness of such guidelines has been obtained.

Aim: To assess whether an evidence-based guideline helps public health professionals improve their preventive programs for osteoporosis better than other information.

Setting: Nation-wide study for community health centers in Japan.

Design: Randomized controlled trial with allocation concealed from evaluators.

Subjects: 100 municipal health centers were selected randomly from all the centers in Japan which responded to our screening questionnaire for this study and had a plan of revising the preventive programs for osteoporosis.

Primary outcome: Change in a score for the concordance of the programs provided by the centers to corresponding evidence before and after the intervention.

Intervention: Use of an evidence-based practice guideline which was compiled by the authors for public health practitioners to prevent community-dwelling people from osteoporosis and osteoporotic fracture. The guideline was approved with the AGREE instrument to have good quality. After the pre-intervention assessment of the concordance score, the independent controller of the trial allocated the centers randomly to one of the intervention and the control groups. The controller sent several copies of the guideline to each center of the intervention group and asked to revise the programs by using the guideline. He also asked each center of the control group to revise their program with any information other than the guideline.

Results: The screening questionnaires were sent to 1,978 community health centers throughout Japan and 1319 centers (66.7%) responded. 100 random samples were obtained and random allocation was successfully performed. The revised programs are being implemented in both groups. A post-intervention assessment will be conducted to know the change in the concordance score of the programs to the evidence through the intervention. **Conclusions:** The first half process of the present trial has been successfully performed. We will soon conduct a post-intervention assessment of the revised programs. The effectiveness of the guideline for osteoporosis prevention will be clarified on the outcome basis next year.

Poverty Is a Risk Factor for Osteoporotic Fractures. M. Sosa¹, M. Navarro², P. Saavedra³, P. Lainez², M. Torres², M. Marerro², C. Medina². ¹Ciencias Médicas y Quirúrgicas, University of Las Palmas de Gran Canaria, Hospital University Insular, Spain, Spain, ²Enfermería, University of Las Palmas de Gran Canaria, Grupo de Trabajo Promoción y Educación de la Salud, Spain, ³Mathematics, University of Las Palmas de Gran Canaria, Spain, Spain.

Background: Some life-styles are related to the development of osteoporosis and osteoporotic fractures. Indeed, poverty is closely related to some life-styles. There are few studies about the possible relationship between poverty and osteoporotic fractures.

Objective: To study in a population of postmenopausal women the possible association between poverty and the presence of osteoporosis, determined by Dual X-Ray Absorptiometry (DXA) and the association between poverty and vertebral and non-vertebral fractures.

Method: Cross-sectional study, performed on 1,139 postmenopausal Canarian women. They completed a questionnaire about risk factors for osteoporosis. A complete medical examination and a detailed assessment of their socioeconomic status was also performed. An X-ray of the lateral spine was also performed. We measured bone mineral density by DXA in the lumbar spine and proximal femur. Finally, we estimated ultrasound parameters at the calcaneus (QUS).

Results: Group I (Poverty Group) was composed by 474 women. Group II (Controls), was composed by 665 women without poverty. Poverty Group had lower values of BMD in the lumbar spine than controls ($0.86 \pm 0.18 \text{ g/cm}^2$ vs $0.89 \pm 0.16 \text{ g/cm}^2$, $p = 0.001$). There were no statistical significant differences at the proximal neck. Indeed, Group I had lower values of some QUS parameters, (SOS and QUI). There were at least an osteoporotic fracture in 37.8% of women with poverty while controls had a fracture in 27.5% ($p < 0.001$). Vertebral fractures were also more prevalent on Group I (poverty), than in controls (24.7% vs 13.4%, $p < 0.001$). There were no statistical differences in non-vertebral fractures between the two groups.

Conclusions: Postmenopausal women with poverty showed lower BMD values in the lumbar spine than controls. Indeed, they had lower values of QUS at the calcaneus and a higher prevalence of vertebral fractures. In postmenopausal women with poverty, the risk of osteoporosis and fragility fractures should be taken into account to establish adequate preventive programs.

Type of fractures	Prevalence of fractures.		p value
	Group I Poverty n= 474	Group II. Controls n= 665	
Total	37.8	27.5	< 0.001
Vertebral	24.7	13.4	< 0.001
Non-vertebral	17.5	17.1	0.872

Disclosures: M. Sosa, None.

Positive Association of Physical Exercise and Coffee Consumption with BMD in Postmenopausal Women: The Fukuoka Cohort Study. R. Takayanagi¹, M. Adachi², K. Ohnaka², H. Kawate², S. Kono³. ¹Department of Medicine and Bioregulatory Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, ²Department of Geriatric Medicine, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, ³Department of Preventive Medicine, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.

The etiology of osteoporosis is multifactorial, and lifestyle factors seem to play an important role in the occurrence and progression of osteoporosis. We have recruited 1294 women (50-74 years of age) in The Fukuoka Cohort Study, interviewed about lifestyle, and measured body composition, blood chemistry and BMD of hip and spine using DXA measurements. We examined the relationship between the BMD values adjusted for age and these lifestyle parameters.

Both hip and spine BMD values were associated positively with body mass index, abdominal circumference, and hip circumference, and inversely with the duration after menopause. The spine BMD was higher in diabetic subjects than in non-diabetic subjects. HbA1c values were also positively associated with both hip and spine BMD. Physical exercise levels were positively associated with the hip BMD ($p=0.047$). Although no clear association was observed for green tea and milk consumption, coffee consumption was associated with higher BMD values of the hip and spine.

Multivariate analysis showed that age, BMI, hip circumference and duration after menopause was associated with both hip and spine BMD independently. Furthermore, positive associations with HbA1c values and coffee consumption remained after adjustment for age, BMI, hip circumference and duration after menopause. This present study firstly supports that coffee consumption may be protective against osteoporosis in postmenopausal women.

Disclosures: R. Takayanagi, None.

Long Term Retention of Knowledge from an Osteoporosis Education Program. P. S. Via*, V. I. Petkov*, R. A. Adler. Endocrinology Section, McGuire Veterans Administration Medical Center, Richmond, VA, USA.

The study objective was to evaluate the effects of education on knowledge gain and retention in a population of high-risk veterans attending an osteoporosis education class. Methods: Veterans with low bone mass were scheduled for an Osteoporosis Education Seminar. Attendees were invited to complete a 15-question anonymous test with content about osteoporosis (risk factors, sources of Ca and Vit D, use of glucocorticoids) prior to the seminar and again at the conclusion of the seminar. The same test was mailed at 6 and 12 months after the education seminar.

Results: During the study period of 14 months, a total of 318 patients attended the Osteoporosis Education Seminar. Of them, 226 agreed to participate in our study and 209 completed both pre and posttests and were included in the analysis. The mean age of study participants was 70.4 (± 9.4) years, 67.3 % were Caucasian, and 94.3% were men. There was a significant increase in osteoporosis knowledge evaluated by the total score of the administered test (paired t-test p-value < 0.0001). The response rate at 6 months was 63% and at 12 months 52%. Responders did not differ significantly from non-responders in any of the examined characteristics. Compared to pre-tests scores, the participants still had significantly higher scores at 6 and 12 months post education 10.1 (2.4) and 10.2 (2.5) vs. 7.6 (2.7), paired t-test p-value < 0.0001. There was a significant decrease in the mean scores at 6 and 12 months post education compared to the post-test scores immediately after the education class (10.2 vs. 12.2).

Conclusions: The knowledge about osteoporosis gained in 2-hour educational seminar was retained over 1 year.

The Influence of Prior and Current Weight Change on Forearm Bone Loss in Menopausal Women, a 15 Year Longitudinal Population-Based Study. The Nord-Trøndelag Health Study, Norway. S. Forsmo, A. Langhammer*. Dept. of Public Health and General Practice, Norwegian University of Science and Technology, Trondheim, Norway.

Low body weight and weight loss has detrimental effects on bone. The purpose of this study was to investigate the effect on forearm bone mineral density (BMD) of weight change 11 years prior to, and during, a five years follow-up study in peri- and postmenopausal women.

In 1984-86, a total of 8,856 women aged 45-60 years, virtually all Caucasians, attended the first Nord-Trøndelag Health Study (HUNT I). Among these women, a random sample of 2,795 was invited to distal forearm densitometry (SXA technology) in 1995-97 (HUNT II), and 2,188 women (mean age: 65.1 years) attended. In 2001, 2,098 women were invited for subsequent forearm BMD, weight and height measurement and 1,421 (67.8%) attended. After exclusion of women reporting hyper- or hypothyroidism or with missing weight data, a total of 1,302 women were eligible for analyses. Weight change was defined as a more than 1 kg increase or loss. The influence of weight change on BMD was assessed by linear and logistic regression and in general linear models, adjusting for body weight, smoking and oestrogen use at HUNT II.

During the 11.3 years between HUNT I and HUNT II, a total of 17.3% had lost and 68.8% had gained more than 1 kg. During the next 4.6 years, weight loss was observed in 40.1% and weight gain in 32.6% of the women. A total of 85 (6.5%) had lost and 284 (21.8%) had gained weight during both periods of observation. Mean annual loss in BMD was 1.03 %, highest in the youngest and oldest age groups. In linear regression models, with either prior or current weight change as independent variables, a statistically significant positive relationship between changes in weight and BMD was found. Women with previous weight loss experienced increased bone loss compared to women with previous weight gain, also when current body weight was stable or increasing. A significant reduction in bone loss was only seen in women who had gained more than 3.5 kg after a history of prior weight loss. In a logistic regression model with prior and current weight change (gain, stable and loss) as independent variables, the adjusted odds ratio (OR) for bone loss in the highest age-specific quartile (most bone loss) was 1.42 (p<0.05) for the category of prior weight loss and 1.37 (p<0.05) for current weight loss, with weight gain as reference categories. There was no interaction between previous and current weight change. The study shows that both prior and current weight loss, independently of each other, are associated with increased bone loss at the distal forearm in middle-aged and elderly women. Weight gain reduces bone loss.

Disclosures: S. Forsmo, None.

Change of Bone Mineral Density and Biochemical Markers of Bone Turnover in Patients on Suppressive L-thyroxine Therapy for Differentiated Thyroid Carcinoma. S. Hong, W. Park*, S. Kim*, M. Nam*, Y. Kim*. Internal Medicine, Inha University, Incheon, Republic of Korea.

Untreated hyperthyroidism and high dose of thyroid hormone are associated with osteoporosis. Bone mineral density (BMD) has been shown to be increased in postmenopausal females with postthyroidectomy hypoparathyroidism. However, their effect on the BMD and biochemical markers of bone turnover in patients on long-term suppressive L thyroxine therapy for differentiated thyroid carcinoma. In this study, we measured BMD of lumbar spine and femur and bone turnover markers in 7 premenopausal, 22 postmenopausal women with thyroid carcinoma at the baseline and during the follow-up period (12th-48th month) using dual-energy x-ray absorptiometry. Biochemical marker of bone resorption was measured by urine deoxypyridinoline and bone formation by serum osteocalcin. None of the women gave a medical history that could possibly affect bone metabolism. All of them had undergone a total thyroidectomy and subsequent thyroxine therapy. Their age ranged from 39-76 years old, with a mean of 51.7 year. TSH was suppressed during the study. The results showed that BMD of femur and lumbar were not changed significantly in pre, postmenopausal women. Postoperative hypoparathyroidism occurred in 4 premenopausal women and 12 postmenopausal women. BMD of femur neck was changed 0.003 ± 0.066 g/cm² (p>0.05). Patients with hypoparathyroidism had higher BMD gain than those without hypoparathyroidism in femur (-2.14 vs 3.65 %, p<0.05). Biochemical markers of bone turnover, serum osteocalcin and urine deoxypyridinoline were not changed significantly. For all patients enrolled in this study TSH exhibited a significant negative correlation with osteocalcin ($r=-0.50$; p-value <0.01) but not with deoxypyridinoline ($r=-0.03$; p-value=0.9) levels. Baseline TSH was negative correlation with baseline lumbar spine BMD($r=-0.47$, p-value <0.05), follow up lumbar spine($r=-0.46$, p-value <0.05) and trochanter BMD($r=-0.44$, p-value<0.05). In conclusion, patients with well differentiated thyroid carcinoma are not at great risk of bone loss. The state of chronic hypoparathyroidism is associated with increased BMD, especially at the femur neck.

Disclosures: S. Hong, None.

Effects of Daily Muscle Trainings on Falls and Vertebral Fractures in the Elderly Osteoporotic Women. T. Horiuchi¹, A. Kanemaru², T. Katoh², H. Tobimatsu¹. ¹Endocrinology, Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan, ²Rehabilitation, Tokyo Metropolitan Geriatric Hospital, Tokyo, Japan.

Objective: We conducted a randomized case control study for one year to examine the effects of the home daily exercises to prevent osteoporotic women from falling and suffering fracture. Subjects & Methods: Ninety-three osteoporotic elderly women were recruited to participate in this study and they were divided into two groups: one is the control whose physical strength we only estimate, whereas the other group were intervened by exercise. The exercise group were instructed to repeat daily muscle training at home. The exercise instruction include muscle training to increase the strength of abdominal, back, quadriceps, gastrocnemius, soleus and plantaris muscles. In order to evaluate muscle strength we measured grasp power (GP), knee flexion strength (KNS), maximal walk velocity (MAW) and 3m timed up and go test (TUGT), lumbar and femoral bone mineral density and bone metabolic markers before and after one-year training, checking the reproducibility and QOL with SF36 every six months. Falls frequencies and vertebral fractures incidences were also examined. Statistics were done using a two-way ANOVA and stepwise multiple regression analysis. The medications for osteoporotics have not been altered in all participants during this study. Results: LBMD were significantly increased in both groups for one year (p<0.05). In exercise group GP, MAW and KNS were significantly increased, and TUGT were significantly decreased (p<0.05). There was a graph interaction between control and intervention group in left KNS, which means that a significant difference between two groups disappeared in one year (p=0.006). Physical component score and mental component score in SF36 were not changed in both groups. Falls frequencies were decreased in two groups, showing a trend of steep reduction in a training group. There was no significant difference in vertebral fracture incidence between two groups. In multivariate regression analysis TUGT was significantly associated with Falls frequencies (p<0.0001). Conclusion: Exercise for the elderly women are effective to increase the strengths of muscles. Exercises might be effective to prevent elderly osteoporotics from falling. We should furthermore continue to perform exercise instruction as an intervention using TUGT.

Disclosures: T. Horiuchi, None.

Back Extensor Strength, Lumbar Spine Mobility and Spinal Inclination as Related Factors for Falls in Osteoporotic Patients. Y. Kasukawa, N. Miyakoshi, M. Hongo, Y. Ishikawa, H. Noguchi, K. Kamo, H. Sasaki, Y. Shimada*. Department of Orthopedic Surgery, Akita University, Akita, Japan.

We have previously reported that mobility of the lumbar spine and back extensor strength (BES) are decreased in osteoporotic patients with a history of falls or fear of falling. However, factors related to the history of falls or tendency for falling remain unclear. The purpose of this study was to clarify possible factors including spinal deformity, mobility and BES related to history of falls or fear of falling in osteoporotic patients. Subjects comprised 92 elderly patients with osteoporosis (mean age, 74 years; range, 60-96 years) who had no neurological or metabolic disorders other than osteoporosis. Subjects were divided into 2 groups: subjects with a history of falls, fear of falling, or need for support when walking (Fall group, n=52; 11 men, 41 women); and subjects with no such history (Non-fall group, n=40; 12 men, 28 women). Angles of thoracic or lumbar kyphosis and mobility of the thoracic or lumbar spine were measured in the upright position and at maximum flexion/extension using a computer-assisted device (SpinalMouse). Spinal inclination reflecting spinal sagittal alignment was also evaluated using SpinalMouse. Bilateral grip strengths were measured using a handgrip dynamometer. Isometric BES was measured using a strain-gauge dynamometer. No significant differences between groups were observed in age, gender, height, bodyweight, or body mass index. Mean grip strength and BES were 24% (p<0.01) and 30% (p<0.05) lower in the Fall group than in the Non-fall group. Angle of lumbar kyphosis and mobility of lumbar spine were 81% (p<0.01) and 31% (p<0.01) lower in the Fall group than in the Non-fall group. However, no significant differences were observed between groups in angle of thoracic kyphosis or mobility of the thoracic spine. Logistic regression analysis was performed to clarify risk factors for falling in these osteoporotic patients. BES, mobility of the lumbar spine and spinal inclination were identified as significant contributors to falls. These results suggest that decreased back extensor strength, decreased mobility of lumbar spine, and increased spinal inclination could represent risk factors for falls in patients with osteoporosis.

Disclosures: Y. Kasukawa, None.

T342

Risk Factors for Osteoporosis and Bone Mineral Density in Late Postpartum Women. C. A. M. Kulak¹, A. A. Franke^{*1}, B. M. Filippetto^{*2}, A. A. Urbanetz^{*2}, V. Z. C. Borba¹. ¹Endocrinology, UFPR, Curitiba, Brazil, ²Gynecology and Obstetrics, UFPR, Curitiba, Brazil.

Calcium and bone metabolism is altered during pregnancy and lactation, some adaptive changes occur during pregnancy to preserve the mother's bone mass. In breast-feeding period these compensatory alterations do not exist. Our purpose was to determine the existence of known risk factors for low bone mass in a group of women in the late postpartum period, evaluate the bone mass in these women and correlate bone mass to the presence of risk factors. We did an observational, transversal study in 81 women in the postpartum period recruited from the Maternity Outpatient Clinic of the Hospital de Clinicas da Universidade Federal do Paraná, during a routine return visit after 40 days of child birth. Patients who had agreed to participate had been submitted to a questionnaire approaching known risk factors for decreasing bone mass and to a DXA bone densitometry measurement in lumbar spine and hip. Blood sample for posterior evaluation of laboratorial parameters was harvested. We analyzed 81 women with an average age of 28.7 ± 7.7 years at 43.4 ± 9.2 days after childbirth. We observed that 91.4% were Caucasian. We demonstrated an average bone density in lumbar spine of 0.989 ± 0.137 g/cm² and hip of 0.931 ± 0.128 g/cm². In accordance with the ISCD criteria, 8 patients (9.8%) had presented a low bone mass for their age in lumbar spine (Z score less than -2.0). These patients were younger, with an average age of 26.4 ± 8.9 years old (RR 0.22; p<0.05), and average BMI of 23.11 ± 3.77 kg/m² against 25.8 ± 4.9 kg/m² of the general group (RR 0.36; p<0.05). This group also showed a greater smoking index, physical inactivity, personal history of previous bone fractures and familiar history of osteoporosis (compared to all of them p>0.05). We did not observe in this group differences in calcium consumption, parity, age in a first gestation, or duration of breast-feeding. Our study group data suggest that general risk factors were more related to low bone mass than the factors related to the gestation and breast-feeding.

High Cholesterol, Smoking and Coffee Consumption but Low BMI Are Risk factors for Fractures - a 20-Year Follow-up of Men and Women. K. L. L. Landin-Wilhelmsen¹, P. Trimpou^{*2}, A. Odén^{*2}, L. W. Wilhelmsen^{*2}. ¹Sahlgrenska University Hospital, Section for Endocrinology, Göteborg, Sweden, ²Sahlgrenska University Hospital, Institution of Medicine, Göteborg, Sweden.

According to some studies there is a link between osteoporosis and cardiovascular disease. The purpose was to study this possible link with access to risk factors for fractures. The study comprised a random population sample of men and women aged 25-64 years, N=1396 (52% women), from the 1985 World Health Organisation (WHO), MONITORing of trends and determinants in Cardiovascular disease (MONICA) study in Gothenburg, Sweden.

The baseline examination in 1985 included history of fractures, physical activity at work and during leisure time graded low (1) to high (4), psychological stress, smoking habits graded non-smoker (1) to >24 cigs./day (5), coffee consumption in cups/day, BMI kg/m², waist/hip ratio, blood pressure mmHg, total cholesterol, HDL-cholesterol, triglycerides all in mmol/L and fibrinogen g/L.

Osteoporotic fractures during 20 years follow-up (n=140) were retrieved from the hospital registers of the city.

Out of the measured factors increasing age, previous fractures, higher smoking habits, higher coffee consumption (Hazard rate [HR] =1.07), higher total cholesterol (HR=1.15) and lower BMI (HR=0.96) significantly increased the risk for fractures.

The gradient of risk for fractures per 1.0 standard deviation (SD) towards higher HR was for total cholesterol 1.22 and for BMI 1.21 (lower) when they were included in the same model. There was a positive correlation between the two variables with a partial correlation coefficient with gender taken into account being 0.153 (p<0.001). For comparison it can be mentioned that when all types of osteoporotic fractures were considered the gradient of risk per 1.0 SD for bone mineral density varied between 1.4 and 1.6 depending on location. In summary, there was an equal importance of BMI and cholesterol for osteoporotic fracture risk, but the association had different directions. As for cardiovascular disease smoking and high cholesterol increased risk for fractures. Coffee consumption increased the risk for osteoporotic fractures, but coffee has not been a risk factor for myocardial infarction according to our experience.

Clinical Factors Associated with Osteoporotic Fractures in a Representative Population of French Women. E. Lespessailles¹, P. Fardellone², C. Roux³, F. Cotte^{*4}, A. Gaudin^{*4}. ¹Rheumatology, CHR Orleans, Orléans, France, ²Rheumatology, CHU Hôpital Nord, Amiens, France, ³Rheumatology, Université René Descartes, Hôpital Cochin, Paris, France, ⁴Health Outcomes Studies, GlaxoSmithKline, France, Marly le Roi, France.

Background: Post-menopausal osteoporosis represents a major socio-economic problem. Bone fracture is the main clinical consequence in this population.

Objectives: The aim of the study was to identify risk and protective factors for fracture in French women aged 45 or more years with osteoporosis

Methods: This study was a cross-sectional observational epidemiological survey carried out in a representative sample of the population of women aged 45 or more years, constituted according to the quota method, a stratified random sampling method. The risk factors of fractures were analyzed in women with osteoporosis confirmed by DXA. The investigation was conducted by face-to-face home interviews between September and December 2006.

Results: Among the 2,613 interviewed women (mean age: 65.8 +/- 11.2 years), the prevalence of osteoporosis diagnosed by DXA was 9.7%. Fractures were reported by 101 (39.8%) subjects identified with osteoporosis (n=254). The odds-ratios of fractures were significantly associated with age (OR=1.03, per year increase; P=0.031) and the following factors (univariate analysis)(table).

Hormonal replacement therapy, osteoporosis treatment, vitamin D and/or calcium supplementation, smoking, alcohol intake and diabetes were not associated with a risk of fracture.

Conclusion: Several risk factors of fractures in osteoporotic women have been confirmed. This study highlighted the role of fall-related factors in osteoporotic fracture.

Main factors associated with a risk of fracture			
Factors	P	OR	95 % CI
History of cardiovascular problems	<0.001	3.27	1.73 - 6.19
Fracture before 40 years	0.001	2.46	1.44 - 4.19
Reduced mobility	0.001	2.42	1.44 - 4.06
PMO history (> 5 y)	0.01	2.33	1.10 - 4.91
Diagnosed rheumatoid arthritis	0.045	1.96	1.02 - 3.75
Intake of sleeping pills	0.031	1.79	1.09 - 3.58
Well-corrected vision	0.003	0.42	0.20 - 0.75

Chemotherapy Is Associated with Increased Risk of Fracture in Elderly Patients with Non-Hodgkin's Lymphoma. H. Lu^{*1}, M. Cabanillas², S. Fang^{*3}, X. L. Du^{*4}. ¹General Internal Medicine, Section of Rheumatology, UT MD Anderson Cancer Center, Houston, TX, USA, ²General Internal Medicine and Leukemia, UT MD Anderson Cancer Center, Houston, TX, USA, ³Division of Epidemiology, School of Public Health, The University of Texas Health Science Center, Houston, TX, USA, ⁴Division of Epidemiology, School of Public Health, University of Texas Health Science Center, Houston, TX, USA.

Background: With advancements in treatment, patients with non-Hodgkin's lymphoma (NHL) can now survive longer. Early detection and supportive care for long term complications from cancer and its treatment is needed. The incidence of osteoporosis increases with age and prolonged corticosteroid use. Corticosteroids are often part of the chemotherapy treatment for NHL. Untreated osteoporosis can lead to fracture, causing significant morbidity and mortality.

Objective: To determine whether chemotherapy is associated with increased risk of

fracture in elderly patients with NHL.

Methods: Retrospective cohort study using the population-based SEER (Surveillance, Epidemiology, and End Results)-Medicare linked data. Cases reported by the SEER cancer registries from 1992-1999 were matched against Medicare master enrollment files. The study population consisted of patients ≥ 65 years with NHL. We searched for any diagnosis of fracture 1 year prior to and thereafter the diagnosis during 11 years of follow-up.

Results: Of the 13,570 patients identified with NHL, approximately 60% received chemotherapy. African-Americans and patients with stage I disease were less likely to receive chemotherapy. Younger patients and those with lower comorbidity scores were more likely to receive chemotherapy. The prevalence of fracture prior to the diagnosis was significantly lower in patients who were to receive chemotherapy (7.9%) than those who did not (11.1%) ($P < 0.001$). Although fracture rate in both groups increased with follow-up, the rate of fractures after the diagnosis of NHL was significantly higher in patients who received chemotherapy (31.1%) compared to those who did not (18.5%, $p < 0.001$). After adjusting for age, race/ethnicity, tumor stage, comorbidity and radiation therapy in the multivariate logistic regression analyses, patients who received chemotherapy had more than double the risk of fracture compared to patients who did not receive chemotherapy. Other risk factors included more advanced age, female gender and non-African American origin.

Conclusions: This population-based retrospective cohort study demonstrates for the first time that chemotherapy for NHL is associated with a significantly increased risk of fracture in elderly patients. Further prospective studies may be needed to confirm this finding in different populations.

Disclosures: H. Lu, None.

T346

Gold Standard Measurement of Physical Activity Energy Expenditure and Bone Mineral Density in Older Adults: The Health ABC Study. D. C. Mackey¹, T. B. Harris^{*2}, T. M. Manini^{*3}, L. Ferrucci^{*2}, S. E. Hardy^{*4}, E. S. Strotmeyer⁴, F. A. Tykavsky⁵, S. R. Cummings, for the Health ABC Study¹. ¹San Francisco Coordinating Center, California Pacific Medical Center, San Francisco, CA, USA, ²National Institute on Aging, Bethesda/Baltimore, MD, USA, ³University of Florida, Gainesville, FL, USA, ⁴University of Pittsburgh, Pittsburgh, PA, USA, ⁵University of Tennessee, Memphis, TN, USA.

Self-reported physical activity has been associated with bone mineral density (BMD) and rate of change in BMD in older adults, but the effects of objectively measured physical activity on bone have not been well characterized. Doubly labeled water is the gold standard method for assessing physical activity energy expenditure (AEE). Our aims were to determine whether AEE is associated with hip BMD and rate of change in hip BMD among older adults.

We measured AEE over 2 weeks using doubly labeled water in 119 participants (51% women, 45% white, 55% black, mean \pm SD age: 75.7 \pm 2.7 yrs, mean \pm SD weight: 76.3 \pm 15.6 kg) from the prospective Health ABC Study. At the time of the doubly labeled water dosing, we measured hip and whole body BMD with dual energy x-ray absorptiometry (Hologic QDR 4500A). We repeated hip BMD measures two (n=102) and five (n=76) years later. We used general linear models to compare mean baseline BMD and change in BMD across levels of AEE.

AEE was not associated with total hip or femoral neck BMD at baseline (Table). The overall rate of change in total hip BMD over two years was -1.44% (95%CI: -0.87 to -2.02%), equivalent to a loss of 13.0 mg/cm² (8.1 to 18.0 mg/cm²), and over five years was -3.31% (-2.26 to -4.37%), equivalent to a loss of 30.1 mg/cm² (20.6 to 39.6 mg/cm²). There were no differences in 2-year ($p=0.335$) or 5-year ($p=0.422$) percentage rate of change in total hip BMD across tertiles of AEE, controlling for age, gender, race, total bone-free lean mass, total fat mass, weight change, and clinical site. Similar results were observed for the femoral neck.

Table. Mean BMD (g/cm²) and 95% confidence intervals by tertile of AEE, adjusted for age, gender, race, total bone-free lean mass, total fat mass, and clinical site.

Activity energy expenditure (AEE), kcal/d	Total Hip BMD (n=119)	Femoral Neck BMD (n=119)
Tertile 1 (94 to < 522)	0.891 (0.849-0.933)	0.741 (0.703-0.779)
Tertile 2 (522 to < 761)	0.907 (0.868-0.946)	0.759 (0.724-0.794)
Tertile 3 (761-2050)	0.864 (0.827-0.901)	0.723 (0.690-0.756)
P for trend	0.304	0.360

Energy expenditure from physical activity measured with the gold standard technique was not associated with hip BMD or rate of change in hip BMD in older women and men. Exercise prescriptions based on simple energy expenditure goals may not influence bone density in older populations.

C-reactive Protein (CRP), Bone Mineral Density (BMD) and Hip Fracture Risk in Elderly Men and Women: The Framingham Study. R. R. McLean¹, R. Roubenoff^{*2}, M. T. Hannan¹, L. A. Cupples^{*3}, D. P. Kiel¹. ¹Hebrew SeniorLife & Harv Med Sch, Boston, MA, USA, ²Biogen Idec, Cambridge, MA, USA, ³BU Sch of Public Health, Boston, MA, USA.

Several of the pro-inflammatory cytokines that regulate immune response also mediate bone metabolism. Many inflammatory diseases are associated with osteoporosis, and previous studies suggest that otherwise healthy individuals with elevated CRP, an indicator

of systemic inflammation, are at increased risk of low bone mass and fractures. We examined the association of CRP with BMD and hip fracture risk in men and women in the now elderly Framingham Study Original Cohort. Non-fasting blood samples were drawn from 310 men and 502 women (mean age 78 yr, range 72-94) in 1992-94 (baseline) and serum CRP was measured to the nearest mg/L by an immunoprecipitation assay. Participants were classified into undetectable (0 mg/L), medium (1 to 2 mg/L) and high (≥ 3 mg/L) CRP groups. BMDs of the proximal femur (neck, trochanter) and lumbar spine (g/cm²) were measured at baseline using a Lunar DPX-L. Incident hip fractures were ascertained from baseline through December 2003. Analysis of covariance was used to compare mean BMD among CRP groups. Cox proportional hazards regression was used to calculate the hazard ratios (HR) and 95% confidence intervals (CI) estimating the relative risk of hip fracture for the medium and high CRP groups versus the undetectable group. All analyses were adjusted for sex and baseline measures: age (yrs), weight (lbs), height (in), current smoker (y/n), caffeine intake (>2 cup/d: y/n), alcohol intake (oz/wk), and current estrogen use (y/n) among women. The proportions (%) of participants with undetectable, medium and high CRP were 68, 13, and 19, respectively.

	Least-squares mean (\pm SE) BMD (g/cm ²) for CRP groups		
	Undetectable	Medium	High
Femoral neck	0.767 (0.005)	0.771 (0.012)	0.777 (0.010)
Trochanter	0.695 (0.005)	0.702 (0.012)	0.713 (0.010)
Lumbar spine	1.147 (0.010)	1.149 (0.022)	1.130 (0.019)

There were no significant differences in baseline BMD among CRP groups for either femur site or for the lumbar spine (all $p > 0.1$). Median hip fracture follow-up was 9.5 yr with 66 hip fractures (men 12, women 54) occurring over follow-up. Participants in the both the medium (HR 0.95; 95%CI 0.49, 1.95) and high (HR 0.99; 95%CI 0.48, 2.05) CRP groups had similar hip fracture risk to those with undetectable CRP. There was a similar lack of association with hip fracture risk when only the women were examined. In contrast to previous findings, these results suggest that low-grade systemic inflammation may not be a risk factor for low bone mass or increased fracture risk among community-dwelling elders.

Risk Factors for Osteoporosis and Fragility Fractures in Postmenopausal Women and Men Older than 50 Attended in a Primary Care Center of Spain: The Camargo Cohort Study. J. M. Olmos¹, C. Ramos^{*2}, J. L. Hernández^{*1}, P. García^{*2}, J. Martínez^{*1}, J. de Juan^{*2}, D. Nan^{*1}, C. Valero^{*1}, J. González-Macías¹. ¹Medicina Interna, Hospital Universitario M. Valdecilla. Universidad de Cantabria, Santander, Spain, ²Centro de Salud "José Barros". Camargo. Universidad de Cantabria. Santander, Spain, Santander, Spain.

The purpose of the study was to determine the prevalence of several risk factors for osteoporosis and fragility fractures in a population of postmenopausal women and men older than 50. We present preliminary results of the first 756 subjects (604 women, and 152 men) included in the Camargo Cohort Study, a community-based study designed to evaluate the prevalence of metabolic bone diseases and disorders of mineral metabolism, as well as the prevalence of fractures and risk factors for osteoporosis and fragility fractures, in postmenopausal women and men older than 50 attended in a primary care center of Northern Spain. Studied women and men were 63 \pm 9 and 65 \pm 8 years old, respectively. Demographic, anthropometrics, and clinical variables were collected, and subjects were evaluated with a questionnaire of risk factors for osteoporosis and fragility fractures. The prevalence of main osteoporosis risk factors in women and men was as follows: familial history of fragility fractures: 18% and 9%; fracture after 40 years: 17% and 16%; tobacco and alcohol consumption: 13% / 17%, and 10% / 38%, respectively. Reduced mobility was present in four percent of women and one percent of men. Early menopause (< 40 years) and low body weight (< 57 kg) was present in 15% of women and 11% of men. Thirty two per cent of women and fourteen of men were treated with benzodiazepines, 22% and 11% reported at least one fall during the previous year, and 13% and 18% had hypoaesthesia. Seven percent of women and nine percent of men were taking inhaled or systemic glucocorticoids, respectively. Six percent of women and two percent of men were receiving thyroid hormone treatment. Mean calcium intake in dairy products was 661 \pm 316 mg in women and 563 \pm 337 mg in men. Besides age, the most prevalent risk factors for osteoporosis and fragility fractures in our series were a history of fragility fractures, benzodiazepine use and previous fall. Early menopause, familial history of fragility fractures, low body weight, previous fall and treatment with benzodiazepines were more relevant in women, whereas tobacco and alcohol consumption were more frequent in men.

This study was supported by a grant from the "Fondo de Investigación Sanitaria", Ministerio de Sanidad y Consumo, Spain (FIS: PI05 0125)

The Effect of Anti-epileptic Medications on Bone Mineral Density- A Twin and Sibling Study. S. J. Petty^{*1}, L. M. Paton^{*1}, T. Fedorova^{*2}, S. F. Berkovic^{*1}, P. Sambrook², T. O'Brien^{*3}, J. D. Wark¹. ¹Department of Medicine, RMH, The University of Melbourne, Melbourne, Australia, ²Department of Rheumatology, Institute of Bone and Joint Research, Royal North Shore Hospital, Sydney, Australia, ³Department of Neurosciences, The Royal Melbourne Hospital, Melbourne, Australia.

Patients with epilepsy taking anti-epileptic medications (AED) have an increased fracture risk. There are also increasing numbers of patients taking AED for indications other than epilepsy. We investigated the effects of AED on bone mineral density (BMD) using a twin/sibling matched-pair design, and examined subgroups including current AED users, users of polytherapy (more than one AED concurrently) and the indication for use of AED for effects on BMD compared with non-AED using co-twins or siblings.

Methods: We identified AED-discordant pairs from our twin and sibling research databases and clinical practices. BMD was measured at the lumbar spine (LS), total hip (TH), femoral neck (FN) and total forearm (FA). Total body bone mineral content (TB BMC) also was determined (Hologic 4500A or 1000W). Lifetime duration (LDT) and number (LNM) of AEDs were calculated. Results were expressed as the within-pair percentage difference (paired t test) relative to the non-user. All data were adjusted for age, height and weight.

Results: Fifty-six pairs discordant for AED use were identified (46 current, 10 past AED users; 47 female, 9 male; 21 MZ, 21 DZ twins, 14 sib pairs matched within 3 years of age) with mean (SD) age 45.6 (15.3)y, height 164.7(9.8)cm and weight 70.6 (16.2)kg. Overall group: no significant within-pair difference in age, height, weight, total fat or total lean mass. Within-pair differences were seen at: TH -4.2% (p=0.017), LS -4.0% (p=0.0318); Among current users: TH-5.4% (p=0.01), FN-4.3% (p=0.045), LS -4.8% (p=0.029). Significant within-pair differences were seen related to: polytherapy [FA -3.4% (p=0.049), TH -8.9% (p=0.043), FN -9.7% (p=0.030) (n=14); mean (SD) LMN 3.3(1.9), mean LDT 20.8y (10.3); AED indication epilepsy [TH -5.4% (p=0.011), FN -4.3% (p=0.046), LS -4.8% (p=0.029) (n=41), LDT (SD) 20.8 (13.7)y]. No significant within-pair differences were seen with non-epilepsy indications for AEDs, mean LDT 4.7(6.3)y (n=14).

We conclude that patients taking AEDs, particularly for epilepsy, and taking polytherapy have reduced BMD compared to their non-AED-using siblings. This may reflect severity of epilepsy or duration and number of AEDs used and requires further investigation. Further study is required for patients taking AED for other indications.

Incidence of Osteoporotic Fractures and Vitamin D Status in Hip-fracture Patients. M. Sakuma^{*1}, T. Oinuma^{*1}, N. Endo², E. Endo^{*3}. ¹Orthopedic Surgery, Sado General Hospital, Sado, Japan, ²Orthopedic Surgery, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, ³Orthopedic Surgery, Nagaoka Chuo General Hospital, Nagaoka, Japan.

Osteoporotic fracture among elderly populations has been increasing in worldwide, and the prevalence of hypovitaminosis D in patients with acute hip fracture was pointed out recently.

The purpose of this study was to determine the incidence of osteoporotic fractures and to examine whether osteoporotic patients with hip fracture have lower levels of serum 25-hydroxyvitamin D (25-OHD) compared to non-osteoporotic cases in a particular geographical area: Sado City, Niigata Prefecture, Japan.

From January to December 2004 osteoporotic fractures of vertebra, hip, distal radius and proximal humerus occurred in Sado City was checked. The incidence, age, gender, were checked in each fracture. The levels of serum 25-hydroxyvitamin D (25-OHD), intact parathyroid hormone (intact PTH), alkaline phosphatase (ALP), albumin, and the number of remaining teeth were examined in both hip-fracture and control groups. In the hip-fracture group, serum calcium, serum phosphorus, urine N-terminal crosslinking telopeptide of type I collagen (NTx), bone mineral density (BMD) of the non-fractured hip, the presence of a vertebral fracture on X-ray, severity of dementia, and physical activity level were also examined.

The incidence per 100,000 population was 232.8 in vertebra, 121.4 in hip, 108.6 in distal radius and 37.1 in proximal humerus, respectively. The total incidence of these four kinds of fracture was 499.9 per 100,000 person year. The average injury age was 81.4 in hip, 77.7 years old in vertebra, 75.7 in proximal humerus and 60.2 in distal radius, respectively. 81% of hip fracture patients had vertebral fracture (more than one fracture).

Both the serum 25-OHD and serum albumin levels were significantly lower in patients with hip fracture than in controls, and the intact PTH level was significantly higher in patients with hip fracture. In the hip-fracture group, 62% of the subjects had hypovitaminosis D (25-OHD < 20 ng/mL) and one-fifth of cases with hypovitaminosis D showed elevated PTH levels (> 65 pg/mL). On the other hand, in the control group, hypovitaminosis D occurred in 18.9% of the subjects. The serum 25-OHD level showed a decrease as the severity of dementia progressed and the activity level decreased.

Our results indicate that about two-thirds (62%) of hip-fracture patients had vitamin D insufficiency, suggesting that this condition is closely associated with hip fracture in elderly people. Therefore, a decrease in serum 25-OHD level is a useful index for the risk of hip fracture in elderly people.

Does Oral Contraceptive Use Adversely Impact Bone Density in Young Women? D. Scholes¹, L. E. Ichikawa^{*1}, A. Z. LaCroix², L. Spangler¹, S. M. Ott³. ¹Center for Health Studies, Group Health, Seattle, WA, USA, ²Fred Hutchinson Cancer Research Ctr, Seattle, WA, USA, ³U of WA, Seattle, WA, USA.

Emerging evidence suggests that contemporary oral contraceptive (OC) formulations may act to suppress bone mass accrual in young women who are gaining bone. We report on a cross-sectional evaluation of OC use and bone mineral density (BMD) in adolescent and young adult women, ages 14-30 years. Participants were enrollees of Group Health Cooperative, a Washington State HMO, who were selected from the health plan computerized databases based on prescriptions for OC use and age. We enrolled 606 women: 389 OC users (42% new and 58% prevalent OC users; OCs contained ≤ 35 mcg ethinyl estradiol, EE); and 217 OC age-similar non-users. BMD (DXA) was measured at the hip, spine, and whole body. Data on OC use and other factors related to bone health were collected via interview and survey. Overall, 51% of the cohort was 14-18 years of age. Relative to non-users, OC users were more likely to be White, to currently smoke, and consume less calcium. Women who reported current OC use for >12 months had lower mean hip BMD than non-users (p=0.10) after adjusting for age, race, BMI, physical activity, calcium intake, and current smoking status, with smaller differences at the spine and whole body. Among 14-18 year olds, adjusted BMD values for OC users (mean current use 6 months, range <1-37 months) did not differ from non-users at any anatomic site (Table). Among 19-30 year-old women (mean current OC use 13 months, range <1-135 months), adjusted mean BMD at the spine was significantly lower with increasing duration of current OC use (p, trend=0.01), with a similar trend for the hip (p, trend=0.31). In this group, mean spine BMD was 4.8% lower for women with >24 months' OC use vs. non-users. Evaluation of cumulative lifetime OC use attenuated these trends (p, trend=n.s.), suggesting there may be some BMD recovery after OC discontinuation. The data from this sizeable study group provide evidence that current prolonged use of OCs containing ≤ 35 mcg EE may adversely impact bone density in young women.

Mean BMD by Duration of Current OC Use and Age Group					
Duration of current OC use (months)	N	Age 14-18 years		Age 19-30 years	
		Adj [†] mean BMD (g/cm ²)	Adj [†] mean BMD (g/cm ²)	Adj [†] mean BMD (g/cm ²)	Adj [†] mean BMD (g/cm ²)
		Hip (s.e.); Spine (s.e.)	Hip (s.e.); Spine (s.e.)	Hip (s.e.); Spine (s.e.)	Hip (s.e.); Spine (s.e.)
0 (non-users) [*]	111	0.992 (0.01); 1.003 (0.01)	1.006 (0.01); 1.017 (0.01)	0.985 (0.01); 1.040 (0.01)	0.985 (0.01); 1.036 (0.01)
>0-12	163	0.993 (0.02); 1.015 (0.02)	1.006 (0.01); 1.017 (0.01)	0.967 (0.01); 1.025 (0.02)	0.954 (0.02); 0.990 (0.02)

Does Low Bone Mass Predict Carotid Atherosclerosis in Postmenopausal Women? The Japanese Population-based Osteoporosis (JPOS) Cohort Study. J. Tamaki¹, M. Iki², Y. Hirano^{*3}, Y. Sato^{*4}, E. Kagita^{*5}, S. Kagamirori^{*6}, Y. Kagawa^{*7}, H. Yoneshima^{*8}. ¹Public Health, Kinki Univ. School of Med., OsakaSayama, Japan, ²Public Health, Kinki Univ. School of Med., OsakaSayama, Japan, ³Internal Medicine, Division of Cardiology, Kinki Univ. School of Med., OsakaSayama, Japan, ⁴Domestic Science, Jin-ai Women's College, Fukui, Japan, ⁵Public Health & Home Nursing, Nagoya Univ. School of Health Sciences, Nagoya, Japan, ⁶Welfare Promotion & Epidemiology, Univ. of Toyama, Toyama, Japan, ⁷Kagawa Nutrition Univ., Tokyo, Japan, ⁸Shuuwa General Hospital, Kasukabe, Japan.

The present retrospective study was conducted as a part of the Japanese Population-based Osteoporosis (JPOS) Study to clarify whether low bone mass predicts the increase of carotid intima-media thickness (IMT) in women. In 2006, the JPOS study followed 1040 women aged 15-79 years in 1996 selected randomly from three areas in Japan (follow-up rate: 68.6%). We analyzed 271 postmenopausal women aged 50 or older in 2006, after excluding the subjects with a history of cardiovascular disease, or any disease or medication affecting bone metabolism. The lumbar spine BMD measured with dual x-ray absorptiometry at baseline was used. McCloskey-Kanis criteria was used for diagnosis of vertebral fractures at baseline. The maximum IMT of carotid bifurcation was measured by B-mode ultrasonography in 2006. The intraobserver test-retest reliability of the IMT measurement was 12.4%. Information of present illnesses was interviewed with a questionnaire. Age-adjusted IMT values among normal, osteopenia, osteoporosis or presence of vertebral fracture were 1.15mm, 1.36mm, and 1.38mm among the women with less than 10 years since menopause (YSM<10) (n=123, mean age at baseline: 55.6±4.1 y), respectively (p<0.05 for trend), 1.30mm, 1.37mm, 1.53mm, respectively (p=0.083) among the women with 10 years or more since menopause (10≤YSM) (n=148, mean age: 66.6±5.9 y). T-score of spine BMD and presence of vertebral fracture were significantly associated with the IMT values with multivariate analysis adjusted for factors shown in the table among the women with YSM<10. Adjusted IMT values by lumbar bone status are

also shown in the table. Low lumbar bone mass or the presence of vertebral fracture may predict the subclinical carotid atherosclerosis in women with less than 10 years since menopause, and in postmenopausal women who have no risk factors of cardiovascular disease.

	Adjusted carotid intima-media thickness values, mean(95%CI)mm, by lumbar bone status		
	Normal -1≤T-score	Osteopenia -2.5≤Tscore<-1	Osteoporosis /Vertebral fracture
YSM<10 (n=123)a,*	1.14 (1.04,1.24)	1.37 (1.27,1.48)	1.39 (1.20,1.57)
10≤YSM (n=148)a	1.36 (1.17,1.16)	1.36 (1.25,1.47)	1.50 (1.37,1.63)
YSM<10 w/o CVD RFs(n=53)b,c	1.08 (0.95,1.22)	1.32 (1.17,1.47)	1.36 (1.05,1.66)
10≤YSM w/o CVD RFs (n=57)c,*	1.11 (0.74,1.47)	1.31 (1.14,1.48)	1.59 (1.40,1.78)

YSM: Years since menopause, w/o CVD RFs: Total cholesterol(TCH) <5.7mmol/L, w/o hypertension (HT) at baseline, or hyperlipidemia or diabetes mellitus (DM) at follow-up. *P<0.05, b P=0.059 for trend test.

a Adjusted for age, TCH, HT at baseline, BMI, SBP, hyperlipidemia, DM, medication use affecting IMT values, smoking & drinking habits at follow-up.

Trabecular Bone Structure in Men of African Heritage: Age Patterns and Familial Resemblance. X. Wang¹, D. Inglis², C. L. Gordon³, Y. Sheu⁴, C. M. Kammerer¹, C. H. Bunker⁴, V. W. Wheeler⁵, A. L. Patrick⁵, J. A. Cauley⁴, J. M. Zmuda⁴. ¹Dept of Human Genetics, University of Pittsburgh, Pittsburgh, PA, USA, ²Dept of Civil Engineering, McMaster University, Hamilton, ON, Canada, ³Dept of Radiology, McMaster University, Hamilton, ON, Canada, ⁴Dept of Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA, ⁵The Tobago Health Studies Office, Scarborough, Trinidad and Tobago.

Changes in trabecular structure with aging may influence bone strength independent of bone mass. We investigated the age-related patterns and, for the first time, the familial resemblance of trabecular architectural parameters in 803 Afro-Caribbean men (33 full-sib and 7 half-sib pairs) aged 40 to 92 years (mean±SD: 58±10 yr) who were recruited from the population of Tobago. All men underwent peripheral quantitative computed tomography (pQCT) measures of the distal radius and tibia. The pQCT images were acquired with an in-plane pixel size of 0.2 mm x 0.2 mm and a slice thickness of 2.2 mm. Specialized segmentation and analysis software (pQCT Pro) was used to assess indices of apparent trabecular structure including: trabecular bone volume/tissue volume (BV/TV, %), average thickness (Th_{AVE}, mm), average marrow hole size (Hole_{AVE}, mm²), number (Num., 1/mm) and connectivity index (CI, %). We determined the % difference between middle aged (40-49 yr; n=206) and older (>70 yr; n=126) men. Familial correlation was estimated among the subset of 33 brother pairs. BV/TV, Num., Th. and CI decreased whereas Hole increased with age with greater differences at non-weight (radius) than weight bearing (tibia) sites (Table). Although the sample size was small, we found statistically significant (P<0.05) familial correlations for BV/TV (r=0.47) at the radius and Th. (r=0.53) and CI (r=0.41) at the tibia, suggesting a genetic contribution to these traits. Further studies are needed to understand the natural history and genetic and environmental determinants of trabecular architectural changes with aging. A better understanding of the factors contributing to trabecular architecture may lead to new ways to preserve bone strength with aging.

Table. Percent difference in trabecular structure between middle-aged (40-49 yr) and older (>70 yr) Afro-Caribbean men.

Skeletal Site	BV/TV (%)	Thick _{AVE} (mm)	Number (1/mm)	CI (%)	Hole _{AVE} (mm ²)
Radius	-10%***	-10%***	-9%***	-56%***	78%***
Tibia	-6%**	-9%***	-7%(P=0.06)	-30%*	49%**

*P<0.05, **P<0.01, *P<0.0001; P value for differences between middle aged and older men.

The Association Between Psychiatric Illness and Falls: Geelong Osteoporosis Study. L. J. Williams*, M. J. Henry*, F. N. Jacka*, M. Berk*, S. Dodd*, M. A. Kotowicz, G. C. Nicholson, J. A. Pasco. Clinical and Biomedical Science: Barwon Health, The University of Melbourne, Geelong, Australia.

Agents used in the treatment of depressive and anxiety disorders are known to cause sedation and have been associated with falls. However it is not clear whether psychiatric illness itself contributes to the increased risk of falling. This study investigated the association between depressive and anxiety disorders and the risk of falls in a population-based sample of women living in the community. Depressive and anxiety disorders for the preceding 12-month period were ascertained by clinical interview (SCID-I/NP); current medication use and falling history were self-reported. Participants were classified as fallers if they had fallen to the ground at least twice during the same 12-month period. Current users of antipsychotic medication and

mood stabilisers were excluded (n=12) resulting in a sample of 961 women aged 20-93yr (median 53yr, IQR 38-67).

Fifty-one women (5%) were classified as fallers. Fallers were older [61 (IQR 51-73) vs. 52 (37-66) yr, p=0.001] and more likely to use antidepressants (27% vs.11%, p<0.001) or benzodiazepines (12% vs. 4%, p = 0.005) than non-fallers. Those with depression (n=110) were younger [48 (36-60) vs. 53 (38-68) yr, p=0.01] and yet more likely to fall (10% vs. 5%, p=0.02). Age-adjusted odds for falling were 2.7-fold greater for women with depression (OR=2.7, 95% CI 1.3-5.5, p=0.007) and this relationship was attenuated after adjusting for antidepressant and benzodiazepine use (OR=2.0, 95% CI 0.9-4.1, p=0.07). In contrast, anxiety disorders were not associated with falls, even after adjustment for age, medication use or depression.

Depression itself contributed independently to the risk of falling. A similar relationship was not observed in those with anxiety disorders. Further research into the mechanistic factors is warranted.

BMD Changes in Male Veterans with Type 2 Diabetes. S. Yaturu¹, S. Humphrey². ¹Endocrinology, Overton Brooks VAMC/ LSUHSC, Shreveport, LA, USA, ²Nursing, Overton Brooks VAMC, Shreveport, LA, USA.

Prevention of osteoporosis requires not only recognition of population at risk, but also screening programs targeting those populations. Subjects with diabetes said to have a higher risk of non traumatic fractures even after adjustment for their bone mineral density (BMD). In a cross sectional study, we compared the clinical and BMD data of 735 men with type 2 diabetes to 3458 men with out diabetes (table 1).

	Subjects with diabetes (735)	Subjects without diabetes (3458)	P value
Age	67.5 ± 0.38	66.2 ± 0.12	0.06
BMI	30.08 ± 0.2	27.8 ± 0.12	< 0.0001
BMD AP spine	1.223 ± 0.008	1.149 ± 0.003	< 0.0001
BMD Hip	0.892 ± 0.009	0.930 ± 0.003	< 0.0001

Most of the subjects with diabetes have metabolic syndrome. Then we compared the BMD data of subjects with diabetes to age, BMI matched population (table 2).

	With diabetes (735)	BMI matched without diabetes (715)	P value
Age	67.5 ± 0.38	67.5 ± 0.39	NS
BMI	30.08 ± 0.2	30.10 ± 0.11	NS
BMD AP spine	1.223 ± 0.008	1.216 ± 0.003	NS
BMD Hip	0.892 ± 0.009	0.942 ± 0.08	<0.01

Interestingly, we noted that there was no significant difference between the two groups at spine. Subjects with diabetes had decreased BMD at hip. We conclude that it would be interesting to look into the area of metabolic syndrome in relation to bone mineral metabolism.

Development of Novel Mini-Tetrapod Bone Fillers. K. Igawa*, K. Yamamoto*, S. Ohba, T. Ogasawara, F. Kugimiya, D. Chikazu, K. Nakamura, H. Kawaguchi, T. Takato*, K. Tomizuka*, U. Chung. Sensory & Motor System Medicine, and Biochemistry & Molecular Biology, University of Tokyo, Tokyo, Japan.

The use of injectable biomaterials is of interest in osteoporotic patients to locally restore bone mass in sites at risk of fracture. Currently available granular type bone fillers are being produced by pulverizing porous calcium phosphate blocks. Because of the irregular size and shape of granules, dead space is often formed and connectivity of pores is not guaranteed. In contrast, the size and shape of the tetrapod is uniform, which can be designed in such a way that connecting pores of the ideal size for cell and blood vessel invasion are formed when the tetrapods are assembled. Four protrusions of each tetrapod help stabilize assembled structure. In addition, by changing sintering temperature and other conditions, alpha-tricalcium phosphate, beta-tricalcium phosphate, hydroxyapatite and octacalcium phosphate can be formed, which have distinct mechanical strength and remodeling speed. We fabricated new small tetrapod-shape artificial bone elements by injection molding of micro particles of alpha-tricalcium phosphate. Maxillary first molar teeth were extracted from 4 mature (5 years old) beagle dogs with preservation of the alveolar bone. Thereafter, left mesial sockets were filled with tetrapods-shape bone fillers. As a control, the right mesial sockets were filled with Osferion® and the left distal sockets were left unfilled. The surface shape of the tetrapod bone fillers was homogeneous in SEM images and they filled space uniformly in CT image. In contrast, the surface shape of Osferion® was heterogeneous and they filled space nonuniformly. The ink absorption test and cell culture test revealed that the tetrapod bone fillers have a good affinity for fluid and cells. In animal test, the dogs were euthanized at 1, 2 months. No side effects related to the fillers were observed. CT analysis showed that the substantial osteogenesis occurred around the tetrapod bone fillers. Histological analysis revealed that substantial bone formation occurred around the tetrapod fillers with osteoclasts resorbing them. These data suggest that the tetrapod bone fillers were safe and effective. We plan to apply these fillers to preventing the alveolar ridge resorption after tooth extraction.

Non-pharmaceutical Strontium and Calcium Supplements Have Inconsistent Mineral Analyses and DXA Imaging Analyses. D. L. Kendler¹, E. M. Lewiecki², R. Hage-Moussa^{*1}, S. T. Robertson^{*1}, J. Zhang^{*3}.

¹Osteoporosis Center of British Columbia, Vancouver, BC, Canada, ²New Mexico Clinical Research & Osteoporosis Center, New Mexico, NM, USA, ³Tang Shan Workers' Hospital, Tang Shan, China.

Strontium (Sr) ranelate is a novel osteoporosis therapy proven effective in the prevention of fractures with postmenopausal osteoporosis. Substitution of Sr for calcium (Ca) in bone may increase bone mineral density (BMD) due to the higher molecular weight of Sr (87.62) than Ca (40.08). These changes are additive to the BMD effects of Sr ranelate associated with its antiresorptive and anabolic activity. Other (non-ranelate) Sr salts can be obtained as nutritional supplements at health food stores or over the internet. These have unknown composition, bioavailability and toxicity. We have previously analyzed by DXA, the bone mineral content (BMC) of 13 Ca and Sr supplements and reported a poor correlation of DXA BMC with the stated Ca or Sr content on the labels.

In the current study we analyzed the 13 supplements for Ca and Sr by Inductively Coupled Plasma Atomic Emission Spectrometry (ICP/AES). Samples were subjected to acid digestion and dilution to determine mineral content.

We observed good agreement between analysis of Ca and label Ca in 5 of 7 tablets; however, agreement was poorer between analysis of Sr and label Sr with only 3 of 6 showing accurate labeling. In all discrepant cases, the stated amount of mineral was higher than the analyzed amount of mineral. DXA analysis of the tablets indicates a good correlation of the DXA BMC determination with the chemical analysis for all samples but as expected, a poor correlation with the label amount.

We conclude that the mineral content of Sr and Ca supplements as measured by ICP/AES correlates poorly with the label amount. DXA-measured BMC of the supplements correlated well with the values obtained by chemical analysis. DXA may be a useful clinical tool for determining the Sr content of supplements. In addition, the DXA image may be useful in identifying artifact due to radiodense Sr-containing tablets that could be a confounding factor in BMD measurement.

Supplement Name	Ca or Sr label per tablet (mg)	Weight of element per tablet by ICP/AES (mg)

Absence of Toxicity Despite High Dietary Vitamin D and Calcium Intake in Non-Human Primates. R. J. Colman^{*}, D. Krueger, N. Binkley. University of Wisconsin, Madison, WI, USA.

Old world primates are widely recognized as an outstanding model of human skeletal physiology. However, laboratory monkey chow contains amounts of vitamin D3 (cholecalciferol) that lead to dietary vitamin D intakes which are much higher on a per kg body weight basis than amounts currently recommended for humans. Despite this, vitamin D toxicity is not recognized in laboratory non-human primates. As such, the purpose of this report is to describe the vitamin D and calcium status of rhesus monkeys (*Macaca mulatta*) for which long-term dietary intake has been closely monitored and explore potential unappreciated vitamin D toxicity. These animals are part of a long-term study on the effects of dietary restriction (DR) and aging. Prior to study initiation, these laboratory-born animals had been on standard Purina monkey chow containing high amounts of calcium and vitamin since birth. In their young adult life, a purified diet was instituted on which males (n=14) have been maintained for 17 years and females (n = 20) for 12 years. Currently, the males are 25.4-31.3 years of age (mean \pm sem: 26.6 \pm 0.4) and the females are 20.7-26.9 years of age (mean \pm sem: 23.4 \pm 0.5). Serum chemistries and 25-hydroxyvitamin D [25(OH)D] were measured and urine calcium/creatinine ratios determined. Serum/urine chemistry determinations were performed by autoanalyzer at a regional medical laboratory; 25(OH)D was measured by HPLC. Control animals (n = 15, age 24.2 \pm 0.7 years) weighed more (10.7 \pm 0.6 kg, p < 0.01) than the DR animals (n = 19, age 25.2 \pm 0.5 years; 8.8 \pm 0.3 kg). For the six months prior to blood collection, dietary vitamin D and calcium intake ranged from 214-447 (mean/SEM 324 \pm 10) IU/day and 772-1608 (mean/SEM 1167 \pm 34) mg/day. If these mean values are extrapolated to humans, a

70 kg human would be ingesting ~2400 IU of vitamin D and ~8500 mg of calcium daily. The mean serum 25(OH)D was positively correlated (p = 0.05) with recent dietary vitamin D intake and was higher among DR animals than control (91 vs. 75 ng/ml, p < 0.01), but did not differ by sex. In the entire cohort the mean serum calcium was 9.8 \pm 0.1 mg/dl and urine Ca/Cr ratio was 0.76 \pm 0.07. The highest individual serum calcium and creatinine values were 10.9 mg/dl and 1.3 mg/dl respectively. Nephrolithiasis has not been appreciated clinically and no nephrocalcinosis or nephrolithiasis was evident upon review of spine radiographs. In conclusion, despite life-long intakes of calcium and vitamin D that many would consider toxic for humans, no evidence of vitamin D intoxication was observed in male or female rhesus monkeys.

Calcium and Vitamin D Supplementation Improves Bone Health in a Population-based Sample of Postmenopausal Women. J. Lappe, K. Davies^{*}, D. Travers-Gustafson^{*}, G. Haynatzki^{*}, R. Heaney, R. Recker. Creighton University, Omaha, NE, USA.

The efficacy of calcium and vitamin supplementation (supp) for improving bone health of populations continues to be debated though strong evidence of a positive effect exists. Thus, we randomly sampled a population of healthy postmenopausal women \geq 55 yrs from 9 rural counties and enrolled 1179 into a double-blind, placebo-controlled, 4-yr study of calcium and vitamin D supp. Specific aims were to determine: 1) the anti-fracture efficacy of calcium (Ca) or calcium and vitamin D (Ca+D) supp; and 2) the comparative effects of Ca+D vs Ca on BMD.

Subjects were randomly assigned to 3 groups: calcium 1400 mg/d (Ca); calcium and vitamin D₃ 1000 IU/d (Ca+D); and placebo (Pla). Baseline measurements were: DXA, spine (sp) x-ray, diet recall, and serum 25(OH)D. At 6-mo visits, fracture (fx) incidence, supp adherence and medical history were assessed. Annually, DXA and serum 25(OH)D were repeated. Women with a t-score <2.5 or a sp fx at any visit were referred to their physician but kept on study.

Mean baseline Ca intake was 1150 mg/day and mean serum 25(OH)D was 72 nmol/L, indicating that most of these women were Ca replete with 25(OH)D levels nearly replete (80 nmol/L). Over 4 yrs, 18 % of the women took bisphosphonates (bis) for \geq 0.5 yrs; they were equally distributed among the 3 grps. 145 women had incident low-trauma fx; the incidence did not differ significantly among the 3 supp groups. However, both Ca and Ca+D increased sp BMD more than Pla (P<0.025). Changes in sp BMD over 4 yrs for subjects on bis were greater than for the non-bis grp (P < 0.005). See Figure. Supp did not result in greater increases in sp BMD in the bis grp. However, in the non-bis, supp resulted in greater increases than in Pla (P<0.05). There was no difference in mean increase between the Ca and Ca+D subgrps. The greatest effect of supp on sp BMD was in non-bis in the lowest tertile of Ca intake at baseline: Ca and Ca+D 2.0%, and Pla 0.0% (P=0.02). Analyses indicate that in the non-bis, increases in sp BMD peak at about 2 yrs (when the remodeling space would be filled in) and then age-related loss resumes.

Anti-fx effects of Ca and D supp are not seen in this population who are nearly Ca and D replete with 18% taking bis. However, in the Ca deplete non-bis grp, supp raises BMD to a new higher steady state. These findings suggest that Ca and D may prevent fx in Ca deplete individuals; studies have not targeted this population.

Diet Effects on Bone Mechanical and Molecular Markers. C. Lorincz*, M. E. Blaauw*, J. Klinck*, R. Reimer*, R. F. Zernicke. Kinesiology, University of Calgary, Calgary, AB, Canada.

The recent changeover of disease etiology has brought to the forefront the need to examine the environmental factors that have influenced the epidemic of chronic disease affecting our society. For bone, fracture associated with osteoporosis can lead to severe morbidity or mortality and is increasing faster than demographic changes in the population. Concurrently, an increase in the consumption of saturated fats and refined carbohydrates have been documented. Emerging data suggest diets high in saturated fat and sucrose (HFS) have a negative effect on skeletal structural integrity and should be investigated to substantiate this risk factor to bone health. The purpose of this study was to investigate the effects of consuming a HFS diet on mechanical, molecular, and blood markers of bone turnover.

Female C57BL/6 mice (aged 9 wk) were randomly assigned to one of two dietary cohorts: high-fat-sucrose (HFS, n=36) or adjusted starch (n=36). Mice were fed their respective diets for 10 weeks. Prior to sacrifice, blood was extracted by way of cardiac puncture and used to test serum levels of vitamin D, parathyroid hormone (PTH), osteocalcin (OC), and tartrate resistant acid phosphatase (TRAP). Upon sacrifice, tibiae were dissected and randomly assigned to group A or group B. Group A tibiae underwent mechanical testing and morphological analysis. Group B tibiae were used to measure the expression of two genes, osteoprotegerin (OPG) and receptor activator for nuclear factor κ B ligand (RANKL).

For blood markers of bone homeostasis, no significant differences were observed between dietary cohorts for vitamin D, PTH, or OC. In contrast, TRAP levels were significantly increased (30%) in the HFS cohort when compared to the starch cohort ($p < 0.05$). HFS mice were significantly heavier than the starch mice ($p < 0.05$). After normalizing for body mass, the mice fed a HFS diet had 23% reduced load at max, 25% smaller cross-sectional area, and 28% thinner cortex when compared to their starch-fed counterparts ($p < 0.05$). Pilot data for gene analysis indicated an 8% decrease in OPG and a 7% increase in RANKL for mice fed a HFS diet. Gene results were not statistically significantly different, however, likely due to low sample number.

Elevated levels of serum TRAP, a marker for bone resorption, alongside unchanged levels of OC, a marker of bone formation, would suggest a negative imbalance in bone remodeling, potentially compromising skeletal structure. Pilot gene analysis indicated an elevation in RANKL expression with a concurrent decrease in OPG expression. Both an increase in RANKL and a decrease in OPG expression have been closely linked with activation of osteoclasts, are consistent with the TRAP results, and are congruent with the observed changes in mechanical properties.

Disclosures: C. Lorincz, None.

Restricting Dietary Protein may Improve Skeletal Integrity in Exercising Female Rats. S. N. Miller*, K. Baek*, M. I. Nilsson*, J. L. Stallone*, J. Lemmon*, H. A. Hogan*, S. A. Bloomfield*. ¹Health & Kinesiology and Nutrition, Texas A&M University, College Station, TX, USA, ²Health & Kinesiology, Texas A&M University, College Station, TX, USA, ³Mechanical Engineering, Texas A&M University, College Station, TX, USA.

We sought to elucidate which nutrient (calcium, protein, or energy) when restricted by 40% had the greatest negative effects on the structural and mechanical properties of bone in exercising female rats. Sixty Sprague-Dawley virgin female rats aged 4 mos. were acclimated to AIN-93M purified diet for 8 weeks prior to the 12-week protocol. Rats were randomly assigned to 5 groups (n=10/group). The control group (CON) ate AIN-93M ad libitum. The protein- (PR), calcium- (CR), and energy-restriction (ER) groups were fed custom diets providing 40% less protein, calcium, or energy, respectively; a global food restriction group (FR) was fed 40% less of all nutrients. All rats performed moderate intensity treadmill training 3 d/wk, 45 min/d. After euthanization peripheral quantitative tomography (pQCT) scans were performed on excised femoral neck (FN) and femoral midshaft prior to 3-point bending and FN compression tests on an Instron 1125. Only FR and ER rats lost body weight (-27% and -26% respectively) over 12 weeks vs. CON. In ER rats, FN total area was maintained, but marrow area was much larger (+75%) vs. CON, suggesting endocortical resorption. Midshaft femur cortical bone mineral content (BMC) and cortical area were lower for both CR and ER versus CON. PR outcomes were not different from those of CON for any variables at midshaft femur. The femoral neck total volumetric bone mineral density (vBMD) for PR was higher than both ER and FR; ER was lower versus CON; FR was not different versus CON. PR exhibited a larger ultimate load (non-significant) at the femoral neck (+8%) and a larger ultimate load at the midshaft femur (+9%) vs. CON. In addition, PR had higher (non-significant) values for stiffness (+15%), elastic modulus (+6%), and ultimate stress (+3%) at the midshaft femur than CON. Restricting only energy produced more negative effects on bone health than global FR, even though FR were fed 40% less of all other nutrients than ER. Unexpectedly, restricting protein intake by 40% resulted in several improved mechanical properties of midshaft femur and increased vBMD at the femoral neck. These are the first data, to our knowledge, to examine the impact of ER, PR, and CR in exercising rodents, offering a possible explanation for the novel results. It remains to be confirmed if reduced protein intake improves acid-base balance, impacting on resorptive activity.

Additive and Synergistic Effects of 17 β -estradiol and Docosahexaenoic Acid on Bone Post-Ovariectomy in Rats. R. C. Poulsen, M. C. Kruger*. IFNHH, Massey University, Palmerston North, New Zealand.

A possible additive or synergistic effect of long chain polyunsaturated fatty acid (LCPUFA) supplementation in conjunction with 17 β -estradiol treatment on maintaining bone mass post-ovariectomy in rats has previously been reported. More recently, the n-3 LCPUFA docosahexaenoic acid (DHA, 22:6n-3) has been found to be particularly bone-protective. The aim of the present study was to determine if combined treatment with DHA and 17 β -estradiol would have greater bone-protective effects than either treatment alone. Six-month old rats were randomised into 5 groups and either sham-operated ("SHAM", n=10) or ovariectomised (ovx) (n=46). A slow-release 17 β -estradiol pellet (providing 1 μ g/day) was inserted subcutaneously into two groups of ovx animals (n=12 per group). All other groups received a placebo pellet. One group of estradiol-treated ovx animals ("OES", n=12), one group of placebo-treated ovx animals ("OVX", n=10) and the SHAM group were fed a balanced diet containing 4% corn oil and 0.5% calcium. The remaining estradiol-treated ("OESDHA", n=12) and placebo-treated ("DHA", n=12) ovx groups were fed the same base diet however a portion of corn oil was substituted for DHA (0.5g/kg body weight/day). Study duration was 18 weeks. BMC, BA and BMD were measured by DEXA at baseline and study completion. Trabecular and cortical BMC, BMD and BA were measured by pQCT; plasma IL-6 by immunoassay and red blood cell (RBC) fatty acid composition by GC at study completion.

Both DHA and estradiol treatment significantly protected against OVX-induced bone loss at the lumbar spine (LS) and femur (F). Combined treatment had an additive effect and final F BMC and LS BMC were greater in OESDHA compared to OES ($p=0.01$ and $p=0.07$ respectively). Cortical BMC and periosteal circumference were significantly higher in OESDHA compared to OES ($p=0.05$ and $p=0.02$ respectively) and a significant interaction between estradiol and DHA was evident for periosteal circumference ($p=0.05$). Both estradiol and DHA treatment were associated with increased levels of n-3 LCPUFAs in RBCs. Combined estradiol and DHA treatment further increased both the percentage of DHA and percentage of total n-3 LCPUFAs in RBCs. Neither estradiol nor DHA treatment alone had any significant effect on plasma IL-6 concentration however plasma IL-6 concentration was significantly lower in OESDHA compared to OES or DHA ($p=0.02$). Combined treatment with 17 β -estradiol and DHA is more effective than either treatment alone in preventing ovx-induced bone loss in rats due to both additive and synergistic interactions between the two treatments.

Disclosures: R.C. Poulsen, None.

Dried Plum Polyphenols Stimulate Osteoblast Activity and Attenuate Detrimental Effects of TNF- α on Runx2, Osterix and IGF-I in MC3T3-E1 Cells. S. Bu¹, T. S. Hunt^{*2}, B. J. Smith^{*2}. ¹Department of Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, ²Department of Surgery, University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA.

Previous studies have demonstrated that supplementation with dried plum, a rich source of polyphenols, can restore bone mass and structure, and increase indices of bone formation (e.g. ALP & IGF-I). The purpose of this study was to determine how dried plum polyphenols influence osteoblast activity and function under normal and inflammatory conditions. MC3T3-E1 cells were plated and treated with polyphenols extracted from dried plums (0, 2.5, 5, 10 and 20 μ g/ml) and 24 hrs later stimulated with TNF- α (0 or 1.0 ng/ml). Alkaline phosphatase (ALP) activity was assessed as an indicator of osteoblast activity, Alizarin red S was used to determine nodule formation, and real-time PCR was used to evaluate alterations in gene expression. All doses of dried plum polyphenols significantly increased intracellular ALP activity under normal conditions at 14 days and restored the TNF- α -induced suppression of ALP ($p<0.001$) to the level of controls. After 28 days of treatment, the 5 μ g/ml dose of polyphenols increased mineralized nodules under normal conditions as evidenced by increased Alizarin red S staining density and number of mineralized nodules. All doses of polyphenols enhanced ($p<0.05$) nodule formation under inflammatory conditions. In the absence of TNF- α , 5 μ g/ml of polyphenols significantly up-regulated IGF-I mRNA levels compared to controls, while the 5 and 10 μ g/ml doses increased lysyl oxidase expression. Increases in Runx2 and Osterix expression induced by polyphenols under normal conditions did not reach statistical significance. TNF- α decreased the expression of Runx2, Osterix, and IGF-I, and polyphenols restored their mRNA levels to that of the controls. Although TNF- α failed to alter lysyl oxidase, dried plum polyphenols up-regulated ($p<0.05$) its expression in the presence of TNF- α . In the absence of TNF- α , the lowest dose of polyphenols down-regulated the expression of RANKL. As expected, TNF- α up-regulated RANKL mRNA and the 5, 10 and 20 μ g/ml doses of polyphenols decreased RANKL expression without altering OPG. We conclude that dried plum polyphenols enhance osteoblast activity and function under normal and inflammatory conditions by up-regulating growth and transcription factors, increasing the expression of an enzyme involved in extracellular matrix synthesis, as well as attenuating the inflammatory response.

Disclosures: B.J. Smith, None.

The Effect of Onion on Ovariectomy-induced Osteopenia: A Histomorphometric Study in Rats. R. Yang¹, T. Huang^{*2}, R. C. Mühlbauer^{*3}, H. Chen^{*4}, H. Lin^{*2}, Y. Huang^{*5}, Y. Lai^{*5}. ¹Department of Orthopaedics, National Taiwan University Hospital, Taipei, Taiwan, ²Institute of Physical Education, Health and Leisure Studies, National Cheng-kung University, Tainan, Taiwan, ³Bone Biology Group, Department Clinical Research, University of Bern, Bern, Switzerland, ⁴Institute of Physiology, National Cheng-kung University, Tainan, Taiwan, ⁵Department of Life Science, National Cheng-kung University, Tainan, Taiwan.

Fruits and vegetables enriched diets have been suggested to benefit bone health. Among those natural foods, onion has been well proved about its effect on reduced bone resorption in animal study. The purpose of this study is to investigate the potential protective effects of an onion-enriched diet on the ovariectomy-induced bone loss.

Experimental Design: Animals with sham operation or ovariectomy were assigned into six groups: The CON group, sham operated control group (n=8); the OVX group, ovariectomized group (n=11); the ALN group, ovariectomized rats oral treated with alendronate (1mg/kg body weight/day) (n=11); the 3%ON, 7%ON and 14%ON groups, ovariectomized rats fed with diets containing 3%, 7% and 14% (w/w) onion, respectively (n=11 for each group). Animals were sacrificed after a six-week treatment course.

Results: The ALN group, which served as a positive control group, showed significantly higher in bone volume ratio (BV/TV) as compared to the OVX, 3%ON and 7%ON groups in cancellous bone of the proximal metaphysis of tibiae ($p < .05$). In addition, onion-enriched food decreased bone loss in a dose dependent manner (BV/TV, 3-45% higher than the OVX rats) and the 14%ON group was significantly higher than the OVX and 3%ON groups ($p < .05$). Further structural analysis of the proximal tibiae showed that both the ALN and 14%ON groups had significantly higher trabecular number (Tb. N.), less separation of trabeculae (Tb. Sp.), and less osteoclast per tissue area (N. Oc./T.A.). Thus, onion as well as alendronate showed efficacious inhibition of bone resorption.

Conclusions: Onion-enriched diet was demonstrated further to protect bone from ovariectomy-induced osteopenia. Further investigations would be of worth in clarifying the molecular mechanisms of onion on bone homeostasis.

Biochemical and Histological Assessment of the Effects of Alkali Therapy on Bone During High Animal Protein Intake. J. E. Zerwekh, L. Zou*, K. Sakhaee, C. Y. C. Pak, O. W. Moe*, P. A. Presig*. Center for Mineral Metabolism and Clinical Research, University of Texas Southwestern Medical Center at Dallas, Dallas, TX, USA.

The Westernized diet is acidogenic due to a high content of sulfur-containing amino acids. Chronic acid loads can result in hypercalciuria and negative calcium balance often attributed to loss of bone mineral. Alkali therapy has been shown to reverse hypercalciuria but little is known regarding its effect on bone turnover. We utilized dynamic bone histomorphometry to evaluate the effects of alkali therapy on acid-induced high bone turnover. We performed serum, urine, and bone histomorphometry in 4 groups of rats (n=9 per group) after 2 months of either neutral potassium salt as potassium chloride (KCl) or alkaline potassium salt as potassium citrate (KCit) administration (4 mEq K/d for each salt) while placed on either a low casein (LC) or high casein (HC) diet.

Compared to animals on LC-KCl diet, HC-KCl diet delivered a substantial acid load as shown by a significant increase in urinary sulfate, lower urinary pH and citrate, increased urinary ammonium and net acid excretion. Acid load also increased urinary calcium (3.5 ± 2.6 vs 6.0 ± 2.0 mmol/L, $p=0.039$) without detectable changes in serum parameters. Dynamic and static bone histomorphometry (Table 1) disclosed a significant reduction (as assessed by ANOVA) in cancellous bone volume associated with a 2.5-fold increase in eroded surfaces and a 3.5-fold increase in osteoclastic surfaces. There was also a near 2-fold increase in bone formation rate for rats on HC-KCl diet. When animals were given KCit in place of KCl, all of the aforementioned changes in urine biochemistry and bone turnover were prevented or attenuated (HC-KCIt vs. LC-KCIt). These findings clearly underscore the deleterious effects of high animal protein intake in promoting hypercalciuria and reducing bone mass through an increase in bone resorption. In contrast, co-administration of potassium alkali as KCit prevented or attenuated these changes and preserved bone mass. Thus, in this animal model of high protein intake, the major effect of alkali therapy on bone was to reduce bone resorption with little or no direct effect on bone formation. These findings may offer an explanation for epidemiological studies that have observed increased BMD in subjects with the greatest intakes of dietary alkali.

The effect of alkali on cancellous bone histomorphometry during low and high protein intake.				
Parameter	LC-KCl	HC-KCl	LC-KCIt	HC-KCIt
BV/TV $p=0.019$	19.3 ± 8.8	10.1 ± 5.2	13.3 ± 4.6	18.4 ± 6.8

Rapid and Robust Biochemical Response to Teriparatide Therapy for Osteoporosis. R. Eastell¹, E. V. McCloskey¹, S. Glover¹, A. Rogers¹, P. Garnero², J. Lowery^{*3}, R. Belleli^{*3}, T. M. Wright^{*3}, M. R. John³. ¹University of Sheffield, Sheffield, United Kingdom, ²INSERM U 664 and Synarc, Lyon, France, ³Translational Medicine, Novartis Pharma AG, Basel, Switzerland.

Teriparatide is a potent anabolic treatment option for postmenopausal osteoporosis. Studies have shown that teriparatide induced large increases in biochemical markers of bone formation after one month of therapy onwards and a later increase in resorption markers. The aim of this study was to establish the very early biochemical response to teriparatide.

We recruited 15 postmenopausal women (ages 55 to 69 years, mean 62) with a BMD T-score less than -1 at the lumbar spine or total hip (mean T-scores at spine and hip, -1.8 and -0.8, respectively) and normal 25-hydroxy vitamin D levels. The treatment regimen was teriparatide 20 micrograms s.c. /day for 28 days. Serum levels of type I collagen N-terminal propeptide (PINP), type I collagen C-terminal propeptide (PICP), osteocalcin (OC), bone alkaline phosphatase (bone ALP), crosslinked C-telopeptide of type I collagen (CTX), and tartrate resistant acid phosphatase type 5b (TRACP5b) were measured on 11 occasions: baseline (an average value derived from 3 samples each taken two days apart immediately before treatment initiation), after 3, 7, 10, 14, 19, 24 and 28 days of treatment and at 56 days i.e. 28 days after teriparatide was stopped. The mean percent-changes from the average baseline and the 90% confidence intervals are shown in the figure.

The changes in PINP are early and large, differing significantly from baseline by day 3. A similar pattern was observed for PICP (not shown). The increase in OC showed a similar timecourse, but the increase was of smaller magnitude. The increase in bone ALP was delayed and smaller than the other formation markers. Interestingly, CTX decreased significantly between days 7 and 14, but TRACP5b did not (data not shown). In conclusion, the anabolic biochemical markers serum PINP and PICP show a robust response to teriparatide within the first week of therapy. These findings have implications for designing and interpreting studies of new anabolic agents for osteoporosis and for monitoring individual patients treated with teriparatide.

BMD Response to Teriparatide in Treatment Naïve Patients Versus Patients Previously Treated with a Bisphosphonate. E. A. File^{*1}, C. L. Deal¹, R. S. Butler^{*2}. ¹Rheumatology, Cleveland Clinic Foundation, Cleveland, OH, USA; ²Biostatistician, Cleveland Clinic Foundation, Cleveland, OH, USA.

rh PTH 1-34 (teriparatide) (TPTD) is approved for the treatment of patients at high risk for fracture. Pretreatment with a bisphosphonate has been shown to blunt the bone density response to TPTD in some but not all studies. This study evaluated whether prior exposure to a bisphosphonate would blunt the skeletal response to TPTD. A retrospective analysis of patients given a prescription for TPTD at the Cleveland Clinic from 1/2003 to 7/2006 was performed. Patients were stratified into two TPTD treatment arms: bisphosphonate naïve and those previously treated with a bisphosphonate. Inclusion criteria for primary outcome analysis were the following: BMD < 12 months prior to initiation of TPTD, follow up BMD ≥ 12 months after therapy with TPTD, and bone turnover markers drawn before and after initiation of TPTD therapy. Primary outcome was absolute change in lumbar spine, total hip, and femoral neck BMD after ≥ 12 months of TPTD therapy. Secondary outcomes included the percent change in markers of bone turnover (urinary NTX, osteocalcin, and alkaline phosphatase). We evaluated the percent of patients who developed significant hypercalcemia, defined as a calcium level ≥ 11.0 on one occasion or > 10.5 on two or more occasions.

Sixty-six (66) patients met criteria for primary outcome analysis, 30 patients were bisphosphonate naïve and 36 patients received a bisphosphonate prior to initiation of TPTD. There was no significant difference between the two groups in the mean absolute change in the lumbar spine, total hip, or femoral neck BMD after ≥ 12 months of therapy with TPTD (see table). Both treatment arms had significant increases in NTX and osteocalcin with no significant difference in the percent change of response. In the entire cohort, which included 96 patients, significant hypercalcemia occurred in 21% (20/96) receiving TPTD. Patients with hypercalcemia had higher mean baseline calcium (10.0 vs. 9.6, $p = 0.0013$). Only 1 patient discontinued TPTD due to hypercalcemia. In our cohort, prior exposure to a bisphosphonate did not blunt the anabolic effect of TPTD. There was no significant difference in the percent change in bone turnover markers in the two groups. Calcium elevations were frequent in patients on TPTD, but discontinuation of therapy was rare.

Location	Absolute Change in BMD after ≥ 12 months of therapy with TPTD		P-Value [‡]
	Prior BP [†] Mean BMD Change (g/cm ²) n=36	BP Naïve Mean BMD Change (g/cm ²) n=30

Effects of 2 Years of Teriparatide Treatment on Bone Strength Assessed by High Resolution CT Based Finite Element Analysis of Human Vertebrae In Vivo: Results from the EUROFOR Study. C. Graeff¹, C. C. Glüer¹, J. Borggrefe¹, M. Charlebois^{*2}, Y. Chevalier^{*2}, P. Varga^{*2}, D. Pahr^{*2}, T. N. Nickelsen³, E. Marin^{*4}, J. Farrerons^{*5}, P. Zysset^{*2}. ¹Medical Physics, Department of Radiology, UKSH, Kiel, Germany; ²Institute for Lightweight Design and Structural Biomechanics, Vienna University of Technology, Vienna, Austria; ³Medical Research, Lilly, Europe, Bad Homburg, Germany; ⁴Medical Research, Lilly, Europe, Madrid, Spain; ⁵Hospital de Santa Creu I Sant Pau, Barcelona, Spain.

A digital finite element (FE) analysis method validated ex vivo (see abstract this meeting) was applied to assess vertebral strength changes in vivo induced by 2 years of teriparatide treatment.

For 43 patients aged 68 ± 7 years taking part in the high resolution computed tomography (HRCT) addendum of the EUROFOR study, HRCT scans of T12 and DXA scans of L1-4 were performed at 0, 6, 12, and 24 months. The patients differed by pre-treatment status: treatment naïve (7 patients), pre-treated with antiresorptives (11), or inadequate response to antiresorptives (25). The HRCT scans of the T12 vertebrae were segmented semi-automatically including the entire vertebral body except for the manually removed processes. A trabecular VOI was defined by peeling off the outer 3 mm of the total volume. Volumetric BMD was calculated in the trabecular VOI and the whole vertebra. For FE analysis the entire segmented vertebrae were converted into digital finite element models with 1.3 mm isotropic voxel size. Material properties were assigned according to a transverse isotropic elastic plastic damage model for bone following a power law based on BMD. The ultimate load under axial compression of the vertebral endplates was determined.

Figure 1 shows percent changes from baseline (all significant: $p < 0.0001$). Increases in bone strength were significantly larger volumetric or DXA-based BMD changes (after 6 months only vs DXA: $p < 0.01$; later: $p < 0.4$)

In vivo HRCT-based FE analysis allows monitoring of teriparatide treatment over two years with an increased sensitivity compared to DXA. Two years of teriparatide treatment are associated with a substantial 28% increase in FE analysis derived bone strength.

GH Treatment Increases Cortical Thickness by Stimulating Endosteal Bone Growth in Young Adults with Childhood Onset GH-Deficiency. L. Hyldstrup^{*}. Dept. of Endocrinology, Hvidovre Hospital, Dk-2650 Hvidovre, Denmark.

Patients with childhood-onset growth hormone deficiency (CO GHD) are usually treated with GH until final height is reached, but the treatment is stopped long before peak bone mass is obtained. Since GH has well known effects on bone growth and bone mineral accretions, it might be useful to prolong GH treatment in CO GHD beyond final height. To evaluate the potential benefit of GH-treatment on cortical bone in this patient-group a randomized controlled, open-label study of young adults with CO GHD was performed. Material and methods: In a group of 160 patients with CO GHD, 109 were randomized to Norditropin® SimpleXx® and 51 patients were randomized to receive no treatment. Male/female ratio was 61/99, with a mean age of 21.2 (2.2) years. Mean (SD) height for males / females was 171.7 (7.5) / 157.5 (8.1) cm, mean weight was 69.0 (13.4) kg / 56.2 (11.1) kg, corresponding to BMI 22.5 (3.4) / 23.3 (3.5). Patients were treated for 2 years, with a maintenance dose of 1.0 / 1.4 mg daily for males and females, respectively. For all individuals hand x-rays were obtained at 0, 6, 12, 18 and 24 months and sent to a central reading facility where they were analyzed in a blinded manner, using digital x-ray radiogrammetry (DXR) of metacarpal 2-4. From this reading information on cortical thickness, bone width, endosteal diameter and metacarpal index was obtained. In the GH-treated group a significant increase in cortical thickness and metacarpal index was seen. The main cause of the increase in cortical thickness is a significant reduction of the endosteal diameter. In the control group the endosteal diameter did not change, leading to a much smaller increase in cortical thickness.

Conclusion: Treatment with Norditropin® SimpleXx® for 2 years in young adults with CO GHD led to a substantial endosteal bone growth with a reduction of the marrow space diameter and consequently an increase in the cortical thickness. Since cortical bone loss later in life is mainly caused by endosteal bone resorption, the effects of 2 years treatment with growth hormone (Norditropin®) before peak bone mass is reached may prove useful in preventing osteoporosis later in life.

	Results after 24 months			
	Cortical thickness	Bone Width	Inner Diameter	Metacarpal Index
Norditropin	1.10	1.02	0.96	1.08
Untreated	1.04	1.02	1.01	1.01
Effect (%)	6.43	0.68	-4.64	6.14
P-values	<0.0001	0.472	0.0006	<0.0001

Teriparatide Treatment in Osteoporotic Patients Treated with Glucocorticoids for Chronic Inflammatory/Autoimmune Rheumatic Diseases. R. La Corte*, G. Limpido*, S. Volpinari*, F. Trotta*. Departement of clinical and experimental medicine, Rheumatology Unit, Ferrara, Italy.

Among osteoporotic patients, with multiple prevalent and/or incident vertebral/femoral fractures, treated with teriparatide all cases with concomitant rheumatic inflammatory/autoimmune diseases treated with glucocorticoids (GC) have been selected to evaluate the analgesic and antifracturative effects of the drug.

Of the 25 selected patients, 9 had connective tissue diseases (2 PM, 5 SLE, 2 UCTD), 3 had vasculitis (2 Behcet's disease and 1 Wegener's granulomatosis); 10 had RA and 2 had seronegative spondyloarthropathies. During teriparatide treatment, all the patients continued GC therapy (prednisone doses between 5 to 12.5 mg/d), in 8 cases as sole therapy, in the remaining associated with anti TNF α -therapy (4), DMARDs (12), and cyclophosphamide (1). In all patients pain was evaluated with a visual analogue scale (VAS) and the quality of life (QoL) with the Italian version of mini osteoporosis quality of life questionnaire (mini-qualleffo) at T0, and after T1, T3, T6, T12 months. Vertebral fractures by radiographic morphometry was performed before starting teriparatide and at 6 and 12 months or when considered necessary. Statistical analysis was performed using non parametric paired Wilcoxon test and analysis of variance (ANOVA) using Bonferroni as post hoc test.

An improvement of VAS $\geq 20\%$ and $\geq 50\%$ was seen at T1 in 13/26 and 2/26 respectively; at T3 in 11/20 and 2/20; at T6 in 5/14 and 6/14; at T12 in 1/7 and 6/7. The next statistical analysis do not consider T12 for the low number of patients. VAS was at T0: $73.5 \pm 4.17_{SEM}$; T1: $60.2 \pm 3.9_{SEM}$; T3: $55.3 \pm 4.8_{SEM}$; T6: $48.3 \pm 5.5_{SEM}$; T12: $31.4 \pm 5.7_{SEM}$ with differences statistically significant (T0 vs T1, $p < 0.0001$; T0 vs T3: $p < 0.0002$; T0 vs T6: $p < 0.003$ and between 4 groups (T0,T1,T3,T6): $F: 14.6$; $p < 0.001$; post hoc test showed a significant improvement from T0 to T3 and a stability between T3 and T6. Mini qualleffo analysis revealed a progressive improvement of QoL but the differences were not significant probably for the disability due to the underlying disease. Five patients withdrew the treatment: in 3 cases for increasing arthralgias (2 at T3; 1 at T6); 1 for inefficacy (T6) and 1 for hepatic replication of lung cancer (T3). Only a patient had a hip fracture and no vertebral fractures were detected. Two patients had a progressive asymptomatic reduction of PTH and 1 had mild hyperuricaemia. These preliminary data show and evident analgesic effect of teriparatide already presents during the first month of therapy in patients treated with GC therapy

Transdermally-Delivered hPTH (1-34) - A New Treatment for Osteoporotic Patients: Results of Phase I Studies. G. Levin¹, C. Mazouz². ¹R&D, TransPharma-Medical, Lod, Israel, ²Clinical affairs, TransPharma-Medical, Lod, Israel.

TransPharma Medical is developing a novel transdermal hPTH (1-34) product designed to help people manage their osteoporosis by eliminating the need for daily injections. TransPharma's ViaDerm Micro delivery system for hPTH (1-34) consists of a reusable, handheld device, used to create microscopic pores which penetrate the outer skin layer, a 1 cm² disposable microelectrode array and a compatible patch containing the hPTH (1-34) formulation.

The company has performed two clinical studies on PTH-ViaDerm system: a proof of concept, single administration study using a 90 mcg patch and a 7-day recurrent administration study with patch doses of 50, 70 or 90 mcg. The single dose administration study was performed in India, while the seven day study was performed in The Netherlands. Both studies were performed in accordance to the Declaration of Helsinki and approved by the appropriate regulatory authorities.

A total of 44 healthy post-menopausal women, age 60-75, were treated with the PTH-ViaDerm system on the upper arm or thigh. The resulting PK profiles of plasma hPTH (1-34) were determined by a specific hPTH (1-34) ELISA for up to 22-24 hours following patch application. Total and ionized calcium in the serum was measured as indicative of treatment safety, and compared to that of a subcutaneous (SC) FORTEO injection (20 mcg). The studies were successfully completed with no serious adverse events and with a favorable systemic and dermal safety and tolerability profiles. All safety data, including serum total or ionized calcium, were well within the acceptable range for clinical use.

Transdermal delivery of hPTH (1-34) through ViaDerm-generated MCs resulted in the attainment of therapeutic levels of hPTH systemic concentrations. The transdermal delivery resulted in a peak hPTH plasma profile with a smaller inter-subject variability than that of SC injection. Relative bioavailability was calculated by comparing the area under the curve of transdermal delivery to that of SC injection, and was found to range from 30%-60%, depending on the dose and delivery site.

These safety and delivery results of the single and recurrent 7-day administration are very encouraging. hPTH (1-34) was delivered via the PTH-ViaDerm system with extremely high bioavailability relative to the therapeutic dose of SC injection. The transient and reversible changes in blood calcium following transdermal delivery of hPTH (1-34), which were similar to those observed in FORTEO, indicate safety of the delivered dose and peptide bioactivity in-vivo. Furthermore, the small variability achieved indicates high reproducibility and reliability. We plan to continue our development process in-house, bringing this high-potential product to an advanced clinical stage.

T372

Teriparatide Treatment Following Bisphosphonate-resistant Osteoporosis. 6 Months Clinical Data of the 'BBB-Study'. B. Mucche¹, B. Jobke², J. Semler². ¹Osteology, Immanuel-Krankenhaus Rheumaklinik, Berlin, Germany, ²MQIR-Dept. of Radiology, UCSF, San Francisco, CA, USA.

BACKGROUND: There are patients with relevant progression (fractures, continuous BMD loss) of their osteoporosis (OPO) despite of good compliance to at least 1 year of bisphosphonate (BIS) treatment. Teriparatide (recombinant human parathyroid hormone 1-34 = rhPTH) is a good option, but due to the high cost, it is only used in a minority of the target patients and only limited experience exists about the effects of previous treatments on bone markers, BMD, QoL and bone structural parameters. In this prospective single center study, clinical data were collected and paired iliac crest biopsies were performed. Data of the first 6 months are presented. **PATIENTS/METHODS:** 25 women (age 69 ± 9 years) with progression of severe OPO during BIS (mean treatment duration 3.5 (1...7) years; 12 ALN/13 RIS; new fragility fractures (n=14), BMD decline $>3.5\%$ (n=11)) were recruited for 18 months teriparatide treatment (plus daily 500 mg Ca & 400 IU Vit.D3 supplementation). DEXA scans of the lumbar spine (LS), femoral neck (FN) and total-hip (TH) were conducted every 6 months on a GE Lunar Prodigy, lab (serum-calcium, Bone ALP and crosslaps) and QoL questionnaire (with VAS for pain) performed at months 0, 1, 3 and 6. Paired bone biopsies by Jamshidi technique at the dorsal iliac crest were taken at M 0 and 6 (data presented by Jobke et al.). **RESULTS:** Consent withdrawal (n=1), compliance $< 75\%$ after 6 months (due to side effects; n=2) were excluded from the analysis. BMD T-scores M0/M6: LS -2.96/-2.20 (p=0.05), FN -2.21/-2.08 (NS), TH -1.94/-1.73 (NS). Lab M0/M1/M3/M6: s-calcium 2.32/2.36/2.46/2.36 (p<0.001 for M3 vs. M0; normal 2.05...2.65 mmol/l; observation of hypercalcaemia at any time, n=4); Bone ALP 14.4/20.5/20.3/28.4 (p<0.001; ULN=21.4 mg/l); crosslaps 239/350/553/850 $\mu\text{g/l}$ (p<0.001; ULN=573 $\mu\text{g/l}$). VAS for pain 48/45/39/48% (p=0.02 only for M3 vs. M0) did not show relevant clinical changes in this cohort. Duration of BIS $> 3.5\text{y}$ delayed changes of crosslaps until M3 (despite trend also at M1). Neither use of ALN or RIS, nor fracture vs. BMD decline had influence on any of the observed results. **CONCLUSIONS:** Early (M1) and continuous (M3, M6) increases of Bone ALP and crosslaps were observed as well as significant increase of LS-BMD at M6. No influence of duration or type of previous BIS treatment could be detected. Our patients seem to represent "real" BIS failures (in contrast to Ettinger et al., JBMR 2004; 19(5):745-51). Mean increases of s-calcium were moderate, but 4 of 22 patients had (intermittent and asymptomatic) hypercalcaemia. No clinically relevant change of VAS for pain was seen.

Disclosures: B. Mucche, None.

Reduction in Serum 25(OH)D During PTH Treatment. J. W. Nieves, E. Cosman, M. Zion*, D. W. Dempster, R. Lindsay. Clinical Research Center, Helen Hayes Hospital, West Haverstraw, NY, USA.

Treatment with 1-34PTH (hPTH) is well known to increase serum calcium levels transiently, however, effects on vitamin D metabolites and endogenous parathyroid hormone (PTH) levels have not yet been described. We report data here on calcium homeostasis variables in two clinical trials, one trial involving patients on prior raloxifene (RLX; n=42) randomized to daily hPTH or RLX alone and one trial involving patients on prior alendronate (ALN; n=126) randomized to daily hPTH, cyclic hPTH (3 months on and 3 months off) or ALN alone. All subjects were supplemented with vitamin D to achieve levels above 20 ng/ml prior to entry into the trial. Serum was measured for intact PTH, 25(OH)D, 1,25(OH)₂D and ionized calcium every 3 months for one year. Intact PTH was measured by radioimmunoassay (Nichols), 25(OH)D and 1,25(OH)₂D were measured by radioimmunoassay (Diasorin). Changes in biochemical variables were similar across the trials; therefore data were grouped for analyses (RLX and ALN control groups were pooled and daily hPTH groups were pooled). In the control group there were no significant changes in any variables. Ionized calcium increased in the hPTH groups within 3 months (all levels stayed within normal range). Levels remained significantly elevated in the daily hPTH group at all subsequent time points, compared to the cyclic hPTH group. PTH levels declined by 15-25% in both hPTH groups within 3 months and remained below baseline (Figure). In the cyclic group, PTH returned to baseline during off-cycles and declined again during on-cycles. 25(OH)D declined by 15-17% within 3 months in the hPTH groups and remained below baseline in the daily hPTH group (Figure). In the cyclic group levels increased during off-cycles and declined again during the on-cycles. 1,25(OH)₂D levels increased 25-30% within 3 months and remained above baseline throughout the study in the daily hPTH group. In the cyclic group, there was a similar pattern with increments and decrements related to on and off cycles. In conclusion, reductions in 25(OH)D are consistently seen with PTH treatment, along with increases in 1,25(OH)₂D, modest increases in serum calcium and decreases in PTH. Given the dramatic differences in their half lives (days versus hours) it is possible that the reduction in 25(OH)D results from exogenous hPTH stimulation of 25(OH)D conversion to 1,25(OH)₂D.

Comparison of Alendronate and Strontium Ranelate in Men with Established Primary Osteoporosis. J. D. Ringe, A. Dorst*, H. Faber*, P. Farahmand*. Medical Clinic 4, Klinikum Leverkusen, University of Cologne, Leverkusen, Germany.

Background: Strontium ranelate is a new therapeutic option for osteoporosis. Due to a simultaneous anabolic effect on osteoblasts and catabolic effect on osteoclasts it is different from all previous treatments. In two large pivotal trials on postmenopausal women a significant risk reduction was demonstrated for both vertebral and non-vertebral fractures. Therapeutic experience in men with osteoporosis has not been reported so far.

Purpose of the study: To study the effect of strontium ranelate on lumbar spine and total hip bone mineral density (BMD) in men with established primary osteoporosis. Secondary endpoints include fractures, height loss, back pain and use of analgetic therapies.

Patients and methods: In this single center, open label, controlled, prospective one year trial we enrolled 68 men with T-score values of lower than -3.0 SD at lumbar spine (LS) and lower than -2.5 SD at the total hip (TH) with one or more prevalent vertebral fractures (vert-fx). Patients in group A (n=34) received 2g strontium ranelate plus 1200 mg calcium and 800 IU Vitamin D daily. The 34 patients of group B were treated with 70mg alendronate once weekly and the same amounts of calcium and vitamin D daily. BMD measurements and x-rays were performed at baseline and month 12.

Results: The increase in LS-BMD after 12 months amounted to 5.1% and 4.1% resp. in strontium ranelate and alendronate patients. The respective mean changes at the total hip site were 3.2% and 2.6%. The mean increases in BMD were significant higher with strontium ranelate as compared to alendronate. The average increase rates at the two skeletal sites of group A are consistent with the respective one year results in postmenopausal women treated with strontium ranelate. In group A we observed 2 vert-fx and 2 non-vert-fx, in group B 2 vert-fx and 4 non-vert-fx (ns). For both treatments a significant decrease in the average back pain and analgetic therapy score was documented with a stronger tendency for strontium ranelate.

Conclusion: Strontium ranelate seems to be at least as potent in men with established osteoporosis than alendronate, which is approved for this indication. These data are encouraging to study further male patients.

Monitoring Bone Mineral Density During the Course of Teriparatide Therapy in a Community Setting. G. Valenzuela*, P. Miller*, A. Rana*, M. Wong*, K. Taylor*, K. Krohn*. ¹West Broward Pulmonary, Plantation, FL, USA, ²Colorado Center for Bone Research, Lakewood, CO, USA, ³Eli Lilly and Company, Indianapolis, IN, USA.

Experts have suggested monitoring patients' BMD at 12 months after initiating teriparatide 20µg/d (TPTD) therapy [Endo Pract (2004)10:139-48]. Medicare provides reimbursement for BMD 1 yr after starting an FDA-approved osteoporosis (OP) therapy. However, clinicians may choose to monitor patients' BMD at other time points. This analysis examines the time from baseline to the first follow-up LS-BMD assessment during the course of TPTD therapy in a "real world" OP patient population in the ongoing, observational DANCE trial. The study design specified investigators to prescribe TPTD for ≤24 months, with 24 months' follow-up after cessation of therapy, and to make all patient-care decisions. In 794 patients with a baseline and ≥1 follow-up BMD measurement (Table), the LS-BMD increase was 5.7% ± 0.3% after 16.6 ± 0.3 months (mean ± SE) to the first follow-up BMD measurement.

Of the 794 patients, 161 were treatment-naïve and 633 had previously used OP therapy, of which 566 had used bisphosphonates (BP) and 67 used other antiresorptives. Patients who had taken both BP and another antiresorptive were included in the BP group. Previous BP patients had their first follow-up BMD measurement at 16.2 ± 0.4 months, which differed (P=0.008) from naïve patients (18.1 ± 0.6 months), but not from those who took other therapies (16.8 ± 0.9 months). Previous BP patients had a 5.0% ± 0.4% increase in LS-BMD, which was lower than naïve patients (7.1% ± 0.7%, P=0.009) and those who took other therapies (8.3% ± 1.2%, P=0.006). Time to first follow-up BMD measurement and LS-BMD increase did not significantly differ between naïve patients and those who used other therapies. These data suggest that physicians in community practice generally adhere to recommended guidelines for monitoring BMD in TPTD patients, but previous BP patients may have follow-up BMD measured earlier than naïve patients. It is not known whether the lower LS-BMD increases in previous BP patients result from BP actions on bone or the earlier BMD follow-up.

Interval from Baseline to First Follow-Up BMD Measurement (Months)			
Interval from Baseline to First Follow-Up BMD Measurement (months)	Patients (n)	Patients (% of total)	Percent Change in LS-BMD from Baseline (mean ± SE)
0 to ≤3	21	2.6	4.7 ± 3.6
>3 to ≤6	103	13.0	3.3 ± 0.7*
>6 to ≤9	136	17.1	4.8 ± 0.8*
>9 to ≤12	225	28.3	5.4 ± 0.5*
>12 to ≤18	193	24.3	7.4 ± 0.8*
>18 to ≤24	65	8.1	6.8 ± 1.1*
>24	51	6.4	6.9 ± 1.3*

The Effects of Intravenous Zoledronate on Bone Turnover and Bone Density Persist For At Least 24 Months. M. J. Bolland*, A. Grey¹, A. Horne*, S. Briggs*, M. Thomas*, R. Ellis-Pegler*, A. Woodhouse*, G. Gamble*, I. R. Reid¹. ¹Department of Medicine, University of Auckland, Auckland, New Zealand, ²Department of Infectious Diseases, Auckland City Hospital, Auckland, New Zealand.

Recently, we have shown that annual administration of intravenous zoledronate increases bone mineral density (BMD) in HIV-infected men for at least 24 months. We set out to determine the duration of effect of zoledronate after 2 annual doses.

We performed a randomized, placebo-controlled trial in HIV-infected men with BMD T score at hip or spine < -0.5 who had taken highly active antiretroviral therapy for >3 months. Zoledronate 4mg infusion or placebo was administered at baseline and 1 year and follow-up continued to 24 months following the last dose.

In the zoledronate group (n=15), lumbar spine BMD increased from baseline by 8.8% at 12m post second zoledronate dose and by 9.2% at 24m compared to an increase of 3.4% at 12m and 4.1% at 24m in the controls (n=17). In the zoledronate group, total hip BMD increased by 3.7% at 12m and 3.8% at 24m compared to an increase of 0.9% at 12m and 1.0% at 24m in the controls. In the zoledronate group, total body BMD increased by 2.2% at 12m and 2.0% at 24m compared to an increase of 0.35% at 12m and a decrease of 0.07% at 24m in the controls. At both 12m and 24m, the between-groups differences at all sites were significant (P<0.01).

CTX levels were 0.14 (0.07) ng/ml at 12m post second zoledronate dose and 0.17 (0.10) at 24m in the zoledronate group, and 0.36 (0.12) at 12m and 0.39 (0.15) at 36m in the control group. Osteocalcin levels were 9.7 (2.8) µg/L at 12m and 11.6 (2.7) at 24m in the zoledronate group, and 17.0 (4.9) at 12m and 19.7 (7.6) at 24m in the controls. For both osteocalcin and CTx, the between-groups differences at both time points were significant (P<0.01). CTx did not change significantly in either group between 12m and 24m, whereas osteocalcin increased significantly from 12m to 24m in both groups but there were no between-groups differences in these increases.

In summary, 2 annual doses of 4mg zoledronate suppress bone turnover for at least 24 months after the second dose of zoledronate, and BMD remains stable between 12 and 24 months after the second dose of zoledronate. This suggests that the antiresorptive effects of zoledronate last longer than 12 months, and raises the possibility that it could be administered less frequently than on an annual basis.

Similar Improvements in Hip Bone Mineral Density with Monthly Oral Ibandronate (150mg) Versus Weekly Oral Alendronate (70mg) in Postmenopausal Osteoporosis. J. L. C. Borges¹, M. Bolognese², S. Epstein³, F. Sedarati⁴, C. Neate⁵, P. D. Miller⁶. ¹Universidade Catolica de Brasilia, Brasilia, Brazil, ²Bethesda Health Research, Bethesda, MD, USA, ³Mt Sinai School of Medicine New York and Doylestown Hospital, Doylestown, PA, USA, ⁴Hoffmann-La Roche Inc., Nutley, NJ, USA, ⁵Roche Products Ltd, Welwyn Garden City, United Kingdom, ⁶Colorado Center for Bone Research, Lakewood, CO, USA.

The purpose of the MOTION (Monthly Oral Therapy with Ibandronate for Osteoporosis Intervention) study was to compare the efficacy of monthly oral ibandronate 150mg with weekly oral alendronate 70mg in improving bone mineral density (BMD) in women with postmenopausal osteoporosis. Here we present BMD data from hip sites.

MOTION was a randomized, multinational, double-blind, double-dummy, parallel-group, non-inferiority study. A total of 1,760 postmenopausal women with osteoporosis were enrolled. Patients were aged 55-84 years, ≥ 5 years since menopause, and had a mean lumbar spine BMD T-score (L2-L4) < -2.5 and ≥ -5.0 SD. Randomization was to either monthly oral ibandronate 150mg plus weekly placebo (n=887), or to weekly oral alendronate 70mg plus monthly placebo (n=873). All patients also received vitamin D (400IU/day) and calcium (500mg/day) supplements. The co-primary efficacy endpoints were the relative change (%) from baseline at 12 months in mean lumbar spine (reported separately) and total hip BMD. Monthly ibandronate would be proven clinically comparable to weekly alendronate if the lower boundary of the one-sided 97.5% CI was ≥ 0.87 percentage points for total hip. Secondary efficacy endpoints included the relative change (%) from baseline at 12 months in mean trochanter BMD and additionally as an exploratory analysis, femoral neck BMD.

Per-protocol (PP) analyses (ibandronate n=725, alendronate n=720) found that the change from baseline in mean total hip BMD was 2.94% with ibandronate and 3.03% with alendronate (95% CI, -0.38, 0.18; non-inferiority met at ≥ 0.87). The change from baseline in mean trochanter BMD was 4.20% in both treatment groups (95% CI, -0.49, 0.43) and in mean femoral neck BMD was 2.07% with ibandronate and 2.30% with alendronate (95% CI, -0.61, 0.13). These data show that monthly oral ibandronate is essentially similar to weekly oral alendronate in terms of improvements in total hip BMD and that the two regimens also produced similar improvements in trochanter and femoral neck BMD after 12 months.

Improved Tendency in Esophageal-Gastrointestinal Mucosal Effect of Enterocoating Alendronate Combined with Calcitriol Drug (Maxmarvil®) Compared with Alendronate Only in Korean Postmenopausal Women. D. Byun¹, J. Mok², H. Park³, K. Lee³, Y. Kim⁴, S. Kim⁵, C. Kim⁶, K. Suh¹, M. Yoo¹, M. Rho¹, H. Park⁵. ¹Endocrinology, Soonchunhyang University Hospital, Seoul, Republic of Korea, ²Endocrinology, Soonchunhyang University Hospital, Bucheon, Republic of Korea, ³Endocrinology, Soonchunhyang University Hospital, Cheon-Ahn, Republic of Korea, ⁴Endocrinology, Soonchunhyang University Hospital, Cheon-ahn, Republic of Korea, ⁵Obstetrics & Gynecology, Chung Ang University Hospital, Seoul, Republic of Korea.

Background: Bisphosphonates (BPs) are widely used for postmenopausal osteoporosis but sometimes their medications are restricted because of gastrointestinal (GI) symptoms which associated with injury to the upper GI tract. Previous studies had tried to reduce the damaging effect on the gastric mucosa by developing new drugs or coating the drugs etc. So we compared endoscopic findings after use of alendronate (5 mg/day) only and recently developed Maxmarvil® drug (enterocoating drug of 5mg alendronate combined with 0.5µg calcitriol).

Methods: Healthy 24 postmenopausal volunteers (50-70 years old) without GI symptoms with normal baseline endoscopy findings were participated. Esophagogastroduodenoscopy (EGD) was taken at the time of the baseline and again at 2 weeks later after daily intake of Maxmarvil (9 subjects) or alendronate (15 subjects). Mucosal injury scores were reported by a blinded endoscopist on day 14 of treatment.

Results: Esophageal and gastric mucosal injury showed reduced tendency in Maxmarvil group but did not significantly different between 2 groups. Esophageal mucosal injury developed 2 subjects out of 15 alendronate only group (mucosal damage score; 4) while none of 9 Maxmarvil group. Gastric mucosal injury developed in 7 out of 15 subjects with alendronate group (mucosal damage score; 18) while 4 out of 9 Maxmarvil group (mucosal damage score; 8). These data showed no significant differences.

	No. of Maxmarvil group (mucosal damage score)	No. of Alendronate group (mucosal damage score)
Esophagus	0/9	2(4)/15
Stomach	4 (8)/9	7 (18)/15
Total	4 (8)/9	9 (22)/15

Conclusion: The mucosal damage scores for the alendronate group (total score; 22) exceeded those for the maxmarvil group (total score; 8) in the esophagus and stomach. But this was not significant between 2 groups. (Fisher exact test, p-value=0.253)

The Change of Bone Markers after Once-weekly Low Dose Alendronate in Postmenopausal Women with Moderate Bone Loss. H. Choi, S. Kim*. Family Medicine, Eulji University Hospital, Daejeon, Republic of Korea.

Introduction: High bone turnover with the bone resorption exceeding bone formation is a major mechanism of postmenopausal osteoporosis. Therefore, inhibition of bone resorption is a rational approach for the prevention. The Objective of the current study was to determine the short-term efficacy of once-weekly low dose alendronate in the prevention of bone loss in early postmenopausal Korean women with moderate bone loss via bone turnover markers.

Methods: This study was a 12-week, randomized, double-blind clinical trial compared the effects of placebo with alendronate 20 mg once weekly. All subjects received supplemental calcium 600 mg and vitamin D 400 IU daily. Fifty two postmenopausal women (the ages between 50-65 year) with lumbar spine BMD at least 2.0 SD below the peak young adult mean were recruited at Eulji University Hospital, Daejeon, Korea. BMD was measured by DXA at baseline and serum alkaline phosphatase, osteocalcin and C-terminal telopeptide of type I collagen was measured at baseline and 12 weeks after treatment.

Results: Fifty two women were randomly assigned either to placebo or alendronate 20 mg once a week for 3 months. Among the fifty two women who participated in baseline, thirty nine continued and completed all 3 months. After 3 months, significantly greater decreases in bone resorption markers in the alendronate group vs. placebo occurred: C-terminal telopeptide of type I collagen $-0.252 \pm 0.200\%$ vs. $0.078 \pm 0.196\%$ ($P < 0.001$), alkaline phosphatase $2.7 \pm 18.6\%$ vs. $17.7 \pm 19.5\%$ ($P < 0.021$), osteocalcin $-8.0 \pm 6.4\%$ vs. $-4.0 \pm 6.8\%$ ($P < 0.071$). Women receiving alendronate had adverse experience incidences similar to those receiving placebo.

Conclusion: Once-weekly low dose alendronate was effective, cost saving and had a good safety profile in suppression of bone turnover in early postmenopausal women with moderate bone loss.

How Quickly Do Oral Bisphosphonates Work, and Are There Differences Between Them? J. R. Curtis, A. Westfall*, H. Cheng, E. Delzell*, K. G. Saag. University of Alabama at Birmingham, Birmingham, AL, USA.

Background: The time necessary for bisphosphonates (BPs) to maximally reduce non-vertebral fracture (fx) risk is uncertain; there is controversy regarding effectiveness differences between BPs.

Methods: Using claims data from a large national U.S. health care organization, we identified persons initiating alendronate or risendronate (no prior use in 6 months). Date of first BP use defined the 'index date'. Claims data identified all non-vertebral and hip fxs before and after the index date. To exclude follow-up visits for prior fx, claims for fx within 90 days after the index date among persons who also had fxs in the 6 months prior to the index date were excluded. Post-index fx rates were computed at 30 day intervals. Because we focused on efficacy, we required eligible persons to be at least 80% adherent (quantified using medication possession ratio, MPR) at 6 months after the index date.

A subset analysis among persons initiating weekly BPs with MPR $\geq 80\%$ was performed and compared 1-year hip and non-vertebral fx risk between new risendronate users and new alendronate users.

Results: Among 46,805 new BP users adherent at 6 months, mean \pm SD age was 61.6 ± 7.9 y. We identified 1,022 non-vertebral fxs and 250 hip fxs that occurred in the first year after the index date. The rate of non-vertebral fx reached a nadir between 3 and 6 months after the index date and remained low thereafter. Results were similar for hip fx. Comparing pre and post-treatment non-vertebral fx rates, there was an absolute fx rate difference of approximately 2.7 fractures per 100 py (number needed to treat = 37).

In the subgroup analysis of new weekly BP users, unadjusted time to hip fx among new alendronate users was significantly lower ($p = 0.004$) than among new risendronate users; the absolute rate difference at 1 year was approximately -0.2% (number needed to treat = 500). The difference in non-vertebral fx rates between alendronate and risendronate users was significant ($p = 0.03$) although rate differences were of smaller magnitude.

Conclusions: Oral BPs appear to achieve maximal non-vertebral fx rate reduction between 3 and 6 months. In unadjusted analyses, we found minimal differences in the absolute fx rate between weekly BPs. Ongoing work will determine if channeling higher risk patients may explain some risk differences between BPs. However, even small differences between specific BPs are likely overshadowed by the larger effect size seen with use of any BP.

Effect of Various Substances on the Reduction of Fractures. M. A. Dambacher¹, K. Articus², M. Neff³, J. Gasser³, A. Kreiss², H. Radspieler¹, L. Quin¹. ¹ZORG International, Zurich Osteoporosis Research Group, Zurich, Switzerland, ²Novartis Pharma, Nuremberg, Germany, ³Novartis Pharma, Basel, Switzerland.

The purpose of this analysis is to give an overview about the published data on fracture risk reduction.

The intervention threshold for the treatment of osteoporosis has changed within the last years. Whereas bone mineral density (BMD) alone was used in the past to determine, whether a patient should be treated or not, nowadays the whole situation of the patient (incl. e.g. age, BMI, previous fractures, family history) has to be considered. These factors combined with the BMD allow to calculate the height of the individual fracture risk, upon which the physician can base his treatment decision. In addition three dimensional assessment of bone structure will gain further importance in the future (fig 1).

We analysed published results of randomized controlled trials of various bisphosphonates, parathormone and strontium ranelate and calculated the absolute and relative risk reduction (ARR and RRR) and "number needed to treat" (NNT).

Whereas all analysed substances were able to reduce the risk of vertebral fractures, only Risedronat (RRR=28%, p=0,02), Alendronat (RRR=50%, p=0,047) and Zoledronic acid (RRR=41%, p=0,002) have been able to demonstrate an additional reduction of hip fractures.

The Efficacy and Tolerability of a Once-A-Month Dosing Regimen of 150 Mg Risedronate for the Treatment of Postmenopausal Osteoporosis - The Merit-OP Study. P. D. Delmas¹, M. R. McClung², J. R. Zanchetta³, A. Racewicz⁴, C. Roux⁵, C. L. Benhamou⁶, Z. Man⁷, R. Eusebio⁸, J. F. Beary⁸, D. E. Burgio⁸, S. Boonen⁹. ¹INSERM, Research Unit 403, Lyon, France, ²Oregon Osteoporosis Center & Providence Medical Center, Portland, OR, USA, ³Instituto de Investigaciones (IDIM), Buenos Aires, Argentina, ⁴Centrum Medyczne Specjalistyczny Gabinet Lekarski, Bialystok, Poland, ⁵Cochin Hospital, Rene Descartes University, Paris, France, ⁶Inserm, Research Unit U658, Orléans, France, ⁷Centro Médico TIEMPO, Buenos Aires, Argentina, ⁸Procter & Gamble Pharmaceuticals, Mason, OH, USA, ⁹Leuven University Center for Metabolic Bone Diseases & Division of Geriatric Medicine, Katholieke Universiteit Leuven, Leuven, Belgium.

The MERIT-OP (Monthly Evaluation of Risedronate Trial in Osteoporosis) study is a multinational, 2-year, randomized, double-blind, active-control (5 mg daily risedronate) clinical trial designed to evaluate a 150 mg risedronate once-a-month (OAM) dose for the treatment of osteoporosis in postmenopausal women. Patients were postmenopausal, 50 years of age or older with a lumbar spine (LS) BMD T-score ≤ -2.5 or a LS BMD T-score ≤ -2.0 and at least one prevalent vertebral fracture. Risedronate was given per-label 30 minutes before breakfast. All patients received daily supplemental calcium 1000 mg and vitamin D 400-1000 IU. The primary efficacy endpoint is to demonstrate non-inferiority of the OAM regimen to the daily regimen as assessed by percent change from baseline in LS BMD at Month 12 using the last observation carried forward. Secondary efficacy endpoints include: percent change in biochemical markers of bone metabolism, in BMD at total proximal femur, femoral trochanter, and femoral neck. Safety endpoints include evaluation of adverse events, clinical laboratory measurements, and bone histology by histomorphometry (at Month 24 only).

A total of 1292 women (94% Caucasian) between 50 and 88 years old, mean age 64.9, were randomized to 150 mg risedronate OAM or 5 mg daily from 47 clinical centers in 13 countries. The mean LS BMD T-score and years since menopause at baseline were -3.2 and 18 years, respectively, across both treatment groups. The study remains blinded at the writing of this abstract. The last patient completed the Month 12 primary endpoint visit in March of 2007. The full Month 12 efficacy and safety results related to the primary and secondary endpoints will be available and presented at the time of the meeting.

The MOTION Study: Tolerability of Monthly Ibandronate and Weekly Alendronate in Women with Postmenopausal Osteoporosis. P. D. Delmas¹, E. M. Lewiecki², S. Ragi-Eis³, F. Sedarati⁴, C. Leigh⁵, F. Cosman⁶. ¹Université de Lyon and INSERM Research Unit 831, Lyon, France, ²New Mexico Clinical Research & Osteoporosis Center, Albuquerque, NM, USA, ³CEDOES Diagnóstico e Pesquisa, Vitoria, Brazil, ⁴Hoffmann-La Roche Inc., Nutley, NJ, USA, ⁵Roche Products Ltd, Welwyn Garden City, United Kingdom, ⁶Helen Hayes Hospital, West Haverstraw, NY, USA.

The MOTION (Monthly Oral Therapy with Ibandronate for Osteoporosis Intervention) study is the first head-to-head comparison of monthly oral ibandronate and weekly oral alendronate for the treatment of postmenopausal osteoporosis. The study compared efficacy (bone mineral density [BMD] at spine and hip and bone turnover markers) and tolerability and safety of the regimens.

Women aged 55-84 years and ≥ 5 years since menopause with a mean lumbar spine BMD T-score (L2-L4) < -2.5 and ≥ 5.0 were randomly allocated to 12 months of double-blind, double-dummy treatment with oral ibandronate (IBN) 150mg once monthly (plus weekly placebo) or oral alendronate (ALN) 70mg once weekly (plus monthly placebo). Treatments were taken in the morning after an overnight fast. Patients also received vitamin D 400IU/day and calcium 500mg/day. Safety was monitored during the study by assessment of adverse events (AEs) and laboratory tests. We present here the AE data.

A total of 1,733 (IBN, 874; ALN, 859) patients were included in the safety analysis population (patients who took at least 1 active treatment dose). The overall incidence of AEs, including those considered related to treatment or leading to withdrawal, was similar across both treatment groups (Table). Of the serious AEs reported (IBN: 4.5%; ALN: 6.4%), very few were considered treatment related ($< 1\%$ per group; Table). There was one death with IBN and four with ALN. The incidence of upper gastrointestinal (GI) AEs was similar in the two treatment groups (Table) but more patients in the ALN group (15; 1.7%) withdrew after drug-related upper GI events than patients in the IBN group (9; 1.0%). In conclusion, monthly ibandronate and weekly alendronate were shown to have very similar tolerability profiles in women with postmenopausal osteoporosis.

Incidence (n, %)	IBN (n=874)	ALN (n=859)
Any AE	659 (75.4)	632 (73.6)
Any drug-related AE	232 (26.5)	176 (20.5)
Any drug-related AE leading to withdrawal	29 (3.3)	26 (3.0)
Any drug-related serious AE	1 (0.1)	5 (0.6)
Upper GI AEs	153 (17.5)	143 (17.2)
Perforations, ulcers and bleeding	4 (0.5)	8 (1.0)
Any drug-related serious upper GI disorders	0	3 (0.3)

Bisphosphonate Therapy and Hip Fractures Within the Risedronate and Alendronate (REAL) Cohort Study: A Comparison to Patients with Minimal Bisphosphonate Exposure. P. D. Delmas¹, S. L. Silverman^{2*}, N. B. Watts³, J. L. Lange^{4*}, R. Lindsay^{5*}. ¹INSERM Unit 403, University of Lyon, Lyon, France, ²Cedars-Sinai Medical Center, Beverly Hills, CA, USA, ³Bone Health and Osteoporosis Center, Cincinnati, OH, USA, ⁴P&G, Mason, OH, USA, ⁵Helen Hayes Hospital, West Haverstraw, NY, USA.

In the published REAL cohort study,¹ we observed that patients on risedronate had a lower incidence of hip fractures during the first year of therapy, but not in the year before therapy, compared with patients on alendronate. That study design did not include a comparison to an untreated control group. Here we present an approach to utilize patients with minimal bisphosphonate exposure as a control group for the REAL study. The original study population was identified within records of health services utilization and included new users of once-a-week dosing of risedronate or alendronate. These bisphosphonate users were followed until a 15 day gap occurred between the completion of a 30-day prescription and any subsequent prescription. To identify the control group within the same data source, we selected patients who filled only a single prescription of alendronate or risedronate over one year. Hip fracture in the first year after the initial prescription was the primary outcome. Cox proportional hazard modeling was used to compare the incidence of hip fractures between patient populations.

In the control group of patients receiving a single bisphosphonate prescription, the one year incidence of hip fractures in patients who were prescribed alendronate (0.81% of 1850 patients) or risedronate (0.78% of 1152 patients) was similar (relative risk 1.0, 95% CI 0.4 - 2.2). Compared to this control group with minimal bisphosphonate exposure, patients on risedronate had a significantly lower incidence of hip fractures, while patients on alendronate were not significantly (table).

Patients with minimal bisphosphonate exposure to either risedronate or alendronate were at similar risk for hip fracture and can be pooled to serve as a control group. Patients on risedronate had significantly fewer hip fractures than this control group, patients on alendronate did not.

¹Silverman et al. Effectiveness of bisphosphonates on nonvertebral and hip fractures in the first year of therapy: the risedronate and alendronate (REAL) cohort study. *OJ* 2007 18:25

Incidence of hip fractures in the initial year of therapy by cohort						
Cohort	Cohort size	Number women with hip fracture	Percent* women with hip fracture	Adjusted** rate ratio vs control	95% confidence interval	p-value
Minimal exposure (control)	3,002	24	0.80	referent

Reduction of Bone Turnover Markers With Annual Infusion of Zoledronic Acid 5 mg in Postmenopausal Osteoporosis: Influence of Age, Renal Function, Concomitant Therapy, and Duration of Treatment. P. Delmas¹, D. M. Black², S. Boonen³, D. C. Bauer², F. Cosman⁴, C. Mautalen⁵, I. A. Skripnikova^{6*}, E. F. Eriksen⁷, P. Mesenbrink^{8*}, H. Hu^{8*}, R. Eastell⁹. ¹INSERM Research Unit 831, Univ of Lyon, Lyon, France, ²Univ of California, San Francisco, CA, USA, ³Univ Ziekenhuizen K.U. Leuven, Leuven, Belgium, ⁴Helen Hayes Hospital, West Haverstraw, NY, USA, ⁵Hospital de Clinicas University of Buenos Aires, Buenos Aires, Argentina, ⁶Russian Ministry of Health, Moscow, Russian Federation, ⁷Novartis Pharma AG, Basel, Switzerland, ⁸Novartis Pharmaceuticals Corp, East Hanover, NJ, USA, ⁹Univ of Sheffield, Sheffield, United Kingdom.

Annual infusions of zoledronic acid (ZOL) 5 mg have been shown to reduce vertebral and hip fractures by 70% and 40% respectively (Black et al, *NEJM* 2007) in postmenopausal women w/ osteoporosis compared w/ placebo. Serum C-telopeptide of collagen-1 (CTX-1) and bone alkaline phosphatase (ALP) were measured in a subgroup of 605 women (300 ZOL, 305 placebo). Mean decreases at 6 mos relative to placebo for CTX and bone ALP were 69% (95% CI: 67,72) and 33% (95% CI: 31,35) respectively, both P < .0001. Our objective was to analyze the influence of age, renal function, concomitant therapy (Stratum II: pts taking raloxifene, tibolone, hormone replacement therapy, or nasal calcitonin in addition to study drug) and duration of therapy on magnitude of bone turnover marker (BTM) decrease. In women ≥75 yrs mean decreases (95% CI) at 6 mos w/ ZOL compared w/ placebo for CTX and bone ALP were 70% (95% CI: 65,74) and 33% (30,36) respectively, comparable to women <70 yrs, for whom they were 69% (62,75) and 35% (30,40) respectively. In women w/ creatinine clearance <60 mL/min mean decreases (95% CI) at 6 mos w/ ZOL compared w/ placebo for CTX and bone ALP were 69% (64,73) and 33% (30,37) respectively, comparable to women w/ creatinine clearance >60 mL/min, for whom they were 70% (66,73) and 33% (30,36) respectively. In Stratum II pts mean decreases (95% CI) at 6 mos w/ ZOL relative to placebo for CTX were 67% (62,72) and for bone ALP were 29% (25,32), both P < .0001, as compared to women in Stratum I, for

whom they were 71% (68,74) for CTX and 36% (33,39) for bone ALP, both P < .0001. BTM reduction differences across strata were accounted for by lower baseline levels in Stratum II. CTX mean decrease (95% CI) from pre-infusion to 10 days after the 3rd ZOL infusion relative to placebo was 77% (72,80) (P < .0001). In summary, ZOL 5 mg reduced BTM independently of age and creatinine clearance, and to a greater magnitude in naive pts than in those receiving concomitant therapy, and CTX-1 levels following the 3rd annual infusion showed rapid and transient decrease, indicating ongoing bone remodeling. The data suggest ZOL reduces BTM values to safe levels in a wide range of osteoporotic women.

T386

Comparison of Bone Architecture via Micro-CT after Long-term Treatment with Risedronate and Alendronate: A Cross-sectional Study in Women with Postmenopausal Osteoporosis. T. E. Dufresne^{1*}, P. A. Chmielewski^{1*}, J. H. Nurre^{1*}, B. Borah¹, X. Zhou^{1*}, R. Phipps¹, G. Woodson², P. D. Miller³. ¹Procter & Gamble Pharmaceuticals, Mason, OH, USA, ²Atlanta Research Center, Decatur, GA, USA, ³Colorado Center for Bone Research, Lakewood, CO, USA.

To compare the effects of risedronate and alendronate on trabecular and cortical bone architecture we analyzed transiliac crest biopsies collected from a sample of 100 women with postmenopausal osteoporosis. Subjects were at least 5 yr postmenopause and had been treated for 3 or more yr with daily or weekly alendronate (n=68, mean age 69.7 yr) or risedronate (n=32, mean age 70.2 yr). Complete biopsies were scanned at 8 µm resolution using a Scanco MicroCT40 scanner. After thresholding and masking, trabecular and cortical bone measurements were derived from these 3-D data sets. In addition, the grey level images were calibrated against hydroxyapatite standards to allow for accurate measurement of mineralization in the cortical and trabecular envelopes.

There were no significant differences in patient demographics either prior to treatment initiation or at time of biopsy, including age, lumbar spine and total hip T-scores, and previous fractures. There were no significant differences in trabecular architecture, cortical porosity or cortical thickness between risedronate and alendronate. The low: high mineralization ratio in both trabecular and cortical bone was significantly higher in biopsies from risedronate-treated subjects than in alendronate-treated subjects, consistent with the higher bone turnover in risedronate-treated subjects seen by histomorphometry (MS/BS 2.55% vs 1.32%, P<0.01).

These results support that long-term treatment with risedronate provided equivalent preservation of trabecular and cortical bone architecture compared with alendronate, despite producing significantly lower suppression of bone remodeling.

Parameter	Alendronate (Median)	Risedronate (Median)	P-value (Wilcoxon Rank Sum Test)
Trabecular bone volume (%)	15.59	16.02	0.57
Trabecular number (n)	1.26	1.31	0.21
Trabecular thickness (µm)	148	151	0.74
Low:high mineralization ratio - trabecular	0.26	0.41	0.01
Low:high mineralization ratio - cortical	0.22	0.30	0.02
Cortical porosity (%)	3.21	3.57	0.41
Cortical thickness (µm)	460	479	0.70

Determinants of Femoral Neck Bone Loss in the HORIZON-PFT Study: Impact of Zoledronic Acid Therapy. R. Eastell¹, D. Black², S. Boonen³, S. Cummings², P. Delmas⁴, L. Palermo^{2*}, E. Eriksen⁵, P. Mesenbrink^{6*}, K. Lippuner⁷, C. Zerbinì⁸, A. Skag^{9*}, P. J. Cauley¹⁰. ¹Univ. of Sheffield, Sheffield, United Kingdom, ²Univ. of California, San Francisco, CA, USA, ³Univ. Ziekenhuizen K.U., Leuven, Belgium, ⁴Univ. of Lyon, INSERM Research Unit 831, Lyon, France, ⁵Novartis Pharma AG, Basel, Switzerland, ⁶Novartis Pharmaceuticals Corp, East Hanover, NJ, USA, ⁷Poliklinik für Osteoporose der Medizinischen Fak. und des Inselspitals der Univ., Bern, Switzerland, ⁸Hosp. Heliópolis, São Paulo, Brazil, ⁹Senter for kliniske studier AS, Bergen, Norway, ¹⁰Univ. of Pittsburgh, Pittsburgh, PA, USA.

The HORIZON-PFT is a multinational, 3-year, randomised, double-blind, placebo (PLB)-controlled trial evaluating the effect of once-yearly zoledronic acid (ZOL) 5 mg, on vertebral and hip fracture risk in 7736 postmenopausal osteoporotic women (65-89 yrs). Femoral neck BMD was measured annually in all participants. In this post-hoc analysis, we examined the determinants of bone loss in the PLB group and whether ZOL is effective in preventing bone loss across all subgroups. Specifically, we examined the effect of ZOL on femoral neck BMD in women stratified by age (<70, 70-79, ≥80 years), weight (<55, 55-64, >64 kg), current smoking status, race (Caucasian, Asian, other) and region (Europe, Asia, Americas), see table. We found bone loss was greater in women ≥80 yr (-1.14/3-yr) vs women <70 yr (-0.76%/3-yr) in the PLB group. This difference was maintained in the ZOL group for older and younger women, respectively (3.90 and 4.33%/3-yr). Bone loss was greater in lighter (-1.29/3-yr) vs heavier women (-0.50%/3-yr) and this was maintained in the ZOL group for lighter and heavier women (3.92 and 4.43%/3-yr). Bone

loss was greater in smokers (-1.42%/3-yr) vs non-smokers (-0.92%/3-yr) and this difference was greater in the ZOL group for smoking and non-smoking women (3.35 and 4.17%/3-yr). We found bone loss was greater in Caucasian (-0.96%/3-yr) vs Asian women (-0.49%/3-yr) and this was maintained in the ZOL group for Caucasian and Asian women (4.08 and 4.37%/3-yr). Bone loss was greater in women from the Americas (-1.47%/3-yr) vs those from Asia (-0.48%/3-yr) and this was maintained in the ZOL group for women from the Americas and Asia (3.50 and 4.44%/3-yr). We conclude that older age, lighter weight, smoking, being Caucasian or from the Americas are risk factors for hip bone loss, and that ZOL is equally effective on hip BMD in each of these groups.\

Factor	Category	ZOL	PLB	p, Rx	p, CAT
Age	<70	4.33	-0.76	<0.0001	0.01
	70-79	4.08	-0.95

In Case of Gastrointestinal Side Effects or Contraindications for Oral Bisphosphonates Treatment with Intravenous Pamidronate Is a Good Alternative. D. A. Eekman^{*1}, M. Vis², I. E. M. Bultink^{*1}, H. J. G. M. Derikx^{*2}, B. A. C. Dijkman¹, W. F. Lems¹. ¹Rheumatology, VU University Medical Center, Amsterdam, The Netherlands, ²Rheumatology, Slotervaart Hospital, Amsterdam, The Netherlands.

Background: oral bisphosphonates (OB) are the preferred treatment for osteoporosis (OP), however they may cause gastrointestinal side effects. In patients with side effects or contraindications it is possible to administer pamidronate intravenously (APD). In a previous 1 year prospective study in 2 groups of each 20 patients, we have shown that the effects on BMD of APD and OB are comparable.¹

Objectives: to compare the effect on change in BMD of the lumbar spine and total hip of long term treatment (≥ 2 years) with APD (60mg intravenously every 3 months) in comparison to alendronate 70mg or risedronate 35mg weekly in patients with OP.

Methods: all consecutive patients receiving OP treatment for at least two years at the Slotervaart Hospital OP clinic were enrolled. Most patients started with an OB according to protocol. In case of intolerance (within 3 months of start of treatment) of an OB or in case of contraindications for an OB, APD 60mg was started. BMD was measured on a Hologic 4500 at the lumbar spine (L1-L4) and the total hip before the start of treatment and at the end of follow-up. Changes in BMD between the groups were compared by an independent student t-test.

Results: 67 patients were enrolled, 34 in the OB group (17 alendronate and 17 risedronate) and 33 in the APD group. Mean follow-up duration (SD) was 4.3 (1.3) years. There were no differences in baseline characteristics or baseline T scores of hip and spine between both groups. There was no significant difference in BMD change between the OB and APD group. (see table)

	Oral Bisphosphonates (n=34)	APD (n=33)
Duration of treatment	4.3 (1.37)	4.2 (1.29) (ns)
Mean (SD) years		
BMD lumbar spine baseline	0.787 (0.17)	0.778 (0.092) (ns)
mean (SD) g/cm ²		
BMD lumbar spine follow-up	0.851 (0.136)	0.844 (0.123) (ns)
mean (SD) g/cm ²		
% change of lumbar spine BMD per year	2.47	2.33 (ns)
BMD Hip baseline	0.721 (0.137)	0.745 (0.126) (ns)
mean (SD) g/cm ²		
BMD Hip follow-up	0.736 (0.142)	0.763 (0.119) (ns)
mean (SD) g/cm ²		
% change of hip BMD mean (SD)	0.31	0.62 (ns)

Conclusion: after 4 years of treatment, the change of BMD of the lumbar spine and hip is not significantly different between patients treated with intravenous pamidronate versus oral bisphosphonates. BMD of the hip remained stable, whereas BMD of the lumbar spine improved with 2% per year in both groups. We therefore conclude that intravenous administration of pamidronate is an alternative for oral bisphosphonates in the treatment of OP. References: ¹ M. Vis et al. Osteoporos Int. 2005 Nov;16(11):1432-5

Benefits of Oral Ibandronate on Non-Vertebral Fracture Risk in Postmenopausal Osteoporosis: Further Analyses From a Pivotal Phase III Study. R. Emkey¹, C. H. Chesnut^{*2}, R. C. Schimmer^{*3}, C. Neate^{*4}, R. R. Recker⁵. ¹Radiant Research, Wyomissing, PA, USA, ²University of Washington, Osteoporosis Research Group, Seattle, WA, USA, ³F. Hoffmann-La Roche Ltd, Basel, Switzerland, ⁴Roche Products Ltd, Welwyn Garden City, United Kingdom, ⁵Creighton University, Osteoporosis Research Center, Omaha, NE, USA.

Ibandronate is a potent, nitrogen-containing bisphosphonate that has shown efficacy and tolerability for the treatment of postmenopausal osteoporosis (PMO) in a number of clinical trials. In the BONE (Bonviva Osteoporosis Trial in North America and Europe) study, 2,946 women (aged 55-80 years, menopause onset ≥5 years) with PMO (1-4 prevalent vertebral fractures, lumbar spine BMD T-score <-2.0 SD) were randomized to receive oral ibandronate either daily (2.5mg) or intermittently (20mg every other day for 12 doses every 3 months), or placebo for 3 years. All patients received daily oral calcium (500mg) and vitamin D (400IU). Daily ibandronate reduced vertebral fracture risk (primary endpoint) by 52% (US; p=0.0003)¹ and 62% (Europe; p=0.0001).² The population was relatively low risk for non-vertebral fractures, with a minority of women (30.5%) having low femoral neck BMD at baseline (T-score ≤-2.5 SD), and >30% having a femoral neck BMD T-score >-1.6 SD. Consequently, no statistically significant effect was seen on non-vertebral fractures in the overall study population. Without appropriate fracture risk and a sufficient number of events, it is not possible to detect a true reduction in fracture risk. Therefore, we carried out a subanalysis in women at higher risk for non-vertebral fractures; women (n=278) with lumbar spine BMD T-score <-2.5 and a history of clinical fractures in the previous 5 years. The incidence of non-vertebral fracture in women from the higher-risk subgroup was reduced to 6.28% with daily ibandronate (n=152) vs 14.9% with placebo (n=126). This corresponds to a significant reduction in the risk of non-vertebral fractures of 60% (p=0.0371) for daily ibandronate vs placebo. This risk reduction is consistent with a previously reported subgroup analysis of the BONE study,² which showed a 69% (p=0.013) reduction in the risk of non-vertebral fractures in a group of patients with similar fracture risk.

In conclusion, daily oral ibandronate significantly reduced the risk of non-vertebral fractures in a higher-risk subgroup, even though the overall population was at relatively low risk for non-vertebral fractures. Importantly, the sub-population analyzed represents the majority of patients typically treated for postmenopausal osteoporosis.

Pamidronate Is Effective for Children with Severe Glucocorticoid-induced Osteoporosis. I. Fujiwara, A. Saito^{*}, K. Ishii^{*}, J. Kanno^{*}, S. Tsuchiya^{*}. Pediatrics, Tohoku University School of Medicine, Sendai, Japan.

Glucocorticoid-induced osteoporosis (GIO) is a dose- and duration-dependent side-effect of glucocorticoid treatment, and in severe GIO patients, fractures and deformities of bone may be seen even during childhood. Bisphosphonates are effective for adult GIO patients, but reports of its use in children are limited. We report efficacy of pamidronate infusion in severe GIO children who experienced spinal fracture.

Five GIO patients (age 3 to 21y, median 8y) received monthly pamidronate infusion (1mg/kgBW) for 3 to 27 months after the diagnosis of vertebral fracture. They had been treated with glucocorticoid due to hematological (Diamond-Blackfan anemia, idiopathic thrombocytopenic purpura), inflammatory (Weber-Christian disease), or respiratory (bronchiolitis obliterans after bone marrow transplantation) diseases, respectively.

Relief from pain was particularly notable, which was obtained one or two days after the first infusion in all the patients. Although not significant, the average Z score of lumbar BMD increased after pamidronate (-4.06 SD at the beginning to -2.96 SD at 12months), but in one, BMD continued to decrease probably because of the immobilization of the patient. No apparent adverse events were seen during and after pamidronate. In conclusion, monthly pamidronate infusion is an effective treatment for children with severe GIO.

The impact of bonemarker feedback on adherence to once monthly ibandronate treatment for postmenopausal osteoporosis (PMO) in Mexican and Chilean patients (BOHEMIA Study)

Poor adherence is a common cause of reduced patient benefit from bisphosphonates therapies used in the clinical area. An open-label, prospective, randomized, multi-center clinical study to investigate the impact of bonemarker feedback on adherence to once monthly ibandronate treatment for postmenopausal osteoporosis (PMO) in Mexican and Chilean patients (BOHEMIA Study) were performed. All patients received oral ibandronate 150 mg once-monthly during 6 months of treatment. A total of 781 patients were enrolled into the study across 25 centers in Mexico (700 patients) and 24 centers in Chile (81 patients), and they were divided in 2 arms at baseline either to receive bonemarker feedback or not to receive it, who were either naïve to bisphosphonate treatment, lapsed bisphosphonate users, or current BP users. We found statistical differences among patients who received bonemarker feedback versus those patients who did not, according results in treatment adherence ($p < 0.001$). It can be observed that patients who use bonemarker feedback had a 95% IC range from 98.8% to 99.8%, while the no user patients had a range from 95.5% to 97.5% ($p < 0.001$). We also found significant differences among patients with bonemarker feedback versus no users in the percentage of change of CTX in basal conditions compared with 3 and 6 months ibandronate treatment. According ibandronate safety, 247 (31.6%) patients had at least one adverse event (AE), while 534 (68.40%) patients did not have any AE. In order of frequency, bone pain was the most common AE (65 cases; 13.8%). According with our results, bonemarker feedback is recommended in order to have benefits in the osteoporosis therapy, supported by the physician opinion, where 49% percent of them recommend bonemarker feedback every 6 months in order to improve the adherence of the patients. The reduction in CTX observed in the patients after ibandronate therapy and the results in terms of adherence to treatment were a good signal for supporting the use of the oral monthly ibandronate in order to improve the persistence in the treatment.

Prevention of Bone Loss in Acute Spinal Cord Patients over One Year with Alendronate: Randomized Double-blind Placebo Controlled Study. N. L. Gilchrist¹, C. P. Frampton^{*2}, R. R. Acland^{*3}, R. L. March^{*1}, P. Maguire^{*1}, A. Heard^{*1}, P. Reilly^{*1}, K. Marshall^{*3}.

¹Canterbury Geriatric Medical Research Trust, Christchurch, New Zealand, ²Department of Medicine, Christchurch School of Medicine, Christchurch, New Zealand, ³Spinal Unit, Burwood Hospital, Christchurch, New Zealand.

The aim of the study was to document the effect on bone mass loss in acute spinal cord injury patients using oral alendronate 70mg once weekly having commenced within 10 days of acute spinal cord injury and administered for a period of 12 months. The study enrolled patients between March 2001 and February 2004, males and females, 18 - 55 years presenting to the Burwood Hospital, Spinal Injury Unit, Christchurch, New Zealand with acute spinal cord injury (C4 - L2, ASIA scores A - D) were randomly assigned to enter a prospective double blind placebo controlled study to compare the safety and efficacy of oral alendronate with 70mg once weekly. The treatment was begun as inpatients. No additional calcium or vitamin D was administered. Vitamin D deficiency at baseline was corrected. Data was collected at baseline 3, 6, 12 and 18 months (bone mineral density, total body and regional areas, hip, lumbar spine and ultrasound at calcaneus). Weight body mass index and adverse events were collected. Bone mineral density loss was prevented at the total body site ($>7\%$ and at the regional site, pelvis $>15\%$, trunk $>4\%$, legs $>7\%$, arms $>3\%$). No significant loss was observed at the spine. All areas at the hip demonstrated prevention of bone loss, total $>16\%$, femoral neck $>16\%$, trochanter $>20\%$, femoral shaft $>15\%$. No significant treatment related side effects were noted. In conclusion this is the first study to use once weekly oral alendronate in patients with acute spinal cord injury soon after the acute event. Bone loss was prevented in most bone sites measured and occurred over 12 months with oral alendronate 70mg per week. There were no significant treatment related adverse events.

Nothing works without Calcium and Vitamin D. C. Guenther^{*1}, A. Kapner^{*1}, H. Schultis^{*2}, C. Spanier^{*1}, D. Arnold-Dahmen^{*1}, V. Schäfer^{*1}.

¹Deutsches Zentrum für Osteoporose, Johannesbad Reha-Kliniken AG&Co.KG, Bad Füssing, Germany, ²Gemeinschaftspraxis für Laboratoriumsmedizin und Mikrobiologie, Weiden, Germany.

Aim: To show in a case report that antiresorptive therapy of osteoporosis is not effective without calcium and vitamin D.

Method: The 75 year old woman with a new L-1 fracture were treated by the family doctor only with one tablette Fosamax 70mg per week. In our clinic we added the basic therapy with calcium and vitamine and investigated different laboratory values including bone markers.

Results: A nine days later occurring laboratory analysis showed an increase of calcium in serum by 2.3%, a decrease of alkaline phosphatase by 15%, an increase of 25-OH-D3 by 53% and a decrease of β -crosslaps by 45%. Simultaneous balneophysical therapy and pain therapy improved the patients condition additional, so that she could continue the care of her husband after being discharged.

Summary and Conclusion: This case report shows that only treatment with highly active antiresorptive agents (in this case Fosamax, but other cases with Actonel 35, Evista, Bonviva, Protelos also regarding bone markers prove this statement too) do not lead to sufficient reduction of bonecatabolism, if the basic therapy with calcium and vitamin D is neglected. Therefore in all bisphosphonate studies calcium and vitamin D have been given as "placebo". Furthermore it can be proved that the bone markers (in this case the high sensible catabolism marker β -CTx of Roche) show therapy effects already after a short time (here after nine days). This case confirms Köster J.C. et al. (Eur J Clin, Pharmacol, 1996; 51:145-147) that under sole Editronat-therapy without vitamin D- supplementation of postmenopausal patients with osteoporosis only 0.4% increase of bone density at the spine and 0.5% at the neck of the femur could be reached while the other group with calcium and vitamin D supplementation noted an increase of 1.9% respectively 5.2%.

Therefore in any kind of osteoporosis therapy with antiresorptive or osteoanabolic (like Forsteo, Preotact or Protelos) drugs basic therapy with calcium and vitamin D should never be forgotten.

Persistence with Risedronate Therapy Is Already High and Further Improved by a Patient Educational Program. P. Hadji. Gyn. Endocrinology, Reproductive Medicine and Osteology, University Hospital Marburg, Marburg, Germany.

Objective: There is concern that persistence with therapy for chronic, asymptomatic diseases, i.e. postmenopausal osteoporosis is suboptimal and this may affect clinical efficacy. Recent analyses, however, show a satisfactory 1-year persistence as high as 68% for weekly bisphosphonates. To further improve persistence with risedronate therapy a patient educational program was introduced in 2000 in Germany by the Alliance for Better Bone Health. Patients can enrol into the program sending in a reply card. They receive reminder letters together with leaflets informing them about osteoporosis in regular intervals over the first 7-month period. In this study we evaluated whether persistence with risedronate therapy improved in patients enrolled into the program versus a control group. **Methods:** Telephone interviews were conducted with postmenopausal women with osteoporosis enrolled into the program ($n = 204$) and a control group of patients that was recruited from physicians in private practice who were not enrolled into the program ($n = 204$). Treatment start was equally distributed between February 2003 and February 2005. Survival analyses were used to determine persistence at 12, 24, and 29 months. Log rank test was used to statistically compare the two groups. **Results:** Average age in both groups was similar (69 years). The majority of patients were taking weekly risedronate. Persistence with risedronate therapy in the patient group enrolled into the program was significantly higher than in the control group ($p < 0.03$). Persistence at 12 months was 91.6% for the group enrolled in the program versus 84.7% in the control group. After 24 months persistence was 84.6% versus 75.7%, and at 29 months persistence was 79.1% versus 75.7%. **Conclusion:** Persistence with risedronate therapy is high in Germany. These data suggest that enrolling patients in a mailed education program can further improve persistence.

Comparison of the Effect of Daily 1mg Minodronate with 5 mg Alendronate in Japanese Women with Postmenopausal Osteoporosis: A Randomized Double-Blind Study. H. Hagino¹, Y. Nishizawa², T. Sone³, H. Morii², Y. Taketani⁴, T. Nakamura⁵, A. Itabashi⁶, H. Mizunuma⁷, Y. Ohashi⁴, M. Shiraki⁸, T. Minamide⁹, T. Matsumoto¹⁰. ¹Tottori University, Yonago, Japan, ²Osaka City University, Osaka, Japan, ³Kawasaki Medical School, Okayama, Japan, ⁴University of Tokyo, Tokyo, Japan, ⁵University of Occupational and Environmental Health, Kitakyushu, Japan, ⁶Saitama Center for Bone Research, Saitama, Japan, ⁷Hirosaki University, Hirosaki, Japan, ⁸Research Institute and Practice for Involuntional Diseases, Nagano, Japan, ⁹ONO Pharmaceutical CO.,LTD., Osaka, Japan, ¹⁰University of Tokushima Graduate School of Health Biosciences, Tokushima, Japan.

The efficacy and safety of minodronate, a new bisphosphonate, were examined in Japanese patients with postmenopausal osteoporosis by a double-blinded, randomized, active-controlled, multicenter study to compare with alendronate.

A total of 270 postmenopausal women ≥ 45 years of age with osteoporosis were randomized into minodronate group (N=135) or alendronate group (N=135). Patients for each group received minodronate 1mg or alendronate 5mg once a day for 12 months.

The changes in lumbar spine BMD in both treatment groups were very similar to each other over the course of study until 12 months. The lumbar spine BMD after 12 months of treatment increased 5.86 and 6.29% from the baseline in minodronate and alendronate group, respectively (treatment difference [95% CI]: -0.43% [-1.29, 0.43; $p=0.0002$]). As for the effect on BMD of minodronate at 12 months, non-inferiority to alendronate was shown. Total hip BMD increased from baseline by 3.47 and 3.27% after 12 months in minodronate and alendronate groups, respectively. The bone turnover markers were rapidly reduced within 1 month in both treatment groups and there was no significant difference between the two groups, except for an earlier reduction in urinary type I collagen N-telopeptide in minodronate group than in alendronate group. The completion rates for 12 months of the study were similar in the two treatment groups (minodronate, 91.8%; alendronate, 89.6%). The overall incidence and severity of clinical adverse events was almost similar between the two groups, including gastrointestinal events (39.6% and 37.0% in minodronate and alendronate group, respectively), and most of gastrointestinal events were mild in the two groups.

The effects of 12-month treatment with 1mg minodronate on lumbar and hip BMD were similar to those of 5 mg alendronate. Minodronate was generally well tolerated and the safety profile was comparable to that of alendronate.

Disclosures: H. Hagino, ONO Pharmaceutical CO.,LTD. 5; Astellas Pharma Inc. 5.

T396

Bisphosphonate use Increases in Patients with Osteopenia and Prior Fractures Following a Multifaceted Osteoporosis Educational Intervention: Canadian Quality Circle (CQC) National Project. G. Ioannidis¹, L. Thabane², A. Gafni³, A. Papaioannou¹, B. Kvern⁴, A. Hodsmann⁵, D. Johnstone⁶, L. Salach⁷, F. Jiwa⁸, J. D. Adachi¹. ¹McMaster University, Hamilton, ON, Canada, ²University of Manitoba, Winnipeg, MB, Canada, ³University of Western Ontario, London, ON, Canada, ⁴Procter and Gamble Pharmaceuticals, Toronto, ON, Canada, ⁵Ontario College of Family Physicians, Toronto, ON, Canada, ⁶Osteoporosis Canada, Toronto, ON, Canada.

The Quality Circles (QCs) project is a disease management process that involves a small group of people who identify and analyze work related problems and recommend solutions. The project was developed to improve primary care physicians' (PCPs) management of osteoporosis in accordance with the Osteoporosis Canada (OC) 2002 Guidelines. The study consisted of five phases: wave I data collection, 1st educational intervention, wave II data collection, 2nd educational intervention, and wave III data collection. During the educational intervention QCs met to discuss physician profiles (snapshots of how they managed osteoporosis) and to participate in an osteoporosis workshop. This interim analysis (wave I & II) evaluated the change in treatment administration in high risk patients with BMD t-scores in the osteopenia range and prior fragility fracture at the hip, wrist or spine. None of the patients had BMD t-scores in the osteoporotic range (defined as a BMD t-score < -2.5). A total of 340 (wave I) and 301 (wave II) PCPs formed 34 QCs. For each wave, PCPs collected data from different patients via chart reviews and a standardized collection form. A total of 8376 (wave I) and 7354 (wave II) patient records were selected. All patients were women 55 years and older. The generalized estimating equations (GEE) method was used to evaluate differences in bisphosphonate use in high risk patients pre and post educational intervention. The cluster variable for the GEE model was physician and the analysis was adjusted for other clinical risk factors for fracture. An exchangeable correlation matrix was used for the analysis. Odds ratios (OR) and 95% confidence intervals (CI) were calculated. A total of 21, 82, 74 and 169 patients during wave I and 45, 144, 133 and 290 patients during wave II had hip, spine, wrist or any (hip, spine or wrist) fractures, respectively. The likelihood of bisphosphonate use increased following the educational intervention for patients with spine (OR: 1.74; 95% CI: 0.104, 2.91) wrist (OR: 2.56; 95% CI: 1.34, 4.90) and any fracture (OR: 2.19; 95% CI: 1.47, 3.26). No change in bisphosphonate use was observed for hip fractures (OR: 1.0; 95% CI: 0.99, 1.01). The use of QCs is an effective knowledge translation approach that increases PCPs bisphosphonate utilization in high risk patients with osteopenia and fracture.

Comparative Efficacy of Osteoporosis Treatment in Postmenopausal Women. Y. Ishida, T. Taguchi*. Department of Orthopaedic Surgery, Yamaguchi University Graduate School of Medicine, Yamaguchi, Japan.

This study was conducted to assess the comparative effectiveness of several medications on bone mineral density, biochemical bone markers, and the incidence of vertebral fractures in postmenopausal women with osteoporosis. We also investigated the difference in the efficacy of several medications according to the age and the bone turnover. The analysis was based on combined data from two randomized controlled trials. A total of 596 postmenopausal women, aged 50 to 85 years, were analyzed on an intention-to-treat basis. Treatment groups were 1) alendronate, 2) risendronate, 3) etidronate, 4) hormone replacement therapy, 5) eel calcitonin, 6) alfacalcidol, 7) vitamin K2, and 8) control (no treatment). Thoracic and lumbar spine radiographs, bone mineral density at the distal radius, and markers of bone turnover were assessed at baseline and at 3, 6, 12, 18, and 24 months of treatment during the 2-year study. Compared with baseline, the 2-year mean changes in bone mineral density were 2.3% for alendronate, 1.9% for risendronate, -0.5% for etidronate, 2.0% for hormone replacement therapy, 1.6% for calcitonin, -3.6% for alfacalcidol, -1.9% for vitamin K, and -3.3% for control. Seventeen (25.6%) of the control patients developed new vertebral fractures. Compared with controls, the fracture incidence was reduced by 69% ($P=0.02$) in alendronate, 66% ($P=0.01$) in risendronate, 56% ($P=0.04$) in etidronate, 65% ($P=0.02$) in hormone replacement therapy, 59% ($P=0.03$) in calcitonin, 44% ($P=0.13$) in alfacalcidol, and 56% ($P=0.049$) in vitamin K. We observed significant reductions in the incidence of vertebral fractures with alendronate, risendronate, etidronate, hormone replacement therapy, and calcitonin, and significant improvements in bone mineral density with alendronate, risendronate, and hormone replacement therapy. With regard to the magnitude of increase in BMD and the magnitude of the reduction in the risk of vertebral fractures, alendronate, risendronate, and hormone replacement therapy have shown significantly stronger efficacy than that in other medications.

Comparison of Effects of Alendronate and Raloxifene on the Lumbar Bone Mineral Density, Bone Turnover, and Lipid Metabolism in Elderly Women with Osteoporosis. J. Iwamoto¹, T. Takeda², M. Uzawa². ¹Department of Sports Medicine, Keio University, Tokyo, Japan, ²Department of Orthopaedic Surgery, Keiyo Orthopaedic Hospital, Gunma, Japan.

The purpose of the present open-labeled prospective study was to compare the treatment effects of alendronate and raloxifene on the lumbar bone mineral density (BMD), bone turnover, and lipid metabolism in elderly women with osteoporosis. One hundred twenty-two postmenopausal women with osteoporosis (mean age: 69.4 years) were randomly divided into two groups of 61 patients each: the alendronate group (5 mg daily) and the raloxifene group (60 mg daily). The BMD of the lumbar spine (L1-L4), urinary level of cross-linked N-terminal telopeptides of type I collagen (NTX), and serum levels of alkaline phosphatase (ALP), total cholesterol (TC), high and low density lipoprotein cholesterol (LDL-C and HDL-C, respectively), and triglycerides (TG) were measured during the 12-month-treatment period. There were no significant differences in the baseline characteristics between the two treatment groups. The trial could be completed in 50 patients in the alendronate group and 52 patients in the raloxifene group. Both alendronate and raloxifene increased the lumbar BMD (+8.0% and +2.4% at 12 months, respectively) following reductions of the urinary level of NTX (-44.6% and -34.5% at 3 months, respectively) and serum level of ALP (-17.7% and -9.6% at 12 months, respectively), with the effects of alendronate, however, being more pronounced than those of raloxifene. Only raloxifene reduced the serum levels of TC and LDL-C (-3.9% and -7.7% at 12 months, respectively) without any significantly effect on the serum HDL-C and TG levels. No serious adverse events were observed in either group. The present study confirmed the greater efficacy of alendronate than raloxifene in increasing the lumbar BMD, through its effect of causing more marked reduction of the bone turnover than that by raloxifene, and some beneficial effects of raloxifene on lipid metabolism in elderly women with osteoporosis.

Comparison of Changes in Bone Mineral Density and Bone Turnover Marker with Alendronate Once-weekly and bi-weekly in Postmenopausal Korean Women. H. Oh^{*1}, I. Joo^{*1}, B. Yu^{*2}, S. Lee^{*3}, H. Lee^{*3}. ¹Family Medicine, Cheil General Hospital, Kwandong University, Seoul, Republic of Korea, ²Family Medicine, Konyang University Hospital, Daejeon, Republic of Korea, ³Family Medicine, Ewha Womens University Hospital, Seoul, Republic of Korea.

Objectives: A pilot study in Japan indicates that alendronate 2.5mg daily dose is as effective as a 10mg dose in increasing the bone mineral density because of the differences of genetic, dietary and environmental factors between Asian and Caucasian populations. And for the convenience of patients and cost-effectiveness, increasing the dosing interval should be also considered. Therefore, we designed the comparative studies which measuring the changes of bone mineral density and bone turnover marker between alendronate 70mg weekly administration and alendronate 70mg bi-weekly administration for the postmenopausal women in the one of the Women's Health Care Centers in Seoul, Korea.

Design: We retrospectively evaluated the postmenopausal women with T score<-2.0 treated with alendronate 70mg weekly or biweekly and compared the changes of bone mineral density and bone turnover marker.

Results: Lumbar bone mineral density was increased by 4.3%, and femoral bone mineral density was also increased by 2.3% in alendronate 70mg weekly group with statistical significance. However, in the group with alendronate 70mg bi-weekly administration, lumbar bone mineral density was decreased by 0.3%, femoral bone mineral density was increased by 1.0% without the statistical differences.(p<0.05) Bone turnover markers showed decreasing pattern, but not statistically significant.

Conclusions: Our study suggested alendronate 70mg bi-weekly administration also has preventive effect on bone loss, even though not strongly, but below the physiologic decrease rate of bone mass.

Table 1. Changes of bone mineral density of the subjects with once weekly and bi-weekly alendronate 70mg administration

	ALN-weekly (N=34)	P value	ALN-bi-weekly (N=27)	P value

Lipid Profile and BMD Changes in Postmenopausal Korean Women Treated with alendronate (10mg) for 2 Years. I. Joo^{*1}, H. Oh^{*2}, B. Yu^{*3}, K. Kim^{*4}. ¹Family Medicine, Cheil General Hospital, Seoul, Republic of Korea, ²Family Medicine, Cheil General Hospital, Kwandong University, Seoul, Republic of Korea, ³Family Medicine, Konyang University Hospital, Daejeon, Republic of Korea, ⁴Family Medicine, Catholic University Hospital, Seoul, Republic of Korea.

Background: Recently, it is known that bisphosphonate which has been used for prevention and treatment of osteoporosis with the mechanism of inhibiting bone resorption also has an association with cholesterol synthetic process. However, few reports to reveal the relationship between the action of bisphosphonate and lipid metabolism with BMD changes in postmenopausal Korean women. We planned this study to recognize the effect of alendronate(10mg) on serum lipid level in postmenopausal Korean women.

Subjects and Methods: We evaluated postmenopausal Korean women aged over 50 who visited the Osteoporosis clinic in the Health Care Center in Seoul from March of 2003 to October of 2005 retrospectively. The changes of serum lipid levels including total cholesterol, triglyceride, HDL were evaluated.

Results: After 2-year alendronate(10mg) administration, total cholesterol level was decreased by 11.8±3.7mg/dl, and HDL level was increased by 5.2±1.4mg/dl with compared to the baseline lipid level. Both of the results showed the statistical significances. Changes of triglyceride and fasting blood sugar levels also showed a declined pattern by 15.4±9.8mg/dl and 6.0±1.4mg/dl, but not statistically significant.

Conclusions: Alendronate might have a beneficial effect on lipid metabolism to decrease cholesterol and increase HDL. With the concern about the postmenopausal natural increase in cholesterol level, alendronate is recommended for prevention of hyperlipidemia in postmenopausal women in addition to prevent and treatment of osteoporosis.

Patient's Satisfaction and Compliance for Risedronate, Once-Weekly Versus Once-Daily: A Multicenter, Prospective, Randomized, 2-way Crossover, Open-Label Study in Postmenopausal Women with Osteoporosis in Korea and Taiwan. H. Kim^{*1}, I. Park^{*2}, I. Lee^{*2}, J. Kim^{*2}, H. Shon^{*3}, J. Choe^{*3}, U. Kim^{*4}, H. Lee^{*5}, Y. Soong^{*6}, S. Tu^{*7}, M. Kim^{*1}. ¹Keimyung University, Daegu, Republic of Korea, ²Kyungbook University, Daegu, Republic of Korea, ³Daegu Catholic University, Daegu, Republic of Korea, ⁴Fatima hospital, Daegu, Republic of Korea, ⁵Yongnam University, Daegu, Republic of Korea, ⁶Chang Gung Memorial Hospital, Taipei, Taiwan, ⁷Changhua Christian Hospital, Taipei, Taiwan.

Postmenopausal osteoporosis(PMO) is characterized by a reduction in bone mass leading to an increased risk of fracture. The Medication for PMO requires long-term persistence with high compliance. The purpose of this study was to determine whether dosing frequency affects compliance and persistence with risedronate, one of the bisphosphonates, in Korea and Taiwan. The study was a multicenter, prospective, randomized, open-label, 2-way crossover (daily to weekly versus weekly to daily) study in postmenopausal women with osteoporosis, who received 24 weeks of treatment (12 weeks with 35 mg risedronate once-weekly and 12 weeks with 5 mg risedronate once-daily dosing). The primary objective was to compare patient's satisfaction of once weekly regimen to once daily regimen using a questionnaire administered to the subjects at 12 and 24 weeks. The secondary objective was to measure compliance (defined as more than 50% of drug taken by tablet count) and persistence (continuing study medication at 12 and 24 weeks). A total of 262 patients were enrolled. 199 patients were included in analysis of the intention to treat (ITT) group, and 185 patients were included in the per protocol evaluation group. Total number of patients included in the safety analysis was 216. The preference of once-weekly dosing regimen was 2 times greater than that of once-daily dosing regimen (52.8% and 25.1% respectively, P-value<0.0001). However, the overall compliance and persistence did not show statistical difference between the two types of dosing regimen (only one patient in each of the dosing regimens was not compliant). Adverse events were reported in 22.8% of patients during the once-daily dosing regimen and in 20.2% of patients during the once-week dosing regimen. There was no statistically significant. The results showed that the patient's preference of once-week dosing regimen was greater. However, compliance and persistence were not different, which can suggest that although preference was higher in longer interval dosing regimen, it did not necessarily lead to the same extent of higher compliance and persistence. Meanwhile, although there were differences in preference, the lack of a difference in compliance may have been because this was a controlled study, and that this may not happen in "real life"

Risedronate Preserves Bone Turn Over as Measured by Biochemical Markers after 5 Years Treatment in Postmenopausal Greek Women. I. C. Koulouris, G. Skarantavos*, T. Kaplanoglou*, P. Katsibri*, P. Soukakos*. First Orthopaedic Clinic, Attiko University General Hospital, Athens, Greece.

Aim of study was to investigate turnover 5-years administration Risedronate in early PO Greek women. Forty early PO women between 48-53 years old(mean 50 years)6 months -1year after the menopause with T score <2SD on lumbar spine DEXA and without any prior metabolic disorders or fractures were separated into 2 groups. Group A (n=30)received 5mg Risedronate 1mcg Alfacalcidol and 1000 mg Calcium carbonate daily for 12 months and 0,5 mg Alfacalcidol and calcium for the rest of the study period while group B(n=10) received the same doses of Alfacalcidol and calcium for the 1st year and only 1000 mg calcium carbonate thereafter.Serum and urine bone turnover markers were measured at 0,6,12,24,36,48,60 month intervals by automated electrochemiluminescence assay.No premenopausal values were available for comparison.Two patients in group A discontinued treatment after 24 months so to investigate the effect of daily administration of Risedronate to early PO Greek women for 5years by measuring sCTX changes uNTX urine Pyrilinks serum BGP.PTHi and 25(OH)D. A questionnaire including VASscore and PPI score concerning quality of life indexes was completed and reevaluated by all patients at the above intervals.1)Group A showed a statistically significant decrease in uNTX(16,15%,p<0.0005)as early as 6 months after treatment whilst there were no statistically significant changes after the 12month period.In group B uNTX was increased(10,9 %,p<0.0005)while the rest of the markers showed a statistically significant decrease for the same period.No values fell below the normal range.2) Group A showed a statistically significant decrease in sCTX(11,69%,p<0.0005) as early as 6 months after treatment whilst there were no statistically sign changes after the 12month period.In group B sCTX was increased (13,32%, p<0.0005)while the rest of the markers showed a statistically significant decrease for the same period.No values fell below the normal range.3)PTHi changes both of groups is not sign.A showed improved indexes in the quality of life scores.Changes in the measured markers especially sCTX uNTX demonstrate that Risedronate effectively decreases the turnover as early as 6 months after treatment and the effect is maintained without further changes from the 6 of the 1st year until end of the 5-years period provided that vitD is sufficient.The fact that no values fell below normal during the 1st year of treatment and bone markers continued to keep these values during the following years of treatment excludes the untoward presence of frozen bone.Quality of life was also improved in the Risedronate group without any untoward GI.effects from upper tract and musculoskeletal system.

Effect of Bisphosphonates on Bone Mineral Density in Subjects with Normocalcaemic Primary Hyperparathyroidism. A. W. C. Kung, K. K. Lee*. Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong.

Normocalcaemic primary hyperparathyroidism (NPHPT) as a disease entity is increasingly recognised in the general population. Whether NPHPT is associated with increased bone loss is not well studied, and whether bisphosphonates are effective in preventing bone loss, if present, is unclear. To determine the rate of change of BMD in subjects with NPHPT and to study the effect of bisphosphonates on BMD changes in these subjects. Subjects with elevated PTH on 2 occasions after exclusion of renal impairment, vitamin D insufficiency (<20ng/ml) and other secondary causes of elevated PTH were diagnosed as having NPHPT. BMD, serum albumin-adjusted calcium, PTH, 25(OH)D, ALP and C-Telopeptide, urinary calcium excretion were monitored at yearly intervals. Subjects were randomized to receive either risedronate 35mg once weekly. 24(0.4%) subjects (female/male=21/3, mean age 71±10 years) were diagnosed to have NPHPT from a cohort of 5,600 healthy community dwelling adults aged >50 years. The mean serum calcium and PTH was 2.39±0.10nmol/l and 69±17pg/ml respectively. 19subjects had BMD T score <-2.5 at anyone site, 5 were osteopenia and none had normal BMD. 13 had osteoporotic fractures. The rate of change of BMD after one year was -1.68%, -0.63% and -1.99% respectively at the spine, total hip and forearm. 14 subjects were randomized to risedronate while 10 received calcium and vitamin D alone. BMD was similar between the 2 groups. At 2 years of treatment, BMD increased by 8.5%, 1.8% and 0.7% at the spine, total hip and forearm in the risedronate group, while the calcium and vitamin D group had bone loss of 1.5%, 0.6% and 0.8% at the respective sites (p all <0.05).None of the subjects had elevation of serum calcium during observation. Subjects with NPHPT had a high prevalence of osteoporosis and fractures. The increased bone loss in these subjects can be controlled with bisphosphonates.

Effect of Anti-Resorptive Agents on Fracture Rates in Subjects Selected for Therapy on the Basis of Clinical Risk Factors or Low Bone Mineral Density. A. W. C. Kung, K. K. Lee*. Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong.

BMD measurement has been the standard used to diagnose and initiate intervention in osteoporosis. However increasing evidence suggests that BMD alone is inadequate to detect all at-risk individuals and clinical risk factors (CRF) evaluation is recognised as an important element for fracture risk assessment. Whether anti-osteoporosis drug treatment would actually prevent fractures in women selected for therapy on the basis of CRFs alone is unclear. To determine the fracture rate in subjects treated with anti-resorptive agents selected on the basis of low BMD or CRFs. Postmenopausal community dwelling Southern Chinese women (n=2,315) were evaluated for CRFs for fractures (previous low trauma fracture, age>65years, BMI<19Kg/ m², family history of hip fracture) and low BMD (T score<-2.5 at any site). Anti-resorptive agents (HRT or bisphosphonates) were given to subjects with any CRF or low BMD. Subjects were followed prospectively for outcomes of incident low trauma fracture. The fracture rate of subjects who had received any form of treatment was compared to those with one or more CRFs or low BMD but received no treatment and those without risk factors. The mean age of the subjects was 64 ± 8 years.The median follow-up was 5(range 1-10) years. Cox regression analysis also revealed reduced odds of fractures with anti-resorptive therapy in subjects selected on the basis of low BMD but not CRFs. Clinical trials are needed to prove that anti-osteoporosis drug treatment would actually prevent fractures in women selected for therapy on the basis of these CRFs alone.

Patient groups	Any anti-osteoporosis Treatment	Fracture rates
No CRF and BMD T score > -2.5	No	4.0%
Any CRF	No	7.5% ^a
BMD T score < -2.5	No	8.9% ^a
Any CRF+ BMD T score < -2.5	No	10.1% ^a
Any CRF with treatment	Yes	6.1% ^a
BMD T score < -2.5	Yes	6.8% ^{a,b}
Any CRF+ BMD T score < -2.5	Yes	8.6% ^{a,c}
Chi-square tests:		
a, vs No CRF and BMD T score > -2.5 and no treatment, p<0.001		
b, vs BMD T score < -2.5 and no treatment, p<0.03		
c, vs Any CRF+ BMD T score < -2.5, p<0.05

Monthly Oral Ibandronate Is Well Tolerated and Efficacious in Japanese Osteoporotic Subjects. T. Nakamura¹, H. Mizunuma², A. Itabashi³, H. Yamane⁴, T. Hannita⁴, M. Karube⁴, K. Takeuchi⁴, R. Ikegami⁴, S. Okamoto⁴, T. Hasunuma⁴, Y. Kumagai⁴. ¹University of Occupational and Environmental Health, Kita-kyushu, Japan, ²Hirosaki University, Hirosaki, Japan, ³Saitama Center for Bone Research, Kumagaya, Japan, ⁴The Ibandronate Clinical Study Group, Tokyo, Japan.

The efficacy and safety of orally administered ibandronate, given once monthly, have been demonstrated in Caucasian women with postmenopausal osteoporosis. However, responses in Japanese women with osteoporosis were yet to be demonstrated. A multi-centre, double-blind, randomized, placebo-controlled study was performed to examine the efficacy and safety profile of ibandronate which was orally administered for four months in this patient group. In total, 137 osteoporotic subjects, aged 55 to 84 years, were randomly assigned to treat by placebo (n=28), 20 mg (n=27), 50 mg (n=27), 100 mg (n=26) and 150 mg (n=26) ibandronate by oral administration 4 times for 4 months. All patients were supplemented by daily calcium (305 mg) and vitamin D (200 IU). At 4 months, urinary CTX (uCTX) concentrations were reduced by 28.9%, 35.7%, 43.0%, 70.9% and 81.7%, respectively (median change from baseline). The decrease relative to the placebo was statistically significant at 50, 100 and 150 mg, but not at 20 mg group. The dose-dependently reduction in uCTX was maintained throughout the treatment period. Other bone turnover markers also showed the dose-dependent suppression throughout the treatment period. At 4 months, mean increases in lumbar spine bone mineral density of 0.7%, 1.4%, 3.1%, 4.0% and 3.2% were observed in the placebo, 20 mg, 50 mg, 100 mg and 150 mg group, respectively. No serious drug-related adverse events were reported. These results first demonstrate that monthly oral ibandronate effectively reduces bone turnover and increases lumbar spine bone mineral density in Japanese with osteoporosis, without serious side effects.

Study Subjects and Ordinary Patients in Treatment of Osteoporosis. A Prospective Observational Study on 106 Consecutive Patients. R. J. Forestier*, D. Briançon, A. Françon*. Rheumatologic and thermal research centre, Aix Les Bains, France.

The purpose of this study is to measure evolution of bone density (BD) and fracture incidence in a routine population and to compare it with published randomised clinical trial. Material and method: We analyzed 302 consecutive patients coming in our hospital for bone mineral density (BD) measurement between June 2005 and December 2006. 106 had a previous measurement, 2 years or more, with the same Hologic QDR 4500. We also collected number and type of fracture, drug intake and some prognosis factors. BD variations were compared with Mann Whitney U test and fracture rate by Chi².

Results: Evolution of bone density is more favorable for patients under active treatment (risedronate, alendronate, raloxifene and hormonal supplementation) than for patients taking no treatment. For patients with calcium vitamin D supplementation and patient changing or stopping treatment, there is not significant difference with no treatment.

Commentary / Conclusions: Bone density increase more under active treatment than without treatment but variations seems smaller than those observed in experimental studies. Fracture rate is similar in both group but higher than in experimental studies groups.

Real effect of osteoporosis treatment could be lower than their potential effect reported in large randomized clinical trial and meta-analysis. Further investigation are needed, with greater sample size, to measure it in "real life"

Treatment	Number of Follow up	p fracture (comparison with no treatment)	Bone Density Variation [CI 95%] in %/year	p bone density (comparison with no treatment)
Active treatment (alendronate, risedronate, raloxifene, hormonal supplementation)	3/33 4,3 years +/-1,4	0.90	+0.30% [- 0.24;+0.85]	<0,001
Calcium +/- vitamin D	0/11 4,01 years +/-1,9	0.85	-2.77% [- 9,05;+3,46]	0,281
Changing or stopping treatment	1/20 4,6 years +/- 1,6	0.81	-0.41% [- 1.00;+0.18]	0,320

Osteoporosis Care Pathways for Hospital Patients with Fragility Fractures: A Paradigm Shift. J. Glowacki¹, M. B. Harris^{*1}, J. B. Simon^{*1}, N. S. Kolatkar^{*2}, T. S. Thornhill^{*1}, M. S. LeBoff². ¹Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA, ²Medicine, Brigham and Women's Hospital, Boston, MA, USA.

The 2004 Health Plan Employer Data and Information Set (HEDIS) State of Healthcare Quality Report found that only 18% of patients received post-fracture evaluation/therapy. We had reported that only 10% of our hip fracture (Fx) patients were vitamin D-sufficient [25-hydroxyvitamin D (25OHD) >32 ng/mL]. We therefore designed, implemented, and revised multidisciplinary pathways to improve care of Fx patients.

The 2004 Admission Pathway (AP) trained the surgeons to obtain serum calcium, albumin, and 25OHD, to start calcium carbonate (600 mg elemental calcium/100 IU cholecalciferol, bid) and multivitamin (400 IU cholecalciferol), and to order an Endocrinology consult. The amended 2005 AP implemented a computer-assisted pop-up reminder and added administration of a single dose of ergocalciferol (50,000 IU). The Discharge Pathway (DP) (implemented in 2003 as computer-based directives) prompts the surgeon to discharge on daily calcium with vitamin D, a multivitamin, additional vitamin D (400 IU cholecalciferol), and outpatient osteoporosis evaluation. We reviewed the medical records of 3 cohorts [from Aug through Dec in 2004 (n=57), 2005 (n=41), and 2006 (n=40)] of consecutive patients ≥ 50 years of age who were admitted with a fragility hip or femur Fx. Effectiveness of AP was defined as measurement of 25OHD during hospitalization, and effectiveness of DP, as a prescription for calcium/vitamin D.

Adherence with the surgeon-driven 2004 AP (33%) was half that for the computerized DP (67%, p<0.001). According to the 2005 AP amendment, 29% received 50,000 IU ergocalciferol; AP effectiveness (41%) was not significantly improved. With retraining of surgeons, AP effectiveness was significantly greater in 2006. The older computer-based DP was more effective (88%) than the computer-assisted AP (60%, p=0.010). These findings led to recent launching of a computer-based AP. The high prevalence of vitamin D insufficiency observed in this study (78%) corresponds with prior reports and reaffirms the importance of incorporating vitamin D recommendations in Fx care pathways. This ongoing work shows increasing effectiveness of computer-based directives and of retraining the multidisciplinary team of caregivers. These pathways represent a much-needed paradigm shift in the care of Fx patients.

EFFECTIVENESS OF PATHWAYS

T408

Proportion of Clinical Vertebral and Nonvertebral Fractures among Women in a Managed Care Population. R. Lindsay*¹, N. N. Borisov^{*2}, M. Steinbuch^{*2}. ¹Helen Hayes, West Haverstraw, NY, USA, ²Procter & Gamble Pharmaceuticals, Mason, OH, USA.

This study used two integrated administrative medical claims databases (Ingenix Lab/RxTM and Medstat MarketScan[®]) to estimate the proportion of fractures that are clinical vertebral or nonvertebral occurring in a managed care setting among women ages 65 and over.

A retrospective cohort study was conducted among women with a new non-traumatic closed vertebral or nonvertebral fracture between July 1, 2000 and December 31, 2003. Fracture rates by 10-year age groups were calculated for 9 anatomical sites: hip, femur, tibia/fibula, humerus, clavicle, pelvis, forearm, wrist, and spine.

As expected, fracture rates increased with age, from 68.6 to 210.7 per 10,000 women per year between 65-74 and 85+ age groups. Hip and pelvis fractures contributed the most to this increase. Overall, the most common fractures were those of hip, wrist, and spine (table). Nonvertebral fractures represented 77% of all fragility fractures among women ages 65 and over. Eleven percent of women experiencing a fracture had a record of an additional fragility fracture within a year of the initial fracture. Women with an initial nonvertebral fracture were more likely to experience a subsequent nonvertebral fracture than vertebral fracture (9% vs. 2%, respectively, p<0.0001). Women with an initial vertebral fracture were more likely to experience a subsequent vertebral fracture than nonvertebral fracture (8% vs. 6%, respectively, p<0.0001). Overall, the majority (70%) of subsequent fractures were nonvertebral.

Rates (per 10,000/year) of vertebral and nonvertebral fractures among women in managed care population by age groups

Age groups	65-74	75-84	85+	Total
Total eligible women population*, 2000-2003	223,774	168,777	56,218	448,769
Nonvertebral Fractures	54.0	97.0	160.4	83.5
Hip	7.9	29.2	68.4	23.5
Femur	2.3	5.4	10.2	4.5
Tibia/Fibula	4.5	4.6	6.0	4.7
Humerus	11.9	18.8	23.9	16.0
Clavicle	1.5	2.4	3.8	2.1
Pelvis	3.2	8.2	17.3	6.8
Forearm	5.5	5.4	5.3	5.5

* Data from Ingenix Lab/RxTM and Medstat MarketScan[®] databases

Due to the relative magnitude of nonvertebral fractures, it is imperative that a therapy for osteoporosis in this high risk population demonstrates proven efficacy beyond the spine to provide a clinical benefit for patients and to be cost-effective in the managed care setting.

The Socioeconomic Burden of Osteoporotic Fractures in Korea. I. Park¹, S. Baek^{*1}, K. Yang^{*2}, S. Moon^{*2}, J. Kim^{*3}, J. Kong^{*2}. ¹Department of Orthopedic Surgery, Kyungpook National University Hospital, Daegu, Republic of Korea, ²Department of Orthopedic Surgery, Yonsei University Hospital, Seoul, Republic of Korea, ³Department of Health Administration, Inje University, Seoul, Republic of Korea.

In contrast to western countries, few literatures have been reported on the economic burden of osteoporotic fracture in Asian countries including Korea. The purpose of this study is to reveal the national burden of osteoporotic fractures in Korea.

From the database of National Health Insurance, the incidence of three osteoporotic fractures was extracted in female and male patients 50 years or older during 2003; the spine (ICD-10 code: S32.0), wrist (S52.6) and hip fracture (S72.0). Health professional and orthopedic surgeons specialized in osteoporosis were cooperated to analyze resource utilization. Costs per unit of identified resources were estimated based on the collected information from multicenters throughout the country. Direct costs includes fee for hospitalization, diagnostic modalities, surgery, care giver, pharmacotherapy, outpatient care, and public transportation while indirect cost includes loss of productivity.

Incidence and socioeconomic burden of hip, spine and wrist fractures in the year 2003 were estimated as shown in the following table.

	Hip	Spine	Wrist	total
Incidence (No. of Cases)	23,280	29,419	25,037	77,736
Cost of treatment (USD)				
Direct cost	7,626	6,827	3,682	
Indirect cost	7,114	8,093	10,008	
Total	14,740	14,920	13,690	
National burden of treatment (USD)				
Indirect cost - Excluded	177,533,280	200,843,513	92,186,234	470,563,027
Indirect cost - Included	343,147,200	438,931,480	342,756,530	1,124,835,210

Korea with increasing proportion of elderly population is currently facing a heavy socioeconomic burden from osteoporotic fractures. This study was conducted first in

Korea using nationwide database to estimate cost and medical resource utilization. These findings suggest a compelling need to establish and implement an efficient health care policy which in the long-term mitigates the national burden of osteoporotic fractures through active prevention.

High Dose Vitamin E Prevents the Formation Atherosclerotic Lesions but Does Not Reverse Loss of Bone Due to Orchidectomy in Rats. S. C. Chai¹, E. A. Lucas^{*2}, B. J. Smith³, M. R. Lerner^{*3}, D. J. Brackett^{*3}, C. Wei^{*4}, L. Devareddy^{*1}, B. H. Arjmandi¹. ¹Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA, ²Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA, ³Department of Surgery, University of Oklahoma Health Sciences Center, Oklahoma City, OK, USA, ⁴College of Agriculture, University of Maryland, College Park, MD, USA.

Previously, we have reported that supplemental vitamin E was effective in improving bone strength in mice as well as preventing loss of bone mineral density in hindlimb-unloaded rat model. In this study, the dose-dependent effects of vitamin E in reversal of orchidectomy (ORX)-induced bone loss was examined. Forty 12-mo old male Sprague-Dawley rats were either sham-operated (Sham, one group) or ORX (three groups) and fed a control diet for 120 days to induce bone loss. Thereafter, rats were assigned to various treatment groups (n=10): Sham+75 IU vit E; ORX +75 IU vit E, ORX+ 250 IU vit E, ORX+500 IU vit E per kg diet. After 90 days of treatment, rats were necropsied and tissues were collected for analyses. Although vitamin E supplementation at any dose was incapable of exerting positive effects on bone, it was able to favorably alter serum total- and HDL-cholesterol and superoxide dismutase, an enzyme that plays a crucial role in the detoxification of products resulting from oxidative stress. Additionally, vitamin E at the highest dose (500 IU) significantly reduced the development of atherosclerotic lesions as well as aortic fatty streak area due to ORX. Hence, we conclude that vitamin E is beneficial in improving lipid profile and prevention of atherosclerotic lesion formation, but unable to restore bone mass once the loss has occurred at least in an ORX rat model.

Improved Strontium Bioavailability in a New Tablet Formulated Strontium Salt. S. Christgau¹, M. Weis^{*1}, K. Krogsgård^{*2}. ¹Osteologix, Copenhagen, Denmark, ²PhaseOneTrials, Hvidovre, Denmark.

AIM: Preclinical and clinical studies have suggested that strontium is useful as a therapy in osteoporosis due to a mild anabolic effect on bone formation concomitant with an anti-resorptive effect. One strontium salt, strontium ranelate (SR), is approved in Europe for treatment of postmenopausal osteoporosis. SR is available in a sachet formulation. Our aim was to assess pharmacokinetic properties of another strontium salt, strontium malonate (NB-S101) formulated in tablets and to compare the strontium bioavailability from a single oral dose of this salt with that of SR.

METHODS: 60 healthy male volunteers were randomized into five groups to receive either NB S101 in doses of 0.6, 1.2 and 2.4 g (containing 277, 554 and 1108 mg ionic strontium) or 2 g SR in sachets, containing 680 mg ionic strontium or placebo. Subjects were fasting from 1PM and given a single oral dose at 7PM. They had frequent blood samples drawn for strontium determinations in the following 24 h, and at 1, 3 and 5 weeks post dosing. Bone turnover was measured at baseline 2, 4 and 24 h using s-CTX (resorption) and osteocalcin (formation).

RESULTS: Pharmacokinetic profiles of strontium uptake from the four treated groups were similar, but SR had a lower T_{max} (3.75±0.37 h) than NB-S101 (5.92±0.53; 5.00±0.55; 5.67±0.41 h respectively for the three NB S101 groups, p<0.05). Strontium uptake assessed by Area Under the Curve (AUC) analysis, revealed a good bioavailability of strontium from NB S101 tablets. The SR group had an AUC_{0-24h} of 356.3±24.4 µg*h/ml compared with 275.3±24.3; 386.9±39.5; 654.6±63.7 µg*h/ml in the three NB S101 groups. Elimination rates were similar for both strontium salts, with T_{1/2} for SR of 116.1±8.3 h compared with 140.4±11.7; 125.2±6.6, 130.7±5.3 h for the three NB S101 groups. A 0.99 g dose of NB S101 was estimated to give theoretical bioequivalence to 2 g SR. NB S101 appeared to induce a dose dependent suppression in the nocturnal elevation in bone resorption measured by CTX. Only for the high dose group did this reach statistical significance at 4 h (29.0% vs 86.3% increase from baseline in the 2.4 g group and placebo, p<0.05). Bone formation was not changed in the strontium treated groups compared to placebo.

CONCLUSIONS: This pharmacokinetic study shows that NB S101 (strontium malonate) tablets containing less than 555 mg ionic strontium delivers more bioavailable strontium ions than a 2 g strontium ranelate sachet formulation containing 680 mg ionic strontium. This suggests that the tablet formulated NB S101 provides better bioavailability. Bone turnover analysis indicates a dose dependent antiresorptive effect of NB S101. Phase II studies are ongoing to assess the effect of NB-S101 on bone turnover and BMD in postmenopausal women.

Strontium Ranelate Reduces the Risk of Vertebral Fracture in Young Postmenopausal Women with Severe Osteoporosis. J. P. Devogelaer¹, C. Roux², G. Isaia³, J. B. Cannata Andia⁴. ¹Service de rhumatologie, Université catholique de Louvain, Bruxelles, Belgium, ²Department of rheumatology, Cochin Hospital, René Descartes University, Paris, France, ³I Divisione Universitaria di Medicina Generale, Torino, Italy, ⁴Servicio de Metabolismo Osseo y Mineral, Hospital central de Asturias, Oviedo, Spain.

Strontium ranelate is an anti-osteoporotic treatment which decreases vertebral and hip fracture risks with a unique mode of action, both reducing bone resorption while promoting continued bone formation. Early fractures occurring within the first 10 years after menopause have a great impact on the further progression of the disease, as it has been shown that the first osteoporotic fracture is a major risk factor for further additional fractures. Subsequently, the assessment of antifracture efficacy of antioosteoporotic treatments in this younger female population aged less than 65 years appears of utmost interest.

Materials and methods. The phase III SOTI study was an international, double-blind, placebo-controlled trial, supporting the efficacy and safety of strontium ranelate 2g/day orally in reducing the risk of vertebral fractures in postmenopausal women with osteoporosis and a prevalent vertebral fracture. An analysis of the data from SOTI was performed to investigate the efficacy of strontium ranelate in women aged between 50 and 65 years (n=353; 168 in the strontium ranelate treated group versus 185 in the placebo treated group).

Results. The baseline characteristics of patients were similar in both groups (mean value ±SD data: age 60.0±3.5 years; lumbar BMD T-score -3.6±1.1; femoral neck BMD T-score -2.5±0.8) with 80.5% of patients having a prevalent vertebral fracture and 23.0% of patients having a prevalent non-vertebral fracture. Over 3 years of treatment, in the intent-to-treat population, strontium ranelate significantly reduced the risk of vertebral fracture by 47% (RR=0.53; 95%CI[0.33;0.85], p=0.006). The incidence of vertebral fractures over 3 years was 16.9% in the strontium ranelate treated group versus 29.6% in the placebo treated group. The reduction in the risk of vertebral fracture is paralleled by a significant increase after 3 years by 13.7% in the relative change from baseline of lumbar BMD (95%CI[11.54;15.87], p<0.001) and by 7.5% in the relative change from baseline of femoral neck BMD as compared to placebo. These changes are in accordance with those of the whole Phase III population.

Conclusion. These data demonstrate a significant vertebral antifracture efficacy of strontium ranelate in young postmenopausal women aged less than 65 years with severe osteoporosis and confirms the efficacy of this anti-osteoporotic treatment, whatever the age of the patients.

Action Seniors!: An RCT of the Otago Home Exercise Program to Ameliorate Fall Risk Factor Profile in Patients at High Risk of Falls. M. G. Donaldson^{*1}, K. M. Khan², B. Sobolev^{*1}, P. A. Janssen^{*1}, W. L. Cook^{*3}, H. A. McKay⁴. ¹Health Care and Epidemiology, University of British Columbia, Vancouver, BC, Canada, ²Department of Family Practice, University of British Columbia, Vancouver, BC, Canada, ³Geriatric Medicine, University of British Columbia, Vancouver, BC, Canada, ⁴Orthopaedics, University of British Columbia, Vancouver, BC, Canada.

Fall prevention is an important element of fracture prevention strategies. Although strength and balance training reduces falls among community-dwelling seniors, we know of no RCTs testing the effectiveness of a strength and balance training program among very frail seniors with low bone mass who attended a dedicated falls clinic. We aimed to determine the effect of the Otago Exercise Program (OEP), a physiotherapist-initiated, home-based, progressive strength and balance retraining program in older men and women who attended a falls clinic. The primary outcome was fall risk factor profile over a 6-month period; secondary outcome was occurrence of falls over a 12-month period.

We enrolled 74 participants aged 70 years and older from two falls clinics in Vancouver, British Columbia. Participants were randomly allocated to the OEP group (n=36) and standard care (SC) group respectively (n=38). Fall risk factor profile was assessed using Lord's Physiological Profile Assessment (PPA) tool which measures vision, reaction time, strength, proprioception and balance. Participants documented falls on monthly calendars for 12 months. We used linear regression to model the relationship between group and change in PPA from baseline to 6-months. We used negative binomial regression to model the relationship between group and the occurrence of falls. We used the Mean Cumulative Function to report the average number of falls per participant by 12-months.

At 6-months 34 and 32 in the OEP group and SC group respectively returned for follow-up. The OEP group was associated with a 9% improvement in PPA z-score from baseline to 6-months (2.3 (1.3) to 2.1 (1.3)) compared to the SC group which remained stable (2.0 (1.3) to 2.0 (1.2)), p=0.55. The OEP group was associated with a 38% reduction in the rate of falls (IRR 0.62, 95% confidence interval 0.3 to 1.4). The average number of falls per participant by 12-months in the OEP and SC group was 1.1 and 3.1 respectively.

This study demonstrated that the OEP did not significantly reduce PPA z-score over a 6-month period. However the reduction in the rate of falls over a 12-month period is consistent with the literature and provides encouraging pilot data for a larger study powered to measure falls as the primary outcome. This is the first study to investigate the effectiveness of strength and balance training delivered within a falls clinic setting among frail seniors at high risk of falls.

Disclosures: M.G. Donaldson, None.

The Effects of Strontium Ranelate on Biochemical Bone Markers in Elderly Women and Men with Reduced Bone Mineral Density. B. H. Durham¹, A. A. Joshi^{*2}, A. M. Ahmad^{*2}, J. P. Vora^{*2}, W. D. Fraser¹. ¹Clinical Chemistry, Royal Liverpool University Hospital, Liverpool, United Kingdom, ²Clinical Endocrinology, Royal Liverpool University Hospital, Liverpool, United Kingdom.

We have investigated the effect that 3 months of strontium ranelate therapy [StR], a bone agent that increases bone formation, has on a panel of biochemical markers of bone formation and bone resorption. We recruited 26 elderly subjects [15F, 11M] average age 64 ± 3yr with low bone mineral density who were assigned into one of two groups. Group A [8F, 5M] received 2 g of StR/day whilst group B [7F, 6M] received growth hormone supplementation [GH] in addition to StR. Fasting serum samples were collected prior to and after 3m of StR and stored at -70°C until analysed. The biochemical markers used to study bone formation were bone alkaline phosphatase [BalP], osteocalcin [OstC] and the amino terminal extension peptide of type 1 collagen [PINP] and for resorption carboxy terminal telopeptide of type 1 collagen [beta CTX] and tartrate resistant acid phosphatase 5B [TRACP], we also measured osteoprotegerin [OPG].

For group A there was no significant change in the means of OPG [2.6 vs 2.5 pmol/L], TRACP [2.3 vs 2.3 U/L], BalP [17 vs 18 U/L]. The mean OstC increased by 6% from 23.8 to 25.1 mcg/L whereas beta CTX decreased by 14% from a mean of 0.49 to 0.42 mcg/L and PINP by 10% from 55 to 50 mcg/L. In group B there were significant increases in the means of all parameters [p<0.05], PINP 68 to 88 mcg/L [29%], OstC 26.5 to 35.8 mcg/L [35%], BalP 22 to 32 U/L [45%], TRACP 2.8 to 3.7 U/L [32%], beta CTX 0.54 to 0.66 mcg/L [22%], the increase in the mean of OPG from 2.3 to 2.6 pmol/L [10%] was not significant. In group B the increase in the rate of bone turnover as demonstrated by the increases in formation and resorption markers was probably due to the GH supplementation. In group A there was no significant change in either formation or resorption markers; it may be that 3m was too short a period for StR to have an influence on bone metabolism and a longer period of treatment would result in a different outcome.

Disclosures: B.H. Durham, None.

Exercise Prevents Falls and Maintains Bone Mineral Density in Elderly Postmenopausal Women. Preliminary Data of the Erlangen Senior Fitness and Prevention (SEFIP) Study. W. Kemmler^{*}, S. von Stengel^{*}, W. A. Kalender^{*}, K. Engelke. Institute of Medical Physics, University of Erlangen, Erlangen, Germany.

The aim of the study was to demonstrate that an intensive aerobic and strength training can maintain BMD at the spine and the hip and can prevent falls in elderly community-living women.

Via population registers we recruited 246 community-living women of 65 years and older. Exclusion criteria were medication or diseases related to bone metabolism, low aerobic capacity (<75 W on ergometry), and medication potentially increasing the likelihood of falls. There were no inclusion or exclusion conditions based on BMD or prevalent fractures. Subjects were randomly assigned to an exercise intervention group (EG: 2-3 sessions/week) or to a wellness control group (WCG: 1 session/week for three 10 week blocks). The exercise training consisted of 20 min of intense aerobic dancing (70-85% HF_{max}), 5 min of specific balance exercises and 35 min of isometric and dynamic (60-70% 1RM) strength training. No machines were used for the strength training part. All subjects were individually supplemented with calcium and cholecalciferol up to a maximum of 1500 mg/d and 500 IU/d. Bone mineral density at the lumbar spine and the hip was measured with DXA and QCT. Falls as defined by the PROFANE workgroup were counted using daily protocols conducted by all participants. Here we present initial 12 month DXA and fall results for 182 participants (EG: n=90; WCG: n=92).

After 12 months there were significant differences between exercise and wellness control group of BMD of the spine (EG: +1.4% vs. WCG: -0.3%) and of the hip (EG: -0.2% vs. WCG: -1.3%). The number of falls was significantly higher in the WCG (n=124) than in the EG (n=72). The same was true for injurious falls (EG: n=28 vs. WCG: n=42). In the exercise group 5 and in the wellness control group 8 fractures occurred but the power of the subset of patients included in this preliminary analysis was too low for the difference to be significant.

In conclusion preliminary results of our randomized exercise trial show that exercise training positively impact BMD at the hip and spine as well as fall frequency and may prevent fall related fractures in elderly subjects. The training scheme used in the study can easily be transferred into rehabilitation programs as no special equipment was used.

Disclosures: K. Engelke, Synarc 3.

3-Year Outcome After Kyphoplasty in a Prospective Controlled Trial Role of Initial Bone Edema and Selection of Cement Type (PMMA vs. Calciumphosphate Cement). I. Grafe^{*1}, G. Nöldge^{*2}, M. Baier^{*3}, K. Da Fonseca^{*3}, J. Hillmeier^{*3}, U. Sommer^{*1}, U. Wolf^{*1}, M. Libicher^{*2}, P. J. Meeder^{*3}, P. Nawroth^{*1}, C. Kasperk¹. ¹Internal Medicine I, Endocrinology, University of Heidelberg, Heidelberg, Germany, ²Radiology, University of Heidelberg, Heidelberg, Germany, ³Orthopedic Surgery, University of Heidelberg, Heidelberg, Germany.

Introduction: Kyphoplasty (KP) is a safe and effective method for reducing pain and improving quality of life in patients with painful osteoporotic vertebral fractures in prospective controlled and randomized trials. We sought to investigate how beneficial short term effects of KP on pain and mobility will affect long term outcome and fracture incidence, and if (a) selection of PMMA or CaP cement for vertebral stabilization and how (b) an initial bone edema of the fractured vertebrae before KP impact on long term outcome after KP

Methods: KP was performed in 40/60 patients with primary osteoporosis and painful vertebral fractures, 20 patients received PMMA- and 20 CaP cement (Calcibon), 20 served as non-KP controls (Con). In another cohort 45 KP-patients received pre-OP MRI of the fractured painful vertebrae to visualize bone edema and were analyzed with regards to VAS score after 12 months (bone edema 27 pat., no edema 18 pat). All patients received pharmacological treatment (oral aminobisphosphonate, 1000 mg calcium + 1000 IE vitaminD3) and physiotherapy. Pain (VAS [100=most severe pain]), mobility (EVOS score[100=full mobility]) and radiomorphology were determined after 6, 12 and 36 months.

Results:

	Pre-KP PMMA/CaP Con	6 mo. PMMA/CaP Con	12 mo. PMMA/CaP Con	36 mo. PMMA/CaP Con
Pain	74.5 / 73.1 66.4	53.1 / 58.5 64.4	53.7 / 57.6 65.7	52.7 / 55.2 64.0
Mobility	40.1 / 47.5 39.8	55.7 / 53.1 43.8	54.5 / 54.6 44.3	53.6 / 56.0 43.6

Number of total new vertebral fractures after 3 years:

KP 21 # (in 14 of 34 patients)

Con 18 # (in 10 of 14 patients) p=0.0341

VAS Pain scores

Pre-KP: Edema 72.2, No edema 70.7

Post-KP: Edema 46.8, No edema 60.3

12 mo.: Edema 48.0, No edema 50.1

Conclusion: KP is superior to conservative treatment of painful osteoporotic vertebral fractures for at least 3 years after intervention and reduces fracture incidence. There was no significant difference between the outcome in patients after KP using either PMMA or CaP-cement for the internal stabilization of the fractured vertebrae. Patients with and without bone edema of painful vertebral fractures benefit from kyphoplasty.

Disclosures: I. Grafe, None.

Comparison of the Effects of Calcium as Carbonate or Citrate on Bone Resorption Markers in Early Post Menopausal Women. S. D. C. Grasby^{*}, A. G. Need, B. E. C. Nordin. Clinical Biochemistry, Institute of Medical and Veterinary Science, Adelaide, Australia.

It has been reported that calcium citrate is better absorbed and more effective than calcium carbonate in suppression of parathyroid hormone (PTH). The implication has been that less calcium as the citrate than calcium as the carbonate is required to achieve the same effect.

A double blind cross over study was undertaken to compare the effects of these two calcium salts on a bone resorption marker in women within 5 years of the menopause. Fasting baseline serum biochemistry, PTH, 25 hydroxyvitamin D and beta crosslaps were measured in 20 women. Subjects were assigned to receive either calcium as the carbonate (1000mg oral) or as the citrate (500mg oral) using a random number generator. The serum measures were repeated 12 hours after the Ca salt taken at 9 pm the previous night. After a washout period of at least 1 week, the process was repeated, but the subjects who received the carbonate form previously now received the citrate preparation and vice versa.

The mean baseline values for serum biochemistry, PTH and 25 hydroxy vitamin D were all within the normal range.

The mean changes from baseline in selected variables after 1000mg Ca as the carbonate and 500mg Ca as the citrate are shown in the table.

Variable	Serum total Ca Ca type	Serum ionised Ca Calculated (mmol/L)	Serum PO4 (mmol/L)	Serum PTH (pmol/L)	Serum cross laps (ng/L)
carbonate	0.068*	0.024	0.137*	-0.572*	-76.65**
citrate	0.033	0.015	0.063	-0.25	-71.25**
P#	0.187	0.418	0.213	0.3.7	0.791

#For difference between the 2 calcium preparations; P calculated using 2 tailed paired T test.

Significance of change from baseline (P<0.05 = *; P<0.005 = **)

In conclusion, total serum calcium and phosphate rose and PTH fell significantly following 1000mg of Ca as the carbonate but not following Ca 500 mg as the citrate. However the bone resorption marker fell significantly and to the same degree on both salts. We conclude that in terms of the primary end point, 500mg Ca as the citrate was equivalent to 1000mg of Ca as the carbonate.

Testing of Mechanical Properties of Hip Protectors Using High Tech Materials. G. Holzer, L. A. Holzer*. Department of Orthopaedics, Medical University of Vienna, Vienna, Austria.

Purpose: To test the mechanical properties of hip protectors using high tech materials compared to conventional hip protectors according to a European Standard.

Methods: Two hip protectors using new high tech materials and five conventional hip protectors (AHIP protector, Astrosorb; AHF Hip pant, Hips, KPH, Safehip, Safety Pants) were mechanically tested using an mechanical testing machine (impact testing with 50 Joule) according to a European Standard (EN 1621-1). Results are peak (max) expressed in kiloNewton.

Results: The results of impact testing of two hip protectors using high tech materials were superior (AHIP protector 9.10 kN, Astrosorb 12.65 kN) to conventional hip protectors (21.97 - 50.62 kN), which differ in performance to mechanical testing. **Conclusions:** The results of this study show that new high tech materials with improved mechanical properties are superior to currently available hip protectors from the mechanical point of view. Utilizing these materials allow designing new hip protectors with increased compliance and adherence. AHIP protector, a hip protector using high tech material, implements modern design, improved wearing comfort and best mechanical properties.

Vertebral Compression Fractures in Patients with Poor Bone Quality: When and Which Osteoplasty? The Need for a Global Approach. R. Iundusi*, G. Cannata*, D. Lecce*, I. Cerocchi*, M. Celi*, U. Tarantino*. ¹Orthopaedics and Traumatology, University of Rome "Tor Vergata", Rome, Italy, ²Orthopaedics and Traumatology, University of Rome, Rome, Italy.

INTRODUCTION: Osteoporosis (OP) is estimated to afflict 200 million women worldwide. About 1.7 million vertebral compression fractures (VCFs) occur every year in Europe and in the US. Vertebral fractures are the most common type of fragility fractures due to alterations in bone quality, quantity and microarchitecture. Usually they occur with low energy trauma and result in pain about the fracture site, loss of vertebral body height, and kyphotic deformity. Only few patients gain benefits using conservative treatments. The aim of our study is to establish when there are the conditions to perform a vertebral osteoplasty and which technique, based on personal experiences and on omogeneous datas from the international literature, is suitable for each patient.

MATERIALS AND METHODS: Vertebroplasty and balloon kyphoplasty are two minimally invasive surgery approaches developed for the management of symptomatic VCFs. Vesselplasty is a new minimally invasive surgical technique which provide pain relief, stabilization of the vertebral body, and it has the ability to provide some correction of deformity with partial restoration of vertebral body height. During vesselplasty procedure an artificial "vessel" system, the Vessel-X[®], is introduced into the vertebral body to achieve augmentation after which low-viscosity bone cement mixed with calcium phosphate is injected into the vertebral body: the Vessel-X[®] are expanded to their predetermined configuration and a few bone void filler material penetrates through the "vessels" interdigitating the vertebral body, reducing one of the most common adverse effects of other minimally invasive techniques such as cement leakage.

DISCUSSION: Treatment of OP has made enormous advances in the past years, resulting in a wide range of options. We remind the importance of a global approach to the osteoporotic patients: the best treatment remains early diagnosis evaluating bone remodelling markers, lumbar and femoral Dual-energy X-ray absorptiometry (DEXA), thoracic and lumbar x-rays imaging and risks fracture assessment to ensure an individual and best appropriated therapy as specific as possible. Vesselplasty is a safe and effective minimally invasive procedure for relief of pain associated with VCFs, and improves mobility decreasing the potential risks associated with immobility. Future trials evidence should investigate if the association of vertebral osteoplasties with specific drugs acting on bone quality and rehabilitation could improve clinical outcomes reducing comorbidities and restoring a good and reasonable quality of life.

Organic Nitrate Use, Bone Loss and Fractures in Older Men. S. A. Jamal¹, D. C. Bauer², J. A. Cauley³, S. R. Cummings². ¹Medicine, University of Toronto, Toronto, ON, Canada, ²San Francisco Coordinating Center, CPMC Research Institute and University of California, San Francisco, CA, USA, ³Epidemiology, University of Pittsburgh, Pittsburgh, PA, USA.

Observational studies report positive associations between organic nitrate use, increased BMD, and decreased fractures among postmenopausal women. To determine the association between self-reported nitrate use, bone loss and fracture incidence in men we used data from the Osteoporotic Fractures in Men (MrOS) study, a large cohort of older men.

Men who reported use of nitroglycerin, isosorbide mononitrate or isosorbide dinitrate (either on an "as needed" or regular basis) in the 2 weeks preceding the baseline visit were classified as nitrate users. BMD at the hip and lumbar spine was measured with a Hologic QDR4500 at study entry and about 4.5 years later. Low trauma non-spine fractures were centrally adjudicated, and 331 men suffered one or more fracture during a mean follow-up of 5.4 years.

We used multiply adjusted linear regression models to determine the association between

nitrate use and % change in BMD, and Cox proportional hazards models to determine the association between nitrate use and fracture. There were 248 nitrate users and 5455 nonusers at the baseline visit. Nitrate users were significantly older than nonusers (76.5 yrs vs. 73.6) but there was no significant difference in body weight (82.7 kg vs. 83.1). Compared with nonusers, users were more likely to have had a fall in the past year, had poorer self-rated health, reported greater impairment of activities of daily living, were less physically active and had weaker grip strength. More nitrate users than nonusers reported use of statins and thiazides. After adjusting for these differences, and clinic site, there was no difference in the change in BMD over 4.5 years of follow up at the total hip among nitrate users -1.9% (95% Confidence Interval [CI] CI: -2.6 to -1.3) compared to nonusers -1.8% (95% CI: -1.9 to -1.7). There was no difference in the % change in spine BMD among users 5.1% (95% CI: 3.1 to 7.2) compared to nonusers 4.6% (95% CI: 4.2 to 4.9). There was no difference in the incidence of fractures among nitrate users compared to nonusers (Relative Hazard: 0.9; 95% CI: 0.5 to 1.5).

Contrary to previous studies in older women, we found that use of nitrates was not associated with increased BMD or decreased in fracture risk among men participating in the MrOS study. The lack of association may be due to limitations of observational data, differences in dose or frequency of nitrate administration, or biological differences in organic nitrate effects by gender. Further research is required to definitively determine the effects of nitrates on bone in men.

TENS (Transcutaneous Electrical Nerve Stimulation) in the Management of Osteoporosis-related Pain. S. Kalra*, A. Sharma*, B. Kalra*, N. Kumar*. ¹Endocrinology, Bharti Hospital, Karnal, India, ²Gynaecology, Bharti Hospital, Karnal, India, ³Physiotherapy, Bharti Hospital, Karnal, India.

Pain is a disabling symptom in persons with osteoporosis, and it often reduces the quality of life. This paper studies the effect of TENS in subjects with osteoporosis, complaining of pain.

30 adult osteoporosis patients with lower limb pain, receiving five sittings of TENS on daily or alternate day basis, were compared with 30 age-matched, disease-matched patients who were administered daily diclofenac and five sittings with sham electrodes.

Pain scores, measured by visual analog score, reduced significantly in both groups, but much more so in the TENS group (from 4.60 ± 0.54 to 1.60 ± 0.54) than the sham electrodes + diclofenac group (from 4.40 ± 0.54 to 3.60 ± 0.54). This difference was maintained after 3 weeks, even though the TENS sittings had stopped. Best improvement was obtained in patients with burning (3.28 ± 0.64) and lancinating (3.12 ± 0.64) pain. Least benefit was in patients with deep pain (2.15 ± 0.35) and restless legs syndrome (2.16 ± 0.56).

The dose of TENS used varied from 5.5 to 9.0 Hz on the initial day to 3.5 to 5.5 Hz on the last sitting. The dose varied insignificantly for different symptoms.

Validated health-related questionnaires were used to assess the effect of physiotherapy sessions in the subjects. Physician communication score improved from 1.43 ± 1.19 to 3.93 ± 0.86 over one month of therapy in all subjects. Time spent by them in stretching/strengthening exercise increased from 0.0 ± 0.0 to 15.0 ± 0.0 minutes per week. The social/role activities limitation due to the disease reduced from 2.25 ± 0.63 to 1.08 ± 0.39 . Cognitive symptom management improved from 1.30 ± 0.63 to 2.00 ± 0.67 .

The health distress score fell from 3.20 ± 0.82 to 1.35 ± 0.47 while energy/fatigue scores raised from 2.25 ± 0.51 to 3.30 ± 0.50 in all subjects. No difference was noted in these scores between the two groups.

This paper demonstrates the beneficial effect of TENS on pain related to osteoporosis, and the advantageous effects of regular physiotherapy on various health-related parameters in persons with osteoporosis.

The Effects of Black Cohosh Root Extract on the Vasomotor Symptom and Bone Metabolism of Menopausal Women. H. Kim^{*1}, H. Choi^{*2}, H. Park^{*3}, B. Kang^{*4}, B. Lee^{*5}, B. Yoon^{*6}, T. Kim^{*7}. ¹Dept. of OB & GYN, College of Medicine, Koin University, Busan, Republic of Korea, ²Dept. of OB & GYN, College of Medicine, Inje University, Seoul, Republic of Korea, ³Dept. of OB & GYN, College of Medicine, Chungang University, Seoul, Republic of Korea, ⁴Dept. of OB & GYN, College of Medicine, Ulsan University, Seoul, Republic of Korea, ⁵Dept. of OB & GYN, College of Medicine, Yonsei University, Seoul, Republic of Korea, ⁶Dept. of OB & GYN, College of Medicine, Sungkyunkwan University, Seoul, Republic of Korea, ⁷Dept. of OB & GYN, College of Medicine, Korea University, Seoul, Republic of Korea.

Introduction: Extract of the rootstock of *Cimicifuga racemosa* (black cohosh) have a traditional reputation as herbal remedies. For the last 4 decades case reports and clinical research with the socially manufactured *C. racemosa* extract have shown a good therapeutic efficacy and safe profile in the treatment of neuroprotective climacteric complaints. Safety concerns associating 6 month use with climacteric complaints and prevention of bone loss, have prompted the search for the effect of BCRE.

Objective: To evaluate the effect of black cohosh root extract (BCRE) on vasomotor symptoms, BMD and bone metabolism in postmenopausal women

Method: This prospective randomized clinical trial examined the effects of BCRE on vasomotor symptom, bone mineral density, and biochemical markers of bone turnover in 90 postmenopausal women. Treatment included BCRE (group I, n=30) or 0.625mg CEE (group II, n=30), control group (group III, n=30) for 6 months. Kupperman index, BMD and biochemical bone marker were measured at 0, 3 and 6 months.

Results: Kupperman index decreased significantly at 3 months and 6 months of the treatment in group I and group II (P<0.05). BMD of lumbar spine increased significantly during the treatment in group I and group II (P<0.05). Urinary deoxypyridinoline decreased significantly at 3 months and 6 months of the treatment in group I and group II (P<0.05).

Conclusion: BCRE appears to be a safe and effective alternate to hormone therapy for vasomotor symptom and prevention of bone loss. It may be especially useful in women with intolerance or contraindication to traditional hormone therapy.

The Effect of Vitamin K2 in Addition to Risedronate on the Patients with Postmenopausal Osteoporosis. H. Kwak, S. Kim. Rehabilitation, Dong-A University, College of Medicine, Busan, Republic of Korea.

Objective: To assess the effect of vitamin K2 in addition to risedronate on postmenopausal osteoporosis

Method: We enrolled 21 postmenopausal osteoporosis women (age: 65.2±7.8 years). Ten subjects received risedronate (35 mg, weekly) and vitamin K2 (45 mg, daily) and eleven subjects only received risedronate. They all received calcium citrate 2,130 mg and vitamin D 600 IU daily. The duration of treatment was 7.7±1.4 months. Bone mineral density (BMD) of lumbar spine and both femurs, serum osteocalcin and urine deoxypyridinoline were examined at baseline and after treatment.

Results: After treatment, BMD, serum osteocalcin and urine deoxypyridinoline were improved in each group but there was no statistical difference between the groups.

Conclusion: There was no evidence of the benefit of vitamin K2 in addition to risedronate in bone metabolism on postmenopausal osteoporosis.

Disclosures: H. Kwak, None.

Baseline Characteristics of Participants in the Soy Phytoestrogens as Replacement Estrogen (SPARE) Study. S. Levis¹, N. Strickman-Stein^{*2}, J. P. Krischer^{*3}. ¹Medicine, University of Miami Miller School of Medicine, Miami Veterans Healthcare System, and University of South Florida, Miami, Tampa, FL, USA, ²Medicine, University of Miami Miller School of Medicine, Miami, FL, USA, ³University of South Florida, Tampa, FL, USA.

After the early termination of the Women's Health Initiative, an increasing number of menopausal women stopped hormone replacement (HRT) and began to self-medicate with over-the-counter products. Soy is particularly popular because of its phytoestrogen content. The aims of this study are to establish the long-term effectiveness of soy phytoestrogens, or isoflavones, in (1) preventing the rapid bone loss seen in the first years of menopause and (2) improving general health-related quality of life and emotional health in menopausal women. This is a 5-year, ongoing, randomized, double-blind, placebo-controlled clinical trial that concluded its recruitment phase in March 2007. Of the 524 women who were screened, 283 met eligibility criteria: age 45-60 years, menopausal for ≥ 6 months but < 5 years, non-obese, no current HRT, and no history of osteoporosis, treatment with bone-active drugs, or cancer. The study randomized 247 women to either soy isoflavone tablets 200 mg/day or placebo tablets (50/50). Each participant will be followed for 2 years during 10 clinic visits, receiving serial measurements of lumbar spine and hip bone mineral density (BMD) and urinary N-telopeptide of type I bone collagen (NTx). The primary outcome variable is change in BMD at 2 years. The mean age of participants at screening was 52.44 years (35.8% of women were ages 52-54); 75% of participants are Hispanic and 90% are White. Nearly 90% of enrolled women reported a high school education and

41.5% are college graduates. At time of randomization, the mean BMD (L1-L4) was 1.130 g/cm² ± 0.125 and the mean total hip BMD was 0.981 g/cm² ± 0.102. In addition, mean lumbar spine (L1-L4) T-score was -0.383 ± 1.04 and mean total hip T-score was 0.981 ± 0.102. No differences in BMD were found between Hispanics and non-Hispanics, or between African American and White women. Comparisons between the two study groups were made by the study biostatistician. They demonstrate that the randomization process produced two equivalent groups with respect to baseline demographic and key clinical parameters. The results of this trial will provide new information on the safety and long-term efficacy of soy phytoestrogens in preventing bone loss and menopausal symptoms. These results will enable women to make informed decisions at the time of menopause. Choices made at the time of menopause will impact rates of bone loss and future incidence of osteoporosis and fractures when these menopausal women become older adults.

Disclosures: S. Levis, None.

T426

Low Magnitude Mechanical Signals Reduce Risk-Factors for Fracture During 90-Day Bed Rest. J. W. Muir^{*1}, Y. Xia¹, N. Holguin^{*1}, S. Judex¹, Y. Qin¹, H. Evans^{*2}, T. Lang³, C. Rubin¹. ¹Biomedical Engineering, SUNY Stony Brook, Stony Brook, NY, USA, ²Johnson Space Center, NASA, Houston, TX, USA, ³Dept of Radiology, University of California, San Francisco, San Francisco, CA, USA.

Long duration spaceflight leads to multiple deleterious changes to the musculoskeletal system, where loss of bone density, an order of magnitude more severe than that which follows the menopause, combined with increased instability, conspire to elevate the risk of bone fracture due to falls on return to gravitational fields. Here, a ground-based analog for spaceflight is used to evaluate the efficacy of a low-magnitude mechanical intervention, VIBE (Vibrational Inhibition of Bone Erosion), as a potential countermeasure to preserve musculoskeletal integrity in the face of disuse. Twenty-six subjects consented to ninety days of six-degree head-down tilt bed-rest. 18 completed the 90d protocol, 8 of which received daily 10-minute exposure to 30 Hz, 0.3g VIBE, applied in the supine position using a vest elastically coupled to the vibrating platform. The shoulder harness induced a load of 60% of the subjects' body weight. At baseline and 90d, Qualitative Ultrasound Scans (QUS) of the calcaneus and CT-scans of the hip and spine were performed to measure changes in bone density. Postural control (PC) was assessed through center of pressure (COP) recordings while subjects stood on a force platform for 4 minutes of quiet stance with eyes closed, and again with eyes opened. As compared to control bedrest subjects, CT indicated a trend that VIBE reduced the loss of BMD in the proximal femur, including integral (0.9 ± s.e. 0.3% vs. 1.17 ± 0.5%; 15% dif; p=0.38), trabecular (1.5 ± 0.4% vs. 2.2 ± 0.5%; 28%; p=0.20), and cortical region (0.4 ± 0.4% vs. 0.7 ± 0.4%; 37%; p=0.28). QUS showed a 0.9% loss in ultrasound velocity for control subjects, as compared to a 0.3% gain for VIBE (p=0.05). The increase in postural instability suffered by control subjects was diminished by VIBE, with a per month increase in maximal forward sway angle (35.4 ± 8.3% reduced to 20.2 ± 6.2%; 43%; p=0.08), root-mean-square (RMS) of anterior-posterior COP displacement (30.1 ± 9.5% reduced to 15.9 ± 5.5%; 47% decrease; p=0.11), and maximal forward sway velocity (53.1 ± 12.0% reduced to 16.2 ± 7.2%; 70%; p=0.01), maximal total velocity (53.8 ± 17.4 reduced to 20.6 ± 6.9; 64%; p = 0.05), mean velocity of sway (43.3 ± 9.7 reduced to 27.3 ± 7.3; 37%; p = 0.1), and RMS velocity (48.0 ± 9.1% reduced to 27.8 ± 7.0; 42%; p = 0.06). These data provide early evidence that low-level mechanical signals can ameliorate the damage of non-weight bearing to several aspects of the musculoskeletal system. Certainly, the preservation of both bone quality and postural control during extended disuse will ultimately reduce the risk of both falls and fracture.

Teriparatide in Clinical Practice - Experience with 158 Patients Beyond Randomized Controlled Trials. C. Muschitz¹, L. Milassin^{*1}, T. Pirker^{*1}, J. Patsch^{*2}, G. Nimberger^{*3}, H. Resch¹. ¹Medical Department II, St. Vincent Hospital, Vienna, Austria, ²Department of Pathophysiology, Medical University Vienna, Vienna, Austria, ³Bioconsult Ltd, Perchtoldsdorf, Austria.

We established a prospective single-center open-label database evaluate response to 9 & 18 month teriparatide treatment (rhPTH [1-34] 20µg/d; 1000mg calcium & 800IU vitamin D/d) for patients with progressive osteoporosis who are not subject to randomized controlled trials.

We included 158 consecutive Caucasian patients (141 females, 17 males). 78.4% were considered as bisphosphonate non-responder and 9.6% as bisphosphonate incompatibility. 1.2% had steroid induced osteoporosis. At 10.8% we performed a bone biopsy due to uncertain diagnostic findings. All patients were subject to standardised diagnostic examinations (iDXA hip and spine - GE Lunar, QCT spine Mindways, serum parameters, vertebral X-ray, medication, side effects). Statistical calculation was performed by rank tests and by an ANCOVA and regression model.

Mean age was 71.94 ± 9.97 years. 86 % presented more than 1 vertebral fracture (mean: 3.6 fractured vertebrae). Serum parameters of bone metabolism were within normal range at baseline.

After nine months alkaline phosphatase increased from 68.87 ± 87 to 93.77 ± 38.36 U/l (p < 0.001), S-OC (ng/ml) changed from 17.21 ± 12.82 at baseline to 71.70 ± 34.90 (p < 0.001), S-CTX (ng/ml) increased from 0.25 ± 0.14 to 0.80 ± 0.49 (p < 0.001), P1NP (ng/ml) increased from 39.12 ± 25.76 to 144.87 ± 22.18 (p < 0.05) and PTH (pg/ml) decreased from 41.65 ± 14.56 to 28.83 ± 12.87 (p < 0.001), respectively. Serum and 24 hour excretion of calcium and phosphorus remained within normal range.

BMD of spine measured by DXA increased from 0.85 ± 0.15 g/cm² at baseline to 0.92 ± 0.16 g/cm² at month 9 (p=0.0004) and to 0.95 ± 0.17 g/cm² at month 18 (p=0.0006). At hip was no

significant increase of BMD (0.75 vs 0.76 g/cm²). BMD of lumbar spine measured by QCT increased from 48.25 ± 29.58 to 52.96 ± 35.31 g/cm³ (n.s.). Concomitant oral medication like proton pump inhibitors, statins, antidiabetics or antithrombotics had no significant influence on BMD or parameters of bone metabolism after nine months. Only one patient had one new vertebral fracture during treatment.

Teriparatide treatment in clinical practice is safe and effective for patients with progressive osteoporosis who are not subject to randomized controlled trials.

Disclosures: C. Muschitz, None.

Effect of Treatment with Depot GH on Bone Remodeling and Heel Ultrasonometry in Dwarfism Due to Mutation in the GHRH-R Gene. F. J. A. Paula¹, M. B. Gois Jr.^{*1}, F. A. Pereira¹, R. C. Pereira^{*2}, C. R. P. Oliveira^{*3}, C. Farias^{*3}, J. A. Barreto-Filho^{*3}, C. M. Santos^{*4}, T. Vicente^{*4}, M. H. Aguiar-Oliveira^{*3}, R. Salvatori^{*5}. ¹Internal Medicine, School of Medicine of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil, ²Internal Medicine, School of Medicine of Federal University of Sergipe, Aracaju, Brazil, ³Internal Medicine, School of Medicine of Federal University of Sergipe, Aracaju, Brazil, ⁴Internal Medicine, School of Medicine of Federal University of Sergipe, Ribeirão Preto, Brazil, ⁵Internal Medicine, School of Medicine of Johns Hopkins University, Baltimore, MD, USA.

GH treatment of individuals with isolated chronic GH deficit (GHD) probably has beneficial effects that exceed the risks. We had evaluated heel ultrasonometry and bone remodeling in individuals with GHD at baseline, after 6 months of treatment with depot GH, and 6 and 12 months after the end of treatment. Subjects with GHD (20) due to mutation of the GHRH-R gene and a control group (CO=20) were evaluated. The groups were matched for age (GHD= 46.1 ± 14.5 vs CO= 46.4 ± 15.9 years), sex (GHD and CO = 10M/10F) and BMI (GHD= 23.8 ± 3.9 vs CO= 23.9 ± 3.6 Kg/m²). The GHD group presented lower weight (GHD= 36.8 ± 3.9 vs CO= 67.2 ± 14.7 Kg) and height (GHD= 1.24 ± 0.07 vs CO= 1.67 ± 0.05 m) ($p < 0.01$). The GHD received depot Nutropin administered every 15 days for 6 months. The initial and final doses were 0.33 ± 0.33 and 0.38 ± 0.08 mg/kg for women and 0.25 ± 0.01 and 0.38 ± 0.04 mg/kg for men. QUS was performed with the Achilles in Sight apparatus. The QUS parameters used were stiffness and T score, which were compared to the values of a normal South American population. Serum osteocalcin, ICTP and IGF-1 were determined. T-score ($p < 0.01$) and stiffness ($p < 0.04$) values were significantly lower in the GHD group. GH induced elevation of the T score, which persisted after the end of treatment, with a significant difference compared to baseline being observed at 6 months and 12 months ($p < 0.04$) after GH discontinuation. The GHD group presented elevation of osteocalcin during treatment ($p < 0.01$), which remained elevated for 6 months after the end of treatment ($p < 0.01$). ICTP showed elevation only during treatment ($p < 0.01$). IGF-1 levels were low in GHD group at baseline (< 10 ng/ml) and increased significantly during treatment. Our results show that depot GH induced a significant improvement in QUS and in bone remodeling parameters in individuals with GHD. The beneficial effect on bone ultrasonometry was maintained for 12 months after the discontinuation of treatment. These results are encouraging and indicate that other studies should be conducted in order to establish the ideal periodicity of treatment with GH, and that data obtained by bone densitometry should be compared to those obtained by QUS in individuals with GHD.

A Theoretical Analysis of Current Density to Increase Bone Mass with Low-Frequency Interferential Electrical Stimulation. M. Shih¹, R. Kamondetdacha^{*2}, J. A. Nyenhuis^{*2}, W. J. Carroll^{*1}. ¹RS Medical, Vancouver, WA, USA, ²Purdue University, West Lafayette, IN, USA.

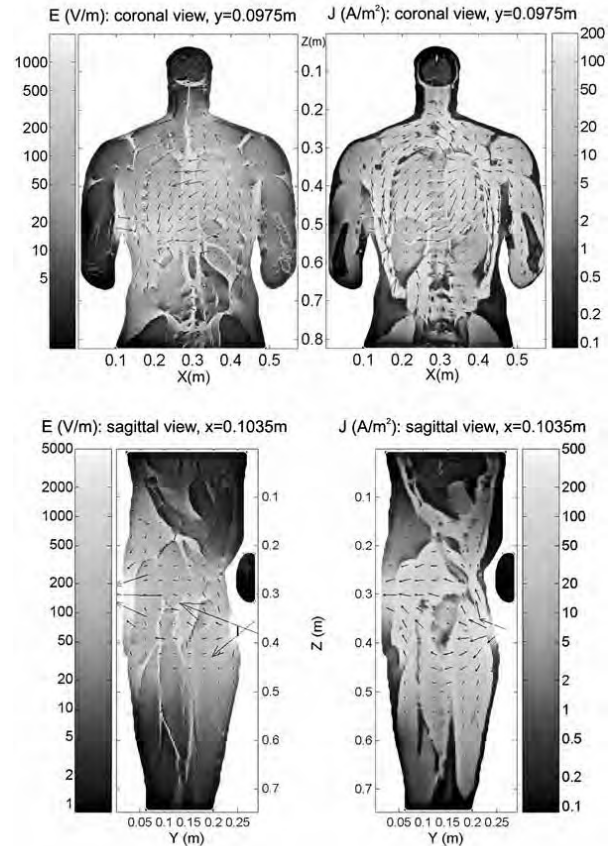

Low-frequency electrical fields have been shown to enhance bone tissues repair when specific frequencies are applied at appropriate current levels. Repeated studies using interferential stimulation (IS) in neonatal rat calvaria cultures confirmed a positive effect of such electrical fields from interferential current on osteoblastic proliferation and bone matrix production. Creation of a therapeutic device capable of strengthening bone in the lower back or hip has awaited a robust frequency-based human body conductivity model. The present work theoretically models the IS to the targeted tissue, i.e., human vertebrae and femoral head and calculates the electric field strengths.

Using a mathematical model of conductivity within the human body (Hugo), the electrical fields and current densities for particular electrical potentials passing through electrodes applied to specific surfaces of the body were calculated. By use of an impedance technique and by applying quasi-static approximation, the current density from electrodes was calculated for a 3-mm resolution with local sub-gridding at a resolution of 1 mm. Electrode pairs were placed on the back at the approximate longitudinal locations of T5 and T11 and also T3 and L3 of the human model; electrodes were also placed over the femur at the front and back of the modeled body (Fig.1).

For an electrode current of 1 A, the predicted electric field amplitude (EFA) in a vertebral body would be approximately 130 V/m. EFA in the vertebral bodies and discs are similar, but the current density is much greater in the discs due to their larger conductivities. The EFA in the femur is predicted to be about 300 V/m for the chosen electrode locations. Waveforms of IS were calculated for different frequency currents applied to electrode pairs.

The experimentally determined therapeutic current would be 27 mA for delivery of 20mV/cm to bone in human. The data, compared with the values reported by Carter (IEEE Trans.

Biomedical Engineering, 1990) with consideration of approximations in the two models, are felt to be in good agreement. Using the same modeling methodology, estimates of EFA closely matched values measured in a Petri dish culture of neonatal rat calvaria in which osteoblastic cell number and matrix production were successfully stimulated.

Results of the 'e-Bone Study': Bone Density Changes with Pulsing Electromagnetic Field Treatment of the Forearm after Disuse. J. A. Spadaro, W. H. Short^{*}, P. R. Sheehee^{*}, D. H. Feiglin^{*}, J. C. Calabrese^{*}, R. M. Hickman^{*}. Upstate Medical University, Syracuse, NY, USA.

A feasibility and dosing study was undertaken to determine if pulsing electromagnetic field (PEMF) treatment, typically used for treating non-union fractures, could moderate the osteopenia that occurs following forearm disuse. This was a randomized, double blind, sham controlled and age and gender balanced trial approved by the IRBPHS at SUNY Upstate Medical University. Entry and baseline was 6-8 weeks after a distal radius fracture or carpal surgery and 99 subjects were randomized to wear a distal forearm PEMF transducer for either 1, 2, or 4 hours per day during the 8 weeks following their baseline visit. 25% of the subjects were randomly assigned (double blinded) to receive identical but inactive sham transducers. Bone mineral density (BMD) and geometry at several sites in the forearm were measured by dual energy x-ray absorptiometry (DXA) and peripheral quantitative CT (pQCT) at baseline, 8, 16, and 24 weeks. Serum markers of bone formation (BSAP) and resorption (CTX) were measured at baseline and 8 weeks. Analyses of the % change from baseline for BMD and other variables was performed using multiple regression and analysis of co-variance based on the general linear model, with means adjusted for the effects of age, gender and baseline BMD. 82 subjects completed all four visits with an average hourly treatment compliance of 88%. Based on previous work, the typical BMD loss at baseline is of the order of 3-5 %. In this study we measured a subsequent average loss of 5-7% for the ultra-distal radius and 3-4 % for the radial shaft. An 'intent to treat' analysis (n= 99) on a composite 'grand mean' of % loss of BMD by DXA or pQCT at six forearm sites from 8-24 weeks showed no evidence of a positive effect of active vs. sham PEMF treatment on the loss after baseline. This was true also for subjects completing all visits (n=82) either on the 'grand mean' BMD loss or at each individual site. Model-adjusted standard errors in BMD change were in the 0.5-3% range. Interestingly, the pQCT data suggested a rapid increase in cortical cross-sectional area and strength index in the distal forearm during the study period. Serum BSAP was unchanged after treatment but serum CTX was clearly decreased in all treatment groups (but unaffected by PEMF). Even with the large between subject variability, the results suggest that the chosen timing and PEMF used here were not sufficient to substantially moderate the rapid bone loss and slow recovery induced by the injury and immobilization.

Establishment of Vascular Calcification Model Using High Dose of Vitamin D in Mice. J. Jin*, H. Jin*, M. Han*, H. Kim*, Y. Jung*, Y. Park*, M. Park*, W. Lee*, J. Choi. Biochemistry & Cell Biology, Kyungpook Natl. Univ. School of Medicine, Skeletal Diseases Genome Research Center, Daegu, Republic of Korea.

Vascular calcification represents an important risk factor for high mortality of cardiovascular diseases. High dose of vitamin D has been used to induce vascular calcification mostly in rats, however, it has not been determined whether it is applicable to mice. Here, mice (n=7 in each group) were injected with various doses of vitamin D (0, 10, 30, 50, 100 x 10⁴ IU/kg) in subcutaneous tissue one time per day for 3 days and mice were sacrificed at day 9 after last injection. Blood chemistry and histological analysis such as Alizarin Red S and von Kossa staining were performed. Vitamin D injected mice were more lethargy and sluggish according to the time. Their body weights were nearly a half compared to control group and their hair appeared no glossiness. Blood calcium, creatine and alkaline phosphatase activity were increased according to the dose of vitamin D. In bone tissues, vitamin D increased TRAP positive staining in trabecular bone area. In soft tissues, calcification was observed in aorta, kidney, and lung, but it was not observed in heart, spleen and brain. Calcification was prominent especially kidney and lung around proximal tubule and alveoli, respectively. Interestingly, calcification in medial layer of aorta was more severe than intimal layer. Collectively, these results indicate that high dose of vitamin D is a good mouse model for medial calcification which is frequently shown in diabetes mellitus and uremic conditions

Fosamax® (alendronate sodium) and Cholecalciferol (Vitamin D₃) in the Treatment of Men and Postmenopausal Women with Osteoporosis. F. Chouha¹, M. Shulman^{*1}, C. Liao^{*2}, T. Koulis^{*2}, J. S. Sampalis^{*3}, A. C. Karaplis⁴. ¹Merck Frosst Canada, Kirkland, PQ, Canada, ²JSS Medical Research, Westmount, PQ, Canada, ³Dept. of Surgery, McGill Univ., Montreal, PQ, Canada, ⁴Dept. of Medicine, McGill Univ., Montreal, PQ, Canada.

Background: Osteoporosis is a debilitating disease associated with significant morbidity and mortality. It is recommended that patients on antiresorptive medication receive supplemental calcium and vitamin D.

Objective: To describe the distribution of serum 25-hydroxyvitamin D [25-(OH) D] in Canadian men and postmenopausal women with osteoporosis and to evaluate the impact, safety, and tolerability of vitamin D₃ supplementation taken as 400 IU daily concurrently with alendronate 70 mg weekly.

Methods: A 16 week, open-label, multi-center, observational study. Eligible patients with osteoporosis were either men or community dwelling ambulatory women, postmenopausal for ≥ 6 months. Outcomes were changes in serum 25-(OH) D levels, adherence, and incidence of adverse events attributed to treatment.

Results: 728 patients were enrolled, comprising 684 with 25-(OH) D evaluation at baseline; 614 (84.3%) and 485 (66.6%) completed week 8 and 16, respectively. The majority of discontinuations were lost to follow-up, 131 (18.0%). The mean (SD) age of the patients was 67.7 (10.3) years old. There were 605 (83.1%) female and 593 (81.5%) Caucasian. The figures illustrate the prevalence of serum vitamin D inadequacy (<75 nmol/L) by cut-off points and statistically significant increases of serum 25-(OH) D with P < 0.001 (between visits 1, 2 and 3)

The mean (SD) change in 25-(OH) D value (nmol/L); 8.6 (22.8) for week 8 vs. baseline (P < 0.001); 13.7 (25.3) for week 16 vs. baseline (P < 0.001); and 5.2 (19.9) for week 16 vs. week 8 (P < 0.001). Adherence (<20% missed dose) at week 8 was 96.7% with Fosamax® and 96.3% with vitamin D. At week 16, adherence was 98.6% and 97.1%, respectively.

103 non-serious adverse events reported by 70 (9.6%) subjects were attributed to treatment, among which gastrointestinal disorders were the majority observed by 50 (6.9%) subjects.

Conclusion: A significant proportion (68.0%) of the study population has vitamin D inadequacy at baseline. Daily vitamin D₃ supplementation taken concurrently with alendronate weekly was effective in significantly improving the 25-(OH) D levels of subjects. Treatment was safe, well tolerated with a low incidence of adverse events and a high adherence.

The Combination of Calcitriol Shows more Bone Sparing Effect by Suppressing Secondary Increment of Parathyroid Hormone in Raloxifene Therapy than when Laloxifene Is Used Alone in Postmenopausal Japanese Women with Osteoporosis and Osteopenia. I. Gorai¹, Y. Tanaka^{*1}, Y. Iwaoki^{*2}. ¹Obstetrics and Gynecology, International University of Health and Welfare Atami Hospital, Atami, Japan, ²Obstetrics and Gynecology, Hiroshima-ken JA Yoshida General Hospital, Takada-gun, Japan.

It has been reported that vitamin D insufficiency is prevalent in osteopenic and osteoporotic postmenopausal women. Secondary hyperparathyroidism decreases the beneficial effects of antiresorptive therapy on bone mineral density (BMD) in osteoporotic women. We aimed to see the effects of raloxifene, 1α(OH)vitamin D₃ and a combination of both on bone density and turnover in postmenopausal Japanese women with osteoporosis or osteopenia (<2.0SD). A total of 153 subjects aged 49 to 81 years [64.8±6.9 years, 16.2±8.5 years since menopause (YSM)] were randomly assigned to 60mg raloxifene (R), 1μg 1α(OH)vitamin D₃ (D) or a combination of both (R+D) daily for 1 year. Lumbar spine (L-) BMD, biochemical indices, and intact (i-)PTH were monitored over 1 year. Baseline 25(OH)D levels were measured at the start of the study. There were no significant differences in the background characteristics among the three groups. Baseline 25(OH)D levels were 24.3ng/ml in D-group, 22.9ng/ml in R-group and 24.2 ng/ml in D+R-group (P=0.3980). PPS analysis was used for statistical analysis. In the combination-treated group there was a significant increase in L-BMD (+3.6% in 6 mo. and +4.4% in 1 yr, P<0.001) and the increases were significant as compared with those in D-treated group (vs.+0.7% and 0.9%, P<0.05). At 6 mo. i-PTH showed significant decrease in D-group (-17.7%, P<0.01), significant increase in R-group (+19.2%, P<0.05) and non-significant change in combination-group (-4.8%) and the change in D-group was significantly different from that in R-group (P<0.05). We found significant decreases in corrected serum calcium in R-group (-4.5% and -3.8%, P<0.01) at 6 mo. and 1 yr. Bone-specific alkaline phosphatase (BAP), urinary cross-linked N-telopeptides of type I collagen (u-NTX) and urinary type I collagen C-telopeptide breakdown products (u-CTX) in combination-group showed significant decreases at 1 mo., 3 mo., 6 mo. and 1 yr (-17.1%--36.7%, -13.5%--34.0% and -28.3%--47.4%, respectively) except for BAP at 1 mo., whereas BAP and u-NTX after 6 mo. (-13.4%--16.7% and -22.3%--28.0%) and u-CTX after 1 mo. (-14.8%--32.3%) significantly decreased in R-group. We conclude that the combination of calcitriol shows more bone sparing effect by suppressing secondary increment of parathyroid hormone and lowering bone turnover more greatly in raloxifene therapy than when raloxifene was used alone in postmenopausal Japanese women with osteoporosis and osteopenia.

A Combination Therapy of Alendronate and Calcitriol Increases in Bone Mineral Density by Keeping Intact Ca Metabolism for the Treatment of Osteoporosis. M. Yamanaka^{*1}, Y. Sakamoto^{*1}, A. Tokita², K. Kitahara³, M. Ishijima¹, H. Kurosawa^{*1}. ¹Orthopaedics, Juntendo University School of Medicine, Tokyo, Japan, ²Pediatrics, Juntendo University School of Medicine, Tokyo, Japan, ³Orthopaedics, Juntendo Tokyo Koto Geriatric Medical Center, Tokyo, Japan.

A combination therapy of alendronate (ALN) and calcitriol (a-D) is widely accepted as one of the best approaches for the management of osteoporosis in Japan. The purpose of this study was to compare the efficacy of a combination of ALN and a-D with that of ALN alone for the treatment of osteoporosis. The subjects were post-menopausal women with primary osteoporosis (20 cases), who were treated with ALN alone for one year. At the beginning of the second year, they were divided into two treatment groups: patients treated with ALN alone for one more year (ALN group) and patients treated with a combination of ALN and a-D (0.5ug/day) (ALN+D group) for a year. The primary outcome was assessed by lumbar spine mineral density (BMD), and secondary outcomes were assessed by biochemical makers for bone metabolism. BMD and biochemical makers were measured at the beginning of treatment and after one and two years. No significant difference in serum 25(OH)D was detected between the ALN group and ALN+D group at the beginning of treatment (23.9±9.4 ng/ml, 20.6±9.9 ng/ml respectively). In addition, no significant difference between the groups in the median increase of BMD was detected in the first year (8.0±4.4%, 6.9±6.7% respectively). The median increase of BMD in the second year was -0.61% in ALN group and +1.77% in ALN+D group (p=0.07). In the second year, the median increase in serum intact parathyroid hormone (i-PTH) of the ALN+D group was significantly lower (p=0.025) than that of the ALN group, while the median increase of urine Ca/Creatinine in the ALN+D group was significantly higher (p=0.033) than that of the ALN group. These results suggest that, similar to treatment with a-D alone, a combination therapy using active ALN and a-D promotes absorption of Ca and inhibits hyperparathyroidism. Our results demonstrate that the combination therapy with ALN and a-D is superior to gain BMD with intact Ca metabolism over ALN alone for the treatment of osteoporosis.

Lasofloxifene Preserves Lumbar Vertebral Strength by Preventing Bone Loss and the Deterioration of Bone Architecture and Geometry in Ovariectomized Rats. M. Li¹, H. Qi^{1*}, Y. Li^{1*}, H. A. Simmons¹, D. T. Crawford^{1*}, D. R. Healy^{1*}, T. A. Brown¹, H. Z. Ke², D. D. Thompson¹. ¹Cardiovascular and Metabolic Diseases, Pfizer Global Research and Development, Groton, CT, USA, ²Amgen, Thousand Oaks, CA, USA.

We have previously demonstrated that lasofloxifene, a selective estrogen receptor modulator, prevented cancellous bone loss and preserved bone strength in ovariectomized (OVX) rats. In this study, we further characterized the effects of lasofloxifene on bone architecture and geometry and their contribution to the preservation of bone strength in the lumbar vertebra of OVX rats. Female rats at 13 weeks of age were OVX and treated orally with vehicle or lasofloxifene at 10 µg/kg/d or 17α-ethynylestradiol (EE) at 30 µg/kg/d for 8 weeks. The vehicle-treated OVX rats exhibited bone loss and compromised bone strength as demonstrated by a significant decrease in total bone density, cortical bone content, and cancellous bone volume and ultimate strength. Deterioration of cancellous and cortical architecture and cortical geometry was also seen in these animals as evident by a significant decrease in trabecular number, trabecular thickness, cortical area and cortical thickness, and an increase in trabecular separation and endocortical circumference. In contrast, lasofloxifene treatment completely abolished the changes induced by estrogen deficiency in total bone density, cancellous bone volume, trabecular number and separation, cortical area, cortical content, and ultimate strength. In addition, the OVX rats treated with lasofloxifene had significantly increased trabecular thickness and decreased endocortical circumference compared with the vehicle-treated OVX controls. The aforementioned effects of lasofloxifene on bone mass, architecture, geometry and strength were similar to those observed in the OVX rats treated with EE. Significant positive correlations were found between ultimate strength and total bone content, total bone density, cortical content, cortical area, cortical thickness, endocortical circumference, cancellous bone volume, trabecular number and trabecular separation with *r* values ranging from 0.338 to 0.571 and *p* values ranging from 0.0351 to 0.0002. The strongest correlation observed was between the ultimate strength and cancellous bone volume followed by trabecular number and cortical thickness. In summary, lasofloxifene protected against estrogen deficiency induced bone loss and the deterioration of bone architecture/geometry, and preserved bone strength at lumbar vertebra of rats. In addition to bone mass, trabecular and cortical architecture as well as geometric properties contributed to the preservation of bone strength by lasofloxifene treatment.

Prevalence of Hypovitaminosis D and Male Hypogonadism in Prednisone-treated Rheumatic Disease Patients. H. B. Lindsley^{1*}, D. Walia^{1*}, H. Singh^{1*}, K. Jennings^{1*}, F. Wolfe^{2*}, D. D. Smith^{1*}, B. P. Lukert¹. ¹Dept Medicine, Univ Kansas Medical Center, Kansas City, KS, USA, ²Dept Medicine, Univ Kansas School of Medicine--Wichita, Wichita, KS, USA.

Inadequate vitamin D nutritional status is an underappreciated health problem in adults at risk for osteoporosis. Serum levels of 25-hydroxy vitamin D [25(OH)D] are rarely ordered as there are no specific symptoms to suggest this deficiency. Serum PTH levels rise as 25(OH)D levels decrease, contributing to osteoporosis. The purpose of this prospective observational study was to identify patients at high risk for osteoporosis, who had insufficient levels of vitamin D (either gender) or testosterone (males). We enrolled 175 patients, 40 years of age or older, on ≥5 mg prednisone daily for a least one month. Blood was obtained for measurement of 25(OH)D (DiaSorin method), PTH, osteocalcin, and free testosterone.

Using 30 ng/mL as a minimum threshold for adequacy of vitamin D, 71% of all subjects had insufficient levels of 25(OH)D, and 23% of all subjects had vitamin D deficiency (<15 ng/mL). 21% were taking at least 100 IU of Vitamin D daily (median=400) and 3% were taking weekly Vit D (≥25,000 IU). Median prednisone dosage was 10 mg daily.

Vit D Grp (ng/ml)	N	25(OH)D level (ng/ml, median±SEM)	PTH (pg/ml)	Osteocalcin (ng/ml)
<15	40	12±2	45±5	3.0±0.5
15-29	84	24±1	32±3	3.2±0.4
30-45	47	34±1	25±4	2.8±0.2
>45	4	89±25	23±4	2.2±0.9

Ethnic differences were apparent: African-Americans (N=19) had distinctly lower 25(OH)D levels, 15±1, compared to Caucasians (N=142), 25±1; whereas PTH levels were higher, 40±8 versus 30±2. There was an inverse correlation between 25(OH)D and PTH levels (Pearson correlation = -0.23). Osteocalcin levels were independent of 25(OH)D levels.

For males 30 of 59 (51%) had low free testosterone levels (<1 ng/mL), 0.79±0.04 (median±SEM), whereas the remaining 29 subjects had normal levels, 1.40±0.14. Median prednisone usage in the low group was 7.5 (±2.0) mg daily, whereas the group with normal levels took 10.0 (±0.6) mg daily.

In summary, there was an unexpected high frequency of 25(OH)D insufficiency and male testosterone deficiency in prednisone-treated patients at increased risk for osteoporosis. Furthermore, OTC Vitamin D supplementation was uncommon and inadequate.

Vitamin D Deficiency in Osteogenesis Imperfecta: Recommendations for Supplementation. E. N. Martin^{1*}, A. Khosravi^{1*}, K. BrintzenhofeSzoc^{2*}, J. R. Shapiro¹. ¹The Kennedy Krieger Institute, Baltimore, MD, USA, ²Catholic University of America, Washington, DC, USA.

The contribution of vitamin D deficiency to BMD and fracture risk is undefined in adult OI. This report presents baseline and 2-year 25(OH) vitamin D concentrations in 50 adults, 18-65 years, and preliminary data for 10 children, 3-18 years, with types I, III, and IV OI. Types V, VI, and VII OI were not included. Values were examined with respect to OI type, BMD, serum PTH, alkaline phosphatase and urine NTX.

Patients received supplements of 400 IU vitamin D/day following then current RDA recommendations, now recognized to be insufficient. Serum levels measured at baseline and 2 year values in adults below 32ng/mL were: type I 79% and 42%, type III 84% and 50%, type IV 100% and 75% (Table 1). In children, preliminary data showed 6 type I patients with baseline and 2 year serum values 38ng/mL and 30 ng/mL, 2 type III patients 23ng/mL and 16ng/mL, and 2 type IV patients 24ng/mL and 13ng/mL.

PTH levels showed the expected inverse relationship to 25(OH)D level. No significant relationship between alkaline phosphatase or NTX and vitamin D levels was found. In adults, there was a non-significant trend for increasing BMD over a 2 year period when patients received 400 IU/day.

As RDA recommendations of 400-600 IU (RDA, 1989) are not adequate to produce serum levels above 32 ng/mL in OI, we propose the following guidelines based on patient weight rather than age because of marked size variation within the OI population (Table 2). Individual monitoring of serum levels as patients alter vitamin D intake is essential. In conclusion, people with OI demonstrate a significant incidence of vitamin D deficiency, which may be due to lack of sun exposure and deficient oral intake. Also, compliance in this population may limit adequate D supplementation. Maximizing calcium absorption and minimizing bone resorption in OI is particularly critical, and so adequate serum vitamin D levels should be maintained. At this time we have not assessed effects of these supplements on parameters of BMD or biomarkers in adults or children with OI.

Table 1: Baseline Serum Levels in Adults

Serum 25(OH) vitamin D level	<10 ng/mL	<20 ng/mL	<32 ng/mL
Type I OI	7%	56%	79%
Type III OI	4%	40%	84%
Type IV OI	17%	50%	100%
Healthy Canadian Adults (1)	6%	34%	N/A
Healthy US Adults age 18-29 years and 49-83 years (2)	N/A	36% and 41%	53.3%
US Adult Inpatients (3)	22%	57%	N/A

Table 2: Recommended Vitamin D Daily Intake

Age (RDA)	Weight (Recommended)	
0-50 years	200 IU/day	50 lbs/ 20 kg
51-70 years	400 IU/day	90 lbs/ 40 kg
70+ years	600 IU/day	110 lbs/ 50 kg
		150 lbs/ 70 kg +
		2000-2800 IU/day

Antifracture Efficacy of Combined Treatment with Alendronate and Alfacalcidol for Osteoporosis in Early-phase Treatment. N. Miyakoshi¹, Y. Kasukawa¹, H. Kodama^{2*}, H. Noguchi^{1*}, H. Sasaki^{1*}, K. Kamo^{1*}, Y. Shimada^{1*}. ¹Orthopedic Surgery, Akita University School of Medicine, Akita, Japan, ²Minamiakita Orthopedic Clinic, Katagami, Japan.

Alendronate, a bisphosphonate, decreases the incidence of vertebral fractures by increasing bone mineral density (BMD). However, because the effects on bone are exerted in an indirect manner by reducing the remodeling space and prolonging the duration of mineralization, several months are required to increase bone strength. Previous reports have shown significant antifracture effects can be expected after 6 months of treatment. Alfacalcidol also displays preventive effects against osteoporotic fractures, despite a small effect on bone mass. We thus conducted a 6-month, prospective, randomized trial of postmenopausal women with osteoporosis to evaluate the possibility of early-phase superiority using combined treatment with alendronate and alfacalcidol compared to either alone, with radiographically diagnosed vertebral fracture as the primary endpoint. Subjects comprised 363 postmenopausal women >60-years-old (mean age, 74 years) and with osteoporosis. Subjects were randomly divided into 3 groups: ALN group (n=119), treated with daily oral administration of 5 mg of alendronate; D group (n=122), treated with daily oral administration of 1 µg of alfacalcidol; and ALN+D group (n=122), treated with daily oral administration of 5 mg of alendronate plus 1 µg of alfacalcidol. Demographic data including age, baseline BMD of distal radius, and number of vertebral fractures did not differ significantly between groups. The number of vertebral fractures at baseline and follow-up were evaluated using spinal radiography. During the 6-month treatment period, new vertebral fractures comprised 11 fractures in 9 ALN group patients (7.6%), 9 fractures in 9 D group patients (7.4%), and 3 fractures in 3 ALN+D group patients (2.5%). In conclusion, combination therapy with alendronate and alfacalcidol exhibited superiority in terms of preventing vertebral fracture over either treatment alone in early-phase treatment (≤6 months). However, as several other risk factors such as spinal hyperkyphosis, lower BMD, and higher bone resorption markers also affect incidence of vertebral fractures, further studies including these factors will be needed to reconfirm the present findings and clarify the antifracture efficacy of combination therapy using alendronate and alfacalcidol in early-phase treatment.

Vitamin D Status, Bone Mass, and Bone Metabolism in Postmenopausal Japanese Women. K. Nakamura¹, N. Tsugawa^{*2}, T. Saito^{*3}, Y. Tsuchiya^{*1}, A. Yoshihara^{*4}, T. Okano^{*2}, M. Yamamoto^{*1}. ¹Department of Community Preventive Medicine, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan, ²Kobe Pharmaceutical University, Kobe, Japan, ³Niigata University of Health and Welfare, Niigata, Japan, ⁴Department of Oral Health Science, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

The purpose of this study was to identify how the serum 25(OH)D concentration is associated with bone mineral density (BMD) of the lumbar spine and femoral neck, and with bone metabolism in postmenopausal Japanese women. This cross-sectional, community-based epidemiologic study design was conducted among 600 ambulatory postmenopausal women. The serum 25-hydroxyvitamin D (25[OH]D) concentration was measured with radioimmunoassay. Other blood biochemical measurements were intact parathyroid hormone and markers of bone turnover, including osteocalcin and type I collagen cross-linked N-telopeptides. BMD of the lumbar spine and right femoral neck were measured with the dual-energy X-ray absorptiometry method using a QDR4500a. The protocol of this study was approved by the Ethics Committee of Niigata University School of Medicine. The mean serum 25(OH)D concentration was 55.6 nmol/L (SD 14.6). The serum 25(OH)D concentration was non-linearly associated with BMD of the lumbar spine, i.e., mean BMDs of the lumbar spine between two groups with and without vitamin D insufficiency (cutoff value 50 nmol/L of serum 25[OH]D) were significantly different. On the other hand, the serum 25(OH)D concentration was linearly associated with BMD of the femoral neck ($R^2=0.020$, $P=0.002$). While mean serum intact PTH concentrations for serum 25(OH)D < 50 nmol/L were significantly higher than those for serum 25(OH)D ≥ 50 nmol/L, markers of bone turnover were not significantly associated with serum 25(OH)D concentrations. This study showed that the serum 25(OH)D concentration should be maintained at a minimum of 50 nmol/L for high BMD, and that the pattern of an association between the serum 25(OH)D concentration and BMD of the femoral neck are different from that of the lumbar spine, suggesting vitamin D status affects cortical bone more than spongy bone.

Prevalence of Vitamin D and Calcium Supplementation Following Low Impact Hip Fracture: A Three Year Retrospective Analysis of Acute Care and Rehabilitation Facility Prescribing Practices. H. Nasr^{*}, J. Semel^{*}. Department of Physical Medicine and Rehabilitation, St. Charles Hospital / SUNY at Stony Brook, Port Jefferson, NY, USA.

Background: In the United States more than 300,000 individuals sustain a hip fracture each year and this number is expected to increase. In recent years there has been much discussion on the role of both vitamin D and Calcium in osteoporotic fracture prevention. While some literature questions the benefit of these supplements in fracture prevention, there is growing evidence that hypovitaminosis D is common in individuals who sustain low impact hip fractures. This study looks at the patterns of Vitamin D and Calcium supplementation following low impact hip fractures.

Methods: Data was collected through a retrospective chart review of hip fracture patients discharged from the acute inpatient rehabilitation service at a large acute Inpatient Rehabilitation Facility (IRF) from 1/1/2003 through 12/31/2005. The abstracted data was entered into a database worksheet. Key data elements collected include: Demographics (Age, Gender, Weight, Height), Past History (Smoking, Alcohol, Medical history, Medications & Vitamin Supplementation, prior level of independence and living situation), Referring Hospital (RH) information (Lab results, Osteoporosis diagnosis, Osteoporosis medications, Vitamins and high risks medications for falls), IRF Information (Lab results, Osteoporosis diagnosis & Medications, Vitamins and High risk medications for falls), Functional Independence Measure (FIM) Scores and Discharge Status.

Results: A total of 498 hip fracture admissions were reviewed. Eighty-nine (89) charts were excluded for high impact trauma or hip fracture as a secondary diagnosis (e.g. stroke with a hip fracture). Data was abstracted for the remaining 409 low impact hip fracture admissions. The majority of admissions were female (307, 75.1%) vs. male (102, 24.9 %) and the average age was 76.1 years (female) and 75.1 years (male). A review of charts revealed that both Calcium and Vitamin D were prescribed in 25 (6.1%) and 43 (10.5%) of cases by the RH and IRF respectively. Calcium only was prescribed in 3 (0.7%) and 8 (2.0%) of cases by the RH and IRF respectively. Vitamin D only was prescribed in 24 (5.9%) and 114 (27.9%) of cases by the RH and IRF respectively. Neither Vitamin D nor Calcium was prescribed in 357 (87.3%) and 244 (59.7%) of cases by the RH and IRF respectively.

CONCLUSION: Our data indicate that the majority of individuals admitted for inpatient rehabilitation following a low impact hip fracture were not prescribed supplemental vitamin D nor Calcium by either the referring or treating hospital. Continued effort is needed to ensure that this population receives adequate Vitamin D and Calcium.

Prevalence of Vitamin D Deficiency in Women Age 45 and Older in a Small Michigan Community and the Effect of Vitamin D Supplementation on Myalgia. R. B. Reddy^{*1}, E. W. Busdicker^{*1}, S. Reddy². ¹Port Huron Northern High School, Port Huron, MI, USA, ²Endocrinology & Diabetes Center, Fort Gratiot, MI, USA.

Vitamin D deficiency is a common secondary cause of osteoporosis, for which perimenopausal women are at risk. The purpose of this study was to determine the prevalence of vitamin D deficiency in women age 45 and older in a small Michigan community which lies at a latitude of 42°. This study also evaluated differences in the 25-OHD levels of these women based on three factors known to affect vitamin D: age, BMI, and season. Additionally, this study observed the effects of vitamin D supplementation on a subset of vitamin D deficient women who experienced myalgia.

A total of 200 women had 25-OHD levels measured from July 2006 to January 2007. The age, BMI, and month during which the level was measured were noted for each subject. Data was analyzed using a Difference of Means Independent Assortment Test. The prevalence of vitamin D deficiency in the entire study population was 49% using a 25-OHD cutoff point of < 30 ng/mL and 25% using a cutoff point of < 20 ng/mL.

Of the 200 women, 62 were age 70 and older and 138 were age 45 to 69. There was no significant difference in 25-OHD levels in women age 45 to 69 versus women age 70 and older (30.4 ± 13.7 vs. 28.8 ± 11.9 , respectively).

Of the 200 women, 82 had 25-OHD levels measured from July to September (summer) and 74 had levels measured from November to January (winter). 25-OHD levels measured in October were not used as it was considered a transitional month. There was no significant difference in subjects' 25-OHD levels in summer months versus winter months (30.2 ± 13.4 vs. 27.7 ± 13.7).

Of the 200 women, 87 were obese ($BMI \geq 30 \text{ kg/m}^2$) and 113 were not obese. Women who were obese had significantly lower 25-OHD levels than women who were not obese (27.1 ± 12.1 vs. 32.2 ± 13.6 ; $P=0.0076$).

Seventeen vitamin D deficient women were questioned about the number and severity of their myalgia episodes before and after taking 50,000 I.U. of vitamin D weekly for four to eight weeks. Data was analyzed using a paired one-tailed student t test. There was a significant decrease in both the number (5.96 ± 5.47 vs. 1.13 ± 2.13 ; $P=0.003$) and the severity (7.17 ± 1.59 vs. 3.13 ± 2.6 ; $P=0.0005$) of myalgia episodes after supplementation. These results show that vitamin D deficiency is a widespread problem among women age 45 and older not limited to the elderly or to winter months with lower levels in obese women. Supplementation of vitamin D improves myalgia. Women who experience myalgia should be evaluated for vitamin D deficiency. The high prevalence of vitamin D deficiency should be communicated to physicians and the general public.

Disclosures: R.B. Reddy, None.

Prevention of Falls and Fractures: What Is the Evidence for Plain Vitamin D and Active D-hormone Analogs? J. D. Ringe¹, E. Schacht², P. Farahmand^{*1}. ¹Med. Klinik 4, Klinikum Leverkusen, Univ. of Cologne, Leverkusen, Germany, ²ZORG (Zürich Osteoporosis Res. Group), Munich - Hong-Kong - Zurich, Switzerland.

Frequent falling is an increasing problem in the elderly with deleterious consequences. Falls break bone, fear of further falling reduces self-esteem, physical activity, social contacts and quality of life. Fractures are the clinically most relevant outcome of osteoporosis and the majority of the non-vertebral fractures are fall-related.

D-Hormone (1,25(OH)₂D; calcitriol), the active vitamin D metabolite, and its receptor (VDR) play an important role in muscle development and function. Older age is significantly associated with decreased VDR expression in skeletal muscle tissue and femoral muscle power and function. These parameters are closely related to D-Hormone serum levels in the elderly suggesting that the age-related increase of falls is at least partly explained by a decrease of D-Hormone and of VDR's.

A significant decrease in the fall rate after 3 years treatment with 0.5 µg calcitriol daily in osteopenic women without vitamin D deficiency has been described. For alfacalcidol (1 µg daily), a pharmacologically advantageous pro-drug of calcitriol, a significant reduction of falls of 50-70% was proved after 9 months in elderly women and men (normal vitamin D levels at onset, > 500 mg daily calcium from diet, creatinine clearance < 65 ml/min). From a meta-analysis it was concluded that both plain vitamin D and active D-hormone analogs reduce the risk of falls. Subgroup analyses however prove that the effect on falls is mainly triggered by the trials with active D-analogs.

Four recently published clinical studies in elderly with or without previous osteoporotic fractures cast doubt on the role of either an annual injection (300,000 IU) or of daily orally given vitamin D (400-800 IU) plus calcium (1 g) on the prevention of falls or fractures. On the other hand newer meta-analyses proved the reducing potency of active D-analogs on vertebral and non-vertebral fractures in postmenopausal osteoporosis and found a clear superiority of active D-analogs over plain vitamin D. In an own head-to-head study the superiority of alfacalcidol versus plain vitamin D has been shown in glucocorticoid-induced osteoporosis. A combination therapy of alendronate plus alfacalcidol was superior in terms of BMD, rate of falls, overall fractures and back pain over alendronate plus plain vitamin D.

Our concept on the advantage of active D-analogs is that these drugs are acting without the physiologically controlled activation in the kidney. This results in significantly higher concentrations in the target tissues and in an increased local expression of VDR's. Plain vitamin D however, can only be active in vitamin D deficient patients with normal kidney function.

Vitamin D Insufficiency in the Adult, Low-Energy Fracture Population. G. J. Roehrig*, C. P. DiPaola*, S. V. Bukata. Orthopaedic Surgery, University of Rochester, Rochester, NY, USA.

This study investigated the prevalence of vitamin D insufficiency in adults 50 years and older presenting with operative low-energy fractures, to determine whether routine high-dose vitamin D supplementation is warranted.

In an 8 month period, data were collected on patients at our Level 1 trauma center and affiliated community hospital, cared for by the study authors. All patients were tested on hospital admission for serum calcium, 25-(OH) vitamin D, and intact PTH levels. Inclusion criteria: age ≥ 50 , low-energy mechanism of injury, and fracture of the axial or appendicular skeleton. Exclusion criteria: pre-existing high-dose vitamin D therapy or 1-34 PTH therapy. The prevalence of hypocalcemia (serum calcium < 8.6 mg/dL), vitamin D insufficiency (serum 25-(OH) Vit D < 32 ng/mL) and deficiency (< 15 ng/mL), and secondary hyperparathyroidism (serum iPTH > 72 pg/mL) were calculated. The means, median, and ranges serum calcium, 25-(OH) Vit D, and intact PTH were determined as well.

Ninety patients were included during an 8 month collection period. Two patients did not have a serum 25-(OH) vitamin D drawn, and two patients did not have an intact PTH level drawn. The average age was 79.9 years. There were 22 (24.4%) males and 68 (75.6%) females. The prevalence of hypocalcemia was 40/90 (44.4%). The mean serum calcium = 8.8 mg/dL, the median = 8.6 mg/dL, and the range = 7.4-10.5 mg/dL. The prevalence of vitamin D insufficiency was 39/88 (44.3%). The prevalence of vitamin D deficiency was 18/88 (20.5%). The mean 25-(OH) Vit D = 26.6 ng/mL, the median = 27 ng/mL, and the range = 7.0-63.0 ng/mL. The prevalence of secondary hyperparathyroidism was 37/88 (42.0%). The mean iPTH = 73.3 pg/mL, the median = 59.9 pg/mL, and the range = 17.3-358.4 pg/mL. The average age of patients with vitamin D insufficiency was 84.1 years. The average age of patients with vitamin D deficiency was 77 years. The ratios of males to females with vitamin D insufficiency and vitamin D deficiency were 10/29 and 7/11, respectively.

Our study demonstrates that hypovitaminosis D and secondary hyperparathyroidism are not uncommon in this high-risk population. Further work is necessary to determine whether restoration of vitamin D stores aids fracture healing, but it is clear that adequate levels contribute to bone health and fracture prevention.

This raises the question of vitamin D supplementation as a standard component of the discharge plan. In addition, given that the cost of high-dose vitamin D therapy is less than one tenth that of the laboratory testing costs, prophylactic supplementation in this high-risk population should be considered. Larger epidemiologic studies are warranted to compare vitamin D levels in this population to age-matched controls.

Increased Markers of Bone Formation Seen Following Bariatric Surgery in Morbidly Obese Patients. N. Sinha¹, E. Stein¹, D. Ortiz¹, A. Schulman¹, G. Strain², M. Gagner², A. Pomp², G. Dakin², C. Sison¹, R. Bockman³.

¹Endocrinology, NY Presbyterian Hospital-Weill Medical College, New York, NY, USA, ²Surgery, NY Presbyterian Hospital-Weill Medical College, New York, NY, USA, ³Endocrinology, Hospital for Special Surgery, New York, NY, USA.

Bariatric surgery has been associated with an increase in markers of bone resorption and a decrease in bone mineral density.

In an on-going prospective study, alterations in bone metabolism were followed in morbidly obese patients after bariatric surgery (Roux-en-Y gastric bypass or biliopancreatic diversion with duodenal switch). Markers of bone turnover, calcitropic hormones and bone density are followed from baseline to 18 months post-operatively. All patients are followed by a nutritionist and vitamin D & calcium are replaced as needed.

Baseline data have been obtained in 105 subjects, 66 women (mean age 36 \pm 8 years, BMI 47.4 \pm 6.3 kg/m²) and 39 men (mean age 44 \pm 9 years, BMI 50.2 \pm 8.7 kg/m²). 38 patients have had surgery and their postoperative data (given as means \pm SD) are summarized in the table below.

TABLE 1: Bone Parameters at Timepoints After Surgery

	Baseline (n=105)	1 mo (n=39)	3 mo (n=24)	6 mo (n=18)	9 mo (n=14)	12 mo (n=10)
BMI kg/m ²	48.45 \pm 7.4	44.1 \pm 5.7	39.4 \pm 5.1	38.2 \pm 5.2	37.0 \pm 6.3	31.9 \pm 5.2
Calcium (8.5-10.1 mg/dL)	9.3 \pm 0.4	9.3 \pm 0.4	9.4 \pm 0.3	9.3 \pm 0.4	9.1 \pm 0.3	9.1 \pm 0.3
25-OH VitD (9-54ng/mL)	20 \pm 10	32 \pm 13	34 \pm 14	31 \pm 12	27 \pm 8	36 \pm 21
1,25-OH VitD (15-75pg/mL)	122 \pm 50	176 \pm 79	204 \pm 92	195 \pm 53	179 \pm 117	243 \pm 72
PTH,intact (9-44pg/mL)	83 \pm 48	72 \pm 32	63 \pm 28	71 \pm 41	63 \pm 35	66 \pm 31
Osteocalcin (5-30ng/mL)	4.5 \pm 2.4	3.9 \pm 1.4	5.4 \pm 1.0	6.9 \pm 0.5	5.0	7.5 \pm 1.9
BSAP (4.5-20.1ug/L)	11.2 \pm 5.1	8.3 \pm 2.5	6.8 \pm 1.8	7.5 \pm 1.7	7.1	8.0
PINP (20-76ng/mL)	43.5 \pm 15.0	53.3 \pm 20.1	65.8 \pm 22.8	89.0 \pm 32.8	68.9 \pm 8.4	77.9 \pm 7.0

u-Ntx (nMBCE/nMCR)	31 \pm 13	40 \pm 14	62 \pm 19	59 \pm 28	52 \pm 6	69 \pm 34

Bariatric surgery results in significant changes in BMI at all timepoints following surgery ($p<0.0001$).

Preoperatively, Vit D insufficiency (<30 ng/mL) was found in 85% of patients. The mean PTH was two times the upper limit of normal, associated with low mean 25-OH VitD levels and elevated 1,25-OH VitD levels.

Postoperatively PTH levels remained elevated at all timepoints with the suggestion of a declining trend. There was a significant elevation in 1,25OH Vit D levels at months 1 and 12. There was a significant elevation in PINP at 1, 6 and 12 months ($p<0.01$). All other bone turnover markers did not significantly change.

Procollagen Type I N-terminal propeptide (PINP) is a sensitive marker of bone formation: levels are proportional to the amount of new collagen produced by osteoblasts. The elevation of PINP seen postoperatively and the lack of change in resorption markers suggests an uncoupling of resorption and formation. The mechanism of increased anabolic osteoblastic activity may be related to changes in PTH activity or the correction of vitamin D insufficiency.

Vitamin D insufficiency is an increasingly recognized problem among obese persons. This prospective study of morbidly obese (BMI > 35 kg/m²) subjects compared levels of vitamin D and PTH using different techniques (vitamin D: DiaSorin radioimmunoassay (RIA) and High Performance Liquid Chromatography (HPLC); PTH: "intact" IRMA assay (iPTH) and Scantibodies third generation IRMA (PTH1-84). Fifty-four subjects (ages 19-63, mean BMI 48 kg/m²) were enrolled in this ongoing trial. Thirty-nine subjects with 25OHD less than 25 ng/ml were randomized to weekly ergocalciferol (D2) 50,000 IU or cholecalciferol (D3) 8,000 IU for 8 weeks. Baseline (Wk 0) data on 15 vitamin D sufficient subjects are provided for initial comparison. Dietary calcium and vitamin D and sun exposure were assessed in all subjects.

Time-point	D-Sufficient (>25 ng/ml)	D2 Treatment		D3 Treatment	
	Wk 0 n=15	Wk 0 n=19	Wk 8 n=11	Wk 0 n=20	Wk 8 n=11
iPTH					
9-44 pg/ml	53.6 (28.6) ^a	76.1 (32.8)	72.2 (22.4)	98.8 (68.8)	76.1 (20.7)
PTH 1-84					
5-39 pg/ml	19.1 (9.1) ^a	26.8 (9.4)	23.0 (6.5)	36.1 (26.1)	24.9 (6.0) ^c

25OHD					
20-57 ng/ml	34.7 (8.9) ^a	14.6 (3.4)	41.1 (17.7) ^b	15.9 (3.7)	26.1 (6.0) ^b
HPLC 25OHD Total					
25-80 ng/ml	25.5 (9.1) ^a	15.4 (5.1)	28.1 (4.7) ^b	16.3 (6.8)	21.5 (3.4) ^b
HPLC 25OHD2	<4.0 (0.12)	<4.0 (0.0)	21.3 (3.5) ^b	<4.0 (0.11)	<4.0 (0.0)
HPLC 25OHD3	25.1 (8.4) ^a	15.4 (5.1)	6.9 (1.9) ^b	16.1 (7.0)	21.5 (3.4) ^b

Table values are mean (S.D.)

^a vs D-insufficient ($p<0.03$)

^b vs wk 0 ($p<0.01$)

^c vs wk 0 ($p<0.05$)

Our findings showed elevated mean levels of iPTH in morbidly obese subjects, consistent with prior studies, but normal levels of PTH (1-84). 25OHD levels increased in both groups by both assays at 8 weeks ($p<0.01$), with a greater change in the D2 group ($p<0.03$). PTH 1-84 levels decreased in the D3 group ($p<0.04$) with a trend in iPTH ($p<0.09$). At these doses, D3 may be more suppressive of parathyroid function.

The Prevalence of Osteoporosis and Vitamin D Deficiency/Insufficiency Among Elderly People with Falls in Denmark. A. B. Vind, H. E. Andersen*, P. Schwarz. Geriatric Department, Glostrup University Hospital, Glostrup, Denmark.

Insufficiency of Vitamin D is a risk factor for falls and osteoporosis among elderly people, and osteoporosis is a risk factor for injury related to falls. We present data on the prevalence of osteoporosis and deficiency/insufficiency of Vitamin D among elderly Danish patients with falls.

In a randomized controlled intervention study on multifactorial fall prevention, including 392 patients above the age of 65 years, who have had an injurious fall, participants in the intervention group are offered a measurement of Vitamin D and a BMD-measurement.

Data are available for 169 participants, mean age 74, range 65-90, 73 % women. Among women 40 % and among men 39 % are insufficient of Vitamin D ($25\text{-OHD} < 50\text{nmol/l}$), 2.4% and 6.5 % respectively are deficient ($25\text{-OHD} \leq 25\text{nmol/l}$). 34 % of women and 15 % of men are supplemented with calcium and Vitamin D at inclusion, and are more likely to be sufficient ($\chi^2=10.67$, $p<0.001$). 29 % of women and 33 % of men suffer from osteoporosis (T-score < 2.5 at hip or spine), 41 % of women and 24 % of men had a fracture at the fall leading to entering the intervention. The proportions of fractures are similar among patients later diagnosed with osteoporosis and those not.

When comparing subjects insufficient of Vitamin D with sufficient subjects, there is no difference between the groups with regard to sex and fracture at latest fall and osteoporosis is more common among sufficient subjects ($\chi^2=5.41$, $p<0.02$).

We conclude, that although less common than in prior studies, the prevalence of insufficiency of Vitamin D is still high in a sample of elderly Danes with falls. Osteoporosis is common, especially among men, and also among those not suffering from fractures at latest fall. Screening for osteoporosis is relevant, as is securing a sufficient supply of Vitamin D.

Patient and Physician Attitudes Toward Vitamin D in Osteoporosis Treatment. S. P. Chan*, J. A. West², L. E. Wehren³, S. S. Sen³. ¹University of Malaya, Malaya, Malaysia, ²Merck, Rahway, NJ, USA, ³Merck, Rahway, NJ, USA.

BACKGROUND: Vitamin D is essential for calcium absorption and bone health, and most osteoporosis treatment guidelines recommend vitamin D supplementation. This study explored the knowledge and attitudes of physicians and patients towards supplement use in osteoporosis treatment.

METHODS: Randomly selected Physicians from Malaysia, Taiwan, Philippines, Korea, and Singapore and their postmenopausal women patients with osteoporosis were surveyed. Physicians rated the importance of vitamin D and calcium in osteoporosis management on a scale of 1(not important) to 10 (extremely important) and estimated supplement use by their patients. Patients reported their use of vitamin D and calcium and their perceptions regarding these supplements.

RESULTS: 237 physicians (37 from Malaysia, and 50 each from Taiwan, Philippines, Korea, and Singapore), and 1463 patients (251, 218, 194, 400, and 400 from Malaysia, Taiwan, Philippines, Korea, and Singapore respectively) completed the survey. 84% of patients in Malaysia, 46% in Taiwan, 16% in the Philippines, and 55% each in Singapore and Korea reported never having discussed Vitamin D supplementation with their Physician. Physicians and patients in all countries reported that calcium was discussed more frequently than Vitamin D. Physicians reported that their patients have little knowledge of the relationship between vitamin D and calcium, and this was confirmed by patient responses.

CONCLUSION: Most osteoporosis patients recognize the importance of calcium, but have less awareness of that of Vitamin D. Lack of understanding about the role of Vitamin D and numerous concomitant medications can reduce compliance with Vitamin D supplementation.

Hyponatremia Induces Bone Loss and Prevents Fat Accumulation in Aged F344 Brown Norway Rats. J. Barsony¹, M. B. Manigrasso*, H. Tam*, A. H. Doshi*, J. G. Verbalis*. ¹Office of the Director, NIH/NIDDK, Bethesda, MD, USA, ²Division of Endocrinology and Metabolism, Georgetown University, Washington, DC, USA.

Chronic hyponatremia is a common abnormality in older people, but long-term pathological effects of this disorder are not well understood. Our recent studies on young rats indicated that hyponatremia is associated with severe osteoporosis. No change in serum parameters of calcium homeostasis and calcium regulating hormones accounted for the bone loss, but the mechanisms involved increased osteoclastogenesis and bone resorption. To better approximate the age of the population most affected by hyponatremia, this study evaluated male F344 Brown Norway hybrid rats (F344BN), a well-known model of aging. We induced hyponatremia for 4.5 months by infusing desmopressin via minipumps (5ng/h) in 22-month-old F344BN rats who were fed a liquid diet enriched with vitamin D and calcium; high dose vitamin D was added during the last 6 weeks to maximize calcium balance. Normonatremic control aged F344BN rats also received

desmopressin, but were fed a solid diet of equivalent composition to the liquid diet. Caloric intake was equalized daily between pairs of hyponatremic and normonatremic rats to allow monitoring the effects of hyponatremia on body composition. Previous reports have shown an inverse relationship between bone mineral density (BMD) and bone marrow fat (BMF) in old rodents and humans and an effect of vitamin D to decrease BMF. We evaluated how hyponatremia changes this relationship via biweekly measurements of BMD, BMF and abdominal fat by DXA. Body weight was similar in both groups before and at the end of the study. As expected, in control aged rats BMD decreased (AP spine -3%, total femur -2%, and proximal tibia -0.7% per month) and BMF increased (AP spine 15%, total femur 8%, and proximal tibia 11% per month) progressively. In hyponatremic rats, BMD decreased at a much higher rate than in the controls during the first 3 months (AP spine -20%, total femur -17.5%, and proximal tibia -20% per month), and BMF remained unchanged at the AP spine, increased only by 8% per month at the total femur and 5% per month at the proximal tibia. During the final 6 weeks on vitamin D injections, BMD did not recover and BMF did not increase in the hyponatremic rats. Abdominal fat increased in the normonatremic group but remained unchanged in the hyponatremic group over the entire study. These findings confirm that hyponatremia induces osteoporosis in aged as well as young rats. Hyponatremia also prevented fat accumulation in aged rats, and eliminated the inverse relationship between BMD and BMF, likely due to induction of Wnt signaling by chronic hyponatremia.

Marrow Fat and Peak Bone Mass. N. Di Iorgi*, F. J. Perez*, D. Lee, T. Wren, V. Gilsanz. Radiology, University of Southern California, Los Angeles, CA, USA.

Recent data suggest that osteoblasts and adipocytes originate from the same mesenchymal stem cells. Our aim was to determine whether there is a reciprocal relation between bone marrow fat and cancellous bone in the axial, and cortical bone in the appendicular, skeleton. To this end, we examined vertebral cancellous bone density (CBD), femoral cortical bone area (CBA), and the density of adipose tissue in the marrow canal at the midshaft of the femurs in 138 young, healthy men and women, 16-25 years of age, using computed tomography (CT) and a reference phantom for calibration. Males were heavier, and had greater values for CBA and marrow fat than females ($P<0.001$). Marrow fat density had strong significant negative relations with cancellous and cortical bone in both males and females; the associations were stronger in females (see diagrams). There was no association between marrow fat and age, weight, BMI and the cross sectional dimensions of vertebral and femoral bone. Our results suggest a link between marrow adiposity and cortical and cancellous bone at or around the time of peak bone mass, supporting the concept that stem cells differentiate into either cell lineage in a mutually exclusive way.

	Males (n=74)	Females (n=64)
Age (yrs)	19.0 ± 1.8	18.9 ± 2.0
Weight (kg)	71.0 ± 12.4	62.0 ± 11.2
BMI	23.8 ± 3.4	23.9 ± 4.2
CBD (mg/cm ³)	172 ± 27	177 ± 29
CBA (cm ²)	5.02 ± .65	4.02 ± .53
Marrow fat (mg/cm ³)*	-50.4 ± 19	-32.0 ± 28

Influence of Exercise and Low Dose Oral Contraceptives on Vertebral and Femoral Bone Mass in Young Adult Women. M. Hartard¹, C. Kleinmond^{2*}, M. Wiseman³, D. Felsenberg⁴, R. Erben⁵, E. R. Weissenbacher^{*1}, K. Friesse^{*1}.

¹Department of Gynecology and Obstetrics, Ludwig Maximilians Universität, Munich, Germany, ²Institute of Preventive and Rehabilitative Sports Medicine, Technische Universität München, Munich, Germany, ³Leibniz Data Processing Center, Bavarian Academy of Sciences, Munich, Germany, ⁴Department of Radiology, Freie Universität Berlin, Berlin, Germany, ⁵Department of Natural Sciences, University of Veterinary Medicine, Vienna, Austria.

It was the aim of the present study to explore further the relationship between oral contraceptive (OC) use and exercise in a controlled, open, non-randomized 24-month trial in a group of 71 women aged 25 - 35 years (mean age 28.5 ± 2.7). After discontinuation of OCs for at least 4 months, physical work capacity (PWC), nutrition, exercise history, bone density, bone markers, and hormones were determined on admission and after 24 months. In addition, bone markers were measured 6 months after start of the trial. Women were classified as exercisers (EX) or non-exercisers (NEX) by measurement of relative PWC at a heart rate of 170/min (PWC170/kg) using bicycle ergometry and additionally by a self-report questionnaire. With-out changing exercise behavior, the women had to decide whether or not to use a low dose monophasic OC preparation (30 µg ethinylestradiol and 75 µg gestodene) during the 24-month study period. Thirty-five women decided to use the OC preparation (16 EX and 19 NEX), 36 women served as controls (20 EX and 16 NEX). At baseline, we found no significant differences between the groups in terms of anthropometry, nutrition, BMD, or biochemical bone markers. After 24 months data from 52 women could be analyzed. OC use was associated with increases in serum triglycerides, sex hormone binding globulin, and cortisol, while it decreased serum FSH, estradiol, and progesterone. Serum osteocalcin was lower in OC users at 6 months after start of the trial, while serum bone-specific alkaline phosphatase and urinary deoxypyridinoline excretion remained unchanged. In both the EX control and the EX OC groups spine BMD decreased during our 24-month trial. OC use did not influence hip or spine BMD in non-exercisers. However, OC use induced a 1.8% loss of anterior-posterior vertebral BMD, a 2.6% loss of lateral vertebral BMD, and a 1.4% loss of hip BMD in exercising women over the 24-month study period. Although the latter BMD changes were not significant compared with baseline values, our data add further evidence to the notion that the combination of OC use and exercise may have negative effects on bone mass in young women.

Addition of Phosphorous to Cadmium Exacerbate the Compromised BMD Gain in Ovariectomized Rats. S. Hooshmand¹, D. Y. Soung², S. C. Chai¹, E. A. Lucas³, L. Devareddy^{*1}, B. H. Arjmandi¹. ¹Nutrition, Food and Exercise Sciences, Florida State University, Tallahassee, FL, USA, ²Center of Musculoskeletal Research, University of Rochester, Rochester, NY, USA, ³Nutritional Sciences, Oklahoma State University, Stillwater, OK, USA.

Ovariectomized (OVX) rats have been extensively used as a model of postmenopausal bone loss because it is generally believed that rats lose bone mineral density (BMD) as a result of OVX. This decrease in BMD has been linked to the hypothesis that ovarian hormone deficiency causes hypercalcemic suppression of the parathyroids which lead to a decrease in vitamin D synthesis and gut malabsorption of calcium. Data from a number of studies from our laboratory contraindicate this hypothesis and showed that OVX animals not only do not lose bone but rather gain, albeit, to a lesser extent in compression with intact animals. The findings of the present study clearly demonstrate this fact. We used five groups of 3-month old OVX Sprague Dawley rats to examine the time- and dose-dependent deleterious effects of cadmium (Cd) on BMD of whole body and as well as the final femoral and fourth lumbar vertebrae BMD. OVX gained 3.9 and 9.8 % BMD in compression with baseline BMD value after three and six months, respectively. High dose of Cd (200 ppm) completely prevented the gain in BMD. When phosphorous (P) was added to Cd, the harmful effect of Cd on bone was pronouncedly exacerbated. The results indicated that Cd+ 1.2 % P had the most deleterious effect on BMD of these animals and caused 7% bone loss (see table). Accumulation of trace elements such as Cd in soils may be transferred via the food chain to consumers and it may become a public concern. However, their effects on bone have hardly been studied. The results of this study demonstrate that Cd at higher doses completely prevents gain in bone mass and addition of P to Cd causes significant bone loss. Since phosphate fertilizer is a significant source of trace element, especially for Cd, overtime repeated application of fertilizer may lead to a gradual buildup of these elements in agricultural products grown in such a soil and become a public health issue. Hence, this study should be considered an early warning as how big of an issue this problem is.

Bone Mineral Density Declines with Age in Zebrafish (Danio rerio). J. M. Keller, J. F. Escara-Wilke, C. Yu*, E. T. Keller. Urology, University of Michigan, Ann Arbor, MI, USA.

Old age in humans is associated with a decline in bone mineral density (BMD). This age-related decline in bone mass may be associated with pathological conditions such as osteoporosis, frailty, and fractures. We are currently developing the zebrafish (Danio rerio) as a model for study of aging and age-related diseases. As such, we maintain a large colony of approximately 3500 aging zebrafish. The oldest fish in our colony to date are approximately 45 months of age, and the average age of natural death thus far is 32.1 ± 5.6 months. In the course of our studies, we observed various skeletal abnormalities in our fish as they aged. We sought to characterize these changes in our population of zebrafish. Radiographic analysis of young (1 year or less) and old (3 or more years) fish showed marked skeletal changes in the spine of old fish compared to young fish, including scoliosis and kyphosis. Changes in radiodensity of the bones were also seen, suggestive of a change in bone density. This was confirmed by micro-CT analysis, which revealed a marked decrease in BMD in old fish compared to young fish. This decrease was seen in trabecular, cortical, and subcortical bone. The average total BMD in old fish was 74 ± 9 mg/cc compared to 360 ± 48 mg/cc in young fish. To evaluate these changes at the tissue level, we stained for mineral in the bone using von Kossa stain on histological sections from these fish. We found a decrease in bone mineral staining in old compared to young fish. These results suggest that the aging zebrafish may represent a potential model for study of osteoporosis and age-related changes in bone in humans. The zebrafish provides an extensive wealth of resources including informational databases, husbandry methods, and genetic tools, and its genome has recently been sequenced. In addition, there are many similarities between human and zebrafish bones. Like humans, zebrafish bone remodeling involves osteoblasts and osteoclasts and shares many of the same signaling pathways, including BMPs, Runx2, and Wnt pathways. These proteins in zebrafish are orthologous to those in humans and are highly conserved. Many zebrafish skeletal mutants are also being discovered. We therefore propose the zebrafish as a potential model for bone diseases and age-related changes in skeletal structure in humans.

Parathyroid Response to Vitamin D Insufficiency: Relations to Bone and Body Composition and to Life Style Characteristics. L. Rejnmark¹, P. Vestergaard¹, C. Brot^{*2}, L. Mosekilde¹. ¹Dept. of Endocrinology and Metabolism C, Aarhus University Hospital, Aarhus, Denmark, ²Osteoporosis Research Centre, Hvidovre Hospital, Copenhagen, Denmark.

Vitamin D insufficiency is very common and is known to cause secondary hyperparathyroidism (SHPT). However, in some subjects the PTH response to low vitamin D levels is blunted, which has been termed functional hypoparathyroidism (FHPT). We studied whether differential PTH responses in women with vitamin D insufficiency are associated with indices of bone metabolism, and body composition.

We studied 1097 recent postmenopausal women recruited from the local background population and identified women with vitamin D insufficiency defined as plasma 25-hydroxyvitamin D (P-25OHD) < 50 nmol/l. Among studied subjects 405 (37%) had vitamin D insufficiency. In women with vitamin D insufficiency, we compared levels of bone turnover markers, bone mineral density (BMD), body composition, body weight, and life style characteristics between subjects with SHPT and FHPT.

P-25OHD levels were slightly higher in SHPT compared with FHPT (p<0.05). SHPT was associated with higher levels of osteocalcin and bone-specific alkaline phosphatase, whereas whole body BMD and hip- and lumbar spine-BMD were significantly reduced (p<0.01). Compared with FHPT, subjects with SHPT had a 7% (p<0.01) higher body weight and a 23% higher fat mass (p<0.01), whereas lean tissue mass did not differ between groups. In SHPT, fat mass was increased by 14% (p < 0.001) at the upper and lower extremities and by 33% (p < 0.001) at the trunk. Lifestyle characteristics differed significantly between groups, as women with SHPT smoked less and consumed less alcohol than those with FHPT. In addition, women with SHPT use of loop diuretics more often than those with FHPT. However, physical activity as well as total energy intake and dietary intake of calcium, magnesium, phosphate, and vitamin D did not differ between groups.

The effects of vitamin D insufficiency on bone seem to be highly dependent on the PTH responses to low vitamin D levels. In patients with primary hyperparathyroidism, an increased body weight has been reported. Similarly, the increased body weight and fat mass in SHPT compared with FHPT during vitamin D insufficiency may suggest that PTH excess contributes to fat accumulation.

Changes in Adiponectin and Leptin Serum Levels in Osteoporotic Postmenopausal Women After Treatment with Raloxifene or Alendronate.

A. Sebastian Ochoa^{*1}, D. Fernández-García^{*1}, R. Reyes García^{*1}, G. Alonso^{*1}, P. Rozas^{*1}, I. Luque^{*1}, B. Torres^{*2}, M. Ruiz-Requena^{*2}, M. Muñoz-Torres¹.

¹Bone Metabolic Unit. Department of Endocrinology, University Hospital San Cecilio, Granada, Spain, ²Biochemist Department, University Hospital San Cecilio, Granada, Spain.

Adipose tissue is considered to be an endocrine organ. Recently, the relation between adiponectin and leptin with bone has been investigated. However, the effect of antiresorptive drugs on these adipokines and their relation with osteoclastogenesis markers have not been studied before.

The aims were to evaluate serum adiponectin and leptin in osteoporotic postmenopausal women and their relation with bone mineral density (BMD) and osteoclastogenesis markers and analyze changes on adiponectin and leptin levels after treatment with raloxifene or alendronate, and their relation with changes in BMD.

We selected fifty-three untreated women (63±7 years) with postmenopausal osteoporosis divided into two groups: women treated with raloxifene (60mg/day; n=20) or alendronate (70 mg/week; n= 33) for one year. We determined at baseline and after 12 months of treatment: anthropometric data, osteoprotegerin (OPG) ultrasensible estradiol (E2), insulin-like growth factor I (IGF-I), adiponectin (HADK1-61K-A, LINCplex), leptin (HADK2-61K-B, LINCplex) and BMD by DEXA (DXA-Hologic QDR 4500) in lumbar spine (LS), femoral neck (FN) and total hip (TH).

At baseline, leptin and adiponectin serum levels of our patients were 1371.4±822.4 pM/ml and 41.47±26.42 µg/ml, respectively. Circulating leptin was related significantly with weight (r:0.42; p<0.01), BMI (r:0.47; p<0.01) and waist (r:0.38, p<0.01), but not with OPG, IGF-1, E2 and BMD in LS, FN and TH. Adiponectin was significantly correlated with age (r:0.38; p:0.012) and OPG levels (r: 0.28; p: 0.04), but not with weight, height, body mass index (BMI), leptin, IGF-1, E2 and BMD in LS, FN and TH. After 12 months, no changes were observed in leptin (p:0.46) and adiponectin (p:0.55) in alendronate group; however, a significant increase in leptin levels (973.47±637.37 pM/ml vs 1305.7±793.4 pM/ml; p:0.031) was detected in the raloxifene group, whereas adiponectin levels showed no significant changes (p:0.46). Moreover, the percentage changes of adiponectin levels did not differ between the two groups (p:0.79); while the percentage changes in leptin levels was different but not significantly, between the two groups (p:0.07).

In conclusion, adiponectin and leptin concentrations do not seem to be consistently related to BMD and osteoclastogenesis markers in patients with postmenopausal osteoporosis. The increase in leptin levels after one year of treatment with raloxifene could be indirectly implicated in raloxifene bone effects.

Prevalence of High Bone Mineral Density T-scores in a Community Population. C. Simonelli¹, P. J. Sinner^{*2}, M. C. Schoeller^{*1}. ¹Osteoporosis Care, HealthEast Clinics, Woodbury, MN, USA, ²Research and Education, HealthEast Medical Research Institute, St. Paul, MN, USA.

There is no designated upper limit of normal for bone mineral density (BMD) testing results with DXA, although a number of pathological disease states may be associated with a high BMD and may potentially increase fracture risk. Diseases associated with high BMD include osteopetrosis, Paget's bone disease, hypervitaminosis A or D and fluorosis among others. Genetic causes for high BMD are often diagnosed before adulthood. The purpose of this study was to determine the incidence of BMD T-scores +2.5 or greater (high BMD) in adults by gender, age in decades from 40-80+ and by site of BMD measurement: lumbar spine (LS), femoral neck (FN) and total proximal femur.

BMD testing using the GE Lunar Prodigy densitometer was performed between November 1999 and January 2007 on 8110 females and 549 males referred to an osteoporosis center for BMD testing. Fracture history of the hip, spine and non-hip/non-spine was recorded at the time of the scan. For individuals who may have had multiple scans, the results of the most recent scan were used in this analysis.

High BMD T-scores increased with age at the LS (figure 1), most notably for men, from 4.4% at age 40-49 to 16.9% at age 80+ and in women from 2.2% at age 40-49 to 5.5% at age 80+ consistent with progressive degenerative sclerotic changes artifactually elevating the BMD. Increased BMD T-scores with aging was not seen at the total femur or FN sites for men or women and the incidence of BMD T-scores +2.5 or greater was rare ranging from 0% to 2.2% depending on site and age. Finally, patients with high BMD scores reported fewer fractures at non-hip/non-spine sites compared to patients with a normal T-score of -1.0 to +1.0 (1.3% vs. 6.7%, p-value = 0.06) and patients with high BMD reported fewer fractures at the spine and non-hip/non-spine sites compared to patients with osteoporosis, BMD T-score -2.5 or lower (0% vs. 11.1%, p-value < 0.001 for spine fractures and 1.3% vs. 24.7%, p-value < 0.001 for non-hip/spine sites). There was no difference in hip fracture rates between patients with high, normal or osteoporotic BMD values.

BMD T-score +2.5 or greater at the femur sites is rare, does not increase with aging and appeared to be associated with a decrease in fracture history at non-hip/non-spine sites. Further study of the significance of potentially high BMD and associated disease states is warranted

Osteoarthritis of Knee Decreases Regional and Total Bone Mineral Density in Japanese Women. S. Takata, A. Abbaspour^{*}, S. Nakano^{*}, Y. Kawasaki^{*}, K. Yukata^{*}, N. Yasui^{*}. Orthopedics, Institute of Health Biosciences, The University of Tokushima, Tokushima, Japan.

We studied the effects of osteoarthritis (OA) of knee on total and regional bone mineral density (BMD) in Japanese women. Two hundred and fifteen patients were divided into four groups: patients with knee OA group (knee OA group, n=37), group of normal level of mean BMD of the 2nd and 4th lumbar vertebrae (L2-4BMD) group (normal group, n=53), group of osteopenia level of L2-4BMD (osteopenia group, n=63), group of osteoporosis level of L2-4BMD (osteoporosis group, n=62). No significant differences were found between the four groups with regard to age, height, weight and BMI. Regional and total BMD were measured by dual energy X-ray absorptiometry using a Hologic QDR 2000 (Waltham, MA, USA). The regional BMD were measured in the head, arms, legs, ribs, thoracic vertebrae, lumbar vertebrae and pelvis. BMD was statistically compared among four groups. L2-4BMD of knee OA group was significantly smaller than that of normal group (p=0.0006). L2-4BMD of knee OA group was significantly greater than that of osteopenia group (p=0.0001). Total BMD of knee OA group was significantly smaller than that of normal group (p=0.0058). There was no significant difference of total BMD between knee OA and osteopenia groups (p=0.1778). Leg BMD of knee OA group was significantly smaller than that of normal group (p=0.0002). There was no significant difference of leg BMD between knee OA and osteopenia groups (p=0.2536). The results showed that L2-4BMD, leg and total BMD of knee OA group were significantly smaller than those of normal group, and suggest that knee OA affects bone mineral metabolism to decrease regional and total BMD.

Disclosures: S. Takata, None.

A Negative Impact of Caloric Restriction on the Bone Mineral Density: An Involvement of Suppression of Growth Hormone-IGF-1 Signaling. M. Tomita¹, S. Motokawa^{*2}, H. Shindo^{*1}, I. Shimokawa^{*3}. ¹Orthopedic Surgery, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, ²Orthopedic Surgery, National Nagasaki Medical Center, Ohmura, Japan, ³Investigative Pathology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan.

Objective: Bone mineral density (BMD) decreases with age. Caloric restriction (CR) suppresses several aging-dependent changes and diseases, and expands the longevity of the rodent. Growth hormone (GH) and insulin-like growth factor 1 (IGF-1) secretions decrease with age; however, the suppressed GH-IGF-1 signaling also leads to increased lifespan. In this study, we investigated the effects of CR and suppression of GH secretion on the aging change of BMD.

Materials and Methods: We used wild type (WT) male Wistar rats and the transgenic rat strain (mini), in which GH secretion was suppressed by overexpression of anti-sense GH gene. F1 hybrid rats (F1), which showed intermediate phenotypes in the GH-IGF-1 level and body weight between WT and mini rats, were also used. From 6 weeks of age, rats were divided into two groups: group AL rats continued to receive food ad libitum, whereas group CR rats were restricted food intake 70% of those for group AL. Rats were sacrificed at 6, 15, and 24 months of age (mo). Femoral BMD's were measured by pQCT.

Results: 1) The BMD of cortical bone did not differ among WT, F1, and mini rats.

2) The BMD of cancellous bone decreased with age in all groups. The cancellous bone BMD in CR group was lower than AL group in WT, F1, and mini rats at any age. The cancellous bone BMD was lower in the following order; mini, F1, and WT rats respectively.

3) F1-AL and WT-CR showed similar cancellous bone BMD on 6, 15, and 24 mo.

Discussion: CR exhibited a negative impact on the cancellous bone BMD. Similarity of phenotypes between CR and the transgenic rats suggest an involvement of GH-IGF-1 signaling in the impact of CR. It should be, therefore, cautious when we apply CR or suppression of GH-IGF-1 signaling as an anti-aging intervention in human.

Relative Contribution of Body Composition to Bone Mineral Density in Young Chinese and Caucasians. X. Wang*, Y. Duan*, A. Evans*, E. Seeman. Endocrine Centre, Austin Health, University of Melbourne, West Heidelberg, VIC, Australia.

To investigate the racial differences in the relationship of body composition and bone mineral density we studied 258 healthy Chinese (182 females) and 391 Caucasians (282 females) aged 18-45 years living in Melbourne. Body mass index (BMI) was calculated using weight/height². Total body bone mineral density (TBBMD), total fat mass, and lean body mass (LBM) were measured by dual energy X-ray absorptiometry (DXA, Lunar, DPX-L) total body scan.

At peak, Chinese had a 4.7-6.5% lower BMI, 14.9-22.9% lower total fat mass and 10.2-12.2% lower LBM than Caucasians in both sexes. There was no racial difference in TBBMD between Chinese and Caucasian women, while TBBMD was 3.1% lesser in Chinese than Caucasians men. Using Pearson correlation test, BMI, total fat mass and LBM had a positive correlation with TBBMD in both races. Moreover, in women, BMI ($r_{\text{Chinese}} = 0.54$ vs. $r_{\text{Caucasian}} = 0.29$, $p < 0.01$) and total fat mass ($r_{\text{Chinese}} = 0.50$ vs. $r_{\text{Caucasian}} = 0.26$, $p < 0.01$) were more highly correlated with TBBMD in Chinese than Caucasians. There was no racial difference in the correlation of LBM and TBBMD between Chinese and Caucasian women ($r_{\text{Chinese}} = 0.38$ vs. $r_{\text{Caucasian}} = 0.23$, $p = 0.08$). For men, there were no racial differences in the correlation of BMI ($r_{\text{Chinese men}} = 0.50$ vs. $r_{\text{Caucasian men}} = 0.31$, $p = 0.12$), total fat mass, and LBM with TBBMD between Chinese and Caucasians. Partial correlation was used to further explore independent correlations between total fat mass or LBM and TBBMD. The correlation coefficient for BMI and TBBMD diminished controlling for total fat mass and age more than controlling for LBM and age in Chinese and Caucasian women. In men, the partial correlation decreased further controlling for LBM and age than controlling for total fat mass and age in both races.

In conclusion, TBBMD was related to BMI, total fat mass and LBM in young women and men in both Chinese and Caucasians. The racial differences in the correlation of BMI, total fat mass and TBBMD was found in women only. In both races, fat mass had more influence on the TBBMD in young women. However, LBM was more related to TBBMD in young men in both races.

Age-related Changes in Vertebral Trabecular Architecture in Female Japanese Macaques. S. C. Agarwal¹, P. Beauchesne*, A. Burghardt², Y. Hamada*, S. Majumdar². ¹Anthropology, University of California, Berkeley, CA, USA, ²Musculoskeletal Quantitative Imaging Research Group, University of California San Francisco, San Francisco, CA, USA, ³Primate Research Institute, Kyoto University, Inuyama, Japan.

There have been few studies of age and sex-related changes in trabecular microarchitecture in nonhuman primates. This study investigates age-related patterns in vertebral trabecular architecture in female Japanese macaques. A total of 30 seventh lumbar vertebrae were selected from adult (age 8-32 yrs.) female Macaca fuscata skeletons with known age and life history variables (such as parity, diet, activity) housed at the Primate Research Institute, Kyoto University, Japan, for a pilot investigation of trabecular microarchitecture using High Resolution Peripheral Quantitative Computed Tomography (HR-pQCT) (XtremeCT, Scanco Medical AG, Bassersdorf, Switzerland). Individuals were categorized into three broad age groups: young (8-13 yrs), middle (14-19 yrs), and old (20+ years), and a mid-coronal area of the vertebral body was scanned to examine bone mineral density, bone connectivity, anisotropy, and classic histomorphometric parameters (bone volume BV/TV, trabecular number Tb.N, thickness Tb.Th, separation Tb.Sp) (scan parameters are as follows: 41µm isotropic voxels, 220 slices spanning 9.02mm, 200ms integration time per angle, 1000 angles over 180degrees, source: 60kVp, 900µA). Significant differences in female connectivity density, and related trabecular histomorphometric parameters (Tb.N, Tb.Th, Tb.Sp) were found between the oldest and younger age groups (ANOVA, $p < 0.05$), while no significant differences in age groups is seen with bone mineral density or bone volume. Further, age related-patterns in trabecular architecture also seem to be related to life history variables, and we hypothesize that reproductive variables such as parity may also be playing a role in age-related bone changes. The age-related patterns seen in the female macaque are similar to those seen in human females and offer a valuable model to examine the effect of age, as well life history variables on the female skeleton.

Differences in Regional Femoral Neck Cortical Thickness with Aging: Implications for Hip Fracture Risk. S. Amin, E. J. Atkinson*, J. Camp*, R. Robb*, L. J. Melton, B. L. Riggs, S. Khosla. Mayo Clinic, Rochester, MN, USA.

Cadaveric studies suggest there are age-related differences in regional femoral neck [FN] cortical thickness [CTH], reflecting an adaptive effect of habitual loading, yet which may be maladaptive to loads during a fall, contributing to fracture susceptibility. Regional FN CTH in an in vivo aging cohort has not been described. In an age- and sex-stratified

random sample of the population, we determined the CTH at four quadrants of the FN (posterior [P], superior [S], anterior [A], inferior [I]), assessed by QCT. We examined for regional differences in CTH by age and explored how observations could be explained by physical activity level (a surrogate for habitual loading) or serum bioavailable estradiol [bio E₂].

Following exclusion of individuals on bisphosphonates or hormone replacement, we studied 304 men (age range: 23-93 y) and 260 women (range: 21-97 y) and created 3 age-groups: young (20-39 y), mid-age (40-59 y) and old (≥ 60 y). In a linear mixed effects model, accounting for correlations from having multiple measurements per subject, we examined the differences in CTH for each quadrant, relative to the [I] quadrant, among age groups. Men and women were analyzed separately.

Age Groups	Men			Women		
	Young	Mid	Old	Young	Mid	Old
N	75	96	133	71	83	106
Age (y)	32	50	75	32	49	74
Bio E ₂ (pg/ml)	15.0	12.5	9.1	25.7	18.6	4.5
Phys Act (kcal x 10 ⁻²)	422	385	313	308	299	254
Total FN CTH (mm)	2.97	2.89	2.72*	2.99	2.91	2.68*
P CTH	2.77	2.76	2.51*	2.80	2.70	2.40*
S CTH	3.00	2.66*	2.49*	2.90	2.58*	2.19*
A CTH	2.77	2.65	2.42*	2.63	2.61	2.39*
I CTH	3.32	3.48	3.45	3.62	3.74	3.78
FN CTH Differences:						
P-I	-0.55	-0.73	-0.94*	-0.83	-1.04	-1.38*
S-I	-0.33	-0.83*	-0.96*	-0.72	-1.16*	-1.59*
A-I	-0.55	-0.83*	-1.03*	-0.99	-1.13	-1.39*

* $p < 0.05$ relative to young age-group; mean values reported in table

In both sexes, FN CTH was thickest inferiorly and did not change with age. In other quadrants, CTH decreased with age, especially superiorly, and more so in women (see table). In both sexes, within the mid-age group only, greater activity was associated with greater CTH in all quadrants ($r = 0.24$ to 0.45 , $p < 0.05$). In the oldest group, lower bio E₂ was associated with decreased CTH in both sexes, but not significantly at [I] FN (for P, S, A and I, respectively: $r = 0.26^*$, 0.24^* , 0.27^* , 0.11 , for men; and $r = 0.44^*$, 0.18 , 0.24^* , 0.15 , for women; $*p < 0.05$). In this group, greater activity was associated with greater [I] CTH in men ($r = 0.26$, $p < 0.05$), but not women ($r = 0.10$).

Physical activity may help to maintain FN CTH in all quadrants with aging, however, with advancing age, low bio E₂ may have a dominant effect at thinning the FN cortex, likely through enhanced endocortical resorption. We hypothesize that the [I] quadrant may be relatively spared from this effect due to the compressive loads related to habitual activity, but requires further exploration. High compressive loads acting on [S] FN at fall impact may be more likely to cause fracture when there is greater relative thinning of [S] to [I] FN cortex, as is seen with aging, and especially women.

Increased Age and a Rod-Like Trabecular Architecture Are Independently Associated with Accumulation of Microdamage in Human Vertebral Trabecular Bone. M. E. Arlot¹, B. Burt-Pichat*, J. P. Roux*, D. Vashishth¹, M. L. Bouxsein², P. D. Delmas¹. ¹INSERM Unit 831, Université de Lyon, Lyon Cedex 08, France, ²Beth Israel Deaconess Medical Center, Boston, MA, USA.

It has been hypothesized that age-related accumulation of unrepaired microdamage may contribute to skeletal fragility. However, limited information is available on microdamage accumulation in human vertebral bone and its relationship with architecture - a key index of bone quality. We studied 23 human L2 vertebral bodies from cadaveric donors (53 to 93 yrs; 15 females and 8 males; Mean = 76 ± 12 yrs). After bulk-staining with xylenol, cores, oriented in the supero-inferior direction, were obtained from the anterior region of the vertebrae and subjected to 3D microCT analyses (μ CT40, Scanco Medical). Measured parameters included bone volume/tissue volume (BV/TV; %), trabecular number (Tb.N), thickness and separation (Tb.Sp), structure model index (SMI), connectivity density and degree of anisotropy. Three 100-micron thick longitudinal sections, obtained from the cores, were used to quantify microdamage. Crack density (Cr Dens) (#/mm²), length (mm) and diffuse damage area (mm²) were measured under UV light and confirmed with confocal laser microscopy. Mean Cr Dens and length were 1.01 ± 0.76 mm² and 70 ± 20 microns, respectively, whereas the mean diffuse damage area was 1267 ± 996 microns². There was no significant difference between sexes, but women tended to have a higher Cr Dens than men (1.21 ± 0.08 vs. 0.65 ± 0.54 , respectively). Cr Dens increased exponentially with age ($r = 0.64$; $p < 0.001$). Cr Dens was negatively associated with BV/TV ($r = -0.55$; $p < 0.01$), Tb.N ($r = -0.56$ $p = 0.008$), SMI ($r = -0.59$; $p = 0.005$) and positively associated with Tb.Sp ($r = 0.59$; $p < 0.009$). As expected all architecture parameters were strongly correlated with each other, and with BV/TV, in particular SMI vs BV/TV ($r = -0.80$; $p < 0.0001$). Stepwise regression demonstrated that SMI, a measure of the relative prevalence of rods vs plates in trabecular bone, was the only parameter predicting Cr dens independent of BV/TV, BMD, BMC and all other architectural parameters. SMI explained 35% of the variance of Cr Dens ($p < 0.005$), independently of age. In conclusion, our study demonstrated that Cr Dens exponentially increased with age in the trabecular bone of elderly human L2 vertebrae, and that the major architectural risk factor for the accumulation of microcracks was the presence of rod-like structures, as estimated by μ CT-based SMI measurements.

Comparison of Early-stage Immobilization and Estrogen-deficiency Induced Bone Loss in Rats Assessed by In Vivo Micro-CT. J. Brouwers*, E. Lambers*, B. van Rietbergen, R. Huiskes*. Technische Universiteit Eindhoven, Eindhoven, The Netherlands.

Osteoporosis can be caused by estrogen-deficiency and by long-term immobilization. While cross-sectional studies have investigated both types of bone loss, the exact pathway of bone loss has not been compared. Therefore, our purpose was to compare early-stage bone loss in immobilization and estrogen-deficiency induced osteoporosis assessed by in vivo micro-CT. 6-month old virgin Wistar rats were divided into an ovariectomy (OVX, n=8) and a sciatic neurectomy (NX, n=8) group. Proximal tibiae were scanned (Scanco vivaCT 40) with a 15 µm resolution at week 0, 1, 2, 3. Bone structural parameters (bone volume fraction (BV/TV), connectivity density (Conn.D), structure model index (SMI), trabecular number, thickness and spacing (Tb.N, Tb.Th, Tb.Sp)) were determined in the metaphysis. A student t-test was performed at week 3 to compare the structural parameters. Also, a repeated measures was done on all measurements to determine differences in response over time between the two treatments. Both the NX and OVX group already showed significant reductions in BV/TV, Conn.D and Tb.Th and an increase in SMI one week post-operatively. The OVX group also showed a reduced Tb.N at week 1, while in the NX group, it had significantly decreased at week 2. Tb.Sp was significantly increased in both groups at week 2. Bone loss was similar in both groups at week 1, while after that, bone loss became more severe in the NX groups at week 2 and 3. After three weeks, BV/TV, Conn.D and Tb.Th were significantly lower and SMI was significantly lower in the NX compared to the OVX group, based on a repeated measures ANOVA done on all measurements and a student t-test done at week 3. Both ovariectomy and immobilization led to rapid, significant changes in all structural parameters within three weeks. The loss of bone and microstructure was similar at week 1 in both groups while the immobilized rats showed a more deteriorated bone microstructure at week 3 than the ovariectomized rats, indicating that the extent and time-course in early-stage bone loss may vary slightly in both osteoporosis types.

Influence of Menarcheal Age on Microstructural Constituents of Distal Tibia in 20 Years Old Women and their Middle-aged Mothers. T. Chevalley¹, S. Ferrari¹, D. Hans², J. P. Bonjour¹, R. Rizzoli¹. ¹Service of Bone Diseases, Department of Rehabilitation and Geriatrics, Geneva University Hospitals, Switzerland, ²Service of Nuclear Medicine, Department of Radiology, Geneva University Hospitals, Switzerland.

Late menarche is a risk factor for fragility fractures, probably by permanently affecting bone structural components so that pubertal-timing dependent alterations persist from peak bone mass to menopause time attainment. We have studied the influence of menarcheal age (MENA) on areal bone mineral density (aBMD) and bone microstructure in healthy young adult daughters (YAD, 20.4±0.6 (±SD), yrs n=124) and, simultaneously, in their middle-aged mothers (MAM, 50.7±4.1 yrs, n=102). We measured aBMD by DXA at femoral neck (FN) and volumetric bone density and microstructure at distal tibia by non-invasive high resolution peripheral computerized tomography (XtremeCT, Scanco medical AG[®], CH) including: total (Dtot), cortical (Dcort) and trabecular (Dtrab) bone density; trabecular bone volume fraction (BV/TV), trabecular number (TbN), mean cortical thickness (Cth) and cross-sectional area (CSA). Mother-daughters MENA were significantly correlated (R=0.30, p<0.01). Median of MENA, were 12.9 and 13.3 yrs, in YAD and MAM, respectively. FN aBMD was inversely related to MENA in both YAD (R=-0.20, p=0.027) and MAM (R=-0.27, p=0.007). In distal tibia a significant inverse relationship was observed in both YAD and MAM between MENA and Dtot (R=-0.26, p=0.004 and R=-0.22, 0.030, respectively), Dcort (R=-0.21, p=0.023 and R=-0.21, p=0.034), and Cth (R=-0.21, p=0.022 and R=-0.19, p=0.058). In contrast, there was a positive relationship between MENA and CSA (mm², R=0.25, p=0.011) in MAM and a trend in YAD. In MAM these significant relationships were independent of years since menopause. The values below and above the median of MENA in YAD and MAM were as follows:

	Mean(SD). *p<0.0001, #p=0.002, \$p=0.016 by Anova			
	YAD Early	YAD Late	MAM Early	MAM Late
FN aBMD (mg/cm ³)	878(97)	838(116)	799(128)	744(89)*
Dtot (mgHA/cm ³)	334(46)	314(51)	308(50)	276(56)*
Dcort (mgHA/cm ³)	934(29)	924(32)	924(43)	904(54)#
Dtrab (mgHA/cm ³)	185(32)	176(31)	161(39)	142(36)*
BV/TV (%)	15.4(2.7)	14.6(2.6)	13.4(3.3)	11.9(3.0)*
TbN (mm ⁻¹)	1.94(0.28)	1.85(0.30)	1.80(0.38)	1.71(0.30)#
Cth (µm)	1214(203)	1163(231)	1165(174)	1082(241)\$

In conclusion, late menarcheal age has a negative influence not only on femoral neck aBMD, but also on several microstructural elements at distal tibia. This influence of pubertal timing on both bone mass and microstructure, as already observed at 20 yrs of age is clearly expressed 30 yrs later at the time of menopause attainment. Alterations in both bone mass and microstructural components could explain the increased risk of fragility fractures associated with menarcheal age.

The Effect of Age on Bone Mass and Bone Material Properties in C57BL/6 Mice. J. G. Hofstaetter¹, D. C. Jones^{*2}, M. Wein^{*2}, M. J. Glimcher³, L. H. Glimcher^{*2}, K. Klaushofer⁴, P. Roschger⁴. ¹Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK and AUVA Trauma Centre Meidling and Department of Orthopaedics, Medical University of Vienna, Vienna, Austria, ²Department of Immunology and Infectious Diseases, Harvard School of Public Health, Boston, MA, USA, ³Laboratory for the Study of Skeletal Disorders and Rehabilitation, Department of Orthopaedic Surgery, Harvard Medical School and Children's Hospital, Boston, MA, USA, ⁴Ludwig Boltzmann Institute of Osteology at the Hanusch Hospital of WGKK and AUVA Trauma Centre Meidling, 4th Medical Dept., Hanusch Hospital, Vienna, Austria.

Little is known about the effects of age on material properties of normal bone. The purpose of this study was to study bone material quality in young and aged normal mice. We used quantitative backscattered electron imaging (qBEI) to determine Bone Mineral Density Distribution (BMDD) as well as histomorphometry of the metaphyseal trabecular and compact cortical bone of the distal femur in 6-week, 4 and 18 months old male and female (n = 6, each) C57BL/6 mice. At 4 and 18 months of age a significant loss of bone mass was observed in the metaphyseal region (-57.1%, p<0.005 and -62.5%, p<0.005, respectively) when compared to 6 week old animals with significantly altered microarchitecture. However, BMDD parameters such as the degree of mineralization (CaMean and CaPeak), the heterogeneity of mineralization (CaWidth) as well as the amount of low mineralized bone (CaLow) remained constant with age. In contrast, in cortical bone the peak values for cortical width and cross-sectional area were seen at the age of 4 months. Interestingly, an age-dependent increase in the degree of mineralization of cortical bone was seen (+4.84%, p<0.05 and +6.77%, p<0.05) at 4 and 18 months when compared to 6 weeks, while CaWidth and CaLow did not show significant changes. Our data showed that despite a significant loss of trabecular bone mass in the metaphyseal region with age in C57BL/6 mice, the intrinsic bone material properties as determined by qBEI remain constant with age. However, cortical bone showed an age-associated increase in the degree of mineralization with altered bone geometry. This may indicate that ageing has differential effects on average cortical and trabecular tissue age and thus on bone material properties.

Three-dimensional In Vivo Trabecular Microstructure Analysis of Spine, Calcaneus, and Femoral Head/Neck/Trochanter in Japanese Postmenopausal Women. M. Ito, M. Uetani*. Radiology, Nagasaki University, Nagasaki, Japan.

Several animal studies using micro-CT have demonstrated that analysis of trabecular microstructure is useful for the assessment of bone strength and efficacy of anti-osteoporotic agents. We have successfully applied multi-slice CT for the clinical assessment of trabecular microstructure in axial skeleton, and demonstrated its potential utility (JBMR 2005). In this study we investigated trabecular microstructure in five different bone sites and their age-related changes for future clinical application. The femoral head (HEAD)/neck (NECK)/trochanter (TROCH), spine (SPINE) and calcaneus (HEEL) were scanned by CT (Aquilion, Toshiba) at spatial resolutions of approximately 200 microns. The calculated 3D microstructure indices included apparent BV/TV (appBV/TV), appTb.Th, appTb.N, appTb.Sp, fractal dimension (FD), Euler number (E), trabecular bone pattern factor (TbPF), structure model index (SMI), and degree of anisotropy (DA). BMD was measured by DXA and QCT. Data for femur and spine/heel were obtained from 67 (50-83 years old) and 65 post-menopausal women (47-82), respectively. For each site, 17 (75.3±6.5) and 32 women (68.1±4.7) with vertebral fracture and their respective age-matched controls without fracture were compared. The study protocol was approved by the ethical committee of Nagasaki University. The results indicate the microstructure parameters in NECK significantly correlated with QCT at the same bone sites, but not with DXA. Those in SPINE had significant correlations with spine QCT/DXA, and FD, E, and SMI with heel DXA. QCT/DXA had no significant correlation with age, except for spine QCT, whereas most microstructural parameters in NECK, TROCH, SPINE (appBV/TV, Tb.N, Tb.Sp and E in all 3 sites, FD in NECK and SPINE, SMI in SPINE, and appTb.Th in TROCH) had significant correlations with age. HEAD microstructure was well constructed with minimal age-related changes, whereas that in TROCH was poorly constructed with clear-cut age-related declines and large variations among individuals. Plate-to-plate transformation was mainly observed in HEAD, rod-to-rod in TROCH, and plate-to-rod in NECK and SPINE. Measurement reproducibility was poor in TROCH and HEEL. In addition to BMD, significant differences were observed between fracture and non-fracture cases in most microstructure indices in SPINE, appTb.N and Tb.Sp in NECK, BV/TV, FD and SMI in TROCH. In conclusion, using CT, much greater age-related changes in microstructure than BMD have been documented, especially appBV/TV, Tb.N and Tb.Sp. Substantial site-dependent variations in microstructure are found, and the spine and femoral neck are recommended sites for microstructural analysis to assess fracture risk and drug efficacy.

Long-Distance Runners Have Greater Cortical Thickness of Distal Tibia but not of Distal Radius. X. Martin^{*1}, N. Farpour-Lambert^{*2}, T. Chevalley¹, R. E. Rizzoli¹. ¹Rehabilitation & Geriatrics, University Hospital, Geneva, Switzerland, ²Pediatrics, University Hospital, Geneva, Switzerland.

Bone repeated loading, such as in long distance runners, is associated with increased bone mineral density. Whether bone structure is altered in runners, in relation to weight bearing skeletal site and sex, is not well established. We investigated femoral neck (FN) and total hip (Hip) areal BMD, using DXA, as well as cross-sectional area (CSA), cortical thickness (CTh) and density, relative cancellous bone volume (BV/TV), trabecular number, thickness and spacing, using high resolution computerized tomography (Xtrem-CT, Scanco, Switzerland) at the level of distal tibia and distal radius, weight bearing and non-weight bearing skeletal sites, respectively, in long distance runners (> 5 hours per week, quantified by accelerometry (MTI/CSA Actigraph)) of both sexes. We recruited 76 young women (15 runners and 61 sedentary controls, mean age \pm SD 25.1 \pm 7.6 and 20.9 \pm 2.0 years, respectively), and 56 men (31 runners and 25 controls, 26.5 \pm 3.7 and 26.9 \pm 3.8 years, respectively). Despite similar levels of physical activity as recorded with an accelerometer, in the runners of both sexes, FN and Hip areal BMD was significantly higher in males runners than in sedentary controls (FN: 1.105 \pm 0.124 vs 0.915 \pm 0.138, $p < 0.05$; Hip: 1.117 \pm 0.120 vs 1.043 \pm 0.122, $p < 0.05$), but there was no difference in females. Adjusted for the sex differences, distal tibia CTh was higher in runners than in controls ($p = 0.013$). For CSA and BV/TV, the significance was $p = 0.074$ and $p = 0.067$, respectively. At the distal radius, all structural variables were higher in males than in females, irrespective of running, which did not influence at all the values of this non weight bearing site. CTh was not anymore different between runners and controls when adjusted for sex, FN or Hip BMD. In conclusion, repeated loading, like in long distance runners, was associated with higher proximal femur areal BMD in males, and higher sex-adjusted distal tibia cortical thickness. The latter difference disappeared after adjustment for BMD variables, suggesting that running-modified cortical thickness is a component captured in the measurement of areal BMD.

Association between FSH and Bone Mass in Postmenopausal Women. K. H. Baek^{*1}, M. I. Kang¹, K. W. Oh^{*2}, J. H. Han¹, S. S. Lee^{*1}, H. S. Kim^{*1}. ¹The Catholic University of Korea, College of Medicine, Seoul, Republic of Korea, ²Sungkyunkwan University, School of Medicine, Seoul, Republic of Korea.

Diminished ovarian function and drop in estrogen levels have long been considered the cause of bone loss. Recently, it has been reported that the pituitary hormone follicle stimulating hormone (FSH), previously thought to target only the gonads, also acts on osteoclasts to activate bone resorption. In conjunction with genetic studies, these data raise the possibility that FSH, independent of estrogen, causes hypogonadal bone loss.

In this cross-sectional study, we investigated the association between the serum levels of FSH and either the bone turnover markers or bone mineral density (BMD) in 160 postmenopausal women (68.6 \pm 5.4 years, 57 to 84 years, BMI 24.4 \pm 2.8 kg/m²). Mean \pm SD years since menopause (YSM) was 18.9 \pm 7.0 years and fragility fracture was noted in 39 subjects (24.4%). Inclusion criteria were cessation of menses for at least 5 years, and no previous hormone replacement therapy. Women with liver or renal disease or endocrine or metabolic abnormalities or inflammatory diseases and/or receiving medicine known to influence bone mineralization were excluded. The FSH and biochemical markers of bone turnover (bone ALP, ICTP) were measured from the serum collected at morning. Areal BMD of lumbar spine, total hip, femoral neck, and trochanter were measured by dual energy X-ray absorptiometry.

The mean \pm SD concentrations of bone ALP and ICTP were 36.1 \pm 16.5 U/L (11.9 - 83.9) and 4.6 \pm 0.9 ng/ml (2.8 - 7.7), respectively. The median FSH concentration was 61.3 IU/L with the 25th and 75th percentiles being 42.9 and 75.2 IU/L, respectively. Partial correlation analysis after adjustment for age, BMI, and YSM revealed that FSH concentrations were not correlated with levels of bone turnover markers or BMD at any site. When categorized the subjects into four levels, we also did not find any statistically significant differences in age, BMI, YSM, prevalence of fracture, mean levels of bone turnover markers and BMD at four sites in the FSH quartiles. These findings suggest that FSH is not associated with increased bone resorption and low bone mass in healthy postmenopausal women.

Elevated FSH Predicts Increased Hip Fracture Risk: The Study of Osteoporotic Fractures. D. C. Bauer¹, S. L. Harrison², P. Garnero³, K. E. Ensrud⁴, J. A. Cauley⁵. ¹UCSF, San Francisco, CA, USA, ²CPMC Research Institute, San Francisco, CA, USA, ³Synarc, Lyon, France, ⁴University of Minnesota, Minneapolis, MN, USA, ⁵University of Pittsburgh, Pittsburgh, PA, USA.

Levels of follicle-stimulating hormone (FSH) increase among postmenopausal women in response to estrogen deficiency, and recent rodent studies suggest FSH may regulate bone mass via a direct effect on osteoclasts. The relationship between FSH and fracture risk is unknown.

We performed a nested case-cohort analysis within the Study of Osteoporotic Fractures (SOF) to determine if FSH levels were associated with bone turnover, bone loss or hip fracture risk. At the 2nd SOF visit (V2), hip DXA (Hologic QDR2000) was measured and non-fasting serum was archived at -190C (N = 8070). Repeat hip DXA was obtained at the 4th visit after a mean follow-up of 3.5 yr. 726 women had documented hip fractures after V2 (mean follow-up of 10.0 yr). After excluding women who reported hormone replacement therapy, we used V2 serum to measure FSH (Beckman Coulter) and PINP (Roche Diagnostics) in 706 women with hip fracture and 607 randomly selected women. Bone loss (in the randomly selected women) and fracture outcomes were examined in multivariate regression and hazard models adjusted for age, BMI, total hip BMD, prior fracture and chair stands.

Compared to women without fracture, those with hip fracture were significantly older (75.7 yr vs. 73.3), lighter (63.4 kg vs. 66.5), performed 5 chair stands more slowly (13.0 sec vs. 12.4) and had lower total hip BMD (0.68 gm/cm² vs. 0.75). Mean (\pm SD) FSH was higher among women with hip fracture (90.7 \pm 33.1 IU/L vs. 80.7 \pm 32.0, $p < 0.001$), but PINP levels were similar (56.3 ng/mL vs. 55.4, $p = 0.57$). After full adjustment, each SD increase in FSH was associated with a 26% increase (95% CI: 10, 45) in hip fracture risk, and fracture risk was nearly 2-fold higher (Figure) among those in the two highest quintiles of FSH (>89 IU/L) compared to those in the lowest quintile (<60.3 IU/L). PINP and FSH were weakly correlated ($r = 0.06$, $p = 0.03$) and further adjustment for PINP did not alter the relationship between FSH and hip fracture. FSH was not associated with bone loss ($p = 0.27$).

We conclude that higher levels of FSH are associated with increased hip fracture risk in older women. FSH is not strongly associated with bone turnover or bone loss in this cohort. Ongoing analyses will determine if the effect of FSH on hip fracture risk is independent of sex hormone levels.

Angiotensin Converting Enzyme (ACE) Inhibitor Use Is Not Associated with Serum Concentrations of Bone Related Hormones in Older Men. T. Kwok¹, C. Ho^{*2}, P. Leung^{*3}. ¹Medicine & Therapeutics, The Chinese University of Hong Kong, New Territories, Hong Kong, ²Chemical Pathology, The Chinese University of Hong Kong, New Territories, Hong Kong, ³Jockey Club Centre for Osteoporosis Care and Control, The Chinese University of Hong Kong, New Territories, Hong Kong.

Purpose - Intake of ACE inhibitors has been found to be associated with greater bone mineral density (BMD) in older Chinese men. The underlying mechanism is unclear. The potential associations of intake of ACE inhibitors with serum concentrations of bone related hormones and metabolic bone markers were examined.

Method - 400 out of 2,000 of the older Chinese men aged 65 years or older in the Mr. Os (Hong Kong) cohort study had fasting serum analyzed for Collagen C-telopeptide, bone specific alkaline phosphatase, total testosterone (T) and estradiol (E), sex hormone binding globulin, insulin-like growth factor 1 (IGF), IGF binding globulin and intact parathyroid hormone. Bioavailable T and E were calculated by published formulae.

Results - 179 subjects (45%) were taking antihypertensive drugs. Out of these, 62 subjects were taking ACE inhibitors. When compared with remaining subjects, subjects on ACE inhibitors were older (72.9 versus 71.5 years) and had higher body mass index (BMI, 24.7 versus 23.4 kg/m²). They had significantly lower total T (16.0 versus 18.1 nmol/L, $P = 0.019$) and lower Collagen C-telopeptide (0.26 versus 0.31 ug/L, $P = 0.048$). However, after adjustment for age and BMI, these differences became non-significant. There was no significant group difference in the other hormonal variables.

Conclusion - Use of ACE inhibitors is not associated with serum concentrations of hormones related to bone metabolism in older men.

A Microdeletion Involving TNK Alters the Phenotype of Dup(3q) Syndrome. J. D. Akunowicz^{*1}, M. P. Sciaudone^{*1}, X. Reveles^{*2}, A. M. Deshpande^{*1}, T. Davis^{*2}, J. A. Aragon-Martin^{*3}, M. Sarfarazi^{*3}, R. J. Leach², M. F. Hansen¹. ¹Center for Molecular Medicine, University of Connecticut Health Center, Farmington, CT, USA, ²Cellular and Structural Biology, University of Texas Health Science Center, San Antonio, TX, USA, ³Department of Surgery, University of Connecticut Health Center, Farmington, CT, USA.

Dup(3q) syndrome is a congenital developmental disorder resulting from a duplication of the distal portion of the long arm of chromosome 3. Symptoms typically include craniofacial abnormalities like cleft palate and craniosynostosis, clinodactyly and other mild upper limb and digital anomalies, delayed skeletal maturation, and mild mental retardation. However, one well characterized patient had an unbalanced 3;22 translocation leading to a chromosomal duplication from 3q25.3 to 3qter. Surprisingly, this patient had a more severe phenotype with microbrachycephaly, high arched palate, micrognathia, and profound mental retardation. FISH analysis using BACs from the chromosome 3q25-3q27 region revealed that the patient had a microdeletion within the region of 3q duplication. FISH analysis using subclones of the BACs within the region confirmed and narrowed the microdeletion to the boundary of 3q26-q27. Quantitative analysis of copy number by primer extension at specific SNP locations (SNuPE) within the region revealed that the microdeletion involved only the TRAF2 and NCK-interacting Kinase (TNK) locus on chromosome 3q26-q27. The microdeletion generated an imbalance in copy number between TNK (2 copies) and the remaining chromosome 3q25.3-qter region (3 copies). This microdeletion was not present in Dup(3q) syndrome patients with the milder phenotype. Our conclusion is that duplication of TNK normally modulates the effect of duplication of other genes within the Dup(3q) syndrome region and that an imbalance in copy number between TNK and the rest of chromosome 3q leads to a more severe Dup(3q) syndrome phenotype.

Carrier Frequency of Recurring Mutation Causing Severe/Lethal Recessive Type VIII Osteogenesis Imperfecta in African-Americans. W. A. Cabral^{*1}, A. M. Barnes^{*1}, F. D. Porter^{*2}, J. C. Marini¹. ¹Bone and Extracellular Matrix Branch, NICHD, NIH, Bethesda, MD, USA, ²Heritable Disorders Branch, NICHD, NIH, Bethesda, MD, USA.

The majority of cases of Osteogenesis imperfecta (OI) are caused by dominant mutations in either of the two genes encoding type I collagen, COL1A1 and COL1A2, with an incidence of 1/20,000 births. Two recessive forms of OI have recently been shown to be caused by defects in the genes encoding cartilage-associated protein (CRTAP) or prolyl 3-hydroxylase 1 (LEPRE1). Although recessive OI accounts for approximately 5% of OI cases overall, we have identified a recurring mutation in the LEPRE1 gene, IVS5+1G>T. The common mutation occurs in a compound heterozygous or homozygous state in 6 of 8 probands (9 of 16 alleles) with severe/lethal recessive type VIII OI (Cabral and Chang et al, Nat Genet (2007) 39:359-365). All six probands with the IVS5+1G>T mutation were born to carrier parents of West-African descent, suggesting the existence of a stable mutant allele in this population. In order to determine the carrier frequency of the IVS5+1G>T mutation in African-Americans, we screened genomic DNA extracted from 1149 random African-American newborn metabolic screening cards from the state of Pennsylvania. Four carriers were identified, predicting a carrier frequency of 1 in 287 newborns (0.35%) in African-Americans. Our results predict a 1 in 330,000 rate of occurrence of lethal type VIII OI in African-Americans due to homozygosity for the LEPRE1 IVS5+1G>T mutation. In addition, screening of this population has identified a previously reported SNP, g.IVS5+115A→G occurring with an allele frequency of 2.2%. This polymorphism is not linked to the mutant allele, but may be useful for haplotype analysis of the African-American population.

Correlation Between Cortical Bone Structure and Biomechanics and Metabolic Indicators in Spontaneously Diabetic, eSS Rats. G. Cointry^{*1}, S. M. Daniele^{*1}, R. Capozza^{*1}, S. Montenegro^{*1}, M. Tarés^{*1}, S. Martinez^{*1}, M. R. Ulla¹, L. Morisoli^{*1}, J. L. Ferretti. Centro de Estudios de Metabolismo Fosfocálcico, Faculty of Medicine, UNR, Rosario, Argentina.

Mechanical and tomographic (pQCT) data of the femur diaphyses and metabolic data were obtained from 9 type-II diabetic adult male eSS rats weighing 400-450g and 10 unaffected, age-paired "e" controls to define their pathogenetic relationships.

Body weight was similar between groups. eSS rats showed a. excessive cortical tissue vBMD and stiffness (vCtD, E) and diaphyseal stiffness, with low resilience and toughness (resistance to crack generation and progress), b. impaired bone mass-geometry indicators (BMC, cortical area, moment of inertia -MI-) with respect to body weight, and c. low diaphyseal strength (fracture load), with respect to controls (ANOVA, always p<0.001). A Bone Strength Index (BSI=MI.vCtD) which disregards mineralization-unrelated microstructural factors, underestimated the actual bone strength. eSS rats were hypercalciuric, and serum PTH varied directly with blood glucose, fructosamine and P and inversely with plasma Ca. Despite their

generally low values in eSS, bone mass and geometry indicators improved as a function of blood PTH, glucose and fructosamine (not Ca or P). Bone "material" or strength indicators did not vary with metabolic indicators in eSS but they did when analyzed together with controls.

Results suggest that skeletal alterations in eSS rats might result from 1. delayed bone growth with respect to body growth; 2. bone matrix hypermineralization and altered microstructural properties, associated to altered glycosylation indicators; 3. excessive stiffness of bone tissue and bones with impaired resilience and toughness (associated to 2); 4. inadequate bone geometry because the reduced bone strain by customary usage reduced bone mechanostat stimulation (associated to 3); and 5. bone weakness (associated to 3-4). An enhanced PTH activity, secondary either or both to hypercalciuria or to the diabetic condition, would be anabolic on bone formation but not enough to compensate for the primary delay of bone growth.

Disclosures: J.L. Ferretti, None.

Bone Formation in Atherosclerotic Vessels: A Physiologic Mechanism to Understanding Heterotopic Ossification. F. H. Gannon^{*1}, Z. Lazard^{*2}, C. Foulletier-Dilling^{*2}, E. Davis², M. Heggeness³, A. Davis². ¹Pathology and Orthopedic Surgery, Baylor College of Medicine, Houston, TX, USA, ²Center for Cell and Gene Therapy, Baylor College of Medicine, Houston, TX, USA, ³Orthopedic Surgery, Baylor College of Medicine, Houston, TX, USA.

Heterotopic ossification (HO) is a process of bone formation that spans several diseases. Our lab has recently published a proposed mechanism of HO in a mouse using BMP2 introduced through a viral vector. Atherosclerosis is a widespread condition with bone formation noted in many of the plaques however this bone formation has not been extensively investigated. We sought a means to understand our proposed mechanism of HO in a human physiologic condition and chose bone formation in atherosclerosis as a means to do so. 10 consecutive vascular specimens obtained from surgical procedures performed on patients with known moderate to severe atherosclerosis were analyzed in a prospective manner. The segments of the vessels most severely affected by plaque were decalcified, serially sectioned, and submitted entirely. H and E sections were analyzed and sections were stained immunohistochemically for HIF, MAC1, SMA, CD 44, and CD68. We found bone formation in both distal extremity and cardiac vessels in 9 of 10 prospective specimens on H and E examination. The bone formation demonstrated evidence of active remodeling with osteoclasts, active osteoblasts, and viable osteocytes. Examination with polarized light demonstrated lamellar bone formation. Immunohistochemical staining revealed the presence of stem cells, smooth muscle cells, and brown fat cells. These result correlated with our previous findings and similar indication of microenvironment regulations were present in both systems. The histologic features of the atherosclerotic plaque containing bone have several characteristics in common to the heterotopic bone formed in animals using a BMP2 model of heterotopic ossification. The presence of HO may be the result of the microenvironment regulation by the brown fat cells enabling the recruited stem cells to differentiate along the vascular and osteoblastic lineages with resultant bone formation and remodeling. Further examination of this disease process will shed additional light on all of the steps necessary to form HO in a number of other clinical conditions.

Possible Hypophosphatasia in a Man With Hypophosphatasemia, Spinal Ankylosis, and Recurrent Fractures. F. N. Hant^{*1}, K. Hermayer^{*2}, M. P. Whyte^{*3}, M. B. Bolster^{*1}. ¹Rheumatology and Immunology, Medical University of South Carolina, Charleston, SC, USA, ²Endocrinology, Medical University of South Carolina, Charleston, SC, USA, ³Research Center, Shriners Hospitals for Children, St. Louis, MO, USA.

We report a 69-year-old man with a 30-year history of ankylosing spondylitis (AS) treated with NSAID therapy. He never received glucocorticoids, and was being considered for anti-tumor necrosis factor (TNF)α treatment. His medical history included multiple dental extractions during adolescence for "soft teeth", and multiple recurrent fractures including a heel while walking at age 44, spontaneous fracture of his right hip at age 55 requiring pinning, left elbow fracture at age 58 (atraumatic), fracture below the plate (atraumatic) at age 61, left hip fracture at age 63, and hip re-fracture at age 68 years requiring surgery. He had taken alendronate 70 mg weekly for four years, but perioperatively this bisphosphonate was held due to concern for bone healing. Radiographs (2006) revealed fusion of the SI joints bilaterally, and ankylosis of the lumbar spine. DXA (2006) of his spine and left hip revealed T-scores of +3.0 and +0.6, respectively. Laboratory studies revealed serum total alkaline phosphatase (ALP) activity < 10 IU/L (normal: 25-100), and low bone-specific ALP activity of 10 U/L (15-41 normal). Serum calcium, vitamin D, and PTH levels were normal, but creatinine was 2.0 mg/dl. Based on his fracture and dental histories, as well as hypophosphatasemia, hypophosphatasia (HPP) seemed possible. HPP, a rare inborn-error-of-metabolism caused by loss-of-function mutation in the gene encoding the tissue-nonspecific isoenzyme of ALP (TNSALP), leads to skeletal hypomineralization and premature loss of dentition. One literature report associates HPP with AS (ZFR 50: 387, 1991). AS features new bone formation at sites of ongoing inflammation, as well as increased fracture risk due to reduced bone mass. Further biochemical and genetic studies are underway. His osteopathy is now being treated with teriparatide (JCEM 92:1203, 2007). TNFα has been shown to stimulate bone resorption, and as a class of medications to treat AS, TNFα inhibitors may delay or change the phenotype of osteoporosis in AS patients. Our patient's response to both anti-TNFα therapy for AS, and teriparatide for his hypophosphatasemia and recurrent fractures, will be closely monitored.

Molecular Exclusion of Mutations in EXT1 and EXT2 as the Cause of Metachondromatosis. S. Mumm¹, M. Huskey^{*1}, W. H. McAlister^{*2}, M. P. Whyte³. ¹Div Bone & Mineral Diseases, Washington Univ School Medicine, St. Louis, MO, USA, ²Mallinckrodt Inst Radiol, Washington Univ School Medicine, St. Louis, MO, USA, ³Research Center, Shriners Hospt Children, St. Louis, MO, USA.

Metachondromatosis (OMIM# 156250) is a rare, autosomal dominant, skeletal dysplasia featuring multiple metaphyseal juxtaepiphyseal exostoses (characteristically pointing toward the adjacent joint, and often involving the bones of the hands and feet), metaphyseal striated enchondromas (see figure), periarticular ossification, and femoral head deformities resembling avascular necrosis. These result in pain and deformities, and often require surgical removal. At least 22 cases have been reported, although lack of large families has precluded identification of the genetic defect through linkage analysis. We have clinically evaluated two families with multigenerational metachondromatosis.

Metachondromatosis shares clinical similarities with hereditary multiple exostoses (HME, OMIM #133700 & #133701), which is also an autosomal dominant disorder; HME is caused by loss-of-function mutations in the EXT1 and EXT2 genes. Like metachondromatosis, HME has cartilage-capped exostoses, primarily in the juxtaepiphyseal region of the long bones. However, in HME, the exostoses point away from the adjacent joint. Accordingly, we examined EXT1 and EXT2 for mutations in our 2 families with metachondromatosis. One proband from each was studied using genomic DNA isolated from blood leukocytes. All 11 exons for EXT1 and 15 exons for EXT2, including the entire coding region and adjacent mRNA splice sites, were amplified by PCR and sequenced in both directions. DNA sequence was examined using VectorNTI-AlignX software. No mutations in EXT1 or EXT2, that would explain metachondromatosis, were found (approximately 95% of this analysis is complete).

The metachondromatosis gene encodes a protein necessary for endochondral bone development, including shaping (defects result in exostoses) and ossification (defects result in enchondromas). We hypothesize that the metachondromatosis protein plays a role in the regulation of the critical pathways, including PTHrP and IHH, essential in chondrocyte differentiation and endochondral bone formation.

Figure Legend

The left knee of this boy at age 2 years shows enchondromas in the tibia and fibula, and exostoses that point toward the knee joint in keeping with metachondromatosis

Testosterone Therapy Increases Vertebral and Hip Strength via Complex Changes in Bone Mass and Structure: A Longitudinal Study Using QCT and Finite Element Analysis in Costello Syndrome. S. Prevhal¹, T. M. Keaveny^{*2}, J. Reeder^{*3}, P. F. Hoffman^{*4}, E. S. Orwoll³. ¹Radiology, UCSF, San Francisco, CA, USA, ²Mechanical Engineering, UC Berkeley, Berkeley, CA, USA, ³Medicine, Oregon Health and Sciences University, Portland, OR, USA, ⁴O.N. Dianostics, Berkeley, CA, USA.

Costello's Syndrome is often associated with hypogonadism, delayed skeletal growth and low bone density. In this case study, a 19 year old prepubertal man with Costello's syndrome was treated with testosterone for 30 months. Therapy was associated with marked increases in areal measurements of bone mineral content, area and density at the proximal femur and lumbar spine. However, QCT analyses showed these changes in areal density were the result of complex alterations in bone mass and structure. Therapy induced increases in bone size (Lumbar Spine +12%, Femoral Neck +14%) and volumetric bone mineral density (LS +25%, FN +2.5%). Finite-element analysis of the femur revealed similarly marked increases in vertebral and hip strength. Vertebral compressive strength increased by 17%, primarily as a result of increased vertebral size and the accumulation of bone mass in the outer shell. Compressive strength of the proximal femur increased (24%) via increased size as well as added cortical and trabecular bone, which was associated with an increase of 40% total mass. Thus, therapy with testosterone in hypogonadal men with Costello Syndrome may have skeletal benefits. Moreover, QCT analyses reveal that testosterone treatment is associated with pleiotropic changes in bone structure, including increased bone size and increased cortical and trabecular mass.

Bone Growth, Adipocytokines and Physical Training in Obese Children. E. Rocher^{*}, C. Chappard, C. Jaffre^{*}, C. Benhamou. U 658, Inserm, Orleans, France.

Childhood obesity is now classified as a pandemic. Very few studies emphasised the effect of physical activity on bone growth and biological factors in obese children. The aim of our study was to investigate the effect of a physical training on bone and biological status in obese children. Subjects, 7-11 yr of age, were randomised to engage in physical training (n=16; 10.5 ± 1.3 years old) or control (n=21; 10.9 ± 1.3 years old) groups. All baseline subjects' characteristics were similar between groups. Trained group underwent a 6-month physical training (90 min. 2d/wk) doing individualized and group aerobic exercises (cycling, rowing, jumping, games, hip-hop...). Whole-Body composition and Bone Mineral Density (BMD) were measured by DXA. Usual sites (lumbar spine (L2-L4) and total hip) were also measured by DXA. Pubertal status, energy output and diet were assessed by validated questionnaire. Lipid metabolism markers such as leptin, adiponectin, glucose, insulin, and bone markers such as osteocalcin and crosslaps were dosed. The mean baseline leptin ± SD were 22.5 ± 22 and 14.1 ± 8.1 respectively for trained and control groups. The mean baseline adiponectin ± SD were 10.1 ± 3.0 and 10.4 ± 2.5 respectively for trained and control groups. The variables mean changes after training are indicated in Table 1. The 6-month physical training did not result in significant mean group differences in body composition, DXA and biological parameters. However, the interindividual variability of the response for the subjects was quite high (for example variation of plasma leptin ranging from -40.5 to 32.2 µg/L). We found correlations between plasma leptin and adiponectin with fat mass after training (respectively r = 0.53 and r = -0.33; p<0.05). Moreover, we found a correlation between plasma adiponectin and osteocalcin after training (r = -0.39; p<0.05). Finally, these findings suggest that leptin and adiponectin are probably involved in the regulation of the body composition and might play a role in bone metabolism in obese children. Nevertheless in our study, BMD and lipid metabolism markers were not influenced by a 6-month physical training in a population of obese children.

Table 1 Baseline and mean changes after physical training in trained group compared to control group

		Trained group	Control group
Body composition	Δ Total mass (kg)	4.30 ± 2.6	3.16 ± 2.6
	Δ Fat mass (%)	0.25 ± 8.2	-1.73 ± 5.7
BMD results	Δ BMD _{whole-body} (g/cm ²)	2.60 ± 1.84	2.64 ± 1.93
	Δ BMD _{L2-L4} (g/cm ²)	0.035 ± 0.03	0.023 ± 0.03
	Δ BMD _{total hip} (g/cm ²)	0.036 ± 0.03	0.025 ± 0.04
Biological factors	Δ Leptin (µg/L)	1.21 ± 21.82	6.28 ± 9.96
	Δ Adiponectin (µg/L)	-1.11 ± 2.86	-0.15 ± 5.01
	Δ Glucose (mmol/L)	-0.14 ± 0.27	-0.24 ± 0.43
	Δ Insulin (mmol/L)	0.55 ± 1.76	0.60 ± 1.74
	Δ Osteocalcin (µg/L)	-4.43 ± 10.42	-4.00 ± 10.71
	Δ Cross laps (ng/L)	238.9 ± 496	167.10 ± 291.7

Diagnosis of Fibrodysplasia Ossificans Progressiva (FOP) Prior to the Onset of Heterotopic Ossification. M. Xu^{*1}, A. Ganguly^{*2}, F. S. Kaplan¹, E. M. Shore¹. ¹Orthopaedics, University of Pennsylvania, Philadelphia, PA, USA, ²Genetics, University of Pennsylvania, Philadelphia, PA, USA.

Fibrodysplasia ossificans progressiva (FOP) is a rare and disabling genetic condition characterized by congenital malformation of the great toes and by progressive heterotopic ossification in specific anatomic patterns. Most patients with FOP are misdiagnosed early in life prior to the appearance of heterotopic ossification and undergo diagnostic procedures that can cause lifelong disability. The genetic cause of FOP was recently identified and genetic testing for FOP is now available. We recently evaluated seven children for diagnosis of FOP prior to the onset of heterotopic ossification. A medical history, physical examination, and skeletal survey were obtained on all patients, as well as clinical genetic testing for the canonical FOP mutation. All seven children (four females, three males; ages three months to six years) had congenital malformations of the great toes, but none had radiographic evidence of heterotopic ossification at the time of evaluation. Five of the seven children had soft tissue lesions of the neck and back suggestive of early FOP flareups, three of whom had undergone invasive diagnostic procedures that exacerbated their condition. Two children had no history or signs of soft tissue swelling or flareups. DNA sequence analysis found that all seven children had the recurrent FOP missense mutation, a single nucleotide substitution (c.617G>A) at codon 206 in the glycine-serine activation domain of activin receptor IA (ACVR1), a bone morphogenetic protein (BMP) type I receptor. This study demonstrates that clinical suspicion of FOP early in life on the basis of malformed great toes can lead to early clinical diagnosis, confirmatory diagnostic genetic testing, and the avoidance of further harmful diagnostic and treatment procedures.

Teriparatide Therapy in Hajdu-Cheney Syndrome. P. J. Tebben, R. D. Tiegs, B. L. Clarke. Endocrinology, Mayo Clinic, Rochester, MN, USA.

To describe the response of two patients with Hajdu-Cheney Syndrome (HCS) to therapy with teriparatide.

The clinical, biochemical, and radiographic data of two patients with HCS are provided.

Case 1: A 55 year-old female was referred for evaluation and management of osteoporosis and HCS. Clinical findings included progressive acro-osteolysis, short stature, delayed closure of several cranial sutures, enlarged sella turcica, premature loss of teeth, low bone density, and fractures. During a 2 year course of conjugated equine estrogen (0.625 mg/day) and alendronate (70 mg/week) her bone mineral density (BMD) at the spine (L2-L4) declined by 8.2% and at the left hip declined by 3.5%. Serum calcium, phosphorus, creatinine, PTH, and alkaline phosphatase were within the reference range.

Due to declining BMD and vertebral fractures, teriparatide 20 mcg daily for 2 years was substituted for the alendronate. A 12.4% and 4.2% improvement was seen in the spine and left hip, respectively, over the initial 6 months of treatment followed by subsequent decrements in BMD at both sites. She also sustained a left tibial fracture after one year of teriparatide. Acro-osteolysis in her hands progressed while on teriparatide, a process that continued after substituting intravenous zoledronic acid (ZA) for teriparatide. Her BMD continued to decline on ZA.

Case 2: A 50 year old male was referred for evaluation of progressive acro-osteolysis affecting his left hand that was first apparent as a teenager. Although the disease was quiescent for several years, he developed similar findings in his right hand at age 35 while working as an artist. Features consistent with HCS included progressive acro-osteolysis, low BMD, and fractures. Teriparatide therapy had been initiated prior to his referral and after three years of alendronate. Serum calcium and total alkaline phosphatase were mildly elevated presumably due to teriparatide. Serum phosphorus and creatinine were within the reference range.

BMD increased by 7.3% and 10.2% at the spine and left hip, respectively, while on alendronate. BMD increased by 5% at the spine, but declined by 6.2% at the hip while on teriparatide. It was also felt that the rate of progression of acro-osteolysis had increased while on teriparatide.

HCS is an autosomal dominant condition characterized by a slowly progressive skeletal dysplasia including acro-osteolysis. Low BMD, fractures, short stature, and typical facial features are frequently described. The molecular pathogenesis is unknown. Beneficial effects of bisphosphonates have been reported in patients with HCS. Our two cases suggest that teriparatide does not effectively improve bone density or slow acro-osteolysis and that bisphosphonate therapy may be superior.

Expression of GCMB, the Master Switch for Parathyroid Development, Is Normal in Parathyroid Neoplasia. A. Hoschar^{*1}, C. Ding², M. Milas^{*3}, A. Siperstein^{*3}, M. A. Levine². ¹Anatomic Pathology, Cleveland Clinic, Cleveland, OH, USA, ²Pediatric Endocrinology, Cleveland Clinic Children's Hospital, Cleveland, OH, USA, ³General Surgery, Cleveland Clinic, Cleveland, OH, USA.

Parathyroid cell development requires the expression of the GCMB gene (6p24.2) in specific cells of the third and fourth branchial pouches during early embryogenesis. GCMB encodes a member of a small family of conserved transcription factors that share a unique DNA binding motif, and is expressed exclusively in parathyroid glands. Although mice and humans that lack functional GCMB fail to develop parathyroid glands, it is unclear whether GCMB is required postnatally to maintain PTH expression and to allow physiological proliferation and neoplastic expansion of parathyroid glands. We therefore studied expression of GCMB in normal (n=9) and neoplastic parathyroid tissue from subjects with a single parathyroid adenoma who were less than 26 years (n=9), between 26-79 years (n=23), and over 80 years (n=6) as well as from patients with parathyroid carcinoma (n=5) or multi-gland disease due to MEN1 (n=4) or non-MEN (n=9). Formalin-fixed, paraffin-embedded tissue sections were stained with affinity-purified anti-human GCMB rabbit antiserum using an automated Ventana BenchMark XT staining system. Antibody binding was detected by biotin-streptavidin immunoperoxidase with the iVIEW DAB kit. Slides were examined by light microscopy and 400-cell count was performed on each case. Each cell was categorized with respect to the intensity of nuclear reactivity, and percentages of each of the four categories were then multiplied by a number as follows: "none" x 0, "weak" x 1, "moderate" x 2, and "strong" x 3. This generates a score that ranges from 0 to 300. All staining was nuclear and GCMB staining was detected in all samples. Scores ranged from 120 for MEN1 to 169 for normal glands, with no significant differences detected between any of the groups by ANOVA. In addition, we isolated genomic DNA from 10 solitary parathyroid adenomas and analyzed the nucleotide sequence of the GCMB genes. No mutations were identified but 3 adenomas were heterozygous (C/T) at SNP rs16870746 located -44 from ATG. Because neoplastic parathyroid tissue often exhibits fractional allelic loss or gene silencing, we conclude that the robust expression of GCMB in normal and all neoplastic parathyroid glands is consistent with an important post-natal role for this protein in maintaining the parathyroid phenotype.

Screening for Asymptomatic Normocalcemic Hyperparathyroidism in the United States. B. Misra^{*}, S. J. Silverberg, J. P. Bilezikian. Dept. of Endocrinology, College of Physicians and Surgeons, Columbia University, New York, NY, USA.

Little is known about the epidemiology of normocalcemic hyperparathyroidism (NPHPT) in the United States. Most of the published data come from referral centers in which a selection bias identifies individuals who already have signs or symptoms of primary hyperparathyroidism (PHPT). A better way to establish the incidence of asymptomatic NPHPT is to screen an asymptomatic population that represents "normal" free living individuals by measuring both the calcium and parathyroid hormone (PTH) concentration. In 2003-2004, the National Health and Nutrition Examination Survey (NHANES), which provides epidemiologic data to monitor health trends in the civilian, non-institutionalized US population, measured PTH and calcium levels in over 6000 individuals. Sample weighting to correct for over- or under- sampling permits calculation of national average estimates. Using a sampled NHANES database of 1909 people age ≥45 with a creatinine clearance of ≥60cc/min (to eliminate those with renal-based secondary HPT), we screened for an elevated PTH (≥65pg/mL) and a mid-range, normal, corrected serum calcium (9-10mg/dL). Using these screening criteria, 248 individuals were identified (60% female) representing 15% of women and 11% of men. The mean PTH in this group was 83±20pg/mL. Most subjects in this sample were 45-54 years old and Caucasian. National estimates using sample weighting confirm the above demographic data, and suggest that 11% of the American population age ≥45 with creatinine clearance ≥60 cc/min fit the above criteria. Clearly, this figure overestimates the incidence of NPHPT, because the calcium and PTH levels were not verified by repeat testing, and the incidence of vitamin D deficiency (40-57% in NHANES III, data available soon for NHANES 2003-2004) and other causes of secondary HPT are not known. Significant adjustments consistent with lower percentages of the population with NPHPT are likely. Nevertheless, this initial analysis demonstrates a method whereby using available unselected free-living cohorts, it will be possible to verify initial normocalcemic and elevated PTH values, rule out vitamin D deficiency and other causes of secondary HPT, and thus gain accurate estimates of the prevalence of NPHPT. Future studies will yield more certain estimates and allow a direct test of the hypothesis that these individuals represent the true forerunner of asymptomatic PHPT.

PTH(7-84) Inhibits PTH(1-34)-induced Production of 1,25-(OH)₂D₃ in Primary Cultured Murine Renal Tubules. K. Nakajima^{*1}, K. Nohtomi^{*2}, K. Takano^{*1}, K. Sato^{*1}. ¹Institute of Clinical Endocrinology, Tokyo Women's Medical University, Tokyo, Japan, ²Department of Internal Medicine, Showa University, Tokyo, Japan.

The serum level of 1,25-(OH)₂D₃ is generally increased in patients with primary hyperparathyroidism, but is occasionally not increased, or even decreased, when hypercalcemia is very severe. Recently, we have seen a 65-year-old male patient with primary hyperparathyroidism accompanied by markedly increased serum levels of intact PTH (4085 pg/ml; normal range 10-65 pg/ml) and whole PTH (842 pg/ml; normal range 9.0-39.0 pg/ml). Serum levels of calcium (12.3 mg/dl) and creatinine (3.5 mg/dl) were moderately increased. Despite the markedly increased PTH level, serum 1,25-(OH)₂D₃ was undetectable (<3 pg/ml). After resection of a huge right parathyroid adenoma (37x20x50 mm), the serum calcium level was normalized. To clarify whether PTH(7-84), a degradation product of whole PTH (1-84) that inhibits bone resorption in skeletal tissue, also exerts an antagonistic effect on the kidney, we studied the effect of PTH(7-84) on PTH(1-34)-induced 1 α -hydroxylase activity in renal tubules.

Neonatal mouse renal tubules were cultured in DMEM/F-12(1:1) supplemented with 0.2% BSA, insulin (5 μ g/ml) and transferrin (5 μ g/ml) for 7 days in the presence or absence of PTH(1-34) and/or PTH(7-84). After changing the medium, 25-OHD₃ was added to a final concentration of 10⁻⁶ M, and 1,25-(OH)₂D₃ was determined after 3 h of culture. Furthermore, effects of PTH(1-34) and/or PTH(7-84) on mRNA expression were investigated by real-time RT-PCR.

PTH(1-34) dose-dependently increased the level of 1,25-(OH)₂D₃ in the conditioned medium, and this PTH(1-34)-induced production of 1,25-(OH)₂D₃ at 10 ng/ml was dose-dependently inhibited by PTH(7-84). Real-time RT-PCR analysis also confirmed that PTH(1-34) increased the expression of 1 α -hydroxylase mRNA. Effect of PTH(7-84) on 1 α - and 24-hydroxylase mRNA in the presence of 25-OHD₃ was not constant and is under investigation in the absence of 25-OHD₃.

These in vitro findings suggest that PTH(7-84) inhibits not only bone resorption in skeletal tissue but also 1 α -hydroxylase in renal tubules. Although hypercalcemia per se inhibits 1 α -hydroxylase activity, non-N-terminal PTH fragments may be also partly involved in the normal or decreased serum level of 1,25-(OH)₂D₃ in severely hypercalcemic patients with primary hyperparathyroidism. This in vitro observation may also account for the decreased serum level of 1,25-(OH)₂D₃ in patients with secondary hyperparathyroidism, in whom the ratio of whole PTH/intact PTH is decreased.

In Multiple Endocrine Neoplasia Type 1 (MEN1) the Estimated Ratio of Mutated p27 Versus Mutated MEN1 Genes Is Below 1:100. A. Ozawa^{*1}, S. K. Agarwal^{*1}, C. M. Mateo^{*1}, A. L. Burns^{*1}, T. S. Rice^{*1}, P. A. Kennedy^{*1}, C. M. Quigley^{*1}, W. F. Simonds¹, L. S. Weinstein¹, S. C. Chandrasekharappa^{*2}, E. S. Collins^{*2}, A. M. Spiegel¹, S. J. Marx¹. ¹NIDDK, National Institutes of Health, Bethesda, MD, USA, ²NHGRI, National Institutes of Health, Bethesda, MD, USA.

p27 (CDKN1B, cyclin-dependent kinase inhibitor 1B; the alternate name for p27 is KIP1) belongs to one of two classes of cyclin dependent kinase inhibitor. Mice with homozygous knockout of p27 develop endocrine tumors but only in the pituitary intermediate lobe. Rats with a homozygous inactivating mutation of p27 have tumors with features of MEN1 and MEN2.

One variant of MEN1 shows sporadic tumors of both the parathyroids and pituitary. The prevalence of identified MEN1 gene mutations in this variant is far lower than in familial MEN1 (7% versus 90%, p<0.0001), suggesting different causes. Recently one index case of this variant had a germline mutation of p27 (Pellegata et al; PNAS 2006).

Our purpose was to estimate the frequency of p27 mutations in MEN1 and MEN1-like states. We sequenced germline DNA from 34 cases and control cases for the p27 gene by PCR of the protein coding exons and intron/exon boundaries. No identifiable MEN1 mutation was a required criterion for inclusion.

We tested 16 MEN1 cases with sporadic tumor of both parathyroid and pituitary. In these 16 cases, parathyroid tumors were single in 2 cases and multiple in 14. Six pituitary tumors over-secreted GH, 6 over-secreted PRL, 2 over-secreted ACTH, and 2 were non-functioning. Eighteen additional index cases with closely related familial tumor phenotypes were also evaluated. There were 11 index cases for families with tumors of the parathyroids and pituitary, 5 index cases of familial isolated tumors of pituitary and 2 index cases of familial hyperparathyroidism with renal angiomyolipoma. One p27 germline single nucleotide change was identified. This predicted a silent substitution of Thr142Thr. Furthermore, there was a normal prevalence of heterozygosity (35%) for a common p27 polymorphism (Val109Gly; GTC to GGC), making a large p27 deletion unlikely in all or most of these cases. Thus there was no pathologic p27 mutation in any of 34 cases. We can estimate the frequency of p27 mutations in MEN1. Assume 1000 cases of MEN1 and MEN1-like variants, about 700 will have MEN1 mutations. Of the remaining 300, we estimate less than 6 p27 mutations. The estimated ratio of p27 versus MEN1 mutation in MEN1 is therefore below 1 to 100. p27 is thus a rare cause of MEN1, but it has implications for understanding endocrine tumors that are disproportionate to its rarity.

Long Term Morbidity & Mortality in Untreated Mild Primary Hyperparathyroidism. J. Iskander^{*}, D. Rao. Bone & Mineral Metabolism, Henry Ford Health System, Detroit, MI, USA.

Optimal management of mild asymptomatic primary hyperparathyroidism (PHPT) continues to be debated despite recent revised guidelines. A small number of prospective studies of untreated PHPT suggested very few disease specific complications, but others differ. Therefore, it is unclear if untreated PHPT is associated with significant longer term morbidity and mortality. Accordingly, we determined long term outcomes in carefully followed patients with untreated PHPT.

We prospectively studied 50 patients (8 men and 42 women, and 21 white and 29 black, with a mean age of 66 \pm 8y), with mild PHPT to determine longer term effects of chronic PTH excess in the absence of parathyroidectomy (PTX). Patients were evaluated every 6-12 months for up to 18y.

There was a small significant rise in serum creatinine, but none of the values were > 1.5 mg/dl during the first 10y of follow up. Serum PTH and calcium did not change. There was a small but significant decline in forearm absolute BMD with consequent decline in T-score but not in Z-scores. Absolute BMDs and T- and Z-scores did not change either at the spine or at the hip. Quality of life scores, by SF-36, generally remained stable over time. Relevant morbidity and mortality data are in Table.

During follow-up, 2 patients started hemodialysis (one 10y after PTX), most likely related to diabetes and hypertension, and 2 patients had kidney stones, one of whom had PTX before the kidney stone incident.

Eleven patients sustained 14 fractures: one each of humerus, ischium, glenoid cavity and femur, 3 - 7y after PTX. Fractures 1-4y before PTX were: 3 foot, 2 finger, and one each of fibula, forearm, femur, ankle, and tibia due to trauma or automobile accident. None of the fractures were considered due to PHPT. Eight patients died at a mean age of 76.3 \pm 7.2y from causes unrelated to PHPT (2 cancers, 3 cardiac, one each in hospice, ruptured aneurysm, and unknown; all unrelated to PHPT). Seven of the 9 patients had PTX because of the formal conclusion of the study in concert with existing guidelines.

We conclude that mild untreated PHPT is not associated with continued bone loss or worsening disease severity. There were the usual age and lifestyle related morbidity and mortality, but no disease specific complications.

Incidents	Pre-PTX (y)	Post-PTX (y)
Fractures (n)	3 (1,2,&12y)	4 (3,4,4,&7y)
Kidney Stones (n)	2 (1&7y)	0
Renal Failure (n)	1	1 (10y)
Deaths (n)	7	1 (6y)

Disclosures: D. Rao, None.

Use of Parathyroid Hormone in Hypoparathyroidism. M. R. Rubin, S. J. Silverberg, J. Sliney^{*}, J. P. Bilezikian. Columbia University College of P&S, New York, NY, USA.

Hypoparathyroidism (HypoPT) is a disorder in which PTH is absent from the circulation. Without PTH, calcium homeostasis is abnormal and bone mineral density (BMD) by DXA is markedly elevated. Calcium and vitamin D supplementation are required but control can be a clinical challenge. PTH seems to be an ideal agent because it replaces what is missing in these individuals. Accordingly, we studied the effects of PTH replacement therapy in HypoPT on biochemical and densitometric abnormalities. We studied 30 subjects (48.9 \pm 13 yr; 21 female) with HypoPT (duration 18 \pm 13 yrs; 17 postsurgical, 11 autoimmune, 2 DiGeorge). Baseline biochemistries were: serum calcium, 8.7 \pm 1 mg/dl (nl 8.5-10.4); PTH, 7.1 \pm 6 pg/ml (nl 10-65); urinary calcium, 261 \pm 123 mg/l; serum phosphorus, 4.4 \pm 0.8 mg/dl (nl 2.5-4.5); total alkaline phosphatase, 66 \pm 20 IU/l (nl 33-96); 25-hydroxyvitamin D, 63 \pm 76 ng/ml (nl 9-52); 1,25-dihydroxyvitamin D, 33 \pm 15 pg/ml (nl 15-60). Baseline calcium supplementation ranged from 0-9 g/d (av.3 g/d); baseline calcitriol doses ranged from 0 to 3 ug/d (av. 0.75 ug/d); baseline parent vitamin D doses (n=9) ranged from 4000-100,000 IU/d (av. 10,000 IU). Baseline DXA-based BMD was by T-scores at the lumbar spine, +1.7 \pm 2.3 (cohort range: -1.60 to +7.90), total hip, +0.57 \pm 1.3 (cohort range: -2.10 to +4.30) and 1/3 distal radius, -0.34 \pm 1.06 (cohort range: -2.6 to +1.5). PTH(1-84) was administered at 100 ug every other day for up to 24 months (range of time: 1-24 months). Calcium supplementation decreased by 33% at 1 month (p<0.01); calcitriol supplementation decreased by 27% at 3 months (p<0.05); parent vitamin D supplementation trended downwards by 31% at 3 months. Serum calcium remained within the normal range, with the greatest increase occurring at 2 months, to 9.3 \pm 1 mg/dl (p<0.01). Urinary calcium decreased at 12 months to 164 \pm 102 mg/dl (p=0.02). BMD decreased at the distal 1/3 radius (-2.9 \pm 2% at 18 months; p=0.02), but increased at the lumbar spine (2.9 \pm 4% at 12 months; p=0.02) and did not change at the total hip. We conclude that the administration of PTH improves calcium homeostasis in HypoPT and allows serum calcium levels to be maintained while permitting a reduction in the calcium and vitamin D regimen. It appears that there are differential effects of PTH replacement on BMD by DXA, as a function of skeletal site and composition. Whether other changes in bone quality occur with PTH replacement are currently under investigation.

Disclosures: M.R. Rubin, None.

Bone Quality in Mild Primary Hyperparathyroidism. R. Zoehrer^{*1}, D. W. Dempster², J. P. Bilezikian², H. Zhou³, S. J. Silverberg⁴, E. Shane⁴, P. Fratzl^{*5}, E. Paschalis¹, P. Roschger¹, K. Klaushofer¹. ¹Ludwig Boltzmann Institute of Osteology, Hanusch Hospital of WGKK and AUVA Trauma Centre Meidling, 4th Med. Dept. Hanusch Hospital, Vienna, Austria, ²Regional Bone Center, Helen Hayes Hospital, & College of Phys & Surg, Columbia University, New York, NY, USA, ³Regional Bone Center, Helen Hayes Hospital, New York, NY, USA, ⁴College of Phys & Surg, Columbia University, New York, NY, USA, ⁵Department of Biomaterials, Max Planck Institute of Colloids and Interfaces, Potsdam, Germany.

Mild primary hyperparathyroidism (PHPT) is a common endocrine disorder characterized by excessive secretion of parathyroid hormone (PTH) and hypercalcemia. The present study examines bone quality in PHPT by applying two imaging technologies: quantitative backscattered electron imaging (qBEI) and Fourier transform infrared imaging analysis (FTIRI). qBEI permits determination of bone mineral density distribution (BMDD), expressed as CaMean, CaPeak, CaWidth and CaLow, and FTIRI describes the extent of collagen maturity expressed as the ratio of 2 of the major bone type I collagen cross-links (pyridinoline/dehydro-dihydroxylysinonorleucine;collx). Percutaneous transiliac bone biopsies were obtained from 51 unselected subjects with mild PHPT (16 men, aged 28-68; 35 women, aged 26-74). Forty of the biopsies were from untreated patients. Seven biopsies were from subjects biopsied after an average of 6 years after parathyroidectomy (PTX). All biopsies were fixed and dehydrated in ethanol, and embedded in polymethylmethacrylate. By qBEI analysis, PHPT differed from healthy controls in that they had markedly higher CaWidth (+15.7%, p<0.0001) and CaLow (+44.7%, p<0.0001), and somewhat lower CaMean (-2.5%, p<0.0001). These differences were reversed in the 7 patients who underwent PTX. For FTIRI analysis, spectral images were acquired of 3 areas (each 400 µm x 400 µm) on separate trabeculae devoid of resorption pits and with primary mineralization evident on at least one surface (based on qBEI images). The collx in the PHPT patients was significantly lower than in normal controls (p<0.001), while those studied after PTX was normal. The difference in collx in PHPT was age-independent but gender-dependent: with women exhibiting a lower ratio than men. Both qBEI and FTIRI outcomes were strongly correlated with bone formation rate and mineralizing surface parameters as determined by histomorphometry. These results are consistent with previous observations of increased bone turnover in this disease, and consequently, reduced mean age of bone tissue. Reduced mineralization density and collx in patients with PHPT would be expected to reduce the stiffness of bone tissue. These observations are relevant to considerations of fracture risk in PHPT.

The Relationship between iPTH and Bone Metabolic Markers. Y. Kodama^{*}, Y. Kato^{*}, K. Kanaya^{*}, K. Wada^{*}, S. Shimamoto^{*}, C. Ishi^{*}. Orthopedics, Tokyo Women's Medical University, Tokyo, Japan.

Introduction: Currently, instead of a bone biopsy, bone metabolic markers are often used to evaluate bone quality, since this is non-invasive test. However, in HD patients, the diagnosis and prognosis based on bone metabolic marker levels were sometimes difficult. The pathological histology of renal osteodystrophy (ROD) is well-known to be related to the level of iPTH. We investigated the relationship between iPTH and bone metabolic markers to evaluate bone quality in HD patients.

Patients: iPTH and bone metabolic markers had been measured in our department. The data from 1200 patients, whose background characteristics were available, was analyzed in this study. The patients were categorized into the following 10 groups, HD group, metastatic bone tumor (meta) group and so on.

Methods: 1. In each disease group, iPTH and bone metabolic markers were assessed using multiple comparisons. 2. In HD group, the correlations between iPTH and bone metabolic markers were examined. 3. For each marker, the patients were divided into two groups based on their iPTH levels: low, iPTH <65 pg/mL; and high, iPTH ≥65 pg/mL. Their correlations were then examined.

Results: 1. HD group showed higher iPTH than other groups. ICTP, NTX, and OC had a similar distribution to iPTH. The meta group showed a significantly higher BAP than other groups. 2. sNTX, OC and BAP had statistically significant correlation with iPTH, but ICTP had none. 3. In "high" group, all bone metabolic markers were strongly correlated with iPTH. In "low" group, however, none of the bone metabolic markers were correlated with iPTH.

Discussion: 1. Two hypotheses could explain the results of multiple comparisons. Bone metabolic markers may simply accumulate due to impaired kidney function and due to the differences in the dialyzer membrane's permeability. Alternatively, the bone metabolic markers truly reflect accelerated bone turnover due to secondary hyperparathyroidism. To confirm these hypotheses, we investigated the correlations between iPTH and the various bone metabolic markers. 2. OC had the highest correlation coefficient with iPTH. In HD patients, OC appears to have the best contribution ratio to iPTH. 3. When iPTH is lower than 65 pg/mL, the histopathology of ROD shows aplastic bone disease (ABD) with 100% specificity. To exclude the influence of ABD, the patients were divided into two groups based on their iPTH levels. In this study, all bone metabolic markers were correlated with iPTH in "high" group. Therefore bone metabolic markers can be used to evaluate the bone quality of ROD in patients without ABD.

Conclusions: ICTP, OC, and NTX had similar distribution to iPTH. In HD group, OC had the highest correlation coefficient with iPTH. In HD patients with iPTH ≥ 65 pg/mL, all bone metabolic markers were correlated with iPTH.

Non-invasive Study of Bone and Cardiovascular Disease in Chronic Hemodialysis Subjects. L. Kooienga^{*1}, A. Furniss^{*2}, A. Bellasi^{*3}, P. Raggi^{*4}, G. Block². ¹Division of Renal Disease and Hypertension, University of Colorado Health Sciences Center, Denver, CO, USA, ²Clinical Research Division, Denver Nephrology, Denver, CO, USA, ³Nephrology, University of Milano, San Paolo Hospital, Milan, Italy, ⁴Division of Cardiology, Emory University, Atlanta, GA, USA.

To assess the relationship between interval changes in bone mineral density (BMD) with changes in arterial health as determined by changes in aortic and coronary artery calcification scores (CACS) and arterial stiffness over a 12 to 18 month follow-up period. This is a single center study of subjects on chronic hemodialysis who underwent medical interviewing, dual energy x-ray absorptiometry, electron beam computed tomography, and pulse wave velocity (PWV) assessment at baseline and at follow-up. In addition, subjects had time-averaged laboratory values obtained from routine dialysis monitoring throughout the follow-up period. Medication exposure was defined as > 3 months of the study period.

59 subjects completed baseline and follow-up evaluations. 3 subjects with a parathyroidectomy during the study were excluded. The mean age was 58.8 (15.2) years, mean vintage was 45.9 (41.9) months, and mean follow-up was 13.6 (1.6) months. 54% of subjects were female, 63% were Caucasian, and 30% were African American. ESRD etiology was from diabetes mellitus in 34% and hypertension in 30%. Mean hip BMD at baseline was 0.813 (0.148) g/cm² and decreased by a mean of -2.6 (4.6) % at follow-up. 17 subjects had an improvement or no change in BMD and 37 subjects had a decrease in BMD. In subjects with improvement/no change in hip BMD vs. those that had a decrease there was no significant difference at follow-up in time-averaged albumin, adjusted calcium, adjusted Ca x P product, LDL cholesterol, PTH, or the % with mean PTH between 150-300 pg/mL. Those with a decrease in hip BMD had a higher % of aspirin use (81 vs 47%; p=0.02), lower Cinacalcet use (27 vs 65%; p=0.02), and a trend towards lower calcium binder use (57 vs 88%; p=0.07) and lower serum phosphorus [4.8 (0.8) md/dL vs. 5.2 (0.7) mg/dL; p=0.09]. They also had a greater change in mean PWV [1.4 (3.6) m/s vs. -0.8 (1.8) m/s; p=0.01] with a concomitant higher median aortic artery calcium score [2496 (47,927) vs. 784 (9514); p=0.05]. However, there was no significant difference in CACS, cardiovascular events, or fractures between the groups.

69% of prevalent HD patients experienced a dramatic loss of hip BMD over a mean 13.6 month follow-up. This loss of BMD was independent of the typical parameters of bone mineral metabolism, time on dialysis, or age. Subjects who lost hip BMD had higher median aortic artery calcification scores and demonstrated significant worsening of arterial PWV supporting the proposed hypothesis linking loss of bone mineral with vascular pathology.

The Mechanism of Skeletal Involvement in Cardiovascular Mortality in Chronic Kidney Disease (CKD). S. Mathew^{*1}, R. Lund^{*2}, K. A. Hruska¹. ¹Pediatrics, Washington University, St. Louis, MO, USA, ²Medicine, Creighton University, Omaha, NE, USA.

CKD is complicated by high mortality rates due to cardiovascular events. Hyperphosphatemia and vascular calcification (VC) have been determined in observational studies to be risk factors. In animal models with CKD, we have demonstrated that renal injury impairs osteoblast function and decreases bone formation rates without suppressing osteoclastic resorption, i.e. produces the adynamic bone disorder. In an animal model of type 2 diabetes with atherosclerosis, induction of the adynamic bone disorder by CKD contributes to hyperphosphatemia by excess skeletal resorption, and stimulates vascular calcification. Control of the serum phosphorus by stimulation of bone formation or phosphate binding inhibited VC. These results have been confirmed in dialysis patients treated with phosphate binders, and improved patient survival was found. In atherosclerotic vascular smooth muscle cells, the mechanism of phosphorus action in VC was sought and found to be stimulation of a heterotopic BMP-2 and RUNX2 directed osteoblastic transcription program. Despite the expression of these osteoblastic determinants in basal conditions, matrix mineralization by atherosclerotic aortic smooth muscle cell cultures was not observed until media phosphorus was increased. The action of phosphorus on mineralization was due to stimulated expression of osterix, a critical osteoblast transcription factor. Phosphorus stimulated mineralization in vitro was silenced by inhibition of osterix through BMP-7, and by inhibition of BMP-2 action through addition of a BMP antagonist, noggin.

In our animal model of CKD stimulated VC, we found the BMP-2/MSX2 program including RUNX2 expression to be present in the atherosclerotic aorta prior to CKD and unaffected by induction of CKD, analogous to the atherosclerotic cell cultures. CKD stimulated aortic osterix expression. Stimulation of bone formation and control of hyperphosphatemia using BMP-7 or phosphate binding agents, decreased aortic osterix expression, osteocalcin expression and aortic mineralization. These studies demonstrate a multiorgan system of the kidney, skeleton, and the cardiovascular system, that fails due to CKD involving loss of skeletal anabolism, hyperphosphatemia and heterotopic mineralization representing kidney-bone and bone-vascular signaling.

Bone Microarchitecture As Assessed by High Resolution Quantitative CT (HRpQCT) in Chronic Kidney Disease. T. L. Nickolas¹, D. J. McMahon¹, H. Eisenberg^{*1}, S. Cabral^{*1}, C. Go^{*1}, M. Leonard², E. Shane¹. ¹Medicine, Columbia University, New York, NY, USA, ²Pediatrics, University of Pennsylvania, Philadelphia, PA, USA.

Moderate chronic kidney disease (CKD) and end-stage kidney disease (ESKD) are associated with increased susceptibility to fracture, due in part to the catabolic effects of secondary hyperparathyroidism on cortical bone. However, the effects of moderate CKD on trabecular (Tb) and cortical (Ct) microarchitecture have not been addressed. High resolution quantitative CT (HRpQCT) (XtremeCT, Scanco Medical AG) is a new imaging technology (resolution <100 microns) that distinguishes Ct from Tb bone and yields noninvasive measurements of Tb and Ct architecture that are more sensitive markers of bone fragility. To assess effects of impaired kidney function on bone architecture, we performed HRpQCT scans in 31 subjects (18 men), aged 51-88 yr, across a range of kidney function. The MDRD formula was used to estimate GFR. Overall, 5 subjects were on dialysis and 9 had normal eGFR. Of the remainder, the median (range) eGFR was 40 ml/min (11-64). HRpQCT variables that were not normally distributed were log-transformed. Univariate analyses demonstrated that Tb deficits were significantly associated with lower eGFR and female gender. Ct deficits were significantly associated with lower eGFR and older age. Linear regression was used to investigate the relationship between HRpQCT microarchitectural parameters and eGFR, adjusted for age and gender. Ct density, but not thickness, was directly related to eGFR. Similarly, Tb parameters were worse in patients with lower eGFR, with decreased Tb density, BV/TV and TbN, increased TbSp and heterogeneity of the Tb network (TbSpSD). By multivariate regression analysis adjusted for gender and age, Tb changes were independently associated with eGFR (Table 1). This preliminary investigation confirms that lower eGFR was associated with both Ct and Tb deterioration that was independent of gender and age. These alterations in Ct and Tb microstructure may contribute to the increased risk of fracture in patients with CKD and ESKD. Further studies are required to elucidate the pathogenesis of the microarchitectural deterioration and its relationship to bone mechanical competence.

Multivariate Linear Regression of Bone Microarchitecture
Against eGFR, Gender and Age

	B	SE	p-value
Ct Density	1.4	0.6	0.03
Ct Thickness	0.002	0.001	NS
Tb Density	0.5	0.25	0.04
Tb Bone Volume (BV/TV)	0.0005	0.0002	0.03
Tb Thickness (TbTh)	0.00006	0.00007	NS
Log (Tb Number, TbN)	0.004	0.002	0.03
Log (Tb Separation, TbSp)	-0.004	0.002	0.03
Log (TbSp SD)	-0.01	0.003	0.01

*Gender and Age were not significantly associated either with cortical or trabecular parameters in multivariate linear regression

Etidronate Inhibits Progression of Vascular Calcification and Decrease in Bone Mineral Density in Chronic Dialysis Patients. Y. Okada, O. Hashimoto*, T. Tanikawa*, Y. Tanaka. First Department of Internal Medicine, University of Occupational and Environmental Health Japan, Kitakyushu, Japan.

Severe atherosclerosis/calcinosis is common in patients on long-term dialysis. No therapy is currently available to suppress the progression of vascular calcification. In the present study, we determined the effect of etidronate (EHDP), a first generation bisphosphonate, on vascular calcification in chronic dialysis patients. 81 patients undergoing chronic hemodialysis were divided into EHDP-treated group (n=37) and control group (n=44). EHDP was administered in a single dose (400 mg/day) just before sleep each day for two weeks followed by suspension for 10 weeks, and a repeat of the cycle every 12 weeks for one year. The area of calcification affecting the abdominal aorta (ACA) was measured with X-ray computed tomography. ACA was measured by an image analysis device and the mean ACA of six slices was calculated. ACA was measured at the start and end of the study (12 months) in each patient. Bone mineral density (BMD) was measured by DXA at the start and end of the study (12 months). Scans were performed for the forearm, at one-third radius without A-V fistula. In the EHDP-treated group, no significant changes in BMD were noted throughout the study. However, BMD decreased significantly in the control group from 0.57 ± 0.17 (mean \pm SD) at enrolment to 0.55 ± 0.18 g/cm² at 12 months (P<0.01). ACA increased significantly in the control group from 71.3 ± 58.6 at enrolment to 83.1 ± 63.6 mm² at 12 months (P<0.01). In contrast, ACA changed in the EHDP-treated group from 71.3 ± 63.3 at enrolment to 73.2 ± 63.5 mm² at 12 months statistically insignificant. The delta increase in ACA in EHDP-treated group was 1.9 ± 18.6 mm² (95% CI 1.33-5.60) which was significantly lower than that of the control group (11.8 ± 19.2 mm², 95% CI 8.19-14.55). The independent association between changes in ACA and various parameters in multivariate linear regression analysis indicated that EHDP was an independent factor for the observed changes in ACA. Our findings suggest that EHDP is potentially useful for prevention of vascular calcification and might improve the prognosis of chronic dialysis patients.

TRAP5b Profiles in Children with Chronic Kidney Disease (CKD). H. E. Price, C. B. Langman*. Pediatric Kidney Diseases, Northwestern University, Childrens Memorial Hospital, Chicago, IL, USA.

Serum tartrate-resistant acid phosphatase 5b (TRAP5b) is derived from osteoclast activity. Levels of TRAP5b rise during growth spurts in children, associated with bone modeling. The osteodystrophy of CKD in children is associated with high-turnover disease from 2^o hyperparathyroidism (SHPTH), resulting in increased remodeling. The purpose of this cross-sectional study was to measure serum TRAP5b in children with CKD, and we asked whether modeling was reflected by its levels. 36 children (23 males (M) 13 females (F)) with CKD stages 1-4 (NKF classification using eGFR) had measures made of hormones and factors related to their osteodystrophy. These included iPTH, 25(OH)D, 1,25(OH)₂D, in addition to TRAP5b (TRAP5b levels were made using an ELISA, Quidel Corporation, San Diego, CA.). Values were compared to 65 healthy children of the same age distribution. As eGFR decreased in CKD, serum TRAP5b increased. There were correlations with iPTH (r=-0.5) and 1,25(OH)₂D (r=-0.5) in children with CKD, but not in healthy children. There was no correlation between TRAP5b & 25(OH)D. When compared to healthy children matched for age and gender, children with CKD had increased levels of TRAP5b in childhood (pre-pubertal) years (F CKD: 19.7 ± 6.3 vs. healthy: 8.1 ± 3.8 U/L, p<0.001; M CKD: 12.2 ± 4.6 vs. healthy: 6.6 ± 3.6 , p<0.01). In early adolescence, healthy children had an increase in TRAP5b, followed by a decrease as they approached late adolescence into adulthood. However, children with CKD had a decrease of TRAP5b in early adolescence followed by a steady decline into adulthood. Thus, the values of TRAP5b in early adolescence were lower when compared to healthy children (F CKD: 13 ± 8.2 vs. healthy: 10 ± 2.7 ; M CKD: 7.9 ± 5 vs. healthy: 9.9 ± 3.3). In conclusion, as kidney function decreases in the childhood years, TRAP5b increases, indicating accelerated bone turnover from SHPTH. However, during a period of expected increased bone modeling, and despite SHPTH, TRAP5b values declined, consistent with reduced linear growth in adolescent CKD. Additional prospective studies underway will further clarify these relationships. Thus, TRAP5b may be an important corollary marker to profile bone modeling, since bone biopsy is not clinically available, and SHPTH reflects bone remodeling. The osteodystrophy of pediatric CKD thus may be able to be better separated into abnormalities of bone modeling, and bone remodeling, with a multi-faceted measurement approach that includes TRAP5b.

Hyperphosphatemia Mediates Oxidative Stress in Bovine Aortic Endothelial Cells. E. Shuto*, Y. Taketani¹, R. Tanaka*, A. Tanimura*, M. Isshiki*, N. Harada*, H. Yamamoto*, E. Takeda*. ¹Department of Clinical Nutrition, University of Tokushima Graduate School, Tokushima, Japan, ²Department of Nephrology and Endocrinology, University of Tokyo, Tokyo, Japan, ³Department of Nutrition and Metabolism, University of Tokushima Graduate School, Tokushima, Japan.

Hyperphosphatemia causes calcification of vascular smooth muscle cells. The calcification is closely associated with progress of cardiovascular disease and mortality in end-stage renal disease (ESRD) patients. We hypothesized that hyperphosphatemia may also contribute the progress of atherosclerosis in early-stage chronic kidney disease by involving endothelial dysfunction. To prove the hypothesis, we investigate the effect of high inorganic phosphate (Pi) loading on the endothelial function using bovine aortic endothelial cells (BAECs). First, we examined production of reactive oxygen species (ROS) by fluorescence ROS indicator (APF: aminophenyl fluorescein), and found that high Pi (1.5-3mM) increased production of reactive oxygen species in a dose-dependent manner compared with control (0.9 mM Pi). The increase in ROS was inhibited by diphenylene iodonium (DPI; NAD(P)H oxidase inhibitor) and phosphonoformic acid (PFA; Na/Pi co-transporter inhibitor). Therefore, both Pi influx and NAD(P)H oxidase activation play an important role in the ROS production in response to high Pi loading in endothelial cells. In second, we examined effect of high Pi on the nitric oxide (NO) production in response to bradykinin in the BAECs, and found that pretreatment with high Pi (2 mM) for 3 days decreased the hormone-dependent NO production. One possible mechanism of the inhibition of NO production was due to phosphorylation of endothelial NO synthase (eNOS) by conventional PKC activated by high Pi loading. These results suggest that increase in Pi influx can mediate intracellular signal such as PKC activation and ROS production, and would be involved in oxidative stress and some adverse effect on endothelial function. Oxidative stress caused by hyperphosphatemia in endothelium may be a novel patho-mechanism for atherosclerosis and cardiovascular diseases in ESRD patients.

Prospective Controlled Study assessing the Clinical Benefit of Evening Administration of Vitamin D in Hemodialysis Patients. K. Takasawa^{*1}, C. Takaeda^{*1}, Y. Takeshita^{*2}, K. Kawai^{*2}. ¹Renal Division, Public Central Hospital of Matto-Ishikawa, Hakusan, Japan, ²Internal Medicine, Public Central Hospital of Matto-Ishikawa, Hakusan, Japan.

Control of serum calcium (sCa) and phosphorus (P) levels is important in improving the survival of hemodialysis patients. We assessed whether sCa is decreased in hemodialysis patients by administering a Vitamin D (VitD) at evening instead of in the morning. We selected 24 patients having a serum Ca level of ≥ 9.5 mg/dl (A1b-adjusted) from 72 hemodialysis patients at our institution. Concerning the 24 patients above, an informed consent was obtained based on the Helsinki declaration. The 24 patients (the average age is 63.4 ± 14.8 years, the mean duration of dialysis is 10.6 ± 8.4 years), who were undergoing oral VitD administration in the morning, were randomized into two groups for morning administration and evening administration of VitD (n=12 per group) and were prospectively followed-up for 6 months. During the follow-up period, the patients were monitored for the sCa levels, iPTH, osteocalcin, bone alkaline phosphatase and the serum P while receiving a fixed dose of VitD as a rule. However, the dose of iPTH was adjusted as appropriate in compliance with the Japanese guidelines and K/DOQI that recommend a dose of iPTH not exceed 180 pg/mL. Out of the 12 patients treated in the morning, one who suffered from cerebral hemorrhage and 5 who received a reduced dose of VitD were excluded, and the remaining 6 patients (2 treated with alfacalcidol and 4 with falecalcitriol) were evaluated. I have excluded the 5 patients in the evening group because that one had renal transplantation, one died of infection and 3 whose VitD dosage had been reduced, and the remaining 7 patients (4 treated with alfacalcidol and 3 with falecalcitriol) were evaluated. The sCa levels were no difference between two groups at the beginning. In the morning group, the sCa level was 10.3 ± 1.0 mg/dl at baseline and 10.4 ± 0.8 mg/dl after 6 months. In the evening group, the sCa level was 9.9 ± 0.6 mg/dl at baseline and was significantly decreased to 9.4 ± 0.6 mg/dl after 6 months ($p < 0.05$). The serum iPTH level was 181.7 ± 133.5 pg/ml at baseline and 208.5 ± 165.4 pg/ml after 6 months in the morning group versus 121.4 ± 139.6 pg/ml at baseline and 142.1 ± 94.9 pg/ml after 6 months in the evening group, showing no pronounced change in the both groups. The osteocalcin levels of the evening group were reduced from 46.6 ± 45.3 to 29.5 ± 22.3 ng/ml, significantly. These data suggest that oral VitD was administered at evening in patients on hemodialysis to address the diurnal rhythm of bone metabolism, and the serum Ca level was decreased as a result in these patients. Evening administration of VitD is more beneficial effect for patients on hemodialysis.

Disclosures: K. Takasawa, None.

Impact of Cinacalcet HCL on Bone Remodeling and Minimodeling in Patients with Secondary Hyperparathyroidism. A. Yajima¹, H. E. Takahashi², T. Akizawa^{*3}, K. Study Group^{*4}. ¹Nephrology, Towa Hospital, Tokyo, Japan, ²Niigata University of Health and Welfare, Niigata, Japan, ³Nephrology, Showa University, School of Medicine, Tokyo, Japan, ⁴KRN 1493 Study Group, Tokyo, Japan.

Purpose: Impact of cinacalcet HCL on hyperparathyroid bone disease was investigated. Methods: Iliac bone biopsy was taken before and after the treatment with cinacalcet HCL for one year in the three hemodialysis patients with secondary hyperparathyroidism, and histomorphometric parameters including remodeling parameters and minimodeling volume were measured in cancellous bone.

Results: Serum intact PTH was decreased from 747.7 ± 391.1 to 140.3 ± 80.5 pg/ml, respectively. Oc.S/BS decreased from (8.5, 6.2, 6.2) to (1.2, 0.2, 1.0) %, Fb.V/TV decreased from (2.1, 0.3, 0.2) to (0, 0, 0) %, Ob.S/BS decreased from (45.5, 20.0, 22.5) to (7.8, 1.5, 1.0) %, OS/BS decreased from (58.1, 44.7, 37.3) to (17.1, 8.2, 13.5) %, BFR/BS also decreased from (0.069, 0.023, 0.044) to (0.004, 0.003, 0.004) $\text{mm}^3/\text{mm}^2/\text{year}$. Minimodeling volume (MLV/BV) increased from (0.49, 0.45, 1.73) to (5.18, 4.95, 4.41) %. In addition, MAR of remodeling sites were decreased from (0.89, 0.79, 0.65) to (0.4, 0.41, 0.39) mcm/day after the treatment of cinacalcet HCL. And MAR of minimodeling sites were decreased from (0.94, 0.84, 0.64) to (0.44, 0.48, 0.40) mcm/day after the treatment. As a result, MAR values were generally greater in minimodeling sites than in remodeling sites.

Conclusions: Cinacalcet HCL well suppressed bone remodeling and turnover, but effectively increased bone formation due to minimodeling in cancellous bone in these patients.

Disclosures: A. Yajima, None.

Minimodeling Reduces the Rate of Cortical Bone Loss in Patients with Secondary Hyperparathyroidism. A. Yajima¹, M. Mitobe^{*1}, I. Takahashi^{*1}, T. Nakayama^{*2}, O. Otsubo^{*1}, M. Inaba^{*3}, Y. Tominaga^{*4}, A. Ito^{*5}. ¹Nephrology, Towa Hospital, Tokyo, Japan, ²Orthopedic Surgery, Towa Hospital, Tokyo, Japan, ³Metabolism, Endocrinology, and Molecular Medicine, Osaka City University Graduate School of Medicine, Osaka, Japan, ⁴Transplant Surgery, Nagoya Second Red Cross Hospital, Nagoya, Japan, ⁵Ito Bone Histomorphometry Institute, Niigata, Japan.

Purpose: Secondary hyperparathyroidism causes progressive cortical thinning due to increased bone resorption at the endocortical surface, and increases cortical porosity due to increased resorption at the intracortical surface. However, patients with severe hyperparathyroidism do not always suffer from bone fractures, perhaps because of the increased

minimodeling occurring in cortical bone. Because bone formation by minimodeling has not yet been reported in cortical bone, we investigated the effects of cortical minimodeling on the reduction of the rate of bone loss.

Methods: Thirty-five patients with secondary hyperparathyroidism were enrolled. Remodeling and minimodeling parameters at the endocortical and periosteal surfaces as well as at the intracortical surface were measured. The relationships between remodeling parameters and minimodeling parameters at each surface were investigated by linear regression analysis. Cortical bone specimens were classified into three groups according to the values of cortical width and cortical porosity. The relationships of minimodeling parameters at the endocortical surface with cortical width and at the intracortical surface with cortical porosity were investigated.

Results: Some minimodeling parameters showed positive correlations with serum parathyroid hormone levels and remodeling parameters. Minimodeling bone volume at the endocortical surface was greater in the narrow cortical width group than in the wide cortical width group, possibly slowing the progression of cortical thinning. Minimodeling volume at the intracortical surface was greater in the high porosity group than in the low porosity group, possibly slowing the progression of enlargement of the intracortical resorption spaces. Minimodeling of the periosteal surface was found in one specimen.

Conclusions: The results revealed enhanced cortical minimodeling in patients with secondary hyperparathyroidism, possibly representing the reduction of the rate of cortical bone loss.

Disclosures: A. Yajima, None.

Bone Loss Following Small Bowel Transplantation. K. S. Awan^{*1}, J. M. Wagner^{*1}, D. Martin^{*2}, D. L. Medich^{*1}, S. Perera^{*3}, K. Abu Elmagd^{*2}, S. L. Greenspan¹. ¹Medicine, University of Pittsburgh, Pittsburgh, PA, USA, ²Department of Surgery, UPMC Thomas E. Starzl Transplantation Institute, University of Pittsburgh, Pittsburgh, PA, USA, ³Medicine/ Biostatistics, University of Pittsburgh, Pittsburgh, PA, USA.

Little is known about the impact of small bowel transplantation (SBTx) on skeletal integrity. We compared bone mineral density (BMD, Hologic Discovery A) in 81 patients who had undergone SBTx (43 \pm 2 years old, average SBTx 2.2 years before, 65% women) with 51 small bowel controls (SBCon), with similar small bowel diseases (47 \pm 13 years old) awaiting transplantation matched for age and gender. In addition to SBTx, surgery could include transplantation of the liver, pancreas, and stomach. Following SBTx, patients receive tacrolimus, supplementary calcium and vitamin D and bisphosphonates if appropriate. BMI was similar for the 2 groups (SBTx 22.7 ± 0.5 kg/m² vs. SBCon 23.1 ± 0.8 kg/m²). Compared with the SBCon, the SBTx group had significantly lower absolute BMD and Z-scores at the hip and femoral neck without differences noted at the spine (Table). 25 hydroxy vitamin D levels were similar in SBTx patients compared to SBCon (17.4 ± 1.5 vs. 21.1 ± 1.9 ng/dl) as were levels of serum calcium (8.9 ± 0.1 vs. 8.9 ± 0.1 mg/dl) and parathyroid hormone (60.5 ± 9.5 vs. 81.6 ± 11.0 pg/ml). Twenty three patients were followed with BMD's prospectively; nine patients before and after transplantation (Pre to Post: mean 1.3 years follow-up); fourteen patients after transplant (Post: mean 1.8 years average follow-up). Bone loss (percent change in g/cm²) was greatest in the patients who were followed through transplantation surgery (Pre to Post), with an average bone loss of 15% at the hip, compared to patients followed after transplantation (Post). There were no significant changes in levels of 25 hydroxy vitamin D, calcium, or parathyroid hormone. We conclude that patients undergoing SBTx have significant bone loss, primarily at the hip, occurring within the first year post transplant despite preventive measures with calcium, vitamin D and bisphosphonates.

Bone Mineral Density in SBTx and SBCon Patients (Table as Mean \pm SEM.)

	Lumbar Spine	Total Hip	Femoral Neck
Cross-sectional			
SBTx Z-score (SD)	-1.3 \pm 0.2**	-1.5 \pm 0.1**	-1.4 \pm 0.1**
SBCon Z-score (SD)	-0.5 \pm 0.3	-0.7 \pm 0.2**	-0.7 \pm 0.2**

Interest of Platelet-derived Products for Bone Repair. L. Begot^{*1}, C. Doucet^{*2}, I. Ernou^{*2}, F. X. Gunepin^{*3}, C. Laplace-buihle^{*4}, J. J. Lataillade^{*2}, X. Holy¹. ¹Histology and Tissue Repair, IMASSA, Brétigny sur Orge, France, ²Département Recherches, CTSA, Clamart, France, ³Service de Chirurgie Orthopédique, HIA Percy, Clamart, France, ⁴Imagerie, Généthon, Evry, France.

The French Army Hospitals have to treat a high number of patients presenting lesions with large loss of bone substance. The size of defects, rendering the bone auto graft strategy unsuitable, suggests a stem cell therapy approach. Progress in tissue engineering make it possible to conceive the development of macroporous ceramic bone substitutes combined to Mesenchymal Stem Cells (MSC) for filling in bone defects. This approach needs cell cultures and implantation in clinical conditions. As platelets are a source of growth factors, Platelet-rich plasma (PRP) could be used as substitute for Foetal Calf Serum (FCS) in cultures and to prepare a platelet-derived Glue (PG) mixture interesting for its properties of adhesiveness, malleability and haemostasis. In this work, we studied the effect of the proliferation and differentiation of MCS in presence of PRP products.

PRP was obtained by apheresis collection and processed for platelet activation to stimulate growth factor release. First, human marrow-derived MSC were isolated and expanded in a medium with 10% FCS or 10% PRP through a process of subculturing. The ability of PRP to enhance MSC proliferation was investigated by measuring cell numbers at consecutive passages, by characterizing MSC phenotype (CD45⁺, CD90⁺, CD105⁺, CD73⁺, CD13⁺) and by performing in vitro osteogenic evaluation (alkaline phosphatase activity, Von Kossa staining, osteocalcin detection). Second, proliferation, survival differentiation were evaluated in glue. Finally, we compared the biocompatibility and functionality of MSC or osteoblastic precursors loaded on bio-ceramics in a mice orthotopic implantation model in presence or not of PG.

Our results showed that PRP medium was considerably more effective in stimulating MSC proliferation than FCS one without affecting their phenotype. Furthermore, MSC cultured with PRP maintained their differentiation properties. MSC and osteoprogenitors were able to proliferate at the surface and within the bio-ceramic in presence of glue. In vitro and in vivo experiments demonstrated that osteogenic differentiation of MSC was improved when PG was associated with the hybrid implant. Osteoblastic precursors appeared to be better candidates than MSC regarding their long term in vivo survival in mice.

In conclusion, our data show that for ex vivo expansion of human MSC prior to transplantation, PRP could efficiently replace FCS and that the PG could be a powerful tool in bone repair. We suggest that PRP biotechnology should be useful in combination with MSC for bone reconstructive cellular therapy.

Long-term Follow up of Bone Mineral Density, Bone Turnover Markers and 25-hydroxyvitamin D in Bone Marrow Transplant Survivors. B. Buehring^{*1}, D. Krueger¹, W. Longo^{*2}, B. Flynn^{*2}, N. Binkley¹. ¹University of Wisconsin Osteoporosis Clinical Research Program, Madison, WI, USA, ²University of Wisconsin Blood and Marrow Transplant Program, Madison, WI, USA.

Increasing data are available showing that long-term bone marrow transplantation (BMT) survivors have deficits in bone mineral density (BMD) with consequent increased fracture risk. As the numbers of BMT recipients are increasing and survival rates improve, the impact of decreased BMD and increased fracture risk on morbidity and mortality also rises. Data defining the skeletal effects of BMT beyond six months post transplantation are limited. As such we report twelve month BMD data as well as six month bone metabolism parameters and 25OH vitamin D [25(OH)D] levels in BMT survivors.

A subset of 15 long-term BMT survivors with hematologic malignancies from a prospective trial documenting BMT effects on skeletal status were used to obtain these data. This sample of eight women and seven men, mean age 40.8 ± 1.6 years, had BMD measured at the lumbar spine (LS), total proximal femur (TF), and femur neck (FN) on a Lunar Expert (Madison, WI) densitometer at baseline, 100 days, six months and one year post transplant. 25(OH)D, osteocalcin (Oc), bone specific alkaline phosphatase (BSAP) and n-telopeptide of type 1 collagen (NTx) were measured at similar time points.

BMD decreased (p<0.01) in all measured regions. TF and FN declined by 10% and 8% respectively at three months and were reduced 12% and 9% at one year. LS BMD was 9% lower than baseline after 12 months. At time of BMT bone turnover was elevated, and subsequently at 30 days Oc was numerically but not statistically lower. At six months both BSAP and Oc were increased from baseline. NTx trended upwards (p=0.07) by 30 days and was not different from baseline after half a year.

Low vitamin D status was extremely common prior to BMT being present in 87% (13/15) and remained suboptimal at 6 months in 67%. No clinical fractures were reported within the first 12 months.

In conclusion, following BMT, despite elevation of bone formation, rapid and pronounced bone loss occurs which persists at one year. 25(OH)D levels were low before transplantation and remained low. Femur BMD results are comparable to other studies, however only minimal loss in LS BMD has been reported elsewhere. Although no clinical fractures were reported in the first year post transplantation, these data suggest BMT patients are likely at increased fracture risk. As such, skeletal status and quality of life assessments in these individuals now 5-7 years post transplantation is planned.

Severe Hypovitaminosis D, Associated with Hyperparathyroidism and Osteopenia/Osteoporosis in a Cohort of Long-Term Kidney Transplant Recipients with Excellent Kidney Function. R. Hayashi^{*1}, M. Stratilova^{*2}, M. Markell^{*1}. ¹Renal Diseases, SUNY Downstate Medical Center, Brooklyn, NY, USA, ²Renal Diseases, Westchester County Medical Center, Valhalla, NY, USA.

Vitamin D deficiency, manifested as decreased 25-OH vitamin D levels, is highly prevalent in hemodialysis patients, and may contribute to hyperparathyroidism and renal osteodystrophy. It is widely believed that successful kidney transplantation, which presumably restores the kidney's ability to activate vitamin D by 1-hydroxylase, will result in restoration of Vitamin D homeostasis, and Vitamin D supplementation is not routinely recommended. We measured 25-OH vitamin D levels in 24 long-term (mean time since transplant - 59.6±11.4 mos) kidney transplant recipients (KTR) with excellent function, mean creat 1.6±0.1 mg/dl. There were 14 women (51%), 80% Black or Hispanic, mean age 48.9±1.8 yrs. 60% were receiving tacrolimus and the rest cyclosporine, 80% were taking prednisolone. The mean 25-OH vitamin D level was 12.9±1.3 ng/ml (range 5-28, normal value >40 ng/ml). Only 1 pt had a value >25 ng/ml and 11 pts (46%) had values <12 ng/ml (severe deficiency). Mean intact PTH level was also elevated (150.6±28.4, range 20-624), with 12 pts (50%) having values >300. There was no relationship between 25-OH Vitamin D level and PTH level. Neither Vitamin D level nor PTH value were related to age, gender, race, time since transplant, creatinine, current calcium or phosphate value, hematocrit, albumin or use of activated vitamin D supplements (8 pts). Bone density scans were available for 6 patients with mean T scores of -2.33 in the L-spine and -1.54 in the femoral neck. We conclude, in our population of primarily minority race KTRs: 1. Vitamin D deficiency is universally prevalent, with severe deficiency occurring in 46% of pts. 2. Persistent hyperparathyroidism is present in over 50% of pts despite the long time since transplant, and excellent kidney function. 3. The degree to which vitamin D deficiency contributes to persistent hyperparathyroidism and osteoporosis, in this population with multiple risk factors, is not known. 4. Hypovitaminosis D is prevalent in a Blacks and Hispanics, in general, and whether this degree of deficiency exists in a Caucasian population of KTR's should be studied. 5. The appropriate dose of Vit D remains to be established, as pts on maintenance active vitamin D preparations in this population had PTH levels that were similar to those not receiving it. It is possible that patients should receive 25-OH Vitamin D as well as the active form is. 6. Long term studies examining repletion of Vitamin D and its effect on the accelerated cardiovascular disease & chronic kidney fibrosis that affects the KTR population are suggested.

Effect of Risedronate on Bone Loss Associated with Liver Transplantation. S. Guadalix^{*1}, M. Gomez-Juaristi^{*1}, G. Martinez¹, C. Vargas^{*2}, J. Meneu^{*3}, A. de Lozar^{*2}, S. Azriel^{*1}, E. Jodar^{*1}, E. Moreno^{*3}, F. Hawkins¹. ¹Endocrinology Service, University Hospital 12 de Octubre, Madrid, Spain, ²Biochemistry Service, University Hospital 12 de Octubre, Madrid, Spain, ³Digestive Surgery, University Hospital 12 de Octubre, Madrid, Spain.

Background: Liver transplantation (LTx) increases the risk of osteoporosis and osteoporotic fractures. Most of the bone loss usually occurs in the first 6 months after transplantation, but many patients remains with low bone mass in the long term. The best preventive measure in this setting is being investigated. Objective: To analyse the effect of weekly risedronate on bone loss in patients with low bone mass after LTx. Patients and Methods: we show preliminary results of a randomized open-label single center prospective study. Forty-three patients (32 males, 11 females; mean age 54.2 ± 11.2 years) with LTx and low bone mass (lumbar and/or femoral T-score <-1) have been included so far. After transplantation (mean time 31.4 ± 15.4 days) patients were randomly assigned to one of two treatment arms: Group 1 (n=21) received risedronate (35 mg orally, once weekly) plus calcium (1000 mg/day) and vitamin D (800 IU); Group 2 (n=22) received calcium and vitamin D at same doses. Primary endpoint is BMD change at lumbar spine (L1-L4) and femoral regions (measured at baseline, 6 and 12 months after LTx; Hologic QDR 4500 densitometer); secondary endpoints include biochemical markers of bone turnover (serum β-CTX and PINP, urinary D-Pyr), and calcitropic hormones (PTH, 25-OH vitamin D) measured at baseline, 3, 6 and 12 months after LTx. Baseline spine X-rays were obtained in all patients. Results: No differences were found in baseline characteristics between groups. At baseline 46.6% of patients had densitometric criteria of osteoporosis, and 16.2% had prevalent vertebral fractures. At 6 months, spine BMD increased in Group 1 (+2.1 ± 6.8 %), and decreased in Group 2 (-0.6 ± 4.6%). Changes were similar at femoral neck and total hip in both groups. Baseline bone resorption markers were increased in 40.5% (β-CTX) and 56% (D-Pyr) of patients. Ninety-three of patients showed vitamin D insufficiency at entry in the study. In Group 1, a significant decrease of serum β-CTX was observed after 3 months (p=0.032) and 6 months (p=0.007). Treatment was well tolerated in both groups. Conclusions: Preliminary data of this prospective trial suggest that risedronate could be effective in preventing the natural course of bone loss associated with liver transplantation.

An Experimental Rabbit Model of Lunate-like Osteonecrosis: Is Transplantation of Bone Marrow Effective for Remodeling of Necrotic Bone. T. Ogawa*, T. Ishii*, H. Mishima, N. Ochiai*. Orthopaedic Surgery, University of Tsukuba, Tsukuba, Japan.

Introduction Lunate malacia (Kienbock disease) is a progressive wrist disorder characterized by osteonecrosis of the lunate. We decided to investigate whether transplantation of bone marrow (BM), a less invasive procedure, would be an effective treatment. There was no animal Kienbock disease model; so, we have developed an experimental rabbit model of lunate-like osteonecrosis using a rabbit's 4th tarsal bone. We investigated the validity of the model and the usefulness of BM transplantation for remodeling of necrotic bone.

Material and Method Thirty six adult Japanese white rabbits were used. The bilateral 4th tarsal bones were removed and soaked in liquid nitrogen for 5 minutes. After the freezing, the bone was inserted in subcutaneous of the back of the rabbit. The total number of the necrotic bone was seventy two. They were divided into three groups, BM transplantation (T), drilling (D) and control (C). In the group T, three drill holes were made cortical surface of the tarsal bone with Kirschner wire, cartilage surface were remained intact, and after subcutaneous insertion they were filled with BM from iliac crest. In the group D, three drill holes were also made but no BM transplantation. In the group C, the tarsal bones were only soaked in liquid nitrogen. Fluorochrome label (Calcein) was injected subcutaneously at 8 days and 2 days before sacrifice. We sacrificed nine rabbits (three from each group), obtaining six specimens of necrotic bone from each group, at 2, 4, 8 and 12 weeks. Bone morphological study (Toluidine-blue), ALP staining and TRAP staining were made, using the undecalcified sections.

Results We compared histological finding of the ratio of the fluorochrome-labeled trabecular bone surface in each group. Group C and D had poor new bone formation from 2 to 12 weeks. In group T, new bone formation, were significantly higher than in the other groups at 4, 8 and 12 weeks (Fig.1). TRAP-positive multinucleated cells were found in group T at 8 and 12 weeks more than another groups. Qualitative analysis, there were found ALP-positive osteoblast-like cells in group T at 4, 8 and 12 weeks more than another groups.

Discussion This study established a new animal necrosis model similar to human lunette, in terms of avascular necrosis and surrounding with cartilage and cortical bone. Using this model we showed that BM transplanted might be effective in new bone formation.

Effects of Immunosuppressants on Bone Metabolism (Bone Mineral Density, Bone Vitamin K Analogs, and Serum Osteocalcin and Calcium) in Rats. H. Wakabayashi¹, J. Kanda¹, A. Takahashi², K. Onodera³. ¹Clinical Pharmacotherapy, Niigata University of Pharmacy and Applied Life Sciences, Niigata, Japan, ²The Clinics of Dentistry for the Disabled, Tohoku University Dental Hospital, Sendai, Japan, ³Dental Pharmacology, Okayama University Graduate School of Medicine and Dentistry, Okayama, Japan.

This study was carried out to evaluate the effects of short-term administration of corticosteroids (hydrocortisone, prednisolone and dexamethasone) on bone metabolism. Growing rats were administered daily with the equiactive dose of corticosteroid (hydrocortisone: 20 mg/kg; prednisolone: 4 mg/kg; dexamethasone: 0.8 mg/kg) at 9 am for two weeks. No significant differences in bone vitamin K analogs (VKs), bone mineral density (BMD) and serum osteocalcin (OC) were observed both in the hydrocortisone-treated group and prednisolone-treated group compared with the control group, whereas significant decreases were observed in MK-4 (one of the VKs), BMD and serum OC of the dexamethasone-treated group compared with those in the control group. Furthermore, we also investigated about a preventative effect against bone loss caused by short-term injection of dexamethasone, using combined administration of alfacalcidol, risenedronate, and menatrenone with dexamethasone. Combined administration of risenedronate and menatrenone with dexamethasone for two weeks prevented the reduction of BMD induced by dexamethasone, especially the administration of risenedronate and menatrenone at 5 pm was more effective to prevent the bone loss than the administration at 9 am. The degree of bone loss induced by drugs has been considered to be dependent on drug type

(corticosteroid type) and dose, duration of treatment, age and sex of recipients. Additionally, the present results suggest that the degree of bone loss induced by drug is dependent on the drug administration time.

$\alpha 5$ Integrin Association with Cx43 Regulates the Function of Osteocyte Hemichannels in Response to Shear Stress. A. J. Siller-Jackson¹, S. Burra¹, S. E. Harris², L. F. Bonewald³, E. Sprague⁴, J. X. Jiang¹. ¹Biochemistry, University of Texas Health Science Center, San Antonio, TX, USA, ²Periodontics, University of Texas Health Science Center, San Antonio, TX, USA, ³Oral Biology, School of Dentistry, University of Missouri, Kansas City, MO, USA, ⁴Radiology, University of Texas Health Science Center, San Antonio, TX, USA.

Primary osteocytes and MLO-Y4 osteocyte-like cells express large amounts of connexin 43 (Cx43) which forms gap junctions and hemichannels. Our previous studies have shown that fluid flow shear stress (FFSS) induces the opening of hemichannels in MLO-Y4 cells. Analysis by gene microarray of MLO-Y4 cells showed elevation of $\alpha 5$ integrin with FFSS and inhibition with a gap junction/hemichannel inhibitor, a result further confirmed by Northern blot assay. $\alpha 5$ integrin blocking antibody significantly decreased FFSS induced dye uptake mediated by Cx43 hemichannels, suggesting a role for $\alpha 5$ integrin in FFSS regulation of Cx43 hemichannels. Immunostaining showed co-localization of $\alpha 5$ integrin with Cx43 not only on the cell surface but throughout the cell body and processes, becoming more pronounced when exposed to FFSS. Cx43 and $\alpha 5$ integrin were not co-localized with vinculin or paxillin, components of focal adhesions, suggesting that the association between Cx43 and $\alpha 5$ integrin is unrelated to the function of integrins in focal adhesions. Co-immunoprecipitation analysis showed the association of $\alpha 5$ integrin with Cx43. To determine the involvement of $\alpha 5$ integrin in Cx43 hemichannel function, $\alpha 5$ integrin siRNA was transfected into MLO-Y4 cells, which leads to a 90% reduction of $\alpha 5$ integrin levels. Interestingly, cellular localization was significantly altered in $\alpha 5$ integrin siRNA-treated cells with the disappearance of punctate expression of Cx43 on the cell surface. In fact, Cx43 was found outlining the entire cell surface border. FFSS applied to $\alpha 5$ integrin siRNA transfected MLO-Y4 cells resulted in the localization of Cx43 in punctate spots on the surface, although less prominent than in untransfected cells. More importantly, $\alpha 5$ integrin siRNA completely abolished hemichannel-mediated dye uptake induced by FFSS. Together, these results suggest that $\alpha 5$ integrin plays an essential role in the function of Cx43-hemichannels and is a likely mechanical sensor or tether that transmits mechanical stress to Cx43 hemichannels.

Mechanical Activation of β -catenin Is Enhanced After Caveolin-1 Knock-down. M. Ma¹, B. Sen¹, N. Case¹, Z. Xie¹, H. Jo², T. Gross³, J. Rubin¹. ¹Medicine, UNC, Chapel Hill, NC, USA, ²Emory/GaTech, Atlanta, GA, USA, ³Orthopaedics, U.Washington, Seattle, WA, USA.

Mechanical loading of bone initiates an anabolic, anti-catabolic pattern of gene response; some of this response may be attributed to induction of β -catenin responsive genes. Caveolin-1, a structural membrane protein, can sequester β -catenin. The skeletal phenotype of the caveolin-1 knock-out mouse is of increased trabecular and cortical bone. This suggested to us that the presence of caveolin-1 might limit the process of osteogenesis; indeed we have shown that delivery of siRNA targeting caveolin-1 (siCav) to stromal cells causes upregulation of Runx2 and osteix and suppression of RANKL. We therefore asked if an interaction of caveolin-1 with β -catenin might constrain mechanical stimulation of the osteoblast phenotype. For these experiments we plated CIMC-4 preosteoblast cells expressing caveolin-1 on BioFlex collagen plates. Application of 2%, 0.17 Hz substrate strain for 2 h followed by 2 h incubation induced a β -catenin gene response: WISP-1 rose to 1.86 ± 0.06 fold ($p < 0.05$), returning to baseline 6 h later. Other β -catenin target genes, Runx2 and osteoprotegerin, were not increased at 4 h after the strain protocol. Delivery of siCav (50 nM) caused an 80% reduction in cav-1 mRNA and >75% reduction in caveolin-1 protein compared to control siRNA (siSCR). After strain, at 4 h, +siCav cells showed not only an enhanced WISP-1 response, but also significant elevation of osteoprotegerin (+siCav+strain 1.7 ± 0.4 fold above +siCav-unstrained) and Runx2 (1.4 ± 0.15 fold increased). RANKL expression was repressed to < 0.4 that of unstrained controls, and was unaltered by siCav, indicating that RANKL repression did not involve caveolin-1. We next explored means of measuring β -catenin activation after mechanical stimulation. Strain caused an increase in cytoplasmic β -catenin levels as assayed by Western after 3 h. Though the TopFlash β -catenin reporter was activated by LiCl in CIMC-4 cells (3.1 ± 1.7 fold above untreated cells), we have not yet shown that strain induces TopFlash activity. However, siCav treated cells showed increases in basal cytoplasmic β -catenin, and basal and strain stimulated TopFlash activity were increased by 2.14 and 2.5 fold respectively. Our data indicates that a reduction in caveolin-1 is accompanied by an increase in the β -catenin pool accessible to exogenous stimuli. This suggests that not only can caveolin-1 limit incoming mechanical signals by sequestering the actionable β -catenin pool, but also that mechanical activation of β -catenin may involve its release from the membrane.

Nmp4/CIZ Contributes to Fluid Shear Stress Induced MMP-13 Gene Induction in Osteoblasts. K. Panyayong¹, J. Yang², F. M. Pavalko³, R. Gerard-O'Riley³, J. P. Bidwell¹. ¹Department of Oral Biology and Occlusion, Faculty of Dentistry, Prince of Songkla University, Hatyai, Songkhla, Thailand, ²Department of Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA, ³Department of Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN, USA.

Mechanical force or load impacts bone remodeling. The expression of matrix metalloproteinase-13 (MMP-13), involved in bone turnover, is elevated in stretched MC3T3-E1 osteoblast-like cells. Strain-mediated forces on bone move fluid through the canalicular-lacunar network resulting in fluid shear stress (FSS) on the membranes of bone cells initiating remodeling. Although the nuclear events mediating putative FSS-induced changes in osteoblast MMP-13 transcription are unknown, previous studies with osteoblasts suggest an overlap between osteoblast FSS- and PTH-induced signal response pathways. MMP-13 PTH response is regulated by a 110 bp 5' regulatory region, conserved across the mouse, rat, and human genes, that supports the binding of numerous transcription factors including Runx2, c-fos/c-jun, Ets-1, and nuclear matrix protein 4/cas interacting zinc finger protein (Nmp4/CIZ), a nucleocytoplasmic shuttling trans-acting protein that attenuates PTH-driven transcription. Nmp4/CIZ also binds p130^{cas}, an adaptor protein implicated in mechanotransduction. Our objective was to determine whether Nmp4/CIZ contributes to FSS-induced changes in MMP-13 transcription. MC3T3-E1 cells were transfected with MMP-13 promoter-reporter or Nmp4/CIZ promoter-reporter constructs, then exposed to FSS (12 dynes/cm², 1-5 hr). MMP-13 mRNA levels and Nmp4/CIZ-DNA binding activity were analyzed by real-time PCR and gel shift assays, respectively. Western analysis of nuclear, membrane, and cytoplasmic fractions was used to assess FSS-induced changes in p130^{cas} subcellular distribution. We observed that FSS (3-5 hr) increased MMP-13 promoter-reporter activity approximately 2-fold in MC3T3-E1 cells attended by a comparable increase in mRNA expression. This was accompanied by a decrease in Nmp4/CIZ binding to its cis-element within the PTH response region, the mutation of which abrogated FSS response. Interestingly, FSS enhanced Nmp4/CIZ promoter activity. FSS also induced p130^{cas} nuclear translocation. We conclude that the PTH regulatory region of MMP-13 also contributes to FSS response and that Nmp4/CIZ plays similar but distinct roles in mediating hormone- and FSS-driven induction of MMP-13 in bone cells.

The Presence of p120-Catenin in Osteocytes and Other Bone Cells. H. W. Sampson, A. R. Parrish*, A. C. Dearman*, W. E. Zimmer*. Systems Biology and Translational Medicine, TAMHSC_College of Medicine, College Station, TX, USA.

P120 is a member of the armadillo supergene family which has been reported to bind cadherins at a juxtamembrane domain and regulate their cell surface trafficking. It can become cytoplasmic regulating activities of Rac, Rho and Cdc42; thus functioning in maintenance of cell shape and enhanced cell motility. It can also enter the nucleus where it is considered to possibly modulate Wnt/ β -catenin/TCF signaling in a synergistic manner in the nucleus to activate matrilysin expression. The purpose of this study was to document the presence of p120-catenin in bone cells. We used conventional RT-PCR, Western blot, immunohistochemical and fluorescent immunohistochemistry in conjunction with light and fluorescent microscopy and confocal microscopy to study in situ bone cells and also MLO-Y4 osteocyte-like cells in culture (a generous gift from Dr. Lynda Bonewald, University of Missouri-Kansas City). The p120-catenin antibody used was a monoclonal antibody at 1:100 dilution and the biotinylated secondary antibody, was incubated in conjugated streptavidin horseradish peroxidase followed by Betazoid 3, 3' Diaminobenzidine. In the case of the fluorescent studies the secondary antibody was Alexa Fluor 488 goat anti-mouse IgG (molecular probes, OR). The in vivo studies were conducted on mouse tibia and all experimental procedures were in compliance with the guiding principles in the "Care and Use of Animals" as published in the Am. J. Physiol., and were approved by the TAMU animal care and oversight committee. All methods used indicated a high concentration of p120 RNA and protein in osteocytes, both in situ and in culture, in osteoblasts, and in chondrocytes of the resting zones and hypertrophic zones of the mouse growth plate. All studies indicated a cytoplasmic or sub-membrane localization. We have demonstrated, for the first time, the presence of p120-catenin in osteocytes and other bone cells. This is an adhesion molecule whose importance in cell signaling is becoming more and more apparent with time and with its ability to move from the plasma membrane, to the microtubule system of the cytoplasm and to the nucleus is positioned to play an important role in cell development and possibly in mechanotransduction.

Disclosures: H.W. Sampson, None.

The Effects of Compressive Loading on Matrix Production by Osteoblastic Cells Cultured in Polyurethane Scaffolds. A. Sittichokechaiwut, A. Scutt, G. C. Reilly. Engineering Materials, University of Sheffield, Sheffield, United Kingdom.

Bone tissue engineering constructs are composed of scaffold materials and matrix synthesizing cells. It is likely that mechanical stimulation of tissue engineered bone will enhance matrix synthesis, however, the underlying mechanisms by which osteoblasts respond to their mechanical environment in 3-D are poorly understood. The aims of this

study are to examine the effects of cyclic compressive loading on bone matrix production in 3-D scaffolds over 20 days of culture. 3-D polyurethane scaffolds with an average pore size 150 micrometres were cut into cylinders of 10 mm diameter and 10 mm height. Scaffolds were seeded with MLO-A5 osteoblastic cells (Kato et al. JBMR 2001), kindly donated by Dr. L. Bonewald, at densities of 2.5×10^5 per scaffold. Cell-seeded scaffolds were dynamically loaded in compression at 1Hz, 5% strain in a biodynamic chamber (BOSE/Electroforce3200). Loading was applied for 2 hours per day at day 5, 10 and 15 of culture. Between loading, scaffolds were cultured in an incubator in standard conditions for up to 20 days. Cell-seeded scaffolds were assayed on days 10, 15 and 20 of culture for scaffold stiffness (Young's modulus of elasticity), cell viability by MTS assay, calcium by alizarin red staining and collagen content by sirius red staining. Cells survived in all loaded samples, final relative cell number was increased at day 10 but slightly lower at days 15 and 20. Calcium content increased in all loaded samples and was significantly higher on day 20 ($p < 0.01$, t-test) compared with non loaded samples. Total collagen also increased significantly at day 15 and 20 in loaded samples compared with non loaded samples ($p < 0.02$). Scaffold stiffness was higher in loaded samples at the end of experiment (~ 39 vs 62 Pa, $p < 0.01$). In conclusion, although the number of viable cells was lower in loaded samples after 10 days, the amount of calcium, collagen and scaffold stiffness was greater, indicating the formation of new extracellular matrix within the constructs. Therefore, cyclic compressive loading at 5% strain for 2 hours every 5 days has the potential to produce more bone matrix than static culture conditions.

Calibration of the ZETOS Bone Loading System. S. Garcia^{*1}, H. L. Ploeg^{*1}, E. L. Smith². ¹Mechanical Engineering, University of Wisconsin, Madison, WI, USA, ²Population Health Sciences, University of Wisconsin, Madison, WI, USA.

An ex vivo bone culture and loading system, ZETOS, has been developed to study morphological and physiological responses of trabecular bone (10 mm diam., 5 mm ht.). A piezoelectric actuator (PZA) expands, compressing the specimen while measuring expansion and load. Calibration was performed when manufactured, but the system's compliance changes with time, requiring recalibration. The purpose of this study was to develop and validate a recalibration protocol for the ZETOS bone loading system. Ten aluminum (alloy 7075-T6) reference bodies (RBs) of known stiffness (40 to 2000 MPa, trabecular bone stiffness range) were designed using finite element analysis (FEA) and manufactured. Geometry was verified using a coordinate measuring machine, at 72 points throughout the RB, showing uniform surfaces (SD = 2.34 μ m). Calibration of the unloaded PZA expansion transducer was performed with a fiberoptic sensor. All RBs were tested in ZETOS, recording force and expansion. A FEA model duplicated the physical compression setup of the RBs in ZETOS. Stiffness was found for each RB by dividing total reaction force by displacement. FEA was validated with physical testing in an Instron by compressing six RBs on a setup replicating the ZETOS system. RB deformation was measured using a 10x microscope and calibrated digital camera. Percent differences of FEA-determined stiffness were found with respect to stiffness from Instron testing. ZETOS force and expansion, and compression from FEA were integrated in a calibration table. For verification of the calibration table, all RBs were tested in ZETOS, as well as 3 metal springs of unknown stiffness, comparing these results to those from the FEA. FEA results had a mean percent difference with respect to Instron testing of 5.08%. The results from the Instron measurements were used to validate the FEA. Verification of RB stiffness determined by ZETOS after calibration resulted in an overall mean difference from the FEA of 1.10%. Results from testing of the 3 metal springs found a mean percent difference in stiffness, compared to their FE models, of 2.25%.

Calibration of the ZETOS loading system is important to assure stiffness measurement accuracy. FEA was an essential tool for RB design and calculated stiffness. The combination of physical testing and FEA enabled a precise determination of RB stiffness. Test results validated the FEA, which provided results that could not be physically measured to generate the calibration table. The successful development of a recalibration protocol of the ZETOS assures accuracy of trabecular bone stiffness measurements. Jones, D.B. et al. Identification of Genes that May Modulate the Musculoskeletal System's Early Response to Unloading. M. E. Squire¹, M. Monaghan^{*2}, L. R. Donahue³, A. Dhundale^{*2}, C. T. Rubin⁴, S. Judex⁴. ¹Biology, University of Scranton, Scranton, PA, USA, ²Center for Biotechnology, Stony Brook, NY, USA, ³Jackson Laboratories, Bar Harbor, ME, USA, ⁴Biomedical Engineering, Stony Brook University, Stony Brook, NY, USA.

Bone and skeletal muscle are both capable of remodeling their structures to accommodate altered levels of mechanical loading. In the absence of functional loading, musculoskeletal tissue is lost at rates that can exceed 2% per month. Based on the functional relationship between bone and muscle, it is plausible that similar molecular mechanisms may be involved in the early stages of their responses to altered mechanical loading. In this study, we examined gene expression in bone and muscle following short-term hindlimb unloading, with a particular interest in genes that were differentially regulated in both tissues. Total RNA was extracted from the whole proximal tibia and soleus of adult (4 mo) female F1 crossbred (BALB/cByJ x C3H/HeJ) mice following 4d of normal cage activity (control) or tail suspension (disuse) (n=5 each). Reference samples were hybridized with either a control or disuse sample onto custom oligonucleotide arrays (n=5 per group) containing 16,442 ESTs (70mer oligos) from the Operon mouse genome library (v2). Following normalization and filtering, 164 (tibia) and 115 (soleus) differentially regulated genes were identified (p<0.05), with only 3 genes common to both lists. Further classification of affected genes based on their "biological function" annotations revealed 17 genes (tibia; 7 up- and 10 down-regulated) and 14 genes (soleus; 6 up- and 8 down-regulated) that belonged to the "cell communication" category. Some of these identified genes have known roles in classic signaling pathways or are known intracellular signal transducers in bone or skeletal muscle. In the "response to stimulus" category, 14 genes (tibia; 6 up- and 8 down-regulated) and 8 genes (soleus; 2 up- and 6 down-regulated) were significantly affected. This list included one gene that was down-regulated 1.2 and 2.0 fold in the tibia and soleus, respectively, following unloading. In addition, one significantly down-regulated gene in the tibia (-1.4 fold) encodes for a receptor protein that has been identified previously as a responder to mechanical stimuli in osteoblasts and osteocytes. Current qPCR studies will validate these findings. Taken together, the results suggest that although some genes may mediate the early response of both tissues to mechanical unloading, the vast majority of genes involved are likely distinct across tissues. Future analyses will be needed to examine whether the lack of common genes is due a difference in molecular mechanisms or a difference in the temporal response in bone vs. muscle.

Ultrasound Induces Hypoxia-Inducible Factor-1 Activation and iNOS Expression Through Integrin/ILK/Akt Pathway in Cultured Osteoblasts. C. Tang¹, W. Fu^{*2}, D. Lu^{*3}, T. Tan^{*1}, R. Yang⁴. ¹Pharmacology, China Medical University, Taichung, Taiwan, ²Pharmacology, National Taiwan University, Taiwan, Taiwan, ³Pharmacology, National Taiwan University, Taipei, Taiwan, ⁴Orthopaedics, National Taiwan University & Hospital, Taipei, Taiwan.

It has been shown that ultrasound (US) stimulation accelerates fracture healing in the animal models and in clinical studies. Nitric oxide (NO) is a crucial early mediator in mechanically induced bone formation. Here we found that US stimulation increased nitric oxide (NO) formation and the protein level of inducible nitric oxide synthase (iNOS). US-mediated iNOS expression was attenuated by anti-integrin $\alpha 5 \beta 1$ or $\beta 1$ antibodies but not anti-integrin $\alpha v \beta 3$ or $\beta 3$ antibodies or focal adhesion kinase mutant. Integrin-linked kinase (ILK) inhibitor (KP-392), Akt inhibitor or mammalian target of rapamycin (mTOR) inhibitor (rapamycin) also inhibited the potentiating action of US. US stimulation increased the kinase activity of ILK and phosphorylation of Akt and mTOR. Furthermore, US stimulation also increased the stability and activity of HIF-1 protein. The binding of HIF-1 α to the HRE elements on the iNOS promoter was enhanced by US stimulation. Moreover, the use of pharmacological inhibitors or genetic inhibition revealed that both ILK/Akt and mTOR signaling pathway were potentially required for US-induced HIF-1 α activation and subsequent iNOS up-regulation. Taken together, our results provide evidence that US stimulation up-regulates iNOS expression in osteoblasts cells by a HIF-1 α -dependent mechanism involving that activation of ILK/Akt and mTOR pathways via integrin receptor.

Bone Density and Body Composition Values in Healthy Japanese Girls. T. Aizawa^{*1}, M. Konishi^{*2}, Q. Zhou². ¹Dept of Health and Sport Sciences, Mukogawa Women's University of Letters, Nishinomiya, Kyoto, Japan, ²GE Healthcare Asia, Shanghai, China.

Reference values for bone mineral density (BMD) and soft tissue assessment with dual-energy X-ray absorptiometry (DXA) provide valuable clinical information to help physicians evaluate children with growth disorders and metabolic diseases. As reference values can vary among populations in different geographic regions, it may be advisable to establish region-specific reference values. We measured the total body BMD and body composition in 557 Japanese healthy girls (ages 12 to 19 yrs) with a Lunar DPX-NT (GE Healthcare) densitometer. BMD increased rapidly (4%/year) as did height, bone area (BA),

and fat free mass (FFM) between ages 12 and 14 years, presumably approximating the end of puberty. Another period of rapid increase was found at from ages 16 to age 17 years, when both BMD and BA increased at 4%/year, although height remained stable. On average, BMD values increase from age 12 to 18 at 3%/year, while BA and FFM increased by about 3%/year and 4%/year respectively. There was a strong correlation between bone mineral content (BMC) and lean mass (LM) ($r=0.734$, $p<0.01$), as well as between bone area and height ($r=0.786$, $p<0.01$) over the entire age range. Between the ages of 12 and 19, BMD, bone area and FFM increased rapidly in this population. BMD values at age 18 and 19 for these Japanese girls were slightly higher values previously reported for Caucasian girls of that age.

Age group	N	Height (cm)	Weight (kg)	BMD (g/cm ²)	BA (cm ²)	FM (g)	FFM (g)
12	13	150.7	42.9	0.996	1714	12166	32249
13	44	155.8	48.5	1.040	1885	11920	35971
14	41	157.5	52.4	1.084	1957	15025	36407
15	52	158.1	52.1	1.100	1958	15190	36265

Bone Mineral Density, Body Composition, Body Mass Index and Height in Children Treated for Acute Lymphoblastic Leukemia. M. Ansari^{*1}, N. Alos², A. Moghrabi^{*1}. ¹Pediatrics-Hematology-oncology service, CHU Ste-Justine and University of Montreal, Montreal, PQ, Canada, ²Pediatrics-Endocrinology service, CHU Ste-Justine and University of Montreal, Montreal, PQ, Canada.

Short stature, obesity and bone morbidity are commonly reported as late effects of therapy for childhood with acute lymphoblastic leukemia (ALL). We evaluated height, body mass index, body composition and lumbar bone mineral density in children after treatment for ALL.

Patients and Methods: Between January 1997 and August 2002, a cross-sectional study was done in children in remission treatment for ALL, using the Dana-Farber-Cancer-Institute (DFCI) consortium protocol 95-01. Lumbar bone mineral density (BMD) and body composition were measured by dual energy X-ray absorptiometry (DEXA). Height, body mass index (BMI), lumbar BMD (areal and volumetric) and body composition (fat mass and lean mass) were converted to z scores, adjusting for age and sex.

Results: 132 patients were enrolled; 99 were evaluated using DEXA. Median age at diagnosis was 3.8 years (0.5 - 12.6 years). Mean follow-up from end of therapy was 3.2 years (0.6 to 7.1 yrs). There was no significant difference in population characteristics between risk groups (Standard and High Risk, SR/HR), including age, height, BMI,

percentage Body Fat (% Fat) and Lean Body Mass (LMB) Z score. The mean Z score for % Fat was -0.715 ± 1.25 SD and the mean Z score for LMB was 1.36 ± 1.06 SD. There was no bone fracture or back pain reported. The mean volumetric lumbar spine BMD Z-score was 0.31 ± 0.97 SD for all patients; 0.36 ± 1.0 SD for HR (n=39) and 0.28 ± 0.95 SD for SR patients (n=60) (p=0.69). No patients had a volumetric lumbar spine BMD (g/cm³) Z-score of less than -2 SD.

Conclusions: Children with ALL treated with DFCl protocol 95-01 in our institution have little side effects related to growth, body composition and BMD, at a median interval of 3.2 years post end of therapy. Longer follow up is needed to confirm these results as well as comparison to cohorts using different protocol therapies.

Disclosures: N. Alos, None.

T514

Bone Ultrasonography in the Longitudinal Monitoring of Bone Status in Patient with Rett's Syndrome. S. Gonnelli¹, C. Caffarelli¹, J. Hayek², A. Montagnani¹, A. Cadirni¹, L. Tanzilli¹, B. Franci¹, B. Lucani¹, R. Nuti¹.

¹Institute of Internal Medicine, University of Siena, Siena, Italy, ²Department of Child Neurology and Psychiatry, University of Siena, Siena, Italy.

Rett syndrome, an X-linked neurodevelopmental disorder primarily affecting girls, is frequently characterized by osteopenia with a consequent increased risk of fragility fractures.

The aim of the study was to evaluate the usefulness of Quantitative Ultrasound (QUS) at phalanges in the assessment and monitoring of bone status in Rett patients.

In 109 Rett girls (10.1 ± 6.1 yrs) and in 101 age-matched controls, serum calcium, bone alkaline phosphatase, parathyroid hormone (PTH), 25-hydroxyvitamin D (25OHD) and QUS parameters at phalanges by Bone Profiler-IGEA (amplitude dependent speed of sound: AD-SoS and bone transmission time: BTT) were measured at baseline and then yearly for 3 years.

At baseline both QUS parameters and 25OHD levels were significantly lower in Rett patients than in controls. Serum 25OHD was inversely correlated with serum PTH ($r = -0.38$; $p < 0.05$) and BTT Z-score ($r = 0.37$ $p < 0.01$). BTT Z-score was significantly lower ($p < 0.05$) in the patients with 25OHD serum levels ≤ 9 ng/ml (-2.49 vs -1.58). Multiple regression analysis showed that BTT was significantly influenced by 25OHD levels. Eighty-two Rett patients completed the 36 month longitudinal study. During the longitudinal study the patients who at baseline were non-ambulatory presented a worsening of their bone status, and BTT and AD-SoS Z-score presented the tendency to markedly decrease. In contrast the BTT and AD-SoS of patients with severe or mild-moderate ambulatory impairment showed mild changes. At years 2 and 3 the difference in Z-score between the non-ambulatory group and the mild-moderate group was significant for both AD-SoS and BTT. At the end of the study period no significant differences in AD-SoS or BTT Z-scores were observed between Rett patients of the non-ambulatory group and those with severe ambulatory impairment. The AD-SoS Z-score at the end of the study period resulted significantly influenced by the changes in ambulatory performance and the use of anticonvulsant therapy.

In conclusion this prospective study suggests the usefulness of QUS parameters at phalanges, namely AD-SoS and BTT, in the monitoring of bone status in Rett patients. More specifically we found that in Rett patients QUS parameters are markedly decreased and that ambulatory impairment and low levels of 25OHD play a key role in the progressive deterioration of bone status.

Disclosures: S. Gonnelli, None.

Prevalence of Osteopenia in Children with Early Juvenile Chronic Arthritis (JCA). L. Kroger¹, H. Kroger². ¹Paediatrics, Kuopio University Hospital, Kuopio, Finland, ²Orthopaedics, Kuopio University Hospital, Kuopio, Finland.

Children suffering from juvenile chronic arthritis (JCA) are at risk of developing osteoporosis due to inflammation, reduced/ limited physical activity and use of corticosteroids.

Because these children may have been suffering from inflammation a long time before seeking medical advice, we wanted to study whether bone mineral density (BMD) is already decreased at the time of diagnosis of JCA.

The material consisted of 52 consecutive patients, aged 5-15 yrs, admitted to the paediatric outpatient clinic in Kuopio University Hospital, Finland between 2004-6 and fulfilling the criteria of JCA. A total of 40 girls (77%) and 12 boys (23%) were included in the study. BMD was measured using dual X-ray absorptiometry (Lunar DPX-IQ). Results were expressed as bone mineral content (BMC; g) and BMD (BMC/ projected area; g/cm). To minimise the effect of bone size on BMD, apparent volumetric BMD (BMDvol, g/cm³) was calculated using a cylindrical model published earlier by Kroger et al.

The mean age was 10.8 yr for boys and 11.8 yr for girls (p= ns). Thirty-three children (69 %) suffered from polyarthritis (PA) and 16 (31%) from oligoarthritis (OA). There were no differences in weight or height between sexes or between different JCA type. BMDvol at the femoral neck was lower in boys as compared to girls (p=0.025). The girls with PA showed significantly lower volumetric spinal Z-scores (-0.46 vs. $+0.52$, $p = 0.01$) and volumetric femoral neck Z-scores (-0.21 vs. $+0.44$, $p = 0.04$) than girls with OA. In all, 29% of children (PA=11, OA=4) showed volumetric BMD Z-score values lower than -1 SD either in lumbar spine or femoral neck. If only areal BMD Z-scores were considered, 13.4 % of patients were found osteopenic. Low BMD values were found both in PA and OA cases.

In conclusion, measuring BMD is important in all children suffering from JCA, since BMD is decreased in substantial number of patients already at the time of diagnosis. This

group of patients needs special attention, eg. supplementation of calcium and vitamin D, and repeated BMD measurements in the follow-up.

Disclosures: L. Kroger, None.

T516

Evaluation of the Muscle-bone Relationship in the Midthigh of Children with Cerebral Palsy. C. M. Modlesky¹, A. Meyers¹, E. Hoffmann¹, J. J. Smith¹, F. Miller². ¹Health, Nutrition and Exercise Sciences, University of Delaware, Newark, DE, USA, ²Orthopaedics, A.I duPont Hospital for Children, Wilmington, DE, USA.

The strong relationship between muscle and bone has led to the proposal of a muscle-bone index in which a measure of bone that reflects its resistance to fracture, such as cortical volume or section modulus (Z), is divided by a measure that reflects muscle strength, such as muscle mass. Understanding the muscle-bone relationship may give us further insight into the mechanisms underlying poor bone development in children. Children with cerebral palsy (CP) who are unable to ambulate independently have poor muscle and bone development in the thigh and a high rate of fracture in the femoral shaft. However, the muscle-bone relationship is poorly studied in children with CP. The purpose of this study was to determine if the muscle-bone relationship in the midthigh is different in children with CP than typically developing children. Nine nonambulatory children with CP (8 to 14 years) and 9 typically developing children within the 10th and 90th age-based percentiles for height, weight and BMI were studied. Magnetic resonance images of the thigh (1 cm thick and 0.5 cm apart) were collected along the entire length of the more involved femur using a torso PA coil (GE 1.5 T; TR = 750, TE = 14, FOV = 16, 1 NEX, Phase = 512; Frequency = 512). Images at the level of the middle third of the femur were identified and measures of bone size, composition and strength [i.e., total and cortical volume, and anterior-posterior and medial-lateral section modulus (Z_{ap} and Z_{ml}, respectively)] and muscle mass were estimated using custom software developed with Interactive Data Language (IDL; Research Systems, Inc, Boulder CO). Indexes that reflect the muscle-bone relationship were determined by dividing total bone volume, cortical bone volume, Z_{ap} and Z_{ml} by muscle mass. There were no group differences in age, Tanner stage or BMI; however, height (1.26 ± 0.12 vs. 1.44 ± 0.08 m) and weight (27.9 ± 10.8 vs. 36.3 ± 4.5 kg) were lower in children with CP than controls ($P < 0.05$). Children with CP also had 55 % lower total bone volume (19.8 ± 6.5 vs. 44.4 ± 11.2 cm³), 55 % lower cortical volume (12.1 ± 4.2 vs. 27.6 ± 7.3 cm³) 61 % lower Z_{ap} (0.31 ± 0.11 vs. 0.80 ± 0.23 cm³) and 60 % lower Z_{ml} (0.29 ± 0.10 vs. 0.73 ± 0.21 cm³) in the midfemur and 58 % lower muscle mass (0.436 ± 0.144 vs. 1.030 ± 0.175 kg) in the midthigh ($P < 0.001$) than controls. However, none of the indexes that reflect the muscle-bone relationship were different between groups ($P > 0.05$). The findings suggest that children with CP who are unable to ambulate independently have a muscle-bone relationship in the midthigh that is not different from typically developing children.

Disclosures: C.M. Modlesky, None.

Poor Bone Growth in Children with Cerebral Palsy Is Underestimated by Dual-energy X-ray Absorptiometry. J. J. Smith¹, F. Miller², C. M. Modlesky¹. ¹Health, Nutrition and Exercise Sciences, University of Delaware, Newark, DE, USA, ²Orthopaedics, A.I. duPont Hospital for Children, Wilmington, DE, USA.

Femoral fracture incidence is elevated in children with cerebral palsy (CP). Prior fracture occurrence increases subsequent fracture risk which increases treatment costs and decreases their quality of life. Therefore, decreasing fracture incidence in this population is important. Size is a major determinant of a bone's resistance to fracture as wider bones are more resistant to fracture than thinner bones. There is evidence that children with CP have considerably thinner bones at the femoral shaft compared to typically developing children; however, the size of the distal femur, a primary fracture site, has not been evaluated. The purpose of this study was to determine if the distal femur is smaller in children with CP who are unable to ambulate independently compared to typically developing children. Nine nonambulatory children with CP (8-14 years) and 9 typically developing children between the 10th and 90th age-based percentiles for height, weight and BMI participated in the study. Bone area of the distal femur (1.4 cm region above the growth plate) was determined using dual-energy X-ray absorptiometry (DXA; Delphi W, Hologic Inc.). Trabecular bone cross-sectional area of the lateral side of the distal femur (approximating the region evaluated using DXA) was determined using magnetic resonance imaging (MRI; GE 1.5 T, 3D fast gradient echo sequence, reconstructed spatial resolution = $175 \times 175 \times 700$ μ m³). There were no group differences in age, pubertal status or BMI; however, children with CP had lower height (1.25 ± 0.04 vs. 1.43 ± 0.03 m) and weight (26.7 ± 3.7 vs. 35.6 ± 1.2 kg) compared to controls ($P < 0.05$). Although bone area determined by DXA was ~ 13% lower in children with CP than controls, this difference was not statistically significant ($P = 0.07$). On the other hand, trabecular bone cross-sectional area determined by MRI was ~ 36% lower in children with CP than controls and the difference was statistically significant ($P < 0.01$). The findings suggest that the distal femur is substantially smaller in nonambulatory children with CP than typically developing children and the degree of the discrepancy is underestimated by DXA.

Disclosures: J.J. Smith, None.

Bone Age Measurements by Ultrasound Are Equivalent to Radiological Assessments. C. Wuester, M. Hartmann*, W. Omran*, U. Cordes*. Clinic for Endocrinology, Mainz, Germany.

The purpose of the study was to show that the measurements of bone age (BA) by ultrasound at the wrist correlates with radiological BA measurements on conventional hand X-rays.

103 patients (age range 9.5 - 22.5 years, mean 14.4) were included. Thirty-one patients had delayed puberty, 17 patients had constitutional short stature, 5 patients GH deficiency and the other were normals. The ultrasound method to determine bone age at the wrist (BonAge™, Sunlight Medical Ltd., Tel Aviv, Israel; arewus, Mainz, Germany) evaluates the relationship between the velocity of the wave (speed of sound) passing thorough the distal radial and ulna epiphysis and growth, using gender- and ethnicity-based algorithms. Three experienced investigators (one radiologist, two endocrinologists) analysed conventional X-rays of the left hand and assigned bone age scores according to the Greulich & Pyle atlas (G&P). The investigators were blinded to the chronological age (CA) and the BonAge™ results. DXA was measured at the spine and hip using Osteocore 3 by MediLink/arewus, Mainz/Germany.

Correlation coefficients of BA ultrasound with the 3 X-ray investigators were $r = 0.80, 0.82$ and 0.88 respectively. The correlation between the three X-ray investigators were $r = 0.92, 0.92$ and 0.96 respectively among each others and not significant different from the correlation with the ultrasound results. BMC rather than BMD correlated best with ultrasonic BA.

Figure 1 shows the mean BA of the ultrasound-based system and the three radiological investigations. There was no statistical significant difference between the four evaluations. We conclude from the data that BonAge™ ultrasound system to measure bone age is precise and accurate. The results show high correlation with radiological assessments. The system has the advantage of being radiation-free which is important in a target group of still growing patients.

Low Doses of Pamidronate for Children with Metabolic and Genetic Diseases. C. Bowles*, R. Kreikemeier*, S. Coughlin*, H. Plotkin*. ¹Pediatrics, UNMC, Omaha, NE, USA, ²Metabolics, Children's Hospital, Omaha, NE, USA.

Retention of calcified cartilage is a well-known dose-related side effect of pamidronate treatment in children and adolescents with OI. Low doses of pamidronate are effective to treat pediatric patients with cerebral palsy and osteogenesis imperfecta.

IV pamidronate (0.75 mg/kg/day for two days) was administered every 4 months to 13 non-ambulatory children and adolescents (age range 1.5 - 12 y.o) with metabolic and genetic diseases. Diagnosis included mitochondrial complex I deficiency, fumarate deficiency, pediatric neurotransmitter disease, myotonic dystrophy, Micro syndrome, Rett syndrome, and undefined genetic syndromes. On the first day of treatment patients received half dose to minimize the acute phase reaction, and acetaminophen was administered every 6 hours during the first 2-day infusion. Lumbar spine (LS) and femoral neck (FN) BMD (DEXA, Hologic Delphi) Z-scores were assessed at baseline, 4, 12 and 24 months. Calcium, phosphorus, magnesium, alkaline phosphatase, osteocalcin, NTx, 25 and 1,25 vitamin D levels in serum, were also assessed. All patients had adequate calcium and vitamin D intakes for age. The study was approved by Children's Hospital IRB.

BMD measurement z-scores at the femoral neck (FN) (N=11) and the lumbar spine (LS) (N=13) showed statistical evidence of an increase in bone mineral density at both the femoral neck and the lumbar spine with pamidronate treatment at 24 months. The rate of increase appears to have been initially less at the femoral neck than the lumbar spine (increases at 4 months: FN: 0.38; LS: 0.85. The increase at 1 year of follow-up at the two sites was similar (FN: 1.08; LS: 1.18). Further improvement in BMD was not seen at the 2 year follow-up.

	Baseline Mean(SD)	4 mo Mean(SD)	12 mo Mean(SD)	24 mo Mean(SD)
LS BMD	0.32 (0.09)	0.38 (0.062)	0.40 (0.059)	0.38 (0.17)
LS Z-score	-3.65 (1.37)	-2.83 (0.92)	-2.63 (1.22)	-2.35 (1.20)
FN BMD	0.25 (0.084)	0.28 (0.081)	0.35 (0.089)	0.36 (0.098)
FN Z-score	-4.62 (0.98)	-4.36 (0.72)	-3.55 (1.27)	-3.80 (0.86)
Serum NTx	62.68 (41.14)	43.16 (16.12)	46.29 (9.56)	35.33 (9.22)
Osteocalcin	25.17 (8.75)	19.2 (8.51)	19.00 (10.43)	35.75 (24.60)

With low doses of pamidronate, there is no significant change over 2-year for serum 1,25 vitamin D, 25 vitamin D, total calcium, ionized calcium, sNTx, or osteocalcin measures. BMD in both LS and FN increase for the first year and remains stable during the second year of treatment.

Disclosures: C. Bowles, None.

Effects of Risedronate on Bone Change at Children with Osteogenesis Imperfecta. C. Galesanu¹, C. Ciubotariu^{*1}, M. R. Galesanu^{*2}, D. Raileanu^{*1}, C. Tache^{*1}, T. Bostaca^{*3}. ¹Endocrinology, University of Medicine and Pharmacy, IASI, Romania, ²Osteodensitometry, Centre of Imaging and Radiologic Diagnosis, IASI, Romania, ³Radiology, University of Medicine and Pharmacy, IASI, Romania.

Osteogenesis imperfecta (OI) is a disturbance in the synthesis of type I collagen, predominant protein of the extracellular matrix of most tissues. In bone, this defect causes osteoporosis, which leads to an increased tendency to fracture. Type I collagen is also a constituent of dentin, sclerae, blood vessels, ligaments and skin; individuals with OI may have also abnormalities of these structures. OI type IA is without dentinogenesis imperfecta. The OI type IB is a rare form with tooth abnormalities. The major signs of OI type I include blue sclerae, hearing loss, mild bone fragility.

The aim of our study was to verify the efficacy and safety of risedronate treatment in children with OI type IA.

Eight children, six girls and two boys were treated 12 months with risedronate. The children weighing under 30 kg received 35 mg risedronate at 14 days and children weighing more 30 kg received 35 mg risedronate weekly.

Three girls were declared with history of fractures (between 8 and 16). BMD was assessed at lumbar spine (LS) using Hologic DXA scanning at time 0 and 12 months. The results at time 0 by DXA-BMD were compared with reference data for bone density published by I.M. von der Sluis in 2002 (Children's Bone Health) Z-score at time 0 (DXA-BMD) was in all cases more -2.5.

At baseline mean BMD at LS was 0.562 g/cm² for girls vs. mean BMD reference data which is 0.896 g/cm²; it was a deficit on 38%. After a year of risedronate therapy the mean BMD at LS was 0.619 g/cm², a gain of 10%. For the boys the baseline mean BMD at LS was 0.790 g/cm² vs. mean BMD reference data which is 1.096 g/cm²; it was a deficit on 28%. After a year of risedronate, the mean BMD at LS was 0.916 g/cm², which is a gain of 15%. No adverse effects regarding gastrointestinal tract under risedronate therapy. No new fractures. The treatment and the following of children going on.

Risedronate therapy is accompanied by an important increase of LS-BMD after a year. Children with OI type IA respond to oral bisphosphonates at standard doses for osteoporosis. Risedronate 35 mg weekly seems to be safe and effective in children with OI.

Disclosures: C. Galesanu, None.

Vitamin D Status of Apparently Healthy Schoolgirls from two Different Socioeconomic Strata in Delhi: Relation to Nutrition and Lifestyle. R. Marwaha*. Department of Endocrinology and Thyroid research Centre, Institute of Nuclear Medicine and Allied Sciences, Delhi, India.

Forty to fifty percent of total skeletal mass is accumulated during childhood and adolescence, which is influenced, by sunlight exposure, physical activity, lifestyle, endocrine status, nutrition and gender. In view of scarce data on the association of nutrition and lifestyle with hypovitaminosis D in Indian children and adolescents, an in-depth study on 3127 apparently healthy (6-18 years) schoolgirls from the lower (LSES =1477) and upper socioeconomic strata (USES=1650) in Delhi was carried out. These girls were subjected to anthropometry and clinical examination for hypovitaminosis D. Randomly selected 404 (LSES =193, USES =211) girls from the two strata underwent detailed lifestyle, dietary, biochemical and hormonal assessment. Clinical features of vitamin D deficiency were noted in 11.5% girls (12.4% LSES and 10.7% USES.). USES girls had significantly higher Body Mass Index (BMI) than LSES counterparts. Prevalence of biochemical hypovitaminosis D (serum 25-OHD <50nmol/l) was seen in 90.8% girls (LSES=89.6% and USES= 91.9%). Mean intake of energy, protein, fat and calcium, as well as milk intake of USES girls was significantly higher across all ages. Among the LSES group, the intake of carbohydrate, fibre, phytate was higher. Physical activity and sun exposure in terms of duration and percentage of body surface area exposed was significantly greater in LSES. In conclusion, in the absence of fortification of food products with vitamin D in India, diet alone appears to have an insignificant role; however lifestyle factors may contribute to the vitamin D status of apparently healthy school subjects.

Effect of Energy Restriction on Bone Turnover in Physically Active Females. C. Sale¹, J. P. Greeves¹, J. P. R. Scott¹, W. D. Fraser². ¹QinetiQ, Farnborough, United Kingdom, ²University of Liverpool, Liverpool, United Kingdom.

Initial military training can result in a negative energy balance in female recruits, which may alter bone turnover and potentially increase the risk of stress fracture injury. The aim of the present study was to investigate the acute effect of reduced energy intake on bone turnover in females and to examine the interaction with daily training.

Seven habitually active females (mean (SD) age: 26 (5) y; height: 1.67 (0.30) m; body mass: 66.7 (9.5) kg) completed all aspects of the study. This study was approved by the QinetiQ Research Ethics Committee. Subjects completed two conditions in a counterbalanced crossover design. Each condition comprised 5 d of energy restriction (50% of normal daily intake), which were separated by a minimum of 7 d. In one condition, subjects completed a 1.5-mile self-paced run on the afternoon of each day (EX) and in the other condition subjects remained sedentary (SED). Energy intake on the exercising days was increased to compensate for increased energy expenditure so that the level of energy restriction was the same in both conditions. Blood and second-void urine samples were obtained after an overnight fast on days 0 (baseline, [B]), 3 (mid-restriction, [D3]), 6 (post-restriction, [D6]) and 7 (recovery, following 24 h with no restriction, [D7]). Blood was assayed for markers of bone resorption (β -CTx), bone formation (P1NP, Bone ALP) and regulatory hormone concentrations (T_3 , IGF-1, leptin and cortisol). Urine was assayed for markers of bone resorption (UfPYD and UfDPD).

Five days of energy restriction resulted in a significant ($p < 0.01$) loss of body mass in both EX (66.4 (9.8) kg to 65.1 (9.5) kg) and SED (66.8 (9.2) kg to 65.0 (8.8) kg). P1NP concentrations declined significantly ($p < 0.05$) from B (44.29 (11.88) $\mu\text{g}\cdot\text{L}^{-1}$) to D3 (39.43 (12.49) $\mu\text{g}\cdot\text{L}^{-1}$) and D6 (38.71 (12.22) $\mu\text{g}\cdot\text{L}^{-1}$) in EX, and from baseline (46.14 (15.91) $\mu\text{g}\cdot\text{L}^{-1}$) to D6 (37.43 (11.33) $\mu\text{g}\cdot\text{L}^{-1}$) in SED. P1NP concentrations remained significantly lower than B ($p < 0.05$) on D7 in SED (40.29 (12.65) $\mu\text{g}\cdot\text{L}^{-1}$). Bone ALP and markers of bone resorption (β -CTx, UfPYD and UfDPD) remained unchanged in both EX and SED conditions. There were no differences in markers of bone turnover between EX and SED. Energy restriction resulted in a significant ($p < 0.05$) reduction in leptin concentrations in both EX (between B and D6 and D7) and SED (between B and D3, D6 and D7), whilst IGF-1 and T_3 concentrations were reduced in EX only (IGF-1 between B and D6 and D7; T_3 between B and D3). No changes in cortisol concentrations were observed. Short-term energy restriction resulted in a reduction in bone formation, as shown by a decrease in P1NP, which occurred independently of moderate exercise training.

Osteoblast Response to Titanium Microtopography Is Dependent on Integrin Alpha-2. R. Olivares-Navarrete¹, P. Raz^{*1}, R. A. Chaudhri^{*1}, J. Chen^{*1}, M. Wieland^{*2}, B. D. Boyan¹, Z. Schwartz¹. ¹Petit Institute of Bioengineering and Bioscience, Georgia Institute of Technology, Atlanta, GA, USA, ²Institut Straumann AG, Basel, Switzerland.

Titanium surface microtopography modulates phenotypic maturation of osteoblast-like cells, production of local regulatory factors, and response of osteoblasts to bone anabolic agents such as 1,25 dihydroxyvitamin D₃ [1,25(OH)₂D₃]. Changes in cell morphology suggest that integrin-mediated signaling may play a role. Alpha-2 and beta-1 integrins are increased in osteoblasts grown on Ti surfaces with rough microtopographies and 1,25(OH)₂D₃ modulates expression of beta-1 on these same substrates, but alpha-5 is not affected. We showed that silencing beta-1 alters osteoblast response to substrate microtopography and 1,25(OH)₂D₃. Here we determined if integrin alpha-2 was specifically responsible for the surface-dependent changes in osteoblast response. Alpha-2 siRNA targeted 21 bases starting at base-3406 of the alpha-2 gene (NM-002203.3). Double-strand oligonucleotides were constructed in a pSuppressorNeo vector containing a U6 promoter. A permanent MG63 cell line exhibiting 70% reduction in alpha-2 protein was established. Normal and silenced MG63 cells were grown on tissue culture polystyrene (plastic) or on Ti substrates with different surface microtopographies and surface energy. Confluent cultures were treated with 1,25(OH)₂D₃ for 24h. Real-time PCR showed that alpha-2 and beta-1, but not alpha-5, alpha-v, or beta-3 integrin subunits were increased on surfaces with rough microtopographies and further enhanced on surfaces with high surface energy, as were mRNAs for alkaline phosphatase, osteocalcin, OPG and TGF- β 1. Alpha-2 siRNA did not alter levels of alpha-5 or beta-1 protein. However, effects of surface topography and surface energy on alkaline phosphatase activity, osteocalcin, and levels of PGE₂, OPG and TGF- β 1 in the conditioned media were abolished. Moreover, response to 1,25(OH)₂D₃ was reduced, even when cells were cultured on plastic or smooth Ti substrates. The results indicate that the stimulatory effects of surface microtopography and surface energy on osteoblastic differentiation depend on alpha-2 and suggest that alpha-2 signaling is involved in osteoblast-dependent regulation of bone remodeling. Silencing also reduced effects of 1,25(OH)₂D₃ supporting our previous studies showing that the synergistic effect of surface roughness and 1,25(OH)₂D₃ is mediated by the same signaling pathways. Silenced MG63 cells responded to microrough surfaces in a comparable manner, whether or not surface energy was high, suggesting that the role of alpha-2/beta-1 is to detect surface structure rather than surface chemistry.

Local Transplantation of Human Multipotent Adipose-Derived Stem Cells Improve Fracture Healing. T. Shoji^{*1}, Y. Mifune^{*1}, M. Li^{*2}, M. Kurosaka^{*3}, T. Asada^{*4}, T. Asahara^{*1}. ¹Laboratory for Stem Cell Translational Research, Riken Kobe Institute, Kobe, Japan, ²Foundation for Biomedical Research and Innovation, Kobe, Japan, ³Department of Orthopaedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan, ⁴Stem Cell Sciences KK, Kobe, Japan.

It's well known that human adipose tissue is one of the sources of multipotent stem cells called "adipose-derived stromal cells"¹. Among them, human multipotent adipose-derived stem (hMADS) cells obtained from young donor demonstrating fast adherent characteristics in culture, have extensive expansion capacity ex vivo, multilineage differentiation potential and long-term engraftment and tissue regeneration capacity. It has already reported hMADS may have therapeutic potential for muscle diseases². Based on these evidences, we test the hypothesis that hMADS contributes to fracture healing in a rat femur nonunion fracture model.

We separated crude SVF from adipose tissue in human young donors. We selected fast-adherent cells and expanded them. They were treated as hMADS cells. A reproducible model of femoral fracture was created in nude rat (F344/nude rat) with cauterized periosteum which leads to nonunion 8 weeks post-fracture³. The hMADS cells (1×10^5 /rat) or PBS was transplanted locally with atelocollagen gel after fracture creation.

Human-specific osteoblast (OB) and endothelial cell (EC) related genes were detected by RT-PCR of tissue RNA isolated from peri-fracture site in the hMADS group at week 2. Differentiated human OBs and ECs were identified in the hMADS group by immunohistochemical staining. They also demonstrated human cell-derived osteogenesis and angiogenesis. Capillary density at peri-fracture site scaled by vascular staining was higher in the hMADS group than the PBS group. Moreover, mean flux ratio of laser doppler perfusion imaging was significantly greater in the hMADS group. 9 of 10 fractures were healed radiographically and histologically at week 8 in the hMADS group. On the other hand, 1 of 10 in the PBS group was observed (Fig.).

hMADS cells transplanted to the fracture site contribute to fracture healing via osteogenesis and angiogenesis in rat non-union fracture model. hMADS the small amount of an easily available tissue source may have a therapeutic potential for fracture healing.

Vitamin A Deficiency Delays Healing Process After Cortical Bone and Bone Marrow Injury. K. Tanaka^{*1}, S. Tanaka¹, A. Sakai¹, Y. Katae^{*1}, H. Hirasawa^{*1}, N. Nakura^{*1}, K. Sabanai^{*1}, K. Menuki^{*1}, H. Yamane^{*1}, Y. Shimizu^{*1}, Y. Arai^{*2}, T. Nakamura¹. ¹Orthopaedic surgery, University of Occupational and Environmental Health, Kitakyusyu, Japan, ²Division of Hard Tissue Research, Institute for Oral Science, Matsumoto Dental University, Matsumoto, Japan.

The necessity of vitamin A in chondrogenesis and generation of limbs has been reported. The role of vitamin A in bone regeneration has not been elucidated. Using three groups of 10-week-old male C57BL/6J mice, we investigated the effects of vitamin A deficiency on healing process after cortical bone and bone marrow injury. One group was vitamin A deficiency (VAD) mice, which were fed the diet without vitamin A from 10 day of gestation to the end of the experiments. Another group was deficiency-sufficiency (VADS) mice, which were fed the diet without vitamin A from 10 day of gestation until weaned and thereafter fed the standard diet. The other was sufficiency (VAS) mice, which were fed only the standard diet. We made drill-hole injury, 1mm in diameter, at the anterior portion of the diaphysis of bilateral femurs. One group was used for sequential analysis of the amount of regenerating bone using in vivo micro CT. The femurs of each group were also harvested at 7, 14, 21 days after operation to do histomorphometry and quantitative mRNA analysis.

Regenerating bone was observed from 7 day in VAS and VADS mice, and appeared to be almost healed until 28 day, while cortical bone defect was still apparent in VAD mice at 28 day. In histomorphometrical analysis, the volume of medullary callus tended to decrease in VAD mice throughout the experimental period and regenerated cortical bone volume of the drill-hole area in the VAD mice was lower than that in the VAS at day 7, 14 and 21. Osteocalcin mRNA expression in VAD mice apparently decreased compared with VAS mice at day 7.

These results clearly demonstrated that vitamin A deficiency suppressed medullary callus formation and cortical bone healing in association with the impairment of osteoblast maturation after cortical bone and bone marrow injury.

Interaction of galectin-9 with Lipid Rafts Induces Osteoblast Proliferation Through the c-Src/ERK Signaling Pathway. R. Tanikawa¹, Y. Okada¹, K. Nakano^{*1}, T. Tanikawa¹, R. Hosokawa^{*2}, Y. Tanaka¹. ¹First Department of Internal Medicine, University of Occupational and Environmental Health, Kitakyusyu, Japan, ²Department of Oral Reconstruction and Rehabilitation, Kyushu Denrai College, Kitakyusyu, Japan.

Galectin-9 is a β -galactoside-binding lectin that modulates many biological functions by interacting with particular carbohydrates attached to proteins and lipids. The role of galectin-9 in bone metabolism remains unclear. This study investigated galectin-9 in osteoblasts with respect to proliferation and lipid raft-dependent regulatory mechanisms. We used human osteoblasts purified from metaphyseal trabecular bone in the proximal femur. The effect of galectin-9 on osteoblast proliferation was tested using WST-8 (consists of tetrazolium salt). Protein phosphorylation was assayed by western blotting and confocal microscopy was used to localize lipid rafts. Galectin-9 induced osteoblast proliferation in a dose- and time-dependent manner. Galectin-9 induced the activated form of c-Src and ERK phosphorylation, and PP2, a Src-family tyrosine kinase inhibitor, inhibited both osteoblast proliferation and ERK phosphorylation. And c-Src si RNA transfection inhibited galectin-9 induced osteoblast proliferation. Furthermore, galectin-9 induced clustering of lipid rafts in osteoblasts. Disruption of lipid rafts by β -methylcyclodextrin inhibited galectin-9-induced proliferation, as well as the galectin-9-induced activation of c-Src. Our results indicated that galectin-9 interacts with lipid rafts and induces osteoblast proliferation through the c-Src/ERK signaling pathway. We propose that clustering of lipid rafts induced by galectin-9 might be an important trigger of the c-Src/ERK signaling cascade for osteoblast proliferation.

The Effects of Chlorobenzenes on Bone Formation. Z. Valkusz¹, G. Nagyri^{*1}, M. Radács^{*1}, B. Hegedus^{*2}, A. Juhász^{*3}, A. Petri^{*4}, J. Julesz^{*1}, M. Galfi^{*2}. ¹Endocrine Unit, University of Szeged, Szeged, Hungary, ²Environmental Protection Group, University of Szeged, Szeged, Hungary, ³Department of Psychiatry, University of Szeged, Szeged, Hungary, ⁴Department of Surgery, University of Szeged, Szeged, Hungary.

Several chemicals used in the agriculture, industry and community as pesticides and fungicides may induce environmental damages and alterations in the homeostasis of biological organisms. It is known that these pollutants such as chlorobenzenes (CIB) have toxic effects on liver, immune-, nervous- and endocrine systems due to their chemical properties. Our aim was to investigate the effects of chronic exposures to discrete doses (0.1 or 1 μ g/kg/day) of CIB on bone structure and activity of liver enzymes in rats.

Wistar male rats (150-250 g) were given tri- and hexachlorobenzenes (1:1) dissolved in ethanol (0.05%) through gastric tube for 1 and 3 months. Control animals were untreated rats (absolute control, n= 10), rats treated with tap water (negative control, n= 10 and

treated with ethanol (positive control, n= 10). At the end of the experimental period the animal's body weight and organ weight were measured (by gravimetric method); serum and femoral samples were taken. Serum liver enzymes (γ GT, SGOT, SGPT) were measured (with colorimetric methods). Electrically-mobilized Ca^{2+} and bone mineral content (BMC) of femur were determined. The bone structure was investigated by histological methods. Data were analyzed with SPSS software.

The activity of liver enzymes, the weight of animals and the main organs did not change significantly applying exposures due to their subtoxic characteristic. Both of the doses, but particularly the 1 μ g/kg/day dose could modulate the electrically mobilized Ca^{2+} and BMC of the femur in a dose- and time-dependent manner. The histology of femur was altered only with 1 μ g/kg/day doses of CIB.

Our data suggest that 1 μ g/bw.kg/day doses of CIB, which is permanently present in our environment may be a risk factor for alteration of bone formation. However, a minimal dose (0.1 μ g/bw.kg/day) CIB is not likely to disturb the bone structure.

Osteoblast-Mediated Bone Formation Is Suppressed at Sites of Focal Bone Erosion in Inflammatory Arthritis. N. C. Walsh¹, C. A. Manning^{*1}, K. W. Condon^{*2}, J. Ratliff^{*2}, K. Iwata^{*2}, D. B. Burr², E. M. Gravalles^{*1}.

¹Department of Medicine, University of Massachusetts Medical School, Worcester, MA, USA, ²Department of Anatomy and Cell Biology, Indiana University School of Medicine, Indianapolis, IN, USA.

Osteoclast (OC)-mediated focal articular bone erosion is a common feature of rheumatoid arthritis (RA). Despite treatment for RA with attenuation of focal bone erosion, most patients do not repair erosive lesions. Therefore osteoblast (OB)-mediated bone formation may be impaired at these sites. We have used the K/BxN serum transfer arthritis (STA) model to determine the impact of inflammatory arthritis on OB-lineage cells at sites of focal bone erosion. In prior studies we determined that differentiation of OB-lineage cells is compromised at sites of erosion, with a paucity of mature OB-lineage cells at these sites. We now confirm by in situ hybridization that OB-lineage cells expressing mRNA for markers of mature OB-lineage cells (alkaline phosphatase and osteocalcin) are absent from sites of erosion, but are present at sites remote from erosion. In addition, the capacity of OB-lineage cells to form bone at sites of erosion was determined by dynamic bone histomorphometry. STA was induced in 12 week-old male C57BL/6J mice and the fluorochromes, alizarin and calcein, were administered with a 10 day interval. The navicular bone was assessed as a predictable site of erosion. Fluorochrome labeling, indicating newly mineralized bone, was observed at sites remote from invading inflammatory tissue (pannus). In contrast, minimal label incorporation was observed at sites where pannus was in contact with the bone surface. Quantitation of mineralized surface/total bone surface (MS/BS, %) confirmed this observation, with a reduction in the MS/BS (%) at the pannus-bone interface compared to bone surfaces remote from the pannus, and non-arthritis navicular bones. Bone formation parameters quantified in the distal femur (a site remote from inflammation) showed no differences between arthritic and non-arthritis mice. Together our results indicate that OB differentiation and bone formation activity is suppressed at sites of erosion in inflammatory arthritis, contributing to net loss of bone at these sites. Previously we have shown that antagonists of the Wnt signaling pathway, DKK1 and sFRP1, are expressed at erosion sites and in this study, qRT-PCR analysis confirms the induction of DKK1 and sFRP1 mRNA at sites of erosion over time. These factors are candidates for inhibiting OB function at these sites in this model of inflammatory arthritis. As proof of principle, a recent study published by Diarra et al., showed that DKK1 blockade in inflammatory arthritis models resulted in protection from focal bone erosion.

A Locus on Mouse Distal Chromosome (Chr) 4 Exerts Genetic Control of Bone Size by Regulating the Differentiated Function of Periosteal Cells. J. E. Wergedal¹, M. H. C. Sheng¹, K. L. Shultz², D. J. Baylink³, S. Mohan¹, W. G. Beamer².

¹Musculoskeletal Disease Center, Jerry L. Pettis VA Medical Center, Loma Linda, CA, USA, ²The Jackson Laboratory, Bar Harbor, ME, USA, ³Medicine, Loma Linda University, Loma Linda, CA, USA.

Genes that regulate bone cross sectional size and strength are important to identify because they are potential therapeutic targets for increasing bone strength in osteoporotics. QTL studies using multiple inbred strain crosses including C3H/HeJ (C3H) X C57BL/6J (B6) have revealed that Chr 4 contains an important locus that regulates bone size. Based on the findings that a region of Chr 4 in C3H, when transferred to B6, increases bone size (Table 1) and that C3H osteoblasts exhibit higher activity than B6 osteoblasts both in vivo and in vitro, we proposed the hypothesis that Chr 4 QTL contains a gene that increases bone size by regulating osteoblast activity. To evaluate this hypothesis, we characterized the processes that contribute to increased bone size by histomorphometry in a B6 congenic strain, B6.C3H-4T. Both periosteal and endosteal bone formation were elevated in the congenic line (Table 1). Furthermore, the increased bone formation was due to increased mineral apposition rate (MAR) rather than increased forming surface (Md.S). These increases in bone formation are consistent with our previous study showing higher osteoblastic activity in C3H mice than in B6 mice and suggest that the genes responsible at least in part reside on Chr 4. To further narrow down the region of the Chr 4 containing the gene of interest, sublines from the B6.C3H-4T have been produced. The subline (B6.C3H-4T-3) demonstrating the largest difference in cross sectional area (19+/-3% difference, p<.001; Mean+/-SE) from the B6 background strain (B6.C3H-4T-3) covered the region between 50 cM and 80 cM. Summary: 1) This study confirms that the congenic line B6.C3H-4T has increased periosteal bone formation due to osteoblast with increased activity. 2)

A subline of the B6.C3H-4T with a smaller segment of Chr 4 from the C3H strain also has increased cross sectional size. These observations are consistent with the presence of a gene(s) on the distal portion of mouse chromosome 4 regulating the differentiated function of periosteal cells.

Table 1. Femur midshaft MAR, bone formation rates (BFR), and mineralizing (forming) surface (MS) at periosteum and endosteum in B6.C3H-4T and B6 control mice (mean±SE).

Attachment of Osteoblast-like Cell on ALD-derived Hydroxyapatite Surface. L. Xu¹, P. Rahkila^{*1}, T. Sajavaara^{*2}, M. Putkonen^{*3}, H. J. Whitlow^{*2}, S. Cheng¹. ¹Department of Health Sciences, University of Jyväskylä, Jyväskylä, Finland, ²Department of Physics, University of Jyväskylä, Jyväskylä, Finland, ³Beneq Ltd., Vantaa, Finland.

Focal adhesions contain structural and secondary signaling molecules crucial to cell function. The attachment, adhesion and spreading of osteoblasts are essential events when studying their proliferation and differentiation on biomaterial surfaces. Different techniques have been utilized for the deposition of hydroxyapatite (HA) which offers an interesting selection of biomimetic surface coating material. Here we have used a novel Atomic Layer Deposition (ALD) method to produce thin HA films for osteoblast culture experiments. ALD is a highly controlled and conformal method for thin film deposition especially suitable for preparation of microelectronic and nanoscale materials and coating of three dimensional structures. In this study, ALD was used to obtain stable and biocompatible nanocrystalline HA films on Si (100) substrate. The topography of the films was analyzed by AFM. Heavy ion elastic recoil detection analysis (HI-ERDA) was utilized for the determination of Ca, P, O and H contents in the films. Crystalline films were obtained when amorphous as-deposited films were annealed at 800°C. AFM showed a quite uniform nanocrystalline HA layer interspersed with macrocrystalline HA. MC3T3-E1 cells were used to test the bioactivity of ALD-derived HA films (ALD-HA). 1×10⁵ cells in serum-free α-MEM medium were seeded onto UV sterilized silicon plates (10×10mm²) coated with annealed ALD-HA and unannealed amorphous films. Cells were cultured for 1 hour and 3 hours. Thereafter the cells were fixed in 4% paraformaldehyde. Vinculin was immunostained by alaxa-546 labeled antibody. F-actin was stained by alaxa-488 labeled phalloidin. Hoechst staining was used to show the cell nucleus. Cell behavior on ALD-HA surface was examined under inverted confocal fluorescence microscope. Osteoblasts adhered to ALD-HA surface after 1 hour incubation, presenting numerous filopodia and some focal adhesion sites. But the cells did not spread well and F-actin was not clearly organized. Vinculin appeared as diffuse perinuclear staining. Well-organized cytoskeleton was noticed in the cells incubated for 3 hours. Forming focal adhesion sites were clearly seen at the colocalization of vinculin and actin filaments. When comparing the amorphous and annealed crystalline surfaces the adhesion of the cells as well as the formation of focal adhesion sites are faster on the latter surface. These results suggested that crystalline ALD-HA is a promising surface coating material for the study of osteoblast/osteoclast biology.

Mechanosensitivity of Osteoblasts Is Regulated by Actin Polymerization Through Activation of RhoA. W. Yang, M. Malik*, K. L. van Golen*, K. Czymmek*, E. Adams*, G. Madden*, A. Kronbergs*, R. L. Duncan. Biological Sciences, University of Delaware, Newark, DE, USA.

While the skeleton is exquisitely sensitive to mechanical stimulation, bone becomes quickly desensitized to continued mechanical loads. We have previously reported that fluid shear rapidly increases the formation of actin stress fibers in osteoblasts and that depolymerization of the actin cytoskeleton increases the activity of the mechanosensitive, cation selective channel and the intracellular calcium response to fluid shear in osteoblasts. Numerous studies from cells derived from a variety of tissues indicate that activation of small GTPases can alter the cellular cytoskeletal integrity. Here, we postulated fluid shear rapidly activates RhoA to increase actin polymerization, thereby regulating the mechanosensitivity of osteoblasts. We found that RhoA was activated within 15 min of application of 12 dynes/cm² fluid shear to MC3T3-E1 osteoblasts. Confocal microscopy demonstrated that this shear-induced activation resulted in phosphorylation of the actin severing protein, cofilin, by LIM kinase II. Cofilin was rapidly translocated to the nucleus. Inhibition of this pathway with Y27623 or C3 transferase prevented shear-induced cofilin phosphorylation and translocation, as well as actin stress fiber formation in osteoblasts. Using Atomic Force Microscopy to determine changes in the elastic modulus of MC3T3 osteoblasts in response to shear, we found that fluid shear produced an 8-fold increase in cellular stiffness that was completely abrogated by inhibition of the RhoA pathway. Using intracellular calcium imaging, we found that inhibition of RhoA did not change the peak calcium response to shear, but did significantly increase the number of cells responding to shear. We have previously observed that MC3T3 osteoblasts rarely respond to a second

bout of shear with an increase in intracellular calcium if that challenge was administered within 30 min of the first onset of shear. However with RhoA inhibition, 50% of the cells that responded to the initial application of fluid shear responded to a second shear challenge. These data indicate that RhoA plays an important role in the loss of mechanosensitivity of osteoblasts to continued loading by increasing the actin cytoskeletal organization and stress fiber formation. This change in actin integrity increases cellular stiffness that may reduce the ability of the cellular membrane to deform to additional shear.

Studies on Improving Bone Bonding Ability of Titanium by Hydrothermal Treatment with CaCl₂. L. Zhang^{*1}, M. Nakagawa^{*1}, Y. Ayukawa^{*2}, R. Z. LeGeros³, S. Matsuya^{*1}, K. Koyano^{*2}, K. Ishikawa^{*1}. ¹Department of Biomaterials, Faculty of Dental Science, Kyushu University, Fukuoka, Japan, ²Department of Removable Prosthodontics, Faculty of Dental Science, Kyushu University, Fukuoka, Japan, ³Department of Biomaterials & Biomimetics, New York University College of Dentistry, New York, NY, USA.

Titanium has been used extensively as an implant material in dentistry and orthopedics. However, the bone bonding ability of Ti is much lower than those of osteoconductive materials such as hydroxyapatite, characterized by delayed bone formation and fibrous tissue interposition at Ti-bone interface. Alkali treatment is reported to be effective in improving the osteoconductivity of Ti. After such kind of treatment, Ti can bond calcium ions to its surface in vivo and this enhances bone formation. We hypothesized if calcium ions are bonded on Ti surface before it is implanted into the bone, the period of bone formation might be shortened. Therefore the purpose of this study is to find a method to fabricate Ca-bonded Ti and thus to improve the bone bonding ability of Ti implant materials.

In order to attain Ca-bonded Ti (Ca-Ti), we investigated hydrothermal treatment with CaCl₂ solution. From the results of X-ray photoelectron spectroscopy analysis, the Ca-Ti was successfully fabricated by using hydrothermal treatment with 10 mmol/L CaCl₂ at 200°C for 24 h. To reveal the bone cell responses to Ca-Ti, rat bone marrow cell experiments were performed. Results showed that Ca-Ti promoted cell adhesion and proliferation, accelerated the production of osteocalcin and the mineralization of the extracellular matrix. A rodent tibia model was applied to determine the in vivo bone response to Ca-Ti surface. Ca-Ti implant showed osteoblasts adhesion and new bone formation within 1 week. When compared with untreated or alkali treated Ti, Ca-Ti showed higher bone contact ratio from the early stage: 1 week 55%, 2 weeks 88%, 4 weeks 96%. The early, direct bone bonding of Ca-Ti forms a striking contrast to untreated Ti which showed late, fibrous tissue-intervened bone formation [Figure].

We concluded that through hydrothermal treatment with CaCl₂, Ti can be altered into the osteoconductive material. Such surface treatment is a promising alternative for modifying Ti (or Ti alloy) implant surfaces for accelerated osteointegration and skeletal fixation.

Figure. Different tissue responses to untreated Ti and Ca-Ti after 2 weeks in rat tibia

Ciz, a Nucleo-cytoplasmic Shuttling Protein Interacts with Extracellular Matrix Proteins. T. Hayata¹, T. Nakamoto^{*2}, Y. Ezura¹, H. Hirai^{*3}, M. Noda¹.

¹Molecular Pharmacology, Medical Research Institute, Tokyo Medical & Dental University, Tokyo, Japan, ²Medicine and Rheumatology, Tokyo Medical & Dental University, Tokyo, Japan, ³Hematology and Oncology, University of Tokyo, Tokyo, Japan.

Ciz is a zinc finger transcription factor with nucleocytoplasmic shuttling activity. We previously showed that Ciz-null mice show high bone mass phenotype, suggesting that Ciz is a negative regulator of bone formation *in vivo*. However, how Ciz suppresses bone formation through protein-protein interaction remains unclear. In the present study, to better understand molecular mechanism of Ciz function in bone formation, we wished to identify the binding partners of Ciz. We performed a yeast two-hybrid screening for Ciz-interacting protein, after constructing a cDNA library from neonatal mouse calvaria. An N-terminal fragment of Ciz (Ciz-deltaZF, amino acid 1-279) that lacks zinc finger domain and contains a proline-rich domain was used as a bait. The proline-rich domain is thought to bind to SH3 domains of signaling proteins. After the screening of 4.2×10^5 clones, 150 positive clones were sequenced. While Ciz is an intracellular protein, 47% of the clones encoded genes for extracellular matrix proteins (ECM), including collagen type 1 alpha 2 (Col1a2), 57%; Col1a1, 10%; Fibulin 2 (Fbln2), 7%; laminin receptor 1 (Rpsa), 7%. Coimmunoprecipitation experiments using *in vitro* translated proteins confirmed binding of Ciz-deltaZF to the fibrillar collagens C-terminal domain of Col1a1 and Col1a2. Association of the transfected Ciz and C-terminal domain of Col1a1 was also confirmed in Cos-7 cells by immunoprecipitation experiments. Although the physiological significance of the interactions is currently under investigation, these results revealed that Ciz interacts with fragments of extracellular matrix proteins at least under the tested condition.

Hypoxia Accelerates the Transformation of Osteoblasts to Osteocytes. M. Hirao, J. Hashimoto, N. Yamasaki^{*}, W. Ando, H. Tsuboi^{*}, A. Myoui, H. Yoshikawa, Orthopaedics, Osaka University Graduate School of Medicine, Suita, Japan.

Osteocytes are derived from osteoblasts, but reside in the mineralized bone matrix without direct blood flow. It has been reported that MLO-Y4, osteocyte-like cells show much higher expression of ORP150, which is induced by hypoxia, than osteoblast-like cells (27th, 28th ASBMR). Accordingly, we hypothesized that the oxygen tension may regulate the transformation of osteoblasts to osteocytes. MC3T3-E1 cells and calvariae from 4-day-old mice were cultured under normoxic (20% O₂) or hypoxic conditions (5% O₂). To investigate osteoblastic differentiation and transformation to osteocytes, alkaline phosphatase (ALP) staining and alizarin red staining were done and expression of various factors (osteocalcin, DMP1, MEPE, FGF23, Cx43, ORP150) was assessed by real time RT-PCR, ELISA analysis, western blot analysis, immunocytochemical analysis, and immunohistochemical analysis. Hypoxic culture promoted the increased synthesis of mineralized matrix by MC3T3-E1 cells. ALP activity was increased initially during hypoxic culture, but decreased during osteogenesis. Osteocalcin production was also increased by hypoxic culture, but decreased after mineralization. Hypoxia accelerated the change of ALP activity and osteocalcin production in cultured MC3T3-E1 cells. Furthermore, expression of DMP1, MEPE, and FGF23, and Cx43 which are osteocyte-specific or osteocyte-predominant proteins, by MC3T3-E1 cells was greater under hypoxic than normoxic conditions. In mouse calvarial organ cultures, the number of cells in the bone matrix and cells expressing DMP1 and MEPE were increased by hypoxia. In MC3T3-E1 cell cultures, ORP150 expression was only detected in the mineralizing nodules under normoxic conditions, while its expression was diffuse under hypoxic conditions, suggesting that the nodules were hypoxic zones even in normoxic cultures. Collectively, these findings suggest that a low oxygen tension promotes osteoblast maturation and subsequent transformation to osteocytes.

Adiponectin Action Influences Osteoblast Related Gene Expression. T. Ikeo¹, A. Kamada¹, I. Tamura^{*1}, S. Goda^{*1}, Y. Yoshikawa¹, E. Domae^{*1}, Y. Takaiishi¹, T. Miki². ¹Biochemistry, Osaka Dental University, Hirakata, Japan, ²Geriatric Medicine, Osaka City University, Osaka, Japan.

Adiponectin, which is one of the adipocyte-derived biologically active molecules, is abundantly present as a plasma protein, and exhibits various biological functions, such as regulating energy homeostasis, increasing insulin sensitivity in the liver and skeletal muscle, and protecting the vascular walls from atherosclerosis. Low plasma adiponectin levels are known to cause insulin resistance and metabolic syndrome. Recently, receptors of adiponectin (AdipoR1 and AdipoR2) were cloned and found to be expressed ubiquitously. We previously demonstrated gene expression of the receptors in osteoblast, indicating that adiponectin may affect bone metabolism. In this study, we investigated the expression of osteoblast differentiation markers in osteoblasts which showed suppressed receptor expression due to small interfering RNA (siRNA), to elucidate the influences of the failure of adiponectin action on bone metabolism.

Murine pro-osteoblastic cell line, MC3T3-E1 cells were cultured in alpha-MEM with 10% FBS. Two days after transfecting siRNA against adiponectin receptors (siRNA-AR), the cells were stimulated by ascorbic acid (VC) and beta-glycerolphosphate (BGP) to induce osteoblast

differentiation. The mRNA expression level was measured using real-time quantitative RT-PCR two days after the addition of VC and BGP.

VC and BGP-dependent induction of bone morphogenetic protein-2 (BMP-2) and osteocalcin were significantly suppressed by siRNA-AR compared with non-silencing siRNA controls ($p < 0.01$). Both mRNA expression levels of BMP-2 and osteocalcin were correlated with that of AdipoR2 ($r = 0.895$ and $r = 0.893$, respectively, $p < 0.001$), while there was no correlation of osteoblast differentiation markers with AdipoR1. Suppression of the gene expression of adiponectin receptor in osteoblasts inhibited the induction of BMP-2 and osteocalcin. Hence failure of adiponectin action may suppress the progression of osteoblast differentiation and bone formation.

Estrogen Receptor-Related Receptor Gamma (ERR γ) Negatively Regulates Osteoblast Differentiation and Mineralization Through Runx2- and Smad-Dependent Pathway. B. Jeong^{*1}, I. Bae^{*1}, I. Kim^{*1}, H. Choi^{*2}, J. Koh¹. ¹Dental Science Research Institution and Brain Korea 21 project, School of Dentistry, Chonnam National University, Gwangju, Republic of Korea, ²Hormone Research Center, School of Biological Sciences and Technology, Chonnam National University, Gwangju, Republic of Korea.

Recently the orphan nuclear Estrogen receptor-Related Receptors (ERR α , β , γ) have been cloned and described their expressions in bone development. This study was undertaken to elucidate roles of ERR γ in osteoblast differentiation. Mouse myoblast C2C12 and pre-osteoblast MC3T3-E1 cells were infected with adenovirus ERR γ (AdERR γ) or siERR γ (AdsiERR γ), in the presence or absence of BMP2. Osteoblast differentiation was determined by alkaline phosphatase (ALP) activity and osteocalcin (OC) production. Mineralization was measured by Alizarin Red staining. For the transcriptional regulation of ERR γ , co-immunoprecipitation, glutathione S-transferase (GST)-pull down, GST-competition and reporter gene assays were done. ERR γ was ubiquitously expressed in various mesenchymal cells, and increased by BMP2 treatment in C2C12 cells. Overexpression of ERR γ significantly inhibited BMP2-induced ALP activity, OC production and mineralization with decreases in BMP2 induction of ALP and OC mRNA expression. AdsiERR γ enhanced ALP activity and OC production in C2C12. Transient transfection of ERR γ significantly inhibited both Runx2-dependent stimulation of OC promoter activity and Smad-dependent modulation of SBE promoter activity. Co-immunoprecipitation and GST pull-down assay showed physical interactions between ERR γ and Runx2-p300 complex or Smad-1 and -5. These results suggest that orphan nuclear ERR γ should be a novel negative regulator of osteoblast differentiation through interfering with Runx2 and Smad signaling.

Downstream Signal Transactivation by FGF-4/Osterix Transgene Partially Imitates Changes of BMP-2 Induced Osteogenic Transcription Factors in NIH3T3 Cells. S. Kuroda, M. Samee^{*}, H. Kondo, S. Kasugai. Oral Implantology and Regenerative Dental Medicine, Tokyo Medical and Dental University, Tokyo, Japan.

Bone morphogenetic proteins (BMPs) are well known potent inducers of osteogenesis. In the process of bone formation, BMP-2 stimulates the three osteogenic master transcription factors: Dlx5, Runx2 and Osterix, mediated by the Smad pathways. Fibroblast growth factors (FGFs) are important signal molecules involved in both intramembranous and endochondral ossification. The transactivation of downstream genes such as Runx2 but not Osterix by FGF/FGF receptor signalings is one of the target initial events for osteoblastic differentiation mediated by the PKC pathway. FGF-4 plays important roles in bone development during embryogenesis, and systemic or local application of the recombinant protein demonstrated increase of bone formation in our previous studies. Furthermore, an additional treatment of FGF-4 over BMP-2 enhanced ectopic mineralization in our implant study. However, the mechanisms by which FGF-4 or BMP-2 signaling for osteogenesis are not well understood. In this study, we profiled the signal transactivation of osteogenic transcription factors including Dlx5, Runx2 and Osterix, activated by transgenes in an NIH3T3 cell culture. NIH3T3 cells were seeded in 24-well plates. Each well harbored 1×10^5 cells in 500 μ l D-MEM with 10% FBS. The experimental periods were scheduled as day 3, 7 and 14. The cells were given a transfection using a plasmid vector encoding for FGF-4, Osterix, FGF-4/Osterix or BMP-2. A vehicle vector was also applied for control. At each time point, the samples were subjected for RT-PCR, alkaline phosphatase (ALP) activity, and histological stainings for ALP positive cells and mineralized nodules. BMP-2 gene transfer was followed by elevation of Dlx5, Osterix and Smad1. On the other hand, FGF-4 transgene did not affect the changes of these gene expressions. However, the combination of FGF-4/Osterix overcame weak effects of FGF-4 or Osterix alone, resulting in up-regulation of Dlx5 mRNA as high as in the BMP-2 transfection. Increase of ALP activity per DNA, which was prominent in the FGF-4/Osterix and the BMP-2 transgenes, was not seen in the FGF-4 transgene. The histological works did not elicit nodule apposition in any of the treatments. Conclusively, the current study demonstrated that not FGF-4 alone but FGF-4/Osterix combination partially mimicked BMP-2 in this fibroblastic cell culture, regarding the signal transactivation of two osteogenic transcription factors, Dlx5 and Osterix, although Runx2 mRNA expression was weak over time. Further studies remain to explore the downstream signal pathways of FGF-4 and BMP-2 using other techniques and different cell cultures.

Gene Networks in Osteoblasts that Are Regulated by the Dlx Gene Family: Requirement for Dlx Transcription Factors in Mesenchymal Commitment to the Osteoblast Lineage. H. Li¹, W. Yang², A. C. Lichtler¹, S. E. Harris².¹Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, USA, ²Periodontics, University of Texas Health Science CTR, San Antonio, TX, USA.

Previous studies demonstrated that Dlx genes promote osteoblast differentiation, are expressed very early in the osteoblast lineage and are stimulated dramatically by BMPs. However, evidence suggests that Dlx genes are functionally redundant, making the study of Dlx genes in regulating osteoblast function difficult. We used a dominant negative Dlx homeodomain-engrailed repressor fusion protein (DNDlx) to inhibit Dlx protein induction of target genes. Co-transfection of DNDlx inhibited Dlx2, 3, 5, and 6 induction of a Dlx reporter construct, and infection of osteoblast cell lines with DNDlx suppresses BMP induced genes. Mouse marrow stromal cells (MSC) expressing DNDlx produced fewer alkaline phosphatase positive colonies and mineralized nodules than control cultures. For comparison, we also expressed Dlx5 which greatly accelerated osteogenesis. Full genome expression microarray analysis of the RNA from these cultures at 11 and 16 days was carried out to discover new and altered pathways regulated by Dlx genes. At 11 days, mineralization had just begun and by 16 days, mineralization is almost complete. Affymetrix array data from 430 2.0 with 41,000 probe sets were analyzed with the Limma program, and genes with a 2.6 or more fold change and $P < 0.01$ were analyzed for functional classification changes using the David program and compared to other gene sets from Gene Expression Omnibus at NCBI. In the 11 day cultures, over 500 genes were specifically inhibited by DNDlx; by Gene Ontology (GO) classification, these included ribosomal proteins, genes associated with osteoblast mineralization and differentiation, such as Osterix and with primary metabolism and mitochondrial function, extracellular matrix and collagen production. Over 120 GO classes are regulated. 398 significant genes were increased at least 2.6 fold by DNDlx, indicating that DNDlx promoted the differentiation of the MSC towards chondrocyte and immunological like phenotypes, probably because DNDlx specifically suppresses the osteoblast lineage. 497 genes were positively regulated by Dlx5 overexpression and many were in the skeletal development and mineralization classes determined by functional clustering with David. We identified 32 poorly annotated genes showing a strong correlation with many osteoblast markers, some induced 10 to 50 fold. Of the 1042 genes downregulated by overexpression of Dlx5, many were characteristic of chondrocytes and immune cells also suggesting that Dlx genes are critical for driving mesenchymal precursors to the osteoblast lineage.

Pyrrolidine Dithiocarbamate Inhibits SOD1 Gene and Cell Growth by Activating JNK Pathway in Human Osteosarcoma Cells (U2OS). G. Ngouala*, V. Afonso*, H. Riera*, P. Collin*, A. Lomri. Lariboisiere Hosp., INSERM U-606 & University Paris VII, Paris 10, France.

It has recently been shown that the alteration of the cell-redox status affects the transcription factor expression and activity. Pyrrolidine dithiocarbamate (PDTC) is a potent antioxidant agent that can switch the expression of genes dependent on the activation of the transcription factors AP-1 and NF B. PDTC is also a metal-chelating compound that acts as antioxidant or pro-oxidant and is widely used to study redox regulation of cell function. In the present study, we investigated effects of PDTC on the antioxidant gene SOD1 and cell growth in human osteosarcoma cells (U2OS), using transfection and cell growth assays. We have previously reported that treatment of cells with TNF-alpha repressed SOD1 gene and protein expression. We now show that PDTC treatment does not protect SOD1 from TNF inhibition, but induced further repression. PDTC effects are not linked to NF-kappaB repression. Transfection experiments of U2OS cells with reporter constructs harboring different promoter regions of SOD1 gene indicated the presence of a functional PDTC-responsive region located between positions -157 and +17 of the promoter. Furthermore, transfection studies of JNK-/- cells with SOD1 promoter did not show any repression by PDTC, indicating that JNK pathway is important for PDTC action on SOD1 gene. In contrast, when JNK pathway was restored in these cells, PDTC was able to repress again SOD1 promoter activity. Furthermore, PDTC induced significant inhibition of osteosarcoma cell growth, probably through SOD1 repression and this effect was not linked to cell toxicity. These results indicate that PDTC-dependent repression of SOD1 and cell growth in U2OS osteosarcoma cells is tightly regulated by JNK pathway and point-out SOD1 as a target gene in the anti-proliferative effects of PDTC in cancer cells

Endogenous Hesr/Hey Genes Redundantly Support Osteoblast Differentiation. S. Maeda¹, H. Kokubo², H. Aburatani³, S. Nomura⁴, S. Komiya⁵, K. Miyazono⁶, T. Imamura⁷. ¹Department of Biochemistry, The Cancer Institute of the Japanese Foundation for Cancer Research, Tokyo, Japan, ²Division of Mammalian Development, National Institute of Genetics, Mishima, Japan, ³Genome Science Division, Research Center for Advanced Science and Technology, University of Tokyo, Tokyo, Japan, ⁴Department of Pathology, Graduate School of Medicine and Frontier Biosciences, Osaka University, Osaka, Japan, ⁵Department of Neuromusculoskeletal Disorder, Orthopaedic Surgery, Graduate School of Medicine and Dentistry, Kagoshima University, Kagoshima, Japan, ⁶Department of Molecular Pathology, Graduate School of Medicine, University of Tokyo, Tokyo, Japan, ⁷Department of Biochemistry, The Cancer Institute of The Japanese Foundation for Cancer Research, Tokyo, Japan.

Bone morphogenetic proteins (BMP) induce osteoblast differentiation of mesenchymal progenitor cells, which event is governed by two master regulators, Runx2 and Osterix. In addition to these transcription factors, other nuclear proteins are also induced by BMP, which roles in osteoblast differentiation are obscure. It has been reported that Hesr1/Hey1 is induced synergistically by BMP and Notch signaling in vitro, and osteoblasts express Hesr1/Hey1 in vivo. Other group showed in the last ASBMR, that ubiquitous overexpression of Hesr1/Hey1 in vivo induced progressive osteopenia in the transgenic mice due to decreased osteoblast differentiation. However, it is still not clear whether endogenous level of Hesr1/Hey1 also acts inhibitory to bone formation or not. To answer this question, we analyzed bones of Hey1/Hesr1 knockout mice. Unexpectedly, the bone mineral density and bone morphometric analysis of Hesr1/Hey1 -/- mice showed no overt phenotype. We considered this result might be due to redundancy between Hesr/Hey genes. Indeed, we found that Hesr3/HeyL gene is also expressed in bone in vivo. So we generated Hesr1/Hey1:Hesr3/HeyL double knockout (Hesr1-/-:3-/-) mice. Some of Hesr1-/-:3-/- mice died before weaning as recently reported by other group. However, survivors of double null mice showed normal growth, which could be subjected to bone analysis. Contrary to our expectations, the bone mineral density of four-allele mutants was decreased. Analysis of mRNA extracted from bones of these mice revealed that osteocalcin was elevated. As we found in vitro, that Hesr1/Hey1 interacts with Runx2 and inhibits its function, this interaction may be, at least in part, responsible for the phenotypes. These data suggest that endogenous expression level of Hesr/Hey genes plays a supportive role in regulating adult bone formation.

Osterix Functions as Downstream of Runx2 and Msx2 During BMP2-Regulated Osteoblastogenesis. T. Matsubara¹, K. Kumiko^{*1}, K. Hata^{*1}, A. Yamaguchi², H. Aburatani³, R. Nishimura¹, T. Yoneda¹. ¹Biochemistry, Osaka University graduate school of dentistry, Osaka, Japan, ²Oral Pathol, Tokyo Med Dent Univ, Tokyo, Japan, ³Res Cent Adv Sci Tech, Univ Tokyo, Tokyo, Japan.

Complete absence of bone formation and osteoblasts in null mice indicates an Sp1 family transcription factor Osterix/Sp7 is necessary for bone development. Osterix expression is known to be associated with BMP2 actions. However, the precise mechanism that controls the expression and function of Osterix during BMP2-induced osteoblastogenesis remains elusive. In this study, we attempted to study this. Since a previous study suggests that Osterix is a downstream of Runx2, we first examined the effects of Runx2 overexpression on Osterix expression. We found that overexpression of Runx2 induced Osterix expression in mesenchymal cell lines, C2C12 and C3H10T1/2, and primary mesenchymal cells isolated from Runx2-deficient mice along with an up-regulation of ALP and osteocalcin expression, demonstrating that Osterix functions as a downstream of Runx2. However, of interest, BMP2 treatment induced ALP activity and Osterix expression in the Runx2-deficient cells. These results suggest that expression and function of Osterix is regulated by Runx2-independent mechanism in addition to Runx2-dependent mechanism. To verify this possibility, we examined whether Smad signaling is involved in this process. Overexpression of Smad1 and Smad4 up-regulated Osterix expression in the Runx2-deficient cells. In contrast, an inhibitory Smad, Smad6 markedly suppressed BMP2-induced Osterix expression in these cells, indicating that Smad signaling is required for Runx2-independent induction of Osterix. Because Msx2 has been shown to regulate BMP2-induced osteoblastogenesis independent of Runx2, we tested whether Msx2 is involved in the Runx2-independent regulation of Osterix. In the Runx2-deficient cells, treatment with BMP2 induced Msx2 expression and overexpression of Msx2 markedly up-regulated Osterix expression and ALP activity. These data indicate an important role of Msx2 in regulating Osterix expression and suggest that Osterix may have distinct roles from Runx2 during osteoblast differentiation. To test this idea, we performed microarray analyses using Runx2-deficient cells introduced with either Runx2 or Osterix, and found that Osterix up-regulated several genes that are distinct from Runx2. In conclusion, our results suggest that BMP2 regulates Osterix expression through Msx2 but independent of Runx2 and that Osterix controls osteoblast differentiation of mesenchymal cells in Runx2-dependent and independent fashions.

Retinoblastoma Binding Protein-1 (RBP1), a Novel Factor Critical For Runx2 Expression and Transcriptional Activation. D. G. Monroe¹, J. R. Hawse¹, M. Subramaniam¹, F. J. Secreto¹, S. Khosla², T. C. Spelsberg¹.¹Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA,²Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

The retinoblastoma binding protein-1 (RBP1) is a broadly expressed transcription factor involved in the suppression of proliferation mediated through the retinoblastoma protein (pRb), a major pathway implicated in the pathogenesis of numerous cancers including osteosarcoma. We have previously demonstrated an estrogen receptor- α -dominant regulation of RBP1 in osteoblasts (OBs), suggesting an important role of RBP1 in OB function. Here we present evidence that RBP1 is involved in Runx2 expression as well as Runx2-dependent transcriptional activation, therefore potentially playing a broader role in general skeletal biology. Overexpression of wild-type RBP1 in the U2OS human osteosarcoma significantly enhances Runx2-dependent activation of a synthetic Runx2-dependent reporter construct (pOSE2-Luc), whereas a mutant RBP1 construct, containing a deletion of the LxCxE motif necessary for RBP1 binding to pRb, fails to enhance Runx2 activity. Similar experiments were conducted in the SAOS2 human osteosarcoma, which lacks pRb activity. Overexpression of Runx2 and/or RBP1 in SAOS2 cells resulted in comparatively weak activation of the pOSE2-Luc, suggesting that an intact pRb/RBP1 system is necessary for maximal regulation of Runx2-dependent transcription. To further characterize the importance of RBP1 in the transcriptional regulation of bone marker genes, we utilized siRNA against RBP1 in mouse calvarial cell cultures. Reduction of RBP1 resulted in a significant transcriptional inhibition of important bone marker genes such as Runx2, osterix, BMP2, osteocalcin, osteopontin, TIEG and BMP2. Similar siRNA experiments targeting both RBP1 and pRb expression were conducted in the mouse MC3T3-E1 osteoblast cell line. Reduction in the expression level of either RBP1 and/or pRb resulted in an inhibition of Runx2-dependent transcriptional activation of these bone marker genes. These results suggest a transcriptional system where both RBP1 and pRb are necessary for maximal Runx2-dependent transcriptional activation in osteoblasts. These data are consistent with previous studies showing that BMP2-treated Rb^{-/-} mouse embryo fibroblasts fail to form bone in vitro and that the Rb knockout mice are not viable. Current experiments are focused on deciphering the long-term effects of RBP1 depletion using both stable shRNA osteoblast cell lines and examining the skeletal phenotype of RBP1 knockout mouse models.

Identification of Osteoblast-specific Co-Regulator Complex for Vitamin D Receptor (VDR). E. Ochiai¹*, H. Kitagawa²*, I. Takada²*, Y. Tushima³*, S. Fujiyama⁴*, S. Sawatsubashi⁴*, M. Kim⁴*, Y. Mezaki²*, K. Takagi³*, K. Takeyama²*, K. Yamaoka⁵*, S. Kato⁶, T. Kamimura³*, ¹Teijin Institute for Bio-Medical Research/ Laboratory of Nuclear Signaling, Institute of Molecular and Cellular Biosciences, The University of Tokyo, Tokyo, Japan, ²Laboratory of Nuclear Signaling, Institute of Molecular and Cellular Biosciences, The University of Tokyo, Tokyo, Japan, ³Teijin Institute for Bio-Medical Research, Tokyo, Japan, ⁴ERATO, Japan Science and Technology Agency, Saitama, Japan, ⁵ERATO, Japan Science and Technology Agency, Saitama/ Teijin Institute for Bio-medical Research, Tokyo, Japan, ⁶Laboratory of Nuclear Signaling, Institute of Molecular and Cellular Biosciences, The University of Tokyo, Tokyo/ ERATO, Japan Science and Technology Agency, Saitama, Japan.

Vitamin D actions in regulating bone metabolism and calcium homeostasis have been well described. Such actions of vitamin D are believed through nuclear vitamin D receptor (VDR), and gene disruption of VDR in mice caused severe rachitic phenotype. And the benefit of vitamin D for bone formation has been shown. Indeed several VDR ligands are applied for clinical use but are expected to reduce side effects like hypercalcemia. Such actions of vitamin D on bone were well known, but the molecular bases of the skeletal vitamin D action are not elucidated in that VDR cofactor complexes formed in osteoblasts. To address this issue, we used biological approach to identify the osteoblast specific co-regulator complex interacting with VDR. Using GST-fused VDR ligand binding domain (LBD) as a bait, nuclear complexes associated with liganded VDR-LBD were purified from nuclear extract of HOS osteoblastic cell line and HeLa as a control cell line. Together with well-reported DRIP/TRAP complex components, CDP (CCAAT Displacement Protein, also known as CUTL1, a homeodomain transcription factor) has identified as a novel ligand-dependent and osteoblast-specific VDR interactant by MALDI-TOF/MS. Furthermore using glycerol density gradient centrifugation, the CDP complex was distinct from the DRIP/ TRAP complex by their molecular weights. By a GST-pull down and co-immunoprecipitation assay, CDP exhibited ligand-dependent interaction with VDR. In a transient expression assay with GAL4-VDR-LBD in HOS cells, CDP co-activated ligand-induced transactivation of VDR. Ectopic CDP expression by adenovirus vector potentiated the expression of the VDR target gene expression in HOS cells and induced osteoblastic differentiation in human osteoblastic SaM-1 cells. From the present findings, it is likely that CDP serves as an osteoblast-specific co-activator complex component for VDR. Currently, recruitment of CDP on the VDR target gene promoters are under investigation and will be presented.

Activation of Liver X Receptor Inhibits Hedgehog Signaling and Osteogenic Differentiation of Marrow Stromal Cells. W. Kim, K. Mouillesseaux*, V. Meliton*, C. M. Amantea*, F. Parhami. Medicine, UCLA, Los Angeles, CA, USA.

Liver X receptors (LXRs) are members of the family of nuclear hormone receptors that are activated by specific oxysterols and pharmacological agents such as TO901317 (TO) and GW3965 (GW). LXRs are involved in a variety of physiologic processes including lipid and glucose metabolism, cholesterol homeostasis, and inflammatory signaling. We previously reported that treatment of bone marrow stromal cells (MSC) with TO and GW inhibits spontaneous osteogenic differentiation of these cells, and therefore speculated that LXR activation may inhibit osteoblast differentiation and bone formation. Recently LXRs were found to influence osteoclast differentiation and activation, with LXR^{-/-} mice demonstrating an improved cortical bone phenotype. We also reported that specific osteogenic oxysterols, including 20S-hydroxycholesterol (20S), induce the osteogenic differentiation of MSC by activating the hedgehog (Hh) signaling pathway. In addition, we found that TO and GW blocked oxysterol-induced osteogenic differentiation of MSC, and therefore hypothesized that LXR activation may interfere with osteogenic differentiation induced by the activation of Hh signaling. In order to test this hypothesis, we examined the effects of TO and GW on sonic hedgehog (Shh)-induced osteogenic differentiation of MSC line, M2-10B4 (M2). Results showed that both TO and GW (1-10 μ M) caused a significant inhibition of Shh-induced alkaline phosphatase (ALP) activity and osteocalcin mRNA expression after 3 and 8 days, respectively. Furthermore, treatment of M2 cells with LXR ligands inhibited Shh-induced mRNA expression of Hh target genes, Gli1 and Patched. siRNA to LXR α and LXR β caused an 80-90% inhibition of mRNA expression for these genes, as well as inhibition of ligand-induced expression of LXR target genes, ATP-binding cassette (ABC) transporter proteins ABCA1 and ABCG1. The ability of TO and GW to inhibit Shh-induced signaling and ALP activity was blocked in cells transfected with LXR α and LXR β siRNA, but not in cells transfected with control scrambled siRNA. These results demonstrate for the first time that LXR activation inhibits Hh signaling and osteogenic differentiation of MSC, suggesting a negative role for LXR in bone metabolism. Modulation of Hh signaling through LXR activation may be a novel therapeutic strategy relevant to a variety of indications including age-related osteoporosis and tumorigenesis that is caused by aberrant Hh signaling.

Expression of Osteoblast-Specific Transcription Factors in Aged Mice. J. M. Patsch¹, M. Rauner¹*, D. Stupphann¹*, K. Tragl¹*, P. Pietschmann¹.

¹Institute of Pathophysiology, Medical University of Vienna, Vienna, Austria,²Ludwig-Boltzmann Institute of Aging Research, Vienna, Austria.

Bone mass and bone stability decline during aging. Impaired osteoblast function is an important mechanism of age-related bone loss. The cellular and molecular mechanisms, which mediate age-dependent changes in osteoblast function, are poorly characterized. Therefore, the first aim of our study was to determine the gene expression pattern of the osteoblast-specific transcription factors runx2 and osterix in aged mice. Secondly, we analysed the gene expression of the osteoblast proteins alkaline phosphatase (ALP), receptor activator of NF κ B ligand (RANKL) and osteoprotegerin (OPG). Bone marrow stromal cells were isolated from 18-months old and 6-weeks old mice. Osteoblast differentiation was induced by adding 5 mM β -glycerophosphate and 50 μ M ascorbic acid to the culture medium. After 7, 14, 21 and 28 days total RNA was isolated, and quantitative real-time PCR analysis was performed. The marrow-free bones were homogenized in liquid nitrogen and also analyzed by real-time PCR. In bone marrow cultures from old mice, the mRNA level of ALP was significantly lower at all time points when compared to young mice. Runx2 mRNA levels also decreased during the first 28 days of culture. We did not detect an age-dependent alteration of ex-vivo gene expression of osterix, RANKL or OPG. mRNA levels of ALP were significantly lower in the bone tissue samples of old mice ($p < 0.05$). In direct correlation with our results obtained from cultured cells, the tissue mRNA levels of osterix, RANKL and OPG remained unaffected by age.

Our results demonstrate that not all osteoblast-specific markers decline with aging. In particular, the expression levels of ALP and runx2 mRNA were downregulated in bone tissue and osteoblast cultures from aged mice. As ALP and runx2 are early markers in osteoblast differentiation, we conclude that aging mainly affects early steps of osteoblasts differentiation.

Interactions Between PTH and the gp130 Cytokine Pathway in Differentiating Osteoblasts. J. M. Quach, E. H. Allan, K. D. Hausler*, M. T. Gillespie, T. J. Martin. St. Vincent's Institute, Melbourne, Australia.

Signaling through gp130 is required for normal osteoblast function, and PTH for accrual of maximal bone mass, yet the crosstalk between these pathways is not well understood. This work is aimed at understanding how PTH interacts with the gp130 cytokines in osteoblasts and precursors, by identifying transcriptional regulators responding to both classes of ligand. A gene array was performed on mouse marrow stromal cells, Kusa 4b10, which were differentiated through 16 days of culture to the time the cells developed functional PTH receptor. The cells were treated with PTH (1-34) or with PTHrP (1-141), and RNA used to probe Affymetrix whole mouse genome microarrays. Several genes known to be regulated through PTHrP (e.g., RANKL, RGS-2, VDR, LIF, IL-6) were used to validate responses on independent Kusa 4b10 RNA samples. Notably, several of the genes enhanced by PTH or PTHrP were involved in the gp130 pathway. These were IL-6, IL-11, LIF and CLCF, as well as the signal-transducing proteins for these cytokines gp130, LIFR, OSMR, and the signaling molecules STAT3, JAK3, SOCS2 and SOCS3. Each of these genes was validated on independent Kusa 4b10 RNA samples. From twelve transcriptional regulators differentially expressed in response to PTH and PTHrP and confirmed by real time-PCR on independent RNA samples, two were chosen for further investigation because pathway analysis indicated links to the gp130 signaling pathway. These were Btg2 (B-cell translocation gene 2) and Zinc-finger protein-36 (Zfp36), both of which have been implicated in bone cell function. Btg2 mRNA was increased 4-fold by PTH at 1 hr, 70-fold with Oncostatin M (OsM), 5-fold with LIF and 3-fold with cardiotrophin-1. Zfp36, which has been shown to bind to AU-rich elements in mRNA and to decrease mRNA stability, was increased 3-fold by PTH, 70-fold by OsM, 2.5-fold by both LIF and cardiotrophin-1. Additionally, both Btg2 and Zfp36 mRNA were rapidly induced by 3 to 4-fold with PTH and 16 to 25-fold with OsM in primary mouse calvarial osteoblasts. Analysis of these interactions between PTH/PTHrP and gp130 cytokine production and action provides new information on local communicating processes in bone.

Identification and Characterization of Runx2 Phosphorylation Sites involved in Matrix Metalloproteinase-13 Promoter Activation. N. Selvamurugan, E. Shimizu, N. C. Partridge. Physiology and Biophysics, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, USA.

Parathyroid hormone (PTH) plays a central role in regulation of calcium metabolism. It acts through its G-protein-coupled receptor on the osteoblast to elicit enhanced bone resorption by the osteoclast. Matrix metalloproteinase-13 (MMP-13; collagenase-3) plays a critical role in PTH-induced bone resorption and endochondral bone formation. Our earlier studies showed that PTH induced MMP-13 gene transcription in the rat osteoblastic cell line, UMR 106-01. We identified the PTH-response elements in the regulatory region of the MMP-13 gene and the proteins (Runx2 and Fos/Jun) binding to them. PTH acts via protein kinase A (PKA) to phosphorylate and stimulate the transactivation of Runx2 through a PKA consensus site. To further identify PTH-stimulation of Runx2 phosphorylation in vivo, immunoprecipitation of Runx2 and Western blot analysis were performed. We found that PTH stimulated Runx2 phosphorylation mostly on serine residues with a small amount at threonine and tyrosine residues in UMR 106-01 cells. To determine Runx2 phosphorylation residues in vivo, Runx2 protein was metabolically labeled in COS-7 cells and subjected to immunoprecipitation, acid hydrolysis and thin layer chromatography. Runx2 phosphorylation was increased at serine residues after 8-Br-cAMP treatment. Further, the Runx2 phosphorylation sites in vivo were identified by transient transfection of a c-myc-tagged Runx2 construct into COS-7 cells, followed by 8-Br-cAMP treatment, immunoprecipitation and matrix-assisted laser desorption/ionization MS analysis. Runx2 was identified to be phosphorylated on serines 14 and 332, and threonine 325 after 8-Br-cAMP treatment. To determine the role of Runx2 phosphorylation sites for MMP-13 promoter activation, the wild type Runx2 and Runx2 mutated at these phosphorylation sites (at single, double or triple sites) were transiently transfected into either COS-7 or C3H10T1/2 cells along with the MMP-13 promoter construct. In the presence of 8-Br-cAMP, the wild type Runx2 construct stimulated MMP-13 promoter activity; while the Runx2 construct having mutations at all three phosphorylation sites was unable to stimulate MMP-13 promoter activity in these cells. Thus, we have identified for the first time Runx2 phosphorylation sites necessary for PKA stimulated MMP-13 promoter activation and this event may be critical for bone remodeling.

Connexin43 Amplifies FGF2-Responsiveness in a Runx2/Protein Kinase C delta- dependent Manner. F. Lima, C. Niger, J. P. Stains. Orthopaedics, University of Maryland, Baltimore, MD, USA.

We examined the molecular and biochemical role of the gap junction protein, connexin43 [Cx43], in the transcriptional response of osteocalcin to fibroblast growth factor 2 [FGF-2]. By luciferase reporter assays, we identified that the osteocalcin transcriptional response to FGF2 in MC3T3 cells is markedly increased by overexpression of Cx43. The transcriptional synergy between Cx43 and FGF2 on osteocalcin transcription is dependent on the dose of FGF2, affecting at 5, 10 and 25 ng/ml. The amplification of FGF2 responsive osteocalcin transcription by Cx43 is mediated by runx2, via its OSE2 cognate element, but not by a previously identified connexin-responsive Sp1/Sp3 binding element. Disruption of Cx43 function with siRNA against Cx43 markedly attenuated the response of MC3T3 cells to FGF2 treatment. Similarly, overexpression of connexin45 - a gap junction protein with "dominant negative" properties with respect to Cx43 function - diminished FGF2 induced osteocalcin transcription. To assess the signal transduction machinery responsible for the Cx43-dependent enhanced FGF2 responsiveness, we used chemical inhibitors and/or siRNA to block ERK, p38 and JNK cascades, as well as, protein kinase C delta [PKC δ] activity. FGF2 was able to induce the phosphorylation of all of these cascades, as shown by immunoblotting with phospho-specific antibodies. Despite the activation of multiple signal transduction pathways, only the PKC δ inhibitor, rottlerin, was able to abrogate the Cx43-dependent enhancement of osteocalcin transcription in response to FGF2. In order to illuminate how Cx43, PKC δ and runx2 mediate the osteoblast response to FGF2, we examined the biochemical changes occurring in FGF2 treated cells. We identified by immunoprecipitation that PKC δ and Cx43 physically interact. Further, we show by immunocytochemistry that upon treatment with FGF2, PKC δ is translocated to the nucleus. By immunoblotting, we show that PKC δ and runx2 are phosphorylated in response to FGF2 treatment. The abundance of phosphorylated protein is increased by overexpression of Cx43, suggesting that the degree of activation is enhanced by increased Cx43 levels. In total, these data show that the gap junction protein Cx43 plays a critical role in regulating osteoblast response to FGF2, as both gain and loss of Cx43 function impact the FGF2-induced osteocalcin transcription. This effect is mediated by PKC δ , which can physically "dock" with Cx43, and, when activated, translocate to the nucleus where it enhances runx2 transcriptional activity.

TGF β Inducible Early Gene-1 Directly Binds to, and Represses, the OPG Promoter in Osteoblasts Resulting in Decreased Support of Osteoclast Differentiation. M. Subramaniam¹, J. R. Hawse¹, D. G. Monroe¹, A. Sanyal², M. Cicek², M. J. Oursler¹, T. C. Spelsberg¹. ¹Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN, USA, ²Endocrine Research Unit, Mayo Clinic, Rochester, MN, USA.

TGF β Inducible Early Gene-1 (TIEG) is a member of the Krüppel-like family of transcription factors that plays an important role in TGF β mediated Smad signaling. To understand the physiological role of TIEG, we generated TIEG-null (TIEG^{-/-}) mice. Calvarial osteoblasts isolated from these mice have a reduced ability to support osteoclast differentiation in vitro. Gene expression studies revealed decreased RANKL and increased OPG expression in TIEG^{-/-} osteoblasts suggesting a role for TIEG in regulating the expression of these genes. Since OPG is one of the most important regulators of osteoclast differentiation, and since TIEG^{-/-} osteoblasts have decreased levels of OPG expression, we sought to determine if TIEG directly regulates OPG expression. A luciferase construct, containing an approximately 1.6 kb fragment of the mouse OPG promoter, was cloned into a pGL3 reporter vector and transiently transfected into TIEG^{-/-} calvarial osteoblasts with and without a TIEG expression vector. The OPG promoter activity was completely abolished in the presence of TIEG suggesting that TIEG directly regulates the expression of OPG in osteoblasts. In order to determine the region of this promoter through which TIEG acts, sequential 5'-deletion constructs were created. Transient transfection of these constructs revealed that the TIEG binding site(s) resides within a 200 bp region of the OPG promoter. To determine if TIEG protein directly interacts with this region, transient ChIP analyses were performed using a TIEG-specific antibody. The results of these studies revealed that TIEG does bind to this region of the OPG promoter. As a confirmation, real-time PCR analysis of these ChIP assays demonstrated that this 200 bp region is enriched by approximately 8-fold in the presence of TIEG protein relative to vector transfected cells. These studies confirm that TIEG interacts with this specific region of the OPG promoter to inhibit its activity. Since we have previously shown that TIEG regulates target gene expression through Sp-1 sites, we scanned this region of the OPG promoter for potential TIEG binding elements. Interestingly, this sequence analysis identified 4 Sp1 binding sites and suggests that TIEG could be acting through these DNA elements to regulate the expression of the OPG gene. Taken together, these results confirm that TIEG directly binds to and inhibits OPG promoter activity and as expected, TIEG^{-/-} mouse osteoblasts display a significant inability to support osteoclast differentiation.

C/EBP β Is a Crucial Partner of ATF4 in Osteoblast Differentiation. H. Tominaga^{*1}, S. Maeda¹, M. Hayashi^{*1}, S. Akira^{*2}, T. Komori^{*3}, S. Komiya^{*4}, T. Imamura¹. ¹Department of Biochemistry, The Cancer Institute of the Japanese Foundation for Cancer Research, Tokyo, Japan, ²Exploratory Research for Advanced Technology, Japan Science and Technology Agency, Department of Host Defense, and The 21st Century COE, Combined Program on Microbiology and Immunology, Research Institute for Microbial Diseases, Osaka University, Osaka, Japan, ³Department of Developmental and Reconstructive Medicine, Division of Cell Biology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, ⁴Department of Neuromusculoskeletal Disorder, Orthopaedic Surgery, Graduate School of Medicine and Dentistry, Kagoshima University, Kagoshima, Japan.

ATF4 is a member of CREB/ATF family basic leucine zipper (bZIP) transcription factors, and plays a crucial role in osteoblast differentiation in cooperation with Runx2. ATF4 binds to DNA element OSE1, which sequence exists in osteocalcin gene promoter, to enhance the differentiation. We and other groups have reported that another bZIP protein C/EBP β also enhance osteoblast differentiation with Runx2 synergistically, through interacting to CEBP-binding element. ATF4 and C/EBP β are reported to be able to form stable heterodimers. Moreover, OSE1 resembles reported DNA binding sequence for ATF4-C/EBP β heterodimers. Thus we hypothesized that the heterodimers could act on OSE1. First we confirmed interaction of endogenous ATF4 and C/EBP β in primary calvarial osteoblasts. We next tested the question by gel shift and luciferase assays. ATF4-C/EBP β heterodimers bound OSE1 with more strong affinity than homodimers of ATF4. The heterodimers induced more intense signals from luciferase constructs of OSE1 and OC promoter than ATF4-homodimers, which activity was elevated to maximum level with Runx2. We finally studied function of C/EBP β on bone formation in vivo by analyzing C/EBP β knockout mice, which phenotype regarding bone has not been studied. C/EBP β null mice showed delayed bone formation like ATF4 null mice. These results suggest that C/EBP β plays an indispensable role in forming active complex with ATF4 and Runx2 on OSE1, in addition to CEBP-binding element, during osteoblast differentiation.

Osr1 Gene Expression Is Regulated by Runx2 and Ikaros Transcription Factors. M. Yamauchi¹, S. Kawai², A. Amano^{*2}, T. Ooshima^{*1}. ¹Department of Pediatric dentistry, Osaka university Graduate School of Dentistry, Suita-Osaka, Japan, ²Department of Oral Frontier Biology, Osaka university Graduate School of Dentistry, Suita-Osaka, Japan.

Odd-skipped gene is one of the pair-rule genes which contribute to Drosophila somite formation. Two mammalian homologues, Odd-skipped related 1 (Osr1) and Osr2, has been shown to be expressed in limb, branchial arches, kidney, eye, and dermis. Osr1 is known to play a critical role in the heart and urogenital development. While, the function of Osr1 in bone formation as well as the regulation of Osr1 gene expression are still unclear. To understand regulatory mechanism of Osr1 gene expression, we cloned mouse Osr1 promoter (4.7kb) and analyzed the promoter activity. We constructed 7 deleted promoters and cloned them into pGL-3 basic vector. As a result, two regulatory regions which consisted of positive regulatory region (-741bp~-144bp) and negative regulatory region (-1651bp~-742bp) were found in Osr1 promoter. GATA1, CP-2, Ikaros, Nkx-2.5, Runx1, and Runx2 binding sites existed around these regulatory regions. Osr1 promoter-luciferase reporter construct and various transcription factors were co-transfected and luciferase activity was measured. As a result, Ikaros and Runx2 decreased Osr1 promoter activity, and it was also found that Osr1 gene expression was dose-dependently downregulated by these factors. Furthermore, point mutation at transcription factor binding site for Ikaros or Runx2 prevented the downregulatory effects by them. We also confirmed the binding of transcription factors to Osr1 promoter with chromatin immunoprecipitation and electrophoretic mobility shift assay. These data indicates that Osr1 gene expression is negatively regulated by at least two transcription factors, Ikaros and Runx2. Ikaros is one of the important regulators of lymphocyte differentiation. Runx2 is a crucial regulator of bone formation. Osr1 is regulated by these transcription factors, suggesting that Osr1 has a functional role in lymphocyte differentiation and bone formation.

Age-Related Intrinsic Changes in Human Bone Marrow-Derived Mesenchymal Stem Cells and Their Differentiation to Osteoblasts. J. Glowacki¹, S. Zhou¹, J. S. Greenberger², M. W. Epperly^{*2}, J. P. Goff^{*2}, C. Adler^{*1}, M. S. LeBoff³. ¹Orthopedic Surgery, Brigham and Women's Hospital, Boston, MA, USA, ²Radiation Oncology, University of Pittsburgh Medical Center, Pittsburgh, PA, USA, ³Medicine, Brigham and Women's Hospital, Boston, MA, USA.

A sub-population of marrow-derived stromal cells (MSCs, a.k.a. mesenchymal stem cells) has potential to differentiate into multiple cell types, including osteoblasts. We tested the hypotheses that there are intrinsic effects of age on human MSCs. We measured the

effect of age on proliferation, cell cycling, apoptosis, p53 pathway genes, senescence-associated β -galactosidase (SA- β -gal), and osteoblast differentiation in hMSCs that were obtained from marrow discarded from men and women (17-90 years) undergoing orthopedic surgery. Low density mononuclear cells were isolated by centrifugation on Ficoll/Histopaque 1077 and hMSCs were established in monolayer culture with phenol red-free α -MEM, 10% Fetal Bovine Serum-Heat Inactivated, 100 U/ml penicillin, and 100 μ g/ml streptomycin. For some experiments, the low-density mononuclear cell suspensions were sorted with FITC-labeled STRO-1 antibody. Viable hMSCs at passage 2 were counted every other day with a hemocytometer. Cell cycle was assessed by FACS. SA- β -gal-positive cells were enumerated cytochemically. Osteoblast differentiation was assayed in basal medium with osteogenic supplements (10 nM dexamethasone, 5 mM β -glycerophosphate, and 170 μ M ascorbic phosphate). For most analyses, nonparametric statistical tools were used.

Doubling time of hMSCs was 1.6-fold longer in cells from the older (78.8 ± 13.5 hrs, $n=13$) than the younger subjects (48.8 ± 0.7 hrs, $n=3$) and was positively correlated with age ($r = 0.60$, $p=0.0137$, $n=16$). With age, there was uniform prolongation of the duration of all phases of the cell cycle, but with age, more cells were apoptotic ($r=0.723$, $p=0.0248$, $n=9$). Further, there were age-related increases in expression of p53 and its pathway gene p21 and BAX (RT-PCR). There were 4-fold more hMSCs positive for SA- β -gal in samples from older (8.9 ± 2.4 , $n=12$) than younger subjects (2.3 ± 1.8 , $n=5$, $p<0.001$). With age, there was a significant decrease in generation of osteoblasts both in the STRO-1⁺ cells ($r = -0.714$, $p=0.047$, $n=8$) and in adherent MSCs ($r = -0.81$, $p=0.010$, $n=8$). In sum, there are age-dependent decreases in proliferation and osteoblast differentiation and increases in p53 and its pathway genes, SA- β -gal, and apoptosis in hMSCs. The p53 pathway may have a critical role in age-related changes of hMSCs, in light of recent murine data that p53 is a negative regulator of osteoblast differentiation. These findings support the view that there are intrinsic alterations in human MSCs with aging that may contribute to the process of skeletal aging.

Wdr5 Is Essential for Osteoblast Differentiation. F. Gori, E. Zhu^{*}, M. B. Demay. Endocrine Unit, Massachusetts General Hospital/Harvard Medical School, Boston, MA, USA.

Wdr5, a BMP-2 induced gene, is developmentally expressed in osteoblasts and accelerates osteoblast differentiation in vitro. Transgenic mice overexpressing Wdr5 in maturing osteoblasts display accelerated endochondral bone formation during embryonic development, associated with earlier activation of the canonical Wnt signaling pathway. To address whether Wdr5 is essential for osteoblast differentiation, plasmid-based small interfering RNAs (siRNAs) were used to stably suppress endogenous Wdr5 protein levels in MC3T3E-1 cells. Levels of endogenous Wdr5 protein were assessed by Western analyses after 7 days in culture, when Wdr5 protein levels are maximally expressed. Clones expressing two of the selected siRNAs targeting Wdr5 demonstrated a significant decrease in endogenous Wdr5 protein levels relative to that of the scrambled (siRNA-S) clone. This reduction of endogenous Wdr5 levels markedly inhibited osteoblast differentiation, resulting in a significant decrease in alkaline phosphatase activity, impaired expression of Runx-2 and osteocalcin mRNAs and absence of mineralized matrix formation. Based on the observation that overexpression of Wdr5 enhances canonical Wnt signaling in osteoblasts, the effects of Wdr5 silencing on a key mediator of this pathway, β -catenin, was examined. A decrease in nuclear β -catenin protein levels was observed with Wdr5 knockdown, suggesting that inhibition of canonical Wnt signaling may, in part, underlie the impaired osteoblast differentiation observed when Wdr5 protein levels are suppressed. Analysis of Wnt target genes demonstrated that suppression of Wdr5 expression resulted in a significant decrease in the levels of c-myc, the expression of which is increased by canonical Wnt signaling. Furthermore, the expression of SFRP-2, which is repressed in response to Wnt signaling, was increased in association with Wdr5 knockdown. Although suppression of Wdr5 protein levels decreased the antiapoptotic protein Bcl-2 and increased caspase 9 activation, only a minimal increase in apoptosis was observed in these cells (from 3.2% to 5%). Thus, our investigations demonstrate that Wdr5 not only accelerates osteoblast differentiation when it is overexpressed, but is also essential for osteoblast differentiation. In addition, our findings suggest that Wdr5 is required for optimal canonical Wnt signaling in MC3T3E-1 cells.

The Role of EphB/ephrin-B Interactions in Cell Attachment and Spreading of Mesenchymal Precursors Derived from Human Bone Marrow and Dental Pulp Tissues. A. Arthur^{*1}, S. Koblar^{*2}, S. Gronthos¹. ¹Division of Haematology, Institute of Medical and Veterinary Science, Adelaide, Australia, ²Faculty of Health Sciences, University of Adelaide, Adelaide, Australia.

The Eph family of receptor tyrosine kinases and their ligands, the ephrin molecules, appear to play an important role in skeletal development during embryogenesis. Our study examined the expression pattern and function of EphB/ephrin-B molecules on mesenchymal stem/precursor cells derived from human bone marrow and dental pulp tissues. Multiple receptors and ligands were identified on dental pulp stem cells (DPSC) and bone marrow stromal stem cells (BMSSC) by real time PCR and immunohistochemistry. The function of EphB/ephrin-B molecules during BMSSC and DPSC attachment and spreading was assessed in the presence of different Eph/ephrin-Fc fusion proteins using an established in vitro cell-spreading assay. In response to either

EphB2-Fc or ephrin-B1-Fc, the stem cells formed rounder and smaller cell bodies demonstrated by F-actin distribution, and restricted their ability to spread. Additionally, immature focal adhesions were identified at the edge of the cell membrane, reminiscent of spreading initiation centres (SIC), which have only been observed at early stages of cell spreading. In the presence of Inhibitors, Eph forward signaling through the mitogen activated protein kinase (MAPK) pathway restricted cellular spreading, while reverse signaling through the ephrin ligand was mediated via the phosphorylation of the Src homology (SH2) domain activating downstream signaling cascade. Collectively, these studies indicated that EphB/ephrin-B molecules provide an inhibitory environment for mesenchymal stem/precursor cell attachment, consequently resulting in the lack of spreading and detachment. These results may have implications for calcified skeletal/dental tissue development and regeneration.

PTEN and Osteoblastogenesis. A. R. Guntur¹, M. C. Naski². ¹Biochemistry, UTHSCSA, San Antonio, TX, USA, ²Biochemistry & Pathology, UTHSCSA, San Antonio, TX, USA.

Osteoblastogenesis is marked by increased expression of PTEN, the chief inhibitor of phosphatidylinositol 3-kinase (PI3K) signaling. Based on this observation we hypothesized that PTEN/PI3K signaling regulates osteoblast differentiation. To test this hypothesis we conditionally inactivated PTEN in osteoblast precursors. This caused a dramatic increase in osteoblast differentiation and bone formation. Moreover, precocious differentiation ensued, indicating loss of physiological restraints. Increased numbers of osteoblasts were in part accounted for by enhanced cell proliferation and diminished pathways of feedback inhibition. Accelerated differentiation coincided with increased levels of the hedgehog-dependent transcription factor Gli2. Increased hedgehog signaling was evidenced by up-regulation of patched, a transcriptional target of hedgehog. We conclude that PTEN is required to restrict osteoblast replication and halt precocious differentiation. The results demonstrate that the PI3K signaling pathway is an attractive target for pharmacological regulation to enhance bone mass.

Role of Type III NaPi Transporter(s) in Osteoblastic Differentiation. C. Haldrup^{*1}, L. B. Nielsen^{*2}, J. Lykke^{*3}, L. Pedersen¹. ¹Dept of Molecular Biology and Inst of Clinical Medicine, Aarhus University, Aarhus, Denmark, ²Dept. of Paediatrics, Glostrup University Hospital, Glostrup, Denmark, ³Dept. of Medical Biochemistry and Genetics, University of Copenhagen, Copenhagen, Denmark.

The role of the type III sodium-dependent inorganic phosphate (Pi) transporters in osteoblastic differentiation and mineralization was addressed using the murine preosteoblastic cell line, MC3T3-E1. These cells differentiate over time into mature mineralizing osteoblasts upon addition of ascorbic acid and β -glycerophosphate. To impair the function of the 2 type III transporters, Pit1 and Pit2, cells were infected with retroviruses, which employ Pit1 and/or Pit2 as receptors for infection and thus inhibit their function. Blocking of Pit1 and Pit2 protein function was confirmed by virus interference studies. Mineralization was analyzed with Alizarin red. Expression of Pit1 and osteocalcin were followed by Northern blotting. Pi uptake was analyzed using 32Pi.
